I am heartily in favor of the law as it now stands, and believe it will do much to elevate the practice of pharmacy. It will help to do away with the competition of those who buy poor drugs and sell preparations from them, cheaper than good preparations cost to manufacture. It will help us to furnish physicians with reliable remedies, thereby adding to the faith in and knowledge of medicine and increasing its usefulness.

The pharmacist should be held responsible for quality, but should be allowed to make or choose the maker of the medicines he dispenses.

Dr. George B. Shattuck called the attention of the society to the bill lately introduced in Congress by a Pennsylvania representative to provide for the preparation and publication of a new Pharmacopœia. The subject was an important one, and had a direct bearing upon the question then under discussion. The present Pharmacopœia had been prepared by the best experts in the country after careful consideration and consultation. As was shown by preceding remarks of some of the well known pharmacists, who had added the weight of their presence to the meeting, the better the changes made in the work were understood the more they were approved of. The book had already been adopted as the legal standard in four large States, and was also the standard adopted by the United States Treasury Department. As many other excellent reasons readily suggested themselves why a new Pharmacopœia was unnecessary and objectionable, and he could not think of one in its favor, the speaker begged to be allowed to offer and move the adoption of the following resolutions:

Resolved, That this society is strongly opposed to a bill introduced into the National House of Representatives January 8, last, by Mr. Randall, entitled A Bill to Prepare and Publish a National Pharmacopœia for the United States. The Society believes that the present revised Pharmacopœia is at least as good a work as is likely to be secured by the passage of this bill.

That all necessary legal authority which the present Pharmacopœia does not now possess can be easily given it.

That the complication which would necessarily arise from two Pharmacopœias is undesirable.

Dr. F. H. Williams seconding the motion, the resolutions were ananimously adopted.

Mr. G. F. H. Markoe, of the Massachusetts College of Pharmacy, spoke against the bill and in favor of the present Pharmacopœia upon much the same grounds as those already given.

Adjourned at 10:30.

FEMALE MEDICAL STUDENTS IN RUSSIA.—The studies of female medical students in Russia are not prosecuted under the most favorable conditions. A telegram states that all those now in St. Petersburg have been compelled to take up their residence in a large boarding establishment provided by the authorities, instead of being free, as heretofore, to live where they please. They are to be at home before 9 o'clock in the evening, under penalty of exclusion from the medical course. The dread of Nihilism permeated every rank and condition of life in Russia.—*Medical Press.*

STATE MEDICINE.

HEALTH IN MICHIGAN.

Reports to the State Board of Health, Lansing, by observers of diseases in different parts of the State, show the principal diseases which caused most sickness in Michigan, during the week ending March 1, 1884, as follows:

NUMEER OF OBSERVERS HEARD FROM, FORTY-TWO.		For preceding week
DISEASES ARRANGED IN ORDER OF GREATEST AREA OF PREVALENCE.	Per cent. of observers who reported the disease present.	Per cent. of observers who reported the disease present.
Neuralgia	79	83
Rheumatism	64	80
Bronchitis	62	78
Consumption, of lungs	62	65
Intermittent fever	60	78
Tonsillitis	60	65
Influenza	50	73
Pneumonia	36	55
Remittent fever	31	47
Scarlet fever	31	25
Inflammation of kidneys	31	38
Erysipelas	24	30
Diarrhœa	21	35
Whooping-cough	19	25
Diphtheria	17	15
Inflammation of bowels	17	8
Measles	14	13
Inflammation of brain	12	8
Cerebro-spinal meningitis	10	8
Typho-malarial fever	7	10
Membranous croup	7	13
Cholera morbus	7	8
Puerperal fever	7	13
Dysentery	5	8
Typhoid fever (enteric)	5	5

For the week ending March 1, 1884, the reports indicate that inflammation of the bowels increased, that influenza considerably decreased, and that pneumonia, intermittent fever, bronchitis, rheumatism, diarrhœa, remittent fever, and inflammation of the kidney decreased in area of prevalence.

At the State capital, the prevailing winds, during the week ending March 1, were west; and, compared with the preceding week, the temperature was lower, the relative humidity and the day and the night ozone more, and the absolute humidity less.

Compared with the average for the month of February in the six years 1877–1882, neuralgia was more prevalent, and pneumonia, diphtheria, bronchitis, remittent fever, typho-malarial fever, and rheumatism were less prevalent in February, 1884.

For the month of February, 1884, compared with the average of corresponding months for the six years, 1879–1884, the temperature was lower, the relative humidity was more, and the absolute humidity and the day and the night ozone less.

Including reports by regular observers and others, diphtheria was reported present during the week ending March 1 and since, at ten places, namely, Calumet, Cazenovia, Detroit, Dowagiac, East Saginaw, Grand Rapids, Kalamazoo, Monroe, Pontiac, Saginaw City. Scarlet fever at 22 places, Bridgewater, Dorr, Detroit, East Saginaw, Grand Rapids, Hersey, Mason, Maple Valley, Monroe, Mt. Pleasant, North Muskegon, Orleans, Pierson, Sherman, St. Joseph, St. Johns, St. Clair, Saginaw City, Union City, township of Union, Vicksburg, and Whitehall. Measles at seven places, Detroit, East Saginaw, Monroe, Orleans, Owosso, Plainwell. Saginaw City. Four cases of small-pox at Bath, Feb. 29.

HENRY B. BAKER,
Secretary.

Lansing, March 5, 1884.

Report of deaths in the city of Lansing, Mich., during the month of February, 1884:

Burial Permit No.	Day of Death.	Name of Deceased.	Age. Years.	Months.	Days.	Sex.
491	1	Jas. R. Stone	65	11	19	M.
490	2	Jennie Maud Clough	11	4	24	F.
492	4	Chas. Welch	60	..	..	M.
493	4	Harriet B. Holmes	68	..	..	F.
494	7	Infant of J. H and M. Kistler	..	..	..	M.
495	8	Pearl Sweet	.1	2	..	F.
496	8	Annie Shiffer	37	10	8	F.
498	15	Olley Sabrina Dell	1	3	..	F.
499	17	Roy Sawtelle	12	..	10	M.
500	19	Chas. V. Ekstein	..	7	21	M.
501	27	Ferren M. Chilcott	24	9	21	M.

Cause of Death.—490, scarlet fever; 491, gangrene, caused by embolism of iliac artery; 492, general debility; 493, paralysis; 494, still-born; 495, whooping-cough; 496, dropsy; 498, inflammation of the brain; 499, fracture of skull; 500, hæmorrhage of bowels; 501, consumption.

Color.—All white.

Nativity.—490, 494, 495, 498, 499, 500, 501, Michigan; 491, Mass.; 492, Ireland; 493, 496, New York.

Deaths in the city in February	11
Population, U. S. census, 1880	8,319
Annual death rate per 1,000 for month	16.653
Estimated population, 1884	10,000
Annual death rate per 1,000 est. pop	13.994

O. MARSHALL, M.D.,
Health Officer.

TO THE SEVERAL STATE BOARDS OF HEALTH:

Gentlemen:—At a meeting of representatives of State Boards of Health, held in Detroit in November, 1883, it was decided to call a meeting of the Secretaries or other rrpresentatives of all State Boards of Health, in Washington, D. C. in May, 1884, for the purpose of conference of State and other health officials in regard to general plans and special lines of practical work which they are called upon to perform, and with the view of the organization of a "Section" devoted to State Board work, in the American Public Health Association, or the formation of a permanent separate organization especially adapted to the needs of State Boards of Health.

Drs. Henry B. Baker, of Michigan, and J. N. McCormack, of Kentucky, were appointed a committee to confer with, and secure the coöperation of, all the State Boards in fulfilling the object of the meeting, and Drs. C. W. Chamberlain, of Connecticut, J. E.

Reeves, of West Virginia, and Stephen Smith, of New York, were appointed a committee on organization, to report at the meeting in May. The American Medical Association meets in Washington in May, and another reason for holding the meeting in Washington is that the representatives of the State Boards may have an opportunity for conferring with members of Congress from their respective States, in regard to national sanitary legislation. It would seem that whenever the health authorities of all the States shall meet, discuss, and agree upon the course they will pursue with regard to yellow fever, cholera, scarlet fever, small-pox, diphtheria, or any disease which endangers public health without regard to State lines or borders, and whenever all State Boards shall act in concert, considerable progress will have been made in solving the problem of what are the best methods for national action in regard to inter-State and marisme quarantines, or inspeetion and disinfection, as well as in the practical control of epidemic diseases within the several States of this country.

A reason for this proposed new mode of action is the belief among leading sanitarians intrusted with the official execution of practical health measures, that while the work of the American Public Health Association is of inestimable value in promoting the interests of sanitary science and sanitary reform, there is a constantly increasing need for an annual conference of State and other health officials in regard to practical affairs of their every-day work, some part of which work can not profitably be discussed in a public meeting consisting largely of persons not familiar with its details, and not directly responsible to the people for the best possible care for the safety of their health and lives.

In fulfilling the duty assigned to it at the meeting, this committee respectfully requests that your board appoint a delegate to the meeting in Washington, in May, 1884, and that you will cause to be sent to this committee, or to be given to your delegate, a certificate of the appointment of such delegate.

It is hoped that each delegate will be prepared to clearly detail specific subjects on which there is need for comparison of views, or for coöperation; and to express his own views, and, if practicable, the views of his board respecting the same. It is respectfully suggested that each delegate prepare a brief paper for presentation at the meeting; because in that way, better than in any other, will each delegate be prepared to express himself clearly and concisely, and the direction which the proposed associated action shall take be most likely to be that best calculated to aid and improve the several branches of the public health service in this country.

Very respectfully,

HENRY B. BAKER,
J. N. MCCORMACK,
Committee.

March 4, 1884.

First meeting to be held on the second day of the session of the American Medical Association.

BOOK REVIEWS.

GANTS' DISEASES OF THE BLADDER AND HAWE'S EXCESSIVE VENERY.—Excessive Venery, Masturbation, and Continence; the Ætiology, Pathology, and Treatment. By JOSEPH W. HAWE, M.D. New York: Bermingham & Co. 1884. pp. 299.

This volume contains the substance of a course of lectures delivered in the University of New York, supplemented as the writer states, by an account of the peculiar methods of treatment of various American and European authorities, thus forming a manual of reference.

The work has been done with no great thoroughness or completeness. In fact, as a work of reference it is not equal to several of the standard treatises from which it is largely compiled. Those parts of the work which are really most telling and attractive are the long quotations from Acton, Hammond (Male Impotence), and similar well-known works. We do not like the *tone* of the book. "Sons of Manhood" is a definition not too loose for the writer's taste, as he employs it more than once.

The value of a work which expressly treats continence among the causes of disease and insanity (p. 62) is at least highly questionable. Its pages abound in falsely colored statements set down as scientific facts, which are merely the theories of obscure writers, or else crude generalities of the author himself. There is an utter want of clearness in the statement of cause and effect, as in the satyriasis of phthisical patients, which he states as proof of the power of masturbation to cause consumption. Few more misleading or unnatural statements have ever been put in print than that "varicocele in young persons" is a "positive sign" of "masturbation or sexual excess—generally the former (p. 22)." See also p. 62: "Masturbation is a universal vice in civilized countries. A very large majority of both sexes indulge in the habit from early childhood. In savage lands it is of rare occurrence." Of which alleged facts no evidence is offered.

"Erotic tendencies," p. 66, are said to be "fostered by sedentary habits," a statement directly in contradiction to experience and good authorities.

On page 76 we find the following: "During sexual intercourse the expenditure of nerve force is compensated by the magnetism of the partner. In all cases, or in almost all cases, there is a return of that nature which prevents injury." Pseudo-pathology can exhibit itself in no worse light than in the above passage. What is this "nerve force" which is to be "compensated" by the magnetism of the partner? It would be well for the author to explain when and how he made this interesting discovery. We are almost forced to believe that the book was written partly for non-professional readers. Otherwise why are common names inserted in parentheses after the scientific?

The poor hypochondriacs who are described as having lost their "manhood," are the unhappy victims too often of books of this class. Their cases would present much less difficulty to the neurologist,

who, unfortunately, sees many of them, could he banish from their minds the rubbish of false pathology they have imbibed about "male impotence," "spermatorrhœa," and "emissions."

The words of Gant in his latest preface cannot be too often repeated to the profession in this connection. (See p. 6, "Diseases of the Bladder," by Frederick Gant, F.R.C.S., Bermingham & Co.) "The author having seen—and quite recently—so much deplorable error and misery resulting to patients from studying diseases of the urinary organs, he has written this treatise in a purely technical form; and thus to render the whole as unintelligible as possible to the public. The majority of the latter class would, indeed, be better able to walk barefooted to Jerusalem, than rightly to comprehend the greater portion of the text. The personal histories of the cases have been purposely omitted."

This has the manly ring, and is a fitting introduction to Professor Gant's fifth edition of his valuable treatise on the bladder, prostate and urethra. The work is well known in former editions, and comes out now enlarged and revised in some parts. The surgical anatomy of the parts is wholly rewritten, and now appears in very attractive form. In all discussions save on the subject of rapid improved lithotrity, the author's views are valuable and abreast of the day, but here there is a distinct failure to recognize the importance of the improvements of Bigelow, and the radical changes they have brought. The subject is handled too cautiously, and points are stated as still in doubt which have long since been completely established. Outside of this deficiency, which is not uncommon with English writers, the treatise is a thorough and complete one, in some respects more so than any other. This is especially true of the various unusual and obscure bladder and urethral affections whose treatment is too slightingly passed over in many American text-books. E. W. A.

The Hip and its Diseases. By V. P. Gibney, A. M., M.D., Professor Surgery New York Polyclinic; Asst. Surgeon Hospital for the Ruptured and Crippled, etc., etc. New York, Bermingham & Co., 1884. Pp. 412.

A prominent idea set forth in this work is defined as "conservatism," or "expectant" treatment of hip disease. A large amount of discussion is given to the relative merits of this expectant or waiting treatment and the mechanical treatment, so-called, of most orthopedists. It is evident that the author has been led into a vagary, in part resulting from a wrong point of view, and from want of comprehensiveness in his survey of the subject. As is often the case with specialists, the very minuteness of his knowledge has led him to become careless or oblivious of the most obvious and fundamental facts of his subject.

The author's mind seems incapable of receiving broad views. It is perversely narrow. The mechanical treatment of hip disease is *not* falling into disuse, and has not proved a practical failure, as the author in effect assures us. How any intelligent observer of the drift of professional opinion could make such an assertion, is not easy to understand.

The following illustrates the strange obliquity of the author's mental eyesight: "Year after year witnesses the introduction of new forms of apparatus, new methods of treatment, or revivals of the same principles in old apparatus, and year after year witnesses the failure of the same to meet the diseases set forth."

Here we find the significance of facts wholly distorted to meet a whimsical theory. The multiplication of orthopedic appliances, all designed to meet the same indication, on the same general principle, is the strongest possible evidence of the value and permanency of that principle. It would be as well to say that the numerous forms of pessaries are an argument against all pessaries, or that the existence of two or more methods of dressing a fractured limb is calculated to throw discredit upon the use of all splints and bandages. Every new hip splint invented is an item of evidence for, and not against, the mechanical treatment of hip disease.

The book is valuable for the minute information it contains on a large variety of obscure affections about the hip. A careful analysis of the varieties of hip disease has been elaborated in a series in the chapters entitled "Sprains of the Hip" (chap. III), "Neuroses of Hip" (IV), "Rheumatism of Hip" (V), "Coxo-Femoral Periarthritis" (VI), "Bursitis of Hip" (VII), "Acute Primary Synovitis" (VIII), "Acute Epephyritis of Hip" (IX), "Diastasis of Head of Femur," "Periostitis of Hip" (X). These chapters are valuable summaries, and are all preparatory to the real important topic of the work, viz.: Chronic Articular Ostitis of the Hip, or real hip disease, whose discussion occupies the latter half of the book (chaps. XI–XVIII). This work contains the first complete chapter ever published upon Bursitis of the Hip, although many writers have alluded to the affection. E. W. A.

DOMESTIC CORRESPONDENCE.

FROM WASHINGTON.

On March 3 Mr. Willis introduced a bill into the House of Representatives (H. R. 5650) for the promotion of anatomical science and to prevent the desecration of graves. It provides for the delivering of such bodies as are to be buried at the public expense, and as coming from any of the charitable or correctional institutions of the District of Columbia, to the medical colleges of the District of Columbia. If the deceased should have requested that he be buried, should his kindred claim him within twenty-four hours after his death, or should the deceased be a stranger or traveler, the body shall be buried. Bonds are required that the bodies are to be used for a prop-

er purpose, and when that purpose shall have been accomplished the remains shall be decently buried. Imprisonment for three years at hard labor is the penalty for using such bodies for improper purposes, for removing them beyond the limits of the District of Columbia, for traffic in such material, and for grave robbing.

This is a measure that is very much needed here. There are three medical colleges in operation in the District, and a fourth on paper. One of them, the medical department of the Howard University, is under government control, for the benefit of the colored race. It has a hospital to draw its material from, and numbers some eighty odd students in attendance. The two remaining and older institutions are the Medical Department of the Columbian University, which has enrolled some eighty students, and the Medical Department of the Georgetown University, which has between twenty-five and thirty students. It would be within bounds to say that there were about 200 medical students pursuing their studies in Washington. Then the Army and Navy Medical Examination Boards have both at times held prolonged sittings here, in which they required material for their purposes. For years past to meet these demands there has been a constant necessary violation of the letter of the law, and it is not pleasant for otherwise respectable members of a community to know that they are obliged to place themselves in an equivocal position, where at any time, by carelessness or a mistake, they may arouse the emotions and feeling of their fellow citizens and bring down their wrath upon them. While in our sister cities it is only the older members of the profession who can call back at times their early experience in resurrecting for the amusement of their younger colleagues; we fear that not many miles away from here there still exists the type of the enterprising student, who is better adapted to such deeds of darkness than to his more prosy studies, who knows the use of the dark lantern, the pick, the rope, the sack and the flask of whiskey for the side pocket, better than he does the microscope, the stethoscope and the thermomemeter.

On March 7, the House of Representatives performed a very graceful act in awarding to the widow of the late Surgeon-General Joseph K. Barnes a pension of $50 per month, which is an increase of $20 over the regular rate of pension at $30 per month. Still there were some comments on the bill in general debate which were noteworthy. Dr. Barnes was Surgeon-General for eighteen years and seven months, and during that time drawing a recognized pay of $400 a month, besides those extras in the shape of commutation, etc., for this and that, which civilians do not understand and Congress tries to find out. Yet his widow is obliged to come before Congress an acknowledged pauper, in indigent circumstances. Mr. Tucker, of Virginia, calling himself an ex-rebel, was strong in his support of the bill, giving these facts as an instance of the expenses of living to officials in Washington, and calling to mind Barnes' services as those of a man who, for over forty years, faithfully served his country, who did duty on the frontier, went to the City of Mexico with Scott's victorious legions and went through all the dangers of the Seminole war, who stood by the bedside of the dying Lincoln, and rendered invaluable service to the dying Garfield, and never received any compensation for either.

NECROLOGY.

YANDELL, LUNSFORD PITTS, was born June 6, 1837, on the plantation known as Craggy Bluff, near Murfreesboro, Rutherford county, Tenn., at the home of his grandfather, Dr. Wilson Yandell. He was the son of Lunsford Pitts Yandell, who figured so conspicuously in the annals of medicine in the West from 1837 to 1878, when he died in Louisville. Lunsford P. Yandell, Jr., was brought by his parents to Louisville a few months after his birth. He was educated in the private schools, enjoying the rare advantages of a personal training by that great teacher, Prof. Noble Butler, in his palmiest days. At the early age of 17 he began the study of medicine, and three years after (1857) graduated from the Medical Department of the University of Louisville. He went with his brother to the old Louisville Dispensary, and there remained, as chief of the clinic, for about a year. During the same time he had charge of the preparation and management of the clinical course at the Louisville City Hospital. In 1858 he went to Memphis, Tenn., to begin the practice of his profession. In 1859 he was appointed to the chair of Materia Medica and Therapeutics in the Memphis Medical College. In this place he won the reputation of being an earnest student and an eloquent teacher. On the 4th of May, 1861, when the war cloud was gathering over the South, he enlisted as a private soldier in the Fourth Regiment Tennessee Volunteers, for the service of the Confederacy. In a few months his knowledge of medicine became known in the army, and he was transferred from the ranks to the place of Assistant Surgeon, subsequently being promoted to the rank of Surgeon. Afterward he became Brigade Surgeon and Medical Director, serving on the staffs of Gen. Polk and Gen. Hardee. He was an active, industrious, enthusiastic student of his profession, a man of amiable disposition and great personal magnetism. He won an enviable name in the medical department of the army. When the fortunes of war turned against the cause he had espoused, and the great army of the South was scattered and almost annihilated, he took the oath of allegiance in North Carolina, April 15, 1865, and sadly turned his face toward Louisville. Here he practiced in the office of his brother, who had preceded him by a few weeks in his return from the South. In 1867 he attended the International Medical Congress, at Paris. While abroad he visited the great hospitals of the continent, as well as those of Great Britain and Ireland. He wrote many interesting letters during the tour; one of the most noted was that in which he detailed his personal experience in the great Vienna Hospital for Skin Diseases. He conceived

an intense disgust for the personal habits and professional deportment of the great dermatologist, Hebra, and contrasted this man with Erasmus Wilson, of London, whom he regarded with high favor. Returning home in December, 1867, Dr. Yandell was married to Louise, daughter of W. R. Elliston, of Nashville.

He settled down to the business of his profession, and in 1869, he was appointed to the chair of Materia Medica and Clinical Medicine in the University of Louisville. There had been great dissensions in the Faculty of the University; the venerable Dr. Louis Rogers and others of the Faculty had resigned, a new organization was determined on, and the trustees of the school wisely concluded to fill the vacancies with young men. Accordingly, Lunsford Yandell, E. R. Palmer, J. W. Holland and R. O. Cowling entered the school. Yandell was the oldest of the four. The University prospered, and rose rapidly to an enviable place among the best institutions of the country. In 1881, Cowling died suddenly, vacating the chair at the University and his place as chief editor of the *Medical News*. Less than two years ago, Lunsford Yandell became the senior editor of the *News*, and his death now for the second time leaves the senior editorship of the *News* and a chair in the University vacant.

Lunsford Yandell was one of the best known men in the profession of this city. He was a man of fine physical development, above six feet in height, of magnificent proportions, and about 200 pounds weight. He had dark complexion, dark eyes, black hair and beard. He was a prince in society, a very popular general practitioner of medicine, and an orator of such force and ability as are rarely found in the medical profession. He cherished an intense love for truth and justice, he was clear-headed, honest and independent. He took great interest in the organization and maintenance of medical societies. He cherished an intense love for the Code of Ethics of the American Medical Association. There was absolutely nothing small in Lunsford Yandell's nature. To-day, he entered warmly into a discussion of a question before a medical society, and although his views were not sustained, the genial smile and good will with which he met his opponents conquered all personal enmity, and won for him the very first place in the esteem of all who knew him. Men whom he did not like personally; whose professional opinions were distasteful to him, he spoke of in the most charitable manner, and when he could find nothing to say in their favor, he frequently was heard to exclaim, "Well, I don't like him, but I believe he is a truthful man, and honest in his convictions." Medical politics in Louisville, during the last fifteen years, have at times developed considerable excitement, disturbing now and then the whole community. In all these questions, Lunsford Yandell has been a leading character. He has always been in the foreground, earnestly contending for what he believed to be the right. His antagonisms have been more general than those of almost any other man in the profession.

His contributions to the literature of medicine are to be found in the *Atlanta Journal of Medicine and Surgery*, in the *Nashville Journal*, and in *Louisville* and *Richmond Medical Journal* of 1867, in the *American Practitioner*, *Medical Herald* and *Medical News*, the latter of which he edited jointly with the late Dr. Cowling from 1878–1880; with Dr. L. S. McMurtrie from July, 1882, to September, 1883, and with Dr. H. A. Cottell from the last-named date to March, 1884.

His most noted literary contribution was to the American Dermatological Association, on the "Predisposing Causes of the Dermatoses." He believed that scrofula, syphilis and malaria were predisposing causes of all but the parasitic diseases of the skin. He believed that mercury, cod liver oil, iodide of potassium and quinine might be relied upon for the cure of all but parasitic diseases. He rejected absolutely all recent discoveries in physiology and medical microscopy. He believed the microscope had greatly retarded clinical study. He had very peculiar and deeply rooted opinions concerning the actions of medicines, derived in great part from his personal experience in the use of drugs, both in his own person and as he observed them in his practice. He believed that the medical practitioner should take sufficient doses of the drugs he prescribes to learn the effects in his own person, and in this way he was led to reject a very large part of the generally accepted doctrines concerning the action of medicines.

Lunsford Yandell was a very active man as a practitioner, as well as a teacher. Whilst he did much to mold the policy of the University Medical School, he exercised a wide-spread influence in molding popular opinion concerning the practice of medicine in Louisville. His patients adored him, and although he made many enemies, as every positive and determined man must, he controlled a very large *clientale*. On the 12th day of March, 1884, Dr. Yandell was busily engaged with his practice until late in the afternoon, when he met a friend in the street who got in his buggy to ride with him for company. He said to this friend, "I am in better health than I have been for years, with the exception of neuralgia, which I find is generally relieved by chloral. He finally drove up in front of his residence after 6 P. M. Alighting from his buggy, he went into the house, took 30 grains of chloral, and, presently feeling better, expressed a desire for something to eat. His wife left him for a few minutes to have the meal prepared, and on her return found him insensible. She telephoned immediately to his brother, Dr. David Yandell, who being himself confined to bed, sent his office partner, Dr. Roberts.

The symptoms growing rapidly more alarming, other medical counsel was sought, and in a few minutes Drs. Roberts, Octerlony, Holloway and Scott, arrived, just in time to witness the last gasp for breath, at 8 P. M. Dr. L. P. Yandell died at his residence in this city. A more profound sensation and general shock never before was created in this community. When the morning papers appeared it seemed that every body in Louisville felt compelled to rush to the scene of the calamity. On the evening of March 13 the Louisville Medical Society, which Dr. Yandell assisted in founding, met in regu-

lar session, and resolved to do no other business than to consider the untimely death of Dr. Yandell. On the same evening, the old College of Physicians and Surgeons, the oldest medical society in the West, convened for the purpose of giving expression to sentiments of sorrow for the loss of one who had, in times past, been a leading member. Other medical bodies of the city met for similar purpose. On the 14th of March, at 3 P. M., the funeral ceremonies began at St. Paul's Episcopal Church. On the arrival of the cortege, every inch of standing room in the church edifice, in the vestibules and in the street about the entrance way, was occupied, the throng swelling, till it extended for squares in every direction. When the procession left the church and started to the cemetery to return to the earth the last earthly remains of the great physician, such a concourse of people was never before seen in Louisville, on any similar occasion. D. S. R.

MISCELLANEOUS.

AMERICAN MEDICAL ASSOCIATION.

PHILADELPHIA, 1400 PINE STREET, Southwest Corner Broad.

The thirty-fifth annual session will be held in Washington, D. C., on Tuesday, Wednesday, Thursday, and Friday, May 6, 7, 8, 9, 1884, commencing on Tuesday, at 11 A. M.

"The delegates shall receive their appointment from permanently organized State Medical Societies, and such County and District Medical Societies as are recognized by *representation in their respective State Societies*, and from the Medical Department of the Army and Navy, and the Marine Hospital Service of the United States.

"Each State, County, and District Medical Society entitled to representation, shall have the privilege of sending to the Association one delegate for every ten of its regular resident members, and one for every additional fraction of more than half that number: *Provided*, however, that the number of delegates for any particular State, Territory, county, city, or town shall not exceed the ratio of one in ten of the resident physicians who may have signed the Code of Ethics of the Association."

Secretaries of Medical Societies as above designated are earnestly requested to forward, *at once*, lists of their delegates.

Also, that the Permanent Secretary may be enabled to erase from the roll the names of those who have forfeited their membership, the Secreteries *are, by special resolution*, requested to send to him annually a corrected list of the membership of their respective societies.

SECTIONS.

"The Chairmen of the several Sections shall prepare and read, in the general sessions of the Association, papers on the advances and discoveries of the past year in the branches of science included in their respective Sections. * * * * *."—*By-Laws*, Art. 2, Sec. 4.

Practice of Medicine, Materia Medica, and Physiology.—Dr. J. V. Shoemaker, Philadelphia, Chairman; Dr. W. C. Wile, Sandy Hook, Ct., Secretary.

Obstetrics and Diseases of Women and Children.—Dr. T. A. Reamy, Cincinnati, Ohio, Chairman; Dr. J. T. Jelks, Little Rock, Ark., Secretary.

Surgery and Anatomy.—Dr. C. T. Parkes, Chicago, Ill., Chairman; Dr. H. O. Walker, Detroit, Mich., Secretary.

State Medicine.—Dr. Deering J. Roberts, Nashville, Tenn., Chairman; Dr. C. W. Franzoni, Washington, D. C., Secretary.

Ophthalmology, Otology, and Laryngology.—Dr. J. F. Chisolm, Baltimore, Md., Chairman; Dr. J. L. Thompson, Indianapolis, Ind., Secretary.

Diseases of Children.—Dr. Wm. Lee, Baltimore, Md., Chairman; Dr. W. R. Tipton, Las Vegas, New Mexico, Secretary.

Oral and Dental Surgery.—Dr. John S. Marshall, Chicago, Ill., Chairman; Dr. T. W. Brophy, Chicago, Ill., Secretary.

A member desiring to read a paper before any Section should forward the paper, or its *title* and *length* (not to exceed twenty minutes in reading), to the Chairman of the Committee of Arrangements at least one month before the meeting.—*By-Laws*.

Committee of Arrangements.—Dr. A. Y. P. Garnett, 1317 New York Avenue, Washington, D. C., Chairman.

WM. B. ATKINSON, M.D.,
Permanent Secretary.

THE BRITISH MEDICAL ASSOCIATION—MEETING AT BELFAST.

The fifty-second annual meeting of the Association will be held on July 29, 30, and 31, and August 1, 1884, at Belfast, under the Presidency of James Cuming, M.A., M.D., F.K.Q.C.P.I., Professor of Medicine, Queen's College, Belfast.

The address in Medicine will be delivered by Sir Andrew Clark, BART., M.D., F.R.C.P., Physician and Lecturer on Clinical Medicine, London Hospital.

The address in Obstetric Medicine will be delivered by George H. Kidd, M.D., F.R.C.S.I., Master of the Coombe Lying-in Hospital, Dublin.

The address in Physiology will be delivered by Peter Redfern, M.D., F.R.C.S.E., Professor of Anatomy and Physiology, Queen's College, Belfast.

Visitors coming from America to attend this meeting, can travel by any of the following routes:

1. A "Cunard" steamer will leave (*a*) New York on Wednesday, July 16, arriving at Queenstown about the following Thursday week, July 24. (*b*) Boston on Saturday, July 19, reaching Queenstown the following Monday week, July 28.

2. A "White Star" steamer will leave New York on Saturday, July 12, and on Saturday, July 19; due at Queenstown about July 20 and July 27.

3. An "Inman" steamer will leave New York on Tuesday, July 15; due at Queenstown about July 23.

4. An "Allan" steamer will leave Quebec on Saturday, July 19, arriving in Londonderry about the 26th or 28th July.

5. An "Anchor" steamer will leave New York on Saturday, July 19; due at Londonderry on July 29.

Londonderry is 95 miles from Belfast, and trains run daily between the two places.

The route from Queenstown to Belfast is from Queenstown to Cork, Cork to Dublin (165 miles by train), and Dublin to Belfast (113 miles).

Communications in reference to the meeting of the British Medical Association at Belfast to be addressed to the Hon. Local Secretaries, John Moore, M.D., Alexander Dempsey, M.D., John W. Byers, M.A., M.D.

MEETING OF THE INTERNATIONAL MEDICAL CONGRESS AT COPENHAGEN.

The time of the meeting of the British Medical Association at Belfast has been fixed so as not to interfere with the International Medical Congress, which is to begin at Copenhagen on August 10.

A steamer will leave Hull, England, on August 2 and 9, for Copenhagen; and on August 5 a steamer will leave Leith, Scotland, for Copenhagen. Both these places (Hull and Leith) can be reached on any day by leaving Belfast on the previous evening by the cross-channel steamers. Visitors, after attending the meeting of the British Medical Association in Belfast, will have ample time to travel to Copenhagen for the Congress.

THE RELATIONS OF THE ENGLISH MEDICAL MAN TO HIS ARISTOCRATIC PATRONS.—There is nothing perhaps that shows more strikingly the difference between the members of the medical profession in this country and those in England, than the reading of the editorial by the *Lancet*, headed "His Lordship's Four Medical Attendants and Butler." The article is very good in itself, but the idea that there should be any occasion for writing it, is what strikes one as being so preposterous. It is simply a comment on a recently published notice in the *Times* of the obsequies at the funeral of the late Lord Hertford, in which, in mentioning those present, occurs the sentence "four medical attendants and butler." The *Lancet* thinks that physicians and surgeons are not justified in attaching themselves to the household of great families—always excepting the Royal household—and that if they do they may consider themselves happy at being allowed a rank so high as to be associated with the butler.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT UNITED STATES ARMY, FROM MARCH 15, 1884, TO MARCH 21, 1884.

Bache, Dallas, Major and Surgeon, leave of absence still further extended seven days. (Par. 1, S. O. 50, Hdqrs Department East, March 14, 1884.)

Matthews, Washington, Captain and Assistant Surgeon, to be relieved from duty in the Department of the Missouri, and to report in person to the Surgeon-General of the Army for duty in his office. (Par. 12, S. O. 62, A. G. O., March 15, 1884.)

Black, Charles S., First Lieutenant and Assistant Surgeon, assigned to duty at Fort Concho, Texas. (Par. 6, S. O. 30, Hdqrs. Department of Texas, March 10, 1884.)

CHANGES IN THE MEDICAL CORPS OF THE NAVY FOR THE WEEK ENDING MARCH 22, 1884.

P. A. Surgeon T. H. Streets, from Museum of Hygiene, Washington, for duty in the Coast Survey service.

P. A. Surgeon C. H. H. Hall, from the Naval Academy to the Museum of Hygiene.

Surgeon Henry Stewart, ordered before the Retiring Board.

OFFICERS OF

THE AMERICAN MEDICAL ASSOCIATION

AND OF ITS SEVERAL SECTIONS 1883–4.

PRESIDENT.

Dr. AUSTIN FLINT, SR., of New York.

FIRST VICE-PRESIDENT.

Dr. R. A. Kinloch, Charleston, S. C.

SECOND VICE-PRESIDENT.

Dr. T. B. Lester, Kansas City, Mo.

THIRD VICE-PRESIDENT.

Dr. A. L. Gihon, United States Navy.

FOURTH VICE-PRESIDENT.

Dr. S. C. Gordon, Portland, Maine.

PERMANENT SECRETARY.

Dr. Wm. B. Atkinson, 1400 Pine St., Philadelphia.

TREASURER.

Dr. R. J. Dunglison, Philadelphia.

LIBRARIAN.

Dr. C. H. A. Kleinschmidt, Washington, D. C.

Place of meeting, 1884, Washington, D. C.; Time of holding meeting, first Tuesday in May.

CHAIRMAN COMMITTEE OF ARRANGEMENTS.

Dr. A. Y. P. Garnett, Washington, D. C.

ASSISTANT SECRETARY.

Dr. D. W. Prentis, Washington, D. C.

BOARD OF TRUSTEES FOR JOURNALIZING THE TRANSACTIONS.

Drs. J. M. Toner, Washington, D. C., President;
M. Moore, Rochester, N. Y.; Leartus Conner, Detroit, Mich.;
J. H. Packard, Philadelphia, Secretary;
H. F. Campbell, Augusta, Ga.; A. Garcelon, Lewiston, Me.;
P. O. Hooper, Little Rock, Ark.;
L. S. McMurtry, Danville, Ky.; J. H. Hollister, Chicago, Ill.

OFFICERS OF THE SECTIONS:

"Practice of Medicine."

Chairman—Dr. John V. Shoemaker, Philadelphia, Pa.;
Secretary—Dr. W. C. Wile, Sandy Hook, Conn.

"Obstetrics and Diseases of Women."

Chairman—Dr. T. A. Reamy, Cincinnati, Ohio; Secretary—Dr. J. T. Jelks, Hot Springs, Ark.

"Surgery and Anatomy."

Chairman—Dr. C. T. Parkes, Chicago, Ill.; Secretary—Dr. A. O. Walker, Detroit, Mich.

"Ophthalmology, Otology and Laryngology."

Chairman—Dr. J. F. Chisolm, Baltimore, Md.;
Secretary—Dr. J. L. Thompson, Indianapolis, Ind.

"Diseases of Children."

Chairman—Dr. Wm. Lee, Baltimore, Md.; Secretary—Dr. W. R. Tipton, Las Vegas, N. M.

"Oral and Dental Surgery."

Chairman—Dr. T. W. Brophy, Chicago, Ill.; Secretary—John S. Marshall, Chicago, Ill.

"State Medicine."

Chairman—Dr. Deering J. Roberts, Nashville, Tenn.;
Secretary—C. W. Franzoni, Washington, D. C

Committee on "Necrology."

Chairman—Dr. J. M. Toner, Washington, D. C.

ORIGINAL ARTICLES.

RESULTS OF AN EXAMINATION OF THE MARKET MILK OF CHICAGO, AND OF THE MILK OF COWS FED ON DISTILLERY REFUSE.

BY CHARLES S. BACON, M.D., SPRING PRAIRIE, WIS.

The following tables contain the results of a number of analyses made during the summer of 1883, at the laboratory of the Chicago Medical College, at the suggestion and under the supervision of Prof. Long. The writer is indebted to Dr. Oscar DeWolf, President of the city Board of Health, for procuriug forty-two samples of market milk through the sanitary police; also for aid in obtaining the samples from the distillery-fed cows. The rest of the samples were obtained by the college janitor, or by the writer, from milk wagons and depots. A few were secured from hospitals or from private houses. The specimens obtained by the police are numbered; the source of the rest is indicated in the table. On account of the care taken in getting the samples, it is believed that they fairly represent the milk sold in the city.

For practical purposes the detection of the ordinary sophistication, which consists in removal of cream and dilution with water, necessitates only the determination of the specific gravity and the percentage of solids and ash. Watering milk lowers its specific gravity, while skimming it increases the density; but a judicious combination of both processes will make the density normal, and hence the test by the lactometer alone is valueless. The determination of the solids, however, combined with the ascertainment of the ash, in order to eliminate any admixture of foreign coloring matter, is acknowledged to be sufficiently exact for ordinary purposes. It was not thought worth while to make use of the unsatisfactory creamometer.

In the more complete analysis of a part of the samples, the separation of the sugar, the nitrogenous matter and the fat was made by Ritthausen's method, 10 c.c. of milk were weighed and diluted to 100 c.c. The nitrogenous matter and the fat were precipitated by 5 c.c. of a solution of copper sulphate of such strength that 1 c.c. contained .020 grams. of copper oxide. This was rendered nearly neutral by a solution of potassium hydrate of such strength that 1 c.c. neutralized 2 c.c. of the copper solution. Now, the precipitate, consisting of copper, casein and entangled fat, is allowed to settle, and the supernatant sugar solution filtered, and the precipitate washed in a mercurial pump. The sugar solution is diluted to 250 c.c., and the amount of sugar determined by Fehling's solution made so that 10 c.c. is equal to .067 grams. of sugar. The precipitate is carefully dried in an air bath at a temperature below 110° C., and then weighed in an air-tight tube. It is then placed in an extracting apparatus, and the fat removed with ether. The process requires two or three hours. Then again dry the copper casein in the air bath and weigh it in the tube. The difference between this weight and that of the precipitate before the extraction of the fat gives the weight of the latter. This result is controlled by evaporating the ethereal extract, drying and weighing the residual fat. The nitrogenous matter is determined by burning the copper precipitate and subtracting the weight of its ash from the weight of the dried precipitate.

By adding the amounts of sugar, nitrogenous matter, and fat obtained in the manner just described to the ash obtained by burning the solids, it was found that the sum did not always correspond to the solids obtained by evaporating the milk. In order to ascertain whether the discrepancy was due to the quantity of the copper sulphate solution used in precipitating the casein and fat, a number of experiments were made. It was first found that 2 c.c., or more of the copper sulphate solution added to 100 c.c. of diluted milk, would give a clear supernatant liquid, while less than 2 c.c. would leave the supernatant liquid more or less turbid. As it appeared that the sum of the constituents was generally too small when a small amount of copper sulphate was added, a few samples were examined using first a small and then a larger quantity of copper sulphate. The following table shows the result:

		Ash.	Sugar.	Fat.	Nitrog. Mat.	Solids by Addition.	Solids by Evap't'n.
1.	2 5 c.c. copper solution	.70	4.31	2.04	3.17	10.22	11 39
	5 c.c. " "	.70	4.29	2 01	3 99	10.99	11 39
2.	2.5 c.c. copper solution	.64	4 34	1.85	2.83	9 66	10.18
	5 c.c. " "	.64	3.83	1.80	3.13	9 40	19.18
3.	2.5 c.c. copper solution	.72	4.49	4 74	3.45	13 40	14 13
	5 c.c. " "	.72	4.71	4.73	3.83	13.99	14.13
4.	5 c.c. copper solution	.82	4.69	5.33	4.07	14 91	14.83
	6.5 c.c. " "	.82	4.59	5.42	4.07	14 90	14.83

It is seen that the nitrogenous matter is considerably increased by using 5 c.c. of the copper sulphate solution instead of 2.5 c.c. It is not changed by increasing the amount above 5 c.c. The fat does not seem to be affected by the amount of the copper so-

lution. The sugar determination, in the last part of the second case, was undoubtedly inexact. It is not probable that the amount of copper affects the sugar determination if the solution was neutralized by the alkali. These observations, together with inferences from the table given below are, perhaps, sufficient to suggest the statement that 2 c.c. of the copper sulphate solution is required to precipitate all the fat, and leave a clear supernatant liquid; while a larger amount does not affect the quantity of fat; about 5 c.c. of the copper solution is required to precipitate all the nitrogenous matter.

Less than 5 c.c. of the copper sulphate solution, in many of the analyses, was used, and hence it is probable that the amount of nitrogenous matter can be determined more accurately by subtracting the sum of the fat, sugar and ash from the total solids. The results of the analyses will now be given, placing first the samples obtained by the sanitary police.

Sample.	Sp. gr.	Ash.	Sugar.	Fat.	Nitrog. mat.	Solids by addit'n.	Solids by evaporation.

The reaction was observed in about half of the samples, and was found acid in every case. The microscope was used in an examination of about a quarter of the samples. In many cases the number of large and medium-sized milk globules was found to be abnormally small. Colastrum corpuscles were seen in one sample, and small granular masses, probably of fungous nature, in another. The significance of these cannot be discussed. No other foreign substances were revealed by the microscope, and the presence of mineral coloring matter is rendered improbable by the normal ash. There remains, then, for discussion only the question of sophistication by means of skimming and watering.

At the outset a standard of normal mixed milk must be adopted. It is, perhaps, sufficient for the purposes of this article to accept 12.5 per cent. as the minimum amount of solids in normal milk. Without doubt healthy cows may sometimes give good milk which contains a less amount of solids, but these cases are so rare that the mixed milk from five or six cows would always contain the amount of solids indicated.

A study of the table shows that of the fifty-eight samples only thirteen, or 23 per cent., are unsophisticated. The average percentage of solids is 11.83. If the value of the milk in any given case is equal to the ratio between the solids and the standard taken, the value of the specimens examined would be about 95.5 per cent. of normal milk. But this number evidently places the value too high, since the average of solids is compared with the minimum of unsophisticated milk. By the table below it will be seen that the average amount of solids in the milk of swill-fed cows is 13.22 per cent. Comparing the market milk with this, its value is found to be 89.5 per cent.

This number, however, does not represent the real

value. If dilution were the only sophistication, it would be sufficiently near to the correct result. But in very few samples is watering the only fraud. If a specimen showed a very low specific gravity with a fair amount of solids, it might represent such a case. With the possible exception of number forty, these conditions are not filled. It is evident that from almost all the samples fat has been subtracted, and this leads to a consideration of the relative food value of the different constituents.

As a rough approximation, the potential energy of fat may be considered two times as great as that of sugar, and also two times as great as the available energy of casein. The quantity of fat thus becomes an important datum. Unfortunately, it was obtained in only 17 cases, and one of these, No. 23. must be omitted for reasons given below. The average percentage of fat in the sixteen samples is 2.73, In the twelve samples of swill milk, the percentage of fat is 3.96. Hence the market milk contains only 70 per cent. as much fat as the swill milk. In the swill milk, the fat is equal to about 30 per cent. of the solids. Calling its food value twice as great as that of the other constituents, it is worth six-thirteenths, or 46 per cent. of the milk. If, now, 30 per cent of the fat has been subtracted, about 14 per cent. of the food is removed.

Still further, it must be remembered that deviation from the normal proportion of food elements, which is assumed to exist in normal milk, causes a loss by requiring an excessive and uneconomical amount of certain ingredients to replace those which are deficient. This is probably an important consideration, but its significance cannot be expressed in figures.

These estimates will, perhaps, justify the conclusion that the market milk, when considered in respect to its nutritive value as determined by its potential energy, is not worth more than 85 per cent. as much as milk of swill-fed cows.

Attention has been called to sample No. 23. It might be supposed that the specimen was obtained from the top of the can, and therefore had an unusually large amount of cream. But if cream is a solution of sugar, casein and salts holding suspended the fat, the proportion of the substances in solution should be the same as in milk. The small amount of sugar and ash in this case leads one to infer that the milk was first diluted and cream then added. This was, possibly, a special preparation for an approaching policeman.

The last three samples, noted on page 12, were from cows grass-fed in pastures and yards. Granular masses were found in the second and third samples, and colastrum corpuscles in the third. It was chiefly intended to compare these results with those obtained by examining the milk of distillery cows.

The latter analyses are given in the following table. A few items in the history of each cow are included. The first nine cows were kept in one stable, the next three in another, and the last in a third. It may be worth while to say a word concerning the management of the dairies. The cows are bought in the country, or from drovers, or at the stock yards. Each cow has a young calf with her, which, the seller claims, was dropped by her a few weeks before. Sometimes, however, the cow refuses to own her calf, and the owner said that numbers three and nine had undoubtedly given milk for a long time before he bought them, although their calves were only a few days old. The prices paid range from thirty to sixty-five dollars. The cows, generally poor when bought, are fattened on the rich distillery food, and, after giving milk for four to ten months, they are sold for beef. From the time they are bought, till they are sold, the cows are kept tied or stanchioned in somewhat crowded stables. The number in a stable varies from five or six to three or four hundred. When many are together, one row faces another for convenience in feeding. Distillery refuse, with a little hay, constitutes their food. The floor is cleaned, and the temperature in summer moderated by flooding the floor with water. The stables are quite open and ventilation takes care of itself. Milking is done wice a day.

No	Age.	Condition	How long the cow has given milk.	Am't of milk per day.	Reaction.		Spec. grav.	Ash.	S'gar.	Fat.	Nitrog. matter.	Solids by ad.	Solids by evap

It needs no discussion to prove that the hygienic conditions, especially in the large stables, are bad. The lack of exercise, the want of ventilation, the presence of large quantities of organic matter, are conditions unfavorable to kine as to human beings. On the other hand, it must be said that the cows generally thrive under this treatment. They look fairly well and grow fat. The comparison of their milk with market milk has already been made. It will be seen that it is quite as good as the samples of milk from pasture cows.

Perhaps a word should be said concerning the method of getting the samples. Each cow was milked in presence of the writer, the milk well stirred and an average sample taken. The reaction was observed in the fresh milk. In addition to the samples given, the reaction of twenty-two more specimens was determined. Combining these with the twelve given cases, the results are as follows: acid, sixteen; alkaline, five; neutral, one; amphoteric, one; doubtful, *i. e.*, acid or neutral or amphoteric, eleven. Investigations, by different observers, have shown such great variations in the reaction of normal milk that no deductions can be made from the above results.

In conclusion, it may be said that neither the microscope, the litmus paper, nor the analyses show a bad condition of the milk. Sample number nine is poor, but that might be expected from an old, poor, and farrow cow, even if she had better surroundings. The proposition may then be made that harmful properties, if any exist, do not depend on a change in the main constituents of the milk, but in elements difficult to detect.

SOME OBSERVATIONS ON THE HYDROBROMATE OF HOMATROPINE.

BY T. E. MURRELL, M.D., LITTLE ROCK, ARK.

[Read before the State Medical Society of Arkansas at the eighth annual session, Little Rock, May 30 and 31, 1883.]

Homatropine was discovered in 1879 or 1880, about which there seems to be some doubt, since both Germany and England claim the discoverer.

Merck, of Darmstadt, first made the crystallized hydrobromate, the preparation now altogether used.

According to the last edition of the U. S. Dispensatory, the alkaloid is prepared from tropine, a substance obtained from belladonna, in combination with amygdalic acid and diluted hydrochloric acid.

Homatropine is quite similar to atropine, both chemically and physiologically. It is not so poisonous, and can be administered in far larger doses, thus avoiding those disagreeable symptoms so common to the use of atropine in the eyes, particularly in children. The most important differences between these two articles is in their relative action and duration on the pupil and accommodation.

In 1879, shortly after its discovery, Dr. Hermann Schäfer conducted a series of experiments with homatropine on the rabbit and on man, in comparison with atropine and duboisine. The following table contains a summing up of the average results. The strength of the solution used was ½ of 1 per cent. of each article.

	Atropine.	Duboisine.	Homatropine.
Beginning of mydriasis	14 min	8 min	9 min
Beginning of failure of acc.....	23 min	10 min	9 min
Pupil ceased to respond to light	25 to 30 min	15 min	15 to 20 min
Height of mydriasis reached	36 min	19 min	30 to 40 min
Total paralysis of acc. reached...	2¼ to 2½ hrs	1 hr.	min 1½ to 2 hrs
Duration of mydriasis	4½ days	4 days	24 hrs
Duration of paralysis of acc.....	4½ days	4 days	24 hrs

These observations are borne out by subsequent experiments, with perhaps slight differences. It will be seen that the pupil begins to dilate most quickly for duboisine, next for homatropine, and last for atropine; and remains dilated longest for atropine, next for duboisine and shortest for homatropine; and that it ceases to respond to light in the same order of dilatation. The loss of accommodation, as will be seen, has a different order. It fails first for homatropine, next for duboisine and last for atropine; reaches total paralysis first for duboisine, next for homatropine and last for atropine; and continues longest for atropine, next for duboisine, and least for homatropine.

This order is modified by varying the strength of the solutions; a stronger solution of atropine acting quickly on the accommodation and persisting longer, duboisine showing less difference, while homatropine invariably passes off in about 24 hours whatever the strength of the solution. A stronger solution of homatropine acts more quickly and powerfully than a weaker one; a 1 per cent. causing paralysis of the accommodation in 50 minutes, a 2 per cent. in 39 minutes, and a 5 per cent. in 20 minutes. Another important difference to be observed in the table is the persistence of total suspension of accommodation. With the one-half per cent. solution it is for atropine, 18 hours; duboisine, 12 hours; homatropine, 3 hours.

Schäfer tested further the effect of eserine in counteracting the effects of these mydriatics. He found that its effect was decided, but fleeting, for atropine; less fleeting and more decided for duboisine; while it completely controlled the action of homatropine.

The tendency of a strong solution of atropine to produce a scarlatinal rash and dryness of the pharynx and fauces in some persons, particularly children, is an objection to its use; but this is not very frequent and never dangerous, while the vertiginous sensations caused by even a one-half per cent. solution of duboisine in many persons offers a barrier to its constant use. No unpleasant constitutional effects have yet been known to result from the application of homatropine to the eye. From its fleeting action it cannot take the place of atropine where permanency of effect is required, as in the treatment of iritis.

It would doubtless answer the purpose here by using the stronger solutions and by frequent instillations, requiring more constant attention to the patient. There is, however, a most important place for homatropine in ophthalmic practice. In selecting glasses for the correction of astigmatism and hypermetropia it often becomes necessary to paralyze the accommodation in order to ascertain the exact refraction of the eyes. An agent that will do this

effectually and with the least inconvenience to the patient, is the one that would most naturally be chosen. Again, in ophthalmoscopic examinations it sometimes becomes necessary in order to study the fundus in detail, or to hunt for peripheral striæ in the lens to dilate the pupil. Whatever will do this with but a short period of annoyance to the patient is the agent so long desired. In the hydrobromate of homatropine we have an article that accomplishes both these ends most satisfactorily.

Of it the 15th edition of the *U. S. Dispensatory* says:

"When it is necessary to paralyze the accommodation the influence of homatropine is rather feeble and uncertain."

We need not be surprised at this when the only notice it receives is a short foot-note. The writer's experience, and that of many others, fully establish the certainty of homatropine as a paralyzant of the accommodation if properly employed.

The correct way of using it to paralyze the accommodation is to instil into the eye a drop of a one per cent. solution every half hour until three applications have been made, and after two or three hours total suspension of the accommodative act will almost invariably be found. Sometimes shortly after the last instillation the accommodation will be found in abeyance, but to be certain it is best to wait a couple of hours. To dilate the pupil for ophthalmoscopic examinations a single application of a one per cent. solution will give a wide pupil in thirty minutes.

The hydrobromate of homatropine is not a very stable salt, and it has been found to lose its strength when kept in solution. This tendency, on account of its expensiveness, is a serious objection to its use by those who have not very frequent demands for it.

About a year ago, Dr. W. F. Mittendorf, of New York, had the kindness to send me some powders of a one per cent. trituration of the hydrobromate of homatropine, sulphate of eserine and daturine, with which he was experimenting, with the request that I give them a trial. I did so, and was so pleased with them that I ordered more, and now constantly use them to the entire exclusion of solutions.

In these triturations the salts are thoroughly incorporated with acacia and sugar of milk, and when applied to the eye are perfectly bland, painless and non-irritant. It is claimed for them that they will not spoil by age, if kept dry. Some powders that I have kept a year are as effective now as when first received. It is only necessary to keep in a wide-mouth, stoppered bottle, and when used, to dust a little into the conjunctival sac with a camel's-hair brush. It is as convenient as any method of application, can be regulated as to quantity with the greatest nicety and is more thoroughly absorbed than a liquid form by reason of its gradual solution in the conjunctival sac.

In quite a number of trials of the trituration of homatropine, applied every half hour for three times, I have invariably found total paralysis of the accommodation one or two hours after the last application, and have successfully worked out the refraction. The patient can call the next day with the accommodation fully returned and try the glasses, so as to see what modifications will have to be made before ordering them ground.

One who has had some experience in selecting glasses will never order the glass adapted to the eye in total paralysis of accommodation. The loss of a few expensive glasses and expressions of disapprobation by the patient, will teach him better.

This is certainly a great saving of time and annoyance to the patient and greatly expedites the physician's work. When a patient comes from a distance it greatly incommodes him to wait a week or ten days for the effects of atropine to pass off in order to make the second test of the glasses. It is unnecessary here to discuss the necessity of using a mydriatic in determining the refraction of the eye in many cases. When using atropine, many persons refused to submit to the annoyance and disability of a week's mydriasis; and, besides, the prolonged exposure of the retina to the flood of light that enters the enormously enlarged pupil, sometimes induced a very intense hyperæmia of the optic disc, and occasionally of the retina.

With homatropine it will be seen that extreme dilatation of the pupil never continues longer than a few hours.

The safety, certainty and convenience of the hydrobromate of homatropine for the purpose mentioned should certainly assign it a fixed place in ocular therapeutics until some better remedy shall have been discovered.

I would call especial attention to the eligibility of the triturations, which seem to meet all the requirements for convenience, agreeableness, efficiency and permanence.

THE USE OF ERGOT IN A PARTICULAR PHASE OF PNEUMONIA. NOTES ON A RECENT CLINIC IN THE MEDICAL WARDS OF MERCY HOSPITAL, CHICAGO.

BY N. S. DAVIS, M.D., PROFESSOR OF PRACTICE AND OF CLINICAL MEDICINE.

At the medical clinic in the Mercy Hospital, on March 28, 1884, the attention of the clinical class was chiefly occupied with a case of broncho-pneumonia in the sixth day of its progress. The patient was an adult male, about 30 years of age; short in stature, but broad across the chest and shoulders, presenting a well-marked sanguine temperament, with some corpulency. His habits had not been strictly temperate, and his occupation that of a laborer, but mostly within doors. He had been subject to attacks of bronchitis for some winters past, and once to an attack of pneumonia, three or four years since. Six days since, while scrubbing floors, and exposed to cold draughts with wet feet, he was attacked with severe pain in the sub-axillary region of the left side

of the chest, accompanied by difficulty of breathing, disposition to cough, and such feelings of indisposition as compelled him to desist from his work and retire to bed. The symptoms named continuing to increase, with the development of considerable general fever, a physician was called, who prescribed some medicines, and placed a large blister on the left side of the chest. On the third day he was removed to the hospital. On admission, his face was deeply suffused with redness; lips dry and slightly purple; tongue coated; skin dry; pulse 110, soft; respiration difficult, with a mixture of dry and moist bronchial râles over the whole chest except the lower part of the left side, where there were less râles, but decided dullness on percussion. The temperature was 39° C. (102.5° F.); the expectoration was not copious, but intimately intermixed with blood. The urine was nearly natural in quantity, but deeper red in color, and the bowels inactive.

The diagnosis was general sub-acute bronchitis with acute pneumonia occupying the middle and lower part of the left lung, in the early part of the second stage, or that of exudation, when the fine crepitant râle of the first stage had given place to some mucous râles, with decided dullness on percussion. After allowing each member of the class to auscultate the patient and to note closely the existing symptoms and physical signs, and pointing out the anatomical changes, with the coexistent diagnostic signs and symptoms, in each stage of ordinary pneumonic inflammation, and the progress of the present case to this its sixth day, and the third after its admission into the hospital, the lecturer remarked that there was no fixed or routine treatment that was adapted to all cases of pneumonia, simply because the morbid processes which constitute the different stages of pneumonic inflammation or pneumonitis, are liable to be modified much by the previous condition of the patient, and the coincident meteorological and sanitary influences that surround him. Cases occurring in the early and middle periods of adult life, in otherwise healthy and vigorous subjects, and in localities free from the causes of either typhoid or malarious fevers, will have the first, or stage of vascular engorgement, characterized by higher temperature, more acute pain, fuller pulse, and a little longer duration; while in the second stage the exudation will be more plastic, and the hepatization consequently more dense, which will correspondingly prolong the third or stage of resolution; and in some cases render it incomplete from the permanent identification of the plastic material with the alveoli and connective tissue of the lung. This does not prevent the recovery of the patient, but leaves him with permanent diminution of air space, and more liable to subsequent degenerative changes in the altered lung. It is this class of cases that are greatly benefited by a prompt and free venesection in the first stage, before the exudative process has made any considerable progress. The prompt abstraction of blood in the first stage of this class of cases benefits the patient in three ways, namely: by directly lessening the vascular fullness, and thereby lessening the amount of the exudation that is to follow; by diminishing the plasticity of such exudation as does follow the engorgement of the first stage: and by enabling other remedies to act more efficiently immediately after the diminished vascular tension caused by the venesection.

On the other hand, cases occurring in the very young or the old, or in those previously debilitated; and more especially in those at any period of life who are and have been surrounded by active malarious influences sufficient to impair both vascular tonus and blood plasticity, the first stage will be shorter, the exudation in the second more rapid and copious, but less plastic, while in the third, if diffuse suppuration does not occur, resolution will be more rapid and complete. If to moderate malarious influences there have been added such sanitary surroundings as develop the causes of typhoid fever, there will be added a still greater diminution of blood plasticity with marked impairment of vaso-motor nerve force, and giving a depressed or debilitated aspect to the whole assemblage of symptoms from the beginning of the attack. Pneumonia occurring under these various modifying influences, seldom presents any time, however early, in which general bleeding would not be more likely to do harm than good. The lecturer stated that when malarious influences predominated, he had often seen the most prompt and decisive benefit derived from giving the sulphate of quinine in doses of three to five decigrams (grs. v to viii) every four hours, with from thirteen to twenty centigrams (grs. ii to iii) of ergotine between, in the first stage of the attack. The direct effect of these agents in restoring the tone of the pulmonary vessels, if given within a few hours after the commencement of the attack, so resists the vascular engorgement and thereby lessens the amount of exudation, as to render the subsequent stages very mild, if not abortive. In cases occurring under strongly typhoidal influences, the quinine is less efficacious and must be given in smaller doses.

But the ergot or its active principle, ergotine, given in conjunction with digitalis to give more steadiness and tone to the action of the heart, is perhaps the most reliable agent we possess for resisting the over-engorgement of the pulmonary vessels during the first stage of the disease.

This had been strikingly illustrated in two cases of recent occurrence under the observation of the lecturer. The first was an adult, male, aged about 40 years, whose business was at the Stock-Yards, and who, in addition to much exposure to wet and cold there, had been out in company until a late hour at night, and while returning home was attacked with chilliness and severe pain in the left side of his chest, followed by a rapid development of all the symptoms of pneumonia. His family physician was called early in the morning and adopted a mild and proper course of treatment. No alarming symptoms occurred until the end of the second day, when the exudation began to increase with such rapidity that before the middle of the third, the left lung was completely engorged and dull on percussion from the apex to its base, and there was commencing crepitation in the lower part of the right. The breathing was much oppressed, short and frequent, with coarse

mucous râles rapidly increasing in the larger bronchi; the pulse soft, weak and 120 per minute; extremities cool, but temperature under the tongue 39.5° C. (103° F.); face suffused with a flush of a leaden or purplish hue; urine scanty and deep red color, and a copious, thin, and very bloody expectoration. It became evident that at the same rate of progress, before the end of another day both lungs would be completely filled with exudation and the patient suffocated. Being called in consultation at this stage of progress, it was agreed that the patient should take two decigrams (grs. iii.) of ergotine every two hours, and ten minims of tincture of digitalis with aromatic spirits of ammonia half way between, and a dose containing thirteen centigrams (grs. ii) of quinine, and two milligrams (gr. $\frac{1}{30}$) of strychnine every four hours.

A blister had been drawn on the chest, followed by emollient poultices, and the latter were continued, with milk and tea or coffee for nourishment. Under this treatment, faithfully executed, before the end of the next twenty-four hours, the whole aspect of the case was changed. The color of the surface was improved, the respirations were slower and deeper, the pulse 108 and more full, the coarse râles less in the chest, and the bloody expectoration diminished one-half. The interval between the doses of the medicines was now nearly doubled, and the improvement not only continued, but the patient made an unusually rapid recovery.

The second case occurred about one week later, and in the North division of the city. The patient was a young man who had been too closely occupied for several months in a dark, or rather artificially lighted and poorly ventilated office, during which the general tone of health had become somewhat impaired. After some exposure to wet and cold he became affected with some soreness in his chest and cough, and called at his physician's office for advice. Nothing more than a moderate degree of bronchitis, with some gastric derangements, were detected, and he was prescribed for accordingly. After three or four days he was taken suddenly with severe deep-seated pain in one side of the chest, much difficulty of breathing, more frequent pulse, and rapid increase of temperature. In a few hours his physician found him with all the symptoms and physical signs of the first stage of pneumonia, occupying the middle and lower lobe of one lung, with slight mixture of blood in the expectoration. All the symptoms increased so rapidly that in less than forty hours from the commencement of the pneumonic attack as indicated by the pain in the side, a consultation was called. At that time the patient appeared to be in imminent danger from the rapidly increasing exudation, which had nearly excluded the air from the alveoli of one lung, rendering it dull on percussion from the clavicle to the diaphragm, with a beginning of the same process in the lower part of the other. There was a leaden hue and dull expression of the face; short and frequent respirations, with an abundant thin and very bloody expectoration, causing coarse, moist râles in the bronchial tubes; pulse soft, small, and 130 per minute; and temperature under the tongue 40° C. (104° F.), but the extremities were cool. The urine was red or high-colored, and less in quantity than natural, and the patient complained of great exhaustion. It was evident that a continuation of progress in the same direction for twelve hours more would prove fatal to the patient. It was agreed that the patient should take two decigrams (gr. iii) of ergotine every two hours, and thirteen centigrams (gr. ii) of quinine with two milligrams (gr. $\frac{1}{30}$) of strychnine every four hours, with milk, koumis, and beef-tea for nourishment. At the consultation the following morning, the attending physician thought the patient in collapse and actually dying. He had remained with the patient through the night; the quinine and strychnine had been given as directed, but instead of the ergotine, an equivalent quantity of Squibb's fluid extract of ergot had been given hypodermically. On examination the patient presented the following singular assemblage of symptoms: the extremities and whole cutaneous surface were cold and wet with perspiration; the pulse hardly perceptible at the wrists, but the systoles of the heart 100 per minute; and yet the respirations were slower, deeper, and almost free from râles of any kind, with less frequent cough and almost entire suspension of the bloody expectoration. In other words, there was decided improvement in the respiratory function, in direct connection with a nearly collapsed condition of the circulation and entire cutaneous relaxation.

With the arrest of the pneumonic exudation it was evident that if any influence could be brought to bear capable of restoring the tone of the cutaneous vessels, and increasing the force and steadiness of the cardiac action, the patient might still be rescued from his perilous condition and perhaps enabled to recover. To accomplish this, he continued the quinine and strychnia as before, but in place of the ergot he was given ten minims of tincture of digitalis, five of tincture of belladonna, and fifteen of the aromatic spirits of ammonia, in sweetened water, every hour until the skin became dryer and warmer, when the interval was lengthened to two hours. He was also to take small and frequent doses of milk and coffee for nourishment. The result was all that could be desired. At a third consultation sixteen hours later, the skin and extremities were warm and dry; pulse 100, and of fair volume, though easily compressed; respirations 24, and deeper than in the morning; cough not frequent, and the expectoration containing but little blood. The bowels had moved twice during the day, and the quantity of urine had increased. Percussion still showed dullness over a large part of the side first affected, but it was evident that the crisis of the disease had passed. The belladonna had induced some dryness of the mouth and fauces with moderate dilatation of the pupils. The same remedies, however, were continued, but at much longer intervals, and the case progressed subsequently to an early recovery without further unusual symptoms.

The lecturer stated in conclusion, that such cases strongly illustrated the necessity of so studying morbid processes as to be capable of appreciating the special character and tendencies of each individual

case, and acquiring such knowledge of the action of remedies as to be capable of selecting and applying the one best adapted to fulfill any given indication or meet any unusual emergency, without regard to the name of the disease.

ON REDUCTION OF DISLOCATIONS BY MANIPULATION.

BY M. M. LOUIS HUTCHINSON, L.R.C.S.I., ETC., CHICAGO,

I would wish to invite your attention to the reduction of dislocations by manipulation, in the hope that others, becoming interested in the matter, might assist us by their information and experience. When we consider that it is the most scientific method of procedure, inasmuch as for its skilful and successful application it entails a knowledge of anatomy and mechanics; and that it possesses the advantages of being easily applied without distress to the patient, and with such little exertion on the part of the surgeon that he can usually dispense with any assistance, and that, moreover, in the event of its failure the other methods can be tried immediately after; surely it is a subject worthy of more attention than it would seem to receive at present. It is seldom made the theme of a lecture, clinical or other; the text-books award it only a fleeting notice, and consequently the student devotes little study to it, as being a subject of no importance; and the average practitioner ignores it altogether, and has at once recourse to one of the forcible methods. I do not presume to disparage these methods, as I know full well that there are cases where they alone are successful; but I venture to submit that in the majority of recent simple dislocations—especially at the hip and shoulder-joints—manipulation should first get a fair trial. Occasionally, the flexions, rotations, etc., that have been described by surgeons, will not suffice, and then the surgeon must try other movements, impossible to clearly describe, but which will invariably suggest themselves to his intelligence—the manœuvers of French surgeons—and by these means he will seldom fail to obtain success.

When a student, I was first attracted by the facilities and advantages of this procedure, and in my own practice I have obtained the most satisfactory results from it. With your permission, I shall briefly describe my last case:

— Wright, wagon-driver, aged 35, suffered from a recent subcoracoid dislocation at the right shoulder-joint. He had had six previous experiences of this dislocation, it occurring with him from the slightest cause. In every case it had been reduced after considerable difficulty by the heel-in-axilla or other of these methods, and he complained that the force employed in these efforts was such that he always suffered for a long time from its effects. I placed him in the dorsal recumbent position, and standing a little behind and to his right side, I placed my left hand on his shoulder, with the fingers behind and the thumb in front—this enabling me at once to steady the part and to feel and guide the head of the displaced humerus—which in all such dislocations can be distinctly felt beneath the coracoid process. I next with my right hand seized his arm by the wrist in the extended position, this affording me the greatest leverage, and raised it in the line of his body to an angle of about 90 degrees; then semi-rotating outwards, I made the very slightest extension, and the bone glided at once into place. I bandaged the arm to his side, gave the usual directions, and in a fortnight the man had resumed his occupation, quite well, thus showing that a more speedy and complete recovery follows the reduction of dislocations by manipulation.

MEDICAL PROGRESS.

SURGERY.

A LEECH REMOVED FROM THE LARYNX FIFTEEN DAYS AFTER ITS ENTRANCE.—Dr. Ramon Sota y Lastra reports a case in the *Revista Medica de Sevilla* of a man 64 years of age, robust and vigorous, who presented himself at the clinic, complaining of an abundant discharge of blood from the mouth, which had persisted for 15 days. The voice was hoarse and diminished, respiration labored and interrupted constantly by cough. The patient had lost one of his brothers with consumption, he himself had suffered from frequent catarrhs; had abused the use of alcoholic beverages, particularly brandy. His voice was always hoarse, and he coughed frequently. Fifteen days previously, while sweating freely, he drank some cold water, felt a sense of constriction in the throat, lost his voice, and respiration became difficult. Since then he had coughed incessantly on account of a tickling in the throat. Soon after drinking the water he commenced to spit blood, in small quantities at first, then in abundance. The swallowing of liquids and solids was performed without difficulty. Sleep was almost impossible on account of threatening suffocation.

Examination demonstrated the absence of fever, the integrity of the inspiratory organs, redness and a granulated appearance of the pharynx. On the posterior wall of the pharynx, behind the velum palati, was a little blood clot. The laryngoscope revealed a leech adherent to the epiglottis, and so placed that its caudal extremity lay upon the summit of the right arytenoid. During the attempts at removal made with the laryngeal forceps, the body of the leech was placed across the glottis and within the trachea. It was only after the fifth attempt that the leech could be seized and removed in spite of the brusque movements of the patient. All the symptoms disappeared as if by enchantment. It was supposed that the patient drank of water containing leeches.

The possibility of confounding these symptoms with tubercular laryngitis, without the aid of the laryngoscope, is very striking, and all means, other than direct extraction, for the removal or killing of the leech, would be likely to produce acute pharyngo-laryngitis. —(*Gazette Heb. des Sciences Medicales*).

On the Treatment of Burns.—Dr. John Duncan (*Edinburgh Clinical and Pathological Journal*), uses in wounds produced by the actual cautery an immediate covering of salicylic wool and collodion. The result is that no suppuration takes place. The wool ought to be teased out to an exceeding fineness at the edges, and laid on in successive thin layers, each of which is brushed with the collodion after its application. It then adheres with great tenacity, and is not apt, even with rough usage, to loosen at the edges. Inasmuch as a very little displacement of the edge of the shield or any loss of adhesion would be fatal to the plan of treatment, it is well, in the first place, to extend the dressing largely beyond the margin of the sore, and from time to time to apply fresh wool and collodion to the margins. At every stage, three, four, five, or six weeks, the wound is beautifully and typically healthy, but it does not cicatrize completely under six weeks. In burns of the first degree there is no dressing which gives so great ease, is so little cumbersome, and interferes so little with the usefulness of the limb. If there be vesication, no matter from what cause, the most perfect freedom from pain, and the most rapid healing, is brought about by pricking the blister, and when it is thoroughly evacuated, covering it with wool and collodion. Where blisters have burst or been ruffled, a dressing which is more easily removed is preferable.

MEDICINE.

The Acute Arteritis which is Consecutive to Typhoid Fever.—Dr. Baéri has made an important contribution to the history of this affection in the *Revue de Medecine*, where he arrives at the following conclusions:

1. There can be produced as consecutive to typhoid fever, an acute inflammation of the arteries; affecting the great trunks as well as the secondary branches of the heart and principal viscera.

2. The acute arteritis of the great trunks (the only one referred to here) is particularly localized at the lower extremity (22 out of 24 cases cited); it is most frequently unilateral, and especially on the right side.

3. In order of frequency the arteries which are most involved are, the posterior tibial and femoral, then the dorsalis pedis, and nearly as frequently the popliteal and anterior tibial.

4. In those cases where the phlegmasia is of considerable extent, the process originates most frequently in the principal trunk, to extend successively to the collateral branches, but sometimes, inversely, it commences with the smaller vessels to extend to the trunk,

5. Arteritis begins at the period of convalescence, when most of the patients first get up and try to walk, and this explains why the affection is so common in the lower extremities.

6. The character of the fever does not seem to have any appreciable effect on the frequency of arteritis, it being met with quite as often in benign cases as in the graver forms of the disease.

7. With regard to the anatomical lesions, the clinical evolution and the termination of the affection, there are two varieties in the arterial inflammation: the acute obliterating arteritis, and the acute parietal arteritis. These are but slight varieties of the same disease.

8. The obliterating arteritis is, anatomically, an embryonic infiltration of the three tunics, disappearance of the smooth condition, which becomes unequal and vegetating, producing in consequence a secondary thrombus which progressively establishes itself as a cruoric clot more or less voluminous, and becoming later a dense, greyish mass, adherent to the arterial walls. Most frequently a certain degree of peri-arteritis accompanies the phlegmasia of the vascular tissues.

9. If the coagulation obliterates completely the lumen of the vessel, and a supplementary circulation is not rapidly established through the anastomoses, the limb mortifies and takes on the external characteristics of dry gangrene. In certain exceptional cases, from venous thrombosis or neighboring phlebitis, moist gangrene may follow or occur, instead of the dry form.

10. Obliterating typhoid arteritis shows itself as follows:

(*a*) Pain more or less severe, exactly along the course of the arterial vessels while sometimes it is restricted to a certain region (as the calf, popliteal space, Scarpa's triangle) it may occupy the whole length of a limb, from the toes to the hip, and even to the iliacfossa. This pain is greatly increased by pressure, certain positions, movements or walking.

(*b*) Very marked diminution in the amplitude of the arterial pulsations; sometimes total cessation.

(*c*) Swelling of the affected member, without œdema or redness, and later with the appearance of violet markings or spots of local cyanosis, resembling even the spots of purpura.

(*d*) Lowering of the local temperature, with or without slight disturbances of sensibility, such as formication, partial anæsthesia, etc.

(*e*) Appearance along the course of the artery of a hard cord, painful to the touch, by consecutive thrombosis.

(*f*) Dry gangrene is the ordinary mode of termination of this affection.

11. Parietal typhoid arteritis is only a much less severe form of the preceding, which has a number of symptoms in common with it, but which is distinguished from it by certain important peculiarities, and by its termination. Its characters are as follows:

(*a*) Pain along the course of the diseased artery, generally less acute and less severe than in the obliterating form.

(*b*) Marked diminution in the intensity of the arterial pulsations, even to a total, but temporary, disappearance of these pulsations. In certain cases the disappearance of the pulsations is preceded, by a variable period, by a considerable exaggeration of their amplitude.

(*c*) Swelling of the affected limb, without œdema or redness, and without the violet spots.

(*d*) Lowering of the local temperature in most cases. In some cases, however, the temperature of

the affected side is raised to several tenths of a degree above that of the sound side.

(*e*) Absence of the hard cord along the affected vessel.

(*f*) A cure is the common termination of this affection.

12. The acute arteritis consecutive to typhoid fever may be confounded with muscular pains, local myositis, or neuralgia, when the hard cord is not present. When it is present, the affection might be taken for a phlegmasia alba dolens or a lymphangitis. The differential diagnosis may be established by noting the symptoms as enumerated.

13. When it is demonstrated that these morbid phenomena have their seat in the artery, that is obliterated by a blood thrombus, the question to consider is whether the arterial inflammation is primitive or developed secondarily about an embolic clot detached from the heart. The presence of a bellows murmur, the weakness, the irregularity, the subdued tone of the sounds of the heart; the acuteness of the pain, its sudden recurrence with the symptoms of obliteration, and finally, the appearance of vascular disturbances in several regions remote from each other, would be in favor of embolism. The normal character of the cardiac sounds and rhythm, the slighter degree of pain, less abrupt but perfectly localized, and the tardy appearance of the ultimate sphacelus, would indicate the primitive arteritis.

14. As to its pathogenesis, typhoid arteritis proceeds from two principal factors—local and permanent irritation from infectious parasitic germs, and from profound disturbances of vaso-motor innervation.

MATERIA MEDICA AND THERAPEUTICS.

INVESTIGATIONS ON INTRA-OCULAR PRESSURE.—Dr. Ernst Gruser has published (*Arch. F. exp. Path. u Pharm.*) the results of some manometric investigations on the intra-ocular pressure, and the effect that atropine and eserine have upon it. By the aid of a specially-contrived apparatus, the author has arrived at the following conclusions: 1. By means of his manometer he is not only able to determine the amount of intra-ocular pressure, or tension, but he can also detect and estimate with accuracy any variations of that pressure. 2. The amount of the intra-ocular pressure depends directly on the height of the vascular pressure. Narcotism similarly alters both, compression of the aorta raises the intra-ocular pressure by from 4 to 5 mm. Hg. Compression of the carotid on the same side causes a rapid fall of 5 or 6 mm. Hg., which, however, gradually rises again to the normal pressure. Tying both jugular veins raises the pressure, but only temporarily. The rapid fall of the arterial blood-pressure which takes place at death is accompanied by a rapid fall in the intra-ocular pressure. 3. In a cat during life, the intra-ocular pressure is on the average equal to 28 mm. Hg.; when dead the pressure is always from 8 to 10 mm. Hg. 4. The movements of the muscles of the iris always affect the intra-ocular pressure, dilatation of the pupil always causing it to rise, and contractions to fall. Section of the sympathetic causes a fall of from 2 to 6 mm. Hg. in the intra-ocular pressure, as well as narrowing of the pupil; irritation of the same nerves causes a rise of the pressure of from 5 to 6 mm., with dilatation of the pupil. 5. Atropine applied to the conjunctiva in quantities sufficient to cause mydriasis raises the pressure (there is sometimes a transitory fall before the rise). 6. Eserine similarly applied causes the pressure at first to rise, but in all cases in less than an hour the pressure had fallen below the normal.—(*Cantrelblat F. Klinischt Medicin. Medical News.*)

ON THE USE OF RESORCINE.—*La France Médicale* publishes a brief of the latest researches in the use of this drug, as given in the *Rivista Internazionale di Medicina e Chirurgia.* M. Rhigi bases his views on 100 observations. He groups resorcine with the aromatics, as among the best antiseptics and most powerful antipyretics. In 62 cases of intermittent fever he found the drug to act promptly, to be well tolerated, and to be readily absorbed. In one case there were symptoms of intoxication, due to imprudence on the part of the patient, who took 4 grammes at a single dose. In another there was a sense of heaviness with pain in the stomach, and in still another a general pruritus, but these symptoms were only of short duration. For this affection he used 4 to 5 grammes daily in an aqueous solution of 100 to 150 grammes. As to its use in this and other affections, he comes to the following conclusions:

1. Resorcine is well tolerated. It produces, but only for a short time, vertigo and tinnitus aurium, congestion of the face, and, very rarely, a sense of weight or pain in the stomach; nearly always there is abundant perspiration for about an hour.

2. Employed externally it is not caustic, and does not give off any disagreable odor.

3. In miasmatic affections, it is a sure means of combatting the febrile temperature and of opposing the malarial infection.

4. It has a certain influence in reducing the recent tumefactions of the spleen, but does not act on chronic tumefactions.

5. In typhoid fever, pneumonia and erysipelas it has a prompt antifebrile effect, but has no influence on the elevation of temperature.

6. In acute gastro-intestinal catarrh, it is of an undoubted usefulness, and has a rapid and positive effect; it may be combined with bicarbonate of soda.

7. In acute blenorrhagic urethritis, it should be preferred as a local application to other means that are more irritating and less prompt in restoring the mucous epithelium.

8. In acute and positive conjunctivitis and in lesions of the cornea it is one of the best collyriums.

M. Masini uses it in solution in affections of the ear, as a detersive, a slight astringent, an antiseptic, and a caustic, preferable to phenic acid, as the latter is irritating, cauterizing and debilitating to the organism, and has a disagreeable odor; preferable to iodoform with its disgusting odor, and to boracic acid, which has much less antiseptic and antiputres-

cent qualities. For an antiseptic solution he used 1 or 2 per cent. of resorcine; in granular otitis, for a marked astringent effect, 4 per cent.; for a strong caustic solution, 50 or 60 per cent.; in otorrhœa, for injections, an aqueous solution of 2, 3, 5 per cent.; in parasitic affections, a vaseline ointment of 10 per cent.

M. Massei recommends warmly the use of resorcine in ozœna, in powder or as a nasal douche. He employs 2 grammes in 600 grammes of water. If this does not relieve he uses the powder, and if a radical cure is not effected, great relief to the odor is afforded.

Bromide of Arsenic in Diabetes.—The *Journal de Médicine et de Pharmacie de l'Algeri* tells us that this drug has been employed four times successfully by Dr. Arpad Bokai. He prepares as follows:

Mix the following in a glass tube:

Arsenious acid } .....aa O gr. 1.
Carbonate of potassa }
Distilled water..... 5 drops.

Heat to limpidity and add enough distilled water to make 10 grammes. Add four drops of bromine and let the mixture stand for a day, when it is ready for use.

A diabetic, 22 years of age, who, at the time of his admission to the clinic, could hardly mount the staircase, was entirely relieved in a little less than three months. In that interval he gained in weight 8 k., 100 gr., and the proportion of glucose, which had varied between 170 and 111 grammes a day, was reduced to 0. During the last days the medicine was suspended and the patient nourished with rice.

The patient was submitted at first to a strict diet for 17 days, which diminished the proportion of sugar to about one-half. He then received the bromide for 11 days in three-drop doses, which was increased to 6 drops a day, in consequence of which the proportion of sugar diminished rapidly, and the analysis gave only traces. After introducing certain modifications to the diet, a small quantity of sugar was noted in consequence for 27 days. Five drops of the bromide was given, and 150 grs. of rice added to the diet list. Finally the drug was abandoned, the diet restrictions removed, and the patient discharged relieved.

Investigations into the Physiological and Therapeutic Properties of Trinitrine.—M. Marieux has studied the effects of this drug, (Bull. et Memoires de la Soc. de Therapeutique) in 23 experiments made on guinea-pigs, frogs, rabbits and dogs, and on man. These experiments were made in the presence of M. Dujardin-Beaumetz, and with the assistance of MM. Eloy and Huchard, with the following conclusions:

1. Trinitrine acts on the brain by producing phenomena of congestion.

2. It accelerates the heart beat, dilates the peripheral vessels, and diminishes arterial tension.

3. This vascular dilatation seems to depend upon a paralysis of the great sympathetic.

4. It acts but feebly upon the respiration, which becomes irregular.

5. It has but little effect upon the secretions.

In toxic doses:—

1. It produces, in the lower animals, clonic and toxic convulsions.

2. With the rabbit and dog, the toxic dose is variable, but is very large in all cases.

3. In man it commences with 10 drop doses of the alcoholic solution.

In the therapeutic application:—

1. It is indicated in all cases where cerebral anæmia might lead to fatal results.

2. It gives good results in rebellious neuralgias of anæmic origin.

3. Its most marked action is in angina pectoris.

4. It is of no use in diseases of the kidneys or lungs.

5. It is contra-indicated in all affections where there exists active or passive cerebral congestion.

6. It can be administered very satisfactorily in 4 to 6 drop doses of the alcoholic solution of 1 to 100, in the 24 hours, either as a potion or in hypodermic injections.

7. When compared with the action of nitrite of amyl, it is less prompt and less sure, but its effects are more enduring. In many cases it would be well to combine the two.

The Physiological and Toxic Action of Ergotine as Illustrated by Case of Poisoning.—Dr. Debréne (*Bull. Génde Thérapentique,*) gives the case of a young woman 25 years of age, ordinarily in good health, but suffering for 8 or 10 years from hæmorrhages coincident with the menstrual flow, She rarely passed three or four months without having one, two or three attacks of hæmoptysis at the second or third day of her courses, the loss of blood being sufficient to produce an anæmic condition which prostrated her for some time. Examination of the chest showed no affection of the lungs. To relieve this condition Boryjean's ergotine was used with benefit, but on one occasion she took of her own accord a dose equal to 5 or 6 grammes of ergotine. This was in the morning (Nov. 6.); it checked the hæmoptysis, but not the menstrual flow. She took her midday meal with a good appetite; in the afternoon there were a few sharp pains in the abdomen; at 6 P. M. she took a cup of chocolate; in fact, up to that time there were no evidences of any poisonous effect. At 6:30 P. M. she complained of a severe, dull pain, deep in the lower part of the abdomen, and of a want of air. Soon after she lost consciousness. The symptoms which followed were a marked dryness of the mouth, throat, and skin, pericardial pain which was extreme, with great difficulty in respiration. A deep pectoral and epigastric pain seemed to follow the course of the bronchi and of the œsophagus, and was compared by the patient to rough rasping with a curry-comb. While continuous, the pain was increased at regular short intervals. Vertigo followed; obscurity of vision, ringing in the ears, a sense of weight in the head, and constriction of the temples, formication in the extremities, chilliness and general coldness, insensi-

bility of the integument to the touch, to pain, to cold and warmth. This anæsthesia began with the fingers and toes, to spread over the whole of the body, including the lips, tongue, etc.

At 10 P. M., in addition to theses symptoms, tonic and clonic convulsions set in, resembling epileptiform spasms and followed by contraction of the flexor muscles, the fingers being markedly flexed upon the palms of the hands; extreme pallor, respiration 50, pulse 50, axillary temperature 97.5. A subcutaneous injection af ether into the forearm produced ready relief of all the symptoms, and a gradual progress, with frequent temporary relapses, was made from this time on to recovery, which was established (Nov. 9), in three days. During the treatment 10 grammes of chloral and more than 12 grammes of ether were administered, with a large amount of coffee.

This case brings out in bold relief the physiological action of ergotine. It shows that the absorption of this drug by the stomach is slow and gradual, and may give rise to a false security. It shows that its action is not so fugacious as has been supposed, and that it is not eliminated so rapidly as has been supposed. It indicates the valuable assistance we have in injections of ether in combating the toxic action of the drug.

In spite of the large amount of coffee given, the amount of urine was not increased; it would seem as if the contraction of the minute blood-vessels of the kidneys prevented an abundant filtration. And this action upon the vessels would explain the vertigo, intellectual torpor, and feeling of extreme weakness, that is to say, the diminution of the spinal excito-motor power (anæmia of the brain and cord), the chills, lowering of temperature, dryness of the skin and cessation of the salivary, sudorific and sebaceous secretions, difficulty of respiration (accumulation of asphyxiated blood in the medulla oblongata), and the convulsive attacks (repletion of the veins of the nerve centers and sinuses of the dura mater).

The deep-seated pains in the chest and epigastric region were evidently due to spasms of the muscle fibers of the œsophagus and bronchi, just as the contraction of the skin was due to spasms of the little muscles attached to the hair follicles.

The most curious of these phenomena is the anæsthesia which was complete from the soles of the feet to the scalp, but which did not prevent the patient from appreciating strong, firm pressure, as if the muscular sense was retained.

OBSTETRICS AND GYNÆCOLOGY.

A FAVORABLE CASE OF RUPTURE OF THE UTERUS.—The *Annales de Gynécologie* give the details of this case in the words of Professor Pajot, and in his happiest style. The case occurred in a multipara. The midwife, after rupturing the membranes, called in a physician, who found the woman suffering from a severe pain in the abdomen, and losing considerable blood; he became demoralized and left the case, when the woman was brought to the clinic. Being anæsthetized, Pajot found a narrowing of the pelvis, a shoulder presentation, the placenta inserted on the inferior segment of the uterus, and a rupture of the vagina and uterus which had its seat in the anterior cul-de-sac, and was prolonged along the anterior wall of the uterus, being sufficient to allow the entire hand to pass through the orifice. The hæmorrhage was excessive. He performed version by external and internal manipulation, and delivered the trunk. The head was well flexed, and the inferior maxilla was easily reached, but it was impossible to disengage the head, on account of the narrowness of the pelvis, which required for its removal a single application of the cephalotribe. On the tenth day, the woman's temperature was 100.4; the pulse 100; she took bouillon and digested well. A diarrhœa which earlier in the case was very obstinate, had about ceased. On the thirtieth day her pulse was 84; temperature 99; well nourished, good color, and out of danger except from possible embolism or hæmorrhage.

OBSERVATIONS ON THE NORMAL TEMPERATURE OF THE HUMAN BODY.—Dr. William Carter, as Physician to the Royal Southern Hospital of Liverpool, has communicated some interesting records of temperature to the *Liverpool Medico-Chirurgical Journal*. After noting the observations so generally made regarding a periodical rise and fall in the temperature of man during the twenty-four hours, a minumum about 6 A. M., and a maximum between 4 and 9 P. M., independent of sleep, he set himself to work to determine whether this periodicity might not be modified in accordance with the ordinary habits of life, and selected for observation the night nurses and night sisters of the Royal Southern Hospital. Their routine is as follows: Rise at a quarter to eight P. M., down at twenty minutes past eight, breakfast at 9, and then enter on their hard duties. Their duties cease at 9 A. M. They take exercise till twelve, when they go to bed. Six of these were selected. They had performed this duty respectively, three years, ten years, seventeen months, two months (2), three weeks and lastly, the night of commencing observation was the first night of the new duty.

The temperature was taken every two hours, with the thermometer in the axilla for five minutes, and continued for five to six days. The record is given in detail, and establishes the conclusions: that a daily depression of temperature takes place in the healthy during night and early morning; that such a change of habit as turns night into day, so far as employment is concerned, does not permanently affect the character of this depression; that a daily range of from two to three degrees Fahr. may take place consistently with health; that an axillary temperature of 96°, or even lower, at some period of the night, is consistent with health, and that the character of the daily oscillation is not markedly affected by food.

The American Journal of Ophthalmology is the title of a new journal announced to appear next month, to be published by Jas. Chambers & Co. The editorial management is to be in the hands of Dr. A. Alt.—*St. Louis Courier of Medicine.*

THE

Journal of American Medical Association.

PUBLISHED WEEKLY.

THE EDITOR of this JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information, should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE..... $5,00.
SINGLE COPIES..... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

SATURDAY, APRIL 5, 1884.

MEDICAL COLLEGES AND THEIR ENDOWMENTS.—A medical college should not be an institution for the manufacture of physicians, but one where the science and art of medicine is taught, where their study and advancement is encouraged. The busy practitioner can seldom keep fully abreast of the times. This partial ignorance is offset by personal experience. The fact, however, makes a thorough drill in college especially desirable. Much has been written and spoken about the time requisite for the instruction of students, the laboratories and hospitals needed, and the personal attention from instructors that is desirable. Too much cannot be said on these points, but back of them all is the first and fundamental requisite —liberal endowments—both for the maintenance of laboratories and the support of professors. Students to-day cannot be taught as simply and inexpensively as fifty years ago. Science, and the practical teaching of it, has made too much advancement for that. Not only are dissecting rooms and chemical laboratories needed, but physiological and pathological as well. Clinical teaching has so far improved that where it is best taught the classes are small, and consequently many instructors are needed, or a great deal of time must be devoted to the work by a few. If many are employed, it is almost impossible to get enough thoroughly good teachers in even our largest cities to fill the places. When there are many it is seldom also that they take the same interest in their work that they would if they did more of it. Teaching becomes with them merely an extra labor, not the one their interest leads them to follow with most diligence. To properly care for a laboratory of any kind and give instruction in it, several hours consecutively must be devoted to it each day. This is more time than a physician dependent, even to a limited extent, upon his practice for support, can devote to it. If the professor's efforts are directed to building up and cultivating a practice by the aid of his professorship, he will not teach with the purpose of imparting the most information and drilling it into the students. Teaching of any kind to be efficient, must, as a rule, be done by those who are independent of the patronage of their school. They can then demand of the students the work and study that is really necessary. Professorships in medical colleges should be so well endowed that those who hold them could devote all their time either to teaching and the preparation for it, or to original investigation and the encouragement of it in others.

Our colleges are very poorly endowed. We cannot expect a change in this respect, however, until the medical men of the country become fully awakened to the fact, and make known the need of endowments to the laity. In the last printed annual report of the United States Commissioner of Education[1] it appears that of all the colleges in the country only seven have productive funds. The rest depend wholly on their income from tuition for support, and even the seven do practically the same, as will be seen from the following statement:

The Medical Department of Yale has a productive fund of $29,102, which yields an annual income of $4,251. The Medical College of Indiana has a fund of $1,000, which yields $50 yearly. Harvard Medical School has a productive fund of $280,391, which yields $7,141 annually. Kansas City Medical College has $1,000, which yields $100. The Medical Department of the University of Pennsylvania has $50,000, with an annual income from it of $3,000. The Medical Department of Howard University has $2,200, which yields $154 yearly. Meharry Medical Department of Central Tennessee College has $2,500, but by the report is not credited as receiving any income from it.

It is a matter of self-interest with our citizens that the physicians in their midst are thoroughly competent. Most persons place at once implicit confidence in the doctor they call. Their health, often their lives, are dependent upon his skill and knowledge.

They have scant means of measuring the ability of physicians. In no other profession can charlatans and pretenders work so safely. The giving of money

[1] Report for 1881, printed in 1883.

for the proper endowment of medical colleges will not, therefore, be a charity to a few medical teachers, but a means of protecting the public, as efficacious and as necessary as general and judicious laws regulating the practice of the profession.

There are schools that have been for years doing their utmost to furnish good teaching that are thoroughly deserving of aid. It is not new colleges that is required but a more efficient management of old ones.

MEDICAL SERVICE ON SHIPS.—During the past two years the subject of better medical service in merchant and emigrant vessels traversing the oceans has attracted considerable attention in England, and it is at present engaging the attention of prominent members of Parliament. It is well known that a large proportion of the ocean traveling is done in English ships and steamers, not only across the Atlantic, but also to Australia and the Indies. According to the following statements of Dr. J. A. Irwin, a well-known English physician, who has recently taken up his residence in New York, there is urgent need of improvement in the direction of more efficient and uniform government regulations concerning the supply of competent medical service on board of all vessels carrying passengers of any class on the oceans. Speaking of the English lines recently to a reporter for a daily paper, he says:

"Of all the lines? You must bear in mind that England has not one mercantile marine medical service but perhaps fifty, each under different orders and regulations, and varying in customs and conditions. There ought to be one national service. There is comparatively little cause of complaint with possibly two or three companies, but the others are open to many objections, more than I can think of enumerating. This diversity of the service is a strong ground of complaint, as it leaves no central responsibility for or power to correct abuses or neglect. There is no regulation or definition of the duties, responsibilities, status, salary, grade, or even of the accommodations of a surgeon on shipboard. There is no fixed pay, or rank, and no examination made of ship's surgeons by any official power. An economical company or miserly owner can engage any incompetent young medical graduate, without reference to anything but the lowest salary he will ship for or the highest price he will pay to practice on the passengers while taking a pleasure voyage or two. The highest wages now paid surgeons on steamships is only $50 a month, or about the wages of a cook or steward. Perquisites are few nowadays; so you see even the best steamers give very insufficient pay.

"Competent men can seldom be had at these rates; when such as are competent are forced by personal necessities to ship as surgeons, they remain aboard only until they can better themselves. Hence, there is little stability about the service, and you seldom find a really competent surgeon for any length of time in a company's employ. The companies and ship owners engage surgeons as they do seamen, by the voyage, and as a consequence are often forced to engage a new surgeon at a day's notice before sailing. Often crowded passenger-ships are sent out in medical charge of young and inexperienced surgeons, liable themselves to sea-sickness, and who do not even know what duties they will have to perform, for instance, on reaching quarantine in your port. At other times men in poor health, which in fact forces them to be at sea for their own strength, will be engaged as surgeons, Of course such cannot be depended upon to perform all the service demanded of them on a crowded vesssel. Then, there is another class still more objectionable; I may call them men ofdefective personal habits, incapable of commanding and retaining practice at their homes. There are many of these incompetents on English lines. Proof of it? Certainly. Here is a return made to Parliament by the Board of Trade last year. It shows that of 141 surgeons who, during the first six months of 1882, had full medical charge of ships carrying passengers to this country,—transatlantic steamers, mind you,—only 27 who possessed any qualifications as a physician and surgeon had reached 30 years of age. Forty-six were under 25 years. And here is a point which will astonish you. Sixty of them would have been ineligible through lack of professional qualifications for any appointment in our Army, Navy, asylum, prison or poor-law service. That is to say, these ships, and your Americans on board of them, have been dependent for medical advice on men who are pronounced by English law to be insufficiently qualified to treat English convicts and paupers.

"Now, I want you to understand that among the ships' surgeons some are all that they should be. I could name men who are competent to fill any position with honor. The trouble is that under the present circumstances the position seems made to suit the half-qualified youngsters, and the competent men are forced into it upon exactly the same terms. The return which I have just shown you, proves that on the 108 ships in question plying between this country and England, there were 33 medical officers who were either dismissed or resigned during the period

named. The surgeons have no assistance whatever on these steamers, not even a hospital nurse, and as a consequence, during the times of general sickness, one man cannot do all the work satisfactorily. I suppose you think that sea-sickness needs no treatment; but I have myself seen two cases of death from heart disease which would not have occurred if the violent vomiting from sea-sickness, which was the immediate cause, had been controlled by treatment."

Many might suppose that the short time now usually occupied in crossing the Atlantic, would give but little time for any other than sea-sickness, and consequently that the quality of medical service was of little consequence. This error will be effectually corrected by the following statistics given by Dr. Irwin:

English statistics, published by order of the House of Commons in 1882, show that of the thirteen principal English lines to this country the mortality in 1881 on one or two of the inferior lines reached one in every 509 of those embarking. The lowest rate was on the Inman line (one in every 3,313); but as this mortality was among immigrants who within a few days of sailing were passed as healthy, the rate is still too high. It must be remembered that these figures represent deaths on board during a short trip on the ocean—usually a healthy thing to take—of only eight or ten days. Further—and here is the most serious consideration—nobody can tell how many of the sick and enfeebled who are landed here die at their destinations of diseases contracted, but not fully developed, on board ship. The trip across the Atlantic is so short that the germs of contagious diseases caught on shipboard do not develop until the affected persons have passed quarantine and are possibly thousands of miles in the interior. Statistics are, therefore, incomplete and untrustworthy.

There is serious danger in this unsatisfactory medical service, not only concerning individual illness of the passengers, whether in the saloon or the steerage, but concerning the general health of the communities to which the passengers and immigrants are bound.

As the people of no country are more interested than those of our own, either in the healthfulness of ocean travel, or in the danger of importing contagious diseases into different parts of the country, it would be well for the profession here, as well as our government, to cordially coöperate with whatever intelligent and judicious efforts are made in England or elsewhere, to improve the medical service on ships of every class.

We make no apology for occupying so much space in the present number on the important subject of milk supply in large cities.

Medical College Commencement.—The twenty-fifth annual Commencement exercises of the Medical Department of the Northwestern University, better known as the Chicago Medical College, were held in the Grand Opera House on the afternoon of March 25, 1884. Rev. Joseph Cummins, President of the University, presided on the occasion and conferred the degrees upon the graduating class, which numbered thirty-eight in regular course, one ad eundem and one honorary. After the opening prayer and music, the Dean of the Medical Faculty announced the certificates for the under graduates, certificates for special work in the Hospital and Dispensary, and the award of prizes. The prizes for the two best theses were taken by C. S. Bacon, of Wisconsin, and George A. Staples, of Iowa. The Alumni prize for the best average scholarship in all the branches of the three years' study was taken by A. C. Helm, of Illinois; the Senn prize for the best anatomical preparation by T. H. Swayne, of Illinois; and the Microscope prize offered by W. H. Bullock of Chicago and J. Grunou of New York, to the candidate for graduation who should sustain the best examination in the theory and practice of microscopy, open for competition to the graduating classes in all the colleges of Chicago, both literary and medical, by C. S. Bacon, of Wisconsin. The practical working of the long college sessions, the thorough grading of classes, and the annual examinations of each class in its grade, instituted by this college is well illustrated by the following remarks of the Dean of the Medical Faculty, in presenting the present class of candidates for graduation to the President of the University:

"*Mr. President:*—The college class represented by the candidates for graduation before you entered their first year, numbering SIXTY-FIVE.

"The effect of the examinations in the branches of medicine embraced in the first year course, was such as to convince FOURTEEN of these that they had better seek some *shorter* and *surer* road to the principal object of their ambition, a *diploma*, and consequently the class in its second year numbered only FIFTY-ONE.

"The effect of the examinations in the studies of that year added to the first, produced the same convictions on TEN additional members. Consequently the class in its third and last year numbered FORTY-ONE.

"I regret to say that the result of the third year examinations has caused *three* (3) of these to be missing from the class as they stand before you today.

"These facts will justify me in assuring you that the 38 young men whom I present to you to-day as candidates for the degree of Doctor of Medicine, and for a formal admission into the ranks of one of the noblest and most responsible of professions, have been subjected to a patient, systematic and thorough course of medical training in every department, from the elementary work in the laboratories of anatomy, chemistry and histology to the direct practical study of disease at the bedside of the sick in the hospitals and dispensaries. More than this—they had been well prepared for professional studies by a good general education. *Seventeen* of the 38 are graduates of literary colleges in good standing, embracing some of the colleges and universities of the highest standing in our country. The remaining 21 have given the medical Faculty full evidence of possessing a good academic education. As the representative of the Faculty of the Medical Department of the University over which you preside, I take pleasure in asking you to confer on each member of the class here presented the degree of Doctor of Medicine, feeling a strong assurance that by their attainments, their industry, and their personal integrity they will prove an honor to their Alma Mater, and a blessing to the communities in which they may live."

SOCIETY PROCEEDINGS.

SUFFOLK DISTRICT MEDICAL SOCIETY.

SECTION FOR CLINICAL MEDICINE, PATHOLOGY, AND HYGIENE. ALBERT N. BLODGETT, M.D., SECRETARY.

Special Meeting, February 27, 1884. Meeting called to order at 8 o'clock, Dr. Robert T. Edes, Chairman, presiding.

The Chairman announced that Dr. Morris, of Philadelphia, who was expected to present an essay, was detained by sickness and would not be at the meeting. Dr. H. O. Marcy, however, had received the paper from Dr. Morris, and would read it. The title of the essay was

ON MILK SUPPLY IN LARGE CITIES[1]

Probably few persons whose attention has not been especially called to this subject have any idea of its importance in an economic as well as sanitary point of view; and it may therefore be well to preface what I have to present to you to-night with a statement, approximate only unfortunately, as full and reliable figures are hard to obtain, of the amount of milk—or what purports to be such—required daily in our large cities.

[1]By J. Cheston Morris, M. D., formerly Attending Physician to the Protestant Episcopal Hospital, Philadelphia.

Dr. H. A. Pooler, of Goshen, N. Y., estimates the amount sold daily in the cities of New York, Brooklyn, and Jersey City, at 500,000 quarts, or 182,500,000 quarts annually. I have elsewhere shown from the statistics furnished by the Railroad Companies and the Board of Revision of Taxes, that the amount in Philadelphia alone is 57,548,470 quarts. The supply of Boston I have sought for, but have not received a reply from the Secretary of the State Board of Health. But if we compare these figures with the population of the four cities named we find in round numbers as follows:

182,500,000	quarts	consumed	among	2,500,000	persons.
57,500,000	"	"	"	900,000	"
240,000,000	"	"	"	3,400,000	"

or about 70.6 quarts annually, or not quite $^2/_5$ of a pint daily for each man, woman, and child. This is rather more than the average of England, less than half that of Wales, not one-third that of Scotland or Ireland, and far below that of Norway, Sweden, Switzerland, and the Tyrol, as we learn from Edward Smith "On Foods" and Brassey "On Food and Labor." We may therefore fairly conclude that this is not an overestimate of the actual supply in these cities. If we now multiply these 240 millions by six cents, the *lowest* price paid by the *consumer* for the article, we obtain the amount annually paid by the inhabitants of these four cities, namely, $14,400,000, or nearly $40,000 daily. Surely then we may well pause for a moment to consider what it is that we buy at such a price, and what its real value is to us.

From Simon's Animal Chemistry, vol. ii., p. 62, we may deduce the composition of cows' milk as follows:

Water		860 parts.
Solids, Butter	36 parts	
Casein	68 parts	
Lactin, coloring matter, etc	30 parts	
Salts	6 parts	
In all	—	140 parts.
		1000 parts.

And Dr. P. Vieth, in the *Analyst* for March, 1883, gives the results of 12,430 analyses made for the Aylesbury Dairy Company, in London, during 1882, which practically accord with the above.

A quart of milk, of the average sp. gr. of 1.031 as given by Dr. Vieth, would then weigh at 60° F. about 15,092 grains, of which 12,979 grains would be water, and 2,113 solids. Of the latter there would be:

Butter	543.3 grains or nearly	1¼ oz. avoirdupois.
Casein	1.026.3 grains or more than	2⅓ oz. avoirdupois.
Lactin, etc	452.8 grains or more than	1 oz. avoirdupois.
Salts	90.6 grains or nearly	1-5th oz. avoirdupois.

If we now take these quantities and value them at market rates, say roughly:

1¼ oz. butter @ 30 cents per lb	.02
2⅓ oz. cheese @ 6 cents per lb	.01
1 oz. milk sugar @ 8 cents per pound	.005
1-5th oz. phosphates, etc	.005
	$0.04

We obtain a value of milk which corresponds curiously with its *wholesale price* paid to the producer in the vicinity of Philadelphia and New York, and its actual minimum cost of production. The latter may readily be ascertained approximatively by estimating the average annual yield of a good dairy cow

at 2,000 quarts, and the food required at five tons of hay or its equivalent, besides some bran, corn meal, roots, etc., so that the farmer is only selling his hay at $15 per ton when he receives 4 cents per quart for his milk, besides taking all the additional labor, investment of capital, and risk of loss.

I have spoken thus of the pecuniary value, let us now consider its food value. By comparing the statements of Valentin, Lehmann, Bidder and Schmidt, Chossat, Bèclard and Carpenter, as to the amount of food required daily, with the rations of the British and French armies and those of the United States (as will be seen on referring to my article in the *Philadelphia Medical Times*, June 21, 1879), and with the amount of solids as given above, it will be seen that *two quarts* of fresh milk and twelve ounces of bread would be sufficient to maintain a laboring man in full health and strength, the amount of nutritive material being greater than the ration of the French cavalryman. On three quarts milk and twelve ounces bread a man would soon fatten. By comparing the cost of sufficient milk and bread to nourish efficiently a man with that of any other food we shall be struck with its cheapness. But it is not in this that its greatest value lies. It is in the exact adaptation of the various constituents, the fatty, the starchy, the saline, and the nitrogenous, to the wants of the human economy, adaptation both in proportion and kind: so that no other article comes so near to being the universal food of man. Not only does he as all other mammalia depend upon it almost exclusively during the first two years of his existence, but during childhood and adult life milk or its products are essential to our well-being, while for invalids it furnishes the most available and reliable form of nourishment, in many cases the only form. Nor does any mode of preparation enhance its nutritive value. In by far the greater number of instances it is more wholesome and nutritious, more easily digested and more readily absorbed just as it comes from its source than in any other guise. It satisfies the appetite, quenches the thirst, relieves weariness, sustains for the work more surely and quickly than anything else.

Of course its mode of administration and the quantity taken must vary with the age of the individual and the object sought to be attained. We frequently hear from patients the complaint that they do not like milk, and never did, that it never agrees with them, constipates them, etc., etc. Now, in most instances, this is merely prejudice, based sometimes on injudicious mode of taking, or on an inferior article, or on the total absorption of the amount taken, which thus leaves no mass of undigested residue to act (as is the case with food containing woody fiber) on the coat of the bowel as a mechanical irritant. If milk is given in divided doses at intervals of three or four hours, to be sipped slowly, while a little bread is eaten with it, it rarely fails to agree with a healthy stomach or even to restore a debilitated one; if there is any sense of oppression it is a good plan to give one or two teaspoonfuls of liquid rennet with, or immediately after it. While any tendency to constipation may be met by the addition of a little *cream* to the whole milk or the use of a rhubarb pill at night. The benefits of an exclusively milk diet in cases of enfeebled digestion, chronic liver and kidney disease, consumption and impaired nutrition generally, will hardly be believed by those who have not made a thorough trial of it.

Such, then, as briefly as I can give it, is the value of milk from a physiological and medical point of view. No dietary is complete without it or its products, and we all feel keenly its loss when compelled to do without it. But how shall we get it pure and good—so perishable, so prone to change, so apt to absorb impurities, and to be the carrier of the zymotic elements of disease instead of the genial nourishment which vivifies?

In the country, in small towns and villages, we may fairly attribute the health we often see among those subjected otherwise to many privations to the ease with which this great necessary of life is procured. But as cities grow in size, as more second and third parties have to come between the producer and consumer, the difficulty of procuring reliable, nutritious milk increases. Human cupidity comes in, and the bountiful nourishment is robbed of its richness by degrees; water is added, cream is abstracted, and what is sold to the mother for her hungering babe is but the ghost of its former self. Some years ago, in the Campo Santo, at Munich, I walked through the halls where are laid the corpses of those awaiting interment. That day there were over thirty, and all but two or three were those of children. I asked my guide if any epidemic was raging. He looked surprised, and said "No." When asked how there came to be such an excessive proportion of young children, he shrugged his shoulders and said, "Many are the children of poor seamstresses and store girls, They have little to eat themselves, and nothing to give their children; the latter are starved and die, often much to their parents' relief." As I looked at the poor, pale, pinched cheeks and wasted bodies, and thought of the effects of cholera infantum, diarrhœa, tubercular enteritis, etc., which play such sad havoc among our children in large cities, the thought occurred to me, how much of all this is the result of the miserable trash with which we delude ourselves and the poor little innocents committed to our care, calling it milk forsooth! Bad air has its victims by thousands; bad food by its tens of thousands. In New York City alone, as I am informed by Dr. H. A. Pooler, the number of deaths among children under five years of age was reduced 3,673 in last year below that of 1882, in consequence, as he believes, of the improvement effected there already in their milk supply, the adulterations having been lessened to the extent of 100,000 quarts daily.

Various methods have been devised in the effort to remedy this supply of adulterated milk. Systems of inspection under governmental authority have been largely resorted to, and with excellent effect; they should be increased and made more stringent. But they are cumbersome and expensive, and too often fail to protect the very classes that need it most. The Aylesbury Dairy Company in London has a most efficient and extensive system of inspection and de-

livery, but this must increase the cost to the consumer. In Paris a Mr. D'Arcy has successfully introduced the method of supply in glass bottles; and in New York Mr. F. Ratchford Starr has done the same; while in Boston Mr. Burnett and others I believe, are largely engaged in distributing milk by the same method. I have also been doing so in Philadelphia since 1878, and my example there was followed by a number of others, so that I feel justified by the results of experience in urging the members of our profession and others who are interested in the welfare and health of the community to endeavor to extend the use of milk shipped in glass jars.

The method which I have adopted, for which the Agricultural Society of Pennsylvania awarded me an honorable diploma in 1879, is as follows:

The cows are well fed, and kept clean, before being milked the udders should be thoroughly freed from dirt. The milk when drawn is strained into a large can in which is suspended a smaller one filled with ice and salt, so as to cool it as rapidly as possible. It is then thoroughly stirred, so as to equalize the distribution of cream; and from a faucet at the bottom of the large can the milk is drawn into quart jars, each of which is then closed and sealed with a label bearing the name and address of the producer and the date of shipment; twenty jars are then packed in a box and sent to the city. The empty jars of the previous day are returned, cleansed, and prepared for shipment again.

The advantages of this method over the usual one among us in large cans are:

1. The milk must be clean; any dirt would show at the bottom of the jar.

2. It is free from contamination by foul air, etc.; in transit, as the jars are heametically sealed.

3. Each customer gets an exact quart, as the jars must be *filled* to prevent "churning."

4. Each customer gets his own share of cream, neither more nor less, as it is put up before the cream has a chance to separate.

5. It is for the interest of each producer to send the best article he can, as his reputation—and therefore the price he gets—depends upon the quality of the article which bears his name; and he can guarantee to the consumer, as long as his label is undisturbed, the quality of the article furnished.

And this brings us to the consideration of a most important point. As I have shown, good milk *costs* four cents a quart to produce; but the competition of trade often drives the wholesale price down to three and a half or three cents. In the eyes of the dealer, and too often of the too close-buying customer, milk is only milk—all milk is alike—and the honest man who sends whole (pure) milk gets no more for it than his neighbor who removes half the cream, or adds a little water "to pay the freight." So long as this is the case in the estimation of the community, so long may they expect to be imposed upon. Just as soon as they recognize the justice and propriety of paying their milk producers in proportion to the quality and value of the article sold, there will be no difficulty in having on our tables in large cities milk just as pure, just as good, just as sweet, nutritious and wholesome, as if taken immediately from the spring house in the country. There is a difference too—and a great difference—in the milk produced by different breeds of cattle. Those commonly known among us may be divided into three groups: the Jersey, or Channel Island; the Devons, or long-horns; and the Durhams, or short-horn. The latter yield abundantly a rather pale blue milk moderately rich in casein, but not in cream or sugar. The Jerseys yield a smaller quantity of milk, rich in yellow cream, but poor in casein and sugar. The Devons, or long-horned red cattle, yield a white milk nearly equal to the Jerseys in cream, and very rich in casein and sugar, and hence having the highest nutritive value. Next to them comes that from grade Jerseys: next, that from good common cows. That from pure Jerseys is deficient in casein, that from pure Durhams is watery.

I have thus, I think, called your attention to a matter of vital importance, and tried to show the way out of the great difficulties which surround the distribution of milk—pure milk—in large cities. The measure of success which has attended this method, and its more and more extensive adoption, lead me to hope that in the not distant future its cleanliness and superiority in every respect will put an end to present milk-can system with all its dirt and liability to fraud and deception.

DISCUSSION.

The paper was attentively listened to, and on its conclusion an interesting discussion was opened by Dr. H. J. Barnes, who said: Personally my experience with the milk supply of Boston has provoked the greatest indignation. It begins as a producer on my father's farm sixteen or eighteen years ago, when we, in common with our neighbors, were in a continued state of irritation by what seemed unfair treatment by the contractors. The violation of agreement as to what they would pay for the milk of a stated season, the sending back of sour milk, usually with the cream taken off, the necessity of holding the milk ourselves when at certain seasons the contractors found they they had engaged more than they could dispose of, were among the causes of trouble, which continue to the present time, judging from the expressions of views at the recent largely attended meeting of producers in Boston, and from the following letter just received from a milk producer:

"The contractors hire the car, and although obliged to carry milk for private parties, yet they generally dictate terms, so it is almost impossible for producers to get at consumers direct. Twenty-seven cents per can of eight and a half quarts, or three and thre-seventeenths cents per quart, is what my neighbors have had thus far this winter. This month one cent more per can, or three and one-fourth cents per quart, while consumers, some of them at least, pay eight, and get extended "topped" milk at that. Producets are compelled to keep a part of their milk at home in order that these cormorants may supply the good people of Boston milk watered and skimmed, with other abominations thrown in. Right glad would the producers be to send their milk direct to the consumers if it were possible, but now it must go through the same old channel."

There is an inevitable variation in the supply and in the demand for milk. The farmers dispose of the milk to contractors who make a price for a certain time and agree to take all that the farmer produces. Often the quantity is much in excess of the demand and the contractor frequently breaks his bargain with the farmers, who then are obliged either to accept a smaller price for the milk or to make butter or cheese in order to utilize the surplus.

The laws of trade ought to regulate this matter, but if a farmer withdraws his dairy, and attempts to make butter, he is met in competition by the manufacturers of oleomargarine, and it does not pay to make honest butter. One of the most objectionable features in our system of supply is the custom of holding the milk in Boston. In many instances milk produced in the morning is taken to the car in the evening and transported to Boston during the night. The next forenoon it is delivered to the distributers, who take it to their barns or sheds, and there put it in the small service cans for delivery the next morning. It is then forty-eight hours old, sixty before the last meal of that day, and seventy-two hours before a fresh supply is obtained. Except with the greatest care milk will not keep in good condition this length of time, and I am informed by men engaged in the business that it is common to use chemicals for the purpose of preserving it. The advantages of holding it this length of time accrue wholly to the milkman, for it gives time for "topping," so called, which means the rising of cream, rendering its easy separation from the milk possible, and how often this condition of the milk is taken advantage of we are informed by the analyses of the State Board. It had become a "recognized industry" among the milkmen. The milk should be delivered to the consumer on the day of its arrival in Boston.

As a consumer in Boston my experience has not been less exasperating. During the first few years of my practice I endeavored to employ cow's milk as a substitute for mother's milk, but always with indifferent success or failure, which necessitated its final abandonment. Subsequently the paper of Dr. Lynde, read before the State Society, prompted me to try its use once more, and this time on my infant daughter. It soon provoked a diarrhœa, and after floundering about with the trial of a number of artificially prepared foods, condenced milk agreed with her, and this was used until going into the country, where I obtained a supply of pure cow's milk, upon which she continued to thrive. Returning to Boston I engaged milk of a friend (?), who said he would give me pure milk, but the child soon showed the effects of the change in the quantity of water eliminated. It was impossible to keep her otherwise than in a constant state of irrigation, but not until a diarrhœa ensued, followed by an intestinal catarrh, was the milk abandoned, and then only to be tried several times during the winter, again, each time provoking disturbance of the digestive organs. Setting the milk revealed the fact that it was regularly and systematically robbed of the cream. The following summer my child took cow's milk in the country, and did well. The next fall I made another change, after a long conversation with the new milkman, the substance of which was that I wanted "straight milk," as the life of my infant depended upon it. This he engaged to furnish, but, if possible, it was poorer than any I had ever before had. Although of the color of Jersey milk it had scarcely a trace of cream, and I went to the office of the city milk inspector to see what I could do about it. I was there informed that much of the complaint of adulterated milk was groundless, but if I wished to prosecute I should have the assistance of his office, but that "the department labored under great embarrassments for the want of a horse." I did not see fit to involve myself in litigation, and wrote to the milkman never to show himself on my premises again except to obtain a settlement of accounts, but up to this day he has never sent a bill. I then engaged milk which, I am happy to say, is of satisfactory quality, and my baby is doing exceedingly well with its use.

I trust and hope the influence of this Society will be exerted in support of the State Board in prosecuting these ungodly men, who by their wickedness compromise the health and lives of our little ones, an expression you will not think too severe when you remember that of the samples of milk analyzed by the Board in Boston ninety per cent. were found to be adulterated.

In regard to putting the milk in glass jars, I am informed by Mr. Burnett that after a trial of one year he found it impracticable. The breakage amounted to a loss of $150 per month in a supply of 400 quarts a day. He now uses large steel cans holding 60 gallons, and is enabled by their use to deliver the milk to consumers but twenty-four hours old, and this is certainly an advantge, and would be a great improvement in the system of distribution of railroad milk.

A gentleman doing business in the way of supplying milk to the consumers in Boston, and a member of the Milk Producers' Association, who was present at the meeting by invitation of the Secretary, spoke as follows:

This question naturally divides itself into three distinct parts—the production, the transportation, and the city delivery. Let us first look at the subject from the standpoint of the producer. He may be a wealthy man, perhaps living in or doing business in the city. He owns a farm for the fun of it, and because he must have a way of providing a summer residence for his family. He buys first-class stock, hires men to do the work, makes a large quantity of milk, which is very likely not to be of a superior quality, for the reason that all means possible are taken to produce a large flow of milk, and from the lack of personal supervision of the men who do the work. This is the class of men who are agitating all kinds of innovations, putting fancy names on their farms, and a team in Boston to sell their supply, which they add to, if necessary, by purchases from neighboring farmers. It is possible for them to find ways of disposing of it to personal friends in the city, and to others who are led by judicious advertising or the desire to see a new thing succeed. That these methods are not business-like is proved by the fact that there is hardly one genuine success in the large num-

ber who have at various times attempted it; and no opposition is feared so little by the trade as that from a farmer who undertakes to sell his own supply.

Next, we find a large class of farmers who are not rich men, who are farmers because they must be; they may own their farms and stock clear, and may have business talent enough to read the papers, buy their grain at the right time, and dispose of their products to the best advantage. Milk being by far the most desirable of these products, they naturally make all other interests subservient to it. Such men have from eight to twenty cans per day, give their personal attention to it, take pride in their reputation, and are a reliable source of supply. As such they are in great demand, not only among the contractors, but the milkmen themselves, who maintain a jealous watch lest some one more favored by the contractor shall get what they esteem to be their best dairies.

A very general impression has gained ground from misrepresentation and ignorance that the farmer is the victim of an immense monopoly from which he has no escape. Nothing can be further from the truth. Imagine one man, as described, with 8 or 20 cans of 8½ quarts each to sell. He can hardly be so located within 30 miles of Boston that he cannot choose to which of two or three contractors he will sell his milk, to say nothing of butter makers and creameries. If he is so near the car that he can deliver it himself so much the better for him; if he is not, a team belonging to some contractor will either pass his house, if on the main road, or if not he can carry his milk out to the corner of the main road, where it will be taken up as the collector passes. He receives a certain price for his milk delivered at the car, and the rates vary from one to two, or in some cases two and a half, cents per can for the carting, the collector being able to do the work for the minimum rate because he goes loaded, few farmers preferring to hitch up and drive 3 or 4 miles for 16 to 40 cents. If, for any reason, one farmer desires to be independent of the contractor, he can, as many do, make butter, or if he does not wish to do that, he can come to Boston and find a milkman who wishes also to be independent, and they having traded, notify the contractor, who is compelled by law to freight the milk, the price being regulated by the Railroad Commissioners.

A third class of farmers are those who keep only one or two cows, and make a small quantity of milk, who never become an important factor in the problem. All these various producers raise fruits, vegetables, grain, and hay, and expect, if they sell them, to be subject to the law of supply and demand, and to be able to receive only so much as is the ruling price on the day the sale is made; but when we look at the milk question we find a very different state of affairs. Our farmers appoint a meeting of a committee from their number who consult on the price to be established for six months from April 1 and October 1, or from October 1 to April 1, as the case may be. The stipulations are that the contractor shall take all the milk produced for six months at a price which he is expected to name in advance, and pay for the same by the 15th or 20th of the month succeeding the delivery. He using his best judgment establishes such a price, and agrees that it shall not be changed except with the consent of the above named committee. When all the facts are considered it is not to be wondered at that mistakes are sometimes made. Has he a remedy? Let us see. The summer of 1882 was very hot and dry in August and the first of September. The price was arranged on a basis of 43 cents per can at the cars in Boston. From September 20 to October 20 it rained a little every day almost, the fall feed was a marvel, the cows gave more milk than in June, and seventy per cent. of the milk that came to Boston was enough to supply the entire demand. The farmees added all the new-milk cows to their herds that could be bought, sold all their calves, and literally flooded the market. January 1, after three months of ruinous business, the price was lowered three cents per can, trade was stimulated somewhat, and the supply was not in such a tremendous excess of the demand; but the six months' business was a disastrous one, owing to the mistake. On the other hand, if butter had been high and grain high, and the fall as dry as the fall of 1883, the farmers would have felt perfectly justified in selling their cows if they wished, or keeping the calves to use the milk, or making butter, and the last thing in the world that would have troubled them would have been whether the people in Boston were supplied with milk or not. The short-sighted policy of the farmers in such respects, more than anything else, prevents the relations existing between them and their customers being as amicable as might be desired.

How to get cans enough to take all the milk he chooses to produce is the one great trouble every farmer has. The contractor tries to have every milkman furnish cans to take the milk from certain dairies, but has those of his own to send to supply any deficiency. These cans go up on the car dirty, and are left by the collector free of charge; are all of a size, eight and one half quarts wine measure. The farmer, having washed them, strains his milk into them, and puts them into the place he has arranged for cooling the milk. In many cases this is a covered tub or trough near the well, or connected with running water from a spring. The contractor or milkman to whom he sells his milk frequently suggests and often helps to pay for this arrangement, which is of vital importance, as upon the care of the milk for twenty minutes after being drawn from the cow depends the value of it as an article of commerce.

How long milk may be preserved by good care and still be as good as fresh milk is a question upon which I would prefer the opinion of scientific men to my own. Certainly experience teaches that it is more desirable to most consumers (if they do not know of the fact) after twenty-four or even forty-eight hours. There is no trouble whatever in keeping it sweet three or four days, if a temperature of 50° F. is steadily maintained, but my experience also teaches that the baker must have as fresh milk as can be obtained if he wants to make a custard of it and get good results. A better cheese can be

made from new milk than it is possible to make from that over twenty-four hours old.

The farmers, at their meetings and through the press, are frequently influenced by impractical men, who do not make milk, but who want to seem interested in their welfare, to do away with all middle men, and come directly in contact with the consumer. As before intimated, this has been done in isolated cases, but not yet successfully. Surely if practical men, of years of experience in the business, actuated by every feeling of rivalry and ambition, can see no way to improve the present plan, it is an indication that none can be found.

Let us now look at the second branch of our subject, transportation. Here enters upon the scene the much-berated milk contractor. This system has been the growth of years of experience, and many men have made financial shipwreck in the attempt to fill the position. With the plans and failures of the past we need have nothing to do, suffice it to say the only chance for any profit as it is now arranged is by saving a little here and a little there, by doing a large amount of work for a very small commission, and utilizing the surplus milk so as to make the smallest possible loss. The prices paid in the country as well as those obtained in the city are published, and the commission, about eight cents per can, or one cent per quart, is known to the farmer as well as to the milkman. The Railroad Commissioners, after thoroughly going over the matter, have allowed the contractors to charge six cents per can freight for milk brought thirty miles, which is a very close approximation to the actual cost. Out of this he has to pay freight to the railroad, buy ice to ice the milk in summer, and coal to heat the cars in winter, hire men to load the cars and deliver the milk upon its arrival in Boston, and guarantee it from accident or loss. If he buys and sells the milk he has two cents per can over the six for freight to protect him from loss in the transaction of his business and the surplus milk. As intimated before, he makes a one-sided contract by which he agrees with the farmer to take a large quantity if it is for the farmer's interest to make it, and to get along with a small quantity if the farmer thinks it is not in his interest to make it. On the other hand, he contracts with the milkman to give him just what he wants whether the farmer make it or not. In order to be safe he perforce buys all the milk on a large territory, preferring to manufacture a large surplus into butter to saying to his customers: "I cannot supply you, and you must look elsewhere."

The leading principle with too many of the men engaged in the sale of milk in the city is to get trade, by any means possible, and build up a route to sell out. Such dealers have no pride in learning thoroughly the proper way to carry on the business; they do not care much what they sell, or whether or not they make a legitimate profit, if in the end they can sell out and come out even or a little ahead. The class of men who have the better portion of the trade, who have had experience in business, and money with which to carry it on, who want to sell a good article and make a fair profit, and who, if there were no ruinous competition, would not, from principle, take advantage of their customers, but would give every attention to their wants, only asking a fair return, are constantly harassed and annoyed, and, as they term it, robbed by these so-called "pick ups."

Another trouble is found in the competition from stores. At the present price, 40 cents per can at the car, a milkman pays 4.71 cents per quart for his milk. It is conceded that a milk-wagon cannot be run for less than 2 cents per quart by all having any knowledge at all of the business, and many close observers say 2½. If we take the lowest figure, the milk costs 6.71 cents at the consumer's door, or 7.21 cents if we take the higher. It is easy to imagine the feelings with which he would regard a card in a window, "Pure milk, 4 cents per quart," when he may have one or more customers in the same block from whom he must get 7, and, if possible, 8 cents per quart, or not pay his bills.

That it would be an advantage to the business if the Board of Health would drive all store-keepers out of the business who are not willing to sell pure milk and sustain the price, is clear. Whether the poor people who buy would be benefited by the advance in quality more than they would feel the advance in price, is not so clear. At all events, it is a fact beyond dispute that any man may, by a little inquiry, find out the character of the man from whom he proposes to buy, and need fear being cheated no more than he would in buying any other class of goods.

In reply to a question, the same gentleman stated that the effect of feeding cows on ensilage was to produce a peculiar sweetish taste in the milk, which is not at all agreeable, and is also contained in the butter made from such milk.

In regard to the statement that a certain milk-producer is putting up milk at his farm in glass jars for delivery in Boston, the facts are as follows: I know the gentleman, and know the source of his milk. It is transported to Boston by rail, and always comes in ordinary tin milk cans. If he delivers it in Boston in glass jars, it is put into jars after it reaches the city. It comes to Boston like all the rest of the milk.

Dr. J. Ayer asked the speaker, "Ought the citizens of Boston to receive milk as good as farmers produce it, thirty miles in the country; or does the carriage, by cars or otherwise, injure its properties?" to which the reply was given that there is no reason why the milk when delivered at the door of the consumer should not be in every way equally as good as when it left the farm on which it was produced. The main source from which damage might be apprehended would be from too early collection, before the temperature of the milk had been sufficiently lowered by cooling in water, or too high a temperature in transit in summer, or freezing in winter. These accidents are obviated by the cans being surrounded by ice as soon as they are placed in the car, or otherwise kept at the right temperature, which should, if possible, be maintained at 50° F.

(*Continued next week.*)

STATE MEDICINE.

The sixth annual meeting of the Sanitary Council of the Mississippi valley was held at Memphis, March 21, 1884.

The only paper or document of importance presented to the meeting was the annual report of the Secretary, Dr. J. H. Rauch, of Springfield, Ill. We give it as follows:

At the last meeting of the Sanitary Council of the Mississippi Valley, at Jackson, Miss., April 3 and 4, 1883, the following resolutions were adopted:

Resolved, That in case the National Board of Health is deprived of making inspections of persons and freight when demanded by the local boards of health, certificates issued under the supervision of a representative or representatives of the Sanitary Council of the Mississippi Valley, shall be accepted as valid by the boards of health of the Mississippi Valley, provided that said inspections be carried on under the rules and regulations heretofore prescribed by the National Board of Health.

Resolved, That the Sanitary Council recommends that the States of the valley make voluntary contributions to be expended under the direction of the Executive Committee of the Council, to continue river and rail inspections, in the event that no funds are placed in the hands of the National Board of Health for that purpose.

Having received notice from the Secretary of the National Board of Health that that body would be unable to continue inspections after June 30, a meeting of the Executive Committee was held at Memphis, on the 21st of June, at which the following proceedings were had:

At a meeting of the Executive Committee of the Sanitary Council of the Mississippi Valley, held at Memphis on the 21st day of June, 1883, the following members were in attendance; Dr. Wirt Johnson, of Mississippi, President; David P. Hadden, of Memphis, Vice-President; Dr. John H. Rauch, of Illinois, Secretary; Dr. G. B. Thornton, President of the Memphis Board of Health and member of the Tennessee State Board, was also present by invitation. After thoroughly canvassing the situation, which up to this date was considered altogether encouraging, the following preamble and resolutions were adopted:

WHEREAS, The inspection service now conducted by the National Board of Health in the Mississippi Valley will cease on the 30th day of June, on account of want of funds for its further maintenance; and, whereas, the commercial welfare no less thau the health interest of the valley demands that these precautions be continued during the summer months, therefore, be it

Resolved, That the supervision of this service from and after June 30 be assumed by the Sanitary Concil of the Mississippi Valley, in accordance with the action of the Council had at its fifth annual meeting, in the city of Jackson, Miss., April 3 and 4, 1883.

Resolved, That the inspection station now maintained by the National Board of Health below Memphis be continued at the expense of the taxing-district government of Memphis.

Resolved, That the Mississippi State Board of Health should establish and maintain an inspection station on the Mississippi river at some point between Vicksburg and the Louisiana State line.

Resolved, That the present corps of inspectors of the National Board of health on duty at the Mississippi river quarantine station below New Orleans and on the river and railroads at New Orleans be continued under the direction of the Executive Committee from and after June 30.

Resolved, That the rules and regulations of the National Board of Health, for the conduct of this inspection service, be, and the same are hereby adopted for its further continuance under the direction of the Sanitary Council.

Resolved, That the supervision of this service, on behalf of the Executive Committee, be assigned to the Secretary of the Council, Dr. John H. Rauch, Springfield, Ill., to whom all reports of inspectors and communications pertaining to the service should be addressed.

It was further agreed that on and after July 1, only the certificates given by the inspectors of the Sanitary Council of the Mississippi Valley would be recognized by the inspection stations along the river, and by the health authorities of the towns and cities in those States which are members of the council.

The meeting adjourned subject to the call of the Secretary, who ot once proceeded to New Orleans for the purpose of personally arranging the details of the service at that important point.

On July 1, 1883, in pursuance of the action above recited, the Sanitary Council of the Mississippi Valley assumed supervision of the river inspection service, which was thenceforth continued uninterruptedly under such supervision up to September 15, when, all danger of yellow fever infection having passed, it was discontinued for the season.

During this period an inspector was maintained at the Mississippi river quarantine station below New Orleans, and two rail and two river inspectors at the port of New Orleans. In addition to these Mississippi maintained a station at Fort Adams, and Memphis, one on President's Island. In the operation of the service the rules and regulations of the National Board of Health were continued, no changes being made either in the *personnel* of the service or in its policy, by the Council, after assuming supervision. The inspector at the quarantine station below New Orleans was relieved from duty on July 31, owing to the action of Gov. McEnery, as hereinafter detailed.

At the request of the Executive Committee the expenses of the maintenance of the service, under the supervision oft he Council, were defrayed directly by those interested, so that the Council was relieved of the responsibility and labor attaching to the disbursement of money. Mississippi, through its State Board of Health, and the taxing district of Shelby County, through the Memphis Board of Health, paid the expenses of the stations at Fort Adams and President's Island respectively. The Illinois Central and Louisville and Nashville railroads paid their own inspectors

in New Orleans; while the river inspectors in New Orleans were paid by the commercial and steamboat interests through the New Orleans Auxiliary Sanitary Association.

No officer or member of the Sanitary Council received any compensation for his services in connection with this work.

From May 15, the beginning of the quarantine season, up to the close of July, there had arrived at the Mississippi river quarantine station, below New Orleans, seventy-three vessels from foreign ports. Of these, forty-seven were inspected up to June 30, under the supervision of the National Board of Health, and during July the remaining twenty-six were inspected under the supervision of the Sanitary Council.

Of these latter, eleven were from ports infected by yellow fever at the date of departure, and three of them—namely, the Berna, July 8, the Merchant, July 16, and the Buteshire, July 17, arrived with cases of yellow fever on board. Among the remaining vessels one was found to have had yellow fever on board in Havana last season, and in seven other cases it was probable that they had been infected at some previous time.

The sanitary condition of the vessel, cargo, crew, and passengers in twelve cases was good, and in the remaining cases, with the exception of the Berna, Merchant, and Buteshire, which were infected—the report of the inspector was qualified. In all cases the vessels were subjected by the quarantine authorities to a thorough general cleansing, purification of bilge, hold, etc., and disinfection with carbolic acid and copperas, and the cargoes were fumigated with sulphurous acid gas. Coffee ships from Rio de Janeiro were either not allowed to proceed up to New Orleans at all, or only after removal of cargo and thorough fumigation of the same.

The arrival of the Merchant July 16, and of the Buteshire the following day, both from Vera Cruz, with yellow fever cases, led the Governor of Louisiana, July 20, to recommend to the Louisiana State Board of Health that no infected vessel be permitted to enter the Mississippi River, and that all infected vessels then at the quarantine station be removed out of the river at once, assigning the reason that their presence at that point had practically rendered the station an infected port in dangerous proximity to New Orleans, and threatened a stupendous calamity to the Mississippi Valley.

At its meeting July 23, the board discussed this communication, and finally adopted a resolution requesting the Governor to issue a proclamation enforcing his recommendations, and declaring non-intercourse between Louisiana and Vera Cruz, Rio de Janeiro, Havana, and other infected ports, which proclamation was made the following day, July 24. The infected vessels were ordered to be removed from the river, and for the first time in a number of years the lower Mississippi was freed from the menace arising from the admission of yellow fever ships to the river.

Immediately upon receipt of information of this action, the request previously preferred to Governor McEnery, to permit the Sanitary Council Inspector to remain at the quarantine station, was withdrawn by telegram, and the inspector was relieved from duty July 31.

In this connection it is proper to remark, that while both the National Board of Health and the Sanitary Council have been advocating for the last four years the exclusion of infected vessels from the Mississippi during the dangerous season, and the use of Ship Island as a refuge station for such vessels, the necessity for absolute non-intercourse has not been recognized. The plan proposed by these two bodies contemplated the maintenance of an inspection station at or near Port Eads. All vessels entering the river would here be subjected to a rigid examination. Those found to be infected would be compelled to go to the Ship Island refuge station; healthy vessels from infected ports would be subjected to such treatment as would render it safe to allow them access to New Orleans; while all others, if found in a good sanitary condition, would be passed without detention. In this way it was believed the public health could be properly protected without inflicting any serious injury to the commercial interests of New Orleans.

On August 13, immediately after my return to Springfield from New Orleans, I recommended that, "unless yellow fever should appear in that city by the 20th instant, inspections should cease on the 31st." Doubts as to the character of the Jackson, Miss., sickness, and the conditions at Pensacola and vicinity, prevented the adoption of this suggestion; but on the 15th of September, New Orleans and the valley remaining free from any suspicious illness, the service was definitely suspended for the season.

From May 15 to September 15, during which period the service was maintained, there were inspected 73 ocean vessels at the Mississippi river quarantine station; 277 steamboats and other craft at the port of New Orleans; 439 steamboats and other craft at the stations of Fort Adams, Miss., and President's Island, Tenn., and 1,421 freight trains on the Illinois Central and Louisville and Nashville railroads at New Orleans. The aggregate inspections comprise 2,210 ocean vessels, river craft, and freight trains, with a capacity of 2,534,870 tons, and carying 39,947 officers, crew and passengers.

Not for many years has New Orleans been so free from alarm or cause of alarm, during the corresponding months, as during the sixty days ending August 31 last, and there was practically no trouble with regard to the yellow fever during the summer in any portion of the region in which the Sanitary Council is directly interested.

In conclusion, it seems proper to add that the utility of the Council has been again demonstrated—this time in the direction of practical administration over a large area, embracing many and diverse interests, and coördinating and utilizing agencies and authorities which, otherwise, would have been limited in their usefulness to their own individual fields. The methods of inspection and sanitary supervision were uniform along thousands of miles of rail and river; and all conflict of authority, all clashing of boards, and all expense and irritation of ill-advised and un-

necessary quarantine, and hence all embarrassment and interruption of travel and traffic were successfully and happily avoided.

There is no question in my mind but that the form of the organization should be maintained in readiness for instant action whenever an emergency arises similar to that with which we were confronted during the summer of 1883.

The minutes of the last annual meeting, that at Jackson, Miss., April 3 and 4, 1883, have been published in full, and copies supplied to the delegates; so that, unless called for, there is no necessity for reading these at this time.

After the reading of the Secretary's report a series of resolutions were reported by the committee on that subject, which elicited much discussion, and were finally laid upon the table.

Dr. Hyer then offered the two following resolutions, which were adopted:

Resolved, That the Sanitary Council of the Mississippi Valley, in annual session assembled, memorialize Congress to adopt the bill introduced into the House of Representatives Jan. 8, 1884, by the Hon. Casey Young, providing for the prevention and introduction of infectious diseases into the United States, and for obtaining information of the sanitary condition of foreign ports and places in the United States, and for procuring information relating to climatic and other conditions affecting the public health.

Resolved, That the thanks of the Council be, and the same are, hereby tendered to Dr. Rauch, the Secretary of the Council, for his arduous and faithful labors under the instructions of this Council in 1883, and the Executive Committee are hereby instructed, if necessary, to adopt the same line of action in regard to the prevention of the introduction of yellow fever or other infectious diseases into the Mississippi Valley during the year 1884.

After the adoption of these resolutions and the transaction of some miscellaneous business, the Sanitary Council adjourned. The officers elected for the ensuing year were mentioned in the preceding number of the JOURNAL.

It was ascertained that the Executive Committee would decide to call the next meeting of the Council at New Orleans, some time before the close of the Cotton Exposition.

During the evening a number of the delegates were entertained by Drs. Thornton, Saunders and Marshfield, in being honored at the "Tennessee Club," or in partaking of hospitalities at their residences.

Most of the delegation from Illinois prolonged their visit another day in the city "built on the Chickasaw bluff," and then proceeded to New Orleans.

The system of "automatic sewage" was investigated and extolled. It will be one of the means, no doubt, of preventing yellow fever from ever getting much headway in their city in the future.

Thirty delegates were present at the meeting, representing eight States.

FOREIGN CORRESPONDENCE.

PARIS LETTER.

PARIS, MARCH 14, 1884.

A short time ago, Professor Germain Sèe read a very interesting paper at the Academy of Medicine on the diagnosis of pulmonary phthisis, in its various forms, which he has since published separately. It may be questioned as to whether there exist or not any cases of consumption without bacilli, or even without the classical tubercles; but the class of phthises without bacilli are, according to Professor Sée the only true phthises. The learned professor, true to his doctrine of the pathological unity of phthisis, declares that there is but one phthisis—phthisis tuberculosi, of which, it is true, the forms are varied. These are: 1. The so-called miliary granulation which is found in the lungs of phthisical patients, and often generalized in all the organs and in all the tissues. 2. The tubercle, properly so-called, grey or yellow, which follows the granulation. 3, The substance infiltrated with grey or yellow matter, which results from the fusion of isolated tubercles. 4. In all the cases of tubercles, whether distinct or confluent, more or less advanced, the caseous condition, which constitutes the first phasis of destruction of the morbid product.

This doctrine of the pathological unity of phthisis has been confirmed by experiment, as all the products inoculated reproduce the same phthisis, variable in its forms, but identical in its basis, always and indefinitely inoculable. Between specificity and virulence, there is but one step: this has been passed. The transmissibility is real; it was only necessary to search for the agent of contagion, and as the smallest quantity of morbid matter inoculated, produces the malady, it is not with an ordinary poison we have to deal, but most probably with a microbe, which Professor Koch, of Berlin, demonstrated in April, 1882. Although other experimenters believed they had discovered the microbe of tuberculosis, Koch was the first who, by a special process of coloring, succeeded in discovering the true microbe under the form of rods, which, by their chemical and morphological properties, differ totally from all the other known forms of parasites. He gave three series of decisive demonstrations: 1. The constant presence of bacilli in all the tubercles and liquids secreted; in miliary granulation, raw tubercle, parietes of cavities and their contents, which keep up the sputa, scrofulous products, lupus (Cornil) and all the products derived from the evolution of spontaneous tuberculosis in animals, have furnished bacilli. 2. The speciality of the chemical and morphological characters of bacilli. 3. Specific characters, that is to say, the virulence of bacilli and their exclusive property of reproducing tuberculosis. Koch cultivated these bacilli in the serum of bullock's blood, by a particular process which was imitated by Baumgarten, who found that whenever he inoculated with the products experimented with, tuberculosis was always engen-

dered. On the other hand, the morbid products, minus bacilli, never engendered the disease.

From these premises Prof. Sée concludes that bacillary expectoration is the sign characteristic (*la signature*) of tuberculosis; the sputa without bacilli belong to other maladies, whence the conclusion that the sputa are contagious, and that it is the pulmonary exhalation which propagates the disease. Of 2,509 cases of phthisis collected from reports from different parts of the globe, bacilli were found in the sputa of 2,417 cases, and in the greater part of the negative cases, it is acknowledged that the experiments were not sufficiently repeated to permit one to affirm the absence of the parasite. On the other hand, whenever the experiments gave negative results the autopsy showed the absence of tubercles.

From these considerations Prof. Sée has thought proper to admit three other forms of phthisis, which he terms pseudo-phthises, which are difficult or impossible to diagnose from true phthisis without examining the sputa as practised by Koch and others after him. These are: 1. Latent phthises, which commence insidiously and continue for a long time without manifesting any physical signs, by a short hacking cough, with or without emaciation. The examination of the products of expectoration often permits one, from the commencement of the malady, to recognize the origin of this cough. In cases of spitting of blood also the origin of which it is impossible to discover by auscultation, the examination of the products of expectoration would often enable one to pronounce an absolute opinion from the first attacks, as to the nature of the hæmorrhage. In this same group will be found hyperacute phthisis, termed miliary, the diagnosis of which is generally impracticable unless the expectoration is examined. In the latter case the presence or absence of bacilli would decide the question. 2. Abnormal phthises, or as Professor Sée terms them, "phthisies larvees" are those in which the phthisis sets in suddenly and assumes the appearance of the acute affections of the respiratory organs, such for instance, acute pneumonia, and is treated as such. It may also be mistaken for acute bronchitis, accidental laryngitis, or simple plenrisy. The error may be said to be inevitable without the microscopic examination of the products of expectoration. 2. A third category comprises broncho-pulmonary affections, which in their turn have also so simulated phthisis, even as regards the auscultatory signs of the latter, as to leave the physician and patient in the greatest uncertainty. Among these pseudo-phthises may be included pulmonary syphilis which differs from tuberculosis by its incurability. M. Sée referred also to bronchial dilatation in which, in spite of appearances, the examination of the sputa enabled the physician to diagnose absence of cavities. In fine, the same remarks may be applied to all pulmonary affections, in which the examination of the sputa can alone remove the difficulty of diagnosis: the absence duly established of parasites in the sputa, would constitute with certainty the absence of tuberculosis. Inversely, the presence of bacilli would enable the physician to recognize the existence of tuberculosis even where the latter had never been suspected.

The consequences of this discovery must lead to another system of therapeusis in the treatment of this dire affection, the object of which must be to attack the parasite at the commencement of its evolution, but as yet nothing has succeeded. A. B.

DOMESTIC CORRESPONDENCE.

LEGAL REGULATION OF THE PRACTICE OF MEDICINE.

EDITOR JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

In 1849, at the Boston meeting of the American Medical Association, that body had a report from an able committee on the subject, among other things, of regulating the practice of medicine by law, the conclusion reached being that it was not at that time expedient to seek the aid of State legislatures in that direction, and this has probably been the dominant sentiment of that organization since, as no further agitation of the matter has occurred. But many things have happened in the thirty-five years since that first Boston meeting of the Association, and it is quite probable that the present members of that body may hold views differing from those of the members of that day.

At least, for years thoughtful physicians have been filled with regret to observe so many persons engaged in the practice of medicine, who possessed no adequate professional education for the service. These incompetents consisted of many who had been to medical colleges of some kind, perhaps of more who had never been in a college, medical or other, and of some who had little or no training in any educational institution—natural doctors, so-called.

To devise a remedy for this evil of magnitude has taxed the serious thought of the wisest among regular physicians for more than a generation. The initial step in the foundation of the American Medical Association was taken in 1845 by the New York State Medical Society in these words: "Whereas, it is believed that a national convention would be conducive to the elevation of the standard of medical education in the United States," and the national convocation of physicians has continually through all the years of its existence labored in the same field, and the labor has not been altogether without fruit; but while it has been giving attention to the education of those who were to become members of its own guild, simply cultivating its own ground, new territory has been opened, and other workers have claimed popular recognition and have received it. And while regular physicians may properly lament the existence of the delusion that gives professional standing to the disciples of exclusive dogmas in medicine, they cannot undertake, on behalf of the people, to produce a more competent corps of medical practitioners without a clear recognition of the fact that other schools of medicine than the regular are integers in the sum that

constitutes the whole number of medical persons who minister to the ailing with the consent and approbation of the public, so that though the regular fraternity could make perfect its own adherents so far as knowledge has advanced, there would still be a class, far from insignificant in numbers, that would be outside their jurisdiction and direct influence.

There must, therefore, be some ground selected for further operations, upon which all well-intentioned practitioners can stand and coöperate for a common end. Fortunately, such a platform is not difficult to find, and it consists in a demand that every aspirant for the privileges of a medical practitioner shall furnish satisfactory evidence that, in addition to a suitable general education, he is sufficiently learned in medical history, anatomy, histology, physiology, chemistry, pathology, pathological anatomy, ætiology, semialogy, mechanical surgery, parturient mechanism, hygiene, and medical jurisprudence. So far as it goes, this scheme for the improvement of the profession of the future is not likely to meet with opposition from the best elements, nor a majority, of the members of any school of practice which has enough of professional *elan* to establish and maintain a State organization of its adherents, and reliable testimony is not wanting that there is a rapidly increasing sentiment among reflecting laymen that the time has fully come when all medical practitioners must be educated persons.

That this scheme embraces no therapeutic doctrine will be distasteful to many excellent physicians, but it is believed that the sober second thought of all classes will recognize that there is little risk in trusting the medication of the ailing to the judgment of any one who is completely master of the departments of medical science recited above. And, moreover, it must be an apparent verity to the most obtuse that while regular physicians, eclectics, homœpaths, etc., have their present standing among the people, no one of the schools can reasonably hope to have its peculiar views of therapeutics recognized by an authority that has the power to cause their general adoption to the exclusion of others, while all can heartily say to the scheme of learning herein outlined, so far as it goes, amen.

To have this measure bear fruit it must be prescribed by the State, and have the machinery of law to enforce it. This could probably be obtained by the judicious management of the friends of the measure, because it rests upon general principles so patent that legislators could not torture it into a proposition for the benefit of any class of citizens other than the whole people themselves, nor accuse it of being inimical to any person whose plaints were entitled to respect. My several years' experience as chairman of a committee of the State Medical Society to procure legislation to regulate the practice of medicine, convinced me that any scheme of value for this purpose must have such intrinsic merit as to command the support of the non-medical members of the legislature, irrespective of the advocacy or opposition of the doctors who may be members of that body. In the legislatures I appealed to, about ten per cent. of the members were physicians of various kinds, and no proposition to regulate practice could obtain the active support of more than a fraction of these, and, as a rule, the lay members would claim that the doctors must be a unit for a bill of the kind to entitle it to their consideration, an impossible condition while it covered therapeutics. It is believed that the good in the plan now presented is so obvious that it will receive the approbation of the non-medical legislators on its merits, independently of the views of the doctors present.

So important is it that any good plan adopted to regulate the practice should be uniform in the several States, or if not identical in terms, at least equivalent in substance, that it would seem a proper act for the American Medical Association, at its May meeting in Washington, to formulate the practicable points that the occasion demands and the popular sentiment will warrant, into an orderly proposition, and give it the benefit of a recommendation that the legislature of each State in the Union be urged by the profession within the State, to clothe it with the force of a statutory enactment. It is to call the attention of the members of the Association to the desirableness of unanimity in this premise that this communication is submitted to them at this time.

Some States have already acted in this matter, other States are moving in this behalf—Dr. Gihon, in the JOURNAL of March 22, details what New York is striving for, and in Indiana, Dr. Rowland, as the chairman of a committee of the State Society, is making an active, intelligent canvass for the same purpose—and it is of importance that there be an authoritative model as a common guide, if we hope to approximate a common standard, and there is no organization but the American Medical Association that could legitimately and with propriety exercise the right or appear in the role, of a common adviser.

JAS. F. HIBBERD, M.D.

Richmond, Ind., March 29, 1884.

WASHINGTON LETTER.

MATTERS IN CONGRESS OF MEDICAL INTEREST.—March 3, Mr. Pettibone, of Tennessee, introduced a bill (H. R. 5603) into the House of Representatives which was referred to the Select Committee on the Public Health, and which was in effect: That the Surgeon Generals of the U. S. A., the U. S. Navy, and Supervising Surgeon-General of the U. S. Marine Hospital Service, shall hereafter constitute the United States Board of Health, with the powers and authority now exercised by the National Board of Health. Sec. 2 requires the consular officers to report to the Secretary of State all matters affecting the public health coming under their notice. Sec. 3 orders sanitary investigations to be made at the Museum of Hygiene of the Navy Department, under the direction of the Surg.-Gen. U. S. Navy. Sec. 4 puts the quarantine service under the direction of the Supervising Surgeon General of the Marine Hospital Service. Sec. 5 orders an annual statement of transactions and expenditures of moneys to be made to the Secretary of the Treasury.

The Senate Bill to establish a University of Medicine in the District of Columbia, and referred to in this correspondence on page 193, is already bringing forth some curious fruit. A so-called graduate of the Allopathic and Physio-Medical, or Botanic schools of medicine, uses its text as an excuse for an apparent discussion of the bill and a real advertisement of himself—he would amend by adding the hydropathic and botanic schools, and accordingly issues his circular.

College Matters.—On March 20, the Medical Department of Howard University held its annual Commencement, with a graduating class of 21, of whom 3 were women.

On March 20, the Medical Department of the Columbia University graduated a class of 14. It also conferred the honorary degree of M.D. on Robert Fletcher, M.R.C.S.

NECROLOGY.

Wolcott, Erastus B., M.D., of Milwaukee, was born October 18, 1804, in Benton, Yates county, New York. His parents were from Litchfield, Conn. He was a lineal descendant of Gov. Oliver Wolcott, one of the signers of the Declaration of Independence.

He commenced the study of medicine when about 18 years of age, under the direction of Dr. Joshua Lee, of New York, and received a degree of M.D. from the Medical College of Western New York in 1829. In 1835 he was appointed Assistant Surgeon in the army, and not long after was stationed at Mackinaw. He there married a daughter of Mr. Michael Dousman, and in 1838 resigned his commission and settled in Milwaukee, where he practiced his profession until the time of his death, January, 1880.

The doctor was a prominent member of the early Territorial and State Medical Societies, and a punctual attendant in days when sessions were held in the winter at Madison, and the state of the roads and public conveyances rendered attendance no easy task. He was one of the organizers of the Milwaukee County Medical Society, in 1846, and was present when it reassembled, in 1879, after many years of inaction. He was also one of the originators of the first local medical society of Milwaukee, and became a member of the American Medical Association in 1878. He was not only actively engaged in his profession, but he held many offices of trust and honor in the city and the State. He was made Surgeon General of the State Militia in 1842, and Major General of the First Division of Wisconsin Militia in 1846, a member of the Board of Regents of the State University in 1850, and one of the first Board of Managers of the National Homes for Disabled Soldiers in 1866, which position he retained until his death. At the time he came to Milwaukee he bore a good reputation as a surgeon, which deservedly increased and became more widely spread as the years passed away. He was gifted with great natural qualifications for this work. He possessed keenness and quickness of perception, was a neat and dexterous operator, was prompt in action, fertile in expedient, untiring in care and attention, and always manifested that gentle consideration for the patient which is ever a prominent attribute of the successful surgeon. Until the time of his last illness he was ever ready to respond to any summons from the poor as readily as from the rich, and by night as cheerfully as by day. There are thousands yet living in Wisconsin, in whose hearts the mention of his name will always call up deep feelings of gratitude and affection.

J. K. Bartlett, M.D., Milwaukee.

HYDRONEPHROSIS.

AN ESSAY BASED UPON THE COMPARATIVE STUDY OF SEVENTY-ONE CASES OF THAT LESION, OF WHICH ONE CASE CAME UNDER THE PERSONAL OBSERVATION OF THE WRITER.

BY GEO. A. STAPLES, M.D.

When the urine accumulates slowly in the kidneys, either because of some obstacle in the ureter or by reason of some malformation of the parts it occasionally happens that the calyces and pelvis renalis become dilated without perceptible inflammation of their walls: urinous or serous fluids collected in such a way, with their consequent lesions, are now known as hydronephrosis.[1]

Since the latter part of the 17th century this affection has been described under different names: first, by Rudolph and Franz, as hydrops renalis, then by Ruysch as expansis renum or hernia renalis, later by Johnson as hydrounal distension, still later by Rayer as hydronephrose.

The old anatomist Ruysch first had his attention called to this lesion through an anomaly observed while dissecting the kidneys of a sheep: so far as I know this is the earliest case on record, and perhaps, historically considered, worth translation from its monkish Latin.

"Nearly two years ago that diligent surgeon and anatomist, Vogelsaugh, at a dissection showed us two kidneys of a sheep so stretched and filled with a watery fluid that each kidney could hold nearly two pints. The ureters were tortuous, and of such capacity that they would admit a large carrot root. Each end of the swollen kidneys had not lost its natural glandular structure, but the space between was composed of membrane. The tubuli pelvis were great sacs of such size that each would admit an acorn stripped of its green cup. By easy manipulation I could force the urine in the bladder toward the ureter and kidneys, but not from the ureter and kidneys to the bladder, except by a strong effort, very sparingly, through a little foramen in the middle of a septum I found between the bladder and ureters. From this cause arose a regurgitation of urine, and in course of time such a large expansion of the kidneys and ureters."[1]

Bonetus (Sepulcretum, Genevæ, 1700) also makes mention of similar cases that were mistaken for hydrovaria; on page 571, Vol. II, he says: "Sometimes not only serum is derived from the kidneys by the emulgents, but even serous and mucous material; when this stays in the pelvis it becomes sandy; when it stays in the emulgent veins, because of its coarseness, a mass is formed shaped like a butterfly, having symmetrical wings and feet." This phenomenon he actually observed at an autopsy made on the Duchess of Ferrara, who appears to have suffered from hydronephrosis. A case of this lesion diagnosed during life as swollen spleen is related in the same volume, as well as probably the first congenital case on record, where the right kidney was enormously swollen, but unaltered in its general conformation.

[2]Rayer was the first writer to give an extended and exhaustive account of this affection; since the publication of his work several writers, Johnson,[3] Vogel,[4] Rosenstein,[5] Roberts,[6] Ebstein,[7] Todd,[8] Lecorché,[9] and especially Simon,[10] in a work that has never been placed before the profession in this country, have added much to our knowledge and treatment of this comparatively rare lesion. Nor in this connection should the writer omit to mention the monographs of such men as Cooper Rose,[11] C. J. Hare,[12] Krause,[13] Hildebrandt,[14] Gusserow,[15] Saexinger,[16] Ackermann,[17]

Hotz,[1] Rosenberger,[2] Labadie-Lagrave,[3] Lanceraux,[4] Fenger[5] and others, that have aided much in the elucidation of this important subject and from which most of this paper has been gleaned.

Hydronephrosis may be either congenital or acquired; of the former variety little need be said here except that it is frequently associated with atresia ani, club-foot, hare-lip, and other malformations, and that where it is double the neonatus is never viable. The ætiology of the latter kind embraces a great variety of causes.

Of such factors may be mentioned calculi or hydatides in the urinary passages, thickening or swelling of the walls of these passages, prolonged or habitual retention of urine in the bladder: these causes, it must be remembered also, are rendered especially operative in females by reason of the anatomical peculiarities of their pelvic organs.

This interesting point is thus ably discussed by Prof. Hildebrandt,[6] whose remarks, with account of cases, I translate: "The connection of an hydronephrosis with a primary disorder will appear clearly if we consider the anatomical seat of the ureters. The ureters take a course on the right and left side next to the portio supra-vaginalis uteri. If now the middle portion of the uterus is angularly bent it is easily seen that both ureters will bend with it and will be pulled down from behind. Then the urine necessarily stagnates on its way to the bladder above the bend; it distends the ureter and the stagnation continues yet farther up to the basin of the kidney. . . . This connection between retroflexion and distension of the ureters was shown even more clearly in a case sent to me from B—— a few months ago.

Mrs. H——, besides the ordinary symptoms of retroflexion, suffered from tormenting pain in micturition and was sent to be examined because of a large soft tumor above the left Poupart's ligament. I found retroflexion and gave as a diagnosis a swelling caused by distension of the ureter in consequence of the retroflexion. I could easily at the same time verify my diagnosis. As I introduced the catheter after straightening the uterus with the sound, and emptied the urine with the aid of outside pressure on the abdominal walls, the tumor, at first as large as a child's head, shrunk to the size of an apple. A diagnosis will be very much more difficult at the inception of the disease, when the ureter is but little distended and the kidney is yet sound.

Case II. Miss F,, a robust girl, in her 17th year, complained of deep-seated pelvic pain with whites, backache, and too free menses with severe molimen. Numerous nervous pains, a tormenting desire to urinate, a feeling of fullness as if the bladder were overdistended, and of spasmodic constriction in its neighborhood, also troubled her, at these times a small quantity of urine would be evacuated without relief. I found a very relaxed uterus, angularly pointed, retroflexed for more than one inch, which easily could be raised by the sound. A soft swelling on the left side somewhat above Poupart's ligament had been observed by the physician who sent the patient to me.

With the most careful examination, while the patient was lying on her back, I could not find this tumor, but when I examined her in the upright posture, I found to the left of and somewhat above the uterus, a swelling, which, when examined by conjoined manipulation, appeared of an oblong form and was somewhat tender, but at different examinations varied in size, shape, softness and resiliency. As the flexion improved the swelling disappeared permanently, and with it the difficulty in urination. I therefore inferred that in this case, also, there was distension of the ureters. Especially characteristic were the subjective troubles of the patient, the change of form and circumference of the tumor when in a fixed position; its disappearance in the recumbent posture, which evidently was caused by the distribution of the fluid along the distended ureter to the kidney; and, on the other hand, its appearance in the upright posture, in which the urine sank down upon the bent angle—symptoms that are pathognomonic of this rare form of urinary disorder.

Prof. Saexinger[1] mentions in these words a cause of the lesion in women: "Many women who suffer from carcinoma uteri die from uraemia because of the complete involvement of the ureters, or degeneration of their outlets, or obliteration of their lumen by large pieces of débris or proliferated masses. The result is a spiral-shaped ureter, that often is as large as a finger, dilatation of the kidneys, pelvis and calyces, atrophy of the renal paenchyma, hydronephrosis."

Dr. A. Gusserow,[2] in an essay upon the same subject, makes these remarks: "The involving of the uropoetic apparatus independently of the bladder in this disease (carcinoma uteri) is of importance. Very frequently one or both ureters are involved, resulting in a destruction of the renal function. Blau found that in 93 cases distension of one or both ureters occurred 57 times. Stenosis or total closure of the ureters rarely happens, because of a cancerous affection in them: ordinarily it is because of pressure on them at their entrance into the bladder by the cicatricial horny thickening of the pelvic cellular tissue. I have also sometimes observed that a cancerous affection of the bladder wall in the trigonum colli had more or less completely displaced the mouths of the ureters, whence, as often observed by others, continence of urine and the symptoms of uræmic poisoning will result; but suddenly, after the formation of a vesical fistula, the pent-up urine will flow away in great quantity and the uræmic symptoms will disappear. In other cases, as long as the affection is unilateral, it may be painless. A few times I have succeeded in remarkably emaciated persons in discovcovering hydronephrotic kidneys by palpation."

Apropos of these statements Mr. Todd[3] reports a

case in which there was great pain in the neck of the bladder and a frequent desire to urinate, with alkaline urine, and, toward the end of life, incontinence from vesical irritability existed; at the autopsy the right kidney was found completely atrophied and the ureter converted into a large cyst; a cancerous mass in the bladder blocking up both ureters was also discovered.

There appears to be a pathogenetic relation between hydronephrosis and cystoid degeneration of the kidneys. This question had been ably discussed by Dr. Th. Ackermann[1] in an article describing the frequent simultaneous appearance of the two lesions, and to this paper we refer any who may be interested.

A patient came under the care of Prof. F. N. Otis[2] suffering from a persistently recurring spasm of the bladder that had resulted in a thickening of the vesical walls, dilatation of the ureters and hydronephrosis; in the opinion of Prof. Otis a contracted meatus urinarius was the primary cause of the whole difficulty.

Various anomalies of development may lead to hydronephrosis. Dr. F. A. Walter,[3] many years ago, described an instance occurring in a man thirty years of age, in whom were found on both sides double ureters and pelves: the right and lowermost ureter opened almost in the middle of the urinary bladder; the right and uppermost, after it had crossed in front of the lower, opened close behind the caput gallinaginis; the upper half of the right kidney "durch örtliche Vereiterung" was changed into a moderately strong bladder, while the half of the kidney corresponding to the lower ureter was perfectly healthy; nothing is said of the permeability of the upper ureter, but the drawing shows it as compared with its fellow to be from three to five times dilated.

Two similar instances of a limited hydronephrosis with double ureters and pelves, the one occurring in an aged widow, and which had been diagnosed as hydrovarium, and the other in a maniac 69 years of age, have been recorded by Dr. A. Heller[4], of Erlangen.

Prof. Simon[5] mentions as a comparatively common, though rarely noted, cause of hydronephrosis the formation of valves[6] at the ostium pelvicum, although the rest of the ureter is perfectly permeable. Of the cases collated below, eleven as to their causation fall into this category.

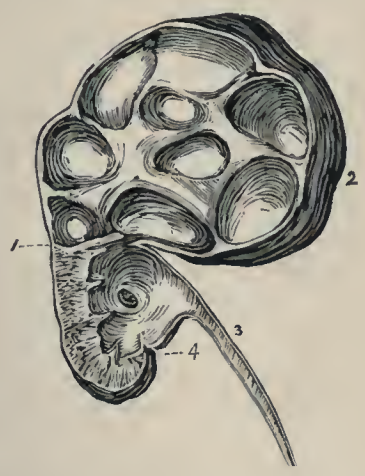
In those subjects where the kidney occupies a very deep situation, and where the initial portion of the ureter manifestly could be easily compressed or flattened; a curious instance of such compression is related by Dr. Labadie-Lagrave[7]. At an autopsy a kidney was found atrophied because of hydronephrosis, this lesion, in its turn, being dependent on a retention of menstrual fluid in one of the halves of a bifid uterus, which, forming a large tumor, by gradual compression, had rendered the ureter impermeable.

Prof. Kehrer,[1] of Heidelberg, in a recent article has called attention to the fact that large hydronephroses are only met with where there is a long continued but not complete obstruction to the flow of urine, or where, as sometimes happens, the obstruction is intermittent. This writer believes that displacement of the kidney, as thought by some, cannot cause a serious continence of the renal secretion.

In certain cases the most careful scrutiny has failed to find any mechanical obstruction, and their ætiology, therefore, is obscure.[2] In literature are recorded other causes of hydronephrosis, as abscess of the bladder, supernumerary renal arteries, congenital absence of ureters (Cruveilhier), imperforation of the ureter in its whole length (Bonnet), diverticula of the bladder (Ebstein); to sum up the ætiology, however, it may be stated that any obstacle to the continuous and free flow of the urine from the calyces into the pelvis, from the pelvis into the ureter, or from the ureter into the bladder, whether it exist on one or both sides, can lead to the development of hydronephrosis.

Many conditions, such as the position of the obstacle, the completeness of the stenosis and the duration of the lesion, may greatly modify the pathology of hydronephrosis: the lesion, too, may be bilateral, unilateral, or in rare cases even partial, *i. e.*, where not all of the calyces of one kidney are involved.

A very interesting case of the latter variety has been described by Prof. Fenger:[3] the patient was a young man in whom had been developed a renal tumor of traumatic origin; this, being punctured, poured forth urine. An inguinal abscess caused the death; and, at the autopsy, a partial hydronephrosis, limited by the superior portion of the kidney and formed by the distension of only one calyx, whose orifice was obstructed by a valve-like growth, was found.



Right partial hydronephrosis from valvular closure of the uretur, from Dr. Fenger's paper on "Partial Hydronephrosis"

[3]Fenger, loc. cit.

It has more often happened, however, that these partial cases exist coincidently with double ureters; in a recent publication a German writer[1] has gleaned from literature seven such instances.

When the obstacle exists in the ureter or bladder there is found inside the hilum of the kidney a spheroid tumor of greater or less size, the walls of which are formed of the dilated pelvis. The kidney, pushed back, compressed and atrophied, fits over the tumor like a sort of helmet, and usually presents a deeply lobulated surface; this distension may, at the same time, occur within the pelvis and calyces.

At first the dilatation is slight and reacts with especial force on the walls of the pelvis, the renal tissue still offering to the touch its normal resistance; a little later the surface of the organ becomes covered with projections produced by distension of the calyces and atrophy of the renal substance, the kidney, as a whole, now assuming the flabbiness of a cyst filled with fluid.

When the pelvis and beginning of the ureter are distended inside the hilum the tumor assumes a pyriform shape, pointing downwards, as a rule, one or both kidneys attain great size and are transformed into immense bags, on whose inner surfaces are seen little islands of renal substance; on making a cross section the basin appears dilated, the papilæ more or less sunken, and the calyces elongated and funnel-shaped; to the touch the papillæ, recognizable by the convergent red striæ, seem roughened.

In the more severe cases the calyces are so dilated as to form large pockets continuous with the dilated pelvis; the latter when exsected and extended upon a table, presents countless folds, is nearly always opaque, of a pure white color, and in its substance blood-vessels can rarely be distinguished. The wall of the sac now is altered to dense connective tissue, that varies in thickness at different points; it has even been observed of the consistency of cartilage; generally, too, when the ureter participates in the expansion its muscular layer is hypertrophied, this condition being strongly marked in those cases where it has been excited in the effort to expel a calculus. The tubular and cortical substances, as a result of continuous compression, become so atrophied that M. Rayer[2] has seen the kidneys of a child that were no larger than a berry or Lima bean, and those of an adult, that, stripped of their membranes, weighed but two ounces. In all hydronephroses the renal blood-vessels are developed out of proportion to the size of the renal parenchyma.

Those curious partial hydronephroses, to which allusion has been made, have been often observed in some of the lower animals, notably in the ox.[3] In this beast cysts of the size of a child's head, and containing urine more or less modified, and sometimes calculi have been seen. Such an anomaly in man, the earliest one, perhaps, on record, has been finely depicted by M. Rayer.[4]

Typical case of right hydronephrosis, posterior view, calculus found in the ureter that was dilated above and normal below where the stone was engaged.
Rayer, Atlas des Maladris des Reins, pl. xxi.

These tumors may attain enormous proportions. In the case of Johann Elzer, reported by Dr. Hotz,[1] the cyst extended from the first sacral vertebra and crest of the ileum clear to the pancreas, behind the border of which the upper limit of the cyst was lost. To the right it extended to and became adherent with the right kidney; it, moreover, included the left kidney, that was transformed into a tumor the size of a child's head. In addition, pushing outwards the left circle of the ribs, it considerably displaced the heart and thoracic organs, and was not limited until it had passed at least three inches beyond the linea alba.

Numerous adhesions to the neighboring organs constitute an unwelcome though frequent complication. In an autopsy performed by Dr. Wilien[2] the cyst was found wholly adherent to the peritonæum, and partially so to the omentum, pancreas, colon descendens, sigmoid flexure and spleen. The coils of intestine regularly are displaced, and for the most part lie in front of the tumor. Diastasis of the recti muscles has also been noted.

The histological lesions in hydronephrosis have been little studied. In severe cases there is first a nuclear infiltration[3] about the uriniferous tubules that is followed by a fibrous condition; the collecting tubes are obliterated, their epithelium undergoing embryonic retrogression; the glomeruli are either fibrous or cystic, and the lining of the convoluted tubes undergoes a fatty-granular degeneration. An examination made by Professor Krause,[4] of Göttingen, showed that the canaliculi of the cortical portion were distended and the Malpighian bodies enlarged. In the medullary substance the loops of Henle were greatly dilated and filled with fibrine casts and calcareous infarctions. The ureters exhibit a great variety of alterations; regularly they are narrowed below and dilated above the points of stoppage. Cases are known, though, where narrowing occurred throughout the whole caliber, this being the

[1] Hotz, loc cit.

[4] Krause, loc. cit.

general condition where the obstacle exists near the ostium pelvicum. It has not rarely happened that the dilated ureter has acquired the dimensions of the intestine. In hydronephrosis arising from uterine difficulties, much dilatation is rarely seen. Coincidently with the widening occur thickening of their walls, hypertrophy of their muscular coat, and often an assumption of anomalous forms. Thus, Dr. C. J. Hare[1] observed an instance in which one ureter perfectly simulated the shape of the letter S.

Hydronephrotic fluid consists of the normal secretion of the kidneys more or less altered. Rarely, as in the case of Lee, (Labadie-Lagrave), it is urine pure and simple. In slight cases there is, of course, little modification in the secretion, but in the more advanced cases there is, as a rule, much change, urea rarely being present.

Half a century ago M. Rayer[2] demonstrated that albumen and urea were present in renal cysts; a careful examination of 600 cub. ctm. from a typical case revealed the following:[3]

Fluid weakly alkaline, specific gravity 1000.
0.33 grm. chloride of sodium, sugar, inosite.
0.47 " urea, biliary coloring.
0.11 " albumen, matter, etc., not detected.

The sediment from another case[4] was composed of numerous crystals of calcic oxalate, an abundance of lymphoid cells, uric acid salts, urea, and much albumen.

In Hotz'[5] patient the fluid was reddish-brown, slightly turbid, and odorless, holding in suspension albumen, broken down red blood corpuscles, but no traces of uric acid. Sir Spencer Wells[6] removed twelve pints of fluid from a young girl, that gave the following results on examination: color, a clear, light yellow; odor, faintly urinous; specific gravity, 1006. On standing a few floculent clouds formed. Urea, urates and chlorides were found in the proportions of normal urine. The microscope showed a few pus cells, many red blood corpuscles, some squamous epithelial and granular cells, but no tube casts or crystals; slight traces of albumen and phosphates, but no sugar were detected. The same surgeon, as well as Mr. Cooper Rose,[7] have mentioned examples in which there was no urea, and even none of the constituents of urine. The account[8] of a very unique case recently published makes mention of a gas, supposed to be carbonic dioxide, that developed in the cyst and gave rise to a metallic, tympanitic sound on percussion, and, when acetic acid was added to the contents of the tumor, gas in considerable quantity was evolved. The accumulation of fluid in these sacs is often enormous. Glass[9] observed a patient born with fluid in the abdomen, which at her death, at 23 years of age, contained nearly thirty gallons (100,000 c.cm.) of copper-colored serum; over nine gallons (36,000 c.cm.), as reported by Dumreicher,[10] were found in a case of P. Frank's—and Prof. Simon[1] watched for several years a patient, from whom, through an artificial fistula, there was a daily discharge of over six ounces (200 c.cm.) of a sero-mucous, albuminous nature.

From a study of the above facts these conclusions are reached: first, that so long as any of the renal parenchyma is capable of work and serous transudation takes place, the normal urinary ingredients in the sac will be preserved and augmented; second, that when total destruction of the secreting portion of the kidney occurs, a fluid more or less sero-mucous in nature remains, that, if a ferment is prevented from entering, will exist undecomposed for an indefinite period of time.

Hydronephrosis of slight degree causes no symptoms, and if the sac be unilateral old age may be reached without the discovery being made that any trouble exists. In more severe cases, however, symptoms referable to impeded activity of the kidneys, and to the presence of a large abdominal tumor, may be expected.

There have been noted severe pain in the bladder and vesical region, with constant desire to urinate (Todd),[2] total anuria, intermittent accumulation and escape of the renal secretion (Morriss),[3] bearing down pains with sensation of constriction (Hildebrand),[4] obstinate constipation from compression of the intestine, a cirrhotic or varicose appearance of the superficial abdominal vessels from disturbance of the circulation (Moreau),[5] etc.

In bilateral hydronephrosis, which sometimes accompanies cancer of the uterus, the supervention of acute or chronic uræmia may be looked for at any time.

Generally a palpable tumor that may be of great size is found in the abdomen. It is situated in the flank, and regularly extends from the region of the lumbar vertebræ forward to the umbilicus, downward to the iliac region, and upward into the hypochondrium. Displacement more or less of the viscera occurs, and on palpation distinct fluctuation, on percussion a dull note, may be expected. These tumors, by their constant growth, interfere more and more with the functions of the diaphragm, though, with the exception of a feeling of tension, they are often painless.

But because of the great advance in abdominal surgery, the differential diagnosis of hydronephrosis from other tumors similarly situated must be regarded of the first importance, though, unfortunately, it is attended with many difficulties.

It is most gratifying, however, to an enthusiastic believer, as the writer is, in the ultimate approach to something of perfectibility in surgical method, in the recognition and therapy of any subject, to trace a gradual, though often slow evolution from chaos to a state akin to order; and in respect to no other malady, as is our purpose to show, has this welcome change been more apparent during the last twenty years than in hydronephrosis.

[1] "The discrimination of an hydronephrosis from tumors of another kind, but especially from ovarian cysts, unless its gradual development be observed, must be very difficult, if not impossible." Many mistakes of surgeons of the first order are, therefore, recorded in medical literature. Nearly two centuries ago Bonetus[2] diagnosed such a case as a swollen spleen, and in our own day men of undoubted skill, as Professors Esmarch,[3] and Billroth[3], and Sir Spencer Wells,[4] with others perhaps less widely known, have each regarded the lesion as an ovarian cyst, and have operated for the latter affection. However, the statement [5] "that the diagnosis of an ovarian cyst from a nephrectasis in a very large tumor cannot be made apparent," is, it seems to me, now susceptible of some modification; for, by bearing the following statements in mind, an accurate diagnosis can be made in a good proportion of cases.

First. If a reliable history of the case be obtainable, it may be expected that any renal tumor, in its earlier stages, would extend forward from the lumbar spine, having first been noticed between the false ribs and ilium; while an ovarian cyst has, in all probability, first appeared in one inguinal or iliac region, and increased from thence upward and inward.[6] "Therefore," as Prof. Krause well remarks, "the importance of a careful observation of ovarian tumors in their early development, is very obvious."

Second. [7]Large tumors of the right kidney usually have the ascending colon on the inner border of the tumor. Tumors of the left kidney are usually crossed from above downwards by the descending colon.

Third. Regularly ovarian tumors are in front of the intestines, renal tumors are behind the intestines. The exception to this rule must occur only in rare and isolated cases. The intestine may not be recognized on percussion, but when rolled between the fingers it contracts into a firm, cord-like movable roll, or the gurgling flatus along it may be detected by the patient or by auscultation; to obtain tympanitic resonance, the colon might be inflated with air through a long elastic tube per rectum; but a surer means is to inject water in addition, whereby, the air can be forced clear to the ileo-cœcal valve. On the left side the tube may sometimes be felt through the abdominal walls. The discovery of intestine in front of a doubtful abdominal tumor should always lead to a careful examination of the urine, which, in renal trouble, may be expected to contain blood, pus, albumen or epithelial débris.

Fourth. [8]In ovarian tumors there is a movability of the cyst *in toto*, a condition that is never seen in hydronephroses.

Fifth. In renal cysts the uterus is freely mobile; in ovarian tumors this is hardly apt to occur. Dr. Rosenberger attaches much importance to this symptom, to which he says too little attention has been given. The best method of examination is by the hand introduced into the rectum, and for its effective accomplishment the use of an anæsthetic is required. [1]By this means, any connection of the tumor with the ovaries, uterus or bladder, may be mapped out with great exactness; with the other hand upon the abdomen, the pelvic organs may be defined from those viscera lying higher up; and, if this palpation can be made with half the hand (four fingers), not only may we determine whether the cyst is connected with the pelvic organs, but whether it extends from above down into the pelvis. This aid to diagnosis is especially valuable in hydronephrosis, as in this lesion the pelvic cavity is not narrowed, and because the dilated kidney can be felt as a single mass reaching into the introitus of the pelvis; moreover, the presence or absence of stones in the ureters, or change in their caliber can easily be made out. Trichmann (Labadie-Lagrave) invented an instrument bearing a certain resemblance to a lithotrite, which, when introduced into the bladder could, at will, stop the mouth of one ureter; thereby determining whether a ureter be at fault. Unfortunately, though the instrument may be employed on either sex, its use requires a practiced hand.

Sixth. [2]Just as ovarian tumors are usually associated with some disturbance in the catamenia or change in the mobility or shape of the uterus, so there is regularly found in connection with renal tumors some history of calculus, nephritic colic, hæmaturia, albuminuria, or change in the quantity or state of the urine. In rare cases, it must be admitted, this rule does not hold good.

Seventh. If some of the contents of the tumor be procured through a small canula, or by aspiration, its examination will greatly aid the diagnosis. If there be found in the fluid paralbumen, colloid substances or cylindrical epithelium,[3] they argue the presence of an ovarian cyst, while any trace of urinary ingredients or of pavement epithelium would indicate an hydronephrosis. A confirmation of the diagnosis may be arrived at by sounding through the canula with a long, slender, metallic sound. This instrument, if the cyst be of renal origin, can be thrust to the deepest portion of the kidney and swept under the liver and dome of the diaphragm, and to some extent down into the pelvis; if the tumor proceed from the ovary, the sound cannot reach nearly as high, but can be easily pushed far deeper into the pelvis. It is proper to add, that though the weight of authority seems to be in favor of an exploratory puncture of these tumors, with the utmost care, there is danger of supervention of peritonitis from the wound.

Eighth. [4]If the tumor be partially emptied, it will, if renal, be felt growing smaller in the direction of the kidneys; if ovarian, in the direction of

the ovaries; and if it be wholly emptied, a repetition of the sounding will be of value.

[1]Incision of the tumor followed by introduction of the finger has been practised. By this method the renal calyces were easily recognized as round or crescent-shaped cavities, that were covered with mucous membrane and bounded by sharp walls. In rare cases fortunate accidents have been of much assistance; thus, as noted above, it has happened that when a patient was placed in a certain position the tumor could be emptied through the bladder by external pressure, and in a few instances the ureter, enlarged, could be felt through thin abdominal walls.

[2]The discrimination of an hydronephrosis from other abdominal tumors is more easy to make, and its discussion will be dismissed in a few words: In renal cyst the swelling does not change its position with that of the patient, in ascites it does; echinococcus cysts are distinguished by the hydatid fremitus, and if situated in the kidneys by the escape of hydatid vesicles in the urine; pyonephrosis usually gives more severe constitutional symptoms and causes recurrent rigors and signs of suppuration, the same being true of perinephritis and renal abscess; finally [3]the "possibility of a horse-shoe kidney must ever be borne in mind" if from the symptoms an hydronephrosis be suspected, but the colon ascendens and descendens take their normal course.

The differential diagnosis between hydronephrosis and certain renal troubles that have a somewhat similar clinical history is often attended with difficulty, and to facilitate matters, a diagnostic table, slightly altered from one devised by Dr. J. A. Octerlony,[4] is appended.

Cancer Renis.	Hydronephrosis.
Generally unilateral tumor of enormous size.	Often bilateral, and of small size.
Tumor stationary, does not move with diaphragm.	Tumor fluctuating.
Runs a rapid course.	Of chronic character.
Well-marked cachexia setting in early.	No cachexia.
Pain generally intense and rarely wanting.	Regularly painless.
Hæmaturia occurs in fifty per cent. of the cases.	No hæmaturia.

Cystic Degeneration of Kidneys.	Hydronephrosis.
Always bilateral.	Often unilateral.
Tumor soft solid, non-fluctuating	Tumor fluctuating.
In later stages, dropsy.	No dropsy.
Hæmaturia.	No hæmaturia.
Occurs in those over 30 years of age	Often congenital and in the young.
Tumor fairly well preserves shape of kidney.	Tumor does not preserve shape of kidney
Tumor slowly increases.	Tumor often of rapid growth.

A neonatus with double hydronephrosis is never viable, and even in those congenital cases when only one kidney is involved, life is often cut short because of the pressure exerted on the thoracic organs. [1]A unique case, however, in an infant, where existed atresia of both ureters with hydronephrosis of one kidney and cystic degeneration of the other, who survived 15 days, is recorded.

In those instances where the malady is bilateral, the danger is proportional to the degree of atrophy in the renal substance, all cases being more or less quickly fatal; these patients are not usually confined to bed but a few days before death, which regularly takes place in a rapid and unexpected manner.

The prognosis[2] in all hydronephroses that are uninterfered with is, in general, unfavorable, for, as the tumor attains great size, it occasions by pressure unbearable distress, and interferes with the functions of nutrition and respiration. The natural sequence is traumatic or spontaneous rupture, (an accident observed in four patients by Prof. Simon), or suppurative inflammation followed by death. Another event to be dreaded in unilateral cases is the involvement of the other ureter, though this accident may be deferred many years. A curious instance[3] of the latter variety is recorded where the first symptoms of the lesion were manifest nearly 50 years before death, that was caused by a calculus caught in the opposite ureter.

A spontaneous cure with *restitutio in integrum* can never be expected, since a kidney so altered and atrophied can never perfectly recover and perform its functions.

No longer ago than 1870 an eminent surgeon wrote in regard to the treatment of this lesion: "Of[4] therapy there can scarcely be any account; a careful avoidance of things hurtful to the other kidney must be the only problem. An opening of the hydronephrosis has been undertaken several times, partly with good, partly with bad results; chiefly it appears from diagnostic errors." And yet, but a few months earlier, an operation destined to revolutionize the surgery of the kidney was performed, for, on April 2, 1869, Prof. Simon, after a long series of experiments and careful study, first successfully practiced nephrectomy.

Purely medical treatment has rarely been of much avail. M. Rayer[5] advises, if the obstruction seem due to a calculus, that an attempt be made to soften or dissolve it, removing as far as possible all the causes that tend to inflame the cyst and increase the secretion of the pelvis and calyces; if the tumor seem caused by a malformation, as is probably the case if nephritic colic have been absent, the same author teaches that by frictions and light compression, the posture of the patient being continually changed, the normal course of the urine may be facilitated; and that, when the cyst walls seem to take on inflammation, an evil result may be aborted by local and general blood-letting, emollient cataplasms and the evacuation of the large intestine by enemata and purgatives.

As it is not possible to recognize this affection till

[5] Rayer, loc. cit., § 833.

it has reached a considerable development, prophylaxis is out of the question. In calculous cases Dr. Rosenstein[1] asserts that the alkaline waters are very efficacious as dissolvents, and in unilateral cases the treatment should consist of a careful regimen, scrupulous cleanliness, stimulation of the skin by frequent baths, and all means that are of use to keep the healthy organ in good working condition.

M. Lecorché[2] advises the abundant use of liquids and the avoidance of animal food where there is any reason to suspect a uric acid diathesis.

Where, as often happens, the ureter closes over the calculus by a sort of spasm, M. Lancereaux[3] proposes the hypodermatic use of morphine. In a case observed by the writer, cataplasms of stramonium leaves have given much relief.

It is of interest to add that there are three[4] recorded cases in which manipulation has effected a cure. In two of these cases, instructions were given for the abdomen to be rubbed with mercurial or iodine ointment, and while this was being carried out the tumors suddenly disappeared, their disappearance being followed by a large discharge of urine. In the third case the mother of the patient was in the habit of rubbing the tumor to relieve the pain, and the effect of the pressure was to cause the tumor to disappear and the bladder to swell up. In only one of these cases, however, was the relief permanent.

"The sum of medical doctrine on the subject amounts to this: Palliate where you can; do no mischief where you cannot." Every attention is to be paid to the general health of the patient, and all matters of diet, hygiene, tonics for the body, and consolation for the mind, are to be administered to support the strength and cheer the spirits. The true method of medical treatment "is to seek temporary relief of urgent symptoms by rational expedients, and either to encourage a buoyant anticipation of ultimate rescue by operation, or to lead the patient by degrees into the usual quiescence of confiding resignation to the inevitable, by the adoption of the tranquilizing motto, *Cede Deo.*"[5]

It is obvious that in the great majority of cases, for the radical cure of hydronephrosis, recourse must be had to the art of surgery, and it is a matter for sincere congratulation, as the data collected below by the writer show, that the experience of less than fifteen years has negatived the assertion, [6]"Die operative Therapie der hydronephrosen hat bis jetzt noch keine glängenden resultate geliefert."

The various operative procedures that from time to time have been practiced, may be resolved into two general classes: First, extirpation; second, the different operations to obliterate the cyst.

Again, broadly speaking, extirpation can be conducted in two ways—either through the peritonæum by abdominal nephrectomy, or extra peritonæum by lumbar nephrectomy.

[6] Hotz, loc. cit., s. 236.

Abdominal nephrectomy may be divided into several steps.

First step. Incision of the abdominal walls. There is some diversity of practice about this incision. Thus, Prof. Esmarch[1] made a cut through the linea alba 15 ctm. (6 inches) in length; in a case of Dr. Kocher's[2] the incision was begun at the xiphoid appendix, and prolonged below the umbilicus; while in a patient of Dr. Martin's[2] the knife was first plunged into a spot about 5 ctm. (2 inches) above the umbilicus. In some instances, as suggested by Prof. Langenbuck,[3] an incision along the outer edge of the rectus abdominis, in the linea semilunaris, is recommended.

Second step. Isolation of the kidney.

After having detached the tumor from the portions of intestine or omentum that adhere to it, the peritonæum covering the anterior face of the kidney, and which generally is very thick, should be incised. Dr. Kocher recommends the incision of the posterior peritonæum to be made outside of the colon ascendens or descendens, or above the transverse colon, attributing one failure, though the operation was unfinished, to the fact that he incised the peritonæum below the transverse colon.

Third step:

The tumor uncovered, the cellular tissue by which it is adherent to the diaphragm, liver, spleen, etc., must be cut, carefully guarding against hæmorrhage that often is excessive, Prof. Esmarch,[4] in one case, being compelled to take, in all, sixteen ligatures. In the second case, for which nephrectomy was practiced, the patient died on the fourth day from hæmorrhage from the pedicle. The remaining procedure is similar to that so familiar in ovariotomy, viz.: Puncture to let off the contents of the cyst, isolation of the mass, ligation of the pedicle, careful sponging of the peritonæum, and closure of the wound.

Lumbar nephrectomy may also be divided into several steps.

First step: Incision of the integument.

Many operators now make the incision of Linser,[5] cutting about 7 ctm. from a line striking the tips of the spinous processes and parallel with it, and extending it from the inferior border of the 12th rib to the crest of the ilium. Mr. Couper,[6] however, and others, have employed an oblique incision as in colotomy; Dr. Klineberger[7] has suggested that it be curved, with its convexity upwards and inwards, thus sparing the last dorsal and first lumbar nerves; Mr. Lucas[8] advocates a combination of an obliqne incision that should be higher than that for colotomy, that is, within about half an inch of the last rib and parallel with it, and of a vertical incision along the outer border of the quadratus lumborum, commencing at the upper edge of the last rib and extending to the iliac crest. The latter plan has been employed

[8] Lucas, loc. cit. p. 615.

by Mr. Barwell, Mr. Morrant Baker, Mr. Golding Bird and Mr. House.

Second step: Uncovering the kidney.

The layers of the lumbar region to be incised are:

1. The fatty sub-cutaneous tissue.

2. A slender muscular layer.

3. The very firm lumbar aponeurosis. Here is an important land-mark, the external border of the sacro-lumbalis that is to be pushed to the inside.

4. The very strong middle lamina of the aponeurosis of the transversalis. This should be incised upon a grooved director that has first been bent on itself to avoid cutting the first lumbar and 12th intercostal vessels, which are first to be tied and then cut.[1]

5. The quadratus lumborum.

After cutting through the external border of this muscle, the anterior lamina of the transversalis, best torn by the forceps and finger, appears. The couche viscérale of M. Tillaux, composed of the kidney and colon joined, is the last structure to come in view. The kidney occupies the superior portion of this region.

Third step: to isolate the kidney.

This step is often very difficult; it has even been found impossible to execute, and the operation has had to be abandoned. The object is to be accomplished chiefly by the finger, aided by the scissors but slightly.

Any tearing of the renal substance, as it is likely to result in severe hemorrhæge, is, if possible, to be avoided. In such a complication Zweissel[2] seized the torn end of the kidney with a Nelaton's forceps and then proceeded to enucleate. Two other grave accidents have happened, injury to the colon, and opening into the peritoneal cavity. The peritoæum is perhaps, to some extent, unavoidably bruised even if it be not severed.

Mr. Barker advises that extirpation of the kidney with its envelope, that is almost an inch thick, should not be attempted, but the kidney should be extirpated alone. He asserts that separation of the kidney from its capsule, enucleating the organ with the finger, is always easier than to separate the capsule from the ambiant tissue; thus, in one of his cases, he lost much time, and copious hæmorrhage occurred in trying to get out the mass entire; later, changing his tactics, he enucleated with ease the kidney from the perirenal tissue, the latter course occasioning but little loss of blood.[3]

In hydronephrosis operated on by the lumbar method, the cyst should be punctured and its contents drawn off for the purpose of reducing its volume, that it may the more readily be drawn through the costo-iliac space.

Fourth step: Ligation of the pedicle.

On drawing out the kidney the pedicle should be grasped with one or two forceps and, as in ovariotomy, ligated. It is better,[4] perhaps, to tie the pedicle in two portions by passing a curved aneurism needle, armed with a double thread, through its middle, taking care to avoid the vessels and tying each part separately, this procedure giving greater security. Prof. Czerny[1] is of the opinion that it is better to cut the ligatures short rather than leave them out of the wound. A separate thread had better also be thrown about the branch of the renal artery that penetrates the superior portion of the kidney. The space obtained by the incision of Linser may be insufficient[2]. A second incision, parallel to the crest of the ilium, may be added, or the twelfth rib may be resected. Prof. Czerny has employed the latter method twice with success; in the first instance he resected 9 ctm. of the twelfth rib; in the second, he cut away subperiosteally considerable of the eleventh and twelfth ribs without opening into the pleura. But injury to the pleural sac may happen unless guarded against with the greatest care, as, in a patient of Dr. Dumreicher's of Vienna, the twelfth rib being rudimentary and the operator mistaking the eleventh for it, the incision was made too high.

Stimulated by this accident,[3] Dr. Hall, a prosector of Vienna, studied the topography of the twelfth rib and found that "the limit of the pleural cavity is represented by a line drawn from the superior border of the first lumbar vertebra to the extremity of the eleventh rib; this line strikes the twelfth rib when it is normal about 3 ctm. behind its cartilage; there the greater part of the anterior face of the rib is covered by the pleura. If the twelfth rib be absent there exists in its place a ligamentous tract that may be incised fatally on mistaking the eleventh for the twelfth." The rational conclusion, therefore, is before incising deeply, to be assured of the state of the twelfth rib.

If there is hæmorrhage from the pedicle, Mr. Lucas advises that it be not re-tied, but that the wound be stuffed tightly with sponges steeped in the perchloride of iron, and that a tight bandage be placed about the abdomen; in this way he saved one patient. The same writer has derived great benefit from wrapping the patient's extremities in cotton wool and flannel to guard against shock. 'Of course in these grave operations antiseptic precautions are called for, and during the first four or five days after the operation anything pressing upon or interfering with the wound which might produce bleeding, must be prevented. The bowels must be thoroughly emptied before the operation; opium and a low diet prescribed in the first days afterwards. The catheter must be used, if necessary, but regularly after the operation if the urine is scanty. It will be conceded that nephrectomy in this lesion is a *dernier ressort*, and as taught by Prof. Czerny, is to be tried when the life of the patient is threatened, and other therapeutics have proven ineffectual. M. Olliver,[5] however, has lately brought forward a point that may be of importance: He is in favor, in those lesions where but one kidney is involved, of the enucleation of the disused organ for the reason, that as often

happens with the eyes, sympathetic trouble might be induced.

That a patient, after nephrectomy, can perfectly perform all of the bodily functions is shown by a case of pyonephrosis operated on by Prof. Czerny. Although very low at the time of operation, May 22, 1879, she rallied ; conceived in August of the same year ; aborted on November 12, 1879, and born in December, 1880, a healthy child, nursing it herself for over a year.[1]

Nephrectomy determined upon, where shall the incision be?

If statistics be of value, those of Mr. Barker[2] give 59 per cent. of cures by lumbar, 50 per cent. by peritoneal nephrectomy. Those of Dr. Harris[3] are also somewhat in favor of lumbar nephrectomy. But these cases include all varieties of renal lesions.

Mr. Knowsley Thornton[4] prefers the operation by Langenbuch's incision, the advantage being that the parts are better exposed than by the lumbar incision.

Mr. Tait goes so far as to advocate an exploratory abdominal section to determine the diseased condition and the advisability of nephrectomy.[5]

On the other hand, M. Quénu is of the opinion that lumbar nephrectomy is to be chosen, in that it permits, after the kidney is reached, an exploration and substitution of nephrotomy for nephrectomy, or *vice versa*. In addition, he believes that the abdominal method is to be reserved for the largest cysts. Mr. Barwell[6] also favors the lumbar method when practicable.

Prof. Czerny, while regarding the lumbar incision as the safer operation, recommends that by the abdomen if the kidney be movable. A very similar opinion is expressed by Mr. Lucas.

Lastly, in the words of Prof. Kehrer,[7] "that the median incision is the easier accomplished and preferable to the flank incision there can be no debate. The motive not to open into the peritoneal cavity is to-day, considering the circumstances, of no value. But I think, nevertheless, that the choice of the seat of incision should depend upon the peculiarity of the case, and upon the place where the swelling lies nearest the integument."

In the first table at the end of this essay, in which are reported the results of 31 nephrectomies for hydronephrosis, it will be seen that 19 of these cases were operated on by the abdominal method, and 11 by the lumbar method, the manner of operating in one case[8] not being learned. Of these 31 cases, 15, or a little over 48 per centum, recovered. Of the 19 cases on whom laparotomy was performed, 8, or a little over 42 per centum, recovered, while of the 11 cases treated by the lumbar method,[9] 7, or over 63 per centum, were permanently cured. It is, perhaps, fair to add, as Mr. Knowsley Thornton has stated, that the higher mortality at present attached to abdominal section was due to the fact that many of the cases were stumbled upon by operators intending to remove an ovarian tumor.

The causes of death in the fatal cases, when reported, will be found in the table referred to above, and which is believed by the writer to be fairly complete.

THE MILK SUPPLY OF BOSTON, AND THE BENEFIT TO BE DERIVED FROM THE SPAYING OF COWS.

BY MR. LLOYD F. ABBOTT.

[Read before the Section for Clinical Medicine, Pathology and Hygiene of the Suffolk District Medical Society, February 27, 1884.]

The milk supply of Boston may be divided into three classes : first, that brought in on the cars, and commonly called railroad milk ; second, that brought in wagons from the surrounding country, and called out-of-town milk ; third, that from cows kept within the city limits. Each one of these may be divided into three classes : first, from the new milch cow ; second, from the farrow cow, or one that has been milked for a year or more ; third, from a springer, or one with calf. The nature of the new milk is very loosening ; it is well known among farmers that the first milkings given to a calf three or four weeks will scour it to death. This milk changes as it increases in age, until at the end of a year the milk of a farrow cow becomes very astringent. This milk, if given to a calf a week old, would have exactly the opposite effect of the other. The milk of the springer gradually changes until near calving ; it becomes more watery, and has a limey taste.

Let us first consider the railroad milk. The distance from the city and the number of hands through which this passes (all of which have to be paid) make the farmers' returns small. The difference between a farrow cow milked out and a new milch cow is usually from $20 to $25 ; the farmer can better afford to let his cows go dry from two to three months than to pay the difference. Railroad milk is therefore mostly produced from new milch cows and springers. Let us visit Mr. B.'s dairy. He makes milk the year round and has cows coming in constantly. Some cows may be milked up to the time of calving, but in most cases they will go dry from one to three months—usually about two—and will give but little milk for some time before. The low price that Mr. B. receives for his milk and the loss he sustains while his cow is giving none, make it necessary for him to use all that he can of it. This, together with the fact that he does not see or know the parties who use it, make it natural that he should send to market milk that he would not use himself. Mr. B. commences to milk at one end of the barn ; the first cow may be a new milch cow, possibly the first milking, and will fill, or nearly fill, a can. The next may be a farrow cow that has been milked for a year or more, or may be a springer about to calve ; in either case will give

but little, and it will take the milk of two or three of them to fill a can. Therefore the milk from the same dairy may be of the greatest possible extremes. Mr. B. having finished his milking, the milk being at a temperature of 100° F., sets it in cold water, which will reduce the temperature to about 55° or 50° F. The milk is then disposed of for the night. The morning's milking is managed in the same way, perhaps with the exception that the collector comes before there is time to cool the milk off. It is then placed in a wagon and carried from one to seven or eight miles to the depot, by which time the milk is thoroughly shaken up and the temperature has risen several degrees. If the car starts from this place, the milk may be put on and iced immediately; otherwise it must wait until the train comes along, and reach a still higher temperature. When on board the cars it is iced, and by the time it has reached the city, from 8 to 10 A. M., the temperature has been reduced to 50° or 45° F. It is then taken from the car to the milk stable, where it remains usually from one to two hours before it is prepared for the consumer and iced. In the meantime the temperature has risen several degrees. The milk remains in the ice chest until two or three o'clock the next morning, when the temperature has been again reduced several degrees. It is then loaded on the wagon and delivered to the consumer. If there is any left over it is taken home, iced, and used the next day. This milk, therefore, is from 24 to 36 hours old before it reaches the consumer, and what is left over has 24 hours more added to it, and still people wonder why milk does not keep longer. This is the supply which reaches the city from 8 to 10 A. M. There are cars which reach the city from 1 to 3 A. M., which bring the milk of the night and morning before; a part of this is used the same day, but most is not used until the following day. It therefore may be used twelve hours fresher, but oftener twelve hours older, than that reaching the city earlier in the day.

As this milk comes from so great a distance it does not pay to carry out brewery grains or refuse vegetables from the markets. The cows are fed on such fodder as is raised in the neighborhood and on meal or shorts. But the milk dealer in the city is so far from his source of supply that he knows but little if any more about the cows or the condition they are in, or upon what they are fed, than the person who uses the milk.

The producer of the "out-of-town milk," being nearer the city, receives more for his milk, which, together with the extra risk of miscarriage from the effects of feeding on brewery grains, makes it about an even thing with him whether he changes his cows once in twelve or eighteen months, or has them "come in" in that time. This milk is from new milch, farrow, and springer cows, and is produced to a great extent from brewery grains; it receives very nearly the same care as the "railroad" milk until it reaches the stable of the dealer instead of going to the depot. The driver of this team starts from 12 to 1 o'clock A. M., which makes it impossible to bring in the morning's milk, and as the milking is the last chore at night, but few of our out-of-town men raising their own milk, and the dairies being scattered, milk is usually collected in the morning for the next day. It will be seen that the "out-of-town" man may bring the milk of the night before, but as a rule does not; it is usually from twenty-four to thirty-six hours old. As the "out-of-town" man goes home in the heat of the day, often reaching it at 3 or 4 o'clock, it is impossible for him to keep his surplus over. He has a certain poor neighborhood where he skippers his surplus milk, that is, sells it on the street, or from door to door, from a third to a half less than the usual price, often making up the difference with water, and the poor will buy it because it is cheap, though not so good. Several years ago, when milk was selling for eight cents per quart, I knew one man who used to make his extra milk one-half water, and sell it for five cents per quart, thus making a "good thing" of it.

The milk raised in the city should be divided into two classes: first, that from cows kept to produce milk for market; and, second, that of cows kept for family use. The first class is found near breweries, or near the salt marshes, and, to a great extent, the food is brewery grains and rotten potatoes, or other refuse vegetables. Many who have cows keep a team to haul brewery grains and go around the market and collect refuse vegetables. The Milk Inspector, in one of his reports, mentions finding rotten potatoes in a milk stable, but as he did not find the cows eating them, did not consider it a case with which he could interfere. This milk may be, and often is, delivered to the consumer warm from the cow, but is thinner in quality, and will not keep as long as milk from cows fed on whole grain, grass, or hay. In fact, the milk partakes to a great extent of the substance on which the cow is fed. The dealer realizes a good price for his milk, and can better afford to pay twenty or twenty-five dollars in difference in exchanging his cows than keep one three or four months that is giving little or no milk. This milk is produced mainly from new milch cows, farrows, and light springers. It is the custom with this class of milk producers to buy a new milch cow and keep her farrow a year or more, and then get her with calf, which gives her a more suitable plumpness, by which means she is disposed of with better advantage to the butcher.

The second class of city cows are those kept for family use, usually well fed, and often overfed. A person wishing a cow for family use, not being posted in the market and no judge of a cow, usually pays a high price; if he is fortunate and secures a good one, he receives a good supply of rich milk. If he keeps a daily record of the amount of milk obtained, he will find that once in about three weeks there will be a time, sometimes affecting three milkings, that the cow will not give more than one-half or two-thirds as much as usual, and that after each one of these turns there will be a gradual decrease, until at the end of a year she will not give one-half as much as at first, and that not nearly as good. Not giving much milk, and constantly giving less, she must be disposed of for beef at a loss; or, if the owner wishes to keep her and have her come in once a year, he must have her got with calf three months after she has come in, when the milk will decrease in quantity as well as in

quality. To sum up, the owner of a cow under these circumstances is sapping the milk which he intended for his family for six or seven months, and going without for two or three months, for the purpose of getting his cow to give milk again and producing a calf, which, although the material he has consumed, if devoted to milk, would be worth a great many dollars, the calf will scarcely bring a dollar, and often has to be given away. Besides this, the owner has to run the risk of his cow's coming in in bad shape, or of miscarriage. There is no domestic animal so liable to accidents of this kind as the cow, owing to her being milked, a disadvantage which no other domestic animal labors under. In such a case she will give little or no milk.

What I propose as a means of improving the quality of the milk, and at the same time reducing the cost of production, is the spaying of cows for milk, an operation but little known even among veterinary surgeons. After two years' experience and inquiry, I have been unable to find any one in Boston familiar with the operation. It consists of removing the ovaries from a new milch cow, which takes away all desire or ability for reproduction, and makes of her a constant milker ever after. These are some of the advantages gained by the operation: First, an increase in the quantity of milk, as the animal has nothing else to do but give milk or grow fat, and by giving milk-producing food the quantity may be increased a third. Secondly, the certainty of having a constant supply of milk of the same quality. Thirdly, producing a richer milk and of even quality, as the animal is always in the same condition, all causes of change having been removed; this alone is inestimable in its advantages to the sick, or delicate children. Without this operation, milk obtained from a new milch cow under the most favorable circumstances will vary much; once in three weeks there will be a time, often affecting three milkings, that the milk is at fever heat, and will not keep as long by one-third as when the animal is in the ordinary condition. It is not an uncommon occurrence for a person in delicate health, or a child, fed on a milk diet, although the milk be from one cow, and the greatest possible care taken of it, to have a bad day or a feverish night, for which no reason can be assigned, but which may be traced to such a cause as this. Fourthly, decrease in the cost of keeping, for by the operation causes are removed which produce waste of material that now goes to milk. Fifthly, by this operation cows may be kept for years, giving the same quantity of milk, thus avoiding the loss sustained while the cow is dry and the liability to accidents during calving. Sixthly, the spayed cow fattens more easily, its flesh is better than that of the ox, more tender and more juicy; indeed, no one is ignorant of the fact that all domestic animals, female as well as male, deprived of their procreative organs, fatten more quickly than those that retain them, and the flesh of the spayed female is more tender and juicy than that of the male. By this means the farmer will realize a better price for his cows when they have passed their days of usefulness as milkers, and the public will be protected from a practice often resorted to by farmers to obtain the best possible price for old cows—that is, to bring them to the bull, intending that gestation should give them more suitable plumpness, so that they may be disposed of to better advantage to the butcher. The result of this is a mere bloated, flabby flesh, which easily taints; broth made from it is not rich, and is without flavor.

I first became interested in this operation early in 1880, through information obtained from a work translated from the French. I afterwards obtained other treatises on this subject and soon became convinced of the advantages to be obtained by it. I made inquiries among veterinary surgeons, but could find none familiar with the operation. While making inquiries upon this subject I learned that Hon. Josiah Quincy had had the operation performed at his farm in Quincy nearly twenty years ago. I was told that it was a failure. To ascertain the facts of the case, I called on him at his home. He told me that spaying was performed under the direction of his foreman, and although he lost a number of cows by the operation he considered it a success, and of great benefit to both the producer and the consumer of the milk; that the cows continued to give a large quantity of milk for a number of years, and that the milk was of a superior quality. It is by his permission that I refer to this. He also informed me that at one time he thought of publishing an article calling the attention of the public to the advantages of this method of producing milk.

My experience teaches me that it will increase the flow of milk and also improve the quality, and that although there will be a slight decrease at the end of a year, the daily average will be equal to that given at the time of the operation. I have one cow that was spayed in November, 1880, was then giving ten and one half quarts per day, and now, after nineteen months of constant milking, nine and a half quarts, and she now comes to the barn every night with milk flowing from her bag. To make a comparison: I have talked with those who have had a longer experience in keeping cows than I have. They all agree that this is a liberal estimate: a cow giving fourteen quarts of milk when she comes in is an extra good one; that at the end of ten months (she coming in once a year) she would not be giving more than three or four quarts, and that not suitable for use, at which time she should be dried off and not milked the other two months; or that an average of nine quarts a day for ten months and none the other two months is all that could be expected, and that this result can be obtained only under the most favorable circumstances. This would give 2,736 quarts. Now I claim that under this operation a cow giving fourteen quarts may be made to average that for three hundred and sixty-five days in the year, as she would increase enough after the operation to make up for any slight shrinkage at the end of the year, making 5,110 quarts against 2,736, and also better milk.

I do not wish to lead any one to think that this operation is without risk, but after two years of practical experience I am convinced that the risk, when the operation is properly performed, is less than in ordinary cases of calving.

THE ÆTIOLOGY OF TYPHOID FEVER.

[A paper read to the Chicago Medical Society, March 17, 1884.]

BY J. F. TODD, M.D., CHICAGO.

In the selection of the subject of this paper, I was not unmindful of the fact that the ground had been traversed by the ripest men in our profession, and that I could add nothing new to the thoughts and opinions that have found a fitting place in medical literature. The topic was chosen because of its inherent interest and importance with the hope that the society might be stimulated to a discussion of the subject. The general prevalence of typhoid fever in this country and Europe during the past few years, and the revival of the theory of "a contagium vivum" constituting its essential cause, has served to develop general distrust in prevailing methods of treatment, and widely divergent opinions respecting its ætiology. The researches of Graves, Brettonneau, Louis, Murchison, Budd and Liebermeister, the contributions of scores of learned authorities, and the recorded observations of thousands of intelligent practitioners of medicine, only enable us to say that typhoid fever is an "essential fever" in a certain sense contagious, in a certain degree preventable, and that it may be properly classed with the self-limited diseases; further than this nothing has been positively established. A variety of views have been advanced respecting its nature, the development of its cause and the laws of its propagation, all sustained by apparently reasonable hypotheses, but they have all failed to advance to the position of clearly demonstrable facts. We are confronted with mortality reports that deride every pretension to even an approximation to an exact knowledge of the cause, prevention or cure of the disease. It remains constantly with us; exciting but little attention from boards of health; seldom referred to by the public press; constantly encroaching upon human life as a certain fatal factor, and an approbrium of therapeutic art. Its essential cause—the nature of the propagating principle and the process of its elaboration—are the principal subjects upon which professional opinion is divided. Since Dr. Budd's time the discussion of this subject has only been rivaled by that of Pasteur and Bastian and their followers on that of the spontaneous evolution of animal life. The extremes of professional opinion in this country are expressed in the published works of two of our most celebrated American authors.

Dr. Flint says in his "Clinical Medicine:" "It is vastly probable, if not certain, that the effluvia from human excrement not containing typhoid dejections may cause the disease."

Prof. Bartholow, in his "Practice of Medicine," pags 689, says: "It is never produced by mere decomposition of animal matters, fæces or the contents ofsewers; it is essential to the formation of the poison that the typhoid germ be present, and this germ finds in these decomposing animal matters a suitable soil for its growth and development."

Dr. Harley and Dr. Bristowe, of England, entertain equally discrepant opinions and express them in yet stronger terms, the former, not content with an enunciation of the view of its spontaneous origin, adopts a classification,naming varieties of the disease with reference to supposed origin and anatomical lesions, as "simple inflammatory," "contagious" and "paludal," "enteric fever." Dr. Bristowe strongly inclines to the view that the cause of the disease is not "a mere inorganic or even organic result of decomposition, but like other contagia an organized living particle which has special endowments and unlimited powers of multiplication," a specific virus yielded by the bowels of patients suffering from enteric fever, and probably by them alone. This view is ably sustained by Liebermeister, and it is probably the commonly accepted view of the profession.

There is an immense amount of evidence that the germs of the disease are developed in typhoid excretæ, and conveyed by water, and the atmosphere, and probably by milk and diseased meat, in quantities sufficiently large to develop the disease in individuals susceptible to the infection. It would tax the patience of the Society even to briefly refer to the chain of evidence quite familiar to you all, no doubt, in support of this view of the propagation of the disease. The proof would seem irrefragible that water contaminated by the alvine discharges of typhoid fever cases is capable of producing the disease. It appears almost equally clear that it can be conveyed in milk, and the evidence is strong enough to warrant belief that it can be produced by meats contaminated with typhoid germs. The most important of all the questions in the ætiology of the disease is the old and mooted one as to whether or not it may originate *de novo*. Having no practical acquaintance with the use of the microscope, and only a general knowledge of the results of microscopical research it would be presumptuous to present the views of investigators in that line of inquiry. It is perhaps fair, however, to say that nothing conclusive or particularly valuable has been learned with reference to typhoid fever, and that it is yet an open question whether the microphyte observed in cases of fever occupy a relation of cause or result. A few years ago it was quite the fashion to ascribe the origin of the whole class of zymotic diseases to sewer gas and the decomposition of organic matter. It was an old belief, sustained by abundance of old authority. On its revival it enlisted the enthusiastic support of many able practitioners, and sanitary engineering and disinfection became the fashion of multitudes who promised the world comparative immunity from infectious diseases; the ordinary attendants of filth and poverty, in the slums of cities, where it most abounds, the character of food, insufficient in quanity, and wretched in quality, lack of clothing and fuel in inclement seasons, the influence of immoral practices transmitted through generations of people, all combined, was for the time treated as a matter of secondary importance when compared with filth as a factor in the production or propagation of zymotic diseases.

That belief, however, is fast giving way, and it is,

in fact, an open question, and a very doubtful one, as to whether the elaboration of typhoid germs is to any considerable degree influenced by filth deposits. Watson's lectures on the ætiology of continued fever clearly outlined the observations of the observant members of the profession before his time and since, and strikingly illustrated the fallacy of the idea of spontaneous origin of fever by reference to the domestic habits of the natives of the Arctic regions, and the tropics, the exemption from the disease in African slave ships and in English prisons, except when the disease was imported. He quotes the opinion of John Howard, whose sagacity in all matters pertaining to the physical requirements of prison inmates was only surpassed by his philanthropy: "That some cause other than filth, ill-ventilation and over-crowding is responsible for the production of fever." He further cites the fact, familiar to us all and confirmed by our own observations, that the putrid atmosphere of dissecting rooms and the noxious effluvia of rendering establishments do not produce the disease. Stokes, in his lectures on fever, gives a graphic account of the filthy condition of an overcrowded town of 6,000 people in the South of Ireland, in which no epidemic of typhoid had ever appeared; in fact, it was considered a remarkably healthy place, notwithstanding the fact that 4,000 people lived on 25 acres of land, breathing the exhalations from 7,000 cubic yards of fetid matter. He also quotes Dr. Pratt, a government medical officer, as stating that filth agencies cannot produce the fever. "Were it otherwise, Ireland would before this have been depopulated from sea to sea."

The theory of the causative influence of sewer gas has been lately quite vigorously opposed by Dr. George Hamilton in a lecture before the "College of Physicians and Surgeons, of Philadelphia," in which he quotes a recent statement of the eminent sanitarian, Geo. E. Waring: "*that the sewer gas theory in regard to typhoid fever was, in the opinion of sanitarians, exploded.*" He cited the fact that the filthiest cities are often exempt from typhoid epidemics, and that the best sanitary conditions confer no immunity from their occurrence—this view is strongly corroborated by a recent report of the sanitary superintendent of New York city, which gives a large increase of typhoid fever coinciding with marked improvement of sanitary conditions, and a season of more than ordinary salubrity. Professor Loomis, in his late work on "Fevers," sustains this view with the statement that the prevalence of the disease is relatively greater in the country, where sewer gas is unknown, than in cities where immunity from its influence is exceptional. In a valuable contribution to the *Medical Record* of New York, Nov. 17, 1883, Dr. Francis Delafield presented a statement of mortality statistics for that city, in which it appears that the mortality from typhoid fever was greater in 1864 than in any year since that time, and that the mortality and prevalence of the disease has so greatly varied during the twenty years, that no constant or highly important relation can be supposed to exist between the ordinary, slightly varying, local conditions and the disease.

In a monograph on typhoid fever, by Surgeon Francis A. Welch, of the English Army, published last year, he presents an analysis of a large number of cases for home and foreign military stations between the years 1860 and 1878 inclusive. His contribution abounds with facts illustrative of the influence of climate in modifying the course and mortality of the disease, with abundant evidence that under all circumstances of military life, in all countries and every variety of climate, the clinical and post-mortem features of the disease are essentially alike. "In heated plains and cool hills, the moisture of the sea-coast, the drouth of central India, combined heat and moisture, combined heat and dryness, the disease existed and developed in the phases familiar to European observers." He reports the existence of large numbers of cases in salubrious localities, and its total absence in others characterised by filth. In the stations on the west coast of Africa he gives a single case for 1867, notwithstanding the existence of the alleged factors of the disease in an unusual degree, "filth of every character abounded; the air, earth and water were polluted with fecal matter, and vegetable matter constantly undergoing decomposition in a climate noted for its insalubrity." He attributed the existence and extension of the disease in military life to its importation from home stations, to infection from civilians among whom it existed as an endemic, and to air and water containing the specific poison. He sums up his conclusions with the opinion that a disease of universal prevalence, occuring under widely varying conditions as to climate and habits of life, and yet retaining its individual character, must be due to the same specific cause. These observations on an extensive scale—occuring in military service—so strikeingly accord with the observations of medical men in agricultural districts, I feel justified in giving the history of a series of cases occurring in my own practice, introducing that, with a brief report from a friend in the interior of the State.

My friend, Dr. George A. Wells, a skillful practitioner of Galva, in this State, kindly sent me the following brief report: "On the 15th of August, 1883, he was called to see Mr. J. C. Swan, a young farmer, 23 years old, and found him suffering from typhoid fever. His mother being sick with dysentery, and having no help in the house, an aunt of the patient, living seven miles distant, came to their assistance. She arrived about the tenth day of the fever; thinking she could better do the washing for the family at her home, she moved all the clothing there, including bedding stained with fecal matter, and washed them. In a few days she was suddenly taken ill with fever, and at varying periods three other cases succumbed to the contagion. The sanitary surroundings at the home of the aunt were very bad; the water of the well was thought to be impure, and a large privy and hog yard was located near the well and dwelling house. There were members of other families, however, whose sanitary surroundings were equally as bad, as constant in their attendance on the young man, but they neither contracted the disease or conveyed its poison." The doctor expressed the opinion that the germs of disease were conveyed

in the soiled bedding, and found congenial soil for active development. The report concludes with the statement: "It is impossible to say where the germs were received in the case of the first patient, as he was traveling over the country with a threshing machine."

My own experience in a considerable practice, extending over twenty years, has convinced me that typhoid fever does not originate *de novo*. For nearly twenty years my practice was confined to country villages and farming districts, situations in which familiar acquaintance with individuals and their surroundings usually enabled me to trace the cases that came under my observation to sources of infection supplied by preëxisting cases. My first patient suffering from this disease was a resident of Chicago, who for three or four weeks previous to his attack, had been in the employment of a railway company and boarding at a village hotel in the interior of the State. There had been no cases of fever in the hotel previously, and for a year none in the village; he could give me no information as to its origin. My patient was taken ill on the 3d of December, 1863, and returned to Chicago late in the following month. The ordinary precautions as to disinfection were advised, but imperfectly observed. On the 3d of the following September, I was called to treat a case of typhoid fever in the family of the landlord of the hotel, and on the 23d of the same month assumed charge of another case. On the 9th of October, 1865, another case developed, and between that time and the 15th of December, I treated five cases. The next case developed in January, 1866, and was the last of a series directly traceable to the imported case of December, 1863. During the period covered by the history of these cases, the disease developed in a farming community six miles north of the village, but I had no opportunity to trace it to its source. From one of these cases, however, the disease was communicated to seven persons living in the village—all of whom were under my management.

In December, 1865, five cases occurred in a farmer's family, the first of which developed in a young man who had been engaged in watching a friend suffering from the disease in a distant neighborhood. The disease appeared in the four following cases in periods varying from eight to fifteen days. During the years 1867 to 1874, inclusive, I treated a large number of cases among Swedish and English immigrants, under circumstances unfavorable for tracing them to the initial case. Many of them gave histories indicating infection on the ocean, and many others occurred in the order so commonly observed, a single dwelling breeding typhoid fever for an entire season. During this period, I cannot recall an isolated case of the disease occurring in my practice. In October, 1878, in an entirely new field of practice, a case occurred in a farming community, in which I could obtain no history of a previous case later than 1870. The patient was brought to my office in a delirious condition, which, with other symptoms, enabled me to make a diagnosis. He resided with a brother-in-law a mile distant from his father's farmhouse. On the sixth day of his illness (the third after my interview), in the delirium of fever and in the night he struck across the fields and reached his father's residence. On my visit that day the family were apprised of the danger of infection. The dejections were ordered to be thrown into a pit and covered with fresh earth. Notwithstanding this precaution, seven persons became affected with the fever, in periods of six, ten, twelve, fourteen, eighteen, twenty-three and twenty-six days from the date of the reception of the first case in the family. Two of the patients were hired men, and leaving in the prodromic period of their illness, communicated it to three friends who attended them in a small village five miles distant.

This epidemic, occurring on a prairie farm, remote from the ordinary sources of contagion, in a neighborhood in which no recognized case of typhoid fever had occurred during eight years previously, stimulated my industry in the search for its origin. The patient first attacked made a business of threshing grain, and travelled over an extensive farming district. After his recovery, I questioned him closely in regard to previous disease in the families for whom he had worked. After diligent inquiry, it was ascertained that a short time previous to his illness, he had worked at a farmhouse in which a Swede immigrant had recently died of so-called inflammation of the bowels, *after an illness of three weeks*. In September, 1881, a young farmer contracted the disease in a grain-threshing tour which brought him in relation with families in which typho-malarial fever (?) had occurred the previous fall. During his illness, a friend living nine miles distant watched with him two or three nights, contracted the disease and communicated it to several members of his family, and they in turn developed a neighborhood epidemic.

In October, 1881, I treated four cases in a family, the fourth of which was a young lady but lately returned from a boarding-school in which the disease had lately existed. In the same month, in a family in which three cases occurred, I traced the infection to a tenement house on the farm in which a case occurred the previous winter. The brief history of these cases perhaps only possesses interest as cumulative evidence to that already existing in great abundance, that the disease has been properly classed by Libermeister as miasmatic contagious. I have never found in my practice the slightest evidence that it is directly contagious, but it has appeared conclusive that the excretæ of typhoid patients contain an exceedingly active disease germ, capable of propagating the disease to individuals susceptible to its influence. The period of time required to develop the germ, or morbific material, after its discharge from the body, will require the most patient investigation. In country practice the lack of skilled nurses, and the habit of changing attendants to suit the convenience of neighborhoods, is a fatal bar to successful inquiry. If bed linen is not frequently changed, and the anus and surrounding parts thoroughly cleansed on the occurrence of alvine discharges, disinfection of the bed-vessels and discharges will amount to nothing for statistical purposes. The neglect of this precaution in whole or part is the rule, not then the exception. The length of time during which the germs

will retain active vitality is another problem equally difficult of solution. It is apparently well established that they may retain their vitality for a year or more.

The cases recorded give but one of relapse. In that case there was no evidence of new infection. It was treated as a septicæmic fever. Five cases of latent character were observed presenting the unmistakable character of the disease, but lacking the nervous prostration and muscular weakness that prohibit gentle out-door exercise. These cases are not included in the preceding reports. In no instance have I observed a second attack of the disease in the same individual. It has appeared, however, that certain families are more than ordinarily susceptible to this and other zymotic diseases. The common remark that certain families are apt to take every prevailing disease, is confirmed by the observations of country practitioners, and stimulates inquiry as to whether or not diathetic conditions, hereditary or acquired, may not influence the extension of acute as well as chronic diseases. My observations do not sustain the Pettenkofer theory or the opposing English theory of the dissemination of the disease. Its virulence and prevalence were about equally observed in wet and dry seasons. Its prevalence has been apparently uninfluenced by habits of life, geological formation or topography of the country. Its prevalence in 1865 was preceded the previous year by that of ague in the creek bottoms and low valley lands, but the succeeding local typhoid epidemics did not occur in such localities during the 20 years of my practice in the country. I treated epidemics of small-pox, rubeola and scarlet fever, and experienced quite as much difficulty in tracing these diseases to their initial cases as I did in those of typhoid fever. The habits of country people in the care of the sick are influenced in no small degree by the ardor of their friendships, and their zeal in rendering service. To this fact we may partly attribute the greater relative prevalence of typhoid fever in country neighborhoods. Another cause consists, perhaps, in the difficulty in securing timely removal and disinfection of fecal discharges; in short, skilful nursing, which implies practical isolation of the patient, exemplary cleanliness, and thorough ventilation of the sick-room. During my observations of this disease, there has been a constantly growing conviction of the fact of its contagiousness by means of fecal germs, and this conviction has been strengthened by the failure of supporters of its *de novo* origin to instance facts to sustain that theory, corresponding with the experience of thousands of general practitioners through the rural districts.

The ætiology of the disease, including the study of the precise nature of the *materies morbi*, the length of time required to elaborate its active properties, either within or outside the body, how long the active properties can exist in fecal matter, and the circumstances under which these poisonous properties are longest preserved, and the manner in which the morbific material gains access to the human system, constitutes a series of the most intricate problems before the medical profession—problems which may require the best efforts of future generations to solve. The mortality resulting from the disease, and its uniformity under the various methods of treatment employed, is a painful reminder of the importance of studying the laws of its propagation, which, clearly ascertained, may enable us to place limits on its prevalence. We can then better afford to await the discovery of a specific for its cure.

MEDICAL PROGRESS.

MATERIA MEDICA AND THERAPEUTICS.

ON THE USE OF IRIDIN IN THE TREATMENT OF THE SICKNESS OF EARLY PREGNANCY.—Dr. D. Barry Hart, (*Edinburgh Clinical Journal*), recommends highly the following:

℞. Iridin.....gr. ij.
Cons. Ros.....9. S.
Fiat pilulæ, with talcs..iij.
Sig. One at night.

This must be followed in the morning by a draught of Friedrichshall water, a teaspoonful of the Carlsbad salts, or a doubly strong Seidlitz powder. Dr. Hart claims simply to apply the known views of Rutherford concerning the action of iridin upon the liver, as inducing a flow of bile, to a condition, pregnancy, that exerts an influence upon the liver, and in this way probably induces vomiting.

A HOSPITAL ELECTRICAL DEPARTMENT.—The last volume (XIX) of the Saint Bartholomew's Hospital Reports, gives an illustration with the descriptive text by W. E. Stevenson, M. B., of the electrical department of the hospital which it is proposed to establish. A lower floor is taken, which supplies a lobby with benches for patients in waiting, a work shop with an engineer's room communicating, and provided with a lathe, sink, shelves for chemicals, etc., etc.; and three warm, dry, commodious rooms with accommodations for dressing and undressing patients. These three rooms connect with each other, and their electric element boards are each connected with sixty modified Leclanché cells (in the cellar below), and are provided with a commutator, interrupter, rheostat, "on" and "off" shunt, galvanometer and induction coil. There are extra trays of six cells to work the coils. The Bunsen's battery for galvano-cautery is composed of six cells. In room No. 1, there will be a frictional machine for producing statical electricity, and an insulated couch and benches; also a small table for operating purposes, such as operations on nævi, circumcisions, etc. There will be an element board, and under this board a couch will be placed on which the patient can recline, and it will be possible to use the galvanic or faradic current at will. In room No. 2, will be a similar element board, worked in the same manner, but it will also be possible to use the current for the electric bath in the adjoining room. No. 3, the bath room. The portable batteries for use in the department and for lending to the wards, will also

be kept in this room, and also the electro-magnets belonging to the hospital. In the workshop all the minor repairs of the electrical apparatus used in the hospital will be carried out, and the man in charge will supply and receive the batteries used in the wards. He will also prepare the galvano-cautery batteries when they are required.

MEDICINE.

The Treatment of Partial Epilepsy by Encircling Blisters, with Transfer of the Aura.—Dr. Thomas Buzzard, in 1868, first called attention to this mode of treatment, and now (*Lancet*) gives a case to illustrate the success which he has met with in the past fifteen years. He considers this treatment as frequently of great service. In the majority of cases there is a distinct effect upon a number of the attacks, now and then stopping them altogether for considerable periods, and in other instances occasioning a very marked prolongation of the intervals between the seizures. On the physiological side, the strange influence exerted upon the site of the premonitory aura by the application of the blisters is very interesting. There has been a transfer (in the case given) of the aura from the right foot and leg first to the left foot, and later to the right groin. There is no marked uniformity in the mode of transfer in such cases. For example, in one patient a tickling in the left arm had always preceded the fit. After the application of a blister encircling this limb the tickling was transferred to the left leg. In another case characterized by a similar aura, the fits, as well as the tickling, ceased after the application of a ring of blister. In a third a sense of numbness in the left wrist was transferred to the right wrist. This was a case of cerebral tumor, as a subsequent autopsy showed. Another patient was a woman whose fits had always been preceded by cramp in the right hand, and who, after the blister, was affected with cramp in both hands before her fits. In the case of a patient whose fits had always been preceded by cramp in the left foot and shaking of it, with numbness of the left leg, a ring of blister was applied to this leg,and in subsequent attacks it was the right leg which became numb and shook. Tingling in the left arm was the aura in another case, and after blistering, a jerking of both arms and the left leg would take place at the beginning of a fit. Strangest perhaps of all was the case of a female patient whose attacks always commenced with cramp in the left hand. She had suffered from a severe fit two days before she came to the hospital, and the left hand then still remained quite powerless, as indeed she said was always the case after a fit. An encircling blister was applied to the left wrist. Next day the left hand had quite regained its power, but the patient complained that the right hand had *ipso facto* become weak. A few days later when she came to the hospital, the dynamometer showed 40° as the grasp of the left hand, and only 18° as that of the right.

Dr. Buzzard quotes an article by Professor Hirt, of Breslau, as corroborating his experience as regards both the therapeutical value of this method and the occurrence of transfer of the aura. In one case of unilateral convulsions without loss of consciousness, in which the attacks were exceedingly numerous every day, and always preceded by a tickling in the left arm, above which the blister was applied, the attacks ceased, and did not recur during the six months preceding the report. In a second case the aura was a trembling of the great toe of the right foot. Blistering was followed by cessation of attacks for two months, and in a fit which then occurred it was noticed that the trembling affected the big toe of the left foot. A third case is that of a shoemaker, in whom the cessation of attacks consequent on the treatment was attended by such feelings of discomfort as to cause him to regret his previous condition! In another example there was transfer of the aura, which consisted of over-tension of the fourth and fifth fingers of the left hand to the other side.

There would seem to be sufficient evidence to show that epileptiform convulsions beginning unilaterally depend upon a lesion of the cortex cerebri. As regards the situation of the centers which receive impressions of common sensation, we can do little more than infer that the place of reception for impressions coming from a skin covering the limb is probably in close association with the center for the movement of its muscles. If this be so, the irritation of a blister causing a molecular change, which is propagated centripetally, may be supposed capable of influencing in some way the liberation of movement.

As a matter of detail, a distinct advantage has shown itself in the blister being employed in the form of a ring or bracelet encircling the limb. An effect has been produced where the previous application of a quadrilateral blister has failed. A ring of blister applied above the ankles, involves cutaneous branches derived from the lumbar as well as the sacral plexus, through the anterior crural and sciatic nerves. A blister acting upon these nerves may be conceived, therefore, to be capable of producing a more intense impression than one which should only affect the branches derived from one or other of these large nerves. Professor Hirt employed blister of but half an inch in width, and it is very probable that a still narrower ring than this would be found sufficient.

The Purpura of Chloroform.—M. A. Moret Lavallie gives, in toe *Annnals de Dermatologie et de Syphiligraphie*, reference to three cases which demonstrate the possibility of the development of a purpuric eruption under the influence of inhalation of chloroform. In two of these cases the eruption was produced in identically the same manner, at the commencement of inhalation, in the course of one to two minutes, a discret eruption of purpuric spots, with a medium diameter of three to four millimetres, the blood being determined to them with such force as to transform several of them into sanguineous bullæ. The eruption did not seem to be about the hair follicles—in all three of the cases it occupied the same situation, that is about the middle of the body, and principally upon the anterior surface of the thorax.

Do these purpuras take rank among the medicinal purpuras, such as are produced by mercury, copaiba,

belladonna, ergot of rye and the preparations of iodine. The eruptions produced by these drugs only appear after the lapse of a certain time. Here we have an eruption appearing with the first inhalations of chloroform, the drug not having had time to impregnate the nervous system, it seems to belong to those purpuras which follow violent emotions, ranking among the nervous purpuras the chloroform acting by producing a brisk shock to the nervous system either by its anæsthetic or simple reflexation, due to the disagreeable impression felt by the patient, who is suddenly compelled to inhale vapors so irritating to the pharyngo-laryngeal and oculo-nasal mucous membranes.

The third case was a robust woman of 25 years, with facial eczema. She was chloroformed to open a deep abscess consecutive to a post-typhoid, costal periostitis. During the first inhalations the skin of the upper part of the chest became of a dull white, then it was covered by a series of large striæ, alternatively white and red. Immediately afterwards, here and there upon the chest appeared a cluster of purpuric spots, the cutaneous base of which had resumed its rosy color as soon as the spots were well defined.

THE PRACTICE OF MEDICINE IN BOMBAY.—Assistant-Surgeon Sakharam Argion L,M., gives (*Trans. of the Medical and Physical Society of Bombay*) an interesting sketch of the indigenous practice of medicine and the European practice of medicine in Bombay.

As regards the indigenous practice of medicine the Ayur Veda has in it the essentials of the Hindu system of medicine. The Hindu Vedas are the oldest written books known to the human family, and a record of what the Ayur Veda contains was known to the people long before it was put into writing, and was handed down from man to man by personal communication. On the Ayur Veda were founded the two subsequent works, Sushruta and Charaka, both written on an identical plan, the former treatise treating more of the subjects of surgery, and the latter those of medicine. A compendium of these was subsequently brought out at a later period by a learned physician and his grandson, known as the Vagbhatas. This is the standard work studied and referred to by the learned physicians of India at the present day. Besides this there are a number of others which treat of different special subjects. Of the fact that the Hindu system recognized the study of anatomy and physiology as essential preliminaries to the study of medicine one can easily satisfy himself by studying the original treatises Sushruta and Charaka; and the symptomatology that obtains therein does not materially differ from what one sees even in these days in a general treatise on medicine. Surgical and midwifery operations, the instruments therein required, and the mode of manufacturing them, have been described in detail. Rectal injection and enema syringes have also been described.

To have studied medicine systematically involved a full and elaborate preliminary literary course which extended over nearly twelve years. A special course of technical studies, when added to this, really made the man what he was then called, and amply deserved to be called, the Physician Royal. Under foreign rule, and lacking support, encouragement, and the proper institutions for the clinical study of diseases, he has died a natural death. He is no more to be seen; his place is taken by No. 2, the king of physicians. who has minor qualifications, is of mediocre proficiency in Sanskrit, and has a vague knowledge of diseases and their treatment. No. 3 is the ordinary practitioner of the country, who has emerged from a reciter of religious histories, a clerk or a schoolmaster, and in after life has associated himself with some senior man in actual practice, as a cook, an assistant, or an apprentice on stipulated terms. Sometimes he claims his descent from a renowned ancestor, and professes to be the possessor of his secrets, handed down through several generations. He is perfectly devoid of any knowledge of anatomy and of medicine. He professes to know the nature of the complaints of his patient by feeling his pulse, and pulse alone, and at times by the examination of the urine, which he conducts by dropping a litle oil in it. He ridicules English practitioners and their drugs by representing the former as having no knowledge of diseases as obtainable from the pulse, and the latter as injurious to constitutions of the natives of the country. No. 4 is the infant disease curer, who is closely allied to the common practitioner, but who has picked up a few English drugs in ordinary use and added them with advantage to his stock of native medicines. No. 5 represents the pretender, who advertises and sets up a great and pretentious display after the manner of European quacks. These five comprehend the Hindu system of practice, and are classed respec-ively Raja Vaidya, Vaidya Raja, Vaidya, Bal Vaidya and Dhongi Vaidya.

Then comes a modification of Hindu medicine, used by a class of practitioners ranking No. 6 in the order given by this writer, and called Hakeem (literally a philosopher). They follow the Greek system of medicine, and their medical literature is to be found in the Arabic and Persian languages. With them anatomy and physiology is not studied, as the Mahomedan religion objects to dissection of dead bodies. Their medicines are chiefly of vegetable origin, and poisonous drugs and metallic preparations, though mentioned, are not practically used, but in special cases lettuce, hyoscyamus and opium in small doses are used by some of them. They act on the principle of elimination, depression and stimulation in the treatment of diseases. They have a number of electuaries possessed of tonic and aphrodisiac properties, in the composition of which amber, ambergris, castor and musk enter largely. They also have their charlatans, who are called (No. 7) Waleying Hakeems.

These practitioners, be they Vaidya or Hakeems, sends their prescriptions to the (No. 8) Gandhee or drug vender, in the bazar, whose name taken literally signifies a seller of odoriferous substances. He, like some of his kind in other countries, sometimes, by frequently going over the list of drugs sent to him for dispensing, and questioning the bearers as to the nature of the complaints, becomes a practitioner himself, and is then (No. 9) the Gandhee practitioner.

According to this account of them they mnst be arrant rogues, for they deal in European drugs, by ordering the refuse of European produce and then adulterating it as much as possible to augment their profits.

The quack specialists form a large and curious class in this account, and fou individuals receive special mention, viz.: 1. The pile and fistula curer. 2. The ophthalmologist. 3. The dentist, and 4. the bone-setter. Piles are cured by the arsenical paste, and fistulæ are relieved by passing a silk thread through them, which has been besmeared with the same paste, and letting it cut its way out. The ophthalmologist pares thin films from leucomatous opacities of the cornea, and couches for cateract. The dentist knocks off by gentle hammering all loose and painful teeth, binds teeth with gold and silver wire, and inserts artificial teeth made of ivory, bone or conchshell. The bone-setter is the type of the old barber-surgeon. He cuts for stone by the median incision, extracts the dead fœtus by piecemeal, bleeds, cups and extracts the guinea worm. His wife is the ordinary midwife, who, in addition, does the work of a menial. He sets bones and shampoos sprained joints; from incautious and light bandaging gangrene of the injured parts has not unfrequently resulted.

An interesting class is that of the itinerant drug vendors; then comes alchemist, a religious person, whose medicines are costly and who cures loss of virility, barrenness, etc., and finally the Makoor, or dweller in the hills, possessed of marvellous secrets, whose patients come to him for relief.

The European practice of medicine first came to India through the advent of the Portuguese. It comprises the qualified practitioners, including Europeans and natives, and the field of action is being overcrowded through the increase in numbers by fresh yearly accessions from European and local universities. The unqualified practitioner, who has not passed his final examination, but practices on equal terms with his qualified brethren, except in his inability to grant certificates. Then come quacks and charlatans. As to homœopathy, a regnlar student practicing in Bombay is not to be seen at the present moment. A European foreigner practicing this system now and then puts in his appearance, and after a short time disappears. Quack followers have, however, established themselves, one of whom, a partner in a native firm of merchants, is a much boasted practitioner. He also practices mesmerism under the initiation of the American theosophists, and is said to heal dozens of people daily before he leaves for his regular work.

There is an association of vaidyas, chiefly composed of members described under classes 3, 4 and 5, and is called "A Society for the Investigation of Medicine as obtained from the Veda."

SURGERY.

An Improved Method of Adapting a Truss in all Forms of Hernia.—Thomas Bryant, F.R.C.S., in the *British Medical Journal* gives his views on the treatment of supposed irreducible hernia, as being that all herniæ, except those that have been subject to some antecedent strangulation, incarceration or obstruction, can be rendered reducible by treatment.

The means adopted to bring about this result are not complicated. They are the recumbent position, associated with limited diet, milk diet being the best, and the administration of small and repeated doses of saline purgatives, together with the local application of cold to the hernial protrusion by means of an ice-bag, or one of Leister's metallic coils. By these means the bowels are emptied of their contents, and the blood-vessels in their walls are rendered less turgid. The fat that may be in the omentum is likewise absorbed. This treatment, to be effectual, should be persisted in for days, and in some cases for weeks, and under it a good result may, with some confidence, be anticipated. Mr. Bryant, by this treatment, has succeeded, in from a few days to nine weeks, in reducing herniæ which had been down from five up to twelve weeks.

But it is his adaptation of a truss to the irreducible hernia that is particularly of interest. Having rendered the hernia as small as possible by rest, diet and the local application of cold, he takes a plaster of Paris "mould" of this hernia and the parts around its neck, and from this mould makes a "cast." Upon this cast a metal plate of tin or copper is moulded and covered with wash-leather, and when this has been efficiently made, as a result there is a pad which accurately fits the hernia, whether umbilical, femoral or inguinal, and this pad has only to be fixed to a spring or belt to make the instrument complete.

The pad, being a mould of the hernia, forms a most efficient protection to it; and touching, as it does, every point of the protrusion, it fairly guarantees no increase in its size; from like reason, the truss keeps its place, and is really comfortable to the wearer, since it presses equally. There is a little knack in taking this cast; all the hairs likely to be in the way must be snipped off, the tumor oiled, and dentists' plaster used by preference, as the commoner kind cracks and makes a mess. When plaster is not at hand for the mould, a piece of gutta-percha, dipped into hot water and softened, may be used for the purpose; and it is possible that this method may prove the most useful, since a hard mould is secured by this method, which is not likely to break.

Cardiac Tonics, Caffeine and Convallaria Majalis.—Dr. Beverly Robinson (*Therapeutic Gazette*, August 15; 1883) advances the claims of the above drugs, substantially as follows: 1. The diuretic action of caffeine is more marked than that of convallaria; digitalis is more powerful than either. 2. Convallaria is well borne by the stomach in the case of those suffering from chronic cardiac disorder, unless the uræmic condition has already commenced. 3. Cardiac power is increased by both drugs, but digitalis is more efficient than either. 4. Digitalis, for restoring the rhythm, is more certain than either caffeine or convallaria, and cumulative effects do not appear where the latter are continued for ten days or more.—*Bulletin.*

THE

Journal of American Medical Association.

PUBLISHED WEEKLY.

THE EDITOR of this JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information, should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor

SUBSCRIPTION PRICE, INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE..... $5.00.
SINGLE COPIES..... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 65 RANDOLPH STREET,
CHICAGO, ILLINOIS.

SATURDAY, APRIL 12, 1884.

HOW TO BECOME A MEMBER OF THE AMERICAN MEDICAL ASSOCIATION.—We are again asked by subscribers who are not members of the Association, to state clearly how membership is to be obtained. We answer, that the chief and most desirable method is to first become a member of a regular medical society, if one exists, in the city or county where you live. If no city or county society exists in your county then go to the State Medical Society of your State and become a member of it. All State and local medical societies which have adopted or approved the Code of Ethics of the American Medical Association, are entitled to send *one delegate for every ten* of their regular members. It is easy for any member who will promise to attend a given meeting of the Association to get appointed as one of the delegates from the local or State society to which he may belong.

Having such appointment and a certificate of the fact from the secretary of the society he must actually attend an annual meeting of the National Association, present his certificate to the Registration Committee, sign the Regulations, pay the membership fee of $5, and be registered as a delegate. Having thus acquired membership by serving at one meeting as a delegate, he remains a *permanent member* so long as he pays into the treasury the *annual* membership fee and complies with the rules of the Association, and is entitled to receive the journal of the Association without any further charge. But if he neglects to pay his annual membership fee for three successive years he forfeits his membership. It was designed by the foregoing plan, first, to encourage the organization and maintenance of local and State medical societies, and second, to make the National Association, primarily, a true representative organization, uniting and harmonizing the society organizations of the profession in all the States and Territories of our country.

The only other mode of obtaining membership, is by attending an annual meeting of the Association, and, through the endorsement and recommendation of the Committee of Arrangements, obtaining an election by *unanimous* vote of the Association. The number admitted in this manner, by unanimous vote, is very small.

COLLECTIVE INVESTIGATION OF DISEASE.—At the last meeting of the National Association, a communication was presented from the committee of the British Medical Association, inviting the coöperation of the American Association in instituting parallel lines of investigation in this country. The subject was more fully explained, and a sample of the memoranda and blank cards used by the committee of the British Association, in the seventh number of Vol. 1 of this journal, August 25, 1883, pp. 216, 217, 218. The communication presented at the last meeting was referred to the standing committee on "Meteorological Conditions of the Atmosphere, and their Relations to the Prevalence of Acute Diseases," with instructions to report at the next meeting of the Association. That committee consists of Drs. N. S. Davis, of Chicago; J. M. Toner, of Washington; H. O. Marcy, of Boston; W. H. Geddings, of Aiken, S. C.; S. M. Bemis, of New Orleans; and H. D. Didima, of Syracuse, N. Y. The chairman of the committee requests each member to communicate to him, as early as possible, such views as he may entertain in regard to the report which should be made to the Association at the meeting now near at hand.

THE MEETING OF THE ASSOCIATION AND RAILROADS.—The Committee of Arrangements at Washington are completing terms with all railroads entering Washington for reduced fare for members who wish to attend the next meeting. For particular information on the subject, apply to Dr. D. W. Prentiss, of Washington, D. C.

PARTIES who wish for space for the exhibition of drugs, chemicals, instruments, etc. etc., should apply to Dr. D. C. Patterson, 919 I street, Washington, D. C.

SOCIETY PROCEEDINGS.

SUFFOLK DISTRICT MEDICAL SOCIETY.

SECTION FOR CLINICAL MEDICINE, PATHOLOGY, AND HYGIENE. ALBERT N. BLODGETT, M.D., SECRETARY.

(*Concluded from last week.*)

Dr. Ayer also asked, "Is the milk injured by churning, or motion, in transportation? My impression has been that the carriage and disturbance were injurious."

The gentleman replied that the printed rules of the Milk Association, posted in the barn or on the premises of the farmer, require every milk can to be full up to the stopper, so as to prevent all churning. It is also required that the cow's bag shall be washed or brushed before milking. The milk should be cooled in another building from that in which the milking is done, and should be kept in the stall no longer than absolutely necessary after being drawn from the cow. The cars used for the transportation of milk are placed on regular passenger trucks, and ride as easy as passenger cars. The motion of the car does not affect the milk at all. The wagons used for delivering the milk after it arrives in Boston are made for that especial purpose, and are set on two springs, and have a peculiar rolling motion which does not shake the milk. With all the care which can be exercised, the milk is injured far more in being carried about for distribution in the milk wagons after it arrives in Boston than it is in being carried thirty, or even forty miles by rail. Even if delivered in the best possible condition, careless treatment after it is in the consumer's house will spoil it in half an hour. Often it is placed where the temperature is raised to 60° or 70° F., when it at once sours, and the consumer blames the milkman.

Dr. Barnes asked if it is possible to preserve milk in good condition for seventy-two hours? to which it was replied that this was perfectly possible. A certain lot of milk was on one occasion missent, and for nearly a week was lost. When recovered the milk was in perfectly good condition in every way. The firm which the speaker represents, not milk contractors but milk dealers, supplies the line of steamships plying between Boston and Norfolk, Va. These steamers always take milk from here the round trip, as no supply can be depended upon in Norfolk. On their arrival in Boston after the trip to Norfolk the milk which is left over is always found fresh and sweet.

Dr. Buckingham stated that the quality of milk is often materially affected by circumstances entirely independent of the age of the milk or its transportation. As a matter of fact the inside of milk cans is sometimes foul, and the corks sour. One way of preventing this would be the use of glass, as proposed by Dr. Morris. By this system, however, one would get the milk of only one cow in a glass, which would be objectionable. The expense of this course, which might be important, is a matter of which he knew nothing.

Condensed milk having been brought into the discussion, he thought that the Swiss condensed milk, the only one of which he has knowledge, contains a great deal too much sugar to be a fit food for babies or invalids.

In answer to a question about the opinion of the Society as to the value of one cow's milk for babies, Dr. Buckingham said that the theory in giving one cow's milk is to avoid variation in the quality of the food. Milk from one cow does, however, vary somewhat from day to day, and it is probable that the mixture of the milk of several cows will vary less than that of any one of them. This he knew to be the opinion of several members of the Society. It is also the view that is gaining ground in Germany.

Dr. Harlow asked how many of the farmers probably adulterated milk to any extent or in any way before sending it to the city.

In reply it was stated that such a thing was very rarely done. Probably not over two per cent. of the farmers attempt to tamper with milk in any way. It would be fatal to their interests to do so, as the milk from such dairies would not be accepted by the contractor nor allowed to go out. The principal adulterators are a set of dealers who supply milk for a minimum price, and in this way build up a large trade in order to sell out. A well established milk route has a considerable commercial value. Unscrupulous men often build up a business in this way, and then sell the route to other parties.

Dr. E. T. Eastman stated that housekeepers often accuse the milkman unjustly. In a case known to him the servant was in the habit of taking off a portion from the top of the can, and supplying the deficiency with water, and the housekeeper complained that the milkman was delivering adulterated milk. This source of deterioration in the milk supplied to families is often forgotten, and the milkman is charged with adulteration.

In reply to the question how the supply of *cream* is obtained which is sold for table use at an advanced price, it was stated that the surplus of each day's milk was passed through a machine called the "separator," which removes the cream and leaves a pure skimmed milk which is sold to bakers, to families for domestic use, and for feeding to pigs. Another method of obtaining cream is also regularly followed. Each day cans of milk fresh from the dairy are poured into large receivers which are surrounded with ice, and are left undisturbed for twenty-two hours. At the end of this time it is skimmed with a conical skimmer, and about ten per cent. of cream obtained, which is the average amount in good milk.

Dr. Edes asked how the milkmen are sure of the quality of milk which they supply to their customers.

The reply was made that the quality of the milk is examined each day, and sometimes a favorite dairy will be found unfit for use, and will be rejected, and a supply from some other source obtained in its place. Suspicion was recently aroused in respect to a dairy, and on "setting" the milk it was found to

yield only six per cent. of cream. The milk from a neighboring dairy was also "set," and yielded fifteen per cent. of cream. Consumers would hardly have been satisfied if this milk had been delivered to them in glass jars sealed in the country, though they could not then accuse the milkman of tampering with it. Often the milk from a reliable dairy will be found sour, and, of course, must be rejected, and used for butter. The quality of the milk also depends on the food of the cow. Brewers' grains are not considered an unhealthy nutriment for cows, but the milk is thin and white.

In reply to a question by Dr. White as to how many cows are represented in one can of milk, it was stated that rarely would one can contain the milk of more than two cows. The farmer milks the cows in succession, and as soon as each cow is milked the milk is strained into the cans, which are successively filled and at once placed in water to cool. After arriving in the city the milk is mixed, and is then drawn into the service cans for distribution.

Dr. Bundy said that he had witnessed the operation of "mixing," and had seen water added in considerable quantities previous to filling the service cans for families.

Dr. Davenport asked if the milkmen consider the required standard too high? The reply was made that the milkmen in general know nothing about the standard, and but little about milk regulations or milk laws, but studiously endeavor to avoid the penalties.

The statement has been made that the cream sold by milkmen was obtained from creameries, as it was impossible to obtain good cream from the tops of their cans. Mr. Abbott stated that in his earlier experience as a milkman he found no difficulty in getting a large share of the cream, the motion of the cars was so slight, and the sudden cooling with ice caused the cream to rise so that most of the cans have a heavy cream on them when reaching the city. Those that did not could be iced and kept over, as nearly every milkman carries a surplus.

Dr. Barnes stated that the Milk Inspector, in speaking of the arduous duties of his office, said that if the city would furnish him with a team he could accomplish much more. Mr. Abbott produced the Milk Inspector's report for the year ending March 21, 1883, showing that the number of visits made and samples inspected was 1,153, or, allowing 300 working days, would be less than four per day, which Mr. Abbott thought, with our system of horse cars and good sidewalks, would not be a very laborious work for an able-bodied man. Our Milk Inspector receives $1,800 per year, and has a clerk at $500, making $2,300; divide this by 1,153, and it will be seen that it costs the city of Boston nearly $2 apiece for every sample of milk inspected. To this must be added $140 for analysis in fourteen cases, as a result of which thirteen persons were prosecuted and twelve convicted. In looking further, we find that at that date 860 store-keepers or retail dealers have been licensed. Is it possible that only that number of store-keepers in Boston have heard that there is a milk law? Such being the case, it is not to be wondered that the milk-dealers speak with contempt of the Milk Inspector and his office.

Dr. Marcy remarked that we should not forget that in the plan for furnishing milk as described and practiced by Dr. Morris, all chances of contamination of the milk from dirty vessels, all manipulation by middlemen, and all abstraction by servants after the milk has been delivered is prevented. The most of the objections urged against milk as now supplied, would at once be removed There seems to be no good reason why a plan which can be carried on in Philadelphia to the satisfaction of the consumer, and at a fair profit to the projector, might not work equally well in Boston.

Dr. Blodgett remarked that a part of the responsibility for adulterated milk undoubtedly rests upon the people consuming it. Very few people in the city know how pure milk looks, and expect a rich yellow milk at all times of the year and under all circumstances. Cow's milk is not all yellow, nor is it always yellow. The farmers endeavor to secure cows which will yield large amounts of milk, but the color is often very pale. The farmer gets three and a quarter cents a quart for milk, and he tries to get the largest possible amount from the cows. A farmer cannot furnish Jersey milk for three and a quarter cents per quart. If people demand a quality in milk which does not belong to it there are no doubt many milkmen who are willing to furnish it of any desired color; and thus the consumer unconsciously encourages adulteration.

Dr. Blodgett further stated that he had made some attempts to ascertain the methods employed in the handling of milk, and that he had seen and heard much which was new and interesting to him, and was particularly struck by the courtesy and freedom with which he had invariably been allowed to make any investigations or pursue any inquiries he thought desirable. He thought that the members of the Section would be favorably impressed with the care and scrupulous attention to cleanliness which are observed in all the operations to which milk is subjected in transit and until it is delivered to the milkmen for distribution. Of course all this does not in any way prevent these persons from adulterating it before they deliver it. But there seems to be no systematic adulteration, as we have too often been led to suppose. A visit to the large milk depots is calculated to inspire a greater degree of confidence in the quality of the milk supply than exists at present in the minds of the majority of consumers.

Dr. H. I. Bowditch then presented the following resolution:

Resolved, That the chairman be requested to appoint a committee of five, whose duty shall be to report upon the whole subject of the providing of milk for Boston, and suggest the means for obtaining it pure for the citizens.

The resolution was unanimously passed, and in accordance with its requirements the following committee was appointed: Dr. H. O. Marcy, chairman, Dr. A. N. Blodgett, Dr. E. W. Cushing, Dr. H. J. Barnes, Mr. L. F. Abbott.

On motion of Dr. Blodgett, the thanks of the Sec-

tion were tendered to the members of the Milk Producers Association for the important information which they have placed at the disposal of the Section in regard to the source, treatment, and adulterations of the milk supplied to the citizens of Boston.

The second paper of the evening was entitled

THE MILK SUPPLY OF BOSTON, AND THE BENEFIT TO BE DERIVED FROM THE SPAYING OF COWS,

by Mr. Lloyd F. Abbott, a former milk producer and dealer. The paper was read by Dr. G. E. Mecuen, who described the process as follows:—

As regards the spaying of cows there is little danger if properly done, and the mortality should not exceed one per cent.

Operation. An incision is made in the flank of the cow, left side preferred, as being handier for the operator, about four inches long, through the skin, then the muscles and fascia are cut, and the peritonæum divided, using the finger as a director. The hand is then introduced and carried upwards and backwards until the uterus is reached, when, by following the horn outwards, we find the ovary, and remove it with the thumb-nail or écraseur; this can be held by the two last fingers of the hand, and search made for the other ovary, and when found removed in the same manner; when the arm and hand are withdrawn and the wound stitched by the interrupted suture passing through all tissues except the peritonæum. During the whole operation a 20 per cent. solution of carbolic acid is used with the steam atomizer, the hands and side of the animal being thoroughly washed in the same solution. The hair should be clipped from the flank before incision. The pain from the operation is slight, the cow struggling only during the cutting of the skin, which does not take more than two or three seconds, and again during the sewing at the end of the operation. The latter is the most difficult part of the whole operation, as cow-hide in its undressed condition is very tough. While the arm and hand are within the belly of the cow the animal really seems to enjoy it, acting as a dog does when one rubs his head.

The advantages from this operation are set forth in Mr. Abbott's paper, and I will merely call special attention to a few of the most important. First, the quantity at a milking is increased, and a great increase takes place in the yearly yield of a cow. As to the milk itself, its quality is improved, the fat and sugar are increased, and although I did not keep a record of the examination of specimens of milk from these spayed cows before and after the operations (examining only for my own information, not expecting to have occasion to refer to figures again), I think that, judging from the large number of milk analysis that have been made, I would be supported in claiming that where fat and sugar are increased casein is decreased. Now this milk will be of the same quality day after day, unless the cow has some acute disease, provided she is properly fed and attended to. If over-fed she is apt to fatten, and fall off in the quantity of milk, as a spayed cow, like any animal deprived of the reproductive organs, is quite easy to fatten, thus adding to her value as beef. By this operation all the danger of abortion, post-partum hæmorrage, accidents during heat, while with the bull, and calving are eliminated. The bad breeding and small cows may be made good milk-producers, and easily fattened for market. But I suppose the greatest advantage of all is the escape of the periodical change occurring in the milk of the unspayed cows every three or four weeks, and lasting a day or two.

Cows are extensively spayed in Texas when young, simply for the purpose of making good beef cattle, the butchers at Brighton abattoir being well aware of the fact. Before operating I visited the abattoir several times for the purpose of becoming acquainted with this anatomy of the cow, and an inquiry at the various slaughter-houses "if they were going to kill a cow" would receive the answer "yes." On the cow being opened I would find only a rudimentary uterus and no ovaries. After examining several I asked the butcher "where the ovaries were." He informed me that they had been removed when the animal was young, and showed me the scar in the hide. The way he had of finding it was that the tissues were all fused together, it requiring care to separate the hide, and the use of the knife, while only his hand was necessary in other parts. It seems to me that this is proof that the operation is a safe one, for the stock-raiser would not run the risk of losing young cattle just for the sake of increasing the weight of a few.

There are two facts which are of interest to us as physicians, namely, first, for two or three days after the operation the flow of milk is reduced to almost nothing. I suppose this is due to the congestion of the broad ligament and tubes. Second, in one case operated on, miscarriage followed ten days after the operation, the calf being macerated so that the hair and skin readily peeled off.

I was present at the spaying of five cows by a veterinary surgeon in which the operation was done through an incision in the posterior and lateral side of the vagina, the surgeon using a speculum to fix the uterus and distend the vagina, then cutting and introducing the hand with an écraseur, and having engaged the ovary, removing it and the other through the same opening, the result being left to nature. From the slight observation I have had as yet, I would favor the flank operation.

Dr. James R. Chadwick said: I was called upon by Mr. Abbott to operate for him in one of his early cases. I did not find that my previous experience with the human species was of any material aid in the operation upon cows. I can testify that the operation appeared to give the cow but little pain, and only during the incision through the integument and its subsequent suture. The cow seemed to be chiefly affected by alarm at having her head and legs securely bound with ropes, but this no more than equaled our fear lest she would break loose during the operation and strike out. I was surprised on making the incision through the flank to find all further progress apparently barred by one of the stomachs; the hand was, however, easily passed between this and the abdominal wall into the pelvis, where the two ovaries were successively seized and torn off by the thumb

nail. But slight hæmorrhage resulted. The only real difficulty of the operation was in perforating the hide with a needle to close the integumental incision. This is readily appreciated by considering the difficulty that would be experienced in trying to sew up a rent in a cowhide boot. Waring assured me last year that the effect of spaying cows had been of great benefit in promoting lactation, and that the mortality was no greater than five or six deaths in a thousand operations.

Dr. Gilbert, of Dorchester, who has also witnessed the operation, said that the cow seemed to suffer no great pain, excepting when the outside skin was being cut, and when the stitches were inserted, at the close of the operation. The risk and discomfort of ether are much greater than the pain of the operation.

Dr. Mecuen stated that one cow from which the ovaries were removed has produced milk continuously for eleven years, and in this entire period has fallen off only three pints. Dr. Brush claims that the amount of milk will remain the same during the life of the animal. The carbolic spray was employed in all cases except the first one. On opening the peritonæum the air rushes into the abdominal cavity, but seems to produce no injurious effects. Both ovaries are removed at once. No dressing other than some substance to protect from flies, etc., is necessary, and the wound is entirely healed by first intention in about a week. The animal should be kept on low diet for a day or two, but in three or four days is allowed to run in the pasture as usual. In one case the cow was five months pregnant. The operation produced a miscarriage at the end of ten days. The fruit was macerated. After spaying, the only condition which will cause the quantity or quality of the milk to undergo variation, is sickness of the animal.

Dr. E. W. Cushing stated that there is always an infant in his house. He has used the milk from a spayed cow for more than a year, and finds it to be a good product and of uniform quality. New milk (after calving) is not good for children, and the milk during menstruation is not wholesome for an infant. Cows and women are much alike in this respect. The milk taken from a pregnant cow is unwholesome for a delicate person, and no mother thinks of nursing her child after she has again become with child. Milk as we obtain it is often neither natural nor healthy, for no animal in a natural condition gives milk while she is carrying her young.

On motion of Dr. Marcy, a vote of thanks was tendered Mr. Abbott for his description of a safe operation, whereby the quality of milk supply may be materially improved and its quantity rendered constant for many years.

Adjourned at 11 o'clock.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting, Thursday, April 3, 1884. The President, R. A. Cleemann, M.D., in the chair. Dr. Cleemann made some remarks on the subject of

DIGITAL DILATATION OF THE OS UTERI DURING LABOR.

He had been taught not to dilate or stretch the os uteri with the finger, and for years this early teaching deterred him from making any attempt to supplement the contractile powers of the uterus by assisting in the process of dilating the os. Some time since he was called to attend a primipara. The waters had been discharged the previous day. The pains had continued, but the os uteri was very small and the cervical rim hard and unyielding. He felt called upon to interfere actively, and tried to dilate the os with his finger. It softened rapidly, and in half an hour was sufficiently dilated to allow the head to pass, and delivery rapidly followed. Since that occasion he has tried the same procedure in several cases, and always with gratifying results, the labors being brought to rapid terminations where previously hours had been wasted in weary and painful waiting.

The irritable condition of the os which had been lectured upon as the consequence of such interference has not been experienced; no injury has resulted in any case. The soft finger can do no more harm, if clean, than a Barnes' or other form of dilator, and there is no danger, as in the case of the latter, of pushing the head aside and converting a vertex into a shoulder or other faulty presentation.

Dr. W. T. Taylor, since he had dared to deviate from the teaching of Professor Hodge, had used his finger to assist the dilatation of the os. He did not do so if the cervix was irritable or its edge wiry.

Dr. Githens had practiced digital dilatation of the os uteri throughout his obstetrical practice, a period of eighteen years. He does not confine it to any class of cases, nor does he wait until after the membranes are ruptured. In any or all cases he finds that a "pain" is accompanied by a contraction of the circular muscular fibers of the cervix, as well as by a contraction of the longitudinal fibers of the body of the uterus. The contraction of the circular fibers retards the progress of the labor. The intention of the digital distension is to paralyze these circular fibers and thus favor the dilatation of the os. In practice this effect is rapidly produced. One or two fingers are swept around the inside of the cervix, the pulp of the finger being next the cervix, and the latter is pulled away from the head. This operation is kept up during the interval between pains; when the pain occurs the finger is withdrawn, and the operation is repeated in the next interval. The membranes are not ruptured by this process. The irritable condition of the os, if such exists, is subdued. If the rim of the cervix is wiry and thin, or hard and thick, it softens and yields. The cervix and vagina, if hot and unyielding, at first become cool and pliant; cervical tears are almost entirely avoided, and the time, pain and exhaustion of the labor are reduced to a minimum. The process is useful in every case of labor throughout the first stage.

Dr. Philip M. Schiedt practices digital dilatation largely. His patients say they recognize the assistance it gives them, and in subsequent labors ask the

doctor to help them. By the great shortening of the first stage of labor resulting from this method the use of the forceps is frequently avoided.

Dr. Parvin would be sorry to see digital dilatation adopted as a rule for all cases. He thinks it shortens labor by increasing the uterine contractions, and not by dilating the os. Voluntary efforts at bearing down are not needed during the first stage; they are dangerous rather than helpful. The method may be useful in some cases after the rupture of the membranes, which is the natural dilating agent. There is also danger of septicæmia from germs on the fingers. He does not think the fingers so good a dilator as Barnes' dilator, because they do not press equally on all sides of the os, but only on one point at a time, and thus cause an unequal thinning with danger of laceration. He thought the danger of a change of presentation by the use of Barnes' dilator very slight. He would prefer a mechanical dilator to the finger whenever dilatation was necessary, but thought something ought to be left to nature. Any sort of interference carries a possibility of danger.

Dr. Elliott Richardson thought there was a possible danger of rupturing the membranes. Our authorities caution us about the introduction of the finger into the uterus, and the too early rupture of the membranes.

Dr. Harris remarked that one point had been overlooked. Why does the os not dilate easily when the head is the dilating agent? It is because it is a round surface over which the cervix does not slide easily. On the contrary, the finger is applied at successive points. One benefit of the method is that any change or danger is at once detected. The method should not be used indiscriminately, and we should not interfere unnecessarily.

Dr. Cleemann would not recommend the method in every case of labor. He has resorted to it in cases where there has been early rupture of the membranes, and the assistance of the bag of waters has been lost. In a recent case he had saved a patient hours of suffering, and the os was not bruised or injured in any way. The sight of any instrument causes the patient much anxiety, and the exhibition of the Barnes dilator, and the water, syringe, etc., cause nervous excitement. The bags sometimes burst, and thus give the patient a terrible shock, with the added discomfort of the escaping water or air. He has always carried them, but does not like to use them.

EXANTHEMATOUS DISORDERS IN THE PUERPERAL STATE.

Dr. Parvin had recently an experience of the invasion of measles and scarlet fever in the obstetric ward of the Philadelphia Hospital. In the first case in which measles occurred, he did not think that the full term of pregnancy had been reached. Authorities state that premature labor is usually caused, a result of the high temperature of the exanthematous fever. One patient had septicæmia in addition, but recovered. The infants were not affected. In one case, soon after labor, the temperature rose to 103°, and the patient was sent to the fever ward. At the second visit a slight rash was observed, which subsequently proved to be scarlatina. Desquamation was very abundant; albuminuria was very marked on the tenth day; rheumatic pains were also felt. The patient recovered. The child remained well. Children have been born with the measles, but he did not know of such an experience with scarlet fever.

Dr. W. T. Taylor, some 15 or 20 years ago, had reported in *American Journal Medical Sciences*, 1853, a case of congenital small-pox. The mother had some febrile symptoms and pain in the back, and the child had the disease, being marked with pits. He had a case of scarlet fever in a mother two days after labor. It proved fatal in two days. The child lived.

Dr. Harris remarked that in the reports of the Rotunda Maternity Hospital, in Dublin, are a number of interesting reports on complications of the puerperal period by exanthematous fevers. Their mortality has been very materially influenced by these epidemics. Erysipelas is the most interesting and most fatal of these complications. In some cases it resembles septic poisoning.

W. H. H. Githens,
Secretary.

FOREIGN CORRESPONDENCE.

London, March, 1884.

Some of your readers who have been present at the annual meetings of the British Medical Association, may have noticed Dr. Price, of South Wales, who considers himself the nineteenth century representative of the ancient Druids; he always dressed in green trousers and a sort of white smock coat, with a fox's skin by way of head covering. It appears cremation was the Druidical means of disposing of the dead. Some weeks ago the neighborhood of Dr. Price's residence was startled one evening by the reflection of a fire on a hill-top near. Upon closer investigation it appeared the doctor was engaged burning the body of his child in a cask of petroleum. After a scene of excitement the charred remains were rescued, and eventually the exponent of Druidism was arraigned before Lord Justice Stephen at the winter assizes at Cardiff. His lordship, after discussing at length the disposal of dead in ancient Europe, ruled that there was no law, old or modern, that rendered the burning of a body illegal, provided it be done in such a manner as to cause no nuisance. The ruling in this case will, no doubt, give impetus to those who are advocates of cremation in this island.

In the last report sent by the German cholera commission, who have gone from Egypt to Calcutta, it is stated Dr. Koch has really discovered a special cholera bacillus, and that he found the water supplied to some patients was teeming with bacilli identical with those found in cholera subjects. Professor Cohn, writing to one of our journals from Breslau, calls attention to the circumstance that just 200 years ago

there was made in the Netherlands a scientific discovery of the greatest importance. In the year 1683 Leeuwenhoek gave notice to our Royal Society that by the aid of his microscope he had detected in the white substance adhering to his teeth "very little animals moving in a very lively fashion." These, says Professor Cohn, were the first bacteria which the human eye ever saw. The descriptions and drawings given by this first observer are so correct, that the organisms drawn by the hand of Leeuwenhoek can be easily recognized and compared with their fellows of to-day.

Mr. Lennox Brown, F. R. C. S., has been investigating the latest idea of the "artificial Italian air" which was mentioned in a former letter. In an able paper read before the society for the encouragement of the fine arts, he declared that peroxide of hydrogen had not been shown to be beneficial; while of the two ingredients with which it was mixed, ammonia was a most poisonous gas, and peppermint was useless. Mr. Brown earnestly advised those who were vocalists not to try the idea with a view of strengthening and improving their voices until more was known of its merits. A statement has just been published showing the deaths which occurred from the use of anæsthetics in surgical operations during last year in the United Kingdom. Only nine are reported to have occurred from this cause in 1883, the number in 1882 having been twenty-eight, and in 1881 fifteen. In many of these cases the fatal result may fairly be considered to be due not to the anæsthetic, but to the operation. In Leeds chloroform was used in over nine thousand cases without a single mischance. With regard to nitrous oxide, it may be said that the risk from it was almost *nil*, for a series of more than twenty thousand operations are recorded in which there was not a single untoward result. One death was caused by it in the Dental Hospital, Leicester Square, in a case where the patient had a serious complication of diseases. It is however, to be feared that the growing practice, especially among dentists, of administering it single handed, will be productive of mischief. It is suggested that the theory and practice of anæsthetics should be more thoroughly taught in our medical schools, and that as a special certificate is given by an expert to qualify a medical practitioner for performing the very simple operation of vaccination, it might be as well to apply at least an equal test to the student's knowledge of sending his patient into a state of insensibility.

A deputation of medical men have just waited upon the Bradford School Board and presented a memorial signed by most of the doctors of the town, praying the board to dispense with "home lessons" so far as regards children under ten years of age. Dr. Rabaglish said that the returns of the Register-General showed the extraordinary fact that since the Compulsory Education Act came into force, the deaths from cerebral effusion amongst children of school age had increased by 20 per cent., and from inflammation of the brain by 50 per cent.

At the Cambridge Medical Society a case was shown of division of the median and ulnar nerves treated by sutures. The wound, which was rather lacerated, divided the ulnar artery, the superficial flexor tendons, and the ulnar and median nerves—the former was tied; the nerves were sutured with fine catgut. On the fourth day after the operation sensation returned in the parts supplied by the injured nerves, and though the wound did badly, and there was both great constitutional disturbance and diffuse cellular inflammation of the fore-arm, yet the union of the nerves never seemed to be disturbed. The patient was produced, and it was seen there was some wasting of the muscles of the thumb, and contraction of the fingers, but that sensation was perfect. The patient could tell which finger was touched, and what part of it. The only inconvenience he experienced was a curious sensation of numbness in parts supplied by median nerve, which was most apparent in cold weather, and on one occasion he suffered from a bullous eruption on the index finger, having incautiously exposed it to the cold.

The London Medical Society had an interesting paper read by Dr. W. H. Corfield upon the diseases resulting from the pollution of the air through defective house sanitation. He considered the fault was more frequently due to dishonest workmanship than faulty design. The chief sources of danger were the common ones of direct communication with the main drain. He mentioned cases where foul air had been conducted from the basement all over a house by means of the bell wires. Enteric fever he looked upon as usually caused by drinking foul water, rarely by inhaling foul air. Diphtheria, however, was caused most frequently by breathing foul air. G. O. M.

SPECIAL NOTICES.

TO THE MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION WHO LIMIT THEIR PRACTICE TO DISEASES OF THE EYE, EAR AND THROAT:

The Secretary of the Section of Ophthalmology, Otology and Laryngology desires to say that owing to a misunderstanding of his duties, no invitations have been sent to any member of the profession to prepare papers for the coming meeting of the Association on the above-named diseases.

He now most earnestly solicits voluntary productions and hopes that all who see this notice, and have the success of this Section at heart will consider themselves personally appealed to. It may possibly be urged that the time is too short. On the contrary it is ample. Please send in the titles of papers now, and write up the subjects afterwards. If the gentlemen to whom this is addressed will kindly take the matter in hand one of the most successful meetings ever experienced will be the result. Prolixity (the bane of nearly all medical societies) will necessarily be avoided, and instead of fancying ourselves in the halls of Somnus, we shall be actively engaged in the elysian realms of the most delightful discussions known to the profession since the foundation of this Association.

Do send in the titles of papers, we beg of you, and make this seeming defeat (caused by your secretary's misunderstanding) a glorious victory. No one, or two, or three dozen are invited to the exclusion of others, but all. Let it not be a failure.

Please send the titles to Dr. J. L. Thompson, 22 W. Ohio street, Indianapolis, or to Dr. D. W. Prentiss, Washington, D. C.

J. L. THOMPSON,
Indianapolis.

THE ASSOCIATION OF AMERICAN MEDICAL EDITORS. ANNUAL MEETING, WASHINGTON, D. C., MAY 5, 1884.

The annual meeting of the Association of American Medical Editors will be held in Washington, May 5, at 8 P. M., in Medical Hall, southeast corner of Sixth and F streets.

The annual address will be delivered by President Leartus Connor, M.D., on "The American Medical Journal of the Future, as Indicated by the History of American Medical Journals in the Past."

Dr. N. S. Davis will open the discussion on "How far can Legislation Aid in Elevating the Standard of Medical Education in this Country?" In which Dr. A. B. Palmer, Dr. Henry O. Marcy, Dr. L. S. McMurtry, Dr. C. H. Hughes, Dr. Frank Woodbury, Dr. William Brodie, Dr. A. N. Bell, Dr. Wm. B. Atkinson, Dr. W. C. Wile, Dr. W. R. D. Blackwood, Dr. Henry Leffmann and Dr. Deering J. Roberts will take part.

All members of the profession, especially journalists and authors, are invited to be present and take part in the meeting.

JOHN V. SHOEMAKER, Secretary.
Philadelphia, 1031 Walnut street.

STATE MEDICAL SOCIETY OF ARKANSAS.

DEAR DOCTOR:

The ninth annual session will be held at Little Rock, on Wednesday, April 30, Thursday, May 1, and Friday, May 2, 1884, commencing at 10 A. M. on Wednesday.

You are earnestly urged to be present and to induce others to join with us in the work of advancing legitimate medicine.

Each county or municipal society shall be entitled to one delegate for every five members, and one for a fraction over five.

"The several committees shall report annually, through their Chairman, respectively, upon the specific subjects to which they have been appointed. It shall be the duty of each committee to make a full and complete report to the society of all matters, business, etc., that properly comes before or presents itself to them upon each particular branch or section." Art. IX., Sec. 2, Constitution.

L. P. GIBSON, M.D., Secretary.
Little Rock, March 20, 1884.

POLITZER treats aural polypi by instilling alcohol several times daily. It must be warm, and shrinking occurs in a few weeks.—*Wiener Med. Blatter.*

MISCELLANEOUS.

LIST OF CHANGES IN THE MEDICAL CORPS OF THE NAVY, DURING THE WEEK ENDING APRIL 5, 1884.

Medical Director P. S. Wales, granted one year's leave of absence from March 28, with permission to leave United States.

Medical Inspector N. L. Bates, ordered to Washington to attend sick officers.

Medical Inspector M. Bradley, ordered to continue duty at League Island Navy Yard.

Assistant Surgeon H. W. Whitaker, ordered to naval rendezvous at Philadelphia, Pa.

Surgeon-General F. M. Gunnell, appointed Chief of Bureau of Medicine and Surgery and Surgeon-General of the Navy, with the relative rank of Commodore, from March 27.

P. A. Surgeon C. W. Rush, ordered to Naval Academy.

Surgeon D. McMurtrie, detached from naval rendezvous, Philadelphia, and to await orders for duty at Navy Yard, Washington, D. C.

Medical Inspector H. C. Nelson, ordered before Retiring Board.

Medical Inspector A. C Gorgas, to be Medical Director from the 4th March, on the active list.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT UNITED STATES ARMY, FROM MARCH 29, 1884, TO APRIL 4, 1884.

Mearns, Edgar A., First Lieutenant and Assistant Surgeon, assigned to duty at Fort Verde, A. T. (Par. 1, S. O. 22, Headquarters Department of Arizona, March 19, 1884.)

White, Robert H., Captain and Assistant Surgeon, to be relieved from duty at U. S. Military Academy, West Point, N. Y., Aug. 28, 1884. (Par. 7, S. O. 74, A. G. O., March 31, 1884.)

Woodhull, Alfred A., Major and Surgeon, granted leave of absence for twenty-two days, to take effect about April 6, 1884. (Par. 13, S. O. 72, A. G. O., March 28, 1884.)

HYDRONEPHROSIS.

AN ESSAY BASED UPON THE COMPARATIVE STUDY OF SEVENTY-ONE CASES OF THAT LESION, OF WHICH ONE CASE CAME UNDER THE PERSONAL OBSERVATION OF THE WRITER.

BY GEO. A. STAPLES, DUBUQUE, IOWA, A.B., M.D.

(*Continued from last week.*)

In the opinion of Prof. Simon[1] the methods for obliteration of the cyst have not yet arrived at a satisfactory value in surgery; though, rightly performed they might work wonders; the reason being that only those tumors are adapted for obliteration whose walls are somewhat shrunken and whose contents could be gradually dried up. This state of things exists in some unilocular ovarian cysts, but exists rarely. These methods may be grouped into two divisions: first, the cyst is to be emptied, air being carefully excluded; second, air being admitted and suppuration induced, it is to be carefully drained.

Examples of the first variety are puncture without leaving in a canula, and puncture followed by the injection of a medicated fluid, such as iodine. By the former plan the vessels that course in the shrunken walls are intended to be so compressed as to abolish their function. By the latter a moderate inflammation, not leading to suppuration, but only so far as to destroy the secreting activity of the cyst or create adhesions, is aimed at.

The single puncture, effected by means of a small trocar or Dieulafoy aspirator, is the least dangerous procedure and only by frequent repetition excites inflammation. Prof. Czerny declares that it is "absolutely void of danger." M. Lecorché[2] advises that the puncture be made anteriorly, in the eleventh intercostal space, carefully avoiding injury to the peritoneum or intestine.

Dr. Cabot[3] advocates in hydronephrosis of recent origin, especially when dependent on traumatic causes, that aspiration or lumbar incision be practiced, asserting that the relief from pressure will allow the ureter to recover its caliber, and, if fever and other unpleasant symptoms do not follow, that the operation be repeated a number of times, one case of recovery after eight aspirations being reported. Regularly, however, relapses demanding more decisive measures are to be expected.

In the second of the three tables collated by the writer are shown seventeen cases treated by this general method of puncture. Of these seventeen cases eleven died, in three instances temporary relief was obtained, and in three a cure was effected. One[1] of the cases in which relief was obtained through aspiration and adjuvant treatment was observed by the writer, and as it presents some unique points of interest, is related in full.

Mrs. M., of German descent and aged forty years, first consulted Dr. G. M. Staples, of Dubuque, Iowa, on May 17, 1881. She was of strong build, free from any œdema, even somewhat thin, and in early life had been a clerk in a store, but had married happily, borne five children, and now lives in comfortable circumstances. Her family history as to health was good.

In 1861, when about twenty years of age, she first began to experience a feeling of uneasiness in the left latero-lumbar region, suffering in addition from a "heavy feeling of sleepiness," with a sense of expansion in the left hypochondrium. As the expansion increased there were added nausea and vomiting, with intense pain, and a fluctuating tumor was soon discernible. The patient was thus first attacked at a ball, after dancing once or twice, and had to be taken home, supposing she had caught a severe cold. Since that time these spells came on with tolerable regularity every two to four weeks, but had no connection with the menses, which were perfectly regular.

The patient when first seen was laboring under an unusually severe attack that was complicated by new and alarming signs of prostration, the pain being very acute, though unaccompanied by rigors. It was chiefly located in the left loin, where it was most severe, but it also radiated toward the left groin and rendered flexing of the thighs painful. The patient stated that these spells lasted generally thirty-six to forty-eight hours and obliged her to go to bed and have fomentations applied, that the attacks were characterized by an almost perfect periodicity, the longest interval ever experienced of freedom from them being seven, the shortest about two weeks.

Although never troubled by colic or other renal difficulty, exposure of any kind or a strong emotion is capable of bringing on a spell, and a tumor, tender

[1] Case XLIX.

on pressure, is soon felt, the more severe symptoms supervening later.

The attack may subside gradually, but oftener it ceases suddenly, and, in either event, relief is coincident with the passage of an increased quantity of urine, giving rise, to use her own words, to the "sensation of something giving way," and marking the disappearance of the tumor. The urine evacuated is of a light color, but on the next day becomes darker and has rarely contained a brick-dust sediment. There has never been hæmaturia, nor has the urine ever contained pus. The affection has always been unilateral.

The affection had been diagnosed by various physicians in St. Paul, St. Louis and Dubuque as tumor of the spleen, phantom tumor, etc. No therapy advised had been of service. Dr. Staples diagnosed hydronephrosis, but his opinion was not sustained by any other surgeon consulted.

On Oct. 28, 1881, Dr. Staples was again called to see the patient, who was suffering from a protracted and unusually severe attack that had already lasted eight days. The same diagnosis was made and aspiration advised. Consent was given after eleven days of suffering, and, on Nov. 1, a No. 2 needle of Codman and Shurtleff's aspirator was thrust into the tumor at the upper part of the left lumbar region, and forty-four ounces of a clear amber-colored fluid, that had the odor and characteristics of urine, were drawn off.

On examination of the fluid it was found to possess a specific gravity of 1010 and a faint alkaline reaction. Fehling's test did not reveal sugar, nor was albumen detected. After concentration of a small portion of the fluid and the addition of nitric acid a few crystals of nitrate of urea were deposited.

The patient was again aspirated on April 20, 1882, and thirty-nine ounces evacuated; and a third time on July 17, 1882, when thirty-seven ounces were obtained. In the former instance the tumor had existed eight and in the latter seven days. On each occasion the patient was about the next day.

In the operation the needle was pushed upward and inward from three and a half to four inches. As the cyst grew smaller its wall, which was quite tough, as the flow of the fluid ceased, was felt to slip away from the instrument with a contractile sensation.

It is proper to add that the increased flow of urine after a "spell" had not been noticed until Dr. Staples called attention to the fact by his inquiries.

About the middle of October, 1882, another protracted attack came on, and the use of the aspirator was urged. Cataplasms of stramonium leaves were ordered instead, and relieved her in a few hours. A like result has attended their use since, and it is hoped that a remedy to take the place of aspiration has now been found. The patient has learned to employ the hypodermic syringe when the pain is unbearable.

Later therapy has consisted in the use of antiperiodics and diuretics, the exhibition of iodide of potassium and extract of stramonium in the intervals between the attacks with the result of much lessening their frequency and abating their severity.

*The etiology of this case is doubtful. It is not believed, however, that the cause is to be ascribed to calculi or any mechanical obstruction, as the most careful and repeated examinations of the urine have failed to show any evidence of stone, and there never has been any renal colic.

The hypothesis is advanced that the true cause is a nervous irritability of the ureter, producing a stricture near the ostium pelvicum. Regularly the ureter would relax when the fluid in the pelvis increases, so as to produce great pressure from above, and, at the time when aspiration was necessary, it is also believed that an invagination or intussusception of the ureter had taken place.

This hypothesis is stated with diffidence, as no author seen by the writer, in treating of the ætiology of hydronephrosis, has mentioned it, but it is not difficult to imagine that, as the tumor, by reason of a protracted spasm, extended downward as well as laterally, the ureter must either double in upon itself or yield in some manner, thereby making a permanent or fatal trouble were the cyst not emptied artificially.

In support of this theory, it may be mentioned that analogous strictures have been observed in retention of urine from spasmodic contraction of the muscular fibers of the sphincter vesicæ, in asthma from spasm of the bronchial muscles, and in spasmodic stricture of the urethra. It is also known[1] that where a moderate urethral stricture or an enlarged prostate exists there may be ordinarily a sufficiently free passage for the urine, but occasionally the bladder becomes overdistended, and complete retention is the result. In such cases the urethra again becomes permeable when by aspiration or puncture the urine is drawn off and the pressure relieved.

The writer has been unable to find accounts of cases bearing close analogy to the above. Dr. W. West,[2] however, has recorded a case in an unmarried woman where there were attacks of acute pain from this cause more or less synchronous with the menses, and in addition a very much disturbed menstrual function and leucorrhœa.

The above case would seem to bear out the opinion of Prof. Czerny that "the single puncture with the Dieulafoy aspirator, under antiseptic measures, is absolutely void of danger." Indeed, the belief that puncture was dangerous was formed at a time when antiseptic methods had not been perfected. The results, as shown by the table, are certainly such as would warrant a persevering trial of a comparatively innocent therapeutic measure, the facts being that in 17 per cent. of the cases tried it was competent to effect a cure, and in 35 per cent. to effect decided improvement.

The injection of medicated fluids, as iodine, has proved futile and is dangerous, for if any of the fluid pass into the abdominal cavity, diffuse peritonitis will result, and even with the greatest care there is much

* Since the preparation of this paper Mrs. M. was aspirated for the fourth time by Dr. Staples, assisted by Dr. Parke W. Hewins, and 55 ounces of fluid drawn off. The patient had over-exerted herself, neglected to employ any therapeutic measures, and, when seen, was largely distended in her left latero-lumbar region. Up to that time her general health had continued good, with little trouble from the kidney; since the last operation she has been perfectly well.

[2] W. West, *Amer. Med. Weekly*, Nov. 14, 1882.

probability that it will induce suppurative inflammation in the sac. In no case on record has this treatment been successful.[1]

The second general method of surgically treating hydronephrosis is by nephrotomy and open treatment of the wound. As the cyst is daily syringed out, its walls through shrinkage and formation of granulations become converted into cicatricial tissue. This method is applicable to all cysts, no matter what may be the state of their contents or walls. The symptoms accompanying the operation are often at first alarming, but with proper care not very dangerous. As suppuration happens considerable fever, with a pulse of 110 to 120 beats, and rigors supervene. These abate, however, in a few days if there is made a free exit for the pus, the latter quickly taking on an innocent character. Complete obliteration usually occurs in from two to five months. Dr. Tuckwell remarks that a gradual puckering of the skin at the seat of incision is to be looked for as a favorable sign, marking the gradual contraction of the sac.[2]

In general, the measures by which obliteration may be accomplished by open treatment are three in number: (a) puncture with a large trocar and leaving in of the canula, (b) thorough cauterization of the abdominal and cyst walls, and (c) incision into the cyst with or without drainage. In operating by the first and oldest measure, the trocar will be thrust in at the most prominent portion of the tumor through the anterior abdominal wall. The peritonæum is but slightly lacerated and there is little danger of peritonitis, the canula that is left behind prevents the opening of the peritoneal cavity to septic influences.

The great drawback is that even with the assistance of a long elastic catheter or a double sound and syringe, the pus can hardly be emptied satisfactorily. Unsuccessful attempts to widen the opening with laminaria have been made, but it soon narrows again.[3] The pus then stagnates, with great danger of pyæmia or septicæmia. In calculous hydronephrosis this event is especially to be looked for. This measure has been tried three times, with two deaths[4] and one recovery,[5] the favorable result being independent of the operation, as the ureter again became permeable after the spontaneous discharge of two stones. In both fatal cases the cysts could not be destroyed, although in the first more than one and in the second two years were consumed in treatment.

Cauterization (b) of the abdominal and cyst walls to create adhesions and avoid opening into the peritoneal cavity has been employed four times,[6] and in all the opening was made by trocar. In one case fatal peritonitis supervened, in the others, in spite of daily drainage and injections, acute or chronic septicæmia was the cause of death.

The third procedure (c) is by an incision through the abdominal and cyst walls; this may be done either by opening directly into the peritoneal cavity, or after adhesions have been created between the parietes of the cyst and abdomen, the tumor may be incised without exposing the peritonal cavity. In some hydronephroses this incision could be made outside of the peritoneum.

The method first mentioned is the older and more dangerous of the two.[1] After laparotomy the cut edges of the cyst and abdominal wounds are to be stitched together, or the cyst before being opened is to be stitched to the wound in the integument. It is obvious that in the use of this method there is great liability to diffuse peritonitis. The results of this plan, however, are good, but are so made probably by the antiseptic precautions adopted. There are on record at least four cases[2] in which this method was employed on the lumbar side all of which were cured, and two instances of abdominal nephrotomy, one[3] of which died, and one[4] recovered. To these might be added the case of Dr. Wölfler's,[5] in which I cannot find the seat of incision, that resulted in a cure.

Prof. Simon regards incision after adhesions have been artificially induced as less dangerous. Recamier and his followers used caustics to create these adhesions; but many years ago Prof. Simon substituted the double puncture with two exploratory trocars; these are pressed through the integument at a distance of ¾ cm. from each other, and the canulæ left *in situ* after withdrawal of the stylets; later, for larger incisions he increased the number of trocars to four, making the double puncture a "mehrfache Punktion." After being thrust in the canulæ are stopped with wax and protected by charpie and plaster. Adhesions form, as Prof. Simon has proved, in twelve to fourteen hours, and for a radius about each canula of 2—3 cm., and are complete in from three to seven days, after which time the incision is to be made. To prevent any possible slipping away of the cyst from the canulæ they shonld be curved and describe a half circle with a radius of from 4 to 7 cm.

This operation can be performed from three different sides; if from behind (incisio renis lumbalis) the peritoneum is never injured; if from the side (incisio renis lateralis) it is rarely cut; if made in front (incisio renis anterior) it will always be cut. The objections to the incisio renis lumbalis are that the soft parts are here the thickest, that the room for incision is scanty, and that to reach the tumor the posterior portion of the kidney must be incised, a proceeding that causes profuse hæmorrhage. By the incisio renis anterior not only the peritonæum but the colon may be injured. Prof. Simon, therefore, prefers the incisio renis lateralis; from this side the renal substance is not likely to be wounded, the integument is little thicker than in front, and an opening can be made to the bottom of the cyst, giving free exit to any pus that might form. In an incision so made two fingers can be thrust to search the interior for renal calyces, calculi, etc. If there is needed a larger outlet the cyst and abdominal walls are to be first stitched together with a long curved needle.

The after-treatment consists in daily washing out the tumor with luke-warm carbolized water and drainage. The bandage should be changed frequently.

[1] Although Prof Czerny, (loc. cit.) says that "in single cysts the injection of iodine into the emptied sac may many times accomplish a lasting cure," I can find no such cure on record. See, however, case LIX.

[1] Simon loc. cit., p. 230.
[2] Cases, lxii, lxviii, lxviii, lxv. [3] Case i. [4] lxi. [5] lix.

Prof. Simon performed the "mehrfache Punktion" eleven times for abdominal tumors, in all of which adhesions were successfully induced. This operation has been performed for hydronephrosis at least three times. In one[1] of the cases death from peritonitis resulted in 22 days, in the other two,[2] cures with fistulæ remaining were effected.

The above plan of treatment is certainly on the Continent regarded with much favor. The opinion of Dr. Ultzmann[3] is that of all modes known to surgery for the relief of hydronephrosis incision of the tumor, when done by Simon's method, is the most advantageous.

A modification of the above method consists in the re-creation of the permeability of the ureter or in the creation of a renal fistula. The clogged ureter may be made pervious either from the vesical or pelvic end; the most natural plan is to sound the ureter from its vesical mouth. In the male this is very difficult; in women, when anæsthetized, after widening the urethra and introducing the finger into the bladder, the mouths of the ureters can be easily touched. If the sound be now directed to the so-called ligamentum inter-uretericum from the middle and then pushed a little outwards, forwards and upwards, it will pass into the ureter and can be thrust to the pelvis renalis. This was done successfully 17 times by Prof. Simon.[4] If stones be present they can thus be forced back, strictures can be made pervious, and valvular stenoses widened.

Rarely can the ureter be sounded from the pelvic end, even with the tumor well incised. In a case, although aided by the endoscopic apparatus and magnesium light, and with his whole hand exploring the sac, Prof. Simon could not accomplish his object.[5]

These procedures failing, for the safety of the patient an external fistula may be made. By this means an infirmity remains, but danger to life is averted. The secretion is usually so scanty as not to be very burdensome, much of the secreting renal substance having regularly disappeared.

It is recommended that a lip-shaped fistula, with the skin adherent to the mucous membranes of the pelvis to prevent closing be made, and that the opening be on a side where the integument is not too thick. In 1870 Prof. Simon thus operated on a man, who, with a daily discharge of 150 ctm. of fluid from the fistula, now works as an efficient nurse in the surgical clinic at Heidelberg.[6]

In the opinion of Dr. Israel[7], the creation of a pelvic fistula is only indicated and possible where the pelvis renalis is greatly distended, but in cases where the calyces are the seat of large pockets, and the kidney thus is changed into a multilocular cystic tumor nothing could be expected from an incision into its substance.

There have been at least eight[1] cases operated on in this manner, all of which resulted in cure, and in most, if not all, the instances cited the cyst as appears from the daily diminution of the discharge, seems to be gradually drying up.

It adds much to the comfort of these patients to attach to the fistula a tube expanded below into a light rubber bag, and secured about the abdomen by a belt, for the purpose of catching the discharge. This apparatus, as Dr. Schramm remarks, can be worn without special discomfort. A most interesting letter from Prof. Pernice, of Greifswald, describing his case, the writer is unable, owing to the already great length of this essay, to insert, but some points described are certainly too important to be omitted.

The patient was an unmarried woman, 23 years of age, in whom the diagnosis of ovarian cyst with very long pedicle had been made, and for which an operation on the 28th of October, 1878, was essayed.

The description of the operation is given literally:

As soon as laparotomy was performed severe vomiting from the chloroform began: after the tumor was freely exposed it appeared to be covered on all sides with peritonæum, and gave the impression (Eindrück) to one as if a cyst of the broad ligament. It was then enucleated for a small space to the right and left, and punctured by the large trocar of Spencer Wells, and a perfectly clear, yellow fluid evacuated.

As the enucleation was proceeded with, it was quite easily accomplished on the left side by grasping the cyst-wall with the forceps, and by tearing away the peritoneal covering with the hand. At the lower part everything went well; the uterus and the left ovary could be obscurely felt in their proper relations. The enucleation was next continued on the right side, where difficulties presented themselves; after the cyst was scratched loose for about 4.5 cm. there appeared on the right wall a hard, glandular, polished organ that could only be a part of the liver pushed forward, or a portion of the kidney. Farther work on this side outside the tumor was impossible, since by every tear or cut a considerable hæmorrhage from the glandular structure spoken of happened. Therefore the tumor was slit up at the place where it had first been incised to get at it from the interior. We succeeded in probing clear to the right renal region and could touch the liver. Upon the right side, corresponding to the bit of glandular tissue alluded to, could be felt a sharply defined ring of the size of a fifty pfennig piece. In this, but somewhat under the plane of the cyst-wall, lay a renal papilla. The smooth glandular lump upon the outer wall of the tumor was then the remains of the right kidney, much pushed out of its normal situation, the tumor itself, the dilated pelvis and calyces. Inserted into the sac was the distended right ureter.

It was then determined upon to draw the partly enucleated tumor out of the abdomen, to take away as much as possible, and stitch the remainder of the hydronephrotic sac to the abdominal wound. That part of the cyst-wall to which the ureter was attached,

[1] Case LVI.

[1] Cases LVIII, LX, LXV, LXVI, LXVII, LXIX, LXXI, LXIV.

with much of the sac, was then cut away. The upper part of the ureter was left behind, ligatured and thrown back. That part of the ureter cut away was found perfectly pervious. After the customary dressing a bandage was placed about the abdomen. The spray was continuously used during the operation which lasted an hour and a half.

The patient rallied well from the operation and made a good recovery, with a fistula remaining; on the first day of March, 1879, there was complete cicatrization of the wound after some slight ulceration; the opening is 3 cm. in length, and is so stopped as to permit the drainage of the urine. Later a satisfactory apparatus, by which the urine dribbled into a flask, was arranged.

The chief point of interest about this case is the notable displacement of the kidney, by which an error in diagnosis was caused. The subject of hydronephrosis in the so-called wandering kidneys is one too extensive to be considered in this essay. The writer refers those interested to an exhaustive work on such lesions, "Die Warderniere der Frauen," Berlin, 1881, by Prof. Landau.

It only remains for the writer to say that Dr. J. Schramm,[1] in a lately published article, states that there have been but four well-defined cases of hydronephrosis in the wandering kidneys that have been operated on. In one case[2] a cure was effected by extirpation of the offending organ, in the other three[3] by a creation of a permanent fistula from the pelvis renalis.

Of the 22 patients, (Table III), in whom the wound was dressed after some one of the open methods, 18, or over 68 per cent. recovered.

The three supplementary tables reveal some interesting facts. Thus, in 50 instances where the seat of the lesion is noted, 24 are found to be right and 26 left hydronephroses. No age, also, appears to be exempt, for in a total of 62 cases, 4 occurred in those between the ages of 1 and 10 years, 11 in those between 10 and 20, 15 in those between 20 and 30, 7 in those between 30 and 40, 14 in those between 40 and 50, 8 in those between 50 and 60, and 3 in those between 60 and 70.

Females appear to be more subject to the malady than males, for of 68 cases in which the sex is recorded, 43 occurred in the former and 25 in the latter sex.

There are, in addition, noted certainly 13, and perhaps more cases in whom, by men of undoubted surgical skill, the diagnosis of ovarian cyst was made and adhered to until after laparotomy or lumbar incision, the tumor lay exposed before their eyes.

From the gloomy declaration in regard to the treatment of hydronephrosis, that "of therapy there need be no account given" to the happier statement, proven by the records collated below, that 63 per cent. of patients operated on are cured by lumbar nephrectomy, 68 per cent. by open methods in general, and, up to date, 100 per cent. by either lumbar incision and drainage or the creation of a fistula, seems a long distance, and yet these are but the results of the last 15 years. It is well, too, to remember, at least for young men, that these wonderful successes were brought about, using the word in its noblest sense, by the empirical method, and that they quite justify the advice of old Aretaeus: "Trial indeed is a good teacher. It is therefore a man's duty to try, for it is ignorance that is timid."

In the first series of the following collection of cases are given, the attempted and accomplished extirpations; in the second, the general operations for obliteration of the cyst. The latter series is subdivided into two groups—(*a*) Operations for obliteration by emptying the cyst and occluding air, and (*b*) operations for obliteration by open treatment of the wound.

Table I.

ATTEMPTED AND ACCOMPLISHED EXTIRPATIONS.

	Date.	Age.	Sex.	Operator.	Operation.	Result.	Remarks.
I.	1865	23	F.	Baum, (Göttingen) communicated by Krause in v. Langenbeck's Archiv., VII, I, p. 219	Puncture, and 1½ years after attempt to extirpate; after laparotomy cyst emptied by trocar, because adherent, cyst stitched to integument.	Death by peritonitis in two days.	Left hydronephrosis with valvular closure of ureter. Right kidney enlarged.
II.	1866	43	F.	Spencer Wells. Diseases of the Ovaries, p. 208.	First punctured, two months later laparotomy; deeper parts of cyst too adherent to remove; omentum and intestines cut, three vessels ligated and wound closed.	Death 30 hours after operation.	Cyst of left kidney as large as a man's head. Right kidney enlarged and pale.
III.	1866	22	F.	Simon. Communicated to Deutsche Klinik, 1868, No 1 by Martini.	Laparotomy: tumor behind colon descendens and cœcum. Extirpation impossible. Cyst emptied by trocar and wound closed.	Death from peritonitis in 7 days.	Large right hydronephrosis, valvular closure of ureter. Left kidney enlarged but healthy.
IV.	1869	19	F.	Esmarch. Published by Schetelig. Archiv., für Gynækologie, B. I., Heft., III., p. 415.	Puncture, 3 months later extirpation; laparotomy, cyst adherent to left ovary and tube: great hæmorrhage, 16 ligatures taken.	Death in 36 hours.	Large left hydronephrosis; cyst walls 1½ cm. thick. Right kidney enlarged, but healthy.
V.	1871	...	F.	Meadows *British Med. Journal*, 1871.	Laparotomy. Extirpation.	Death on the 16th day from hæmorrhage from the pedicle.	No trace of renal substance in the cyst; tumor diagnosed ovarian.

TABLE I.—CONTINUED.

Date.		Age.	Sex.	Operator.	Operation.	Result.	Remarks.
VI.	1872	16	F.	Sp. Wells, loc. cit., p. 216.	Diagnosis made after laparotomy; cyst punctured and its wall fixed to integument; a day later it refilled and a glass tube was inserted.	Death from uræmia in four days.	Right hydronephrosis; previously diagnosed multilocular ovarian cyst.
VII.	1873	49	F.	Campbell, *Edinburgh Med. Journal*, 1874, p. 36.	Laparotomy; nephrectomy.	Cure.	Cyst involving lower third of kidney and diagnosed ovarian.

TABLE II.

OPERATIONS FOR OBLITERATION OF THE TUMOR. (A.)

Date.		Age.	Sex.	Operator.	Operation.	Result.	Remarks.
XXXIII.	1860	....	....	Martineau. Simon, Ch., der Nieren, p. 274.	Single puncture, without leaving in canula; 9 litres of bloody fluid withdrawn. Later punctured by bistoury.	Death from peritonitis as fluid entered the abdominal cavity.	Large hydronephrosis.
XXXIV.	1862	....	....	Jos. Thomson. Langenbeck's Archiv., V, p. 328.	Incision between the two last ribs, then cyst punctured by trocar. Operated on three times.	Death from spontaneous rupture of cyst 1½ years after last puncture.	Large left hydronephrosis.
XXXV.	1862	3½	M.	W. J. Little. Langenbeck's Archiv., V, p. 333.	Single puncture, three times in 3 months; then punctured twice, leaving in the canula.	Death from fever three years after first puncture.	Large congenital right hydronephrosis.

TABLE II.—CONTINUED.

Date.	Age.	Sex	Operator.	Operation.	Result.	Remarks.
XXXVI. 1865	4	M.	Hillier, *Med Times and Gazette*, 1865, Vol. I, p. 320.	Punctured several times; unsuccessful attempt to make permanent fistula.	Improvement.	Large congenital hydronephrosis simulating ascites.
XXXVII. 1867	64	F.	Béhier. Virchow's Jahresbericht, II, p. 173.	Single puncture, repeated 10 days later.	Death from erysipelas.	Very large right hydronephrosis, diagnosed ovarian cyst.
XXXVIII. 1867	...	F.	Bérard. Virchow's und Hirsch's Jahresbericht, 1868, II, p. 161.	Twice punctured.	Death.	Enormous right hydronephrosis, diagnosed ovarian cyst.
XXXIX. 1868	59	F.	Sp. Wells, loc. cit.	Twice punctured in 3 months.	Death five months after second puncture from traumatic rupture of cyst.	Large left hydronephrosis—seven stones found in it.
XL. 1868	44	F.	Simon, loc. cit.	Puncture, two canulæ left in to promote adhesions. Punctured a second time.	Death from congestion of lungs on 14th day.	Large right hydronephrosis, with valvular closure of ureter.
XLI. 1871	24	M.	P. H. Pye. Smith, Trans. Path. Society, Lond., Vol. XXIII.	Single puncture.	Death two months later from diarrhœa.	Left hydronephrosis of traumatic origin.
XLII. 1872	16	F.	Sp. Wells, *Med. Times and Gazette*, 1872, Vol. I, p. 483.	Puncture.	Death from uræmic fever with temperature of 110 degrees.	
XLIII. 1872	20	M.	Holmer, pub. by Fenger, Nordiskt Med. Arkiv., Band, V, Nr. 12.	Aspiration—2,000 c ctm. clear fluid drawn off.	Death from inguinal abscess caused by old perinephritis.	Partial right hydronephrosis.
XLIV. 1876	34	F.	Rosenberger, Berliner *Klin. Wochenschrift*, 1880, No. 19.	Puncture.	Death in 3 weeks.	Left hydronephrosis, diagnosed ovarian cyst.
XLV. 1879	11	M	J. L. Hicks, *N. Y. Med. Record*, Apr. 17, 1880.	Aspirated three times. First, two pints; second, two quarts; third, two quarts of fluid drawn off.	Cure.	Right hydronephrosis of traumatic origin.
XLVI. 1880	12	M.	Croft, *Brit. Med. Journal*. 1881, I, p. 123.	Aspirated eight times. At first 79 ounces of fluid were drawn off.	Cure.	Left traumatic hydronephrosis—hæmaturia for 5 days.
XLVII. 1880	51	F.	O. W. Doe, Boston *Medical and Surgical Journal*, 1880, No CIII, p. 274.	Aspirated twice. At first 16, at second time 6½ ounces were obtained.	Cure.	Hydronephrosis, coincident with stricture of rectum, probably cancerous.
XLVIII. 1881	...	F.	Lucas, *Brit. Med. Journal*, Sept. 29, 1883.	Aspirated several times.	Temporary relief.	
XLIX. 1881	40	F.	G. M. Staples.	Aspirated four times. First, 44; second, 39; third, 37, and fourth time 55 ounces were drawn off.	Marked improvement.	Left intermittent hydronephrosis.

TABLE III.

OPERATIONS FOR OBLITERATION OF THE TUMOR. (B.)

Date.	Age.	Sex.	Operator.	Operation.	Result.	Remarks.
I. 1855	48	M.	Nelaton. Simon, Chirurgie der Nieren, p. 281.	Caustic potassa applied; later incision with trocar. Several times injected with iodine.	Death in 55 days.	Left hydronephrosis diagnused as splenic tumor.
LI. 1864	13	F.	Dumreicher. Langenbeck's Archiv., Band VIII, p, 705.	Punctured several times, then injections of iodine; also of ferri sequichlor. Three times catheter inserted, and cyst daily syringed out with luke-warm water.	Death a year after first puncture.	Right hydronephrosis with many adhesions, regarded as a hydrovarium.
LII. 1865	48	M.	Touren. Virchow's Jahresber., 1866, II, p. 149.	Vienna paste applied five times; syringing out of cyst, and injections of iodine.	Death 17 days after operation.	Right hydronephrosis.
LIII. 1865	64	F.	Sp. Wells, loc. cit.	Puncture with trocar, again with bistoury and tent inserted.	Cure after discharge of 2 stones per urethram.	Right hydronephrosis.
LIV. 1868	...	M.	Siotis. Virchow's und Hirsch's Jahresbericht, 1868, II, p. 161.	Caustic applied, and puncture.	Death from peritonitis.	Left calculous hydronephrosis—right kidney doubled in size.
LV. 1868	26	M.	Dolbeau. Simon, Ch. der Nieren, p. 281.	Caustic applied. A few days later opened by trocar. Cavity daily syringed out.	Death in several months.	Right hydronephrosis.
LVI. 1868	39	M.	Simon. Reported by Hotz, *Berl. Klinische Wochenschrift*, 1869, No. 23.	Double puncture, with incision in most prominent part of swelling. Two catheters put in, and cyst daily syringed out.	Death from peritonitis.	Left hydronephrosis in horse shoe kidney.

TABLE III.—CONTINUED.

Date.	Age.	Sex.	Operator.	Operation.	Result.	Remarks.
LVII. 1870	...	F	Rose. Simon, loc. cit.	Punctured, and wound kept open	Death two years later. Other kidney involved.	Large left hydronephrosis.
LVIII. 1870	26	M.	Simon, loc. cit., p 288.	"Mehrfache Punktion," with subsequent incision. Iodine injections and cauterization of calyces fruitless Fistula made.	Cure, with renal fistula..	Right hydronephrosis.
LIX. 1876	13	M.	Wölfler, *Wiener Med Wochenschrift*, 1876, No. 8.	Three successive punctures, with injections of very dilute iodine twice.	Cure.	Congenital hydronephrosis, with much urea in fluid.
LX. 1877	21	F.	Winckel, Verhandlungen der Deutschen Gesellschaft für Chirurgie, 6ter Congress, p. 34.	Exploratory puncture. Fluid drawn off, then trocar inserted and "mehrfache Punktion" successfuliy performed. Drainage tube inserted.	Cure, with fistula. Apparatus fixed to patient, who was exhibited to the 6th Congress of German Surgeons.	Right hydronephrosis in a supposed wandering kidney.
LXI. 1878	19	M.	R. F. Weir, *N. Y. Med. Record*, May 6, 1882.	Aspirated three times, then abdominal nephrotomy and drainage.	Cure.	Left hydronephrosis.
LXII. 1877	27	F.	Thornton, *Brit. Medical Journal*, May 26, 1883	Tumor in right loin twice antiseptically incised and trained. Tumor in left side opened, and drained later. Ovariotomy also performed.	Cure.	Double cysts of kidneys, supposed to be due to compression of ureters by early pregnancy.
LXIII 1879	21	M.	R. F Weir, *N. Y. Med Record*, M'rch 13. 1880.	Twice aspirated ; then lumbar nephrotomy and drainage,	Cure.	Left hydronephrosis. Metallic probe passed freely into ureter, but no calculus found.
LXIV. 1879	27	F.	Ahlfeld, Arch. für Gynækol., 1879, XV, p 114.	Laparotomy Sac adherent behind when vessels entered. Creation of fistula determined on, as three papillæ were found. Cyst stiched by 12 suture to wound. Operation three hours long.	Cure, with pelvic fistula.	Hydronephrosis in wandering kidney. Diagnosed ovarian cyst. Colon ascendens in front of the cyst. Tumor right
LXV. 1880	47	F.	G. A. Peters, *N. Y. Med Record*, May 6 1882.	Lumbar nephrotomy. Two drainage tubes inserted, and cavity daily irrigated with carbolized water.	Cure, with fistula, thro' which fluid dribbles slightly.	Very large left hydronephrosis.
LXVI. 1880	60	F.	Landau. Archiv. für Chirurgie, Bd. XXVI, Heft 3, 1881.	Exploratory puncture, with negative results. Punctured 4 times and evacuated ; then ureter, cyst and abdominal wall stitched together. Again punctured and drained. Permanent fistula made.	Cure. with fistula.	Right hydronephrosis in supposed wandering kidney.
LXVII. 1880	47	F.	Svensson, Hygeio, Stockholm, July, 1881.	First aspirated, and 200 c c. fluid drawn ; again one month later, and 600 c c. obtained ; a third time, and 300 c.c obtained. Oct, 28, 1880, cyst sewed to abdomen by 7 or 8 sutures to create adhesion. Nov. 7, Paquelin's cautery burned through cyst walls, and 1700 ctm clear fluid drawn off. Two drainage tubes inserted, and irrigation by warm solution salicylic acid.	Cure, with fistula. Cavity steadily diminishing.	Left hydronephrosis.
LXVIII. 1881	11	M.	Tuckwell, *Lancet*, July 29, 1882.	Aseptic lumbar nephrotomy and drainage. Aspirated at first.	Cure.	Left hydronephrosis, supposed to be congenital.
LXIX 1881	47	F.	Schramm, *Berl. Klinische Wochenschrift*, Sept, 10, 1883.	Laparotomy twice ; exploratory incision first with Franzel's trocar ; 800 c.c reddish urinous fluid let off. In the first laparotomy the sac collapsed, as too big a trocar was used Right ovary extirpated. This on March, 10, 1881. On Nov. 23, 1881, by small trocar, 1200 c. ctm. fluid let off. Sac stitched to integument. Artificial pelvic fistula made. Daily diminution of discharge.	Cure, with fistula, to which an apparatus was adjusted.	Large right hydronephrosis in wandering kidney.
LXX. 1882	10	M.	A. T. Cabot, *Boston M. and Sur. Journal*, Feb 22, 1883.	Twice aspirated ; then lumbar nephrotomy. Cyst wall stitched to skin.	Cure.	Right hydronephrosis of traumatic origin.
LXXI. 1878	23	F.	Pernice. Private letter to writer.	Laparotomy. Cyst tapped by Sp Wells' trocar. Part of cyst and ureter cut away. Cyst stitched to wound, and fistula made.	Cure, with fistula.	Right hydronephrosis in an abnormal movable kidney. Diagnosed ovarian cyst.

ALCOHOL AND THE FATS IN THE TREATMENT OF PHTHISIS.

[From a Clinical Lecture by P. H. Cronin, Ph.B., A.M., M.D., one of the attending Physicians of Cook County Hospital.]

REPORTED BY J. K. SUTTON, M.S.

It has been said by a well-known authority on the subject of phthisis, that there is nothing in the whole range of medical science, which the student ought to study more carefully than the cachexia, or special form of ill health, associated with the occurrence of tubercle and general scrofulous affections. Indeed, it may be said that in every phase of his professional career, a knowledge of the pathology of scrofula, in its general or special aspect, is an absolute necessity.

Experience has fully demonstrated that not to causes within the province of the medical man, solely, can the origin of tubercle or the scrofulous diathesis be traced. Yet it must be acknowledged that by the confidence naturally acquired by him, as the trusted friend of the most exclusive families, he may exercise a potent influence for good in teaching how the public may control the inroads of consumption, by prudent marriages, sanitary attention to offspring, and the absolute need of fresh air, with freest ventilation, in the dwellings of rich and poor alike. In short, it is by the mode of life as citizens of the world; in the social relations of husbands and wives, parents and children, as well as in the public relations of teachers and pupils, masters and workmen, that the extent and ravages of consumption can best be controlled.

But all of this, at which I have merely hinted, is for your future study, and since the tendency of modern medicine is to "throw physic to the dogs," in so far as its practice extended in the days of our fathers, I doubt not that the majority of you will devoutly kneel at the shrine of the goddess Hygeia and pay homage to that growing sentiment in the profession in favor of general sanitation, as influencing the preservation of the highest standard of physical well-being.

The cases before us to-day clearly demonstrate that phthisis is truly, as its name implies, a wasting disease. The wan features, the sunken eyes, the shriveled skin, and general emaciation are the most eloquent exponents of poor nutrition and malassimilation, and since this bodily condition calls for a remedy, it might be well to study as briefly as the sequence will permit, the causation of phthisis, before entering upon its treatment.

That phthisis is a constitutional disease, goes for the saying. It is characterized by lesions commencing with induration of a lobe or lobule of the lungs, ending in the disintegration of the new material and of the structures involved in this induration; the formation of cavities, and the accumulation and constant discharge of purulent secretion, with or without miliary tubercle. Constitutionally, the result is the deposit of a soft, unorganized matter, white or pale yellow in color, firm, somewhat resembling curd or soft new cheese, though less tough, sometimes granular and friable, and consisting largely of albuminous material. It is often found associated with a purulent-like fluid, and is frequently to be met with in rounded masses varying from the size of a millet seed to that of a hen's egg, or larger. This material may be enclosed in cysts or simply deposited within the natural canals of the body, or it may be diffused, as if by infiltration, through the textures of the various structures. To the rounded masses is given the name of tubercle, and the material itself has obtained the name of scrofulous or tuberculous matter.

The disease manifests a remarkable tendency to certain specific forms of nutritive disorders, which ultimately lead to extreme wasting of the systemic structures. Indeed, it would seeem as though the vital forces were incapable of completing tissue organization, owing to the constant accumulation of systemic debris, acting as a hindrance to repair of the waste resulting from tissue metamorphosis. That such is really the case I need not tell you. It is known that the venous radicles and lymphatics serve to build or renew tissue, as well as to act the part of scavengers for the organism by the removal of effete material. Now, when the scale of nutrition is below par, whether as the result of actual want of food or improper assimilation, the function of repair is necessarily arrested, while destruction or consumption goes on with even more than wonted vigor. Soon this want of balance in the nutritive function manifests itself, in hectic and the accompanying structural changes so familiar to all of you.

As regards loss of weight, it is astonishing to note to what an extent bodily waste may go on without extinguishing the lamp of life. Chossat, in his "*Recherches experimentales sur l'inanition*," has shown that the average loss of weight occurring in healthy, warm-blooded animals, between the commencement of starvation and death, is 40 per cent. In other words, an animal without the intervention of disease, dies when it has lost two-thirds of its body weight. Dr. Tanner is said to have lost one pound daily during his noted fast. The researches of Chossat possess for us the additional interest of locating the loss sustained by the different tissues of the body. Thus, fatty tissue almost wholly disappears, 93½ per cent. going to waste. The blood loses 75 per cent., the spleen 71 per cent., and the pancreas 64 per cent. of their substance. The muscles of locomotion show a loss of 42½ per cent., while the nervous system exhibits a waste of less than two per cent.

As in starvation, *per se*, so in the quite as effective starvation of phthisis. Indeed, the tissue waste, if we except that of the pulmonary organs, noted in consumption, bears a striking analogy to the structural loss so manifest in ordinary inanition. It is evident that the atrophy of the pancreas, so well marked a feature in phthisis, must lead to imperfect preparation of fatty material for assimilation. This soon reduces the needed supply of adipose tissue to a minimum. The spleen fails in its wonted action, and the blood itself becoming lessened in quantity, necessarily embarrasses the lungs and heart and kidneys. The nervous tissue alone preserves a nearly wonted vigor. Indeed, it is remarkable, that the

mental faculties remain intact, excepting that the effect of the disease upon the mind is such as often to impair the ability to realize the extent of a serious affection.

In view of the fact that the body requires thirteen times more carbonaceous than nitrogenous food, for its sustenance, the daily consumption of carbon being 4,000 grains, that of nitrogen about 300 grains, the prime indication for treatment of a disease characterized by so large a percentage of waste of carbon as is manifest in phthisis, is a plentiful supply of easily combustible material. Such a material we have in alcohol, freed from the impurity of fusel oil, which latter is of slow oxidizable power and absolutely poisonous.

Experiment has shown that the combustion of one gramme of pure alcohol raises the temperature of seven liters of water one degree Centigrade. Cod-liver oil, in the same quantity, brings to a like degree of temperature nine liters. Hence, the relative heat-producing powers of alcohol, and the well-known nutrient oil are, as say, three to four. Calculated on the above basis, three and one-half ounces of cod-liver oil suffices to maintain one-third of the body heat for twenty-four hours, while about four ounces of alcohol, or about the quantity contained in a liter of light wine, serves the same purpose. There is this difference, however, between the two forms of nourishment. The oil, if tolerated, is decidedly curative, and thus becomes a positive benefit throughout the life of the individual using it. Not so with the use of alcohol, for in the majority of cases the cure is quite as bad as the disease, physically, and not infrequently leaves the patient a moral wreck.

The fats then, chief among which is cod-liver oil, form the main-stay of rational treatment of phthisis. But in the case of this highly-prized remedy we meet with an obstacle at the very door of promised relief. For, if cod-liver oil be nauseating to one in vigorous health, it is positively disgusting to a phthisical patient. Then, too, the system of such a patient is illy-prepared to assimilate the raw oil, and with food within easy reach of him he may die.

Here, however, the chemist and skillful pharmacist come to the relief of physician and patient alike. Nature's methods are studied, the wasted pancreas is assisted by the rest afforded by emulsionized oil. The administration of nutrient salts, as the phosphates of lime and magnesia, give needed energy to the venules and lymphatics, the blood is enriched by the assimilation of milk and other well-balanced foods, while the various symptomatic manifestations, such as cough, night sweats, dyspepsia, hæmorrhage, and general nervous unrest, yield to systemic or special treatment, and finally God's air and sunshine thrown around all, the hope grows stronger daily that the energizing hand of nature may assist our own in leading our patient to renewed life and happiness.

PROFESSOR D. W. YANDELL, OF LOUISVILLE.—We regret to learn that this distinguished member of the profession, after suffering several weeks of confinement with rheumatism, has been obliged to visit Florida in the hope of a more perfect recovery.

MEDICAL PROGRESS.

MATERIA MEDICA AND THERAPEUTICS.

THE BEST TIME FOR ADMINISTERING MEDICINES.—*The Midland Medical Miscellany* has an excellent article on this subject, in which it answers the question: Before or after meals? Such is the question often asked of the doctor, but the answer is not always ready. Medicines that are irritating should be given after meals, when the stomach is full, viz.: the salts of copper, zinc, iron and arsenic, in large doses. Small doses, intended to act on the stomach terminals of the vagi, must be given when the organ is empty. Chemical reasons also have their influence, thus, oxide and nitrate of silver, intended for local action, should appear in the stomach during its period of inactivity, lest, at other times, chemical reactions destroy the special attributes for which these remedies are prescribed. Iodine and the iodides further illustrate this point. Given on an empty stomach they promptly diffuse into the blood, but if digestion is going on, the acids and starch form products of inferior activity, and thus the purpose which they were intended to subserve is defeated. Substances prescribed to have alveal action on the mucous membrane, or for prompt diffusion unaltered, are preferably given before meals. The condition of the stomach veins after meals is such as to lessen the activity of diffusion of poisons, and hinders their passage through the liver. It follows that active medicaments in doses near the danger-line, are more safely administered after meals.

When shall acids and alkalies be given, before or after meals? First, as to acids. When acids are prescribed with the view to check the excessive formation of the acids of the gastric juice, they may be given before meals—as, by the laws of osmosis, they will determine the glandular flow of the alkaline constituents of the blood. The same reasoning would hold good when the alkaline condition of the blood was in excess; osmosis being favored, the acid would reach the blood more readily. Second, as to alkalies. These may be given just before meals, when the acid forming materials in the blood diffuse into the stomach glands, and after digestion is completed, when the alkalies diffuse directly into the blood, without interference from the contents of the stomach. An alkali taken during the time when the reaction of the stomach juices should be strongly acid, must necessarily hinder, if not arrest, the digestive process for the time being. The metallic salts—notably corrosive sublimate, alcohol, tannin, and some other agents—impair or destroy the ferment, or digestive power, of pepsin. Wine that is intended to act as a food, is most beneficial when taken slowly during the course of the meal. The objection as regards the ill effect of alcohol on pepsin, is not applicable here, except to the stronger spirituous wines in large quantities, for the ordinary medicinal wines do not have sufficient alcoholic strength to injure this ferment. Iron, phosphates, cod-liver oil, malt, and similar agents should, as a rule, go with food through

the digestive process, and with the products of digestion enter the blood.

Hydrastis Canadensis in Uterine Diseases.—Prof. Schatz, of Rostock, in the *Deutsche Medical Zeitung*, speaks highly of this drug, which he has used in the form of the fluid extract (Parke, Davis & Co.) in functional disturbances of the uterus and ovaries, anomalies of menstruation, and direct or reflex, or simply congestive disturbances, which exclude operation and call for medication. This drug contracts blood-vessels, and thus diminishes congestion of the genital organs. In long-continued or large doses it diminishes the frequency of menstruation; the flow is also diminished, and pain is lessened, and often removed entirely in vaginal hæmorrhage and dysmenorrhœa that has no local cause, as well as in diseases of the uterus and its neighborhood. Its effects are noteworthy in many myomata, the hæmorrhage occasioned by them being much lessened and sometimes entirely prevented. He generally gives twenty drops of the fluid extract four times daily, not only whilst hæmorrhage is actually present, but in preference a week before the anticipated painful or profuse menstruation. This drug occasionally, after lengthened employment, improves the appetite. This from one who, according to the *Medical Press*, from which we quote, has removed the whole uterus at least ten times, is certainly very high recommendation.

Subcutaneous Injection of Iron.—Experimenting on the behavior of iron within the animal system, Dr. Glacoeke reports in the *Archiv. für Experimente Pathologie und Pharmakol.*, that he has found the ferrum citricum oxydatum to be the best form of iron for subcutaneous injection. No reaction takes place at the site of the puncture. The iron is excreted through the kidneys, not through the glomeruli, but through the epithelium of the tubuli uriniferi. The excretion is complete within twenty-five hours. The liver to a greater extent takes part in the elimination. The injections are made in the long dorsal muscles or in the nates. The solution should not be more than one month old, and for adults doses of 1½ grains in a 10 per cent. solution are recommended.

In the case of an extremely chlorotic girl, in whom the proportion of hæmoglobin in the blood was 38 per cent. of the normal, it rose after fifty-four injections to 82 per cent., and the patient had in the meantime gained sixteen pounds in weight; the menses also, which had been absent for nine months, returned. Good results were also obtained in a case of secondary anæmia from hæmorrhage from the stomach.

If too much iron be injected, toxic effects may be manifested, in the shape of general *malaise*, vomiting and weakness. Diarrhœa may also come on.—*Medical Press.*

Gallic Acid in Hæmorrhage from the Urinary Organs.—Lionel S. Beale, in the *Lancet*, recommends the use of gallic acid in this affection in large doses, and persisted in for several days. As gallic acid probably acts according to the strength of its solution, which bathes the bleeding tissue, it is necessary to insure the introduction of a certain quantity in the blood by the frequent administration of successive doses; as it soon passes away from the blood, being carried off in the urine, we must give it in quantity and often enough to more than compensate for this loss. He has found it valuable in chronic bleeding from the surface of the mucous membrane of the pelvis of the kidney, ureters, bladder, and urethra, and from villous growths, as well as in the very obstinate hæmorrhage from large fungous tumors of the kidney and bladder. The remedy should be given in frequent doses, day and night, until the bleeding is very decidedly reduced in degree, when it may be ordered once in six hours, or less frequently. Gallic acid seldom disagrees in any way. It does not cause constipation, and even when the crystals are swallowed in a state of suspension in water or mucilage, the stomach is not disturbed by their presence. The glycerine of gallic acid is, however, the most pleasant form in which to prescribe the remedy. This contains one part of gallic acid in four. Forty minims will contain ten grains, and may be given in distilled water, peppermint, orange, or other water.

Dr. Beale has given ten-grain doses every three hours, without intermission, for three weeks, no objection having been made on the patient's part.

Condensed Mare's Milk.—The *Lancet* gives a reference to a preparation by a Russian company, called "Carrick's Russian Condensed Mare's Milk Company," which may be found useful in many cases of delicate infantile digestion. The similarity of human milk to that of the mare is well known. Cow's milk is quite unlike both, and it is not wonderful that many infants are unable to digest it. The mare's milk is concentrated to one-eighth by evaporation in vacuo, and is sufficiently preserved by the addition of 3 per cent. of sugar, so that the milk obtained on dilution is not unduly sweet.

OBSTETRICS AND GYNÆCOLOGY.

Phenomena Observed at the Catamenial Periods of Patients who have been Subjected to Porro's Operation.—*La France Medicale* reports M. Abel Damour's communication to the Clinical Society on his observations of thirty cases where Porro's operation has been successfully performed, which number embraces about half of all that have survived the operation, as there were only 62 living women. In 23 of these cases the menopause followed the operation without any of the phenomena indicative of a return of the menses. In 8 of the cases, painful sensations alone, or accompanied by a catamenial discharge, were noted. These painful sensations consisted of flushes of heat, a feeling of fullness, cramps, cephalalgia, general fatigue, oppressions, tendency to syncope, disturbance of vision, and noises in the ears.

In a patient operated upon Dec. 30, 1879, by Dr. Championniére, in March, 1880, on going to the

close-stool, she passed about half an ordinary glassful of fluid blood, by the rectum, and this was repeated five times at intervals of two months at the proper menstrual period. Otherwise there were no general indications of pain. There were no hæmorrhoids. Dec., 1883, the patient while urinating passed several red clots, and a small quantity of yellowish blood. Urination was painful, and this was the last manifestation of menstruation. A patient operated on by Prof. Porro, May 21, 1876, had during four days of the menstrual epoch a swelling of the cicatricial tissue of the pedicle and a discharge of a thick, ropy, limpid fluid. In two cases of Prof. Braun, there was in one a single vaginal hæmorrhage, in the other a monthly hæmorrhage, which continued periodically. Prof. Tarnier's case lost quite a considerable amount of blood during two days, five months after the operation. In two cases of Prof. Breisky, one suffered from three attacks of hæmorrhage, without any lung trouble being diagnosticated, the other had two attacks of vaginal hæmorrhage at menstrual epochs. Dr. Ramello, of Turin, operated upon a case July 3, 1880. On Jan. 17, 1884, he states that his patient has enjoyed excellent health ever since the operation, but that on the first day of each month, at the period corresponding to the menstrual epoch, she suffers from a slight headache, which is followed by epistaxis. Prof. Breisky noted in a third case that at each month there were pains in the breasts.

SURGERY.

MODE OF LIMITING INJECTIONS TO THE ANTERIOR URETHRA.—M. P. Aubert, in the *Lyon Medical*, recognises the division of the male urethra by the subpubic sphincter into the anterior urethra and the posterior urethra. The most serious complications of blenorrhagia come from the passage of inflammation to the posterior urethra, as there it can readily extend to the epididymis or bladder. Among the causes which facilitate or provoke directly this extension to the deeper part of the canal, are injections. The bad effect of these injections results from the mode in which they are used. If practised upon the open canal, they do not penetrate deep enough to involve the whole of the anterior urethra. If practised upon the closed canal, the tension of the fluid overcomes the resistance of the urethral sphincter, and the contagion is carried to the deeper portions by even the most innocent fluids. To overcome these difficulties, Aubert takes a thin rubber tube of a caliber much smaller than that of the urethra, and of the length of 10 to 12 centimeters, and after having oiled it, he introduces it into the urethra, the nozzle of the syringe is attached to its free end and the injection is proceeded with. This carries the injection to the bottom of the anterior urethra, and as the tube does not fill up, the whole of the canal and the meatus externus is not compressed, the liquid makes it escape without passing the urethral sphincter, and washes thoroughly that portion of the canal which is anterior to it.

MEDICINE.

SCARLATINA AS A CAUSE OF PUERPERAL SEPTICÆMIA.—Dr. F. P. Atkinson, in a short article in the *Practitioner*, argues as follows against the probability of puerperal fever having its origin in scarlatina:

1. Cases have over and over again been reported where the parturient woman has been the subject of scarlatina, and the peculiar symptoms of puerperal septicæmia have been entirely absent, and also where there have been cases of scarlatina, not only in the same house, but in the same room, and even in the same bed with the parturient woman, without the occurrence of any ill effects.

2. He has been creditably informed by a medical man that he (the medical man) was once called away from a case of scarlatina he was watching, to attend two cases of midwifery, and that neither of the lying-in women had any unfavorable symptoms afterwards.

3. He was also told that one medical man attended three cases of confinement when his hands were freely peeling from scarlatina, and that not one of these cases had anything the matter subsequent to their confinement.

In spite of these facts, he believes that serious harm might result, were pus from the ulcerating surface of the tonsils to come in contact with an abraded surface of the uterus or vagina.

His treatment for puerperal septicæmia, he sets down as quinine, two or three grains, with five minims of the tincture of digitalis, alternating every two hours with from three to five grains of resorcin. Ice-bags to the head and spine, body sponging with vinegar and water, and uterine syringing with a solution of permanganate of potash, three or four times daily. Plenty of good liquid nourishment and brandy.

FOOT-AND-MOUTH DISEASE IN THE HUMAN SUBJECT.—The *Lancet* tells us of a very remarkable epidemic of aphthous sore-throat in Dover, England, which seems to have been connected with foot-and-mouth disease in a dairy. In all there were 144 attacks; 130 receiving their milk from the dairy in question; this dairy received a partial supply from a country dairy where the disease was prevalent, and the customers supplied with this milk all suffered, and 14 persons in addition, who had their supply from the country dairy itself. The special influence of cream, as conveying the *materies morbi*, was shown by the fact that the proportion of attacks in adults, as compared with children, was large, and many adults who took no milk had partaken of cream in their tea. The symptoms of the sufferers were shivering, followed by headache and fever, pains in the limbs, parched lips, and a vesicular eruption in the throat. In some cases the tonsils were enlarged, and in others they separated, the process being accompanied by enlargement of the glands. The medical officer of health is preparing a report based upon a careful investigation, and it will be interesting to note if any were attacked who did not partake of the milk, and thus as secondary cases show the presence of personal infection.

THE

Journal of American Medical Association.

PUBLISHED WEEKLY.

THE EDITOR of this JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information, should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE..... $5,00.
SINGLE COPIES..... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 65 RANDOLPH STREET,
CHICAGO, ILLINOIS.

SATURDAY, APRIL 19, 1884.

REDUCTION OF DISLOCATIONS BY MANIPULATION.—In this journal for April 5, 1884, we inserted a short article on this subject under the head of original communications, by Dr. M. M. Louis Hutchinson, whose titles would indicate that he had received his education on the other side of the Atlantic. One of the leading motives for inserting the article was to make it the occasion for correcting the erroneous views the writer entertained concerning the status of surgical progress in this country.

Concerning the reduction of dislocations by manipulation, Dr. Hutchinson makes the singular assertion that the subject is seldom lectured upon in the medical colleges, and that very little attention is given to it in the text-books and other works on surgery. So far is such a statement from being true, that we doubt whether there is a regular medical school in this country, in which a course of lectures on surgery has been given at any time during the last twenty years, that did not include direct and full instruction concerning the reduction of dislocations, especially at the shoulder and hip, by manipulation. Prof. H. H. Smith, of the University of Pennsylvania, reduced a luxation of the humerus by this method, and published an account of it in the *Medical Examiner* of Philadelphia in 1858. He also gives full instruction on the subject in his valuable work on "The Principles and Practice of Surgery," published in 1863. Prof. Daniel Brainerd, of Chicago, who died in 1866, had for several years before his death, both practiced and taught this method of reduction, as applied alike to the heads of the humerus and femur.

In regard to the reduction of dislocations of the femur at the hip by manipulation the attention of the profession was first prominently arrested by a very valuable paper contributed by Dr. W. W. Reid, of Rochester, N, Y., and published in 1857. Since the publication of that paper by Dr. Reid concerning the reduction of dislocations of the hip by manipulation, and the case of dislocation of the humerus at the shoulder, published by Dr. Smith in 1858, this method of reduction has been as familiarly taught, both in the medical schools and works on surgery, in this country, as any other important item of surgical knowledge.

PROFESSORIAL CHANGES.—It is understood in professional circles in Philadelphia, that at the close of the present college term in the medical department of the University of Pennsylvania, Prof. Alfred Stillé will positively retire from the chair of Practice of Medicine, and will be succeeded by Dr. Wm. Pepper, the present Provost of the University. The one has well earned his right to a seat on the higher plane of honorable retirement, while the other is equally fitted to enter upon the active duties of one of the most important positions to be found in the profession.

At a recent meeting of the Faculty and Trustees of the Chicago Medical College, Dr. W. H. Casselbery was appointed Professor of Materia Medica and Therapeutics, Dr. W. W. Jaggard Adjunct Professor of Practical Obstetrics, and Dr. F. S. Johnson Lecturer on Histology. These gentlemen had been giving instruction in their respective departments during the past college term with more than ordinary ability and success.

DOES ALCOHOL UNDERGO COMBUSTION IN THE HUMAN SYSTEM?—In the brief clinical lecture on the use of the fats, or Oils and Alcohol in the Treatment of Pulmonary Phthisis, in the present number of the JOURNAL, the lecturer speaks of the action of alcohol as though its combustion in the living system was an established fact; and even informs his class of the quantity of heat that would be evolved from the combustion of a given number of grammes of alcohol. He appears to be still living in the palmy days of the chemico-physiological doctrines of Baron Liebig, and of course is oblivious to the fact, that all the experiments of the last quarter of a century demonstrate, first, that nearly all the alcohol taken into the living human system, instead of undergoing combustion, is eliminated unchanged through the lungs, skin, and kidneys. The late Dr. Anstie, after the most persistent and extensive experimental research, could show

the retention of only from 30 to 45 cubic centimeters (fl. ℥j to ℥jss) of alcohol, in the adult human system in the twenty-four hours. And second, that even this small amount did not disappear by any process of combustion, was made evident by the fact that the temperature, as shown by the clinical thermometer, was lowered instead of increased during the time the alcohol was retained. That alcohol, while present in the human system, circulates in the blood unchanged, and by its presence, retards molecular movements, lessens the exhalation of carbonic acid gas, as well as all other products either of combustion or of tissue changes, and also diminishes both temperature and nerve sensibility, has been proved by observations and experiments so numerous and varied, during the last half century, that we had supposed the purely chemical theories of a past generation had become obsolete, at least, at the bedside of the sick.

HYMENEAL.—In the column of miscellaneous items of the present number of the JOURNAL, will be found a notice indicating that the genial and well-known permanent secretary of the American Medical Association has been taking to himself a "better half;" thereby not only renewing the joys of youth, but providing against the loneliness of solitary age. We tender to both parties our cordial congratulations, and the earnest wish that life, to them, may be long and happy.

RAILROAD FARE TO WASHINGTON.—All delegates and members of the Association intending to attend the meeting in Washington on the first Tuesday in May, will find matter of interest to them under the head of special notices in another column of this journal.

IS IT consistent with the By-laws for officers and members of the Association to furnish copies of the addresses, reports, and papers they may present at the annual meetings, to such medical journals *as they choose, or to the daily* secular press?

We answer this question by copying, for the information of all parties, the following paragraph from Section IV of the By-laws:

"Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the *exclusive property* of the Association, and shall be published and sold for the exclusive benefit of the Association." (See Trans. Vol. 33, p. 628.)

Also as bearing on the same question, we republish the following resolution adopted by the Association at the meeting in Cleveland, June 6, 1883:

"*Resolved*, That the Board of Trustees are hereby instructed to proceed with the publication of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, at as early a day as practicable, to take the place of the annual volume of Transactions and that the duties formerly devolved upon the Standing Committee of Publication be transferred to the Board of Trustees; and that the Secretaries of the Association *during or immediately* after each annual session, be required to transfer to the *editor of the journal the record of proceedings, addresses, and all written reports of committees and officers, papers and contributions*, that may be referred for publication, either in *general sessions* or in any of the *Sections*."

SOCIETY PROCEEDINGS.

THE CHICAGO GYNÆCOLOGICAL SOCIETY.

Chicago, March 28, 1884.—The Chicago Gynæcological Society held its regular monthly meeting, Friday evening, the 28th ult., in parlor 44, Grand Pacific Hotel.

Dr. E. C. Dudley reported verbally a case of Ovariotomy, Complicated with General Miliary Tuberculosis of the Peritonæum. He presented to the society a very interesting specimen, an ovarian cyst, which he had successfully removed two months before at Nora Springs, Iowa. The case had been reported to him by Dr. S. G. Blythe, of Nora Springs. The patient was 23 years of age; had been married two and one-half years; had always suffered from dysmenorrhœa; had never been pregnant. In September, 1883, she noticed some enlargement in the left inguinal region. She had previously suffered from inflammation of the left broad ligament. Dr. W. H. Byford, of Chicago, seeing her at this time, diagnosed pelvic abscess. She subsequently consulted Dr. D. A. McCallum, of Montreal, who, in the following December, diagnosed ovarian cyst. Patient reports that this cyst grew rapidly, and a few weeks later disappeared, apparently by rupture of its wall and the discharge of its contents into the peritoneal cavity. Dr. Dudley did not question the probability of this occurrence, because he had previously operated successfully upon a case in which the patient had, during the five months preceding the operation, suffered five times from rupture of the cyst wall and discharge of its contents into the abdominal cavity, with resulting peritonitis each time. In the Nora Springs case, the cyst gradually refilled, till the summer of 1883, after which the increase was more rapid. In December, 1883, patient suffered from a serious attack of peritonitis which threatened her life. From this she recovered; operation under ether (Jan. 23, 1884) lasting one hour and fifty minutes; present Drs. S. G. Blythe, J. Q. Adams, of Nora Springs, Iowa; N. L. Kean, of Norwood, Iowa; and Christian Fenger, of Chicago. Incision in the median line, between the umbilicus and symphysis pubis, four and one-half inches long; weight of tumor, twelve pounds; fluid thin, opaque, yellow. This fluid was by accident thrown away, so that no adequate examination was made; tumor mono-cystic; left side thick walls. Upon opening the abdomen, the entire peritonæum, parietal, intestinal and omental, as well as that covering the tumor, was found extensively involved in miliary tuberculosis. A small cyst of the right ovary of the size of a hean's egg, with thin walls, also covered with evidence of tubercular peritonitis, was not removed; adhesions very extensive and very firm, parietal, intestinal and pelvic; pelvic adhesions being universal. The pedicle was severed near the uterus, and treated by intra-peritoneal ligature and cautery. A large double soft rubber, perforated drainage tube was introduced through the lower end of the wound, and carried into the cul-de-sac of Douglas. The operation was completed at 2 P. M.,

patient placed in bed and surrounded by hot bottles; extremities warm; condition apparently good; slight vomiting of bile; pulse 130; axillary temperature 99.

January 24. 1 A. M.—Vomiting incessant; extreme sense of suffocation; pulse 156, very feeble; jactitation; extremities cool; pain in the distribution of the cœliac axis; collapse seemed imminent; brandy in tablespoonful doses was given by stomach, and in two-ounce doses by enema; but the temperature, taken in the vagina, registered 103, and this fact alone deterred the operator from opening the abdominal wound to look for secondary hæmorrhage. 4 A. M., pulse 140, and all the symptoms less urgent; patient asked for more brandy, which was given by enema; 8 P. M., pulse 132; axillary temperature 100; vomiting had ceased; had had a very comfortable day; had passed flatus downward.

January 25, 8 A. M.—Pulse 120; temperature 99. 8 P. M., pulse 121; axillary temp. 99.3; brandy and milk have been freely given and retained; large amounts of bloody serum have passed through the drainage tube.

January 26.—Condition substantially the same; nothing passed through the drainage tube, and it is removed; the patient continues to an uninterrupted recovery.

The operation was in the strictest sense performed with antiseptic precautions. The spray was not used except in the room before the operation. The opening through which the drainage tube had protruded, now, two months after the operation, is not closed, and is reported by Dr. Blythe to discharge constantly large amounts of ascitic fluid. Dr. Dudley is now in doubt as to the propriety of attempting to close this opening, not knowing whether some of the fluid now discharged through it would not, if the opening were closed, be reabsorbed into the circulation, and in this way prevent the constant drain upon the patient's vitality. He was of the opinion that the original diognosis of pelvic abscess by Dr. Byford was probably correct, and that the tumor may, therefore, have been of inflammatory origin. He then introduced Dr. Christian Fenger (present by invitation), who made the following remarks upon the pathology of the case:

The specimen was exhibited before the society, and examined by Prof. Christian Fenger, Surgeon Cook County Hospital, and Prof. of Pathology and Diseases of the Genito-Urinary Organs, Chicago Medical College. During the examination Dr. Fenger observed: There is nothing peculiar about the inside of the cyst. It has a few cauliflower excrescences about it, which, of course, is a common thing. Microscopical examination of this specimen shows nothing but the usual cylindrical epithelial papillomatous formations, of the same structure as cylindrical epithelial carcinoma. Some small nodules in the wall are fibrous, but there is no tubercular tissue in them; consequently there is inside of the cystoma no signs of tuberculosis. Outside of the cyst you can see miliary tubercles. There are miliary tubercles all over the cyst, all over the peritonæum, and intestines, in fact everywhere all over the whole peritoneal cavity. When the attack is recent, the tubercles are always miliary. There is one point, however, more remarkable here, that is the condition of the fallopian tube. It is enlarged, the walls thickened considerably, and the lumen larger than usual. Microscopical examination shows all over in the walls and mucous membrane miliary tubercles, with the characteristic giant cells. It is worth while to call your attention to these peculiarities. It is possible, although it can't be proven, that this is the primary tuberculosis, and the miliary tuberculosis of the peritoneal cavity is the secondary. Miliary tuberculosis of the peritonæum will not creep down into the fallopian tubes, go through the mucous membrane so very easily, and cause tuberculosis, That is not the way in which the trouble generally arises. It is much more common that there is a primary conglomerated tuberculosis of the uterus and a secondary miliary tuberculosis of the peritonæum. It would take too much time to go further into this question, besides, it would not be of much use, but there is another point which this class of cases call forth very strongly, and that is the following: At the time, when the operation was over, and we knew that there was acute, diffuse miliary tuberculosis of the peritonæum, then we naturally asked ourselves, what does this mean, in reference to her recovery from the operation? We could not answer anything concerning that question, so to speak. The statistics of Spencer Wells furnished one single case out of a thousand, in which the patient, a single woman, 23 years old, died one hundred and fourteen hours after the operation from tubercular peritonitis. This is all we could get from that source. Of course, the few remarks I make here to-night are based on what I have been able to find in the literature, and possibly other members of the society have found the same thing, on the influence of miliary tuberculosis of the peritonæum on operations in the peritoneal cavity. First; let us look one moment at the view of miliary tuberculosis of the peritonæum as held up to 1880.

In Ziemssen's Encyclopædia, whose literature comes down into the seventies, the writer says concerning tuberculosis of the peritonæum, that as a rule, it takes a chronic course, and explains what is meant by chronic, by weeks or months after the diagnosis is made, and then sure death. The disease is always fatal, either from ascites and marasmus or miliary tuberculosis in other organs. As to opening the abdominal cavity in tuberculous peritonitis, he does not dream of that. He says if ascites is abundant, puncture of the abdomen to relieve symptoms can be resorted to, but the puncture causes fresh inflammation, and is apt to cause considerable hæmorrhage into the peritoneal cavity. He of course does not write this, without consulting all of the literature of miliary tuberculosis, or simply tuberculosis of the peritonæum, which he has had access to. Lately, however, there have been reported some cases where tubercular peritonitis has been met with in abdominal operations, and these cases seem to contradict altogether what we used to believe up to 1880.

Prof. Küster, of Berlin, out of whose article on iodoform treatment of wounds of the abdominal cavity I simply take one remark, says, that Schröeder has told him, that he has met with peritoneal tuberculosis while performing ovariotomy, and that he

powdered the tubercular peritonæum with iodoform, and the patient recovered without any trouble. This is all I know about ovariotomy in a tubercular peritoneal cavity.

Now, it happens that a few weeks ago an article on this very same subject was written by Kœnig. The article is on "Tubercular Peritonitis Simulating Abdominal Tumors." Three cases are cited, as follows:

October 15, 1883, a woman came under Kœnig's care. A couple of months previous she had distension of the abdominal cavity, loss of appetite, and loss of flesh. When she was examined, there was found above the symphysis a fluctuating tumor; percussion elicited dullness in the median line; clear percussion note on the sides. Laparotomy was made, but when the wall of the abdomen was cut through, he came into a cavity filled with a not very clear serum, and fibrinous masses. A layer of fibrinous masses covered the uterus and ovaries, as far as forming the wall of the cavity. This material was scooped from the uterus and from the walls of the abdomen and intestines, as far as he dared to. Examination showed it to be tuberculous. The cavity was then washed out with carbolic acid, and powdered with iodoform, and the abdominal wound closed as usual. This occurred on the 15th of October. On the 16th of November she was sent from the hospital, with no fever, normal appetite, and all the indications of complete restoration to health.

The next case was that of a woman 30 years of age, who had had three children. Four months before coming into the hospital, the abdomen had enlarged some, and two months before, the menses stopped. When she came in there was a fluctuating tumor extending from the symphysis to the umbilicus; the intestine lay behind the tumor; the uterus was retroflected; at the left side the ovary could be felt; at the right side of the uterus a solid tumor could be felt, the size of an orange, to which fluctuation from the tumor was transmitted. The urine contained some pus and some albumen. Laparotamy showed tuberculosis of the peritonæum, and the incision led into a cavity, in which was the same kind of serous fluid as in the other case; in the posterior part of the cavity were found the intestines, ovaries, and uterus, covered with the same kind of material as in the other case. The wound was treated in the same way, washed out with carbolic acid, powdered with iodoform, and a drain inserted. She recovered with no reaction whatever, but there was for a long time suppuration from a fistulous opening, which finally closed up. The abdomen was in a normal condition, and the patient was able to do her work again. One year after the operation, there was a tumor of medium size, which afterwards disappeared. Two years after the operation, this woman was perfectly healthy and able to do her work.

The next case was that of a woman with a tumor in the right side of the abdomen. When the patient came into the hospital there was, in the right half of the abdomen below the liver, and reaching from here down in the lumbar region, an oval, painful tumor, of the size of the fist. It was supposed that patient had a tuberculous kidney, that was floating, as was thought, and to demonstrate its presence an incision was made in the lumbar region, but a healthy kidney was found, and consequently the wound was closed. An incision was made in the median line, and he found the ascending colon surmounted by tuberculous nodules, enough to form this tumor. There were miliary tubercles all over the peritonæum. The operation had no serious consequences for the patient. She recovered from it in October, 1881, but in March, 1882, she died from general tuberculosis.

The fourth and last case was a girl 23 years old, with tuberculosis in her family; always healthy before, and only a couple of months before she came into the hospital the abdomen had enlarged. The medical attendant felt a fluctuating, round tumor the size of an egg upon the right side; menses normal.

Kœnig found, when he saw her, the abdomen enlarged, somewhat elastic, and in the left side above Poupart's ligament, a small elastic tumor, and two smaller tumors could he felt from the vagina as well as from the rectum? As these tumors enlarged and were painful, the peritoneal cavity filled up with ascitic fluid, an exploratory incision was made. A quantity of bloody serum was taken out, and all over the peritonæum numerous tuberculous knuckles were found. The omentum and intestines were covered with nodules, not miliary tubercles, but conglomerated tubercles of a larger size and beside these, thousands of miliary tubercles all over the peritonæum. The wound was united after the peritonæum had been washed out and powdered over with iodoform. Recovery took place three weeks after the operation. Since this was published four months have elapsed. The patient is getting stronger, and feels at the time of publication perfectly well. I refer to these cases because they have been very interesting to me, as showing the sudden change which has taken place in the aspect of tubercular peritonitis, and as proving that we need not feel so much alarm as we have heretofore the next time we meet with tubercular peritonitis, in any operation of the peritoneal cavity. Neither Kœnig nor anybody else would, of course, dare to recommend laparotomy for tuberculous peritonitis as a justifiable operative procedure. But it may be a question for somebody else to solve, whether it is beneficial in tuberculous peritonitis to have the abdomen opened and iodoform sprinkled in the cavity.

Dr. A. Reeves Jackson, President:

I feel an unusual degree of interest in the case which has been detailed to us, and in the accompanying specimen; also in the cases cited which seem to have a bearing upon it. Of course the interest centers in the pathological condition of the peritonæum. A case of similar character occurred to myself about nine years ago, in which was disclosed a state of the peritonæum such as has been described here to-night. It was an operation for removal of an ovarian cystoma, and as I turned back the lips of the abdominal incision, the appearance of that portion of the peritonæum covering the anterior and lateral abdominal walls alarmed me. I had never seen anything like it before, nor have I seen anything like it since until to-night. The affected portions of the peritonæum

were studded with thousands of little round, smooth bodies, averaging about the size of the ova of the shad, although some were smaller and some rather larger. They appeared to form a layer, beneath the epithelium. They were yellowish-gray in color, distributed on a steel-gray field. There was no redness of the peritonæum, and no peritonitis. Although I did not understand the nature of the condition, I considered it serious, and thought the case would be fatal. During the few days succeeding the operation there were three attacks of septicæmic symptoms, caused apparently by a recurring collection of bloody serum in Douglas' *cul-de-sac*, and which was each time relieved by puncture and evacuation. The patient recovered, and I saw her a year ago, a large, robust, healthy woman. I now suppose the little round bodies I saw were miliary tubercles; that their presence was caused by the irritation of the growing tumor.

Rindfleisch in speaking of miliary tubercle of the peritonæum, states that it originates in, and is usually confined to, the epithelium, although it may extend to any part in which connective tissue exists.

Dr. Wm. H. Byford.—Mr. President: I feel that the society owes Drs. Dudley and Fenger great obligation for the presentation of this subject in the manner they have, and I, for one, have been exceedingly interested in the case, and in the research made by Dr. Fenger in the literature of the subject. Of course I cannot be expected to say much upon the subject of tuberculous peritonitis; in the first place, because the subject is new, and in the next place, I have noticed such conditions in but one case. Seven years ago, last 4th of July, I was called to Iowa to operate upon a Norwegian woman who had an enormous ovarian tumor, weighing about 40 pounds. She was a good representative of the consumptive patient. She had begun to expectorate. Sometime before that there had been hæmatemesis. She was emaciated to the very last degree. Upon opening the abdominal cavity, a large amount of fluid escaped—5 to 10 pounds. The serum was not much out of the way in color. The tumor disclosed was of the multilocular variety, with one large cyst. On examination, the surface was found studded over with these small deposits, which I then believed to be simply fibrous, resulting apparently from ordinary inflammation. There was also in the fluid coming from the peritoneal cavity a large amount of flocculi of different shapes—round like shot, flat pieces, and elongated strings, amounting to several ounces. This induced me to believe that there was peritoneal inflammation, but it did not strike me then as being tuberculous. I did not examine microscopically. I now believe this patient had tubercular peritonitis. The tumor was removed the 4th of July. I put a drainage tube of rubber in lower end of the wound and left the patient in, as I thought, a moribund condition. Her pulse was exceedingly small and weak, and her face exceedingly pale. I had, however, two very skilful attendants to put in charge of the patient after I left. About three months after the time of the operation the patient was able to sit up, after long treatment by tonics, nutritious diet and hygienic measures. Drainage from the abdomen must have kept up over 6 months. It was certainly open several months. I saw the husband of the patient about 3 months ago, and he told me the cough gradually subsided, expectoration became less, she had gained flesh, and that she was a very healthy woman. I have had opportunity to see no other case that resembled anything like the appearances in this cyst, and I have operated about 150 times.

In relating the history of the case, Dr. Dudley mentioned the assertion by the patient that the tumor had bursted, that fluid was effused into the peritonæum, and that it had recurred again. I think this is not of very uncommon occurrence. I have noticed it a number of times in my life. Tumors of considerable size have appeared in the abdominal cavity, apparently disappeared, and in the course of some months fill up again, and finally have to be removed. I remember of removing two tumors from a patient wherein this same thing had occurred. I was glad to hear Dr. Dudley say that the diagnosis I made when I first saw the patient was probably true, and that the cyst may have originated from inflammatory conditions. I believe that occurrence often takes place. I do not mean to say the number of cases would be proportionably large, but that this condition occurs occasionally. I think I have known cases of the kind, where the symptoms of inflammation preceded for some months the ovarian tumor, and that where the tumor finally showed itself to result from inflammation. I would like to mention to the society as confirmatory of this probable method of origin of the tumor, the fact that during the last meeting of the American Gynæcological Society, I read a paper upon the subject of Pelvic Abscess, in which I took the ground that an abscess might be converted into a serous cyst, and mentioned a case under observation. I think it will be found in the future, by close observation, that sometimes ovarian cysts do originate in this way.

Dr. E. W. Sawyer—The report of the case, and remarks of the gentlemen who have preceded me, have been particularly instructive and interesting. The gynæcological aspect of the case I do not feel competent to discuss. If it is in order, however, to speak of the disease, so prominently mentioned in this case, I would like to confine my remarks to miliary tuberculosis. I have really been surprised at what I have learned here to-night. Living in the East and following the hospitals in New England exclusively, I have received different ideas on miliary tuberculosis from those expressed here to-night. First, I have been taught with great emphasis that miliary tuberculosis was an acute disease. I well remember the graphic manner in which Prof. Ellis was wont to describe and speak of cases of miliary tuberculosis before the class. * * * * The hospitals and private practice afforded numerous instances for the study of chronic catarrhal pneumonia, phthisis pulmonalis, many of these cases being the subjects of miliary tuberculosis. In the surgical wards, I have more than once seen cases of tuberculous testicle in which the victim died with miliary tuberculosis; in children also with basilar tuberculosis; in fact, under

all circumstances, the course of the disease was short. Such a thing as chronic miliary tuberculosis had never occurred to me before to-night; on that account, this meeting has been particularly interesting to me. Heretofore I would not have hesitated to make an unfavorable prognosis. I should have felt certain that death would have supervened quickly; not a matter of months, as stated to-night, but a question of but a few days or weeks.

Dr. S. then related the history of several cases terminating fatally in a few days, and in which the autopsy revealed tubercles in different organs, remarking that the evidence which these cases afforded confirmed him in the belief that miliary tuberculosis was an acute disease, and always fatal.

Dr. Fenger, in reply to Dr. Sawyer, expressed the opinion that miliary tuberculosis of the lungs is always acute; about the brain he did not know any more than others say, who have seen cases occur. Miliary tuberculosis of the serous cavities is not so acute; for instance, miliary tuberculosis of the pleural cavities. We know from experience it is not very quickly fatal, in no way so severe as in the lungs. Furthermore, tuberculosis of the serous cavities is a local affection, while tuberculosis of the lungs, for reasons which are apparent, is a constitutional malady.

CHICAGO MEDICAL SOCIETY.

The Chicago Medical Society held its annual business meeting in the parlors of the Grand Pacific Hotel on the evening of April 7, 1884, with Dr. D. W. Graham, President, in the chair, and Dr. L. H. Montgomery, Secretary.

There were present 88 members at the meeting, and there were heard the annual reports of the Secretary-Treasurer, the Committee on Library, the Auditing Committee, and reports of outstanding committees, all of which were duly received, and show the Society to be in a most flourishing condition, as may be seen from the appended report of the proceedings. The meeting concluded by electing officers for the ensuing year and appointing delegates to the American Medical Association, most of whom have pledged themselves to attend.

After the reading of the minutes of the last meeting, which remained approved as read, the Secretary's annual report of the proceedings of the Chicago Medical Society for the current year ending April 7, 1884, was presented:

Mr. President and Members of the Society:

During the year we have held nineteen regular meetings and one special meeting. Thirty-eight scientific essays and papers, written by thirty members, and a number of reports of cases in writing, have been presented with a larger number of pathological specimens than during any former year for a very long time, besides several instruments and mechanical appliances that have been exhibited.

Five hundred and four members and 134 visitors have attended twenty of the meetings, being in all 638 physicians and students, compared to 450 members and 120 visiting physicians, or 570 persons, in attendance during 1882, and 304 members and 99 visitors, or 403 persons in 1881.

The largest number in attendance at any of the meetings was about 100. The smallest number that attended any of the meetings is only 12. The average number of members in attendance at each meeting is $24^{14}/_{20}$, of guests $6^{14}/_{20}$, or a total of $31^{8}/_{20}$ compared to 30, the average number that attended the Society the year previous, and 24, the average attendance during 1881.

We have received into active membership 35 new members, (this number does not include the accessions this evening, which number 8), compared to 34, the number admitted in 1882, and 18 elected to membership during 1881; or 87, the entire number received in the Society during the three years' time of the present incumbent's *regime*.

The membership list one year ago consisted of 210 members, and 181 constituted the number at the close of the year 1881. An increase of 35 during the year would make the total membership 245. Of this number one has passed to the silent land, one resigned, and one left the city. This number of 3 deducted will leave a correct and accurate list of 242 members constituting this Society. There are others who have removed from the city that wish to retain their membership, so that out of our total membership some 6 or 8 are non-resident members, to which a reference will be added later.

Perhaps no part of the records will find more ready appreciation than the faithful *verbatim* reports of the discussions. I say faithful, as implying, as near as possible, that of a retentive memory, in addition to the comprehensive notes that were taken at the time of debate. And as discussion is clearly an important feature of our sessions, where they have appeared in print, an endeavor has been made to give to the profession everywhere most clearly the individuality of the members, and the views of those who participated, without partiality being shown to any one. The list of papers includes a varied assortment of topics, the best that has ever been written by the members and presented here. Doubts are entertained if there is a local scientific society in our country that has a better showing in this direction, if more than a few equal us in this respect. In many of the papers there was so much value, that they have been sought by other associations and re-read, as well as being quoted, in every instance in abstract form or in their entirety, in several medical journals.

A number of important committees have been appointed during the year, one of the most important of which is the Committee on Library. A review of their work has also been embodied in this report (for fear, perhaps, that they would not be present or prepared), but I notice its chairman present, and you will therefore hear from him in detail a more interesting report than this one.

Twenty delegates from this society attended the meeting of the American Medical Association in Cleveland last year, besides the other permanent mem-

bers of the Association from this society who attended, swelling the number to 34.

LISTON H. MONTGOMERY, Secretary.

65 Randolph St., April 7, 1884.

Upon motion by Dr. E. Andrews, duly seconded, the report of the Secretary, just read, was received and placed on file.

Synopsis of First Annual Report of the Committee on Library to Chicago Medical Society; Edmund Andrews, M.D., LL.D., Chairman:

APRIL 7, 1884.

Mr. President and Members of the Committee:—Your committee beg leave to submit the following report:

The value of money, books, and pledges placed at our disposal are as follows, viz.:

Appropriated by the society	$500.00
Contributed by physicians, dentists, and druggists	317.00
Money pledged by four gentlemen to meet transportation of books from Europe and other expenses	50.00
One hundred and ten volumes of books donated by various parties. Estimated cost value	155.00
	$1,022.00

Of the cash above stated, we have expended the following sums:

Paid W. T. Keener, of which $500 was paid by the Treasurer of the society according to the appropriation	$528.15
Paid for postage both ways on circulars sent to 1,500 men	63.00
Paid for stationery and printing	15.45
Paid for express charges and sundries	2.50
	$609.10
Which sum deducted from $817, the amount actually collected as above stated, leaves cash on hand	$207.80

This latter sum, with the $50 pledged by the four gentlemen, will more than cover the cost and transportation of books which we have ordered from Europe. The precise cost of the transportation cannot be ascertained beforehand. Several well-known works are omitted because new editions are about to appear, which will be best to defer purchasing until next year.

By careful economy of the funds, we have been able to purchase the Great French work, called the Dictionere des Sciences Medicales. One hundred and twenty "half volumes" are now out, and the rest will soon be issued. This magnificent work will give us the best thoughts of the French profession on every medical and surgical topic.

Then followed a list of 149 volumes purchased, with a list of 11 of the representative journals purchased.

The following journals have been donated: *The Chicago Medical Journal and Examiner*, THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, *The Weekly Medical Review.*

Mrs. George C. Clarke has donated 62 bound volumes, being a portion of the library of her father, the late Dr. J. W. Eldridge, one of Chicago's earliest eminent physicians. This collection is valuable, because it gives us almost the beginning of American, and some early English medical literature, many of the books being published in the previous century. Others having donated or contributed books, are: W. T. Keener, 3 vols.; Dr. Adam Miller, 1 vol.; Dr. R. B. Treat, 9 vols.; Dr. R. Ludlam, 9 vols.; Parke, Davis & Co., 11 vols.; Dr. A. B. Stockham, 3 vols.; Dr. A. H. Foster, 3 vols., worth at new price $30; Dr. Justin Hayes, 1 vol.; Dr. H. P. Merriman, 6 vols.; Anonymous Donor, Godding's Two Hard Cases; Dr. E. Andrews, 3 vols. The summary of volumes: Bought of W. T. Keener, 160 vols.; ordered from Europe, but not arrived, 74 vols.; books donated, 110 vols.; total, 344 vols.

We find an increasing interest and enthusiasm on this subject on the part of the profession, and plans have been laid before us for raising very much larger sums annually for a period of years.

It will be an easy thing comparatively to place on the shelves 25,000 volumes of medical works.

The authorities of the Public Library coöperate with us more cordially, and are now diligently at work cataloguing and shelving the books preparatory for use. In accordance with the advice of the society, which we heartily endorse, the Librarian will keep the books always ready for reading in the library, *and not loan them out.*

Very respectfully submitted,

E. ANDREWS, Cha'n
F. C. HOTZ,
OSCAR C. DE WOLF,
} Committee on Library.

Upon motion duly seconded, the report was received, accepted, and placed on file.

Dr. Edmund Andrews offered the following:

Resolved, That the thanks of this society be presented to Mrs. George C. Clarke, for the donation of 62 volumes of medical works for the Public Library, which was received with plaudits, and the resolution unanimously carried.

The following officers were elected for the ensuing year:

Dr. D. A. K. Steele, President.
Dr. Charles W. Purdy, 1st Vice-President.
Dr. Curtis T. Fenn, 2nd Vice-President.
Dr. Liston H. Montgomery, Secretary (re-elected).
Dr. E. Fletcher Ingals, Treasurer (re-elected).

Drs. Wm. E. Quine, G. C. Paoli, and D. R. Brower, committee on membership and miscellaneous business.

Dr. D. W. Graham, to fill vacancy on Library Committee, caused by Dr. Oscar C. DeWolf's time expiring.

The following delegates from the Chicago Medical Society were elected at the annual meeting of the Society, April 7th, 1884, to the American Medical Association for the year 1884.

Dr. F. M. Wilder,	Dr. W. T. Montgomery,
Dr. W. W. Allport,	Dr. E. F. Ingals,
Dr T. W. Miller,	Dr. C. T. Parkes,
Dr. R. E. Starkweather,	Dr. E. Burrons,
Dr. N. E. Rice,	Dr. A. Reeves Jackson,

Dr. J. G. Kiernan, Dr. Frank Billings,
Dr. J. F. Todd, Dr. E. F. Gaston,
Dr. W. E. Clarke, Dr. C. S. DeVeny,
Dr. Simon Strausser, Dr. C. J. Simons,
Dr. A. H. Cooke, Dr. Philip Adolphus,
Dr. J. E. Walton, Dr. T. W. Brophy,
Dr. J. S. Marshall, Dr. H. J. Reynolds,
Dr. L. H. Montgomery, Dr. J. H. Chew,
Dr. C. W. Chaffee. Dr. E J. Doering,

After the transaction of much additional business, including the presentation of the reports of the Treasurer and Auditing Committee, the society adjourned. LISTON H. MONTGOMERY, M.D., Secretary.

STATE MEDICINE.

STATE BOARD OF HEALTH OF CONNECTICUT.

BY DR. C. W. CHAMBERLAIN, SECRETARY.

MORTALITY IN FEBRUARY, 1884.

The report is delayed for several reasons, failure to receive one or two reports by reason of illness of the reporters, and absence on my own part in sanitary work in different parts of the State. If without too much trouble the reports could all be made by the 15th, this abstract could be made more promptly. There are many towns yet that no reports are received from. It is hoped eventually to secure a reporter in every place. When one once forms the habit, it is not much trouble to send a report of what has come under one's own observation. The places that are never named are those from which no reports are made, either regularly or at intervals. The number of our correspondents is steadily increasing, and now includes all regions of the State.

The month does not present as good a record as it should, for a short one. The total mortalities are too high, and the ratios are higher than those for the same months in previous years. The most noticeable event is the return of acute tertian ague. For some time past reports have been made of this recurrence, now here, now there, until it has extended over nearly all the region that has been invaded by malaria, where dumb ague and the like and the continued type of disease had been the rule. The last new start is reported from Middlesex county, from Durham and adjacent towns, thus completing the whole area, except here and there localities that have not yet showed the movement. It has been irregular both as to time and space, and at first suggests a renewed onslaught of malaria as it first appeared, but there is no increase in the periodic type, and, as a rule, after the appearance of quite a number of cases, the frequency diminishes and scattering cases continue to be encountered. As clearly defined cases of tertian ague had rarely been seen over a large area, where the decline of the periodic type and the decrease in malarial cases indicated an entire disappearance of the disease, the reappearance excites attention and the developments will be closely watched, to learn what the prospects are that the malarial type has become a permanent one. As typho-malarial fever still lingers in England, we may expect the same result here, but whether acute ague is to be a regular affliction is another question.

The epidemic of diphtheria continued unabated during February. In Hartford the death rate is even higher than in January, and the number from zymotic diseases and the infantile deaths are slightly increased over those of January. The total mortality since January, 1883, from croup and diphtheria is 295, a condition unprecedented in the sanitary history of the State. There is certainly a need for systematic sanitary work, which none but a well-organized board of health can accomplish. Fortunately, the scarlet fever did not spread, and since February there has been some decrease in the prevalence of diphtheria. As shown by the table, the disease has appeared in several cities. Bloomfield, Thomaston, Plainfield, Westport, South Manchester, Avon and North Manchester report several cases each. The disease is unusually common.

Scarlet fever appears in the table reported from several cities. In Glastonbury seven children in one family were attacked; two were buried in one grave, and the others were seriously sick, and the death of two children in another family is reported. In adjacent towns cases were reported—from North Manchester, New Canaan, Willimantic, Greenwich, New Hartford, Stafford Springs and Haddam—but no general prevalence.

Measels and whooping-cough are quite common. The former has been very prevalent in the northern part of North Manchester, and epidemic in Willimantic. Suffield and Plainfield also report cases. One fatal case is reported from Willimantic, and there are several in the cities.

Influenza and bronchitis have been more common than lung fever. For the last two years the maximum mortality from lung fever has been in the spring months, instead of the first quarter of the

year, as has been the general rule heretofore for a long time.

Malarial fever is extending into Windham county. Hampton and Plainfield report cases. A fatal case of thypo-malarial fever is reported from Granby, and with the exception of the developments before mentioned, are about the usual manifestations for the season.

The prominence of typhoid fever is indicated by the table, but it is more in the cities than in the country. The unusual prevalence of dysentery and diarrhœal troubles at this early season was noted last month. It is still more noticeable in February. A death from a severe type of dysentery occurred after a short illness in the southern part of the State. Quite a number of diarrhœal troubles are reported, one fatal in Granby, one in Plainfield, and an unusually large number of cases, both among children and adults, are reported from quite a number of places. Whether this is an indication of an increasing tendency towards choleraic disorders is an interesting question that will be closely studied. The month has been unfavorable to consumptives and to the aged, and marked by a prevalence of bronchitis and congestive lung diseases.

In the succeeding month small-pox appeared in Norwich from paper rags, and Waterbury near the quarters of the epidemic of two years ago. The disease is well under control by efficient work in both places.

PROPOSED IMPROVEMENT OF THE MEDICAL AND SANITARY SERVICES ON BOARD TRANS-OCEANIC PASSENGER VESSELS; THE BILL BEFORE CONGRESS.

The following bill (H. R. 6178), introduced by Hon. H. W. Slocum. of New York, was prepared by the committee appointed by the American Medical Association at the meeting in Cleveland in June last :[1]

SUPPLEMENT TO AN ACT ENTITLED "AN ACT TO REGULATE THE CARRIAGE OF PASSENGERS BY SEA."

Be it enacted by the Senate and House of Representatives of the United States of America, in Congress Assembled:

SECTION 1. That in every steamship or other vessel carrying or bringing passengers, other than cabin passengers, to the United States, there shall be properly constructed and separated from other parts of the vessel two compartments or spaces to be used exclusively as hospitals—the one for the men and the other for the women; such hospitals to be located on the main deck or the deck immediately below it, and never on any lower deck, and to be in no case less in size than the proportion of eighteen clear superficial square feet for every fifty such passengers and crew; and such hospitals shall be supplied with proper beds, bedding and utensils, and kept so supplied throughout the voyage.

SEC. 2. And every steamship or other vessel carrying or bringing passengers, other than cabin passengers, exceeding with the crew fifty in number, and less than six hundred, shall be required to carry a duly qualified, competent and *regularly licensed* surgeon or medical practitioner, and where the number of such passengers and crew is over six hundred, a junior or assistant surgeon, or medical practitioner, in addition, which surgeon and medical practitioners, junior and senior, shall be rated as such on the ship's articles, and shall be provided with surgical instruments, medical comforts, and medicines proper and necessary for diseases and injuries incident to a sea voyage, and for the proper medical treatment of such passengers and crew during the voyage, and with such articles of food and nourishment as may be proper and necessary for preserving the health of infants and young children; and the services of such surgeons or medical practitioners shall be promptly given without fee in every case of sickness, disease, or accident to any of the passengers or crew, or to any infant or young child of any such passenger who may require their services; and the medical officer, where there is but one, and the senior, where there are two, shall also be required to perform the duties of sanitary officers, to make daily inspections of all inhabitable portions of the vessel, and daily reports thereon in writing to the master of the steamship or passenger vessel, together with such suggestions and recommendations as in his judgment may be necessary to the preservation of health on board. He shall also exercise constant vigilance in regard to the condition of the provisions and water, and promptly report to the master anything which may appear to him to be deleterious to the health of any person on board.

SEC. 3. For the proper exercise of these functions, and the maintenance of the respect to which such medical and sanitary officers are entitled, they shall be provided with a steward or apothecary competent to dispense medicines under their direction, and for their special service, and their tenure of office, remuneration, and right to suitable quarters, subsistence and attendance, shall be upon the same basis as, and coördinate with the purser, first officer and chief engineer of the vessel on which they serve.

SEC. 4. For a violation of either of these provisions, or the disregard of the recommendations *made in writing* by the medical and sanitary officers, as herein provided, the company to which the steamship or other passenger vessel belongs shall be liable to a penalty not exceeding two hundred and fifty dollars in every case.

SEC. 5. That this act shall take effect and be in force from and after its passage.

[1] Dr. A. N Bell offered the following resolution, which was adopted by the Association :

Resolved, That, being impressed with the truthfulness and importance of the Memorial of the Parliamentary Bills Committee of the British Medical Association, under date of March 17, 1883, the American Medical Association urges upon the Congress of the United States the subject of competent medical and sanitary service, and proper provision for its maintenance on board all trans-oceanic vessels, and that a committee of five be appointed to promote this object, and to report again upon the condition of the subject at the next session.

The committee consists of Dr. A. N. Bell, New York; Dr. A. L. Gihon, U. S. Navy; Dr. I. N. Quimby, New Jersey; Dr. H. O. Marcy, Massachusetts; and Dr. Henry H. Smith, Pennsylvania.

DOMESTIC CORRESPONDENCE.

MEDICAL LAW IN VIRGINIA.

EDITOR JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

Sir :—That the members of the Association may be able to compare the several State laws for the regulation of the practice of medicine, I append a copy of the act which has recently passed the Legislature of the State of Virginia, for which I am indebted to Dr. Wm. C. Dabney, chairman of the committee of the Medical Society of Virginia, for whose active efforts in accomplishing this step in the right direction the profession is under obligations. The necessity for such a law is manifest, since up to the time of its enactment there was "no law whatever in Virginia with respect to the qualifications of persons offering themselves as practitioners of medicine. It was *not even necessary that the applicant for practice should be able to read or write.*

The usual effort was made to exempt from examination all persons holding diplomas, but very properly the law, as passed, does not recognize the diploma of any medical college as evidence of competency. The number of examiners through an oversight, has been made *thirty-two* instead of *twelve.*

The character of examination contemplated is shown by the following "proposed blank forms for questions" asked each applicant by each examiner, which form, after being filled up, is to be sent to the President of the Board, and to be read at the annual meeting of the Board.

Chemistry, 15 questions, such as, name the antidotes for corrosive sublimate and describe their modes of action.

Anatomy, 15 questions, such as, name the boundaries of Scarpa's triangle, and state what vessels and nerves are found within it, and give their relations to each other.

Physiology, *Ostetrics* and *Materia Medica*, each 15 questions.

Practice of Medicine and Surgery, 6 questions under each of the following headings :

1. Causes of—(example—State the causes of pneumonia, perityphlytic abscess. cerebral hæmorrhage. typhoid fever, etc.)
2. Symptoms and stages of—(example—pleurisy, bulbar paralysis, etc).
3. Pathology of—(example—Nephritis, diphtheria)
4. Diagnosis of—(example—Gout, rheumatism, pericarditis, etc).
5. Treatment of—(example—pneumonia, valvular disease of heart).

Six Surgical Operations—

The following is the text of the Act:

AN ACT TO REGULATE THE PRACTICE OF MEDICINE AND SURGERY.

Be it enacted by the General Assembly of Virginia :

1. There shall be for this State a Board of Medical Examiners, consisting of three members from each Congressional district in the State, and two from the State at large, whose term of office shall be four years, or until their successors are appointed and qualified. The term of office of the Board first appointed shall commence on the first day of January, 1885.

2 The said board shall consist of men learned in Medicine and Surgery, and shall be appointed by the Governor on the 1st day of November, 1884, and every fourth year thereafter, from a list of names to be recommended by the Medical Society of Virginia Vacancies occurring in such Board for unexpired terms, shall be filled in the same manner. Such recommendations shall be by the votes of a majority present at some meeting of the said Society, and the same shall be certified to the Governor by the President and Secretary of such meeting. Provided, however, that in case such Society fail to make such recommendations prior to the time of appointment, or if the Governor shall, in any case, consider the persons so recommended, or any of them, unsuitable, then he shall appoint such Board, either in whole or in part, without regard to such recommendations[1] If any of said examiners shall cease to reside in the district for which he was appointed, it shall vacate his office.

3. The members of said Board of Medical Examiners shall qualify and take usual oath of office before the county or corporation court of the county or corporation in which they shall respectively reside. The officers of said Board shall be a President, Vice-President and Secretary (who shall also act as Treasurer)—such officers to be members of and elected by said Board. The first meeting of the same shall be at Richmond, and such time as the Governor shall notify the members by mail to assemble. Subsequent regular meetings shall be at such times and places as the Board may prescribe, and special meetings may be had upon the call of the President and two members; but there shall not be less than one regular meeting per annum. Five members of said Board shall be a quorum; said Board may organize at its first meeting, and may, at its first or any subsequent meeting, prescribe rules, regulations and by-laws for its own proceedings and government, and for the examination of candidates for the practice of medicine and surgery by its individual members.

4. It shall be the duty of said Board, at any of its meetings, and of the individual members of said Board, at any time, to examine all persons making applications to them who shall desire to commence the practice of medicine or surgery in this State. When the examination is by an individual member of the Board, he shall report the result of the same to the President thereof; and when an applicant shall have passed an examination satisfactory as to proficiency before three individual members of said Board, or before the Board in session, the President thereof shall grant to such applicant certificate to that effect. A fee to be presented by said Board, but not to exceed five dollars, shall be paid to said Board (through such officers or members as it may designate) by each applicant before such examination is had. In case any applicant shall fail to pass a satisfactory examination before the Board or before the three individual members to whom he shall first apply, he shall not be permitted to stand any further examination within the next three months thereafter; provided, however, no applicant shall be rejected upon his examination on account of his adherence to any particular school of medicine or system of practice, nor on account of his views as to the method of treatment and cure of diseases.

5. The fund realized from the fees aforesaid shall be applied by the Board towards its expenses, including a reasonable compensation to the President and Secretary.

6. Any person who shall obtain a certificate as aforesaid from the President of said Board, shall cause his name to be registered in the Clerk's office of the County or Corporation Court for the county or corporation in which he shall reside; and it shall be the duty of said clerk to register the name of every such person presenting such certificate, together with the date thereof and the name of the President of the Board signing the same, in a book kept for the purpose as a part of the records of his court, which shall also give the date of each registration, and his fee for each registration shall be one dollar, to be paid by the person whose name is registered.

7. No person who shall commence the practice of medicine or surgery after the first day of January, 1885, shall practice as a physician or surgeon for compensation without having first obtained a certificate and caused his name to be registered as aforesaid. Any person violating the provisions of this section shall pay a fine of not less than fifty nor more than five hundred

[1] Amended then so as to give the State Medical Society three months in which to make new nominations.

dollars for each offence, and shall be debarred from receiving any compensation for service rendered as such physician or surgeon.

8. Any person who shall have been assessed with a license tax as a physician or surgeon by any Commissioner of the Revenue in this State at any time prior to the first day of January, 1885, shall be taken as having commenced the practice of medicine or surgery prior to that date; but any person who shall not have been so assessed shall be taken as not having commenced such practice prior to that date.

9. Any physician or surgeon who shall commence to practice after the first day of January, 1885, and who shall reside in an adjoining State within ten miles of the boundary line of this State, shall be entitled to stand the examination and receive the certificate hereinbefore provided for, and such certificate shall be registered as hereinbefore provided, in that county in this State which is nearest his place of residence; and such certificate and registration shall make it lawful for him to practice medicine and surgery.

10. Nothing in this act shall be taken as including or affecting in any way the practice of dentistry, nor shall it include physicians or surgeons residing in other States and called in consultation in a special case with a physician or surgeon residing in this State; nor shall it be construed as affecting or changing in any way the laws in reference to the license tax to be paid by physicians, surgeons and dentists.

Very respectfully, your obedient servant,

ALBERT L. GIHON,
Medical Director, U. S. N.

U. S. Naval Hospital, Washington, D. C., April 8, 1884.

FROM WASHINGTON.

On March 19, Dr. C. K. Mills, of Philadelphia, delivered the Toner lecture at the Smithsonian Institution, taking for his theme: "Premature Diseases among Men in Public and Private Life, brought on from Over Mental Strain." He said he was indebted for the suggestion of the subject of the lecture to Dr. Toner, who, from his long residence in Washington, had had an unusual opportunity of noticing the premature breaking down of men in public life, one prominent example being presented in the case of Vice-President Wilson, whose death was caused by over work and mental strain. He dwelt upon the effects of mental strain in producing pneumonia, Brights, and other diseases, and gave the marked symptoms which preceded the development of positive disease. Statistics showed the average age, taking all classes of men in the United States, to be about fifty years. In comparing a few of the most eminent English and American statesmen, the average age of the English was found to be seventy-two years, and that of the American seventy. The break-downs were apt to occur before the age of fifty. His opinion was that this premature decay began in the schools from over-stimulation to the brain where there was a difference of mental inheritance, which rendered natural to one what was laborious and next to impossible for an other.

A bill was introduced into the House of Representatives (No. 6108) on March 24, by Mr. McCord, to pay the College of Physicians and Surgeons, at Keokuk, Iowa, $25,000 for the loss by fire of their college and hospital buildings on April 17, 1863, while in use by the United States troops as a post hospital.

Bill 6165 was introduced in the House of Representatives by Mr. Laird on March 24, to make the pay of hospital stewards of the first class in the U. S. Army, the same as now paid to ordnance and commissary sergeants, $34 per month, and the additional pay for re-enlistment, as is now allowed by law.

Bill 1920 was introduced in the Senate by Mr. Mitchell, to appoint Dr. A. P. Frick an Assistant Surgeon, U. S. A., to date from Nov. 1, 1882, and to relieve him from the operation of general orders relative to requirements of all candidates for appointment in the Medical Corps.

Representative Barksdale has reported favorably, April 4, from the Committee on Commerce, House bill 4835, for the purchase of the property known as the Seamen's Retreat, in the town of Middletown, N. Y., consisting of 30 acres, at a cost not exceeding $280,000, and the use of the same for the purposes of a Marine Hospital at the port of New York. The committee say this enactment will do no more than put the port of New York on an equal footing with respect to Marine Hospital service with ports of less commercial importance. They say that New York is the only seaport city in the United States with a large population which has not been provided by the general government with a Marine Hospital.

Representative Rosecrans introduced a bill (H. R. 6265) March 31, declaring that acting assistant surgeons, having been regularly examined and found qualified, shall be eligible to appointment as assistant surgeons of the army, and authorizing the President to nominate such to fill vacancies. It was referred to the Committee on Military Affairs.

March 31, Representative Steele introduced a bill (H. R. 6277) to credit all officers of the Medical Department of the Army with whatever time they may have actually served, whether continuously or at different periods, as commissioned officers, or enlisted men, since April 19, 1861, either in the regular or volunteer forces of the United States. This was also referred to the Committee on Military affairs.

GARFIELD HOSPITAL.—The directors of this hospital have appointed as the staff of the hospital, the following: Consulting Surgeons, Drs. Fred May and N. S. Lincoln; Consulting Physicians, Drs. W. W. Johnston, J. Taber Johnson, and Dr. A. G. P. Garnett; Visiting Surgeon, Dr. J. Ford Thompson; Visiting Physicians, Drs. C. E. Hayner, and J. W. H. Lovejoy; Ophthalmologist and Otologist, Dr. Swan M. Burnett; Resident Physician, Dr. Cutts.

MEDICAL ASSOCIATION OF THE DISTRICT OF COLUMBIA.—The annual meeting of this association was held April 4. The officers are as follows: President, Dr. Joseph Borrows; Vice-Presidents, Drs. King and Johnston; secretary, J. F. Hartigan, and S. S. Adams, Treasurer. Drs. J. W. Buckley, J. W. H. Lovejoy, D. C. Patterson, J. T. Johnston, C. W. Franzoni, W. H. Taylor, C. E. Hazner, T. E. McArdle, and E. C. Morgan were appointed a standing committee The board of censors appointed consisted of Drs. J. O. Stanton, T. C. Smith, and T. E. McArdle. Delegates to the convention of the Amer-

ican Medical Association, are D. R. Hagner, A. Peter, T. C. Smith, W. W. Johnston, W. H. Taylor, L. Mackall, T. E. McArdle, W. G. Palmer, E. M. Schaeffer, G. B. Harrison, H. D. Fry, W. C. Briscoe, L. L. Freidrich, J. R. Bromwell, R. T. Holden, J. H. Yarnall, L. Tyler, J. Borrows, and H. E. Leech.

COSTAL EXSECTIONS AND EMPYEMA.

NEW ORLEANS, MARCH 24, 1884.

N. S. DAVIS, M.D., LL.D., Chicago, Ill.

Dear Sir:—Estlander's thoracoplasty, while conferring a great boon upon patients "across the water" suffering with chronic empyema or even hydrothorax, or pleuro-cutaneous fistula, is not a new surgical procedure in America. Our late Dr. Warren Stone advocated and utilized resection of the ribs for such cases more than 30 years since successfully. I have seen him perform it personally a little less than 20 years since.

The phenomena present in Estlander's cases are identical with those of more antiquated reports of cases, yet his detailed reasoning embodies more technical ground than is generally accredited to the conditions pro and con. Apart from the fistulous outlet, the late Dr. Stone usually selected the sixth and seventh intercostal space, as well as I can recall.

If this will be of any importance to your collected data, let all honor be paid to our native American surgeon within our own confines.

I am, respectfully,
GEO. N. MONETTE, M.D.

MEDICAL LEGISLATION.

EDITOR OF THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

In the issue of your Journal of April 5, under head of "Legal Regulation of the Practice of Medicine," a physician of Indiana offers an article from which we cull two points, viz.:

First. That the doctor thinks the medical men, members of the Legislature, could not agree as to the minutiæ of a bill to regulate the practice, and therefore efforts in that direction failed, and that any bill presented should be endorsed by the lay members.

Second. He advises the American Medical Association to formulate a bill or to advise as to provisions for such.

As to the first proposition, we think the doctor is correct, and this is the principal reason why, as chairman of Committee on State Medicine for Indiana, we advised, and the Committee reported to the State Medical Society, session of 1883, that no bill as emanating from the State Society, should be presented to or urged upon the Legislature, by any Committee of such society, but that the physicians should, if possible, guide the work of laymen in that direction.

The doctor's first proposition practically annuls his second, for the American Medical Association could only hope, by any action it may take, to reach the same class as can be reached by State Medical Associations. The formulation of an ideal bill by the American Medical Association to regulate the practice, will fail of its object, if that be to *assist in having the several State Legislatures* adopt the formulated bill and pass it to a law. The American Medical Association cannot reach the Legislatures as quick or as effectually as can the State Associations.

The truth is, we had better let the States alone and permit each to work its way. It might be well for the American Medical Association to *endorse* the *essential* feature of such a law, viz.: the separation of the examining from the teaching powers, but nothing more.

There are always fanciful and impracticable ideas put forward, but we must remember that as to the details of a bill for the purpose mentioned, what will be proper or acceptable in one State will not be so for another.

As for Indiana, the medical men who desire any law to regulate the practice, have about concluded to accept any one that has embraced in it the *essential* feature above mentioned. The people will also accept such; the field is well worked, and any re-arrangement to conform to some ideal law of intricate details, will work great hurt and perhaps destroy all.

THAD. M. STEVENS, M.D.,
Chairman Committee on State Medicine.

Indianapolis, Ind., April 7, 1884.

SPECIAL NOTICES.

THE AMERICAN MEDICAL ASSOCIATION.

SECTION OF PRACTICE OF MEDICINE.

Dr. John V. Shoemaker, of Philadelphia, Pa., Chairman, Dr. W. C. Wile, of Sandy Hook, Conn., Secretary.

The Chairman submits the official programme for the meetings of the Section of the Practice of Medicine, to be held in Washington, D. C., Tuesday, Wednesday, and Thursday afternoons, May 6, 7, and 8, 1884.

The following special subjects have been promised, and those who are announced to enter into the discussions have accepted and will be present.

1. Discussion on "A Contribution to the Clinical Study of Epilepsy," will be opened by Professor William Pepper, of Pennsylvania. Dr. Roberts Bartholow, Pa.; Dr. Horatio Wood, Pa.; Dr. J. S. Jewell, Ill.; D.r James T. Whittaker, Ohio; Dr. O. P. Hooper, Ark.: Dr. Eugene Grisom, N. C.; Dr. James E. Reeves, W. Va.; Dr. T. B. Lester, Kansas; Dr. Joseph P. Logan, Ga.; Dr. W. K. Bowling, Tenn,; Dr. John S. Moore, Mo.; Dr. James F. Hibbard, Ind.; Dr J. J. Caldwell, Md.; Dr. John A. Murphy, Ohio, and Dr. A. P. Grinnell, Vt., are expected to take part.

2. A discussion on the "Clinical Study of the

Heart Sounds," will be opened by Professor Austin Flint, Sr., of New York. Dr. Edward Janeway, N. Y.; Dr. William Pepper, Pa.; Dr. Frederick C. Shattuck, Mass.; Dr. John H. Bemiss, La.; Dr. Jas. Wilson, Pa.; Dr. Richard McSherry, Md.; Dr. Jas. R. Leaming, N. Y,; Dr. John S. Lynch, Md., and Dr. A. B. Palmer, Mich., are expected to take part.

3. A discussion on "Tuberculosis" will be opened by Dr. Henry F. Formad, of Pennsylvania. Dr. Austin Flint, Sr., N. Y.; Dr. William Welch, N. Y.; Dr. N. S. Davis, Ill.; Dr. George M. Sternberg, U. S. A.; Dr. R. S. Fitz, Mass; Dr. Henry O. Marcy, Mass.; Dr. James Tyson, Pa.; Dr. Edward Janeway, N. Y.; Dr. Charles Dennison, Col.; Dr. Henry F. Campbell, Ga.; Dr. W. T. Belfield, Ill.; Dr. Alonzo Garcelon, Me.; Dr. E. O. Shakespeare, Pa.; Dr. G. C. Smythe, Ind.; Dr. Harold C. Ernst, Mass.; Dr. W. Geddings, S. C.; Dr. Trail Green, Pa., and Dr. John Lynch, Md, will take part.

The following are also promised:—

Ayres, S. G., M.D., New Theory and Instrument of Diagnosis.

Bartholow, Roberts, M.D., subject to be announced later.

Crawford, S. K., M. D., Ætiology of Enteric Fever.

Duhring, Louis A., M.D., Dermatitis Herpetiformis.

Flint, Austin, Jr., M.D., Dietetic Treatment of Diabetis Mellitus.

Green, Trail, M.D, The New Officinal Chlorate.

Griswold, Gaspar, M.D., Irregular Apoplectic Attacks from Other Causes than Hæmorrhage and Embolism.

Janeway, Edward, M.D., Simulation of Pathognomonic Signs and Symptoms.

Jackson, S. K., M.D., Typhoid Fever.

Keyt, A. T., M.D., Retardation of the pulse in Mitral Insufficiency.

Linn, G. A., M.D., Specific Treatment of Diphtheria and Croup.

Marcy, Alexander, Jr., M.D., Muscular Hypertrophy of the Stomach.

Marcy, Henry O., M.D., The Germ-Theory of Disease.

Miller, J. P., M.D., Phthisis, its Successful Treatment.

Prentiss, D. W., M.D., 1. Importance of Uniformity in the Pharmacopœia. 2. A Plea for Greater Interest in the Pharmacopœia on the part of Physicians.

Reed, R. Harvey, M.D., Irritation of the Capsule of Glisson.

Schenck, W. L., M.D., Occult Causes of Disease.

Tyson, James, M.D., The Milk Treatment of Disease.

Welch, Wm. H., M.D, Pathology of Myocarditis.

Whittaker, James T., M.D., The Ætiology of Pericarditis.

Wilson, James, M.D., The Diagnosis of Tumors of the Anterior Mediastinum.

Accepted and approved by the Chairman of the Committee of Arrangements.

A. Y. P. GARNETT, M.D.

WASHINGTON, D. C., April 2, 1884.

RAILROAD NOTICE.

AMERICAN MEDICAL ASSOCIATION.

WILLIAM B. ATKINSON, M.D.,

Permanent Secretary, 1400 Pine Street, Southwest Corner Broad, Philadelphia.

TRUNK LINES EAST OF CHICAGO, ST. LOUIS AND CINCINNATI.

Allegheny Valley.	Baltimore & Ohio.
Boston & Albany.	Boston, H. T. & W.
Buffalo, N. Y. & P.	Chicago & Alton.

Phil., Wil. & Balt.	N. Y., Penn. & Ohio.
Pbg., Cin. & St. L.	Vandalia Line.
Wabash, St. L. & Pac.	

These roads agree to return delegates at one-fourth of the lowest unlimited rates from Washington to points within the territory embraced by the Trunk Lines.

Round trip tickets will not be sold, but delegates will be furnished with certificates that will secure the reduction upon the return trip.

VIRGINIA MIDLAND R. W. CO.

Round trip tickets will be issued on all their roads.

From local points 4½ cents a mile one way for the round trip.

From through points 4 cents a mile one way for the round trip.

These rates hold over the Richmond & Danville.

BOSTON, NORFOLK & BALTIMORE S. S. LINE.

Special rates.

Baltimore to Washington.....$ 9.50
Baltimore to Washington and return..... 19.00

with choice of following routes:

Boston via steamer to Norfolk; up Potomac river to Washington via steamer.

Boston via steamer to Norfolk and Baltimore; via B. & O. R. R. to Washington.

Return via either route or rail to N. Y., and Fall River Line to Boston.

Delegates living on railroads that run into Norfolk, can reach Washington by steamer, which leaves Boston daily, except Sunday, at 4 P. M.

Round trip tickets between Norfolk and Washington $1.50. State rooms $1. Meals $1.

SOCIETY NOTICES.

Office of Secretary State Medical Society,
No. 81 Twelfth Street,
Wheeling, W. Va., April 28, 1884.

Dear Doctor:—The Medical Society of the State of West Virginia will hold its seventeenth annual session at Clarksburg, commencing at 2 o'clock P. M., Wednesday, May 21, 1884.

The last meeting of the Society was rendered more than usually interesting by the intelligent discussion of the papers read. That the meetings may be made as profitable as possible to all who attend them, the subjects of the papers to be presented should be announced to the members before the meeting. To enable us to prepare and send out a programme, all those who contemplate presenting papers at the coming meeting are requested to send *the subject* at their earliest convenience.

We expect to secure reduced rates on railroads, and the Secretary will take pleasure in sending the necessary order to every member.

N. B.—The order for commutation must be procured before leaving home to attend the meeting.

Your ob't servant,
S. L. Jepson, Secretary.

MISCELLANEOUS.

We find some of the French journals are still venting their wrath upon our periodical medical literature, but as we cannot get the same amount of amusement out of their succeeding efforts as in the one published on page 277, and as our valued contemporary seems to think that publication *not* a kindly act, we forbear. But we really could not resist publishing that translation. The *Medical Record* has no cause to fear the publication of any such criticism in its own country; and it is so sweeping in its supposed application to the whole eternal Yankee Nation, with the saving clause at the end which singles out certain rapacious Anglo-Germans, that we could not allow it to remain in such obscurity.

Paralysis of the Little Finger of the Left Hand Following an Injection of Ether.—MM. Arnozan and Salvat report in the *Journal de Medicine de Bordeaux*, the case of a servant girl thirty-two years of age, who, while under treatment for broncho-pneumonia, received an injection of ether, by means of a Pravaz syringe, the needle of which was inserted under the skin of the internal surface of the left fore-arm, about its middle. At the time of the injection, pain was produced at the point of insertion; an hour or two later a swelling ensued of the size of a hen's egg, it was red, inflamed, and painful to the touch. When the patient wished to raise her hand, she felt a sense of weight from that point down to and including the hand. At the end of eight days, all these symptoms of pain and swelling had disappeared; but the day after the injection she noticed that the little finger was completely flexed upon the hand, and she could not move it in any direction. Fifteen days later movement returned, but much less marked than normal. She did not call attention to this until five weeks had passed from the time of the injection, when it was found that she could not raise her little finger to the level of the ring finger. It was possible to extend the two last phalanges, but not to influence by extension the first phalanx upon the metacarpal bones. There was no diminution in size of the fore-arm, or other deformation. If pricked with a pin, she felt the movement, but experienced no pain, except when it was passed deep. The anæsthetic surface so mapped out occupied the region of the ulnar nerve, the limits of anæthesia not being positive, as between the sensible and insensible points there was an intermediary zone. At the seat of the puncture were some small pimples, effaced easily by pressure, but they disappeared in from fifteen to eighteen hours, and there was no hæmorrhagic infiltration; these pimples were confined to the anæsthetic region. The application of electricity to the ulnar nerve produced a response of extension of the first phalanx, and under its systematic use for almost two weeks, perfect relief was afforded. There were no formications or pains in the anæsthetic region, the little finger simply felt heavy.

Hymeneal.—Atkinson—Smith. At their home, April 4, 1884, by Rev. W. W. Barr, D.D., S. Jennie Smith and William B. Atkinson, M.D., all of Philadelphia. No cards.

List of Changes in the Stations of Medical Officers, U. S. Navy, for the Week ending April 12, 1884.

P. A. Surgeon S W. Battle, ordered before Retiring Board.

Surgeon H. M. Wells, detached from Naval Hospital, New York, to report at Bureau for special duty.

P. A. Surgeon C. T. Hibbett, placed on waiting orders.

Surgeon H. Stewart, placed on retired list from April 10.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department United States Army, from April 5, 1884, to April 11, 1884.

Sutherland, Charles, Colonel and Surgeon, to be relieved from duty in Division of the Pacific, and to report to the Commanding General Division of the Atlantic for duty as Medical Director of that division and of the Department of the East. (Par. 4, S O. 7, 8, A. G. O., April 4, 1884.)

Bailey, Elishael, Colonel and Surgeon, ordered to report to the Commanding General Division of the Pacific for duty as Medical Director of that Division and of the Department of California. (Par. 4, S. O. 78, A. G. O., April 4, 1884.)

Smith, Joseph R., Major and Surgeon, directed to represent the Medical Department of the Army at the Annual Meeting of the American Medical Association, to be held at Washington, D. C, on the 6th of May, 1884, and on the adjournment of the Association to return to his proper station, San Antonio, Texas. (Par. 7, S. O. 81, A. G. O., April 8, 1884.)

Sternberg, George M., Major and Surgeon, ordered to be relieved from duty in the Department of California, and to report to Commanding General of the Department of the East for assignment to duty.

Moseley, Edward B., Captain and Surgeon, ordered to be relieved from duty in the Department of the East and to report to the Commanding General of the Department of the Columbia for assignment to duty. (Par. 4, S. O. 78, A. G. O., April 4, 1884.)

Wilcox, Timothy, Captain and Assistant-Surgeon, ordered to be relieved from duty in the Department of the Columbia, and to report to the Commanding General of the Department of the East for assignment to duty. (Par. 4, S. O. 78, A. G. O., April 4, 1884.)

Official List of Changes of Stations and Duties of Medical Officers of the United States Marine Hospital Service—January 1, 1884, to March 31, 1884.

Fessenden, C. S. D., Surgeon; to proceed to Cairo, Illinois, and Memphis, Tennessee, as Inspector. March 5, 1884.

Purviance, George, Surgeon; granted leave of absence for 30 days, February 16, 1884.

Smith, Henry, Surgeon; to rejoin his station at Norfolk, Virginia, March 7, 1884.

Irwin, Fairfax, Passed Assistant-Surgeon; relieved from duty at Norfolk, Virginia, to assume charge of Cape Charles quarantine station, March 7, 1884.

Carmichael, D. A., Assistant-Surgeon; to report to Surgeon Purviance for examination for promotion, March 5, 1884.

Armstrong, S. T., Assistant-Surgeon; to report to Surgeon Fessenden for examination for promotion, March 5, 1884.

Bennett, P. A., Assistant-Surgeon; leave of absence extended ten days, Jan. 18, 1884.

Ames, R. P. M, Assistant-Surgeon; detailed for temporary duty on relief boat; Ohio River flood sufferers, Feb. 16 and March 1, 1884.

Devan, S. C., Assistant-Surgeon; upon expiration of leave of absence to proceed to St. Louis, Missouri, for temporary duty Feb. 6, 1884.

Kalloch, P. C., Assistant-Surgeon; to proceed to Charleston, South Carolina, for temporary duty, Feb. 1, 1884.

Bevan, A. D, Assistant-Surgeon; granted leave of absence for seven days, March 13, 1884.

Wasdin, Eugene, Assistant-Surgeon; granted leave of absence for fifteen days, March 4, 1884.

Battle, K. P, Assistant-Surgeon; to proceed to New York, N. Y., for temporary duty, Feb. 4, 1884.

RESIGNATION.

Cooke, H. P., Passed Assistant-Surgeon; resignation accepted by the Secretary of the Treasury, to take effect Feb. 5, 1884, Jan. 31, 1884.

APPOINTMENT.

Battle, Kemp P., M.D., of North Carolina, having passed the examination required by the Regulations, was appointed an Assistant-Surgeon by the Secretary of the Treasury, February 2, 1884.

PROMOTIONS.

Carmichael, D. A., Passed Assistant-Surgeon; promoted and appointed Passed Assistant-Surgeon by the Secretary of the Treasury, from March 1, 1884, March 18, 1884.

Armstrong, S T., Passed Assistant-Surgeon; promoted and appointed Passed Assistant-Surgeon, by the Secretary of the Treasury, from April 1, 1884, March 28, 1884.

OFFICERS OF

THE AMERICAN MEDICAL ASSOCIATION

AND OF ITS SEVERAL SECTIONS 1883–4.

PRESIDENT.

Dr. AUSTIN FLINT, SR., of New York.

FIRST VICE-PRESIDENT.

Dr. R. A. Kinloch, Charleston, S. C.

SECOND VICE-PRESIDENT.

Dr. T. B. Lester, Kansas City, Mo.

THIRD VICE-PRESIDENT.

Dr. A. L. Gihon, United States Navy.

FOURTH VICE-PRESIDENT.

Dr. S. C. Gordon, Portland, Maine.

PERMANENT SECRETARY.

Dr. Wm. B. Atkinson, 1400 Pine St., Philadelphia.

TREASURER.

THE BACILLUS TUBERCULOSIS AND THE ÆTIOLOGY OF TUBERCULOSIS.—IS CONSUMPTION CONTAGIOUS?

SECOND COMMUNICATION.

[Read before the Philadelphia County Medical Society, Nov. 14, 1883.]

BY H. F. FORMAD, B.M., M.D.

Lecturer on Experimental Pathology and Demonstrator of Morbid Anatomy in the University of Pennsylvania; Mütter Lecturer in the College of Physicians of Philadelphia.

(Continued from page 153, vol. ii.)

V.—THE BACILLUS TUBERCULOSIS—ITS NATURAL HISTORY, MORPHOLOGY, DETECTION, HABITAT, SIGNIFICANCE, AND DIAGNOSTIC VALUE.

I will now speak about the bacillus proper, and will allude here briefly to its natural history, morphology, habitat, significance, detection and diagnostic value.

The bacillus discovered by Koch, of Berlin, as is well known, is a vegetable organism, and belongs, according to Cohn's classification, to the group of filamentous bacteria (Desmo-bacteria), variety Bacillus.[1]

The tubercle-bacilli form, according to Koch, a species of bacillus by themselves, and on Koch's authority as a *mycologist* we can accept this statement as correct until proved otherwise.

The tubercle-bacilli present themselves as thin, slender rods, in length varying from one-third to the whole of the diameter of a human red blood-corpuscle; in breadth they do not exceed one-fifth to one-tenth of their length. They vary in size in different locations, and, according to observations made by myself conjointly with George Bodamer, my assistant, they vary also greatly in size in different artificial culture-media. In nearly dry soils they appear, as a rule, much smaller than in moist soils. They are blunt at the ends, and frequently contain unstained spores in varying number, which give them a beaded appearance that might be (and has been) mistaken for short torula chains of micrococci. The rods are sometimes slightly curved, and they frequently appear in pairs, forming a V-shaped figure; occasionally the rods are seen crossing one another. Often they appear within animal cells in tissues and other matters which they invade, quite isolated and scanty, so that there may be seen only a few bacilli, or only one bacillus, in a whole microscopic field. Sometimes they occur in large, dense masses, particularly so and most commonly within and around cheesy fragments met with in the contents of lung cavities, as Koch himself first pointed out.

It may be of interest to note that tubercle-bacilli may considerably multiply in sputum when it stands in a bottle for some time, as first observed by Bodamer in my laboratory. Williams, of the Brompton Hospital for Consumptives, records also that he has seen the bacilli multiply in sputum after standing in a room for ten days.

For demonstrative purposes it is well to inspissate tuberculous sputum, or to dry it (as I have seen in Koch's laboratory); for examination it is then moistened with water, and it will then show more bacilli than when fresh.

The methods of detecting the bacillus are so well known that I will not consider in this communication the merits of the different dyes employed. Moreover, success does not depend upon the method or the dye, but mainly upon the skill and the accuracy of the dyer,[1]

As is generally known, the principle in staining bacilli rests upon the fact that bacteria absorb and retain aniline dyes more readily than do the surrounding animal organic materials which they inhabit. When sputum dried upon a glass cover, or a section containing them, is well stained, for instance by aniline violet, and then washed in very dilute nitric acid, only the bacilli will retain the dye, while all the rest of the organic material composing the specimen will be decolorized, and may readily be stained by some other dye without modifying the violet color of the bacilli.[2]

A magnifying power of four hundred diameters is

[1] The statements made by Beneke, Klebs, and Schmidt, that the bacilli are crystalline bodies, have been withd awn; while views to the effect that "bacilli" are to be identified with blood-fibrin, etc., were at no time taken into serious consideration by microscopists.

[1] To detect bacilli is a very simple matter, although by far not so easy as to prepare a specimen of urine and to find the all-important tube-casts; and yet how many physicians (even those perfectly familiar with microscopic technology) will be sure when they discover tube-casts, if they attempt to examine the urine at all?

[2] The staining fluids for bacilli we more commonly use are those after Ehrlich's formula, slightly modified:

nearly always sufficient to detect stained tubercle-bacilli. In fact, we found that where we failed to find bacilli with a good one-fifth objective, neither our one-twelfth Zeiss oil immersion lens nor the Abbé's condenser would reveal any when used (as we always do) for control. If the bacilli are very numerous (as sometimes in lymphatic glands), a mass of them may be recognized easily by the naked eye in a well-stained section as a small stained speck.

Occasionally bacilli may also be seen when unstained. Baumgarten[1] discovered the same tubercle-bacillus simultaneously with, and independently of, Koch, in unstained caustic potash preparations of tubercle-tissues. Koch[2] also states that tubercle-bacilli may be readily seen, especially in artificial tubercles when simply teased in water, or preferably in blood-serum. We have also observed tubercle-bacilli, without resorting to staining, in cultures such as chicken bouillon, identifying them subsequently by means of the usual staining process. In stained preparations too much washed in acid, or in specimens ill preserved, a part or all of the tubercle-bacilli may also be seen decolorized, though still quite distinctly visible.

Tubercle-bacilli are, as a rule, motionless as seen in stained preparations made from the substances they inhabit; but the observations of Bodamer and myself appear to show that the bacilli of Koch may also have an actual (not communicated) motion when for some time cultivated in liquid media. But at the same time, it was observed that the development of the cultures was not as extensive in liquid media (bouillon) as in a solid medium (coagulated blood-serum). Conversing with Koch on this point last summer, he remarked that this was quite possible, and suggested that perhaps the bacilli in their movable state acquire flagelli or cilia at the ends, although he had not yet made such observation. Koch, quite properly, does not seem to consider that motion is an invariably differentiating feature for bacteria.

In cultures (coagulated blood-serum being the preferable nidus) the tubercle-bacilli grow as a dry, scaly, tortuous, whitish-gray mass, spreading themselves exclusively on the surface. The growth is very slow, and is favored by a temperature of 30° to 40° C. (86° to 104° F.)

Dr. Koch kindly demonstrated to me a number of specimens of bacilli, and in particular the appearance of these bacteria exhibiting under low amplification the peculiar S-like figure in the growths in masses. Koch seems now to lay more stress upon this low-power appearance, and upon the pathogenetic properties of the bacillus tuberculosis, as a distinguishing feature from other bacilli, than upon the color test. During the conversation he admitted that some other bacilli may also yield the same micro-chemical reaction as the tubercle-bacilli, but insisted that the latter bacilli cannot be stained brown. The failure of the tubercle-bacilli to take the brown stain, he said, was the reason that they cannot be well photographed (blue- and red-stained objects not being suitable for photographing). He obligingly explained to me the details of his methods and the determination of the value of cultures. I learned from him that those cultures in which the bacilli have no spores are not capable of propagation, nor are they fit for inoculation of animals.

Klebs, to whom Koch had given some of his cultures of tubercle-bacilli, declared that they also contained micrococci. Kock presumes that Klebs has misinterpreted the granules of the coagulated blood-serum (in which they grew) as micrococci. I can testify that bacilli alone were present in those cultures of Koch which I had the opportunity of examining. This is also true of a bacillus-culture in a flat salt-dish obtained from Koch's laboratory by Dr. Shakespeare, of this city; this culture was still perfectly pure (and free of micrococci) when examined by Dr. Shakespeare and myself, three months after the arrival in America.

Concerning my own bacillus cultures which I recommended last autumn (and which are now more often successful than before I went to Berlin, through the use of the complete outfit of Koch's apparatus, supplied by the University of Pennsylvania) I will report later. But it may be said that, even under the most favorable conditions, to obtain success with the tubercle-bacillus culture is at times a difficult task.

Before leaving this part of the subject, I must say that I owe many thanks to the director of the German Imperial Board of health, Dr. Struck, and to Dr. Koch and his assistants, for the very liberal and kind treatment which they extended to me in their laboratory; also for allowing me to study the whole working of their famous institute, and demonstrating to me their methods of work, including the construction of their ingenious apparatus, and permitting me to exercise all the important manipulations in bacteridian studies after Koch's method; and, furthermore, for allowing me to prove that I had succeeded also in staining and recognizing the tubercle-bacillus before I went to them.

I cannot blame Koch for not demonstrating to me how to produce genuine induced tuberculosis with his bacillus within eight days, a favor which he extended only to Watson Cheyne;[1] not because I have not yet the "faith" in the infallible action of the tubercle-parasite, but because Koch was then working at the subject himself, and does not consider the task as much finished as his over-zealous followers do. I was, moreover, informed, while in his laboratory before leaving Berlin, that no one besides himself and

First Stain.—Watery saturated solution of aniline oil, five parts; alcoholic saturated solution of aniline violet, one part; mix and filter.

Second Stain.—Watery solution either of vesuvin or of Bismarck brown; filtered.

Direction for Preparation and Order of Staining.—Sputum in thin layer smeared upon glass cover and *well* dried; immerse (*a*) into first stain for twenty-four hours (rapid staining being not reliable in doubtful cases); (*b*) into dilute nitric acid (one to five parts of water) for two or three seconds; (*c*) wash in alcohol; (*d*) into second stain for two to five minutes; (*e*) wash in water and then in alcohol; (*f*) dry it and mount in Canada balsam or glycerin. Failures to detect bacilli will occur; first, when specimen consists of salivary mucus instead of expectorated material; second, when sputum too thick or too thin is smeared upon cover; third, when not enough heated in drying, or when burned; fourth, when too long in acid; fifth, when too much washed; sixth, when bacilli are absent; seventh, when not recognizing them.

For preparations to be kept, and for tissues, the fuchsine dye, as first stain is preferable, and certain modifications of method necessary.

[2] *Berliner Klin. Wochenschr.*, 1882, No. 15.

[1] See *Practitioner*, April, 1883, page 249.

his assistants ever worked in the laboratory on the tubercle-bacillus beyond staining tissues, sputa, etc., containing it. Besides, the cultivation of the tubercle-bacillus takes a longer time than usually is allowed to outsiders who come to be instructed in Koch's laboratory.[1]

The Habitat of the Tubercle-Bacillus.—After reading most of the numerous compilations in reference to the present standing of the tuberculosis question, it would seem that Koch has established that his tubercle-bacillus is always associated with tuberculosis, and with the diseased products and the various excreta in this disease—and in this disease alone. Since Koch's publication appeared, a number of observers, authoritatively and otherwise, assert the invariable presence of the bacillus in *all* tubercular products; and, further, it is claimed as a proved matter that the bacillus is found in the beginning of the disease—viz., in the youngest tubercle-tissues.

This is, however, not in accordanee with the facts. Neither in Koch's own publication, nor in the records of any microscopist (when the original papers are examined), is the invariable presence of the bacillus in tuberculous lesions or excretions, and its absence in non-tuberculous matters, either clearly shown or proved. Moreover, the authors of nearly all the literary productions are in favor of the contagiousness of tuberculosis, and they disregard, as a rule, the negative evidence.

The question of the occurrence, and partly that of the significanceof the bacillus called by Koch the *tubercle-bacillus* in tuberculous lesions, divides itself into several parts, and hinges upon the results of the following investigations:

1. The examination of tissues affected by tubercular disease for the bacillus; and, if present, the time of its occurrence.

2. The examination, *intra vitam*, of blood of tubercular patients.

3. The examination of the products discharged or eliminated with the excretions by individuals suffering from tubercular disease.

4. The examination of air,—viz., of the breath of phthisical patients, and of the air of sick-rooms and hospitals generally.

5. Comparative studies in animal tuberculosis.

6. The occurrence of bacilli in lesions and substances other than tubercular.

I will state now, briefly, what so far have been the results of the investigations upon these points.

1. Tubercle-bacilli have been detected quite often in the various forms of tubercles of lung, and in scrofulous and tuberculous lymphatic glands; and likewise, although not so frequently, in tubercles of the various serous cavities; and in tubercular ulcerations of the mucous membranes and the skin. But it must be noted that only a few microscopists have recorded examinations of tubercle-tissues for bacilli, and among these there was *not one* who did not meet with a case or a certain number of cases in which tubercle-bacilli were either totally absent in the tissues, or only present in some of the tubercles. The great bulk of bacillus work done comprises merely examinations of sputum.

The facts concerning bacilli in tissues are as follows:

Koch[1] found bacilli in the majority of tuberculous lesions he examined, but still not in all, as he states himself: he only *supposes* that his bacilli, even if they escape observation, are still present in all cases and in all tubercles. His proposition, however, that in some tuberculous lesions only unstained spores of tubercle-bacilli are sometimes present, or that bacilli may be invisible, and not taking the staining when dead, or even may be absent if the tuberculous process comes to a "stand-still," is, of course, purely hypothetical. There is still another good reason for the assumption that the proportion of non-bacillary tubercles may be much larger in Koch's own examinations. As Koch says himself, he preëminently recognizes only such structures as tubercular which contain his bacillus, regardless of their morphology otherwise; it is therefore possible that he may have innocently excluded a number of non-bacillary tubercles from the list of his tubercle records. Koch himself, however, says that he failed to detect bacilli in some scrofulous glands, and in two cases of tubercular synovitis, and further admits the prevalence of bacilli in degenerated tissues.

As far as examination of tubercle-*tissues* for bacilli is concerned, only the following observations besides those of Koch are recorded (so far as is known to the writer), and with the following results:

Dr. Geo. M. Sternberg, U.S.A.,[2] who is a man recognized as a competent mycologist, here as well as in Europe, failed to find tubercle-bacilli in the lesions of several cases of tuberculosis.

Heneage Gibbs[3] also failed to discover bacilli in a number of tubercles, particularly in the reticular form; in fact, he had met several times with non-bacillary tuberculosis. Gibbs states[4] that "he had examined the lungs of guinea-pigs which had become tuberculous after being kept in the air-shafts of the Brompton Hospital for Consumptives, and had found no bacilli in them; and he knew of an instance in which a guinea-pig, inoculated with sputum from a case of phthisis, presented a glandular abscess in the thigh which abounded in bacilli, whereas the internal organs, although full of tubercles, did not yield a single bacillus."

I do not think it is likely that Heneage Gibbs, with his large experience and universally recognized skill in bacteria-stainings, would fail to discover bacilli if they had been present.

[1] I found that the "pilgrims from all nations" who (through influence brought to bear upon the authorities) succeed in being admitted for a while to Koch's laboratory, are instructed principally in the most rudimentary manipulations of mycology; and to most of them the assistants have first to point out what a bacterium looks like. Besides these "pilgrims," the German Government sends regularly young sanitary officers to be instructed in mycology. Of course this is a very useful matter to the "pilgrims" and to the young sanitary officers, even if only one out of twenty-five ever devotes himself to mycology; but it is no beneficial matter to Koch and his kind assistants, who, through this constant interruption, are terribly interfered with in their scientific work. In fact, the working of the Imperial Laboratory is sometimes completely delayed in this way, as it was last summer, during the Hygenic Exhibition. Yet the beneficial influence upon sanitary science which this excellent institution exerts is very great.

2 Phila. *Med. News*, 1882.
3 London *Lancet*, February 24, 1883.
4 *Lancet*, February 12, 1883.

Watson Cheyne,[1] whose anatomical conception of tubercle is inseparable from the bacillus, of course says that non-bacillary tubercles, like the above, are no tubercles at all. Hence his statement, that in all tuberculous structures (that is, in all structures which *he* calls tubercle) the bacilli are invariably present, is, from his standpoint, perfectly warrantable. He also confirms the fact that recently-formed tubercle-nodules made up of young lymphoid cells are, as a rule, without the bacilli, while the older tubercles, always containing epitheloid cells (on account of retrograde changes), usually do contain bacilli. Now, Watson Cheyne, in this connection, with great self-confidence propounds, "The bacilli being the cause of this disease (tuberculosis), only the nodules containing epitheloid cells are tubercle."[2] Still, the same writer has expressed surprise[3] that "very extensive tuberculous processes may be found in animals with only very few bacilli."

T. M. Prudden, of New York,[4] who made extensive and excellent morphological studies in reference to the occurrence of the bacillus in tuberculous lesions, *failed to find bacilli in any part of the body in three cases of profuse tuberculosis*. In one case of Prudden's, the tubercle-bacilli were abundant in the walls and edges of a lung cavity and its immediate vicinity, while no bacilli could be found in the diffuse and miliary tubercles of the rest of the body. Prudden further states, "In a large proportion of the cases in which bacilli were present; they seemed to have a decided predilection for tubercle-tissue in a degenerated and disintegrating condition, either cavities in the lungs, cheesy and breaking-down areas, or tubercular ulcers; although present with great frequency in small numbers in well-formed, intact tubercle-tissue. * * * The bacilli were present in greater abundance in the respiratory organs and intestinal tract than in other parts of the body less directly in communication with the external world. It is further evident that in nearly every case there are many miliary tubercles of all forms, and in many cases much diffuse tubercle-tissue, from which the bacilli appear to be entirely absent."

Spina[5] did not succeed in detecting bacilli in a number of cases. Even if the number of Spina's failures to see the bacillus should be larger than in cases of other observers, Koch's favorite demolishing argument that Spina and all others who failed to detect the bacillus in any case do not know *what* that parasite of his looks like, is entirely unjustifiable. Moreover, Spina's work was controlled by no less an authority than Stricker, of Vienna, and the correctness of the results of the investigation in its essential parts is vouched for by Stricker.

Cornil and Babés[6] detected the bacillus in the lesions of a number of cases of tuberculosis; but they also showed that bacilli are totally absent in some cases, and not constant in otherwise typical tuberculous lesions.

Malassez and Vingal,[1] from the results of observations of their own, state that there seems to be no doubt that true tuberculous lesions occur which possess very few or even no tubercle-bacilli.

Fräntzel,[2] in a discussion before the Berlin Medical Society, stated that he found a number of scrofulous (tuberculous) ulcers and lymph-glands not to be "bacillary."

C. Macnamara[3] reports a case of primary tuberculosis of bone and of the marrow of bone, in which no trace of tubercle-bacilli could be discovered in any of the lesions.

George Bodamer, having succeeded in staining and demonstrating the bacillus in sputum and in tissues in the spring of 1882 (immediately after the announcement of its discovery and the method of its staining by Koch, and probably prior to any one else in America), and having worked together with me nearly incessantly in bacillus stainings and cultures ever since, (including also a certain time in the pathological institutes in Germany), also failed to detect the bacillus in a certain number of typical tuberculous lesions of various kinds.

As will be seen from my report, I found tubercle-bacilli to be absent (or I could not detect them, if this expression should be preferred) in four cases of primary peritoneal tuberculosis, in two cases of primary tubercular pericarditis, in one case of tubercular joint-disease, and in several cases of miliary tuberculosis; this does not include some cases of induced animal tuberculosis which did not show bacilli.[4]

Dr. Lawrason, of New Orleans, who worked with me last spring in the pathological laboratory of the University, and who had demonstated his skill in staining bacilli in tissues before the Pathological Society of Philadelphia and elsewhere, also found tubercle-bacilli wanting in some of the most typical tuberculous lesions.

Weigert, Bollinger, Baumgarten, Ziel, Councilman, Schuchart, and Krause, and Koch's own assistants, are yet to be mentioned as having recorded a few examinations of tuberculous tissues for bacilli with negative and varying results; but detailed statements of their investigations in this direction are not known to me.

The direct conclusion to be drawn from the total evidence relating to bacilli in *tissues* just quoted is, that tubercle-bacilli are not invariably present in even typical tuberculous lesions; furthermore, that none of the investigators brought forward any proof or evidence that the bacilli are present or appear in the beginning of the disease. On the contrary, the results of the investigatons of all observers, including those of the discoverer of the bacillus himself, point plainly towards establishing the fact that tubercle-bacilli inhabit preëminently disintegrated tissues.

2. *Examinations of the blood and lymph intra vitam* of patients suffering from tubercular disease, which

[1] *Practitioner*, April, 1883.

[5] Studi n über Tuberculose, Wien, 1883,
[6] *Le Progrès Médical*, 1883.

[1] *Le Progrès Médical*, No. 20, 1883, and in a second communication quoted by the *Lancet*, Dec. 15, 1883.
[2] *Berliner Klin. Wochenschr.*, December, 1883.
[3] *Brit. Med. Journal*, Dec. 15, 1883.
[4] At this point I wish to correct an impression which a certain statement in one of my former communications on this subject seemed to convey—namely, that bacilli are invariably present in tuberculous products.

in my opinion would be quite an important matter in the study of tuberculosis, are not recorded by any observer. All attempts which we made in examining the blood of tuberculous patients during life gave, as will be recorded later, negative results. It is true that we observed in specimens post-mortem some blood-vessels filled with thrombi containing a few bacilli. Further, there are records by Cornil, Weigert, Ponfick, and Koch relating to bacilli observed post-mortem in the walls of veins, of large lymph-ducts, and of arteries, in tuberculous cases. As to the route and manner by which the bacilli gained entrance to these places, inferences might be drawn, but no definite conclusions arrived at until the bacilli have been observed during life in the blood or lymph. I will not touch upon this part of the question at present.

The blood from cases of hæmoptysis as expectorated has been examined by Hiller[1] and Williams,[2] and bacilli discovered, but no inference from this can be made as to the bacilli in the circulating blood.

3. *Examination of products discharged or eliminated with the excretions* by individuals suffering from tuberculosis has been practiced quite extensively, and by a number of observers especially in reference to phthisical sputum. To these sputum-examinations I will return immediately.

There are a few investigations recorded in reference to tubercle-bacilli in the fæces, in discharges from the ears and in those from the nose, and in urine voided by patients affected with local tuberculosis of the pertaining parts. Tubercle-bacilli were often detected, and thus a diagnosis of tubercular enteritis, tubercular otitis, and tubercular meningitis, (if bacilli in nasal discharge) and tuberculosis of the urinary tract, was made.

The tuberculous nature of ulcers, of synovitis, and of surgical lesions of various locations, it is claimed has been occasionally settled (?) in this way.[3] But, on the other hand, the discharges from some typical tuberculous lesions failed to show bacilli.

Damsch[4] claims that tuberculosis of the genito-urinary tract can be diagnosticated by inoculating a drop of urine from such a case into the anterior chamber of the eye of a rabbit, which operation will be followed promptly by iris tuberculosis in the animal. This latter observation, however, I believe, requires confirmation.

The examinations of sputum, practiced now probably by all microscopists in the world, proved to be of much more value. I will quote the observers who made and recorded more or less extensive examinations of sputum, and the results and conclusion they arrived at, to show that there are some points which are misinterpreted by some clinicians and others.

Koch[5] does not claim that sputum from every phthisical case contains bacilli; he met with cases without bacilli in sputum. He did not find, however, bacilli in cases said not to be tubercular.

[3] Schuchart and Krause, in Volkmann's Clinic, Chirurg. Centralblatt, 1883.
[4] Deutsch. Arch. f. Klin. Med., 1882.
[5] Loc. cit.

Ehrlich[1] records twenty-six cases of phthisis in which bacilli were invariably present in the sputum; in other lung affections similar bacilli were not found.

Balmer and Fräntzel[2] examined one hundred and twenty cases of phthisis for bacilli with positive results, and came to the conclusion that the quantity of bacilli was in direct proportion to the gravity of the disease, and that the bacilli were larger and often contained spores in acute cases, and were smaller in size and quantity in chronic cases. They never saw bacilli in the sputum of cases other than phthisis. They also quite properly conclude "that the sputum affords to bacilli a more favorable place of growth than does the still living lung-tissue," because they found bacilli to be extremely scanty in the tuberculized lung-tissue surrounding a cavity, while the contents of the latter and cheesy degenerated parts of the lung were crowded by them.

Heron[3] records sixty-two cases of examination of phthisical sputum, in which bacilli were constantly present.

D'Espine[4] records examinations of sputum from twenty-five cases, but could not confirm the correctness of the assumption that the bacilli stand in any relation of quantity to the gravity of the disease, although he affirms that they are constantly present.

Williams,[5] having examined the sputum of one hundred and thirty cases for bacilli, with only three negative results, concludes, however, that there was "no definite ratio between the activity of the disease and the number of bacilli, although they were few in cases where the disease was quiescent."

Kowalsky[6] claims to have examined the sputum of six hundred cases of phthisis, with bacilli nearly invariably present.

Chiari,[7] in a number of cases examined, never failed to find bacilli.

Fiehl[8] found bacilli in the sputum of seventy-three, Doeschfeld [9] of forty-six, and Gradle and Woltmann[10] in thirty-five consecutive cases of phthisis examined.

Detwiler and Meissen[11] examined eighty-seven cases of phthisis, finding bacilli in all but two. Although bacilli were more numerous wherever great destruction of lung tissue existed, they did not observe any definite ratio of bacilli in sputum to the gravity of the disease. The presence of elastic tissue in sputum they consider as significant for diagnosis, and as constant as that of bacilli.

S. West[12] found bacilli present in every case of phthisis which he examined, though in some cases they were present in such small numbers as only to be found after repeated and very careful examination. He further adds: "The more cheesy matter or fluid from a cavity there was in the expectoration, the more bacilli we might expect to find; consequently, in a

case of acute tuberculosis, before breaking down of the lung, we should expect to find none." He also states that there seemed to be but little variation in the size of the individual bacilli in different cases, although bacilli in acute cases appeared to contain spores.

R. S. Smith[1] records seventy-seven cases in which he had made the examination of sputum; of these, forty-nine were from "tubercular phthisis," and invariably showed bacilli; the remaining twenty-eight, comprising various other affections of lungs, some of them closely simulating phthisis, did not show bacilli. The affections examined with negative results were such as "chronic bronchitis, bronchiectasis, chronic syphilitic pneumonia, slight hæmoptysis with no evidence of any disease, chronic pleuro-pneumonia with dulness on percussion and copious purulent expectoration, chronic pleurisy, apex pneumonia with subsequent breaking down from gangrene and with cavity (?), sarcoma of lung, gray hepatization, congestion from mitral disease, diabetes with bronchitis, two cases with strong family history of phthisis, cough with purulent expectoration, but with no evidence of local disease in lungs," etc. Bacilli were also wanting in "slight phthisical cases when the patients were rapidly recovering." I think, however, that errors in physical diagnosis can by no means be fully excluded here.

Heneage Gibbs,[2] from his extensive observations, states that the sputum did not show bacilli in some cases which upon the autopsy-table showed the lungs riddled with tubercular masses: he explains that the patient died before the destructive process had gone far enough to cause the bacilli to be ejected.

Whipham[3] records twenty cases which he studied in relation to bacilli in sputum, and made the observation that the bacilli disappear from sputum at times when the condition of the patient improved.

The report upon the examinations of sputum for bacilli from the pathological laboratory of the University of Pennsylvania will embrace the results from nearly two hundred cases of pulmonary diseases observed. These show that bacilli in sputum are diagnostic, but not prognostic, in phthisis; that the old-fashioned test, the presence of pulmonary elastic tissue in sputum, is a very reliable one (gangrene and abscess being so easily excluded); and, further, that the absence of tubercle-bacilli in sputum proves nothing.

Spina and Stricker[4] met tubercle-bacilli in simple bronchiectasis, bronchitis, croupous pneumonia, etc.

Sattler, in the translation of Spina's book,[5] page 164, adds the record of an autopsy of a case of similar nature mistaken for phthisis on account of bacilli in sputum.

Kundrat[6] related a case which occurred in the spring in Nothnagel's clinic, where a diagnosis of tuberculosis was based upon the detection of bacilli; but, post-mortem, the case proved to be one of chronic catarrh with bronchiectasis. He also mentioned a case, under Prof. Schrötter, where bacilli were repeatedly found by himself and others, and the necropsy showed only bronchitis and emphysema. Hence, he was not disposed to admit that the discovery of bacilli in the sputum was absolutely diagnostic of tubercle.

Riegel, of Giessen, and others, failed to find bacilli in the sputum of cases of diabetic phthisis. But I think the diabetes had nothing to do with keeping the bacilli out, as I have detected multitudes of bacilli in the sputum from a case of diabetic phthisis observed and confirmed by autopsy by Dr. Charles H. Reed, of this city.

Levinsky[1] and Koryanyi[2] both detected tubercle-bacilli in the sputum of patients with syphilitic lesions of the lung.

It is very probable that many of the cases of pulmonary disease in which bacilli were not discovered might nevertheless have been phthisical: in fact, the character of the control cases, as given by R. S. Smith (quoted above), fully justifies such assumption. From the autopsy-experience of clinicians and pathologists whom I consulted, and from observations of my own, I can testify that the only sure way to decide the nature of doubtful cases, such as, for instance, those recorded by Smith, is the autopsy: otherwise the negative evidence in relation to bacilli goes for naught, This is also substantiated by the observations of Gibbs, Whipham, and West, quoted above, viz.: that bacilli may fail to appear in sputum where there are no cavities and no ulceration in the lung. I have seen autopsies reveal phthisis in cases where no bacilli were found during life, after careful examination over and over again repeated; and I also happened to witness the autopsies of three cases of non-tubercular lung disease which during life had been diagnosticated phthisis on account of bacilli discovered in the sputum.

The examination of sputum may thus, in doubtful cases, be quite misleading; for if, in any given case, bacilli are not found, it should be taken into consideration, *first*, that the bacilli may be enclosed in the tubercle-tissue, as in miliary tubercle, which rarely produces destruction of the lungs, and consequently they may fail to appear in the sputum; and, *second*, that the examiner may fail occasionally in any case to succeed in preparing a successful preparation of stained bacilli. On the other hand, if bacilli are present, they sometimes may not be pertaining to the case, but be accidentally introduced through use of a vessel uncleansed and used by another patient, or otherwise; and, finally, it may be inferred, but it is by no means proved under rules of scientific scrutiny, that similar bacilli do not occur in the sputum of cases other than tubercular.

From our present knowledge of the occurrence of Koch's bacillus in sputum we must therefore conclude:

1st. That the presence of bacilli is a valuable *diagnostic* sign of tubercular disease of the lung.

2d. That the quantity of bacilli found does not, as

a rule, indicate the degree of the disease, and hence is *not a prognostic sign.*

3rd. That the absence of tubercle-bacilli is *no proof whatsoever of the absence* of tubercular disease.

4th. *The examination of air*—viz.: *of the breath of patients* suffering with pulmonary tuberculosis, and of the air of sick-rooms and hospitals generally—has given some positive, although not definite, results.

C. Theodore Williams [1] "recently selected one of the ventilation-shafts at the Brompton Hospital for Consumptives in which the flues of several wards converge, and in which extraction takes place at the rate of three hundred to four hundred feet a minute. In this current he suspended glass plates smeared with glycerine for a period of five days. The plates were then washed with distilled water, the fluid mixed with a little mucilage and evaporated down to half, and the residue tested for bacilli, which were found in fair abundance."

R. C. Smith [2] "succeeded in demonstrating bacilli in the breath of consumptive patients by making them breathe through two thin sheets of gun-cotton placed in the outer compartment of an ordinary respirator. This layer of cotton is then converted into collodion, run in thin films on slides, and stained for bacilli."

A. Ransome,[3] on examining the breath of several advanced cases of phthisis, found specimens of bacillus in two cases, while in several other cases the organism was not found, and it was not found in the aqueous vapor condensed in the waiting-room of the Manchester Consumption Hospital. The collections had been made by exposing cover-glasses smeared with fresh white of eggs or a little mucus for a certain length of time. Gibbs' method was used in staining.

Celli and Guarneiri[4] made similar examinations with quite different results. They were unable, after the most careful search, to find tubercle-bacilli in the air of an unventilated room in which phthisical patients had been sleeping. The expired breath of those patients was likewise found to be entirely free from bacterial contamination. Nor could the tubercle-bacilli be discovered in air which had been passed through the sputa of tuberculous patients, although in every case the expectorations were found to contain them in large numbers. (They were also unsuccessful in attempts at inoculation with fluids impregnated with this presumably vitiated atmosphere).

Profs. Sarmoni and Marchiafava[5] examined the breath of a number of phthisical patients for bacilli, with absolutely negative results. (They conclude that phthisis is not directly contagious, but might be indirectly so by means of dried, powdered sputum, which floats as dust in the air).

V. Wehde[6] made, under direction of Bollinger, in Munich, the following experiments in relation to examination of air. Plates smeared with glycerin were exposed for forty-eight hours in closed roms in which there were a number of advanced acute cases of phthisis. No bacilli could be found after applying the usual tests in an appropriate manner. (He further testifies that after injecting the material collected, as above stated, into the peritoneal cavity of eleven rabbits and guinea-pigs, no tuberculosis was produced).

5. *Comparative studies of animal tuberculosis.*—Spontaneous animal tuberculosis is unquestionably identical with human tuberculosis. There are a few morphological specializations, which I mentioned in a former chapter,—*e. g.*, in tuberculosis of birds and in bovine tuberculosis or pearl-disease; but the essential, peculiar histological features are the same in all. Tubercle-bacilli appears also to be present in nearly all cases of spontaneous animal tuberculosis. I detected bacilli in a tuberculous bronchial lymph-gland from a phthisical tiger, which I had kept in alcohol for eight years, and in one from a monkey of more recent date; and several times I found bacilli in spontaneous bovine, chicken, rabbit, and guinea-pig tuberculosis. I also studied tuberculosis in the bear, lion, leopard, and in a large variety of apes (dead of typical consumption, from the Zoölogical Garden), with results identical with those obtained from studies in man. But this was long before the "outbreak" of the "bacillary campaign," and consequently Koch's parasite was not looked for in these latter cases.

Bollinger[1] found bacilli in the udder of a cow affected by pearl-disease (bovine tuberculosis).

There are no observations on record concerning the occurrence of tubercle-bacilli in the excretions and the manure of animals affected by tuberculosis (sputum is not produced by animals),—not even any reliable observation of bacilli in the milk.

Artificial or induced tuberculosis in animals will be considered in connection with the experiments farther on.

6. *The occurrence of bacilli in lesions and substances other than tubercular.*—Bacilli not distinguishable from tubercle-bacilli are met with in lupus and leprosy. The bacillus met with in lupus is unquestionably identical with the tubercle-bacillus, as is evident from the investigations of Max Schüller, Pfeiffer,[2] Dontrelpont,[3] and Babès and Cornil.[4] Yet the dermatologists are hardly inclined to recognize lupus and tubercle as inseparable, there being already a defined tuberculous lesion (the scrofuloderm) on the dermatological list, and, further, they refuse to identify the two lesions on clinical and anatomical grounds.

The bacillus of leprosy, in specimens which I had the opportunity to examine, appears to me also perfectly identical with the small forms of tubercle-bacilli; although the lepra-bacillus may perhaps look more sharp-pointed to the eyes of others, and may fail to take the brown stain. There is nothing surprising in the fact that the same species of bacillus

[4] Loc. cit.

inhabiting soils of different character and different chemical composition, perhaps, may acquire varying micro-chemical properties and slight modification in shape. The experiments of Damsch[1] further suggest the identity of leprous and tubercle-bacilli in their effects. There is no reason to believe that leprosy is a variety of tuberculosis, yet we must either declare lupus, leprosy, and tubercle to be identical lesions, or else declare the tubercle-bacillus not to be peculiar to tuberculosis.

I observed bacilli not distinguishable by the shape and micro-chemical tests from tubercle-bacilli in the false membranes in two cases of diphtheria, and in one case of scarlet fever with extensive pseudo-membranous angina. Two of these cases proved fatal; the autopsies did not reveal tuberculosis in any part of the body. The false membrane was prepared by crushing it between two cover-glasses, and was treated like sputum.

In syphilis of the lung the cheesy material and the sputum (as above stated) was found to contain tubercle-bacilli by Levinsky,[2] and also by Koryanyi.[3]

Lichtheim[4] and Craemer[5] may be mentioned yet in this connection, as having each found the tubercle-bacilli, or bacilli like them in every respect, in the fæces of a number of non-tuberculous patients, as well as in the tuberculous. This is, however, energetically contradicted by Gaffky, of Koch's laboratory, on the ground that he (Gaffky) failed to discover in fæces of normal persons in Berlin any bacilli which reacted to micro-chemical tests like tubercle-bacilli.

The discovery of Professor Bologh[6] that bacilli similar to tubercle-bacilli are found in the marshes around Pesth, Koch also tries to demolish by the statement that such bacilli were not detected in the mud of a Berlin city canal.

In sections of phthisical lungs I often observed masses of bacilli in those portions which were without tubercles, but which were affected secondarily by simple acute inflammatory changes, and the air-vesicles merely stuffed with exudate undergoing rapid disintegration (coagulation necrosis); while the real tubercle-tissue contained no bacilli, or sometimes only a few in the giant cells. I think Prudden[7] also noted this.

Surveying now the whole question of the habitat of the bacillus tuberculosis, it becomes evident that Koch's dogma—that only that is tuberculosis, and everything is tuberculosis, where his bacillus is found—is overdrawn and cannot bear criticism. It would be much safer to reverse this proposition, and to *consider that bacillus alone a tubercle-bacillus which inhabits evident tubercular lesions* or their products,—*e. g.*, sputum, and nothing else. For we have no difficulty in diagnosticating under the microscope a tubercle without the bacillus; but *a dilemma arises at once if we see questionable bacilli without the tubercle, or outside of sputum.*

VI.—EXPERIMENTS AND EVIDENCE, "PRO" AND "CONTRA."

It has been shown that the clinical evidence in reference to the contagiousness of phthisis is so meager that assertions as to its parasitic origin are unwarranted. (see chap. iv.) Moreover, statistics negative such theory. This being the case, it would seem as if experimenters are trying to prove that which is not the reality.

The testimony of the defenders of this theory, however, appears strengthened since the publication of the discovery of the bacillus and of the experiments of Koch. This is to be in a measure explained by the impression which Koch's well-constructed article made upon the minds of some of our leading clinical teachers, who involuntarily felt themselves induced to teach and to write about the doctrine of the contagiousness of phthisis. The profession at large does not care for Koch's discovery, whatever its value may be; but the opinion of the leading clinicians endorsing such discovery forms a guide, and may prove one of the most efficacious means of influencing the profession in regard to the question of the contagiousness of phthisis.

Having arrived, from my own experiments, at conclusions different from those of Koch, I thought it at present timely to announce at least the results of my observations, as my detailed report can not appear for some months to come. It is my personal observations, together with my conclusions obtained from a careful perusal of the control experiments and of the records of the observations of others, which have determined my present attitude in the question of the ætiology of tuberculosis.

The total evidence *pro* and *contra* gives me the impression that the doctrine of the contagious character and parasitic causation of tuberculosis can not be sustained.

I will now submit a brief analysis and summary of experiments made and evidence offered in relation to the question of the parasitic origin and specific nature of tuberculosis.

For the establishment of a theory in regard to a parasitic origin of a disease by means of experiments on animals, etc., the following propositions must be affirmatively decided:

1. The disease produced experimentally in animals by means of inoculation with products of the human disease, must be proved to be identical with the disease occurring spontaneously in man.

2. There should be some evidence showing that inoculation in man is followed by the same results as follow the inoculation of the same material in animals; and that the disease is really contagious.

3. There must be found a definite parasite at the beginning of the diseased process in all cases, and in all tissues involved by the disease, and in sufficient quanity to account for the changes.

4. Given a parasite that is the cause of the disease, its action should be specific, *i. e.*, it alone should be the causative factor, and should, when isolated and inoculated into an animal liable to the disease, always produce that disease.

5. The lesions of a disease resulting from the inoculation ot a specific parasite must also contain that parasite, and the specific properties of reproducing the same disease when re-inoculated.

6. Finally, a given parasite and no other substance should, the conditions remaining the same, be capable of producing the disease.

Koch makes an effort to answer all the above propositions in the affirmative in reference to tuberculosis. As a thorough and experienced mycologist, he knew that this is unavoidably necessary in order to establish the ætiological relation of his bacillus to tuberculosis.

Tuberculosis was known before Koch to be inocuiable, and was, upon popular notions and traditionally, regarded by some as a contagious disease. Taking such theory for granted, it was necessary to find the parasite. In fact, Klebs, Toussaint, Max Schüller and Aufrecht made excellent investigations, which even suggested the parasitic nature of tuberculosis, although the proofs offered by these investigators were not sufficient.

Koch's investigations, with his superior advantages, methods and diligence, have been crowned with better success, and have brought forward facts of standing and permanent value to mycology, botany, and partly to medicine. His evidence in the question of the parasitic nature of tuberculosis is strong, but his conclusions from this evidence were overdrawn and too hasty. They are, thus far, not so much justified as he and his followers think they are. There is great lack of that absolute proof that is necessary for the settlement of a question of such magnitude and social importance.

Koch has, in relation to tuberculosis, brought forward definite affirmative proof for only some of the above-named propositions, and this, again, *only partial*. Valuable contributions to this end have been also made by others. But we must have *full proof for each and all* of those propositions, and these must be really applicable to tuberculosis, before we can accept the theory of a parasitic character and of the contagionsness of this disease.

Submitting now, a brief criticism of the bacillus theory of Koch and his followers, I will take up separately each of the above-stated propositions, all of which it is necessary to prove in the affirmative before there is any reason for the establishment of such a theory in regard to tuberculosis.

1. *The disease produced experimentally in animals by means of inoculation with products of human disease, must be proved to be identical with the disease occurring spontaneously in man.*

In favor of the identity of human tuberculosis with that produced experimentally in animals there has been brought forward the fact that the products in both contain identical bacilli. But this surely does not prove the identity, because similar bacilli may be found in the lesions of various kinds of processes, resulting in cheesy products. (See bacillus chapter.) Besides, there are many spontaneous and artificially-induced tubercular lesions in which bacilli could not be demonstrated. Hence, we can not rely upon the bacilli as a proof for the identity of the lesions.

Koch, and those who imitated his experiments, diagnosticate and declare all those artificially-induced lesions as tubercular which occur in nodes and in which they found the tubercle-bacillus, without taking (so far as I know) into consideration any structural peculiarities or other conditions. Now, tubercle-bacilli will surely be found in the lesions, whatever these may be, as they were introduced into the animal in those experiments. Further, in the opinion of these gentlemen nothing is tubercle where there are no tubercle-bacilli. Therefore, how can we rely upon their statements as to what the lesions they induced in animals really were?

It is hardly within the province of the mycologist to teach us what is tubercle and what is not tubercle.

Tuberculous lesions with extensive cheesy changes and tissue-destruction, cavities, etc., such as occur spontaneously and often quite speedily in man or animals, cannot be induced experimentally by means of inoculation, unless very large quantities of some purulent tuberculous materials are used, and abscesses result. When an animal dies several or many months after the operation of natural tuberculosis, extensive caseation of the organs may occur.[1] The only kind of induced or artificial tuberculosis in animals which may be ascribed to the effects of inoculation is one that corresponds in naked-eye appearance to secondary miliary eruption of tubercle as occurring in man—the acute miliary tuberculosis. This acute miliary tuberculosis in man, which I observed also in animals as a syontaneous disease, occurs only in wasting diseases accompanied by various grave symptoms, anæmia, and great emaciation; while the induced disease in animals occurs suddenly, and induces no symptoms, no blood-changes, no emaciation, etc.

In many instances where the experimenters have produced, by means of tuberculous materials, within two to eight days after the operation, a miliary eruption, it is not probable that those miliary nodes were tubercles, and were due to the effects of bacilli, which are known to grow extremely slowly, and it is not certain that the experimenters took pains to distinguish them from true tubercle, or were competent in all instances to do so. This is eminently true of the inhalation tuberculosis.

Tappeiner's induced inhalation tuberculosis ot dogs,[2] so much relied upon by Koch and others for the establishment of the mode of the spreading of phthisis, and partly of the bacillus doctrine itself, has been proved to be a fiction. Tappeiner, as so often quoted, subjected dogs to an atmosphere heavily charged with phthisical sputum, so that the dogs were nearly bathed in the latter (known to contain bacilli, for weeks. But, in spite of this, the animals grew fat, if anything, and, after the lapse of a certain

[1] I was much surprised last summer to see in Berlin, at the Hygienic Exhibition, in Koch's pavilion, specimens of the character just stated exhibited as inoculation-tuberculosis, and still more to hear the demonstrator explain (surely without being authorized by Koch) that these specimens were to demonstrate the rapid effects of the bacillus.

[2] Virchow's Arch., lxxiv, 1878, and ibid, lxxxii, 1880.

time, acquired local pulmonary affections in the form of nodules, not likely to have been tubercular in nature, of which only in one case were some observed in the liver and kidneys.

The experiments of Schottelius,[1] Wargunin and Rajewsky,[2] Weichselbaum,[3] and of others,[4] and my own experiments also (to be reported subsequently), make Tappeiner's assertions perfectly untenable. Tappeiner's own account of his experiments, and the microscopical description of the structure of Tappeiner's "tubercles," by Grawitz and Friedlander in Virchow's institute, clearly indicate that he had nodular broncho-pneumonic foci, and not tubercles. (See explanation of these formations in the first chapter of this paper.)

I will, however, show later that pulmonary tuberculosis may occasionally be produced in rabbits by these means.

Furthermore, the bacillus theorists assert that inoculation-experiments, and these alone, can prove the tubercular nature of the nodular eruptions obtained artificially in animals. The identity with human tubercle is considered established, because inoculation nodes from the animal and tubercles of man act alike. They claim that whatever can produce tubercle on inoculation contains the tubercular virus, and is tubercle. Under such conception, finely-powdered sterilized glass should be classed with tubercle, because it, as I can reaffirm now, is capable of inducing tuberculosis when introduced into the tissues of healthy animals.

The following deserves a passing mention. According to Orth[5] and Bollinger,[6] there is some doubt as to the identity of human and animal tuberculosis. The results of the experiments of both these observers show that tuberculosis could only be induced by feeding animals with materials from animal tuberculosis; while tuberculous materials taken from man had no effect upon animals when given as food. On the other hand, the Würzburg feeding experiments upon man[7] prove that animal tuberculous materials have no effect on man.

Although, judging from my own experiments, there is to my mind no doubt that some forms of artificially-induced tuberculosis in animals acquire gradually characters which make them identical with the spontaneous tuberculosis in man or beast, yet I do not think it is at all proved that the lesions so rapidly arising from the effects of the inoculation with the bacillus of Koch are identical with tuberculosis in man. The proof, then, upon this point, the supreme one for the settlement of the question of the nature of tuberculosis, is yet to be furnished.

2. *There should be some evidence showing that inoculation in men is followed by the same result as follows the inoculation of the same material in animals, and that the disease is really contagious.*

[1] Virchow's Arch., lxxii., 1878, and ibid., xci., 1883.

[3] Centralblatt, No. 19, 1882.
[4] To the same conclusion, I hope, will also come my esteemed friend Prof. Brose, if he repeats his experiments published in the *Medical Record*, January, 1884.
[5] Virchow's Archives, vol. lxxvi.
[6] Arch. f. Exper. Path., vol. i.
[7] Schottelius, loc. cit.

In favor of the direct inoculability of tuberculosis in man the following is presented:

At a recent meeting of the Académie de Médecine, M. Verneuil related the following history. In July, 1877, a house surgeon (*interne*) at the Ste. Eugénie Hospital, who performed all the post-mortem examinations, one day noticed a papule at the base of the nail of his third finger. The apex presented a white spot, and a few drops of pus escaped from it. It was frequently cauterized, but the phalanges became attacked, and a cold abscess spread over the back of the hand. After three years' treatment, having failed to produce any improvement, M. Verneuil amputated the finger. The house surgeon was believed to be cured, and practiced in the provinces. Quite recently he has been again attacked by cold abscesses in the lumbar region, causing intense pain; during violent attacks of pain the arms exhibit clonic convulsive movements. M. Verneuil has operated a second time. He is convinced that his patient became inoculated with tuberculosis when performing a necropsy. A similar misfortune happened to Laennec. One day, when operating on a tuberculous patient, he slightly cut himself with a saw. A swelling appeared on the wounded part. Laennec cauterized it with antimony chloride. The swelling disappeared, but twenty years subsequently he died from tuberculosis.[1]

We have seen that clinical evidence and statistics do not elucidate a contagion for tuberculosis, and that the few isolated instances of apparent contagion offered cannot stand the test of scientific scrutiny. An infectious or contagious disease can have only one cause, and cannot be at one time due to a contagion, and at other times arise from a variety of causes; hence the latter part of the proposition must be answered in the negative.

This being the case, the *parasitic* origin must also be denied it, as a necessary consequence:

As to the first part of the proposition, too little is known of scientific observation upon this point in regard to tuberculosis. According to the exhaustive investigation of Dr. Law,[2] there is no evidence that tuberculosis has ever been conveyed through vaccination.

I must mention, though, an actual inoculation-experiment upon man, not so much on account of its inherent value, as because it has been quoted with great reliance in support of the infectiousness of tuberculosis. Demet, Paraskeve, and Zallonis, in Syra, Greece,[3] "inoculated a man of 55 with tubercle. He was suffering from gangrene of the left great toe, due to the obliteration of the femoral artery, and his death was inevitable, as he had refused to submit to amputation. His lungs were carefully examined and found to be sound. They inoculated the upper portion of the right leg with sputa from a man who had abscesses in his lung. Three week later there were signs of commencing induration at the summit of the right lung. The patient died on the thirty-eighth

[1] Paris Correspondence of the *British Medical Journal*, quoted by Boston *Med. and Surg. Journal*, No. 10.
[2] National Board of Health Bulletin, No. 40, 1882.
[3] Quoted by *Med.-Chir. Review*, Oct., 1874, from *Gazette Médicale*, 1872, page 192.

day after the inoculation, from gangrene. At the necropsy there were found at the apex of the right lung seventeen small tubercles, varying in size from that of a mustard seed to that of a lentil. Two similar tubercles were found in the left apex, and two others in the liver. The experimenters concluded that the embryonic state of the tubercles and their limited number were due to the short time since the inoculation."

This isolated experiment, as well as any of the experiments on animals, is valid only when we take it for granted that the experimenters are able to differentiate spontaneous from artificially-induced tuberculosis. This is not probable in the case just quoted. We are told that the man experimented upon was suffering from an exhausting disease, and it is well known that at least one-third of the autopsies in such cases reveal tubercular disease.

Directly bearing upon the proposition under consideration are again those Würzburg feeding-experiments, in which material known to be infested by tubercle-bacilli was used, often raw, for years as food, under strictly scientific supervision, with absolutely negative results, and which tended to show that man does not react at all upon the tubercle-bacillus.

3. *There should be found a definite parasite at the beginning of the diseased process, and in sufficient quantity to account for the changes in all cases, and in all tissues involved by the disease.*

In relation to tuberculosis this proposition cannot be answered in the affirmative; and it is by no means as definitely settled as some high clinical authorities hold with Koch, that there is but one "specific parasite" in tuberculosis.

Klebs,[1] Toussaint, and Schüller[2] have observed *micrococci* to be constantly present in tuberculous lesions and products (and have induced artificially the disease with the isolated micrococci), and no one has *proved* anything to the contrary; while Koch and Baumgarten[3] discovered *bacilli* in the same lesions. Koch claims for his bacillus more than is consistent with the laws of physiological and pathological life and sound argumentation, and more than is in correspondence with the actual proofs offered in relation to the pathogenetic properties of this bacillus.

The reports of some competent microscopists and pathologists (when the originals are examined) show that the tubercle-bacillus is not invariably present in all cases and all products of tuberculosis; and, if present, it is often not seen in sufficient quantity to ascribe to it the claimed significance; and, furthermore, it is, as a rule, not present in the beginning of the disease. On grounds of personal investigation I can offer similar testimony.

The bacilli should be present in every lesion and in all cases, and in the beginning of tubercular disease, and not chiefly in its degenerated products, if tuberculosis is to be called a parasitic disease, in accordance with the laws of pathology. In all well-established parasitic diseases the parasite is a necessary factor, and is invariably present, unless there should be established for the "tubercle parasite" an exceptional, new, and mysterious mode of action.

The truth of the matter appears to be, and, indeed, from my daily observations in the laboratory upon a large quantity of material, I regard it as a fact, that the tubercle-bacillus of Koch is a mere concomitant of cheesy disintegrated materials, even if it be preëminently of tuberculous cheesy materials.

4. *Given a parasite that is the cause of a disease, it should, when isolated and inoculated into an animal liable to that disease, always reproduce that disease; but its action should be specific,—i. e., it (the parasite) alone should be the causative factor.*

There is no doubt that Koch's tubercle-bacillus, when isolated and cultivated for many generations and then inoculated into certain animals, is capable of inducing tuberculosis, or a nodular eruption not distinguishable from it, more readily than other irritants, so far as tried. Success in inoculating is particularly frequent in rabbits and guinea-pigs (although not so common as Koch claims), but only conditional and rare in other animals.

Thus it appears that the above proposition could be answered for tuberculosis and the bacillus in the affirmative if only the following points were proved:

1st. That the nodular lesion thus induced is really tuberculosis, identical with the human disease.

2d. That this bacillus is the only bacterium or the only irritant capable of inducing tuberculosis; and,

3. That its action is specific,—*i. e.*, that the bacillus is the only agency or factor at work, the sole cause of the disease.

The first point is not proved, as probable as it may appear. The other points are open to the following considerations and objections:

It has been proved that in tuberculosis micrococci, as well as bacilli, are causal, the evidence being "strong" for either "parasite;" whereas the bacillus alone should be the causal factor. As long as not *disproved*, Kleb's, Toussaint's, and Schüller's investigations (in relation to the micrococci as causal factors) have as much claim as Koch's. The method of cultivating those tubercle-micrococci, as practised by those investigators, was one not favorable for the development of the tubercle-bacilli. Further, Watson Cheyne's assertion that bacilli *must have been* present in the cultured materials with which those investigators inoculated successfully, is altogether a gratuitous assumption, and his few and imperfect control experiments with Toussaint's micrococci were not satisfactory, and, in fact, neither prove nor disprove anything.[1] Koch did not try the effects of any other fungus than that of his bacillus in relation to tuberculosis.

Koch further claims that the specific character of his bacillus is supported by the rapidity of its effects, and brings forward the inhalation experiments of Tappeiner and the experiments upon the eye. The former I have shown to be valueless, as those nodules

[1] Klebs now admits the bacilli, but denies that they are invariably present, and denies on grounds of experiments their exclusive pathogenetic properties, although he admits that they are a not unimportant admixture to his micrococci.

[2] Loc. cit.

[3] Loc. cit.

[1] See Watson Cheyne's report, *Practitioner*, April, 1883, pp. 272–276.

produced in the lung, especially if rapidly formed, are not tubercles. I have also reason to believe that the same is the case with many of the experiments on the eye, especially in those cases in which an apparently acute miliary tuberculosis of the lung rapidly followed the inoculation; in fact, in some instances this eruption occurred in a much shorter time than is at all possible for tubercles to develop.

Koch has not proved that his bacillus is the only agency at work in the production of tuberculosis. Although he undoubtedly inoculated the pure bacillus, he ignored the specific reaction of the soil; and it is the latter which I hold plays the most important *role* in determining the formation of tubercle. In introducing the bacillus into the animal organism, another factor—the injury inflicted, and its effects upon the living cells of the body—must be taken into consideration.

In some animals all the tissues of the body react equally upon the introduction of irritants; in others only some one of the tissues responds, such as the serous membranes. This surely demonstrates the specific action of the soil.

I must again call attention to the fact that in making his experiments, Koch injected the bacilli into any part indiscriminately in scrofulous animals, while in non-scrofulous animals (dogs, rats, cats) he injected them only into the peritonæum or the anterior chamber of the eye, where, we know from experience and from repeated experiments, any irritant of sufficient intensity may create tuberculosis.

This cannot be explained by the assumption of Koch that the bacillus must merely be enclosed in something, so as not to be eliminated, before it can exert its effect.

To me it appears that the reason why we must inoculate in serous cavities to produce tuberculosis in the dog or cat, is, because we want not so much the specific action of the irritant (say of the bacilli) as the properties of the serous membrane. It is now well known that any chronic inflammation of serous membranes may lead to primary tuberculosis. It is proved that we do have a primary tubercular synovitis or a primary tuberculous pericarditis; and that bacilli could be instrumental in its production is highly improbable.

In surface tuberculosis like that of the lung, the bacilli, in my opinion, also play only a secondary *r-le.*

Koch himself admits that it is not likely that the bacillus when inhaled by man could get a foothold in a normal lung. He says distinctly in his original articles that the lung must be predisposed for the reception and the action of the bacilli. Under such predisposition he understands and enumerates the following lesions: "*desquamation of the epithelial lining of the respirartory tract, stagnating exudates and secretion in the lung, adhesions, anomalies of respiration,*" etc. Now, here is a matter of mere interpretation of these lesions. Koch innocently calls them "predispositions," while every pathologist will designate some of these lesions as suggesting already-existing pulmonary phthisis. In fact, at the present standing of our knowledge of pulmonary phthisis we can have no desquamation of the vesicular epithelium without preceding tubercular infiltration.

Watson Cheyne is also considerate enough to say,[1] "* * * it seems to me that the lung must in addition be prepared for the reception of the bacillus, as may be the case if congestion or slight inflammation be present at the time of the inhalation of the organism."

That in inoculations into serous cavities the latter do not act merely in preventing the bacillus from escaping or being eliminated, and that the stagnating secretions in the lung do not act merely as a glue to retain the bacillus in order to allow the accomplishment of its effects, is, to my mind, proved by the following experiments of Bollinger. Bollinger,[2] in order to show that tuberculosis could not be transplanted by vaccination, made superficial *cutaneous* inoculation in rabbits with tuberculous materials with negative, and deep *subcutaneous* inoculations with the same material, followed by intense inflammation, with positive results. In both cases the wounds were covered by a layer of collodion to prevent the "elimination" of the bacillus.

Thus it appears that the bacilli by themselves have no effect upon the healthy organism or the normal tissues. A predisposed soil is the chief factor and is pre-eminently necessary for the production of tuberculosis; while, on the other hand, it is not proved at all that the bacillus is invariably necessary for the production of tuberculous lesions. Although the tubercle-bacillus is more liable to excite tuberculosis in an already inflamed and ill-nourished soil than all other simple irritants so far tested, it (the bacillus) might be readily substituted by other irritants.

The matter must unquestionably be tested further, but from the above evidence it is clear that a general fear of the bacillus tuberculosis as a contagion is unjustificable, and that the ordinary dust suspended in the air is to certain persons as dangerous as the bacillus.

5. *The specific lesions of a disease resulting from the inoculation of a specific parasite must also contain that parasite, and have the specific properties of reproducing the same disease when re-inoculated in other animals.*

Koch claims that the products obtained in animals by inoculation with bacilli are capable of producing tuberculosis when inoculated into a second animal, while the products obtained by inoculation with innocuous substances do not have this effect. The former proposition is true, but the latter, I hold, is not in accordance with facts. In my own experiments, to be detailed in my forthcoming report, tubercles produced by inoculation with innocuous material under antiseptic precautions were likewise capable of producing tubercles when inoculated into other animals, having thus the same action as the innocuous material primarily used.

I have also shown above (see bacillus chapter) that in secondary tuberculous products bacilli may be absent.

---

[1] Loc. cit., p. 314.

[2] Zur Ætiologie der Tuberculose, *Prager Med. Wochenschrift*, Nos. 4 and 5, 1884.

The experiments of Martin,[1] which tend to show even the progressive virulence of products obtained from re-inoculation with tuberculous material in a series of animals, have been substantiated by no one.

Martin's assertion, also, that inoculations with products obtained by the introduction of innocuous substances never produce true tuberculosis, and that after a series of re-inoculations these products lose their power of acting even as local irritants, is, according to control experiments, positively wrong. On the other hand, views have been expressed, based upon experiments (I think also by Martin), that products obtained by inoculation with non-tuberculous substances, when re-inoculated may gradually become specific, and increase in virulence in producing tuberculosis.

6. *Finally, a given parasite and no other substance should, the conditions remaining the same, be capable of producing a parasitic disease.*

In my previous studies, judging from the literature alone, I was fully impressed with the idea that tuberculosis had a specific exciting cause, and that it could be induced by inoculation with tuberculous materials. Moreover, having made numerous inoculations with tuberculous matters, I convinced myself of this fact. Hence I accepted the view that tuberculosis is inoculable in certain animals.

But at the same time, after repeating under various modifications the well known control experiments, I found that, beyond doubt, even true tuberculosis could be induced by substances other than tubercular, and that failures to induce tuberculosis with tuberculous materials were in certain animals nearly as common as successful inoculations with innocuous substances.

To these experiments I will return in my forthcoming report.

It will be also necessary to first consider the evidence of those observers who, from the results of their own exhaustive experiments, negatived the exclusive or specific infectious properties of tuberculous materials. This negative evidence is by far more voluminous and strong than the admirers of the hypothesis of the contagiousness of tuberculosis suppose; excited admirers having especially arisen since the ingenious article of Koch appeared.

It is, however, remarkable that some of the writers on tuberculosis fail to understand that the pivot of the question of the ætiology of tuberculosis does not rest upon the fact alone whether or not the bacillus induces lesions analagous to tuberculosis, but preëminently upon the fact whether innocuous substances have or have not the same effects.

Thus, above all, the negative evidence must be carefully inquired into, not by relying upon the crippled and sometimes misrepresenting and meager quotations of some of the compiling writers, but by submitting the original communications of the authors and experimenters to a careful perusal.

Together with the accounts of the much-quoted experiments of investigators who succeeded in inducing tuberculosis in animals with tuberculous substances only, the reading and thorough examination of the records and results of experiments of the observers to be mentioned below are unavoidably necessary.

The following observers all refer to many or few experiments of their own, in which tuberculosis resulted from the inoculation with either innocuous substances or with specific matters other than tuberculous:

Some of the observers enumerated did not consider the miliary eruptions obtained experimentally as true tubercles, but the majority did so, and, as I will show later, presented excellent and reliable experiments and sound reasoning in support of their views.

Shall all the above evidence go for naught merely because Koch has discovered a bacillus which is capable of inducing in animals lesions resembling tuberculosis?

I trust it will not. Koch has, so far, no authority to claim *exclusive* pathogenetic properties for his bacillus, as he made himself no satisfactory control experiments with substances other than tuberculous. The few control experiments he offers, viz.: that *sterilized* blood-serum (!), tuberculous material soaked in alcohol, and fresh scrofulous glands, or pus from

[1] *Journal d' Anatomie et de Physiologie*, April, 1881.

[1] Hänsell, who inoculated animals with gummous growths and syphilitic pus, obtained an exquisite miliary tuberculosis from the effect of these substances. In this connection may also be mentioned the following:

Damsch (*Centralbl. f. Med. Wissen.*, July 21, 1883), who obtained tubercular eruptions and nodes in the brain in rabbits through inoculation into the eye with the cultivated bacilli of leprosy. Similar in culation with leprous material led to a perfect miliary tuberculosis in rabbits id the hands of Kaposi, of Vienna, (*Wiener Med Presse*, Jan. 21, 1883)

Pfeiffer, Dontrelpont, Cornil and Babés, loc. cit., had the same experience with lupous material

Bodamer (Inaugural Thesis, Univ. of Penn., 1884,) had, as the result of inoculating with the pure cultivated actinomyces fungus, a striking general miliary tuberculosis in rabbits.

Inoculation with materials from glanders gives also rise to tubercles in the lungs, etc, not distinguishable under the microscope from the true miliary tuberculosis. But Löffler, who kindly demonstrated to me this fact in Koch's laboratory, and who also gave me a specimen demonstrating it, explained that the nodules in the lungs were not tubercle, because the bacilli found therein behave differently in staining.

tuberculous lesions, did not induce tuberculosis, prove little or nothing in favor of his bacillus.

Watson Cheyne, in his excellent report, displayed great care, diligence, and skill in his experiments and observations intended to corroborate Koch, but in making his control experiments he likewise was not very particular. So, in relation to inoculations with non-tuberculous substances he came to the conclusion that "not one of the twenty animals (inoculated with innocuous substances) became tuberculous"! But when the detailed account of Watson Cheyne's experiments is read over, it is amusing to learn that only nine out of the twenty-five supposed negative experiments were really known to be negative, because eleven of the rabbits experimented upon had been stolen before Cheyne had a chance to examine them, two rabbits died within a few days, or long before tubercle could develop, and in three rabbits the experimenter really records lesions that might have been tuberculous, in spite of the absence of bacilli in them, which latter circumstance, however, induced him to call the result a negative one.

These are instances of the way in which experimenters with preconceived and peculiar ideas upon a subject may unconsciously be misled in forming conclusions from their own experiments.

Further, it is interesting to note that in the "classical" experiments of Solomon,[1] Baumgarten,[2] Tappeiner,[3] etc., among other substances, the following materials were used extensively for control: "Caseous glands from scrofulous child;" "caseous material from various sources;" "muscle, testicle, and kidney from tuberculous guinea-pig;" "cheesy pus from man and animals, cheesy infarcts, caseous tumors," etc. All these substances, which are known usually to contain the bacillus, were inoculated while fresh into animals, and are recorded by the experimenters above stated as having failed to produce tuberculosis. This is surely not consistent with the doctrine of Koch.

Wherever inoculation with innocuous substances was followed by positive results, the over-zealous germ-theorists call it "*accidental tuberculosis.*" They say that at the time of former experiments the communicability of tubercle by a mediate contagion was not recognized, and as the precautions necessary for thorough disinfection of instruments, surroundings, etc., were probably not observed, the channels for the introduction of the *bacillus* were, in all previous experiments, left unguarded: hence, they argue, *it must have been* this ubiquitous bacillus which induced the tubercle.[4]

Further admitting, however, that innocuous substances may induce tubercle-like bodies, they claim that these bodies are not infectious, *i. e.*, they are *false* tubercles.

All these objections would be very plausible if they were based upon actual observations and facts; but, unfortunately for the bacillus theory, they are not; they are *mere unfounded assumptions.*

The fact established by experiments, that a true tuberculosis can be induced in animals by inoculation with innocuous and various other substances, and the significance of this fact, can surely not be overthrown by the imperfect evidence that the bacillus is more liable to do so, and still less by the mere unauthorized opinions of some of the writers.

Erroneous conclusions and views may easily be formed through the misconception of the significance of experiments.

At the meeting of the Pathological Society of London (Dec. 4, 1883, quoted from the *Lancet*, Dec. 8, 1883), Dr. Wilson Fox announced the following: "He was unwilling that his former observations[1] should still be quoted as opposed to the doctrines of Koch and those who had been more recently working at the subject; and therefore he had felt bound to come forward and make known the modification which his views had undergone. At the same time," Dr. Fox, however, added, "there was perhaps some danger of phthisiophobia or phthisiomania. During the past thirty years there had been many changes in the doctrine of phthisis, and hardly any doctrine has lasted more than five years."

But what had happened to induce Dr. Fox to lose faith in his own honest and excellent former work? So far as I could learn, it was the following: Dr. Fox had requested a Dr. Dawson Williams to repeat his former experiments. This bacillus-excited gentleman introduced *carefully* some "*putrid fluids*" and some *setons* into a few guinea-pigs and—did not obtain tuberculosis! Now, they think, it was at once evident that in all the former successful inoculations with non-tuberculous materials the mischievous bacillus of Koch must have gained entrance.

The reasoning of the London gentlemen appears to have been here as follows: *Putrid matter and setons do not induce tuberculosis; but the bacillus does. Hence the bacillus is the sole specific cause!*

But what is gained or proved for the bacillus theory if any one given substance, when inoculated into an animal, does not induce tuberculosis? Does, through this, the necessity of contagion at once arise? Surely not. If, for instance, as I will prove, finely-powdered, sterilized glass is capable of induc-

[2] Loc. cit.
[3] Loc. cit.
[4] In this connection the following incident is interesting, particularly on account of the high authority of the observer:
Some experiments were made under the supervision of Virchow (*Berlin. Klin Woch.*, 1880), principally with the view of testing whether the milk of animals affected with "pearl-disease" or bovine tuberculosis could reproduce the disease when fed to other animals. Virchow's own objection to experiments of this kind is that the various chronic inflammatory processes which occur spontaneously in animals are not sufficiently well known even to veterinary specialists. Further, in pigs, which he used in considerable numbers, scrofulous glands occur so frequently, from their alliance to man through their omnivorous habits, and their detection during life is a matter of such great difficulty, that results founded upon their presence must be accepted with great caution. The possibility of coincidence was also well illustrated by two cases in which several animals were found to be tuberculous after having taken the milk for some time from a cow which was diagnosticated during life as affected with bovine tuberculosis, but whose lungs were found at the autopsy filled with echinococcus cysts, and with no trace of tuberculosis.
The milk of another animal, which subsequently was found to be profusely affected by bovine tuberculosis, had, on the other hand, no effect when given as food to a number of healthy animals.
The only result that Virchow thinks is perhaps justified from these experiments is that more animals were found to be tuberculous among a certain number which had been fed upon the "pearly" milk, than among the same number which had been fed upon healthy milk.
(The above statements, first quoted by Dr. Whitney, of Boston, Professor Virchow corroborated in a conversation with me upon this subject last summer.—H. F.)

[1] Loc. cit.

ing a true tuberculosis, then it does not matter if putrid matter or setons failed to do it.

Cohnheim's acceptance of a theory of a specific poison for tuberculosis, which formed as its direct outgrowth, the basis of the bacillus theory, was also not justified from Cohnheim's own experiments. If he once succeeded[1] with innocuous substances in producing *peritoneal* tuberculosis, it is of no consequence that he subsequently[2] failed to induce an *iris tuberculosis*.

Negative results prove nothing under the above circumstances and in the presence of positive results. Most of the observations made in bacillus studies prove really nothing for the ætiology of tuberculosis, and some interpretations of the results of experiments in this direction are quite deficient, and not consistent with the principles of experimental pathology. Furthermore, some of the positive evidence must be excluded on account of the evident deficient knowledge of pathological anatomy on the part of some of the experimenters.

I am glad to be in the position to offer in my next communication a new series of observations and experiments on tuberculosis. These experiments, instituted under the auspices of Dr. Pepper, provost of the University of Pennsylvania, and executed by myself and assistants under all rules of scientific precautions and with full facilities for such work, plainly demonstrate that *the ætiology of tuberculosis does not rest with Koch's "parasitic" bacillus or any other "contagion."*

The experiments referred to will be given in full details in a special report now in progress and soon to be published with appropriate illustrations, etc.

I desire, however, to announce here that my experiments prove that finely powdered, sterilized glass, ultramarine blue, and other substances, are by themselves capable of producing tuberculosis in animals or tissues liable to this affection.

Further, I will offer proof that this effect (tuberculosis) ensues without the intercurrent action of any bacterium. And, finally, that in those instances where miliary, nodular eruptions have been induced by the tubercle-bacillus (or substances containing it), the action of the latter is a purely mechanical one, like that of simple irritants.

Further, these experiments show that the only advantage which the bacilli have over other finely divided matter and simple irritants is that the former multiply and thus intensify their action, while mechanical irritants have not this property, and hence must be introduced in larger quantities. The more finely divided the matter, the more prompt seems to be its effect, and I believe it is impossible to render any matter more finely divided than the bacilli.

Like others, I also often succeed in tracing the formation of the tubercle-nodules to the effects of the irritating particulate matter, if the latter were or could be made distinct enough to be seen within the nodes. When ultramarine blue was used for inoculation, granules of the latter substance were seen within the nodes when bacilli were used to that end, then bacilli could be detected within the nodes; but in either case these primary nodular eruptions, *if rapidly formed*, do not yet represent tuberculosis, as I will show.

It is generally conceived that a specific infectious disease, such as instanced by variola, syphilis, anthrax, etc., can have only one cause or one poison which will produce that disease and nothing else, and cannot be substituted by anything else.

For tuberculosis this is not true, for we have bacillary and non-bacillary forms of tuberculosis.

It is now no more a question of observation and experimentation, but rather one of interpretation and understanding of the results; for we have seen that the evidence from experiments and microscopical studies is nearly sufficient.

But there are misconceptions. If that only is tuberculosis where the bacillus of Koch is found, or that only which arises from the effects of this bacillus, then Koch's theory of the exclusive pathogenetic properties of the bacillus is correct, and under such a definition tuberculosis has only one cause. But if true tubercles exist and can be produced without the bacillus, which has been shown to be the fact, then Koch's theory cannot be accepted from a pathologico-anatomical standpoint; or else we are obliged to admit two or more kinds of tuberculosis,—one due to Koch's parasite, and others to a variety of causes.[1]

So far, however, we have no reason, from a pathologico-anatomical standpoint, to subdivide tuberculosis, and therefore I am of the opinion that Koch's view of the exclusive pathogenetic property of his tubercle-bacillus, is decidedly overdrawn, and even not warranted by facts. Neither the specific action of Koch's bacillus, nor the specific character of tubercle, nor the contagiousness of phthisis or of any form of tuberculosis, is proved.

Only after a complete harmony of the facts derived from pathologico-anatomical, experimental, and clinical studies in tuberculosis with those revealed by mycology, and not from either of these alone, can we arrive at a settlement of the question of the ætiology of tuberculosis.

Further details concerning this question will be incorporated in my report. This will embrace also studies into the onset, and distribution of tuberculous affections.

From the above analysis of the bacillus question, and of the ætiology of tuberculosis, the conclusions follow—

1. That the bacillus of Koch is a valuable diagnostic sign of tubercular disease.

2. That nothing is proved by its discovery for the ætiology of tuberculosis.

3. That the too ready acceptance of the bacillus doctrine is not justifiable, and is likely to do more harm than good.

4. That neither phthisis nor any form of tuberculosis is contagious.

---

[1] Loc. cit.

[2] Sitzungsberichte d. Schlesischen Gesell., 1878.

[1] A suggestion to separate an "infective" form of phthisis from ordinary phthisis had been made by Dr. Reginald Thompson (London *Lancet*, No. 6, 1880, quoted by R. S. Smith, Bristol, *Medico-Chir. Journal*, No. 1, 1883). "In a series of 15,000 cases observed 15 cases (only one per one thousand) proved to be of an infective kind,—viz.: with history of contagion and absence of phthisical family history."

A CLINICAL NOTE ON BRONCHO-PNEUMONIA, WITH SPECIAL REFERENCE TO SURFACE REFRIGERATION FOR CONTROLLING HIGH TEMPERATURE.

BY L. S. MCMURTRY, A.M., M.D., OF DANVILLE, KY.

No pathological process is of more vital interest than that of fever, and no question in therapeutics has of late years elicited more discussion than the application of cold water to the surface of the body for the reduction of high temperature. Whatever may be the mechanism of fever from a physiological stand-point, it is a well-established clinical fact that very high temperature long continued is a most potent factor in the fatality of acute diseases. Although wholly a consequence of the pathological processes going on in the system, it is of itself a powerful menace to life. While quinine, salicylate of soda, and digitalis have been employed for their antipyretic influence, we can assume that the most powerful agent in this respect is the cold bath. The attention which this subject of necessity claims in every department of medical practice will render the observations here recorded of interest, and, may be, of value.

On Friday, December 22, 1883, I was called to see F. S., aged five years, and encountered the following symptoms and condition: The patient is a very robust boy, of healthy parentage and large for his years. On the previous day he experienced a chill, followed by fever, soreness of the chest and cough. At the time of my first visit I was informed that he had suffered with a cold for several days, and had grown rapidly worse since the chill of the preceding afternoon. The temperature was 104° F[1], pulse 120, and the respirations numbered 42 per minute, being superficial and labored. The cough was bronchial and somewhat suppressed. The normal pulmonary resonance was appreciably impaired over the left lung, and coarse *râles* were audible over its entire surface. The condition of the alimentary canal suggested a cathartic, which was at once prescribed.

On the following morning the physical signs were conspicuous and characteristic of broncho-pneumonia, having extended over both lungs. With each respiration the alæ of the nose were dilated and all the extraordinary muscles of respiration brought into action. The pulse was 140 per minute, temperature 104.5°, and respiration 48 per minute. The cathartic had acted during the night, and the patient took a small quantity of milk. I prescribed ten grains of quinine with one-fourth of a grain of pulverized digitalis, to be given at once, and directed that the patient receive a warm sponge-bath every hour. I saw the patient six hours later, and no material change was found in his condition. He complained of pain in the belly, and suffered from dyspnœa. I prescribed tinct. ipecacuanha comp.; (liquid Dover's powder, squibb,) in doses of four drops every three or four hours as indicated.

On Sunday morning, the third day in my care and the fourth of the disease, the condition was thoroughly alarming. Pulse 160; temp. 105.8° F.; respiration 60. The patient had brief snatches of uneasy sleep during the night, with increasing restlessness, followed by a tendency to somnolence. There was no cyanosis, or other evidence of carbonic-acid poisoning. I recognized the danger of the excessive and prolonged body-heat, and determined to resort to active measures for its rapid reduction. A large bathing tub containing sufficient water to immerse the entire body, was placed beside the bed; and after placing a cold cloth upon the head, he was gently lifted into the tub. The temperature of the water was 98° F., and cold water was added until the temperature of the bath was reduced to 60° F. At the end of eight minutes the thermometer showed a reduction of the patient's temperature to 102.5° F., when he was removed and placed in bed. The good influences of this method of treatment were evident from the moment it was instituted. As soon as placed in bed the patient fell into a tranquil sleep. An hour later he took a small quantity of milk. At the end of three hours the temperature had ascended to 105.2° F., and the bath was repeated. This method was continued throughout the day and night, administering the bath every two or three hours, as soon as the thermometer indicated a temperature of 103.5° F. The thermometric observations were made every hour, and I remained almost constantly with the patient, giving personal attention to the technique of the treatment.

At noon on the following day (Monday) the baths were discontinued, the patient having received eleven cold baths in twenty-nine hours. At this time the temperature was 102.5°; pulse 138; respiration 48. The physical signs gave evidence of resolution, and the patient took milk in small quantities at intervals. No material change was noted during the afternoon of this day, and the following day (Tuesday), the temperature, pulse and respiration being, with slight variations, as just indicated, and we were anxiously, but confidently, awaiting the trustworthy evidences of convalescence.

On Wednesday morning brain symptoms appeared, and put aside for the time all our cherished expectations. Ideation was confused and illusions occurred. Patient complained of intense headache, the eyes were suffused, and coördinated muscular movements were performed with difficulty. At noon the temperature was 104.5°. The rubber-coil cap was applied to the head. At this time very cold weather was prevailing, and water reduced to the freezing point by exposure to the atmosphere after being drawn from the cistern, was applied. From a bucket elevated above the head of the bed, a continuous current was passed through the rubber coil. In the evening of this day the symptoms were those of depression, with somnolence. Five grains of calomel were administered at 6 P. M.

Thursday morning the symptoms had appreciably improved. Patient had two copious bilious stools during the night. The temperature came down to 102.2°, and the cold applications to the head were

[1] The thermometric obsevations in this case were made with a Hicks' thermometer, tested and corrected at the Kew laboratory at Richmond, Surrey.

discontinued. Ideation was clearer; patient had a severe paroxysm of coughing; takes milk at intervals. Respiration 34; pulse 112. Very little change was manifest in the symptoms during the remainder of this day. Patient slept at intervals, and took nourishment in small quantities.

Friday morning the improvement was marked. Temp. 99.5; pulse 102; respiration 28; mind clear; expression good. The physical signs were those of progressive resolution. He slept several hours during the forenoon of this day, and asked for food on awakening. From this day, just one week from date of my first visit, convalescence was established, and continued without further interruption.

In arranging these notes and recalling the phases of this severe illness, I cannot but feel how much the successful issue is due to the unremitting attentions of the intelligent parents of the patient. In the application of the heroic methods of treatment I received throughout their cordial aid and coöperation.

MEDICAL PROGRESS.

THERAPEUTICS.

ON THE USE OF IODINE AND OF THE ERGOTINE OF IRON IN GOITRE, AND PARTICULARLY ON ITS PARENCHYMATOUS INJECTION.—Dr. Bawvens has a long and interesting article on the subject in the *Bulletin de l'Académie Royal de Médicine de Belgique*, in which he gives the following useful indications for the treatment by these drugs:

INDICATIONS.

TINCTURE OF IODINE.	ERGOTINE.
(*a*) Cystic goitre, successful.	The same.
(*b*) Soft, diffused recent goitre, sometimes successful	Success certain.
(*c*) Vascular goitre, dangerous and useless.	Success certain.
(*d*) Exophthalmic goitre, dangerous.	Its physiological action ensures success.
(*e*) Degenerated goitre, harmful.	It has been successful even in an ossified goitre.
(*f*) Fibrous goitre, useless.	It may succeed.
(*g*) Cancerous Goitre, useless.	Useless.

DANGERS.

(*a*) The inflammatory swelling is always intense; the symptoms of compression of the trachea, of the vessels, and of the nerves of the neck are very marked, so as to threaten a cerebral congestion and sometimes asphyxia. The pain, produced by the injection, is very severe.	The tumefaction is nothing when one considers the action of contracting, which is but little appreciable in the simple cystic goitre, but sometimes intense with a degenerated goitre. In the case of an abscess, by the use of the bistoury or trocar, all the symptoms of compression are made to disappear. The pain of the injection is almost nothing.
(*b*) Several cases of death have been recorded: Schwalbe, Sücke, Hicguet, etc.	It is not at all dangerous.

READINESS OF APPLICATION.

To have a sufficient effect, from 1 to 5 and 6 grammes should be injected at a time, which requires either a special instrument or the pain of five injections. In order that the canula and mountings of the syringe shall not be attacked by the iodine they must be gilded. To lessen the pain of the injection, it is often necessary to have recourse to ether in the atomizer. The result of the injections is often not appreciable until after two to five months of treatment, and the injections cannot be repeated at will.	Pravaz' syringe is all that is necessary, and the injections are given as required, leaving ordinarily an interval of three to four days between each.

RESULTS.

This has been successful in certain cases. Levéque has noted 32 out of 48, but on the other hand, there have been a great many failures. Lebrecht records 322 cases of thyrodectomy, in all of which iodine had failed.	In the eight cases in which it has been tried, each one has proved a success.

The preparation of ergotine (d'Iron) referred to is compared with that of Boujean as being double the strength of the latter, and instead of being syrupy and viscid, it is transparent, clear, and can be injected pure.

MEDICINE.

THE USE OF VERATRINE IN GENERAL OR LOCALIZED PRURITUS.—Dr. J. Cheron (*Jour. des maladies des femmes; Gaz. des Hopitaux*) treats the pruritus, which is so difficult to relieve, and which appears at the menopause, with an eruption of prurigo, urticaria, eczema, herpes, or without any such eruption, by the use of a pomade composed of:

Veratrine.....15 centigrammes.
Lard.....30 grammes,

of which he applies a piece the size of a small pea, morning and evening, a a soothing ointment, when the pruritus is localized in the groins, armpits, abdominal walls, etc.

But when the pruritus is more general, the internal use of veratrine is preferable, in the following doses:

Veratrine.....2 centigrammes.
Pulv..... .....glycyrrhizæ, 9 s.

Divide into 40 pills. Take 2 to 6 pills a day, one-half hour before eating, or three hours afterwards, never taking but one pill at a time, and increasing by one each day, until the maximum dose (3 milligrammes) is reached.

A CASE OF SUDDEN SPASMODIC ICTERUS.—M. Potain (*Gaz. des Hopitaux*) refers to several stories related in reference to the sudden appearance of icterus, as in the case of the two duellists, where on crossing their swords, one became suddenly so yellow that his

adversary dropped his sword in amazement, the case of a patient of Bouillaud, who, feeling very well, got up in the morning and proceeded to shave himself, when a letter was handed to him containing very bad news, and when he turned to finish his shaving, he found himself turned yellow; and the case of the woman whose husband was taken by the Commune, and about to be shot before her eyes, she turned yellow at the moment of taking aim by the detail of soldiers.

He then relates the case of a very nervous and irascible woman, in good health, who the day before her entrance into the hospital, about 10 A. M., became violently angry. Some hours later she was surprised to learn from her neighbors that she was jaundiced, and came to the hospital to be treated for the affection, which was readily relieved. The only admissible explanation of this phenomenon seems to be the influence of the abdominal sympathetic system, in its relations with the emotional centers, resulting in a sudden dilatation of the vessels of the liver, the equilibrium is disturbed and a partial vacuum created, which causes the biliary fluid to transude from the hepatic cells into the blood-vessels; whereas, in the normal state, the contrary is the case.

ON THE NEURALGIAS OF DIABETES.—Dr. Comillon (*Revue de Medicine*) gives us an extended article on this subject. In the literature of the subject he finds Griesinger in 1859, indicating the frequency of sciatica in glycosuria, who was followed by Braun in 1868, and a number of others in succession; but Worms, in 1881, was the first to establish the close relation between neuralgia and glycosuria, and to give a certain physiognomy to the three characters of the acuteness, the tenacity and the symmetry of the neuralgia. In recording his observations, he established the following four propositions:

1. There exists a special form of neuralgia peculiar to diabetes, which presents the character of being located symmetrically in the same nerve branches.

2. Up to the present time, this symmetric neuralgia has been observed in the inferior dental nerves, and in the sciatic nerves.

3. The neuralgia of diabetes is more painful than that of all others.

4. It does not yield to the ordinary treatment of neuralgia, (quinine, morphia, the bromides,) but is aggravated and extended in accordance with the degree of glycosuria.

In support of these views of Worms, Dr. Comillon quotes Drasche, and others who reach the same conclusions, and he has gathered from these sources and from his own practice twenty-two cases of diabetic neuralgia upon which to base his conclusions, as follows:

Symptoms—The neuralgia is not generally an initial symptom, but occurs only after there is a notable degree of weakness, emaciation and polydipsia. Its onset is sudden and unexpected, occurring on awakening in the morning, as a continuous, piercing, lancinating or fulminating pain, and giving at intervals paroxysms which surpass in intensity and duration most violent forms of neuralgia. These paroxysms occur three or four times a day, a slight movement or emotion being sufficient to produce them. However severe they may be in the daytime, they are worse at night. The pain is not always confined to the course of the nerves; it extends sometimes to the muscles and to the bone. Digital pressure along the course of the nerve exaggerates the pain; more extended and firm pressure quiets it. Movements increase it, and it is the same with rapid changes of temperature. With the most severe attacks there is no fever, the skin is cool, and the pulse normal. One of the most prominent and constant symptoms is the symmetry of the neuralgia, this occurs rarely at the onset, most frequently one member is attacked at first, to be followed in a few days by its fellow; with the latter the same nerve branches are affected, and if in the first the pains do not pass a certain zone, not occupying the whole extent of the nerve, they preserve the same course in the second. Exceptionally the pain is equaly in intensity on both sides, but most frequently it predominates in one or the other.

In one of Drasche's cases, the affection took on almost from the first a bi-hemiplegic ? character. At first it was located in the right hip, extending in a few days to the arm, forearm and fingers of the same side, and finally the inferior and superior extremities of the left side became involved. The relations of the degree of glycosuria is not definite; in most cases, it is only when the glycosuria is very abundant that the pain is present, but in some cases the neuralgia has appeared when the glycosuria is at its minimum.

Progress and Prognosis.—In the most favorable cases the neuralgia after resisting the use of morphia, yielded to progressive doses of salicylate of soda—in other cases the ordinary anti-diabetic treatment (diet, alkaline mineral waters) caused a prompt cessation of the pain. Relief was coincident with a diminution of the sugar, but when the patient committed some irregularity of diet, or from other exciting causes, the neuralgia returned. When the diabetic character of the neuralgia is recognized early the prognosis is not grave. By submitting the patient to a rigorous diet it yields after a time. But if it remains unrecognized for a long time, there follow alterations of the muscular tissue, and atrophy, and paralysis of sensibility of the skin; lesions which are difficult to relieve.

Diagnosis.—All neuralgias occurring in the course of diabetes are not necessarily of a glycogenic origin. But when a diabetic complains of a sharp, fixed pain along the course of a nèrve it is pretty sure to be of this nature. What has already been said of its character would, of course go far to establish the diagnosis.

Pathogenesis.—In considering this, Dr. Comillon, after reviewing the ideas of others on the subject, calls attention to the fact that diabetes has been looked upon as a manifestation of the uric acid diathesis, and he is convinced that glycosuria affects specially those persons who have had serious attacks of rheumatism or gout, bringing forward a number of considerations to sustain him in this opinion, therefore he gives uricæmia a prominent place of at least as much importance as hyperglycæmia in the pro-

duction of the neuralgia of diabetes. The last question which he considers is as to the peripheric or medullary lesion which causes this condition. The absence of hyperæmia, of vesicular eruptions, pemphigus and of paralysis would seem to exclude the idea of a neuritis. On the other hand so tenacious a neuralgia, affecting homologous nerves, and without known external causes, would seem to indicate a transitory lesion, unconnected with the anatomical elements of the medullary centers. All the symptoms point to a transitory lesion, whether this be located in the meninges, the gray or white substance is but a matter of speculrtion as no autopsy has yet been made.

A Case of Syphilis Cured by Means of an Intercurrent Typhoid Fever.—M. Defize, in the *Arehives Médicaies Belges*, relates the curious history of a patient, who in June, 1882, was affected by multiple chancres, which were soon followed by the symptoms of confirmed syphilis; pronounced adenitis in the groin and neck; general syphilitic papules, particularly one on the face; alopecia, marked emaciation, etc. Very little mercury had been given, and the specific treatment had been very incomplete. This was the condition of things when, in January, 1883, he was taken down with the ataxo-dynamic form of typhoid fever; all the symptoms were present with the exception of the lenticular spots, which were masked by the syphilitic eruption. The treatment was limited to cold water baths, tonics and diet. The duration of the fever was a month and a half. Once relieved of the typhoid fever, there remained no traces of the syphilitic affection. He had a good appetite, increased in flesh and strength. The writer refers to two other cases treated by his colleagues, which resulted as happily. He quotes Kaposi as recognizing in syphilitic cases a suspension, but not cure, of the syphilis, during the presence of the exanthematous fevers; here he claims a cure.

OBSTETRICS AND GYNÆCOLOGY.

On the Condition of the Gums in Pregnant Women.—M. Pinard treated of this subject in 1877, and now Dr. Henry Didsbury has made it the subject of his insurgural thesis, which is discussed in the *Revue Medico-Chirurgicale des Maladies des Femmes*. This disturbance of the gums consists of a swelling and softening, beginning about the second month of pregnancy. Dr. Didsbury describes three grades of the affection; in the third stage the inflammation is so marked as to give a violet red color to the gums they are puffed out, and the interdentary spaces stand out in marked relief. The tartar and the epithelial debris collects about the necks of the teeth, and the inflammation may extend to the alveolar periosteum, when the teeth become denuded and finally come out, being themselves in a perfectly healthy condition.

This gingiritis is located especially on the anterior portion of the maxillaries; it is rare to see it go beyond the canines, and the convex surface of the maxillaries is the only part affected. The other symptoms which present themselves are pain and local hæmorrhages.

The ætiology of this curious affection must remain as hypothetical. The treatment should be energetic. The tartar must be removed, and the condition met by astringents, chlorate of potash, etc.. and in severe cases by the tincture of iodine, chromic and a mixture of hydrate of chloral, and astringents.

On the Relations of Hepatic Colic to Pregnancy and Labor.—Dr. Cyr has devoted some attention to this subject, his remarks upon which are considered at length in the *Rev. Med. Chir. des Maladies des Femmes*. He reports 51 observations. In 11 of these the first attack took place during pregnancy, in 4 cases it followed a miscarriage, and in 36 it occurred after labor. It seems to be associated with certain factors, as: suppressed lactation, a defect or diminution of activity. a want of proper regime, and hereditary antecedents.

The last factor, that heredity was found to influence 4 cases as an hepatic heredity, 1 case as an arthritic, and in 5 cases there were previous or concurrent arthritic symptoms. In fact, pregnancy alone was the cause of the great mass of cases. How shall this action of pregnancy be explained? In a general way it is admitted that biliary calculi have a particular tendency to be formed, from some modification in the composition of the bile, either from the sluggishness of its circulation, or from some obstacle to its passage through the biliary ducts.

Pregnancy exerts an influence upon the liver which results at times in a more or less marked fatty degeneration, but it is not satisfactorily proven that this condition is favorable to the formation of calculi.

The direct or indirect compression of the liver during the last months of pregnancy is incontestable, and as a consequence a slowing of the circulation of the bile would ensue, with a tendency to the separation of the elements in that fluid, and the precipitation of cholesterine. This question of the connection between pregnancy and hepatic colic is interesting from a diagnostic point of view, that one may be prepared for its occurrence during pregnancy and soon after confinement, so as not to be misled by an erroneous interpretation of the symptoms, with its consequences.

The prognosis in pregnancy, except in cases of jaundice, is not affected by the presence of hepatic colic. The physician should insist upon certain hygienic precautions, such as relate to exercise, to alimentation, and to other means, the prophylactic value of which are recognized.

SURGERY.

An Instrument for Temporarily Closing Either Ureter.—Silvermann (*Berlin Klin. Wochenschr.*) figures and describes a new instrument by which either ureter can be closed long enough to al-

low of unmixed urine from either kidney to be collected for examination.

The instrument consists of a metallic double catheter, with quick curve, and a window 3½ cm.x 5 mm., near its point. The window can be closed by a shutter moved by a stilet. Within the catheter there is contained a firm elastic catheter, which terminates in a small expansible gutta percha balloon or tampon. When collapsed, this tampon is contained within the point of the catheter.

The instrument is passed into the bladder till its beak impinges upon the posterior wall in the middle line, guided by a finger in the vagina or rectum (in men). The window is then opened, and the tampon made to expand by pouring mercury into it through the elastic catheter. By the introduction of 20 c,cm. of mercury, which weigh about 270 grms., the tampon can be filled up to the size of a goose's egg, and, guided by the finger to either side of the middle line, will by its weight effectually prevent any outflow of urine from the ureter upon that side. The bladder can be emptied and washed out through the other channel of the metallic canula, and urine from the free ureter allowed to collect for from fifteen to twenty minutes, in which time quite enough for satisfactory examination can be obtained.

Silvermann had used it twenty-two times in women, and five times in men, and did not find its use attended with discomfort to the patient or followed by any evil effects.—*Centralbt F. Chir., Glasgow Med. Jour.*

OTOLOGY.

TREATMENT OF CONSTRICTIONS OF THE EUSTACHIAN TUBE BY ELECTROLYSIS.—M. Mercié has presented to the Paris Académie de Médecine a report on the experiments of Dr. Garrigue Dézarennes in the employment of this mode of treatment. He introduces into the rubber sound, while in position, a bougie composed of a bundle of very fine silver threads, which are curved upon themselves at the extremity, so as not to wound the walls of the tube. When the metallic thread reaches the back of the sound, it marks a point on the external portion, which indicates the degree of penetration, so that the exact location of the constriction is thus determined.

The sound being kept in place and the thread passed in, the moment it passes with difficulty it is forced no further, and in the external auditory canal a small silver olive-shaped conductor is passed to the immediate neighborhood of the tympanum. By connecting the shaft of the olive-shaped conductor with the positive pole, and the metallic thread which had entered the sound with the negative pole, a weak current (two or three elements of Chardin) is allowed to pass. The operation does not take more than a couple of minutes, and after its use the bougie, which had been tightly squeezed by the walls of the sound, passes readily. These results promise in electrolysis a great benefit, in cases of constriction of the Eustachian tube.—*Gaz. des Hopitaux.*

OPHTHALMOLOGY.

ON THE USES AND DOSE OF CYANURET OF GOLD AND OF POTASSIUM IN THE TREATMENT OF ATAXIC PAPILLARY ATROPHY.—M. Galezowski having reported (*Gazette des Hopitaux*) a case of atrophy of the optic papillæ which was consecutive to a locomoter ataxia of syphilitic origin, in which the ataxic affection was checked and vision greatly relieved by the use of the cyanuret of gold and potassium in hypodermic injections, the *Gazette* gives the formula and doses:

M. Galezowski employs the cyanuret of gold and potassium in hypodermic injections in doses of 5 milligrammes to commence with, then 10 milligrammes, every day or every other day. His evolution is as follows: Cyanuret of gold and of potassium, 20 centigrammes; aqua dist. 10 grammes. A fresh solution is more active and less irritating than preparations made in advance, and used sometime after. The injections should be inserted by preference in the back, along the spine, and at considerable distances from each other. They should penetrate deeply into the cellular tissue. Simply inserted in the thickness of the skin, they produce eschars, abscess, and phlegmonous inflammation of the skin. These accidents are easily prevented by taking the proper precautions.

NEW INVENTIONS.

NEW SURFACE THERMOMETERS.—M. Constantin Paul (*La France Medical*) has furnished three models of thermometers to take the local superficial temperature; one is vertical, one is circular, and one is horizontal. For their proper application two things are requisite; adhesion to the skin, and isolation from the surrounding atmosphere. This is accomplished by means of rubber arranged like a cupping glass. They can be applied anywhere to the surface where there is no hair, the air is exhausted from the rubber cup, it adheres to the skin, to which the thermometer bulb is brought in contact, and it is left at will, so that when removed the maximum remains as a permanent register, as in other clinical thermometers. The vertical, horizontal and circular positions given to the tubes are simply for ease of application in different situations.

AMONGST those upon whom the University of Aberdeen has just conferred the degree of LL.D., are Archibald Forbes, the famous and intrepid war-correspondent; Dr. George King, Professor of Botany, and Director of the Botanic Gardens, Calcutta; and Professor Lapworth, of Mason's College, Birmingham.—*British Med. Jour.*

DELEGATES FROM THE DISTRICT COLUMBIA.—Of the list of delegates to represent the Medical Association of the District of Columbia, as published in our last issue, Drs. Joseph Borrows and W. G. Palmer have declined, and Drs. W. W. Godding and J. F. Hartigan have been elected in their place..

THE

Journal of American Medical Association.

PUBLISHED WEEKLY.

THE EDITOR of this JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information, should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE..... $5,00.
SINGLE COPIES..... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 65 RANDOLPH STREET,
CHICAGO, ILLINOIS.

SATURDAY, APRIL 26, 1884.

WHAT ARE THE CONDITIONS FOR RETAINING PERMANENT MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION?—This question was suggested by a perusal of the following letter:

"*Dear Sir:*—I have been a permanent member of the American Medical Association more than a quarter of a century. I signed the *regulations* when I became permanent member." If I attend the May meeting in Washington, must I sign again to be allowed to have my tickets? I have paid all my dues up to date. I claim that I am a permanent member, and will be until expelled. I believe in the new Code of Ethics of the State of New York, and cannot *sign again*. Please answer, that I may know whether *permanent* member, means *permanent* for one year, or until you are proven guilty of some óvert act and expelled from the same. Yours respectfully."

It is evident that the writer of the foregoing letter regards the payment of the annual membership dues, as the only condition necessary to be complied with, in order to retain indefinitely the position and privileges of permanent membership in the national Association. The same view is undoubtedly entertained by many others. Indeed, no other one thing has surprised us so much as the degree of ignorance which exists among members of the Association concerning many of the plainest and most important provisions of its Constitution and By-laws. For instance, the clause of the constitution or plan of organization relating to permanent members, reads as follows:

"The *Permanent Members* shall consist of all those who have served in the capacity of delegates, and of such other members as may receive the appointment by unanimous vote, and shall *continue* such so long as they remain in good standing in the body from which they were sent as delegates, and *comply* with the *requirements* of the *By-laws* of the *Association*. Permanent members shall at all times be entitled to attend the meetings, and participate in the affairs of the Association, *so long as they shall continue to conform to its regulations.*

The last clause of the fifth By-law says: "Any permanent member who shall fail to pay his annual dues for three successive years, unless absent from the country, shall be dropped from the roll of permanent members, after having been notified by the Secretary of the forfeiture of his membership."

The reader will see from these provisions of the Constitution and By-laws, that the continuance of permanent membership is made to depend upon the three following conditions: 1. Remaining in good standing in the body or society from which he was originally sent as delegate. 2. So long as he shall comply with the requirements of the By-laws of the Association. 3. So long as he shall pay the annual membership dues. Failing in any one of these three conditions, he forfeits his permanent membership, while the right to attend the annual meeting in Washington or elsewhere, is made to depend directly upon the willingness of the member to *continue to conform* to the *regulations* of the Association. If, in accordance with the last paragraph of Section second of the plan of organization, the Association, through its registration officers, require every member to sign a card or certificate in which is a clause making the signer acknowledge obedience to the Constitution, by-laws and Code of Ethics of the Association before he can be registered and receive his card of admission to the meetings, and any permanent member or delegate refuses to sign such card, he by such refusal to "*conform to the regulation*," simply forfeits his rights as a member; not by trial and expulsion, but by a deliberate and voluntary violation of the condition on which the enjoyment of the rights is made to depend. The duration of permanent membership, therefore, must depend entirely upon the choice of each member for himself. He can make it continue as long as he lives, by simply *complying* with the *conditions* specified in the Constitution and By-laws, as indicated above; or he can terminate it in one year, or one day, by refusing such compliance with either one or all of said conditions.

DR. FORMAD'S ARTICLE.—When, many weeks since, we received and published in the JOURNAL the first part of Dr. Formad's paper on the Bacillus of Tu-

bercle, we expected to receive the remaining part simultaneously with its appearance elsewhere.

For some reason, however, the copy did not come to hand until a few days since. Yet such is the intrinsic importance of the subject, and the high value of the paper, that we have felt justified in completing its publication in the present number.

CLOSE OF THE PROGRAMME OF WORK FOR THE MEETING OF THE ASSOCIATION.—The Chairman of the Committee of Arrangements at Washington, informs us that the *Official Programme* giving the titles to papers, etc., and their assignment to Sections, was to be positively closed on the 24th inst.; it having been kept open nearly a month longer than the By-laws require.

SOCIETY PROCEEDINGS.

CHICAGO SOCIETY OF OPHTHALMOLOGY AND OTOLOGY.

The society met Feb. 13, 1884. After transacting the usual routine business the following paper was read by Dr. E. L. Holmes on the Prognosis of Choroidal Sarcoma and Life Insurance:

"On Dec. 3, 1874, I extirpated the right eye of Mr. ——, 47 years of age, who came to me with the following symptoms: the pupil was closed, the cornea slightly vascular, the vessels of the conjunctiva much congested and tortuous; the tension of the globe was greatly increased.

The eye had been blind twelve years, had suffered from periodic pain two years, and from constant and severe pain eight months.

I expressed the opinion that the affection was glaucoma, following iritis or choroidal tumor. The case reported in Knapp's Archives, Vol. 6, proved to be a glio-sarcoma of the choroid, with small round cells.

Within a few days I have been requested by a life insurance company to express an opinion regarding the nature of this tumor, as the patient had applied for a policy.

The prognosis in cases of choroidal sarcoma has been of great interest to me, since my individual experience has been at variance with the opinions generally expressed on the subject.

I have been taught to believe that the average duration of life after the removal of the globe is only four years. In this case more than nine years have elapsed, with no symptoms of local nor of remote recurrence.

I occasionally meet a gentleman in most excellent health, one of whose eyes I extirpated with melanotic sarcoma fourteen years ago. I have enucleated the globe twenty-six times for this form of tumor, and have always urged the patient to inform me of any evidence of future local manifestations or of any impairment of the general health.

In only one case have I ever received a favorable or unfavorable report. In this case there was a speedy return of melanotic growths in the orbit, in the liver and different portions of the integument.

On the other hand, I have received subsequent reports in nearly all cases of glioma, for which I have removed the globe twenty-four times, and in which the glioma re-appeared in the orbit within a few months.

My own experience would not lead me to regard sarcoma of the choroid as a very malignant disease. Under all the circumstances, I am surprised that I have been able to obtain the subsequent history of so few of my patients, the more so in view of my experience with glioma.

The difference of opinion expressed by authors as to the ratio of fatality arises, I suspect, from the difficulty in following the subsequent history.

In reference to life insurance I can only say, I believe the application of a patient who has been affected by sarcoma could not be favorably entertained by the medical examiner."

Dr. Boerne Bettman mentioned two cases of eneucleation of one eye for sarcoma and glioma. In neither of these individuals had a return of the disease been noticed.

Fully six years have elapsed since the sarcoma was removed, and three years since the extirpation of the retinal growth.

Dr. W. T. Montgomery related an instance of reappearance of the tumor and death of the patient a year after enucleation of the eye. The sarcoma was in an advanced stage, and had broken through the globe.

Dr. Bishop then addressed the society on Acute Inflammation of the Middle Ear, its Causes and Treatment.

The causes of this disease may be arranged under the three following heads: I, natural causes; II, traumatic causes; III, predisposing causes.

Under the first category cold winds and drafts occupy a prominent position. Sudden and extreme changes in the temperature and humidity of the air are prolific causes of this disease. Water is a source of great evil. Swimmers and sailors are frequently subject to inflammatory attacks of the ears. The water may enter the middle ear through the Eustachian tube from a douche, and set up a violent irritation.

II. The second class of causes includes fracture of the temporal bone, contusions of the cranium and sudden forcible condensation of air in the external auditory canal from any cause, such as explosions of fire-arms, falls upon the ear. The harmful practice indulged in by parents and teachers of boxing and cuffing the ears is to be condemned. Several cases were cited of destructive inflammation and loss of hearing caused by this barbarous treatment. Picking and cleansing the ears with pins, toothpicks, pencils, introducion of beans, pebbles, insects, frequently give rise to much trouble.

III. The predisposing causes are the most numerous. All those diseases, conditions and practices which debilitate. Whatever causes congestion of the middle ear predisposes to an inflammation, such as quinine, excessive use of alcoholic beverages, strong coffee, tea, and much tobacco smoking, scarlet fever, diphtheria, and naso-pharyngeal catarrh.

During the first stage of the disease, the treatment should be palliative, constant application of cold, local depletion. Three or four leeches placed in front of the tragus will afford speedy relief. The hypodermic injection of morphine is preferable to instillation of Magendie's solution in the ear. The solution cools rapidly, and the change of temperature is apt to increase the inflammation. Tobacco smoke blown into the external ear, through a pellet of cotton, is a very efficient remedy. General refrigerant remedies must be employed. Laxatives, sudorifics, diuretics, should be prescribed on general principles. Nutritious but non-stimulating diet should be enjoined. A simple method to evacuate the middle ear is the following one. It is the reverse of the Valsalvian method of inflation. The patient is instructed to incline the head forwards, compress both nostrils with the thumb and finger, and close the mouth. Then he is directed to draw in the breath, as it were, thus producing by the inspiration a partial vacuum in the nasal cavities and pharynx. Immediately the fluid secretions in the tympanum are forced into the throat and expectorated. If there is great swelling of the walls of the Eustachian tube, the method may not at first succeed, but is easily practiced when the tumefaction is reduced. Patients should be directed to swallow after trying this experiment; the air re-enters the middle ear, and equilibrium of pressure is restored. Catheterization is recommended when this method fails. When rupture of the M. T. is inevitable, paracentesis is resorted to. During the second stage cleanliness should be strictly observed. When pain has ceased, the dry method of treatment with pulverized boracic acid or iodoform is introduced.

The carbolic acid treatment has not been satisfactory in the doctor's hands. A five per cent. solution is neeessary to destroybacteria; he is fearful that a solution of this strength might cause suppuration. One part of bromine to 1,500 parts of water, and one part of corrosive sublimate to 20,500 of water will destroy the bacteria in ten minutes. When the trouble shows a tendency to become chronic, the following formula is prescribed:

℞. Iodoform.....ʒi.
Zinc. Sulph.....gr. ii.
Aq. Dist.....ʒi.
M.

Dr. Gradle opened the discussion by stating that micro-rganisms are one of the causes of suppuration of the middle ear. Experiments have proven that progressive suppuration is always due to micro-organisms. As long as the discharge is profuse, bacteria are always present, they diminish and no longer increase in the the discharge as the inflammation subsides. Such micrococci have been found in abscesses, and are of considerable significance. His experience in the treatment of this disease has been limited entirely to the antiseptic method. He no longer uses boracic acid, having found a more efficient substitute in the combination of one per cent. of corrosive sublimate and bismuth. It checks suppuration more rapidly, and destroys the factor after the first application. A five per cent. solution of carbolic acid will not, according to the doctor's opinion, produce suppuration.

Dr. Starkey has seen good results follow the use of peroxide of hydrogen.

Dr. Holmes disapproved of paracentesis of the M. T. in acute suppuration of the middle ear. He thought the trouble would only be aggravated by such interference.

Dr. Montgomery stated that Politzer has abandoned operative treatment in acute suppuration, but practices the method in catarrhal inflammations where there is a serous secretion.

Dr. Hotz expressed doubt as to the possibility of performing the negative Valsalvian method in this disease, during the stage of inflammation, owing to the swollen condition of the mucous membrane lining the Eustachian tube. He could not satisfy himself that leeches put on the mastoid process were not as efficacious as when placed on the tragus. They relieve pain, and should be prescribed in every case. He is fully satisfied with the action of boracic acid, and does not approve of bismuth. This powder does not dissolve, and by accumulating in the ear might act as an irritant.

An interesting case of foreign body imbedded in the fundus oculi was then shown by Dr. Hotz.

The patient was injured six months ago, a piece of a steel punch penetrated the eye after passing through the upper lid.

Some time afterward he noticed a dimness of vision, followed by almost complete loss of sight. Externally no scar or sign of inflammation is visible; the pupil is somewhat dilated. The vitreous in the upper anterior part shows some cobweb-like opacities. In the upper and inner part of the fundus, close to the papilla, is seen a black, slender and round body, apparently about ¼ inch long, one end is fastened in the tissues of the eye, the other end of the splinter projects into the vitreous, reaching close up to the lens. The piece of steel is firmly fixed, it does not change its position during movements of the eye. The papilla, in fact, entire fundus, is blurred, owing to the neuro-retinitis.

BOERNE BETTMAN, M.D., Secretary.

RESORCIN.—Le Blond and Fissiâux recommend resorcin for chancroids in woman. It acts more quickly than iodoform, and has not such a disagreeable odor; it may be used either in powder or in 25 per cent. solution. Poisonous effects have never been observed.

April 10. The opacities in the vitreous have entirely disappeared, the fundus is much clearer, and vision has decidedly improved.

STATE MEDICINE.

MICHIGAN STATE BOARD OF HEALTH.

(Reported for the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.)

The annual meeting of the State Board of Health was held at its office in Lansing, April 8, 1884.

The members present were President Avery, Drs. Lyster, Hazlewood, Vaughan, Tyler, and Secretary Baker.

Reports of the sanitary condition of the Wayne county poorhouse and asylum, and of the Barry county jail were made by the committees who examined these institutions; and these reports were ordered printed.

Dr. Vaughan read a paper prepared by Dr. C. P. Pengra, which gave results of investigations relative to the purification of water by freezing. As a result of a series of elaborate experiments conducted in the University laboratory, Dr. Pengra found that, contrary to the general impression, freezing does not render water pure. Ordinarily he found less infusoria and bacteria in ice than in the water from which it was frozen, but the ice contained them in numbers sufficient to preclude its use. In harvesting ice, the greatest care should be taken to get it from a pure source. This valuable paper will be published in the report of the board.

The Secretary presented a summary compiled from lists of medical practitioners, registered under the new law. The number of counties in the State is 80, from 76 of which reports have been received. The number of registrations returned is 3,285, but in some cases physicians are registered in two or more counties. The number reported to have graduated is 2,351; those who had attended some college but had not graduated, 208; those who had attended no college, 726. The number, belonging to all schools, reported as having graduated, is 72 per cent. of the whole number; The non-graduated collegiates are 6 per cent., and the non-collegiates are 22 per cent. of the whole number. The "graduates" are from all classes of medical colleges, hospitals, medical societies, etc. The number of different "schools" of medicine reported in these sworn statements is about 75, including "Cureopathic," "Indian," etc. In at least one instance it is reported that the sworn statement had to be signed by a "mark," the practitioner being unable to write even his own name. The number registered as belonging to the four most prominent schools of medicine are as follows: Regular, 1,533; Homœopathic, 490; Allopathic, 398; Eclectic, 366. The proportion of graduates to practitioners is: Regular, 87 per cent.; Homœopathic, 74 per cent.; Allopathic, 81 per cent.; Eclectic, 47 per cent. (Of all schools, as above stated, the per cent is 72.)

It was decided to print the names and addresses of the health officers in Michigan as soon as full returns are received. The number in the State is nearly 1,400. A new edition of the document on the prevention and restriction of scarlet fever was ordered, the last edition of 30,000 copies being nearly exhausted. It was also decided to publish facts relative to several outbreaks of trichiniasis in Michigan.

The following resolutions were unanimously adopted:

Resolved, That this Michigan State Board of Health respectfully and earnestly memorializes Congress to pass the bill, introduced into the House of Representatives Jan. 8, 1884, by the Hon. Casey Young, or of some similar bill, providing for the prevention of the introduction of infectious diseases into the United States, and for procuring information relating to climatic and other conditions affecting the public health.

Resolved, That we consider the National Board of Health the best existing and the proper agency to carry on the work mentioned in the preceding resolution.

The Board discussed the merits of several textbooks on physiology and hygiene, with special reference to the effects of alcohol on the human system, and approved for use in the schools. Martin's "Human Body," briefer course, second edition, containing special chapter on alcohol and other narcotics; and Dr. Eli F. Brown's "Alcohol; Its Effects on Body and Mind."

The amount of office work during the quarter has been large, and has included the perfecting of arrangements for holding a Sanitary Convention at Hillsdale; preparation of the proceedings of the Ionia Sanitary Convention for the printer; the making of a compilation of the public-health laws of Michigan; proof-reading on 96 pages of the Annual Report; issuing blanks for the return of the new health officers in each city, village, and township in Michigan; issuing the regular weekly bulletins of meteorology, and of sickness in Michigan; the correspondence of the office (postals are not usually copied), covering 750 pages of letter-copying book, of which over 150 pages have direct reference to the prevention and restriction of communicable diseases in Michigan; and the regular computations of data relating to meteorology and sickness.

FIRST CONVENTION OF THE INDIANA STATE SANITARY SOCIETY.—*Reception Committee:* Hon. Jason B. Brown, Chairman; Mayor D. W. Johnson, J. D. Shields, M.D.; Hon. A. P. Charles; C. C. Frey, Esq.; J. H. Andrews, Esq.; Peter L. Carter, Esq.; C. B. Cole, Esq.; J. H. Charlton, M.D.; Hon. W. D. Marshall; J. W. Stratton, Esq.; L. M. Boland, Esq.; E. E. Rettig, Esq.; W. T. Branaman.

Committee of Arrangements: Peter Platter, Esq., Chairman; Hon. D. W. Johnson; Capt. Joseph Balsley.

Committee on Programme: L. S. Oppenheimer, M.D., Chairman; S. H. Charlton, M.D.; T. S. Galbraith, M.D.

Committee on State Medicine: Thad. M. Stevens, Chairman, Indianapolis; William Lomax, M.D., Marion, Grant County; J. D. Gatch, M.D., Lawrenceburg; George Sutton, M.D., Aurora; J. M. Wooden, M.D., Greensburg.

The first session of the Indiana State Sanitary Convention was opened at Seymour, Indiana, March 12 and 13, 1884, with Dr. Norbourne N. Shipman in the chair. Letters of regret were read from prominent sanitarians. Dr. Thad. M. Stevens, of Indianapolis, read a paper on the purposes of a State sanitary society. Legislation concerning the destruction of filth was treated by Rev. George L. Curtis, of Jeffersonville. His conclusion, drawn in part from the experiences during the recent flood, were suggestive of the effects of filth as a cause of disease. In the afternoon Hon. F. J. Van Voorhees, of Indianapolis, presented a paper on food and raiment, showing the necessity of proper food, well prepared, and sufficient clothing, made on common sense principles. The proper ventilation of homes and public buildings was the subject of a paper by Dr. W. S. Haymond, of Indianapolis. A paper on chest pressure, by Prof. Thomas Harrison, of Brownstown, was read, illustrating the inevitable injuries following tight lacing. In the evening Dr. Shipman read an address on the proper way to teach sanitation. Mrs. Virginia L. Oppenheimer read a paper on sanitary cooking. On Thursday, the second day, Dr. M. L. Boas, Secretary of the County Board of Health, presented a sanitary survey of Jackson county, in which he was particularly severe on farming out medical attendance at the asylum. Dr. J. M. Moulder, of Kokomo, read a paper on the influence of tobacco and alcohol on the human race. Dr. E. S. Elder, Secretary of the State Board of Health of Indiana, read a strong paper on the objects and uses of the State and local boards of health, The importance of compulsory vaccination was argued by Dr. T. A. Graham, of Jeffersonville. Dr. J. W. Hervey, of Indianapolis, one of the veterans in sanitary work in Indiana, read a paper on the influence of habits and uses on the public health. A committee read resolutions on the death of Dr. L. P. Yandell, of Louisville, which were adopted. Dr. S. H. Chalton, after presenting a synopsis of his sanitary survey of Jackson county, was requested to complete it for the committee on publication. There was a large attendance at the closing session of the convention in the evening. A paper on nearsightedness in children was read by Dr. W. Cheatham, of Louisville, which was illustrated by several magic lantern views. A pleasant feature of the meetings was the free discussion of the papers presented. After votes of thanks, the convention adjourned.

It is the purpose of the State Sanitary Society to call other conventions at an early date.

DOMESTIC CORRESPONDENCE.

FROM WASHINGTON.

Medical Matters Before Congress.—April 7, Representative Murphy introduced a bill (H.R. 6524), declaring that all persons who, during the late war of the Rebellion, served in the Union Army as contract surgeons, shall be entitled to all the rights, benefits, and privileges conferred on surgeons and assistant surgeons of the army under the various provisions of the homestead laws. It was referred to the committee on military officers.

Medical Societies, etc.—A new Medical Society has recently been started here, which has been incorporated as the Medico-Chirurgical Society of the District of Columbia. Dr. Robert Reyburn is the President, and, among others, it includes all the colored practitioners of medicine in good standing in the District. It seems to emanate mainly from the faculty and graduates of the medical department of Howard University.

NECROLOGY.

OBITUARY NOTICE.

B. H. Reynolds, M.D., died at his residence in Manchester, Delaware county, Iowa, Nov. 13, 1883. He was born in Greene county, New York, July 22, 1839, and consequently was little over forty-four years of age. When a boy of ten years, he came with his parents to Indiana. In 1861 he enlisted as a soldier in the 76th Regiment Illinois Volunteers, and served nearly three years. During the war he gave evidence of skill in nursing, and was twice placed in charge of a hospital, as hospital steward. One of these hospitals was at Vicksburg, Miss. While in charge of them he was highly complimented by the governmental inspectors upon the excellent sanitary condition of his wards, and his careful attention to hygienic details. At this time he decided upon his future course, and began his medical studies. In fact, he was even during this period called by most of his comrades "doctor." At the close of the war he attended a course of medical lectures at the University of Michigan. In 1866 he came to Masonville, Iowa, and began the practice of medicine, but did not complete his course of study until the winter of 1871–'72, when he graduated at the Iowa State University. In 1874 he removed to Manchester, Iowa, where he continued his practice until death. He married Miss Jennie Peterson, of La Porte, Ind., Feb. 9, 1864. She still survives him, but he left no children. For a number of years Dr. Reynolds was President of the Delaware County Medical Society. Its members attended his funeral in a body, as a mark of respect for their departed Fellow. He was also a member of the Iowa State Medical Society, and of the American Medical Association. He attended the last session of the latter at Cleveland, Ohio, in June, 1883. He was a member of the M. E. Church of Manchester, and his funeral occurred from thence, on Saturday, Nov. 17, 1883. It was very largely attended, people coming from all parts of the county to attend the funeral of their physician and friend. As a physician, Dr. Reynolds was deservedly popular. Possessed of a wonderfully genial and kindly disposition, his very presence brought comfort and good-cheer to his patients in their dis-

tresses. Cut down in his prime, and in the midst of a large and busy practice, it seems difficult to understand *why* he should be so taken, and to yield submission to his removal. Of apparently strong and vigorous constitution, firm and elastic step, and imposing presence, few gave promise of longer life than he. But the silver cord is loosed, the golden bowl is broken, and he has gone to his long home. A post-mortem examination revealed a very extensive meningitis, more severe at base of brain. In the anterior and middle fossæ, the membranes were everywhere firmly adherent to the skull. The bone itself was also softened and fragile. The petrous portion of left temporal bone was easily broken by slight manipulations. A large effusion of sanious pus was found within the membranes, estimated at about 2½ ounces in quantity. In the right temporal region was a considerable extravasation of blood. In view of these lesions, it seems almost incomprehensible that there was so little disturbance of reason and mental activity. He was almost constantly rational, until about twenty-four hours before death.

N. S. C.

ROBERTSON, CHARLES, M.D., died at his residence in McConnelsville, Morgan County, Ohio, March 24, 1884. He was born at Leesburgh, Va., July 13, 1799. His parents moved to St. Clairsville, Ohio, about 1810, where he learned printing, in the office of the Ohio *Federalist*, then edited by the late Charles Hammond, Esq. The doctor was appointed postmaster at St. Clairsville. He studied medicine with Dr. W. Wood. Dr. Robertson was the oldest living charter member of the Morgan County Medical Society. He was for several years a member of the Ohio State Medical Society, and a delegate to the American Medical Association in 1856. He was married to Eveline S. Foulke, by whom he had four children, only one of whom is living. Eveline died, and he married Dessa Brown, of Pittsburgh, Pa., by whom he had one child, who with her mother survive him. When the doctor was first married he moved to Woodsfield. He removed to McConnelsville in the spring of 1826, formed a partnership with Dr. S. A. Barker, which continued till Dr. Barker was appointed Registrar of the land office, and removed to Zanesville, Ohio. Dr. Robertson graduated at the Jefferson Medical College, Philadelphia, Pa., in 1849. He was Enrolling Surgeon of the Fifteenth District of Ohio in the late war. He was a very successful physician, and for nearly half a century was an eminently useful member of the Morgan County Medical Society. He was one of its most energetic and worthy members, a true friend to his associates and a noble man. H. J. NOYES, M.D., of Ohio.

AN INTERESTING TREE.—At a recent meeting of the Berlin Medical Society, Prof. Virchow showed photographs of a gigantic plane-tree in the island of Cos, under the shade of which Hippocrates is said, by tradition, to have held medical consultations. The tree now stands in the market-place of the town of Cos, on the east side of the island. The branches, which spread over nearly the whole market-place, are supported by marble pillars.

SPECIAL NOTICES.

INTERNATIONAL HEALTH EXHIBITION.

The Secretary of the Library Committee presents his compliments to the editor of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, and requests the insertion of the following paragraph:

INTERNATIONAL HEALTH EXHIBITION.—A somewhat novel feature in connection with the exhibition this year will be the establishment of a library and reading-room, a home for which the Executive Council have assigned in the large double room in the Albert hall, overlooking the conservatory. Steps have been taken to secure a representative collection of works on vital statistics; of reports and regulations relating to public health; of regulations with reference to injurious trades and works thereon; and of reports, statistics, and other works on the science of education. Foreign powers have been invited to lend their coöperation in this effort to create an internationat library of works of reference bearing on the two divisions of the exhibition, and several responses have already been received. India and the Colonies have also been asked to contribute towards the same end. Publishers and authors have likewise been invited to forward copies of their works. In addition to the library of reference, there will be a reading room, to which the current numbers of periodical publications of a sanitary or educational character will be admitted. All books and periodicals sent to the library and reading room will, under certain regulations, be arranged for the use of visitors, and not merely for exhibition. The books will be submitted to the jurors, and a full catalogue will be issued. All parcels for the library and reading room should be addressed, carriage paid, to the Secretary of the Library Sub-Committee, Royal Albert Hall, London, S. W.

April 2, 1884.

FLORIDA MEDICAL ASSOCIATION.

The Florida State Medical Association will hold its annual meeting in the city of Jacksonville, on Wednesday, June 4, 1884, at 12 M.

County Medical Societies are invited to send delegates, and all physicians who are graduates from regular schools of medicine, are cordially invited to be present.

Essays are promised by the following physicians:

Dr. R. B. S. Hargis, "Malaria and the Relations of Micro-Organisms to Disease."

Dr. R. P. Daniel, "The Tongue in Disease, and its Diagnostic Value."

Dr. C. J. Kenworthy, "Phthisis Pulmonalis."

Essays expected from other prominent physicians.

T. M. Palmer, M.D., Orator.

Efforts will be made by the Committee of Arrange-

ments to obtain half rate tickets on railroad and steamboat lines for delegates to the Association.

E. T. SABAL, M.D., Pres.

Attest: A. W. KNIGHT, M.D., Sec.

Office of Secretary, Jacksonville, Fla., April 3, 1884.

ROCKY MOUNTAIN MEDICAL ASSOCIATION.

The thirteenth annual meeting of this association will be held in the City of Washington, on Wednesday evening, May 7, at 8 o'clock P. M. The place of meeting will be announced by the Secretary of the American Medical Association from the platform, on May 6.

The annual address will be delivered by the President, Dr. J. F. Hibberd; of Richmond, Ind.

As the number of members of this association is yearly decreasing, it is hoped that there will be a full attendance.

JOHN MORRIS, Sec.

5 Franklin St., Baltimore, Md.

RAILROAD NOTICE.

Dear Dr. Davis:—I am authorized to make the following statement. It came too late for insertion in the *Courier-Record*, where it was intended to be published, but I thought if it were printed in your journal, it would still reach a large number of persons interested, in this State.

The Piedmont Air-Line have tendered the Medical Association of Texas one round-trip rate, of $49.50, to Washington, to the convention of the American Medical Association, in May. This rate will be participated in by the Gulf, Colorado and Santa Fe Road. and the G. H. & S. A., and the N. O., Tex. Railways. This rate, good for thirty days, and parties wishing to do so, can stop off at points on the return to Texas. The trains leave Houston at 6 P. M., and arrive at Washington on the third morning at 10 o'clock. Through sleeper from New Orleans to Washington, without change.

For information, and for sleeping-car berth, apply to

JAMES M. MEANS,
Gen. Tex. Pass. Agt., Houston, Tex.

April 14, 1884.

BALTIMORE & OHIO R. R.

The Baltimore and Ohio R. R. will run a special train of palace coaches, exclusively for physicians and members of their family, leaving Chicago on Sunday, at 3 P. M., May 3, arriving at Washington about 4 P. M. of next day. Fare to Washington is $17.50 from Chicago. Return fare at one-fourth the unlimited rate. Tickets good for 30 days. By charter of sleeping cars on this train at $100 each, 26 berths to a car would make the rate $3.85 per berth.

The fare via the P. F. W. and Pennsylvania Roads, also a direct line from Chicago to Washington, is the same on their regular trains, namely, $17.50, and all other lines have made rates in the same proportion, as was announced in last week's JOURNAL, which will doubtless secure a larger attendance than at any of the previous meetings.

NEW BOOKS.

LIST OF CHANGES IN THE STATIONS OF MEDICAL OFFICERS, U. S. NAVY, FOR THE WEEK ENDING APRIL 19, 1884.

Medical Inspector H. C. Nelson, detached from Navy Yard, Washington, and placed on waiting orders.

Surgeon D. McMurtrie, ordered to duty at Navy Yard, Washington.

Medical Director P. S. Wales, to continue on duty as member of Ration Board.

Surgeon H. M. Wells, to special duty at Hot Springs, Ark.

Medical Director Geo. Peck, ordered as President of Board of Medical Officers, detailed for special duty at Coaster's Island, near Newport, R. I.

Medical Director A C. Gorgas and Surgeon I. C. Wise, members of above Board.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT UNITED STATES ARMY, FROM APRIL 12, 1884, TO APRIL 18, 1884.

Baily, Joseph C, Major and Surgeon, leave of absence extended tor three months. (By par. 8, S. O. 83, A. G. O., April 10, 1 4.)

Newton, R C., 1st Lieutenant and Assistant Surgeon, relieved from duty at Fort Sill, Ind. Ter., and ordered to Fort Elliott, Tex., for duty. (Par. 1, S. O. 77, Headquarters' Department of the Missouri, April 14, 1 4.)

Vilcher, James E., 1st Lieutenant and Assistant-Surgeon, assigned to duty at Camp Poplar River, Mont. (Par. 2, S. O. 37, Headquarters Dept. of Dak., April 7, 1 4.

Chapin, Alonzo R., 1st Lieutanant and Assistant-Surgeon relieved from Duty at Fort Douglas, Utah, and ordered to Fort Laramie, Wyo., for duty. (Par. 2, S. O. 33, Headquarters, Dept of the Platte, April 15, 1 4)

Wales, Philip G., 1st Liutenant and Assistant-Surgeon, ordered to report to the commanding general, Dept. of the Columbia, for assignment to duty. (Par. 11, S. O. 84, N. G. O., April 11, 1 4)

OFFICERS OF

THE AMERICAN MEDICAL ASSOCIATION

AND OF ITS SEVERAL SECTIONS 1883-4.

PRESIDENT.
Dr. AUSTIN FLINT, SR., of New York.

FIRST VICE-PRESIDENT.
Dr. R. A. Kinloch, Charleston, S. C.

SECOND VICE-PRESIDENT.
Dr. T. B. Lester, Kansas City, Mo.

THIRD VICE-PRESIDENT.
Dr. A. L. Gihon, United States Navy.

FOURTH VICE-PRESIDENT.
Dr. S. C. Gordon, Portland, Maine.

PERMANENT SECRETARY.
Dr. Wm. B. Atkinson, 1400 Pine St., Philadelphia.

TREASURER.
Dr. R. J. Dunglison, Philadelphia.

LIBRARIAN.
Dr. C. H. A. Kleinschmidt, Washington, D. C.

Place of meeting, 1884, Washington, D. C.; Time of holding meeting, first Tuesday in May.

CHAIRMAN COMMITTEE OF ARRANGEMENTS.
Dr. A. Y. P. Garnett, Washington, D. C.

ASSISTANT SECRETARY.
Dr. D. W. Prentis, Washington, D. C.

BOARD OF TRUSTEES FOR JOURNALIZING THE TRANSACTIONS.

Drs. J. M. Toner, Washington, D. C., President;
M. Moore, Rochester, N. Y.; Leartus Conner, Detroit, Mich.;
J. H. Packard, Philadelphia, Secretary;
H. F. Campbell, Augusta, Ga.; A. Garcelon, Lewiston, Me.;
P. O. Hooper, Little Rock, Ark.;
L. S. McMurtry, Danville, Ky.; J. H. Hollister, Chicago, Ill.

OFFICERS OF THE SECTIONS:

"Practice of Medicine."
Chairman—Dr. John V. Shoemaker, Philadelphia, Pa.;
Secretary—Dr. W. C. Wile, Sandy Hook, Conn.

"Obstetrics and Diseases of Women."
Chairman—Dr. T. A. Reamy, Cincinnati, Ohio; Secretary—Dr. J. T. Jelks, Hot Springs, Ark.

"Surgery and Anatomy."
Chairman—Dr. C. T. Parkes, Chicago, Ill.; Secretary—Dr. A. O. Walker, Detroit, Mich.

"Ophthalmology, Otology and Laryngology."
Chairman—Dr. J. F. Chisolm, Baltimore, Md.;
Secretary—Dr. J. L. Thompson, Indianapolis, Ind.

"Diseases of Children."
Chairman—Dr. Wm. Lee, Baltimore, Md.; Secretary—Dr. W. R. Tipton, Las Vegas, N. M.

"Oral and Dental Surgery."
Chairman—Dr. T. W. Brophy, Chicago, Ill.; Secretary—John S. Marshall, Chicago, Ill.

"State Medicine."
Chairman—Dr. Deering J. Roberts, Nashville, Tenn.;
Secretary—C. W. Franzoni, Washington, D. C

Committee on "Necrology."
Chairman—Dr. J. M. Toner, Washington, D. C.

ORIGINAL ARTICLES.

THE PHYSICAL AND HEREDITARY NATURE OF VICE.

BY U. P. STAIR, M.D.

The question as to whether the basis of moral states, which find their expression in conduct, are to be sought for in existing brain activities, pathological or physiological, is one which is taking a more or less leading place in modern scientific thought.

Stripped of all its theological associations, and viewed solely from a scientific standpoint, to say nothing of its legal bearings, the question becomes one of no little importance.

Is there, then, a pathological or abnormal basis for vice to be found in the brain of the so-called criminal classes?

The first point of importance to be noted is the claim that, lying at the bottom of those perturbations of conduct which characterize these classes, and which constitute their chief or sole cause, is to be found a lack of proper brain development, and that this physical defect is the constant heritage of these classes, through hereditary transmission. Thus, it is a very common form of the argument to treat the relations existing between vice and crime and a lack of mental culture, as inseparable, and always as that of cause and effect. Moreover, there is a manifest tendency to regard physical diseases of other organs than the brain as also causes of moral perturbations, so that, as a logical consequence, the educator, but very largely the physician and sanitarian, are henceforth to be held responsible for the moral, as well as the physical delinquencies of the race.

Now, we wish, as briefly as may be, to inquire whether these claims are true; whether, for instance, common observation of the social facts around us will warrant us in accepting the doctrine that ignorance, simply, from a lack of brain development, is the cause of the vice and crime so prevalent in our midst.

In the first place, it must be admitted that a very large class indeed of the best people, morally speaking, of our own country, as well as across the water, are far from being cultured or educated people. Especially is this true in the rural districts. Here, and often amongst the lowliest and least cultured ones, are to be found the moral bone and sinew of our land; whilst it is no less an undeniable fact that no insignificant number of our great criminals are from the educated and cultured classes. There are cultured villains as well as grossly ignorant ones. It follows, then, that mental culture solely, though associated with its consequent brain development, as a standard of moral rectitude, is wholly worthless. The main question is, Is there brain power enough to discern vice from virtue, right from wrong, with strength of will to choose between them? This, it would seem, covers the whole ground. The relation of cause and effect, then, between ignorance and crime, is largely a forced one. On the contrary, it is far more likely that they are children of the same parentage, namely, poverty and degraded social position. A constant struggle for existence begets carelessness in moral distinctions. In the same struggle is to be found, also, a fruitful source of the enforced ignorance which is so common an associate.

Then, again, in respect to the hereditary aspect of vice, are we warranted by the facts of daily observation in regarding moral traits, or even mental peculiarities, as being capable of hereditary transmission? We know it may seem idle, to many, to open this question. But it is not a question to be answered in the interest simply of a preconceived theory. The question is one of fact, and we are endeavoring to see if the facts of daily observation lead unmistakably to this view, or whether they cast doubt upon it.

We have no disposition to inquire into the ultimate nature of heredity. It may be sufficient to remark, however, that the speculative theories of Mr. Darwin and others, wherein they would imply an absolute *material* nexus between parent and offspring, are entirely too vague for any practical, or even scientific value. It is coming to be recognized that heredity probably does not involve a material transmission at all.[1] It is more likely that the type or plan of organization upon which one or all of the different tissues of the body are built up, carries with it all that there is embraced in the term. For example, Prof. Formad, of Philadelphia, believes, and with good reasons, that a defective organization of the connective tissue lies at the foundation of scrofula and tuberculosis. For the same reason, we may regard some physical defect as constituting the tendency, also, by which certain mental diseases are transmitted. It is a common error for those whom we think exaggerate the influence of heredity, in biological processes, to seize upon cases of the rarest exception as evidence

[1] Richardson, Diseases of Modern Life, p. 30

in favor of their views, while the vast majority that oppose are passed over in silence. Thus, Mr. Darwin refers with evident gratification to an instance recently sent him by an American correspondent, where a man with traumatic enlargement of the tips of both thumbs transmitted the peculiarity to various branches of the family line. However, it should be remembered that if the instances where accidental deformities were never transmitted at all could all be recorded, they would doubtless be as infinity to one. Besides, it is quite probable that the defect here said to have been transmitted may have been due to the abnormal type of tissue organization which results in phthisis and its associated "clubbed nail" condition.

The same method of reasoning is also pursued by many of those who are now engaged in the investigation of mental and moral perturbations. Thus, a recent writer unhesitatingly declares that "It is a demonstrable fact, that children of illegitimate parentage are peculiarly liable to become addicted to vice and crime, as a result of an hereditarily defective moral sense."[1] To this we must demur, most decidedly, until the "demonstration" is forthcoming. On the contrary, we have in mind at the present hour, at least a dozen or more of the offspring of such parentage, and not one of them shows the least more vicious or criminal tendencies than children of legal unions. In fact, some of them exhibit an unusually scrupulous regard for moral distinctions. It would seem, as well, that the doctrine of transmitted intellectual peculiarities can scarcely be sustained by common observation. Certainly, there has been but *one* Homer, Shakespeare or Milton; but one Cæsar or Napoleon, Phidias, Michael Angelo, Demosthenes or Webster, while numberless weaklings, throughout the history of the past, have held their crowns only by force of arms. If heredity prevails in the realm of intellect, why was the greatness of these names born with these particular individuals, and above all, why did it so utterly perish at their death?

The further claim, upon which so much is based in recent times, that the present bulk of brain and consequent mental status of man, has been acquired only through the transmitted experiences of the race, through ages of time, is just now being sorely tested. The Australian Bushman, who has been heretofore regarded as so low in the scale of humanity, that he had no idea of a God, and the extent of whose mentality consisted in his being able to count to the number of four, has recently, by the influence of Christian teaching, been raised up to the enjoyment of a civilized home, in which the sewing-machine and cabinet organ play their usual part; and that, too, in the short space of ten years' time.[2] We feel at liberty to thus trespass upon what may seem to be unscientific ground, for the reason that the writer from whom we just quoted suggests, from his point of view, that moral delinquencies may be quite as amenable to correction through the influence of medicine, as through that of the church.

In returning to speak of the claim that in the vicious and criminal classes there is an "atypical" or abnormal brain development, corresponding to the moral condition, let it be remarked that this abnormality, if it exists, must consist, grossly speaking, in quality, rather than in quantity. We believe that it is now nowhere maintained that brain mass, simply, at least within certain limits, is to be considered a standard by which mental capacity is to be judged. Neither can any particular *form* of brain be essential to vigorous and healthy mental action, as is conclusively shown by Dr. J. C. Dalton in the New York *Med. Journal* of March 8, 1884. Hence, any change in position or direction of certain gyri or fissures, or number of convolutions, could have but little weight in determining the question. When we remember, further, that it is only the most profound dsseases of the nervous system, associated with which are also grave general disorders, that show any pathological lesions whatever, the possibility of demonstrating the existence of vice in the subject by the use of the scalpel becomes extremely improbable—indeed, after speaking with great force and clearness upon this point, Dr. Spitzka declares that only in paretic dementia, with organic disease elsewhere, "does the autopsy approximate the dignity, from every point of view, of a scientifically positive test.[1] If, then, such grave troubles as mania and melancholia present no appreciable lesions whatever which can be discovered by the closest scrutiny, is it at all likely that a physical basis for the far more occult moral manifestations can be laid bare by dissection?

Conceding for the moment that there is an atypical brain development lying at the bottom of vice and crime, let us inquire along what particular lines shall improvement be attempted, and what particular methods are to be adopted, in order to antidote the vicious brain? Will an appeal to the intellect simply be sufficient? No doubt the higher brain is the organ both of the intellect and the moral sense. Will an education which appeals to the intellectual faculties only, carry with it moral growth and strength also? Intellectual growth alone only changes the character and social standing of the criminal. Ignorance and the lowest forms of vice are associated. Culture and the higher crimes, such as forgery and embezzlement, are on equally as good terms. We are well aware that it is fashionable just now, to sneer at moral influences in shaping human conduct. Man is a creature of circumstances. His mental and moral energies are but the reflex of the activities of his nervous system, and that is as the current physical conditions make it. We have just had the "startling" conclusion forced upon us, with a "dogmatism" equal, at least, to that of the "moralist" or theologian, that "Inebriates are the result of physical causes and conditions; that they are grown and manufactured as much so as cotton and wool, and the machines to work them into fabrics."[2] But, on the other hand, when the "inexorable power" of heredity is being appealed to, all known physical law is set at defiance. Mental and moral qualities, which possess no appreciable physical equivalent, are transmitted, as accumulated experiences, so much in weight avoirdupois, so that

Mr. Spencer declares "that thus it happens that the European inhabits from twenty to thirty inches more brain than the Lapman," and Maudsley that "the true thief is born and not made," and M. Ribot that the passion for gambling may even be acquired by the fœtus *in utero*, while "moral anæsthesia" is transmitted by a single genetic act, and the delicate and almost transcendental impress which constitutes the essence of heredity is still grossly spoken of by some authors of high repute as "seeds" and "germs" with as much assurance as though they were objects of daily observation and manipulation.

It is to the unfortunate criminal classes, however, to which is applied the law of heredity thus rigidly interpreted, and it is likewise to them that is denied the benign influences of proper moral training, which has been, as we think, of immeasurably more consequence, as a cause of their low moral and intellectual status. We have ventured to doubt that moral traits are by any means as uniformly transmitted by heredity as is commonly claimed. We are not deterred from this view, even though Mr. Spencer declares that "If any one denies that children bear likeness to their progenitors in character and capacity, if he holds that men whose parents and grand-parents were habitual criminals have tendencies as good as those of men whose parents and grand-parents were industrious and upright, he may consistently hold that it matters not from what families in a society the successive generations descend." It is plain that Mr. Spencer ignores here, one of the most important factors in the problem, namely, moral training, the home influence and the precept and example of parents and associates upon the tender sensibilities of the child. This thought is so vigorously and aptly expressed by a recent French writer, Mr Alfred Fouille,[1] that we cannot do better than to give his views at some length. After speaking of the theories of Mr. Spencer and Mr. Darwin relative to the debasement of society through the influence of heredity, he says: "In fact, the law of mental and moral heredity, which is their principle, is much more vague and loose than the law of physical heredity. What is the meaning of the unprecise expression 'a society lowered by the artificial preservation of the individuals least capable of taking care of themselves?' Does Mr. Spencer mean that parents, in the habit, for example, of soliciting at the charitable institutions, will beget children endowed wilh the innate disposition to go to the same institutions? England certainly offers a spectacle of this kind of poor who are assisted from father to son by the parishes. * * But whose fault is it? Is it not the fault of the bad education received by the children rather than heredity of temperament?

If those children were brought up with the children of a lord, would they exhibit an innate propensity to beg or to be assisted by others? We believe generally that Messrs. Spencer and Darwin, as well as Messrs. Jacoby and Ribot, attribute too great a part to heredity, too little a one to education and circumstances." This, then, would seem to embrace the whole field of argument. What is applicable here to the poor and degraded classes of England, is equally applicable to the so-called criminal classes, not only there, but in our own country also.

It may be further observed that the most recent interpretations of leading alienists tend to obliterate entirely the line of demarkation between sanity and insanity. But certainly if sanity is but a relative term only, if it is not a standard or fixed mental condition, then all attempts at a logical discussion of the question in hand may as well be abandoned at once. But we think we are fully justified in assuming that this healthy standard exists. Then, given a healthy brain, whether selected from the Australian aborigines, or the Caucasian branches of the race; whether from the slums of London, New York, or Chicago, and place its possessor under the earliest and most favorable moral influences, and there is certainly very little to show, even despite the power of heredity, why the highest ethical results may not accrue to which the race has yet attained.

In view of the foregoing observations, then, it is maintained:

First, that ignorance is not a necessary cause of vice; that the amount of wrong doing, as a result of ignorance, is infinitely small when compared with that indulged in from a wilful disregard of the moral code.

Second, that at the present stage of investigation of cerebral pathology, it is scarcely to be expected that anything but negative results would follow any serious effort to demonstrate a physical basis for vice in the brain, by the use of the scalpel and microscope; and,

Third, Following upon this, and in perfect harmony with it, observation and experience fail to establish the claim that vice and crime are qualities capable of being transmitted by heredity to any such extent as to constitute a distinct and definite class in human society; and, above all, that there is a *moral* force in the social world, to which, in its sphere, heredity is wholly subservient, which is as positive and potent in its influence as that of gravitation in the physical universe, and he who would teach sociology and ignore the former, is as unsafe a leader to follow, as he would be who should attempt to teach physics and ignore the latter.

PARALDEHYDE, SUGAR AND GERM DISEASES.

[Read before the Baltimore Academy of Medicine, November 20, 1883.]

BY J. R. UHLER, M.D.

The substances that I am about to describe are interesting alike for their properties and suggestiveness, since they belong to a class of bodies that, through fermentation and degradation, are closely allied with alcohol and acetic acid. Paraldehyde was first employed by the Italians, and if we can trust accounts in the journals and individual experience, it is a very useful addition to the list of antispasmodic

and sleep-producing agents. In both the concentrated and dilute state it smells and tastes somewhat like sweet spirits of nitre, but when a drop is placed on the back of the tongue, a more pungent, musty, and bitter sensation will be experienced. The odor from its vapor quickly fills an apartment, but it seems to evaporate more slowly than chloroform or ether. Its chemical formula is $C^6 H^{12} O^3$, and, as the name indicates, is either a more condensed form of, or is very similar to, dehydrogenated alcohol. At ordinary temperatures it is a colorless liquid, neutral or slightly acid to litmus paper, and boils at 225° Fahrenheit. Its specific gravity is ·998, and at 52° F. it dissolves in eight parts of water. Paraldehyde is usually given largely diluted with water, and passes unchanged from the body by way of the lungs, the breath smelling very distinctly of it. The dose is from ʒss to ʒiiss, and the effect usually proportionate to the quantity administered. In cases of melancholia, accompanied with sleeplessness, the larger amount is frequently required, but the best plan is to commence with ʒss, and gradually increase until its effects are visible. The sleep occasioned by this agent is not usually so profound as that induced by choral, but when the latter causes unpleasant effects, or the patient has to use a sleep-producer for a long time, paraldehyde is a very efficient aid. It does not cause excitement in the early stage of its action, nor is the heart interfered with, and altogether it appears to be a safer remedy than other hypnotics. To produce sleep during fevers it is very useful, and may have an advantageous effect upon the duration of some cases by modifying the cause. The distress of the opium eater is mitigated by it, alternated with chloral, and in hysteria it is at times invaluable. I have used it since last July as a hypnotic in a case of what might be termed dread of sleep, and also in very obstinate wakefulness from melancholia, accompanied with suicidal tendencies. In the first condition, ʒss acted as well as the same quantity of chloral, and upon awakening there was neither depression, nausea, or other unpleasant effects. The case of melancholia had been using chloral once or twice nightly for more than two years in ʒss or ℈ij doses, though on two occasions as much as an ʒj was taken on her own responsibility, without producing death. So large a quantity caused much irritation of the stomach, as well as vomiting, and this without doubt saved her life. Very obstinate eruptions also followed the abuse of the drug, and disintegration of the red-corpuscles seemed to take place in spots under the skin, resembling purpura. The eyelids, and tissues in the neighborhood of the lower ones, became distended with yellow serum, and a squamous skin disease, accompanied with diarrhœa and great prostration, set in. No albumen or tube-casts were found in the urine, and upon the withdrawal of the drug the urgent symptoms gradually disappeared. Half a drachm of paraldehyde would sometimes make this patient sleep for two hours, but generally four or five times that amount was required. I have also given it in phthisis, measles, neuralgia, diphtheria, spasmodic croup, asthma, and in a case supposed to be whooping-cough, with the most prompt and gratifying result. Other sufferers from pertussis have been greatly benefited, and have had the number of paroxysms much diminished, and I deem the drug worthy of further trial in hypnotic doses in this very obstinate affection. In Bright's Disease, epileptiform convulsions, and inflammation of the upper part of the spinal cord, paraldehyde may do harm, as it seems to "act first upon the cerebral hemispheres, and then extends its influence to the medulla and cord." An overdose is said to "suspend the action of the medulla oblongata and respiratory centers, and after these the heart." I have tried it internally on infants of three, six, and twelve months; upon children, adults, and in extreme old age, but have never seen any harm occur except when there was already some stupor, which it seemed to increase. The drug will, without doubt, prove useful in rheumatism, gout, prurigo, chordee, hysteria, chorea, hiccough, hepatic colic, muscular twitchings, and many diseases where spasm is an important symptom. Dropped upon an abrasion of the wrist, it smarted like alcohol, but appeared to have little effect upon the healing of the sore. Inhaled in small quantity, with free access of air, in phthisis, diphtheria, and spasmodic cough, it sometimes caused drowsiness, and seemed to excite a slight burning sensation in the throat, but otherwise produced no unpleasant effects upon the glottis or lungs. Alone or alternated with tincture of veratrum viride or chloral, it is worthy of persistent trial in tetanus, as the physiological action of paraldehyde appears to teach that good might be expected in that condition, and it is known to be antagonistic to strychnia. Some experiments that I have tried seem to indicate that strong paraldehyde has antiseptic properties resembling the substance from which it is made. A piece of raw beef kept in the pure material shrivels, hardens, and whitens, but does not perceptibly decay, and under the microscope shows an appearance somewhat like that which alcohol or acetic acid produces.

A similar piece of raw muscle placed in equal quantities of paraldehyde and water, behaves in a corresponding manner, but at the point where the two liquids meet, pale yellow globules are visible to the naked eye, that float about in a film and look like fat.

Fragments of raw beef were also suspended from the bottoms of corks in bottles, so as to be surrounded by the vapor of pure paraldehyde and paraldehyde mixed with water, and seemed at moderate temperatures to undergo little or no decomposition. They became harder and darker than similar muscles immersed in strong and diluted paraldehyde, and smelt very distinctly of the drug when removed from the bottle; but at the end of five weeks, though much shrunken, had not otherwise perceptibly changed. Placed under the microscope at this time, the muscular fiber resembles in most respects that which has been kept in strong alcohol. In the cold concentrated condition, paraldehyde dissolves a small quantity of cholesterine, and other fatty constituents of gall-stones, affording most beautiful crystals for the microscope. Urine mixed immediately after its passage with one-third its bulk of paraldehyde, at the expiration of six weeks is still acid to litmus paper.

Microscopic examination on the second day showed crystals of oxalate of lime, and now it contains the same, with a few masses of triple phosphate. There is some sediment in it that looks a little suspicious, but I have not found any vibrios as yet, nor this there any free ammonia.

Paraldehyde mixed with sterilized grape sugar solution in an inverted test tube, and subjected to the proper temperature, does not cause fermentation in the course of six days. Yeast mixed with an equal quantity of paraldehyde, does not ferment cane or grape sugar solution in four and six days, respectively, as I have proved in the following manner: A number of test tubes, after washing, were purified by boiling in water, and when cool enough, were immediately filled with solution of cane sugar, that had also been boiled. Into these, at 70° F., some yeast that had been kept in paraldehyde for twelve hours, and then allowed to evaporate without heat, was placed, and the tubes were inverted in more of the sterilized cane sugar solution. At the end of twelve, twenty-four, thirty-six, forty-eight, and every twelve hours until the termination of the fourth and sixth day, they were examined, but no carbonic acid was formed. The same experiment was performed many times in a more perfect manner with raisin water, sterilized by heat, the yeast and paraldehyde being added in equal quantities after it had cooled, but no fermentation occurred. More dilute preparations of paraldehyde and yeast were also tried in various manners, with week raisin juice that had been boiled, until at last a point was reached where the sugar fermented. With small quantities of yeast and less paraldehyde, results were often contradictory, as germs from the atmosphere during the long time required, are likely to get in the sugary fluid where the inverted tubes stand, set up fermentation, and thus deceive. A portion of the yeast also diffuses itself throughout the liquid, and thus gives less gas in the tube than it ought. These difficulties were finally overcome by using cotton wadding that had been boiled to close the mouth of each tube to keep the yeast in, and the tubes, when full, were immersed in clean mercury. As the tubes containing wadding are hard to turn upside down without admitting air, this plan was finally abandoned, and we were satisfied with simply inverting them in clean mercury. To determine whether the yeast that had failed to ferment with the large quantity of paraldehyde, had been killed or was merely delayed in its action by the presence of the drug, of which the solution strongly smelled, it was diluted with some fresh sterilized raisin juice, and again put into test tubes, inverted over mercury and allowed to remain during four days, but it did not form carbonic acid. The same solution was diluted still further and tried again, but failed entirely to give off gas, and it was not until we had used it many times that we were enabled to get a feeble effect, showing that most, if not all, of the germs were killed. Yeast was likewise smeared around the interior of a bell-glass containing air, and subjected to the fumes of the drug placed in a saucer beneath it, for periods varying from six minutes to twenty-four hours. That under the influence the shortest time suffered least, but all of the specimens, when mixed with sugar, sooner or later fermented. The majority were greatly delayed, and a few, where the contact was shortest, seemed to be accelerated, but as it is almost impossible to get the same number of active yeast plants in each tube, comparative results, except after many hundreds of experiments, conducted at the same time, are not to be relied upon. Another inverted jar, after being smeared on its interior with yeast, was placed over a saucer containing water, on which a small vessel floated, holding paraldehyde. By means of a rubber tube this jar was filled several times with air from the lungs, and the whole was then set aside for twelve hours. At the end of that time the yeast was mixed in tubes with grape sugar solution and allowed to act on it. No effect was produced for thirty hours, but shortly afterward traces of carbonic acid became visible, and gradually increased. Yeast was also placed in one end of an open glass tube, and paraldehyde in the other; through this the breath was taken for half an hour, so as to drive the paraldehyde vapor, and air from the lungs over it, and the yeast was finally put in grape sugar solution to test its activity. At the end of twenty-four hours a single bubble of gas showed that fermentation had begun, and five hours later it was fully established, the gas filling the tops of the inverted tubes. The object of these experiments was to imitate the condition of yeast in the trachea and lungs, and see what effect paraldehyde would have upon it there. Altogether, though not yet through with the investigation, the following conclusions seem warranted.

1. Strong paraldehyde either destroys entirely or greatly delays the fermentation of yeast.

2. Its activity seems to approach that of the substance (alcohol) from which it is derived, therefore less than 20 per cent. in a fluid will not entirely prevent fermentation.

3. A certain amount of time and contact is required, hence it is not quite so active in the gaseous as in the more concentrated liquid condition.

4. Ammonia is not given off from urine in which it is dissolved during five weeks.

5. It dissolves cholesterine and other constituents of gall-stones, but not so well as ether or boiling alcohol.

6. It hardens muscle lying in it or subjected to its vapor, even in the presence of water.

If paraldehyde acts in the system as it seems to do elsewhere, it is evident that, while in the body or being eliminated, that it must exert some influence upon the tissues or foreign living bodies which it touches, and if the contact be sufficient to kill or retard the development of certain kinds of bacteria or yeast plants, then such diseases as depend upon their presence ought to be modified or prevented. That bacterial diseases occur, is now generally admitted, and that modified yeast plant ones are also met with in man and animals, from analogy seems highly probable, but whether we shall call these effects diabetis, diphtheria,[1] phthisis in its earliest stage, embolism of

[1] I am not ignorant of the bacillus tuberculosis, but think that there may be an earlier stage, due to the overgrowth of cells, yeast plants, etc., as suggested by Salisbury, Cutter, Formad, and others.

the liver and kidneys from the small particles sticking in the capillaries and pores, giving rise to yellow atrophy and nephritis, of yellow fever in man, or pleuro-pneumonia in the lungs of cattle, must be left to the future. At present it will be well to cautiously try paraldehyde, both in the stomach and by inhalation, for pneumonia, bronchitis, hay fever, syphilis of the throat or nose, influenza, catarrh, and all spasmodic chest diseases, and if cholera, malaria, yellow fever, diphtheria, typhus, small-pox, scarlatina, measles, or any other contagium, enter the system through the stomach or air-passages, there is a possibility that this drug or certain modifications of it, when used promptly, may destroy, atrophy or change some of the specific germs locally, and thus prevent the full development of the disease. Do not think that I expect too much of this drug, or that it will render harmless or destroy all kinds of germs, for this is hardly possible, since each species thrives under special conditions of acidity or alkalinity, best suited to itself. But if it, or any germ excrement, will retard the growth of one single form in any given part of the body, so as to render the yeast plant nearer the size of a vinegar fungus, and the latter more like bacterium, or teach us to control germs by other germs, we shall be fortunate indeed. So far I have used paraldehyde in four cases of measles, that ran a very mild course, with scarcely any eruption, but as this may have been a coincidence, and not the effect of the medicine, we must wait for increased light. To obtain this, the drug should be studied, not only practically at the bedside, but systematically on living animals in connection with urea, cholesterine, leucithin, uric acid, bile, and the refuse products of the system, remembering that paraldehyde may do harm as well as good, and that it forms a modified link or part of a link in the great chain of fermentation and degradation products, that start from life and sugar, and go on through alcohol, acetic, lactic and butyric acids, to end in ammoniacal decomposition and death. Bearing in mind also that it is not as a general antiseptic that it will prove most useful, but as a local one, directed to a single or few parts of the economy, and liberated unchanged in a volatile form from the lungs. The importance of this latter information cannot be over-estimated, since the list of bodies that act there is small indeed, and the number of deaths from diseases of the lungs more than equal to those from any other cause. Not only as physicians and hygienists are we affected, but as eaters and men having dominion over the brutes, and I pity the person who can tranquilly see cattle stamp and look imploringly for aid, without a desire for something to break up germs in their lungs. Self-interest, therefore, as well as humanity, will sooner or later compel us to utilize all knowledge of fermentation, and the refuse products of the system, in a more complete manner than we have done heretofore, and not leave the best practical results of our laboratory work in the hands of the brewers, candy makers, picklers and old women.

An examination into the constituents of the canners and jelly-makers' trade, as well as the structure of our common garden fruits, shows that nature and art both throw up barriers against the entrance of minute organisms by the formation of a more condensed covering of the can or rind, and it is only when these are broken that fermentation takes place. The human body also, by its skin and membranes, performs the same function, and in disease, by the throwing out of lymph during inflammation, endeavors to limit it. Many of the white tissues also appear to be protected from breaking down too quickly by a minute quantity of that most insoluble substance, *cholesterine*, and this may be *its* greatest use in the economy. Hardening, therefore, the coagulation of albumen, deposit of fibrin, and such like processes, are the means used by nature to keep germs passive, and it is very interesting to note that nearly all of our powerful antiseptics act in a somewhat similar manner. Thus, the bi-chloride of mercury and carbolic acid both coagulate, while table salt, acetate of potash, glycerine and sugar draw water from the parts, and alcohol is a condenser of tissue used from time immemorial. If paraldehyde can be added to the list as a local hardener for certain internal parts of the body, or if its study as the modified excrement of alcohol, and relative of acetic acid, will lead to the use and discovery of other excrementitial substances to act on tissues or specific germs in different parts of the body, and thus produce either an excrementitial or restorative treatment of disease, it will be a boon indeed. What we need is *not only new*, or *more positive knowledge* of the *sizes* and *habits* of *germs*, but a better *appreciation* and *utilization* of the *facts already known*, and it is strange how blindly we grope with the light all about us. To give but one instance, look at the yeast-food sugar. Ever since man was formed it has gratified the palate of the eater, and yet, strange to say, as a therapeutic agent, except in combination with soap for boils, and to render medicines pleasant, it has been almost entirely ignored. This, also, is the substance that has been longest employed to prevent the products of the garden from spoiling, and every housekeeper knows that good preserves are kept by plenty of sugar. Were the profession asked which is the most powerful antiseptic, one would reply, corrosive sublimate, another carbolic acid, iodine, arsenic, or chromic acid, but I would say sugar, and why? Because it can be used internally, as often as we please, alone, or together with other substances, without poisoning or danger, and if this, combined with pleasantness, is not an advantage, I would like to know what is? I have to thank these reflections upon paraldehyde, and a Baltimore physician, for the stimulus that gave rise to the thought of the therapeutic importance of a large quantity of sugar. One night, in a society, it was stated that a mixture of quinine grs. xii, muriate tincture of iron ʒj, sugar water ʒiv, that had been recommended to cure diphtheria, had failed in two cases. The author, who was present, said the prescription had neither been compounded nor used exactly as he directed, but had been employed in too thin a solution, which would not stick to the throat, and that strong, simple syrup should have been the vehicle. This made me think that it was not the quinine and iron, after all, that had done most of the good, since they had disappointed us in so many cases, but the

thick, sugary solution, in combination with the muriatic acid, acting like the saccharine matter in the old lady's preserves, preventing fermentation and degradation. If such be the fact, it would be well to give the plain or acid sugar treatment a fair trial in external ulcers, affections of the vagina, bowels, and erosions of the uterus, as I have done, and thus ascertain the value of this harmless agent, that both *starts* and *stops fermentation* in accordance with the quantity present, and, learning from diabetis, use it internally for the prevention and cure of purpura and allied hæmorrhagic conditions where there is a want of coagulability of the blood. It would likewise be judicious, while searching for new causes of disease and strong agents to destroy them, to reflect upon the porosity of the body, and ask ourselves which are the more hurtful at any given time or place, dead or living germs, and how, when killed, are they to be removed without destruction of tissue.

If we coagulate, necrosis may ensue, and if nothing is done, a similar result from rapid growth will very likely follow. The fact that most of the zymotic diseases produce death through the liver and kidneys is a proof, if germs have anything to do with it, that very minute particles are clogging these smallest spaces in the human economy, and if they fill up pores of like capacity, they or their progeny must be of similar size. The uniformity of the effects also seems to show that the specific character of both rod-like and spiral bacteria does not consist so much in any poisonous quality, as in the fact that they are mechanically of the best form to cause a deposit of fibrin and fill up certain pores in Peyer's patches or elsewhere[1], and thus do harm. If this be so, anything that will enlarge, temporarily fill up, or contract pores, or cause germs to become sluggish, smaller or greater, through starvation or overfeeding, will be useful. Applying these principles to diphtheria, for example, we would not only give teaspoonful doses of thick sugar solution in combination with the muriated tincture of iron every half hour, day and night, to temporarily close pores, impede motions, starve bacteria and acidify the fauces, but paraldehyde and alcohol internally as strong as they can be borne, to act upon them in the lungs, trachea, and other parts that are harder to reach. We would thus determine clinically the value of thick syrup, acid and this drug, and be prepared to use or abandon as nature, when interrogated, directs. The trials that have hitherto been made in diphtheria, seem to indicate that sugar and muriated tinct. of iron, when freely used, prevent fetor, and paraldehyde appears to limit extension to the wind-pipe, but may do harm by increasing stupor when nephritis is present. More severe cases, however, must be treated, and many comparisons be made, before we can venture to give positive opinions of this drug, or answer the questions involved in such a subject as the starvation and keeping above hurtful germs by the employment of excrements that will not nourish or stable substances that they cannot readily pull down; but we have commenced, and that is something. If the fermentation of yeast and formation of aldehyde, joined with memories of the old lady's preserve jar, can help us continue, or suggest plain paths for others to follow, then the sweet things of our childhood will become preserves indeed, when they help to save a human life.

[1] This will explain why some persons take contagious diseases, and others with different sized pores do not. It also shows how when all the proper sized pores have been destroyed, second attacks of the same disease become impossible.

A CASE OF JAUNDICE WITH FATTY EXCRETIONS.

BY J. M. SWIFT, M.D., NORTHVILLE, MICH.

Mrs. B., aged 41; bilious temperament; subjected for some years to occasional attacks of jaundice; active habits; of medium stature, very obese, weighing 185 pounds; sterile, hyperæmic rather than anæmic, digestive function uniformly perfect, some little dyspnœa attendant upon active exercise, but general health has been usually good. Intellect is active, bright, vivacious, and always hopeful; avocation, house-wife, and peripatetic music teacher, both riding and walking a good deal. The lipogenesis is the only apparent indication of deficient oxidation.

This lady was taken with an "attack of jaundice," ten weeks ago, usual symptoms; constipation, clay-colored stools, nausea, slight headache, pain in the region of the liver and under shoulder-blades, itching of the skin, dizziness, and "faint-feeling." No fever, except an occasional slight pyrexia lasting for a few hours early in the attack. I was called to see her in the seventh week of the disease. Prescribed mercurials with rapid favorable results. Her husband informed me that she had passed "two pot-fuls of tar and dark coffee grounds!" I dismissed the case after two visits, which was then rapidly convalescing; natural stools; yellow tinge of skin and conjunctivæ disappearing. The patient was up and about the house, good appetite, and "felt all right." I left her March 22. April 5 was called again to see her. She had taken a severe cold, and also over-eaten, as I was informed and believe. All the previous symptoms were present, except no increase of temperature above 99½°, the pain and nausea not severe, but breathing a little difficult, and icterus very marked. Vegetable alteratives, podophyllin leptandrin, dandelion, etc., were resorted to, resulting in bilious stools, green in color, and copious. Mixed with these alvine excretions there were concretions as large as a large filbert, and of all sizes smaller down to a grain of rice, of what had every appearance of tallow.

Doubtless the aggregate of these in three days would weigh four to six ounces, and at this time there are small amounts occasionally passing her bowels. This fatty substance is unmixed with fæces, but has a greenish hue, and under the glass exhibits some cholesterine. No food containing fat has been taken for weeks by the patient. The clay or *putty* stools have given place to a more healthful appearance, though still green much of the time. The urine is loaded with bile, and floating upon the surface are innumer-

able oil globules, some of them very large. The secretion of the kidney is scanty, but not remarkably so.

The patient at this writing is comfortable, but not improving satisfactorily.

Is there anything peculiar in this case?

As would naturally be expected, the patient is much thinner now, but no unusual wasting is apparent. Appetite fair, temperature normal, and no acceleration of the pulse; patient also rests well.

MEDICAL PROGRESS.

MATERIA MEDICA AND THERAPEUTICS.

ON THE ABSORPTION OF NEUTRAL SALTS IN THE STOMACH.—Dr. W. Janorski (*Revue Médicale de Louvain*, and *Bulletin Général de Thérapeutique*) has made a series of experiments upon this subject and upon man, which led him to make the following report (*Zeitschrift für Biologie*):

1. The absorbent power of the human stomach is not the same for all salts; it varies according to the chemical composition of the saline substance which is employed.

2. The acid carbonates undergo the most rapid absorption, the chlorides the most feeble. The sulphates occupy a place between the two.

3. The difference in absorption is more pronounced the longer the solution remains in the stomach.

4. The presence of acids in the stomach increases the absorption (probably by the formation of acid salts) and makes more evident the difference in absorption which exists between the different salts. Carbonic acid is particularly active; on the contrary, an alkalinity of the contents of the stomach retards the change in the contents.

5. The presence of chloride of sodium in the gastric juice does not accelerate the digestion, nor increase the gastric juice; it exercises, on the contrary, a negative influence.

6. The quantity of hydrochloric acid which is secreted becomes greater in amount, according to the increased alkalinity of the saline solution, and to its longer stay in the stomach.

7. The introduction of distilled water into the stomach causes the secretion of an acid liquid (hydrochloric acid) which is the more marked in its acidity, according to the low temperature of the water so introduced.

8. When a salt undergoes chemical dissolution in the stomach, its basic and acid elements are not absorbed in accordance with their respective weights of combination.

9. One hour after the introduction of a pint of a saline solution into the stomach, a certain quantity of liquid still remains, which contains some of the salt; whilst in a half hour after the introduction of the same quantity of distilled water, the stomach contains no fluid.

From these observations, certain practical considerations are reached by Dr. Janorski, viz.:

1. It is most advantageous to administer salts in the form of acid carbonates, or with carbonic acid in excess; in fact, the absorption occurs more rapidly, the irritation of the mucous membrane is less, and the stomach empties itself most effectually. All the experiments of Dr. Janorski, with the aid of mineral waters, rich in CO^2, confirm this in every respect.

2. The introduction into the stomach of alkaline liquids diminishes the absorption of the salts and retards digestion, while producing a secretion that is greater in quantity than after the introduction of other solutions.

3. The introduction of acid substances into the stomach favors, on the contrary, the absorption of its contained matters. The use of acids, particularly of soda water and other acid drinks, seems therefore indicated, particularly in an overloaded stomach.

4. The presence of chloride of sodium in the stomach, does not seem, according to these experiments, to present that advantage for gastric digestion that has been attributed to it. This salt does not produce an increase of the secretion of the gastric juice, but rather of the peptones, and it does not contribute to a more rapid digestion. It is worth noting, however, in considering stomach digestion, that here the contents of the stomach are submitted for a longer time to the influence of the gastric juices, as the stomach empties itself slowly, and the antiseptic action of the chloride of sodium deserves to be taken into consideration in this connection. Whenever it seems advantageous to prolong the presence of a liquid in the stomach, and thus prolong its action upon the gastric mucous membrane, it would be useful to add a certain quantity of chloride of sodium to the liquid, or to render it alkaline; the mechanical functions of the stomach would probably be lessened, under these circumstances, which is an important point in cases of irritability of that organ. Inversely, the mechanical activity of the stomach is excited under the influence of acids. On account of this diminution of the mechanical functions of the stomach, is probably founded the property which certain drugs possess in quieting the pains of the stomach in certain cases of cardialgia, such as chalk, the carbonate of magnesia, of soda, and other carbonates and oxides.

5. The introduction of the chlorides in a neutral solution does not increase the gastric absorption, neither does the use of the neutral carbonates, which are either not absorbed at all, or absorbed only in proportion to their transformation into chlorides (in presence of the secreted hydrochloric acid). It is of importance to note that the chloride of iron is a salt which is absorbed with difficulty. When we consider, on the contrary, that the acid carbonates are of all salts the most easily assimilated, which is equally demonstrated in the acid carbonate of lime of the mineral waters, we must admit that the bicarbonate of iron should be the preparation of all

others of the salts of iron, which would be absorbed the most readily. This is confirmed by the fact that ferruginous waters, rich in carbonic acid, produce, in spite of their small proportion of iron, a greater therapeutic effect, which is more certain, than the pharmaceutical preparations that are given in much larger doses.

6. One hour after the introduction into the stomach of a pint of a saline solution, about a fourth part remains; if the liquid is pure or acidulated water, no traces remain ofter the same lapse of time. So that when we administer medicines in a liquid form, we can readily allow our patients to partake of food an hour later, without any fear that the drug will be diluted or chemically modified, so as to no longer exert its therapeutic effect.

On the Action of Salicylate of Soda Upon the Uterus. — Dr. Balette (*Bulletin Général de Therapeutique*) has found the salicylate of soda in ordinary therapeutic doses to quiet the pains of dysmenorrhœa, by exerting a sedative action upon the central nervous system.

It seems to increase the menses, and in some cases to cause their reappearance. In four cases, the use of salicylate of soda in large doses produced abortion—in two of the cases at the end of a day and a half, and in one case at the end of two months. (?) In five other observations, the drug in moderate doses produced no such result. Therefore, in many cases, the action of salicylate of soda in weak doses has no abortive effect upon the uterus. In his experiments upon animals, this drug had no oxytocic effect.

However, as there are women who are predisposed to abortion, and as experience shows that in large doses the drug has produced abortion, it would be wiser not to give the salicylate of soda in pregnancy, except in special cases, and then to determine with care the degree of tolerance as shown by the patient.

On the Use of Injections of Iodine (Intra-Venous); of Quinine (Intra-Venous); and of Fowler's Solution into the Spleen.—M. E. Ricklin (*Gazette Medicale de Paris*) has given a very interesting grouping of methods as above stated, used in accordance with what he calls parasiticide therapeutics, to bring parasiticide drugs in direct contact with the blood by means of intra-venous injections. He gives the results obtained by M. Vander Heyden in the treatment of certain infectious diseases by intravenous injections of iodine. The injections were made by the use of a Pravaz syringe. The solution consisted of 7 parts of distilled water, one part of iodine and 2 parts of iodide of sodium, which was injected into the median vein of the arm, which was distended by compression above the elbow joint. These injections were very well borne, but the therapeutic results were not remarkable.

M. Hoffman has been using intra-venous injections of chlorhydrate of quinine in cases of typhoid fever, erysipelas, pyæmia, pneumonia and pulmonary phthisis. The solution used for these injections consisted of alcohol at 450 holding in solution 1 grain of chlorhydrate of quinine for each cubic centimeter of the vehicle. The most minute precautions are necessary to render the injections inoffensive, which renders its use very troublesome, and not warranted by the results obtained. One case is cited of grave typhoid fever. On the fifteenth day of the disease, at 11 A. M., the temperature was 39.3.° In a half-hour a quantity of the solution equivalent to 2 gr. 1. of the salt was injected into a vein. At 12:45 P. M., the patient had a chill; the temperature had gone up to 41.5°. At 4:30 P. M., the temperature was 37.5°; at 9 P. M. it was 35.9°. The following morning it was 37°; in the evening it was 38.6°, and the next day the febrile movement had returned to its original intensity. This hazardous mode of medication never had more than a more or less passing antipyretic effect, which could be obtained by other means without exposing the patient to phlebitis, gangrene or embolism. Two of M. Hoffmann's patients were attacked by spasms after intra-venous injections, but they were not followed by any serious results.

M. Peiper records a case of leucæmia with enormous engorgement of the spleen. He was treated by injections of of Fowler's solution into the spleen, one cubic centimeter for each injection, and to the extent of ten injections during the course of eight weeks. They were well supported, and the spleen diminished markedly in size. Prof. Mosler, under whose direction this treatment was conducted, recommended that it be used only in cases of hard engorgement of the organ, and in cases that are not subject to the hæmorrhagic diathesis. Further to ensure success, the patient should first be submitted to the internal administration of medicines capable of acting upon the contractile tissues of the spleen, and each injection should be followed by the application of ice over the seat of puncture, to be kept up for several consecutive hours. It was undoubtedly owing to the want of these precautions that death occurred in the case in the service of Prof. Kussmaul, where sclerotinic acid was injected into the spleen, in consequence of the penetration of the liquid into the splenic vessels.

M. Ricklin concludes his review of the subject by referring to the experiences met with in injections of preparations of iron, but these have already been referred to in these pages.

OBSTETRICS AND GYNÆCOLOGY.

Rachidian Congestion of Menstrual Origin.—Mr. Oudiné (*Jour. de Med. et Chir.*) has added some observations upon several cases to the discussion on this subject. The rachidian congestion, according to his views, has ordinarily an abrupt beginning, like the cause which produces it. But there must be a distinction made between those rachidian congestions which occur in the adult female during the period of utero-ovarian activity, and those which occur during the menopause. With the first the phenomena occur abruptly as the consequence of sudden cold, fright, etc., with the suppression of the menses. Then follow, after a few hours, and more rarely a day or two, creeping sensations, pains and torpor,

with or without paralysis. With the second these symptoms come on more gradually, during three, four, five months, and longer, after the day when the subject ceased to be regular, and a feeling of discomfort sets in, with pain that is more or less intense at the period which should correspond to the normal menstrual flow. Then disturbances of motility set in, which develop little by little progressively, until the last stage, that of paraplegia. When this is reached it manifests itself most generally by interference with motility and sensibility, rachidian pains, and irradiations of pain in the extremities.

The disturbance of motility is seldom a true paraplegia, but more commonly a simple paresis, which is not permanent but in exceptional cases. It is more marked when the subject is up and about than when lying down, which is accounted for by the accumulation of the serum in the lower part of the canal and the pressure which it exerts upon the cord. The patients drag their legs one after the other, while the feet brush along the ground. The two legs may be affected in different degrees. The anal and vesical sphincters are rarely influenced in the exercise of their functions. The interference with sensibility is generally but little marked, and is shown by formications, and, more rarely, by anæsthesia. One case cited by M. Oudiné had lost completely all appreciation of the existence of the legs. The pains seated along the course of the spine are sometimes extremely intense, and may increase by very violent crises.

The progress of these symptoms is extremely variable. Some subjects exhibit abruptly all these symptoms, and, in the course of a few hours, they pass off. This is noticeable in young women when therapeutic interference has aided nature to restore the catamenial flow. But at the menopause, the symptoms may persist for a long time, for many weeks or even many months. Here the prognosis, which is always favorable in the first form, as relief is afforded during a period varying from several days to a few months, becomes graver. The cure is rarely effected, and the congestion may terminate in softening of the cord.

When it has been determined that the rachidian congestion is the cause of the paraplegia, which is not always easy, for the paraplegia of hysteria presents a marked analogy to this form of paralysis, the proper treatment is to resort to local blood-letting, such as wet cups to the lumbar region, leeches to the vulva to reëstablish the menses if possible, and to the various emmenagogues. M. Desnos prescribes ergot in powder, to the amount of 0.50 centigrammes to 1 gramme a day, with or without opium, according to the degree of tolerance of the patient, to diminish the congestion of the cord.

SURGERY.

HÆMATURIA IN THE RETENTION OF URINE, AND DISTENSION OF THE BLADDER.—Professor Guyon, in his clinic at the Hopital Necker, Paris (*Jour. Med. et de Chir.*), discusses fully the condition so frequently observed in old persons, with retention of urine, where a discharge of blood follows the evacuation of the bladder. He shows that in many of these cases the hæmorrhages are not due to traumatisms, but to an excessive congestion of the vesical mucous membrane.

In one case presented by him this condition was very remarkable; the patient, suffering from retention, had been relieved by the passage of a large sound, which produced a very rapid evacuation. The internal surface of the bladder was of an ecchymotic redness, but the mucous membrane itself was healthy. This vesical congestion is present in all similar cases, and suggests very clearly that, in treating retention of urine, the conditions of the vesicular circulation should not be abruptly disturbed by evacuating too rapidly all the liquid contained in the bladder, as one is always tempted to do. As a consequence of this rapid evacuation, syncope and sudden death have been recorded in very exceptional cases, but more commonly hæmorrhages result, the presence of which are explained by the marked abundance of the vesical venous plexus, which, suddenly relieved of pressure, distends itself forcibly.

The first rule, then, would be not to empty completely the bladder, and not to remove more than half of its contents. To do this properly, the bladder would be emptied slowly and by means of an instrument of small caliber, which would take from a quarter to a half-hour to do its work—that is, where the occurrence of hæmorrhage is to be feared. The accidents produced by this intense congestion may be very rapid and even mortal; at other times they are less grave, and their results may be noted as of all grades, from a cystitis to a pyelo-nephritis. In such cases the cystitis would not be produced by the transformation of the urine, it would depend upon the intense vesical congestion. This, however, would not militate against the use of antisepsis, for in old persons the alteration of the urine takes place very readily. Guyon washes his instruments with boracic acid, and oils them with phenic oil; after using the catheter he injects into the bladder about 150 grammes of a warm solution of boracic acid—4-100. This recognition of consecutive haematuria is very important, not only as regards treatment, but also in prognosis, as distinguishing an organic lesion from a simple disturbance of the circulation.

ON DISTENTION OF THE BLADDER.—In the normal state, the distension of the bladder produces an effect which soon becomes painful and even agonizing if it is prolonged, but it also produces a congestion which extends to the whole of the peri-vesical system. As a proof of this is the semi-erection of the penis which it causes in the old man. The whole venous system of that region, the prostate in particular, is in this congested condition under the influence of over-distension. Another point is that the bladder is but little sensitive to contact, while very sensitive to distension. This is shown very markedly in cases of lithotrity, while under the influence of chloroform. The bladder for a half-hour will support readily the contact of the necessary instruments used in the operation, but if it is distended by the injected fluids it commences to contract. The same thing is noticed in cases of stone. It is astonishing how indifferent the

bladder is to the presence of a stone. M. Guyon is of the opinion that most of those affected with stone in the bladder suffer no pain. It is only in cystitis that contact alone will cause contractions of the bladder.

These facts are important in operations upon the bladder for the removal of stone. If, for example, in such a case, after dilating the canal, and bringing instruments in contact with the bladder, an attempt is made to dilate the bladder by injections, there may suddenly occur serious accidents as the result of this distension. In a case of cystitis, it is natural to suppose that washing out the bladder would relieve the patient, but if the fact is overlooked that the slightest dilatation may result in very serious accidents, a considerable surgical fault is committed. These injections into a bladder which has already made great efforts to empty itself must increase the pain. Under such circumstances M. Guyon uses injections with great reserve, and with many precautions he considers it preferable to commence with *instillations* and gradually to arrive at injections.

Distension is the point of departure for a number of affections of the bladder. The number of cases of cystitis produced by the distention and the retention of urine is considerable, and in all patients where this disposition exists, one cannot be too emphatic in insisting upon urination without delay. The dilatation of old age is gradual, and very different from that of the young subject, where it is often caused by traumatism. This shows that by using very gradual means the bladder can be habituated to distension, and it is in these cases of chronic distension that one sees, as a consequence, the dilatation of all the urinary organs, the ureters, calices, pelves, which are permanent in their character and impossible to relieve.

NEW INVENTIONS.

The Bead Inhaler.—Dr. Benjamin Ward Richardson, in *The Asclepiad*, gives the illustration of an apparatus for inhalation which is shaped like an inkstand, with a neck and regulating cap, through which the liquid is poured into the receiver, and with a mouthpiece fitted inside with a talc inspiratory valve and with an expiratory valve. In the receiving bottle there is placed a string of glass beads, held on a line of cotton wick or floss silk. The beads fill the receiver, and form a free surface for the volatile fluid, without danger of the escape of the fluid except in the form of vapor during the inhalation, hence the name of *bead inhaler*. In changing one liquid for another nothing has to be done but to draw out the beads, to wash them, if necessary, in a little spirit, and, after washing the bottle, to replace them in the bottle. He claims for it the advantages of small size and easy portability, steadiness for standing on table at bedside, readiness for receiving and retaining the volatile fluid, possession of a wide surface for evaporation, easy adaptability to the mouth of the patient in any position, and cleanliness of action.

Ten minims of the nitrate of amyl poured upon the beads yields a charge which, by taking care that the cap closes securely and the tube valves acts correctly, will answer, without losing effect, for twelve hours.

Urethral Toxæmia.—This is a term used by Dr. Maclaren in an article in the *Edinburg Clinical and Pathological Journal*, to designate phenomena which have been classed under the head of gonorrhœal rheumatism, which latter term Dr. Maclaren considers a misnomer, as the phenomena are invariably associated with a specific inflammation of the urethra, and fulfil all the conditions of septic intoxication. He reports five cases in males under thirty-five years of age, in apparent good health up to the time of infection, and in only one example was there any history of previous rheumatic disease.

The systemous infection appeared in two cases on the third day, in two others on the eighth day, and in the remaining case about the third or fourth week after the onset of the gonorrhœal discharge (one case had suffered four years previous from a similar toxæmic attack. No prodroma, the first evidences being slight pain and considerable swelling in one or more joints or bursal sheaths. In four there was a metastatic form, involving a large series of great and small joints. In one it was limited entirely to the knee. There was no relation between the degree of pain and the amount of swelling. Severe persistent pain in one case at the acromio-clavicular articulation, and for nearly an inch over the bones on either side of the joint, indicated a participation of the periosteum in the morbid process. Slight transient redness sometimes was present at the onset, but on no occasion was there shown any tendency to suppuration. Groups of muscles were sometimes for several days extremely tender, and in one case the sclerotic and conjunctiva were injected and painful. Anæmia marked. Temperature never exceeded 103°. In all cases in the morning it frequently fell to 97°, and in one case reached 96°. Urine carefully examined, but no uric acid was found. Although in all the cases the severity of the symptoms was greatly mitigated in a few weeks, in none had they ceased to appear at the end of three months. Treatment simply emperical, viz.: injections of hyd. chlor 1–2,000, or acid carbolic 1–100, counter-irritation to upper part of thigh, rest, local application of flannel, plaster dressing. Tinct. iodine, sinapisms, and many anti-rheumatic remedies were tried, as the alkalies, pot. iod., quinine, colchicum, salicylate of soda, but these latter were without benefit. For the anæmia iron and ergot were given. The medical efficacy of the ergot was not decided.

It has been estimated by various writers that from 1 in 200 to 1 in 400 of individuals suffering from gonorrhœa become the subjects of urethral toxæmia.

For the removal of nævi in patients who shrink from the knife, Dr. Beatty has successfully employed liquor asenicalis, which he applies with a brush night and morning, until ulceration takes place.

THE

Journal of American Medical Association.

PUBLISHED WEEKLY.

THE EDITOR of this JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information, should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE..... $5,00.
SINGLE COPIES..... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 65 RANDOLPH STREET,
CHICAGO, ILLINOIS.

SATURDAY, MAY 3, 1884.

WOMAN'S HOSPITAL MEDICAL COLLEGE OF CHICAGO.—Since our last week's issue, this institution has held its regular annual Commencement exercises in Hershey Hall, in the presence of a fair audience.

Twenty-seven young women received the degree of M.D., and were cordially welcomed into the ranks of the profession by Prof. W. H. Byford, President of the college. The institution is enjoying a fair degree of prosperity, and we are informed that a new college building will be erected during the present season.

LEGACIES TO HOSPITALS AND MEDICAL COLLEGES.—From the Cleveland daily papers we learn that the late H. B. Hurlbut, of that city, left provision in his will that the revenue yielded by his estate should go to his wife during her lifetime, and on her death $200,000 should be given to the Cleveland City Hospital, and the balance of the estate, estimated to amount to $1,000,000, to the establishment and maintenance of a gallery for the cultivation of art in that city.

The same papers announce that Mr. J. L. Woods has donated a liberal sum for the building of an elegant new edifice for the Medical Department of Western Reserve University, while Messrs. H. B. and Oliver Payne have added to the grounds for its accommodation.

Considering the direct and very important relation between the interests and welfare of all classes, and the highest standard of education and training of medical men, it is surprising that more attention has not been given, by men of wealth everywhere, to the endowment of medical colleges and hospitals on such terms as to secure the most systematic and thorough practical training of medical men, on whose attention and skill all must, at some time, depend for relief.

THE REJOINDERS.—As we expected, our remarks on the articles furnished by Drs. Hutchinson and Cronin, have elicited a letter from each in reply, which we cheerfully insert in this number of the JOURNAL. The first serve only to show what we had suspected, namely, that he had formed his estimate of the teaching in all medical colleges by that of the one he attended in the days when Druitt's Surgery was the most recent text-book. Regarding Dr. Cronin's letter we will only ask, if alcohol undergoes either assimilation or combustion in the human system, how does it happen that during its presence, not only the products of combustion, but the sum total of all eliminations, are diminished, and the temperature reduced, if changed in any direction? If the amount which it is claimed disappears in the system and not capable of being directly recovered in the excretions and eliminations, is actually either added to the tissues by assimilation, or oxidized as in combustion, how does it happen that M. Dupré finds something giving all the reactions of alcohol in the excretions several days after the use of the alcoholic liquids has been discontinued? Does not this fact go far to show that the alcohol which apparently disappears in the system is merely held mechanically by its strong affinity for the albuminous elements of the blood and tissues, and is only given up slowly through a period of several days? Finally, if the very general tendency of the human race to use alcohol in some form, is proof of its nutritive and sustaining qualities, how is it about tobacco, opium, etc.? Are they also foods?

SHUT ITS DOORS AND CLOSED ITS BLINDS.—The Joplin (Mo.) Medical College closed its doors before the end of its last college term. Cause—Inanition.

ARE PHYSICIANS ESSENTIALLY SANITARIANS?—In answering this question, the April number of *The Sanitarian* says: "Preventive medicine is at best only taught elementarily in a few medical colleges, and in these as an *addendum* to some other subject deemed to be more important—in *none* systematically as a prerequisite to graduation." This is not quite literally true.

Certainly, in the Chicago Medical College (and, we think, in some others also), there has been a dis-

tinct chair or professorship of State Medicine and Public Hygiene almost from the commencement of the College, occupied by a full professor, attendance upon whose teachings and examinations is as much a "prerequisite to graduation" as upon those of the professor of Practical Medicine or Surgery.

ILLINOIS STATE MEDICAL SOCIETY.—Our readers in Illinois should remember that the next meeting of the State Medical Society will be held in Chicago, commencing on the third Tuesday in May.

SOCIETY PROCEEDINGS.

FIFTY-FIRST ANNUAL MEETING OF THE TENNESSEE STATE MEDICAL SOCIETY, HELD AT CHATTANOOGA, TENN., APRIL 8 AND 9, 1884.

The Medical Society of the State of Tennessee met at the hall of the Iron and Coal Association in Chattanooga, at 11 A. M., Tuesday, April 9.

The Society was called to order by the President, Dr. A. B. Tadlock, of Knoxville. Prayer was offered by the Rev. J. W. Bachman.

The President appointed as a Committee on Credentials Dr. B. B. Lenoir, Dr. W. F. Glenn, Dr. D. D. Saunders.

The Committee retired to act on the names which had been handed in for membership.

Dr. W. F. Glenn being temporarily absent, Dr. W. F. Clary was appointed a member of the Committee *pro tem.*

Hon. Hugh Whiteside, Mayor of Chattanooga, on being introduced, extended a cordial greeting and a hearty welcome to the Society on the part of the city; stating that much good could be accomplished to the State by these meetings, and that he and the citizens of Chattanooga, whom he represented, sincerely hoped to make this a pleasant meeting socially, as well as to aid in its success in a business point of view. His address, though brief, was pointed and eloquent, and was received as a heartfelt, outspoken expression of generous hospitality.

The President returned the thanks of the Society to the Mayor for his cordial welcome, and said that the Society would gladly accept the courtesies of this city, whose people are so well known for their progressive spirit.

Dr. H. L. McReynolds, Vice-President of the Chattanooga Medical Society, and a member of the Committee of Arrangements, then delivered the following address on the part of the local profession:

Mr. President and Gentlemen of the Society:

With pleasure beyond my power to express, I welcome you to-day, not only in the name of our resident members, but in the name of the whole people of Chattanooga, to our thriving and progressive city.

A decade has passed since this Society last convened in Chattanooga, and if there be any here to-day who participated in that meeting in 1874, I doubt if they are able to realize the wonderful growth and advancement this city has made from the mere village then, to the splendid city she now is, and bids fair to attain in the near future. Not that the progress has been unrestrained by flood and pestilence, for she has been visited by both. But, notwithstanding these, on account of her superior railroad and water facilities, her immense beds of coal and iron ore, surrounded by fine farm and garden sites, she has defied adversity.

Six years ago this city was scourged with yellow fever, but, thanks to our noble profession, few lives were lost; and only last year and the year preceding we were visited by small-pox but again I say, thanks to the medical profession, that disease has ceased to be so much of a terror as formerly, having been deprived of its former power to destroy life through the discovery of the immortal Jenner. Notwithstanding all this, to-day our health statistics will compare favorably with any city in the Union.

That the medical profession has, within the last ten years, made more rapid advancement toward the goal of perfection; has investigated further into that most complicated of all machines—man; laid more peace-offerings at the feet of pain-racked and suffering humanity than any other decade preceding it, no one well informed in the history of medicine will deny. And we hope the time will soon come when no disease, however malignant, will be beyond the control of the skilled physician. But we can not hope, with any reasonable foundation for that hope, that the charlatan, with his wonderful pain-killer, discovered in the Wild West, shall ever cease to mount his dry-goods box on the corner; or that the ignorant of our population will ever cease to be gulled and deceived by every quack and pretender who travels through the country.

Hoping, Mr. President and gentlemen, that this meeting will be of great practical benefit to us all, and through us to the afflicted and suffering who have committed themselves to our care, and believing that an exchange of views and experience is the only true way to attain a thorough knowledge and a liberal view of any science, we the more heartily welcome you on this occasion. We welcome you in the name of the medical profession of this city; we welcome you in the name of the people of Chattanooga; we welcome you in the name of suffering humanity, and invite you to the hospitalities of our homes.

The Committee on Credentials then presented the following report of delegates and members in attendance:

Dr. J. Berrien Lindsley and Dr. P. D. Sims, delegates from the State Board of Health.

Dr. Ruth A. French, delegate from the Knox County Society.

Drs. D. D. Saunders and W. W. Taylor, delegates from the Shelby County Society.

G. A. Baxter, Chattanooga; C. C. Fite, Nashville; Jno. Blankenship, Maryville: E. B. Hale, Talbott; P. D. Sims, Chattanooga; A. B. Tadlock,

Knoxville; B. B. Lenoir, Lenoir's; W. F. Clary, Bellbuckle; V. Gibbs, Chattanooga; J. H. Vandeman, Chattanooga; W. G. Bogart, Sweetwater; A. J. Swaney, Castalian Springs; W. M. Vertrees, Nashville; H. Berlin, Chattanooga; W. T. Hope, Chattanooga; Mary T. Davis, Knoxville; W. F. Glenn, Nashville; M. Campbell, Nashville; Duncan Eve, Nashville; Deering J. Roberts, Nashville; J. L. Atlee, Athens; F. B. Sloan, Cowan; R. F. Evans, Shelbyville; W. R. Townsend, South Pittsburg; E. B. Hale, Chattanooga; S. T. Smith, Dunlap; T. J. Ried, Mason: L. Y. Green and C. S. Wight, Chattanooga.

The following were recommended for membership, and by unanimous vote, were elected:

Drs. W. Stewart, Rockwood; J. M. Masters, Knoxville; D. H. Lane, Calhoun; J. R. Nankivell, Charleston; W. T. Foute, Lenoirs; G. W. Drake, Chattanooga; D. E. Nelson, Chattanooga; S. T. Smith, Dunlap; E. B. Wise, Chattanooga; J. M. Lasiter, Dunlap; L. B. Dunn, Chattanooga; T. C. V. Barkley, Chattanooga; Green B. Garner, Hillsboro; J. B. Cox, Hollow Rock; Cooper Holtzclaw, J. R. Rathmell, W. H. Beatty, Chattanooga; W. S. Johnson, Morgantown; A. P. Vanderveer, Charles Spencer, Chattanooga; W. L. Stephens, Rockwood; H. H. Loveman, Chattanooga; R. E. Jameson, Apison; E. B. Ketcherside, Jasper.

Drs. J. W. Russey, Rising Fawn, Ga.; E. P. Nicholson, Valley Head, Ala., and D. A. Morse, Oxford, Ohio, a delegate from the Ohio State Medical Society, were extended, by unanimous vote, the privileges of the Society.

The President, Dr. A. B. Tadlock, then delivered his address, which was a lengthy and able paper. The general bearings of medicine and its relationship to the public, and the question of irregulars, and the correction of these evils, were elaborately treated.

The Society then adjourned to 2 P. M.

AFTERNOON SESSION.

The Society was called to order at 2 P. M. A letter and paper were received from Dr. C. E. Ristine, of Knoxville. The paper was entitled "Excitation of the Clitoris," and, on motion, was referred to the Committee on Publication.

By motion the President and Secretary were instructed to send greetings by telegram to the State Medical Association of Alabama, now in session at Selma, Alabama. Dr. Masters, of Knoxville, then read a paper on the Hygiene of the Eye. The paper was referred to the Publication Committee.

A telegram was received from Dr. J. F. Grant, of Nashville, regretting his inability to be present.

The Secretary, Dr. C. C. Fite, of Nashville, then read his report, which is as follows:

NASHVILLE, APRIL 7, 1884.

To the Medical Society of the State of Tennessee:

GENTLEMEN:—Please find attached to this report a statement in regard to the Transactions of 1883, which were well received and sought by the profession in various portions of the country. A catalogue of the books now in the Library of the State Board of Health is also appended. The Board opens their shelves as a depository for the property of the Society. Many valuable volumes have been lost on account of not having a permanent medical library in which to preserve them. The collection is in the bookcase C of the State Board of Health Library, in the State Capitol.

I had the honor of calling your attention last year to the number of travelling quacks in this State. Most of our sister States have, by requiring diplomas and by strict examinations, shut out this horde of vampires, and so they are fattening on our people.

We are maintaining our reputation for hospitality, and open wide our doors and welcome them. The profession is apparently glad to see them, for as a profession we give no word of warning. The daily press of our cities is profusely decorated with their pictures and glowing descriptions of their wonderful skill. Articles are published without being marked as advertisements, and the unwary take this as an editorial endorsement, and swarm like bees about their doors to be deceived and humbugged. I say to you, gentlemen, that we should blush when we read these disgusting laudatory articles penned by the charlatans themselves. We should blush that the proud old State of Tennessee allows them to thus degrade the honorable name of the doctors—that word second to none in the world, when a title of honor and well earned, is daily besmirched and bedraggled by the conscienceless villains. These are strong words, but true ones, as everyone knows.

Nashville has a fine assortment of these light-tongued gentry now plying their trade in our midst, and the profession is apparently indifferent to it.

It is our duty as philanthropists, as citizens of this commonwealth, to tell the people the plain unvarnished facts, and say that these men are unworthy of credit or respect. They voluntarily place themselves outside the bonds of honorable medicine.

We, as a profession, ask no protection; we ask no legislation in our behalf, but for the ignorant masses we should demand protection of our law-makers, and if we unite our efforts we can do it almost without serious opposition. It is true this Society has memorialized the Legislature time and again, but in a half-hearted way; it did not have the vim of determination in it, and we did not stand together. Instead of worrying ourselves about the New York code and such small matters, we should go home to the root of the evil, and make our great work of healing the sick and preventing disease what it really is—the noblest life on earth. This we can do by cleansing the temple of these loathsome worms that now degrade our honorable calling. Some present may be of the opinion that I overdo this. I say, gentlemen, it can not be overdone. There is no medium ground. No compromise can be made. We should state the truth or nothing, and I intend to keep this up until it is done, and I hope to live to see right triumphant. We must throw off the fetters of tradition, and look this living issue square in the face, and do our duty to our people and ourselves.

We are in the woods on this question. We are lagging behind, and as the other States take their position and drive these people out, we receive them, be-

coming the receptacle for the worthless and debased from all parts of this broad country.

Now, gentlemen, in closing, allow me to thank you for the honor you have conferred on me by electing me for three consecutive years your secretary. I am not a candidate for re-election, and would not accept a re-election if you saw fit to so honor me. My other professional duties are so great that it would be impossible to give the time and energy to the office that it requires. With sincere thanks for numberless courtesies, and with grateful appreciation for your confidence, I will retire from a work I love, and would like to continue were it possible to do so.

Faithfully yours,

C. C. FITE, M.D.

On motion of Dr. Lindsley, seconded by Dr. Roberts, the report was received and referred to the Committee on Publication.

Dr. D. D. Saunders, of Memphis, offered a motion to appoint a committee to memorialize the Legislature on the subject of suitable enactments to protect the public from quacks and charlatans.

Dr. Gibbs moved an amendment that the committee to be appointed prepare a bill, after comparison with all the laws on the subject that are obtainable, and that this bill, so prepared, be discussed at an adjourned meeting of the Society, to be held at Nashville, the first Tuesday in October.

Dr. Roberts seconded Dr. Gibbs' amendment, and the amendment was accepted by Dr. Saunders.

Quite a spirited discussson then ensued, which was opened by Dr. Saunders, who, in a pointed and eloquent manner, argued in behalf of action taken by the Society. We can not begin to give anything but a brief synopsis of his remarks, which were received with considerable applause by many of the members. He said, in substance:

Mr. President, the report of our Secretary gives me pain. Can it be possible that we are going to allow these men to disgrace us when we can prevent it? The older members are to blame. What can the younger members do when we, the older ones, are so selfish and indifferent? It is a shame and disgrace to us. Our neighboring States are enacting laws to prevent these vampires from committing frauds on the people. We have not done our duty. I say, gentlemen, we are wrong. Our Secretary made a similar report last year, and again like a trumpeter repeats it, and we should heed the voice.

Dr. Deering J. Roberts, in his remarks, was opposed to any legislative action whatever. He stated that where State laws were in force in regard to quacks and charlatans, the people were no better off than where the statutes were not so encumbered.

Dr. J. Berrien Lindsley spoke in favor of postponing action, and while he was in favor of better organization of the profession in Tennessee, he thought that the proper place to secure this was in the State, county and local societies. He was afraid to invoke legislative enactment.

Drs. P. D. Sims, A. J. Swaney, Duncan Eve, W. F. Glenn, Loveman, and others, participated in the discussion in behalf of immediate action.

Dr. H. Berlin gave some pertinent illustrations of the medical surveillance of Prussia.

Dr. Drake was opposed to legislation.

On motion, the amendment of Dr. Gibbs was laid on the table. Dr. Saunders' motion was then adopted after the amendment had been tabled.

Dr. Saunders moved that there be two members of the committee from East and West Tennessee, and three from Middle Tennessee.

Upon motion, it was decided that the committee report on the following day. The following committee was appointed by the President:

Drs. D. D. Saunders, W. W. Taylor, Memphis; Drs. J. H. Vandeman, H. L. McReynolds, Chattanooga; Dr. R. F. Evans, Shelbyville; Dr. W. F. Clary, Bellbuckle; Dr. J. F. Grant, Nashville.

Dr. Roberts, the Treasurer, then made his report, which was referred to an auditing committee, consisting of Drs. Lenoir, Vandeman and Hale.

The report of the Committee on Publication was then presented by Dr. Roberts, Chairman. The report was received and filed.

The Chairman of the Committee on Changes in the Constitution, Dr. S. F. Grant, not being present, the result of their deliberations was reported on by Dr. Roberts, and the amendments suggested were first considered separately, and adopted with but few, if any, material alterations, and then adopted as a whole.

The changes may be briefly summed up as follows: Abolishing the Censors and establishing in lieu a Judicial Council, composed of the ex-presidents of the society, three of whom constitute a quorum; fixing the time of meeting, when not otherwise ordered, for the second Tuesday in April; changing the assessment from $3.00 to $5.00 as an initiation fee for new members; $2.00 for members in attendance, and $1.00 for members not in attendance.

The society then adjourned until 9 o'clock next morning.

SECOND DAY.

The Society re-convened at 9 A. M., Wednesday, April 9, and was called to order by the President.

Dr. E. M. Eaton, of Chattanooga, presented a paper, "A Study of the Vital Statistics of Small-pox in Chattanooga in 1882-83." By request of the author, the paper was not read, but referred to the Publication Committee.

Dr. Mary T. Davis, of Knoxville, then read a valuable paper on "Hot Water Therapeutics," which was referred to the Committee on Publication.

Dr. Roberts moved that the ex-Presidents, Dr. R. F. Evans and Dr. B. B. Lenoir, personally tender the thanks of the Society to Dr. Davis for her admirable paper.

Dr. H. Berlin, of Chattanooga, then read a paper entitled "Efforts of Therapeutics." Referred to the Committee on Publication.

Dr. Roberts presented a patient of Dr. J. G. Sinclair, of Nashville, together with a brief clinical report of the case, one of a rare and unusual form of eye disease, with the regrets of Dr. Sinclair at being unavoidably prevented from being present.

Dr. R. F. Evans, of Shelbyville, then read an in-

teresting and practical paper on "Eczema," which was referred.

Dr. John Blankenship, of Maryville, then read a paper on "Scrofula." Referred to the Committee on Publication.

The Treasurer, Dr. Roberts, moved that the new constitution take effect after this meeting. Carried.

Dr. Rathmell, of Chattanooga, read a paper on "Hospital Gangrene, with Cases." The paper was referred to the Committee on Publication.

Dr. Swaney, of Castalian Springs, read a paper on "Puerperal Fever." By motion of Dr. Roberts, the paper was referred to the Committee on Publication.

Dr. Vertrees, of Nashville, asked that his paper be referred to the Committee on Publication, as he was too hoarse to read it. The request was granted, Dr. Vertrees giving a synopsis. The paper was on Diphtheria.

The Secretary read the report of the committee to settle with the Treasurer, the Treasurer's accounts being approved.

The following telegram was read, it was in answer to one sent by this Society:

SELMA, ALA.

"We thank you for your very kind greeting and consideration. Our meeting is a large one, and we earnestly hope that the Association over which you gentlemen preside, is in a growing and flourishing condition. T. A. MEANS,

Secretary of Alabama Medical Association.

A telegram from Dr. F. L. Sim, of Memphis, stating that personal illness alone prevented his being present, was read.

Dr. S. T. Hardison, of Lewisburg, read a paper on "Senile Prostatic Diseases."

Dr. Swaney discussed the treatment of the above conditions.

Dr. C. C. Fite requested that he be allowed to retire at one o'clock, as he had to go to Nashville on the first train, and Dr. Baxter was elected Secretary *pro tem.*

All the papers that were read proved very instructive, and provoked a very interesting discussion. They were able and interesting documents.

Drs. F. B. Ferguson, of Rich Creek, and S. T. Hardison, of Lewisburg, were present, and registered during the morning session. Drs. W. C. Ransom, of Farmington, A. B. Robinson, of Chapel Hill, and C. M. Drake, of Knoxville, having also arrived during the morning, and their application for membership having been favorably reported on by the committee, they were unanimously elected to membership.

Dr. T. J. Cotnam, of Stevenson, Ala., was present as a visitor, and invited to a seat in the Society.

The same courtesy was extended Dr. S. B. Wells, of Red Clay, Ga.

The Convention then adjourned until 2 P.M.

AFTERNOON SESSION.

Dr. G. A. Baxter, of Chattanooga, being called upon by the Society, read a paper on "Uncomplicated Spinal Shock," which was much commended by Dr. Saunders, of Memphis, and Dr. Vertrees, of Nashville, and referred to the Committee on Publication.

Dr. Glenn, being called upon for a paper, made an address upon "The McDade Treatment of Syphilis," affirming that in his own experience, it was a complete failure.

Dr. Saunders followed, confirming Dr. Glenn's conclusion.

Dr. Vertrees, Dr. Morse, Dr. Sims and Dr. Glenn participated in a spirited discussion upon the method and administration of mercury in this disease.

Dr. J. B. Lindsley, President of the State Board of Health, read the following communication from the State Board of Health upon the subject of "Vital Statistics:"

Mr. President:—By direction of the State Board of Health, my colleague, Dr. P. D. Sims, and myself have the honor of appearing before you as its representatives. We are charged with the pleasant duty of conveying to you the warm congratulations and hearty good wishes of an important State Board, which owes its existence to the long continued and well directed efforts of your body, and which recognizes the fact that without the cordial and active assistance of the medical profession of Tennessee, its brilliant prospects for high usefulness will prove a mere mirage of the desert.

Indulge me in a brief historic retrospect. At Chattanooga, in 1874, a committee was appointed to draw up a report upon a new constitution, looking to new life and energy in the Society, which had not been keeping step with other intellectual influences in the State. In the Transactions for 1875 we find a very elaborate paper from this committee, in which the advancement of preventive medicine was announced as one of the four great objects to which this association should devote its energies. On page 26 of these (1875) Transactions we learn that at the previous meeting (1874) a committee had been appointed to memorialize the State Legislature to create a State Board of Health. This committee reported through their chairman, Dr. E. M. Wight, that they had drawn a bill covering the wishes of the Society, and had presented the same to the General Assembly for its enactment, but which, they were sorry to say, had failed in its passage to become a law. The Society then adopted the followino:

Resolved, That the chairman, Dr. E. M. Wight, be requested to write carefully the report of the committee on a State Board of Health, for the proposed report of the proceedings of the Society, and that the committee be continued. This eloquent address may be found on pages 42–48 of said Transactions.

At the next session, 1876, we find that the committee on the State Board of Health, through Dr. Wight, presented an exhaustive and lengthy report. This able and elaborate paper fills ten closely printed pages of the Transactions for that year.

On pages 34–36 of the Transactions for the year 1877, we find the report of the committee on State Board of Health, by W. K. Bowling, chairman. We quote from it the result of the above stated patient efforts:

"The State Board of Health of the State of Ten-

nessee is now a finality. We have the Board organized and at work. It has only come into existence because the State Medical Society demanded it. It is your legitimate offspring. We charge you now with its future care, and appeal to you to give it every aid, and the best support in your power."

It is proper to add, that all this time, Dr. J. D. Plunket was Treasurer of the Society, and took a very active part in enlightening the members of the Legislature, and the public, as to the merits of the measure. Hence, in April, 1879, when the board was created, Drs. Plunket and Wight were among the original members, and the former became the first President of the board. Dr. Wight, to the day of his death, was one of its most disinterested and active workers.

The history of the board since then is familiar to the profession. It has made progress. It has retrograded. The great subject of vital statistics must be tackled again and again until a satisfactory law is obtained. Continuous and costly efforts must be made to enlighten the people of Tennessee, until in matters of public health, this, the University State of the South, takes its place alongside Massachusetts and Michigan, as preëminently an exemplar.

Dr. Hope then offered the following motion:

"*Resolved*, That the President appoint a committee of five on the State Board of Health, whose special duty it shall be to aid in the passage by the next General Assembly, of a satisfactory law upon vital statistics." Carried.

Dr. P. D. Sims, of Chattanooga, in an eloquent eulogium, called upon the Society to contribute to the fund for a monument to Dr. J. Marion Sims. This was seconded with enthusiasm by Dr. Saunders. Action was deferred to the night session.

ELECTION OF OFFICERS.

Dr. Hope nominated Dr. D. D. Saunders, of Memphis, for President. Dr. Roberts seconded the nomination, and requested that Dr. Davis be empowered to cast the vote of the Society for Dr. Saunders, which was done, and he was declared unanimously elected. He accepted in an appropriate and eloquent address.

Dr. A. J. Swaney, of Middle Tennessee, Dr. W. T. Hope, of East Tennessee, and Dr. T. J. Reid, of West Tennessee, were elected Vice-Presidents.

A motion to proceed to the election of a Secretary was laid upon the table, as the Society was well pleased with its present Secretary, Dr. Fite, and therefore declined to accept his refusal to serve another term.

Dr. Deering J. Roberts was re-elected Treasurer.

The Society then adjourned to take an excursion in the city and to re-assemble for business at 8 P. M.

At 4 P. M. the delegates adjourned to the Union Depot, and by invitation boarded a special train which had been provided for their use. They visited all the leading industries of the city, including the South Tredegar Iron and Nail Works, Lookout Rolling Mill, and the new Citico Furnace, and each and every one expressed surprise and amazement at the extent and variety of the industrial progress of Chattanooga.

NIGHT SESSION.

The Society was called to order by the President at 8 P. M.

The committee on memorial to the Legislature made a report, of which the following is a copy:

To the Honorable Legislature of the State of Tennessee:—We, a committee appointed by the Tennessee Medical Society at its last meeting at Chattanooga, on April 8, 1884, beg leave to state that from our personal knowledge, the people of this State, which you have the honor to represent, are being imposed upon in body and person, and in many instances permanently injured in health, and even killed, by ignorant and unauthorized persons who call themselves doctors, and who have no diplomas from recognized medical schools, or certificates from authorized medical boards. We deem it our duty to make you conversant with these facts, that you may, as the regular and proper guardians of the peace, happiness, and lives of the people, take such legislative action as may protect your people from this source. So far as the regular profession of medicine is concerned, we wish you to understand that we ask your action not for ourselves, but in behalf of your own people, leaving us to take care of ourselves, which we claim to be able to do.

We would most respectfully suggest in the accomplishment of the above object, that you may partially effect it by passing an act which prohibits the collection of medical fees by any other than a legalized physician.

D. D. SAUNDERS,
J. H. VANDEMAN,
R. F. EVANS,
W. F. CLARY,
W. W. TAYLOR,
H. L. MCREYNOLDS,
J. F. GRANT,
Committee.

On motion, the report of the committee was received, and the committee continued.

The following committee was appointed on Vital Statistics at the request of the State Board of Health:

W. T. Hope, Chattanooga; F. L. Sims, Memphis; R. Cheatham, Nashville; J. B. Murfree, Murfreesboro; J. B. W. Nowlan, Nashville, chairman.

The Judicial Council reported that the name of Dr. R. J. Hoyle, of Farmington, Tenn., be dropped from the roll of membership on account of irregular practices. Dr. Hoyle was expelled, and the Secretary instructed to notify him of the fact.

Dr. W. W. Taylor introduced the following resolution, which was carried:

Resolved, That a committee be appointed on county medical organization, to consist of not less than three members, one from each section of the State.

Dr. H. L. McReynolds, Chattanooga; A. H. Swaney, Castalian Springs, and W. W. Taylor, Chairman, Memphis, were appointed.

The following resolutions were then made and carried:

By Dr. P. D. Sims—That the Tennessee State Medical Society appropriate to the Marion Sims

Monumental Fund the sum of $50, and that the Treasurer of the Society be, and is hereby instructed, to forward from the fund of the Society this amount to Dr. Maury, of Memphis, the custodian of said fund in Tennessee.

By Dr. Townsend—That all members who propose to read papers at the annual meetings of the State Medical Society, inform the Secretary of the Society of the title of their papers, previous to the meeting, and that the Secretary issue a list of such papers in his call for the annual meeting.

By Dr. Gibbs—That the Committee on Arrangements be requested to make arrangements for a three days' meeting at the next regular meeting.

By Dr. W. W. Taylor—That the thanks of this Society are due, and are hereby tendered the city papers, for the very full reports furnished of our proceedings.

By Dr. Tadlock—That thanks be extended to the N., C. & St. L., and other railroads, for excursion rates; also thanks to the Medical Society of Chattanooga, for their work in the meeting.

By Dr. Masters—That a vote of thanks be extended to Dr. J. H. Vandeman for the royal manner in which he entertained the members of the Society on last evening.

By Dr. Vertrees—Anybody who has done anything for the Tennessee State Medical Society, and who has not been thanked, receive the thanks of the Association.

By Dr. Vandeman—That the thanks of this Society are due, and are hereby tendered to Dr. A. B. Tadlock, for the zeal and impartiality with which he has presided over our deliberations during this session.

The following committees were appointed by the President:

Delegates to the American Medical Association—Drs. Duncan Eve, Nashville; W. F. Glenn, Nashville; C. C. Fite, Nashville; J. B. Lindsley, Nashville; R. A. Hardin, Savannah; W. A. H. Coop, Friendship; J. G. Sinclair, Nashville; G. B. Thornton, Memphis; D. D. Saunders, Memphis; A. J. Swaney, Castalian Springs; R. F. Evans, Shelbyville; W. T. Briggs, Nashville; W. R. Townsend, South Pittsburg; W. M. Vertrees, Nashville; A. B. Tadlock, Knoxville; J. H. Vandeman, Chattanooga; H. Berlin, Chattanooga; G. A. Baxter, Chattanooga; W. G. Bogart, Sweetwater; H. H. Loveman, Chattanooga; and Deering J. Roberts, Nashville.

Committee of Arrangements—Drs. W. F. Glenn, chairman, Nashville; A. Morrison, J. W. Maddin, J. R. Buist, N. D. Richardson, Nashville.

Committee of Necrology—Drs. Thos. Lipscomb, Shelbyville; Thos. Menees, Nashville; P. D. Sims, Chattanooga; R. W. Mitchell, Memphis; J. M. Boyd, Knoxville.

Committee on Credentials—Drs. J. B. Lindsley, Nashville; G. B. Thornton, Memphis; A. B. Tadlock, Knoxville.

Committee on Business—Drs. V. Gibbs, E. M. Eaton, Chattanooga; S. B. Boyd, Knoxville; F. Bogart, Sweetwater; J. B. Murfree, Murfreesboro.

Committee of Publication—Deering J. Roberts, T. A. Atchison, C. S. Briggs, Nashville; W. W. Taylor, Memphis; C. C. Fite, Nashville.

The Society adjourned to meet on the second Tuesday in April, at Nashville.

SOCIAL FEATURES OF THE MEETING.

The reception on the evening of the 8th, at the handsome residence of one of the Society's former presidents, Dr. J. H. Vandeman, corner of Fifth and Chestnut streets, was a pleasant event.

The banquet given by the citizens of Chattanooga, at the hall of the Iron and Coal Association, on the evening of the 9th, after the adjournment of the Society, was a sumptuous feast, and heartily enjoyed.

The toasts on the occasion were apropos, and developed a raciness of wit and an eloquence that gave a glorious finale to a most successful meeting.

STATE MEDICINE.

REPORT OF PROCEEDINGS OF THE ILLINOIS STATE BOARD OF HEALTH.

The regular quarterly meeting of the Illinois State Board of Health was held in Chicago, at the Grand Pacific Hotel, on Thursday and Friday, April 17 and 18, 1884. Present—Newton Bateman, presiding; W. A. Haskell, A. L. Clark, R. Ludlam, W. R. McKenzie, John H. Rauch. The President called the Board to order Thursday at 10.30 A. M. The minutes of the previous meeting, January 17, were read and approved. Under the call for reports from officers, the Secretary presented the following quarterly report:

QUARTERLY REPORT OF THE SECRETARY, JAN 1—MARCH 31, 1884.

During the quarter ended March 31, 1884, there were received in the Secretary's office 615 communications, letters, reports, etc., exclusive of 183 diplomas submitted for verification, and the affidavits and other papers accompanying applications for certificates in nearly 200 cases. There were sent out, during the same period, 760 letters, postals, circulars, etc., and other communications, and the usual quantity of the Board's publications—reports, registers, preventable disease circulars, etc., of which 227 packages were sent by express. Eighty telegrams were received and one hundred and twenty-two sent.

Certificates, entitling to practice medicine and surgery under the Medical Practice Act, were issued to 152 graduates upon diplomas from legally chartered medical institutions in good standing.

Among these were a number issued to practitioners previously holding the certificates of the Board, issued after examination. There are now not to exceed 50 practitioners of this class in the State, who have not since graduated from a medical college, in accordance with the recommendations of the Board. To midwives, 12 certificates have been issued—6 upon diplomas or other recognized credentials, and

6 upon examination. There were, in all, 12 examined during the quarter, of whom 6 were rejected.

The Diplomas of 1883-84.

Applications based upon the diplomas issued at the close of the last session have been received from graduates of eleven different colleges, which have either failed to fully comply with the Schedule of Minimum Requirements of the Board, or against which charges have been received that such compliance has been perfunctory and insincere.

In eight of the cases where the colleges have failed to fully comply with the schedule, the applicants have signified their intention—in response to a suggestion to that effect—of submitting themselves to an examination by the Board on those subjects omitted by their respective schools.

They will present themselves at this meeting, and I recommend the adoption of this course with regard to the diplomas of that class of colleges.

During the month of March I spent two weeks visiting Eastern colleges, with reference to this matter, and was much gratified at the spirit manifested concerning the Board's efforts to improve the status of medical education, especially from the better class of colleges.

I regret not being able to devote more time to these personal visits. They are much more satisfactory and profitable than anything which can be accomplished by correspondence.

On the whole, there is every reason for encouragement in the results of the work thus far. One of the most satisfactory proofs of the timeliness and wisdom of the Board's action is found in the attitude of the graduates themselves. Expressions of approval from a very large number, and, as already stated, of a willingness to submit to an examination by the Board from others have been received.

PREVALENT DISEASES.

Small-pox has reappeared at a few points in the State, viz.: at Chicago—two cases—one from Cincinnati and one from Indianapolis; at Cairo and East St. Louis, several cases from the river; at Charlestown, Coles county, a tramp, said to be from the pineries of Wisconsin, or Michigan; at Coulterville, Randolph county, five cases among negroes, contracted from a negro roustabout. At the close of the quarter, an outbreak is also reported at Yorkville, Kendall county.

In all these cases (except Chicago) the rules and regulations of the Board, and necessary advice and instructions, printed and written, were at once furnished. These are now so well understood, and the community generally is so well protected by recent vaccination and revaccination, that there is no spread of the disease beyond the first case. Some sensational statements were made about the cases at Cairo, but investigation proved them to be unfounded.

Scarlet fever has been reported from a few localities, but not to such an extent as to warrant special mention.

THE CATTLE DISEASE.

On the 13th of March, the Board was appealed to by the State Board of Agriculture concerning information received that foot-and-mouth disease (epizootic aphtha) existed among cattle in Effingham county. Coupled with the reports of its existence in Kansas and elsewhere, the information demanded the most serious attention. Its highly contagious character, the rapidity of its spread, and the difficulty of eradicating the contagion, combine to render it one of the most dreaded of all the animal plagues, from an economic standpoint. It is estimated that the direct money loss from this disease to English stock-raisers in 1872 exceeded $65,000,000, and the average annual loss in France is computed at 5,000,000 francs for twenty successive years.

There is no legislation in this State concerning the disease, beyond the authority conferred upon the State Veterinarian to investigate contagious and infectious diseases among animals. But the power to condemn infected animals, to quarantine, or enforce otoer measures for the arrest of such diseases, and to prevent their spread, is limited specifically to pleuropneumonia or glanders.

In this emergency, it was evident that, if the disease really existed, it could only be dealt with through the State Board of Health by virtue of the powers and authority vested in it by the second section of the act of May 25, 1877. Steps were, therefore, taken to ascertain the foundation for the reports; the State Veterinarian was dispatched by the Governor to Effingham county, and subsequently to a number of other points.

Professors Morrow and Prentice also visited herds in various localities, said to be infected.

Meanwhile, I had consulted with Dr. E. P. Salmon, the chief veterinarian of the Department of Agriculture at Washington, and had carefully studied and compared all the reports of the disease from the several localities, and finally arrived at the conclusion—subsequently confirmed by the veterinary experts—that the disease existing in Illinois, Iowa, Missouri, Kansas, and Nebraska, was not foot-and-mouth disease.

SANITARY COUNCIL.

The sixth annual meeting of the Sanitary Council of the Mississippi Valley was held in Memphis, Tenn., on the 21st of March. Beyond the reception of the reports of officers and committees and the transaction of the usual routine business, nothing of importance was attempted. The object of the meeting was merely to keep the organization in readiness for action should an emergency arise requiring its intervention. A resolution was adopted, thanking the Executive Committee for its labors during the season of 1883, approving its course and instructing it to adopt, if necessary, the same line of action in regard to the prevention of the introduction of yellow-fever, or other infectious disease, into the Mississippi Valley during the year 1884.

Recent changes in the personnel of some of the most important sanitary organizations originally represented in the Council, are cause for congratulation, and for the first time in many years there is now

good reason to believe that all Boards of Health, State and local, in the Valley, will act as a unit.

Respectfully submitted,

JOHN H. RAUCH, Sec.

On motion of Dr. Clark, at the conclusion of the reading, the report was accepted and ordered placed on file.

The Secretary made an informal supplementary statement regarding his action on applications for certificates, based on the diplomas of the session of 1883–84. On motion of Dr. McKenzie, the action of the Secretary was approved.

Fifteen candidates presented themselves for examination, among them being six graduates of colleges which had not fully complied with the Board's schedule, and whom it was proposed to examine only on the subjects omitted, namely, preliminary education and hygiene.

At 11 o'clock, on motion of Dr. Clark, the Board went into executive session for the examination of sundry cases concerning colleges and individuals, representatives of three colleges being in attendance, and desirous of a speedy hearing.

At 1 o'clock, P. M., the Board took an hour's recess for dinner, and at 3 o'clock, after having transacted sundry routine business, the executive session was resumed and continued until 6 o'clock, when the session was adjourned to Friday morning.

FRIDAY, APRIL 18, 9:30 A. M.

The Board met, pursuant to adjournment, present as before. The Secretary presented the correspondence and other papers in a large number of cases, which occupied the attention of the Board during the remaining hours of the session.

The Secretary was authorized to attend the proposed conference of representatives of State Boards of Health, to be held in Washington, D. C., during the meeting of the American Medical Association.

In the case of Dr. W. W. Bower, of Mt. Sterling, Brown County, charged with being identified with the "American Anthropological University of St. Louis," the Secretary was instructed to forward Dr. Bower's denial and explanation to the Hon. John Eaton, Commissioner of Education, by whom the charge was laid before the Board, and to request of General Eaton that he forward any evidence in his possession, tending to prove that said Bower was concerned in the sale of the diplomas of the so-called university.

The Auditing Committee reported that it had examined and approved of bills for the current quarter, amounting to $2,664.80, and recommended that the same be paid.

The Secretary reported that only two of the candidates who had undergone the full examination, had attained the required percentages entitling them to pass, and that both of these were men who already held diplomas from medical colleges.

At 8 o'clock, P. M., the Board adjourned.

THE Missouri State Medical Society adjourned to meet in Sedalia, Mo., May 13th, 1884. The *Medical Review* says the date has been changed to the 20th by order of the President.

BOOK REVIEWS.

A TREATISE ON PHARMACY: Designed as a Text-Book for the Student, and as a Guide for the Physician and Pharmacist, containing the Officinal and many Unofficinal Formulas, and numerous Extemporaneous Prescriptions. By EDWARD PARRISH, late Professor of Theory and Practice of Pharmacy in the Philadelphia College of Pharmacy, etc. Fifth edition, enlarged and thoroughly revised, by Thos. S. Wiegand. With 256 Illustrations.

This work has long been indispensable to the practical pharmacist, as well as the student of pharmacy, and is a valuable reference book for the physician. This new edition, the fifth, has been rendered necessary, not alone by the progress of science, but also by the late revision of the U. S. Pharmacopœia. All the new preparations of the pharmacopœia have been embodied in the work, together with all essential tests, and the improved system of weights and measures. The syllabi, which have proved such a valuable features of previous editions, and upon which Prof. Maisch bestowed so much care, are retained in this edition.

The first five chapters of this treatise are devoted to subjects introducing to a study of pharmaceutical processes proper. The first two chapters appropriately treat of the proper arrangement of a dispensing store and laboratory. The chapters devoted to pharmaceutical chemistry and Galenical pharmacy embrace the technique of the science of pharmacy. The portion of this treatise in which physicians will be most interested, is part VII, entitled, extemporaneous pharmacy. This part treats of prescriptions and the art of selecting and combining remedies. The appendix to this part treats of the management of a sick chamber; the preparations used as articles of diet for the sick; physicians' outfits; and some recipes of important popular remedies. While the suggestions, intended for the laity, upon the management of the sick chamber, are most excellent, we are at a loss to understand the reasons which determined the editor's choice of such subjects for consideration in a text-book on pharmacy. While directions for the preparation of arrow-root, tapioca, and beef-essence find an appropriate place in such a treatise, one is at a loss to find the relevancy of directions for deportment around the dying-bed upon the preceding page. The chapter on Elixirs is both interesting and instructive, and contains some new formulæ of much popularity. This book is amply illustrated, and the paper, printing and binding, are expressive of the best modern typography. Indeed, the mechanical execution of the book is faultless.

A DISCONSOLATE looking doctor on meeting a Hibernian friend attributed his sorrow to the fact that he had just returned from his vacation and found his wife in bed with cerebro-spinal-meningitis. "Holy Moses," says Pat, "and why didn't yees shoot the Oitalian scoundrel?"—*Medical Age.*

FOREIGN CORRESPONDENCE.

PARIS, APRIL 4, 1884.

Dr. Debove, one of Professor Seé's most zealous disciples, has implicit faith in the bacillary theory of tuberculosis as propounded by Professor Koch, of Berlin. During the summer session of last year, Dr. Debove was appointed, on the death of Professor Lasèque, to fill, *pro tem*, the chair of Clinical Medicine at "La Pitie" hospital, when he delivered a series of lectures, by which he endeavored to demonstrate the parasitic origin of pulmonary tuberculosis, and the conclusions to be derived therefrom as regards the ætiology, diagnosis, and treatment of this affection. According to Dr. Debove, the bacillus is the characteristic element of the tubercle, which definitively settles the question as to the unity of phthisis; moreover, as this same bacillus is found in the greater part of the lesions which have up till now been put down for scrofulous, it follows that the term scrofula should be expunged from the nosological table as it exists in the standard works of the day. The contagiousness of pulmonary phthisis, which has been admitted for some time, has become a fact intimately associated with the parasitic doctrine, without our being able to define precisely the means by which the parasite enters the body, nor the individual organic modifications, hereditary or acquired, which favor or check its development. And yet it is these modifications that it would be necessary to know exactly in order to establish in a rational manner the prophylactic treatment of phthisis. As regards curative treatment, Dr. Debove has not much confidence in the utility of drugs, nor yet in the climatic treatment of the disease, his sheet anchor being hyperalimentation, or, more properly speaking, artificial feeding.

Dr. Debove was led to adopt this method of treatment on the grounds that anorexia was not so frequently as has been represented, an initial symptom of tuberculosis; but, on the contrary, it is anorexia that frequently leads to phthisis. He therefore asks that whether in suppressing the cause, the effects will not be also suppressed, and whether, in consequence, by an abundant alimentation, the progress of the affection would not be checked. This he proposed to effect by feeding the patient by means of a soft India rubber tube, with a funnel attached to the superior extremity. But as nitrogenous material would constitute the principal element in the diet of phthisical patients, it would be necessary to compose a mixture that would pass easily through the tube, and be as digestible as possible. With this view, a mixture composed of milk, or beef tea and raw eggs, including the white and yellow parts, to which may be added some raw meat finely chopped up, or better still, powdered meat. Dr. Debove commences by administering a mixture composed as follows: 25 grammes of powdered meat, 1 egg, and ½ a litre of milk or beef-tea, which he gradually increases to 3 litres of milk or beef-tea, or 6 to 12 eggs, and 300 grammes of powdered meat in 3 meals. He recommends that not more than 1 litre should be introduced into the stomach at a time. He considers the washing out of the stomach unnecessary, and abstains from every other form of medication, excluding even cod-liver oil. In case of severe diarrhœa, however, he administered bismuth and opium.

Dr. Debove adopts this method in all the stages of the disease, that is, of pulmonary tuberculosis, and in all the cases in which he has succeeded in feeding the patient in the manner above described, he noticed a series of phenomena which were constantly produced: the vomiting ceased, digestion was perfectly performed, the sweats disappeared, the dyspnœa was relieved, the strength returned, the evening fever abated, the cough and expectoration were diminished, and the weight of the patient increased. One circumstance was particularly noticed, that is, the vomiting of the alimentary substances introduced by the tube was altogether exceptional, and when the patient had been troubled with repeated and obstinate vomiting, excited by paroxysms of coughing, the vomiting was checked, the diarrhœa ceased, and the appetite returned. This method of treatment should be continued for some time, and after it has been considered necessary to stop it, the patient should continue to feed himself with powdered meat, about 100 grammes in one meal, for some months longer, and in addition to his other repasts. But notwithstanding the favorable results obtained by this method of hyperalimentation, the prognosis of the cases so treated by Dr. Debove and others in this way does not seem to be more promising than that of those treated by the ordinary methods, as Dr. Debove himself asserts that one cannot hope to guarantee a tuberculous subject, when once cured, against a subsequent attack. All that one can do is, to check the progress of the present attack, and thus permit the lesions to cicatrize.

The contra-indications of this method of treatment are: the greatly advanced lesions, for one cannot hope to do much with a patient whose intestines are affected with extensive ulcerations which are manifested by an obstinate diarrhœa of long standing. As for the state of the lungs, this is less a question of degree than one of extensiveness. In a patient whose lungs are studded with tubercles, one can only hope to prolong his existence by a little. In the acute forms of the malady, the method is powerless. The same is the case when there is high and continued fever, indicating the progressive course of the lesions. The treatment is more successful with chronic cases. The earlier the remedy is applied, that is to say, at the commencement of the first manifestation of the malady, the cure would be more hopeful and rapid than if adopted at a later stage.

Encouraged by the success obtained by this method of treatment, Dr. Debove was induced to apply it to other cases of anorexia and cachexia, and with satisfactory results. Judging by analogy, the author considered that the method might with advantage be employed in chronic cases of pneumonia and hysterical subjects who frequently refuse all food, or if any is taken, it is vomited up. Dr. Debove considers that in certain affections of the stomach, albuminuria, and in chronic dysentery, where milk may not be

well borne, the powder of milk administered in this way will render great service. In certain surgical affections also, in which the surgeon may hesitate to operate owing to the debilitated condition of the patient, this method of hyperalimentation, or artificial feeding, will be found highly serviceable.

DOMESTIC CORRESPONDENCE.

ACTION OF ALCOHOL.

TO THE EDITOR:—

In the last issue of your valuable journal, a somewhat brief synopsis of a clinical lecture delivered by me, served as the basis of an editorial notice, that, though accepted by me with all the meekness that should characterize the bearing of a junior hearkening to the voice of a "father in Israel," bears within it a few elements of error.

In speaking of the combustible power of alcohol, as compared with that of cod-liver oil, I instanced an experiment not unfamiliar to chemists of to-day, and which was no doubt familiar to Baron Liebig. Indeed, we know that alcohol must be rich in heat-producing power, its chemical formula ($C_2 H_6 O$), ethyl hydrate, clearly justifying such an opinion. Its power in raising the temperature of water was referred to by me, and an application of the knowledge of this fact served in part to explain its action in the treatment of wasting diseases. This I did with the knowledge that the ablest authorities sustained me.

Previous to 1860, it was generally conceded by the profession that the greater portion of any alcohol taken into the system, was completely oxidized, only a small fraction being eliminated by the emunctories. In the year mentioned, Perrin and Lallemand endeavored to prove that nearly all the alcohol ingested was completely eliminated unchanged. But the whole matter has been so completely gone over by Anstie, Thudicum, and Dr. A. Dupré, that the investigations made in 1860 may be truly regarded as *passé*, in fact as well as in time. Dr. Dupré's observations, the most important of those made, may be summed up as follows: The amount of alcohol eliminated each day does not increase with the increase of alcoholic diet; and therefore, all the alcohol consumed daily must, of necessity, be disposed of daily. But since it is not eliminated within that time, it must be destroyed in the system. The amount of alcohol eliminated in both breath and urine, forms only a minute fraction of that taken into the system.

In the course of his experiments, Dupré found that after an abstinence of six weeks, on the part of those accustomed to the use of alcohol, and even in the case of one who did not use it in any form, a substance eliminated in the urine, and perhaps also in the breath, which, though apparently not alcohol, gave all the reactions ordinarily sought for in the detection of the minutest trace of that agent. The quantity of the material so closely simulating alcohol is so small, that its precise nature has not yet been determined. It is well to note in this connection, that the alcoholic material mentioned was considerably reduced during a period of alcoholic ingestion, only regaining its normal standard when the consumption of alcohol had for some days been abandoned.

It cannot be denied that on this subject there are conflicting views—what subject of medical study is entirely free from controversy? Yet the weight of evidence, both scientific and practical, goes to show that alcohol, in dietetic quantities, is retained and forms an aid to tissue construction. Bouchardat, Sandras and Duchek, conclude that alcohol is freely consumed in the body, little escaping by the urine, except where very large quantities are taken. Anstie, the authority quoted by yourself, is of opinion that the greater part of the alcohol ingested is consumed, though Parkes and Wollowicz believe that a considerable quantity escapes with the sweat and breath. Dupré's experiments, more recent than those of Anstie, prove that only a fractional part of alcohol escapes from the body, and Anstie says this never occurs but when narcotic doses are taken.

Thus it is shown that while in dietetic doses assimilation of alcohol may be complete, just as in any other form of nutriment, an excess of so highly diffusible and easily oxidized material, must as a matter of course, be thrown out of the system. The excess of nitrogen contained in animal food is subject to the same law.

The use of alcohol in every age and by every nation, since creation's dawn, demonstrates that it satisfies a natural instinct; that it literally refreshes the system exhausted by mental or physical labor, not only quickening the appetite for food and aiding the digestion, but sparing the digestive organs themselves, by limiting the amount of solid food otherwise required by the body. In short, it offers itself in the blood, as a substitute for the tissues that would be otherwise destroyed. "Alcohol," says Moleschott, is the savings bank of the tissues. He who eats little and drinks alcohol in moderation, retains as much in his blood and tissues as he who eats more and drinks no alcohol."

We may therefore conclude from the latest light given us upon this subject—and Anstie is not the latest illumination, by any means—that of any amount of alcohol taken, not in excess of the demands of the system, only a very minute proportion can be recovered from the secretions. The remainder evidently undergoes metamorphosis, and is eliminated in a new form. Hence, the doctrine that alcohol is a food, is true not only in a chemico-physiological sense, but in its more literal acceptation, inasmuch as it favors the formation of fatty products, especially noticeable in the increase of adipose tissue and by its well known tendency to produce fatty liver, kidney, and gall-stones if taken to excess.

Yours respectfully,

P. H. CRONIN, M.D.

N. W. Cor. North Clark and Oak streets.

INTERCOMMUNICATION OF STATE MEDICAL SOCIETIES.

BY A. S. V MANSFELDE, M.D., ASHLAND, NEB., SECRETARY OF THE NEBRASKA STATE MEDICAL SOCIETY.

EDITOR JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION:

Dear Doctor:—In my forthcoming report to the Nebraska State Medical Society, the following will occur:

In looking over the report of the Proceedings of our society, my attention was arrested by the following resolutions, incorporated in the report of the Committee on Foreign Correspondence, by its chairman, our efficient Corresponding Secretary, Dr. R. R. Livingston:

Resolved, That the President and two Secretaries of this Society are hereby empowered and required to designate suitable gentlemen, members of this Society, to represent all State medical societies with which this body has fraternal relations, and notify the proper officers of foreign societies of this action, requesting said foreign societies to designate suitable parties to represent this Society at their respective meetings, and that said foreign societies be requested to issue commissions to the gentlemen designated from our membership to represent them. The President and Permanent Secretary being hereby authorized to issue similar commissions to those gentlemen selected from the membership of foreign societies to represent this Society in their respective bodies.

Resolved, That the commissions provided for in the foregoing resolution shall clearly define the duties of the representative to whom the same shall be issued, and a failure to comply with the requirements of said duties, shall forfeit said commission.

Nowhere in the Proceedings following the one in which these resolutions are incorporated (the year 1877) could I find any recognition of these resolutions, and yet the great value of them, if properly executed, must be apparent to every one who has the success of his own society, the advancement of medical science, and fraternization of all physicians in the United States, at heart.

This is a very lucid example of the many instances strewn upon the pages of man's history, when suggestions of the utmost importance fall silently to the ground, for want of proper support, until some one less capable of hatching great ideas, but more ready to nurse them into maturity, stumbles on them, and again revives an interest in the project which they foster.

Gentlemen, the value of these resolutions, as it appears to my mental vision, is inestimable, wherever medical science has votaries who, not lost in their devotion to her, yet remember that they are men, with the qualities of the citizen, the husband and father, clothed also with the responsibilities of these prerogatives.

By no means, I take it, can the interests of the profession be so strongly united, and therefore made efficient, as by the manner of presentation suggested in the resolutions of your Corresponding Secretary.

I take the liberty to again present them to you; the Phœnix, born out of the ashes of the past, and ask your candid opinion, after due deliberation, whether this creature, born again, is not worthy your best and undivided attention?

In the forthcoming report of the Committee on Revision of the Constitution, I have asked that the following be inserted:

COMMITTEE ON FOREIGN CORRESPONDENCE.

This committee shall consist of duly accredited representatives (members of this Society) of the several State and Territorial Medical Societies.

They shall receive and review the Transactions of the societies whom they represent, and through their chairman, the Secretary of Foreign Correspondence, present annually a report of the advance in medicine made by said societies. They shall also report such other matters as their societies may wish to communicate to the Nebraska State Medical Society.

DUTIES OF THE REPRESENTATIVES OF FOREIGN SOCIETIES.

It shall be the duty of the representative of any foreign society to communicate all advances in matters medical and governmental made by his society during the year just past, as well as of all matters, of whatever kind, his society may wish to be brought to the notice of the Nebraska State Medical Society, to the Corresponding Secretary, as chairman of the Committee on Foreign Correspondence. And finally, the representative shall guard the interests of his society to the best of his ability, where and whensoever it is demanded.

Non-compliance with the obligation herein set forth, shall be followed by a prompt revokal of the commission held by said representative; after due notice is given to the society to whom he is accredited.

MEDICAL SERVICE ON OCEAN VESSELS.

TO THE EDITOR OF THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

Sir:—Infectious disease is the only foreign enemy which threatens, and may one day invade and decimate the United States.

The danger is not visionary. Small-pox and other zymotic fevers are practically endemic in many of the larger European cities, but being usually confined within narrow bounds, seldom excite public attention, yet there are times when, even in England, the pestilence stalks forth from the slums to scatter disfiguration and death among the wealthiest and the highest.

Why may it not do so here? New York sanitation is notoriously far from perfect. Lesser outbreaks are of frequent occurrence throughout the country, and since the conditions, atmospheric or otherwise, which occasionally break down all limitations of infection are more or less undetermined, who can question the possibility of our being brought face to face with the national disaster of an uncontrollable epidemic.

This much is certain: the present defective sanitary administration on ocean steamships offers an easy

ingress to infection, which existing quarantine arrangements are powerless to oppose.

When, as not unfrequently occurs, zymotic fever appears on ship-board during the trans-Atlantic passage, it is evident that many of the persons in such necessarily close proximity to the sufferer are likely to contract the disease unless efficient isolation and disinfection are immediately enforced. It is equally certain that when the period of incubation is unfulfilled at the time of disembarkation, neither will these persons have been of any inconvenience to the ship officials while on board, nor can the most careful examination at quarantine distinguish them from the healthy. They are therefore permitted to proceed to their various destinations, there to become centers of possibly indefinite dissemination.

That this actually happens, and frequently, is proven by the fact that almost every appearance of zymotic disease in any part of the United States is, as the present outbreak of small-pox at Easton, Penn., directly traceable to the recent advent of immigrants. The reasons are not far to seek: the medical officers of steamships are appointed by the owners without due regard to their fitness for the post, and are dependent upon persons whose first, if not only, care is to make the voyage with as little expense and inconvenience as possible; they are not allowed a particle of independent administrative authority in even the most purely sanitary matters, nor are they provided with the means necessary to combat disease; and lastly, many of the vessels employed are so constructed that the isolation of infected persons is absolutely impossible.

A recent example is from many points of view interesting: a steamer belonging to one of the reputedly safest trans-Atlantic lines arrived at this port some months ago with a saloon passenger on board suffering from small-pox, and shortly after arrival another case was discovered among the steerage. The vessel was granted *pratique*, discharged her passengers, returned to England, and in due course arrived here again with another consignment of passengers, and another case of small-pox; this time a steward who had served on the ship during a previous voyage, but who only developed symptoms of the disease 32 days after the former cases had been removed. There are persons, and apparently in authority, satisfied with the assumption that cases of infectious disease following thus closely one upon another are unfortunate coincidences for which no person may be held responsible. In the public interest, more careful inquiry would seem to be desirable. The interval of time precludes the possibility of this steward having been infected directly by either of the previous cases, or during his former stay in this city. It is highly improbable that he contracted the disease from an independent source at Liverpool, since small-pox was not prevalent there. Remaining is the choice of two equally unpalatable solutions: either the steamer was inefficiently disinfected after the removal of the first cases, and variolar germs surviving not less than sixteen days after the supposed disinfection (?) infected this man during the latter days of the eastward passage; or there were a succession of small-pox cases on board this vessel, which were not recognized or were intentionally concealed from the health officer of this port, and from the public. A visit to the ship strongly confirmed the last supposition.

The hospitals for infectious disease were situated not upon the upper deck, but between the decks, in the forward part of the vessel, opening off, and ventilated *exclusively* into, a covered-in passage running through the first-class saloon the entire length of the vessel. In fact, if the builders had set themselves the task of constructing and locating these hospitals so as to disseminate throughout the inhabited parts of the ship every germ of infection coming from within, such an end could scarce have been more skilfully attained. And this is not an isolated instance of total disregard of sanitary law on ocean steamers.

Within five months, dating from the 11th of January, 1882, no fewer than twenty vessels infected with small-pox entered the port of New York; upon four only was even partial quarantine enforced. The remaining sixteen were granted *pratique* as soon as the passengers and crews had been vaccinated. No doubt it was better to vaccinate than do nothing, but under the circumstances, vaccination cannot be regarded as protective, since it is admitted that it cannot even modify small-pox, previously contracted, unless it has been so timed that the maturation of the vaccine vesicle shall precede the period of variolous invasion.

The order by which the surgeons on trans-Atlantic steamships are required to vaccinate the steerage passengers within twenty-four hours after starting, is in most instances practically ignored, seldom complied with during the time named, and when attempted, with what results may be judged from the report of the health officer. One surgeon reported 200 vaccinations, of which not one proved successful, another 250, of which only two proved successful, and so on. But even if this order were carried out to the letter, it would be at best but a choice of evils, and I think the wrong one. That the medical officer of a crowded steamer should neglect other more pressing duties to vaccinate steerage passengers during the first day, or even days of the voyage, would be manifestly inexpedient for the general welfare. On other grounds it would be both cruel and unscientific; cruel as disturbing unnecessarily persons already miserable, many of whom would be in the throes of sea-sickness and might claim at least to be let alone; unscientific, and calculated to discredit this most valuable of prophylactics, as challenging an epidemic of erysipelas under conditions combining to favor its development and spread.

Thus is quarantine administered, and thus is the United States sown with foreign infection, which will assuredly one day take root and flourish.

Is it wise to wait until the panic of that day shall call forth extreme precaution in measures repressive of convenient travel and healthful immigration.

Surely it were better that Congress should at once, by moderate legislation, guard the country against pestilence, and insure the protection of intending citizens during the ocean transit.

This may be done by (1) requiring all persons

coming to the United States to show evidence of having been vaccinated at least fourteen days previous to embarkation; (2) by insisting that the vessels carrying them shall provide proper hospital accommodation, and necessary assistance for the care of the sick; and (3) by establishing a competent service of marine medical officers, who, being entirely independent of interested influences, will see the law observed throughout the voyage, and will be responsible to Government for the faithful discharge of their duties, and intelligent coöperation with the quarantine authorities. I am, sir, your obedient servant,

J. A. Erwin, M.A., Cambridge, Eng., M.D.,
Late Visiting Physician to the Manchester Southern Hospital for Women and Children,
April 19, 1884. 363 Fifth Av., N. Y.

ON REDUCTION OF DISLOCATIONS BY MANIPULATION.

April 22, 1884.

Sir:—In reading the last edition of your Journal, I was not a little surprised at your reference to my communication on the above-named subject, and I now trust that in a spirit of fairness you will give equal publicity to my reply. You have asserted that one of your motives for inserting my communication was to make it the occasion of correcting my erroneous views concerning the status of surgical progress in this country. In such a case, I think that your comments should have appeared in the same number of the Journal, together with the article commented upon—whereas they failed to appear until two weeks afterwards—and this, to say the least, was somewhat lacking in courtesy, and entirely at variance with editorial custom.

In stating that manipulation was but little taught in schools, I based my belief on the information of several medical men here, with whom I had conversed on this subject—and this, together with the fact of the patient whose case *I* published, and who had been treated six times for a recent simple dislocation of the humerus by four or five different surgeons here, none of whom had employed manipulation, sufficiently warranted me in my assertion. During the five years I spent at the study of medicine in Dublin, where the standard of medical education is admittedly high and thorough, I remember there were only a few lectures delivered on this subject, and that in the instructions given by private teachers ("grinders" or "coachers" as they were familiarly yclept), it was very little dwelt upon—and I afterwards found that the same was the case in London. With regard to that part of my assertion concerning the text-books, I know that manipulation has been fully and ably dealt with in some few works, as in the one instanced—Prof. H. H. Smith's work on the Principles and Practice of Surgery—but these are not text-books, and reference to the well-known and generally read text-books on surgery of Druitt, Bryant, and Holmes will bear out my assertion that only a very fleeting notice indeed is awarded therein to the subject. Manipulation has been taught in almost all countries by a few individual professors, as in the United States, by Profs. Smith, Hodgen, and Brainerd, and in Great Britain and Ireland, by Messieurs. White, of Manchester, and Croly and Stokes, of Dublin, and a few others, but this is no proof whatever that manipulation is at all sufficiently taught, much less that "direct and full instruction" on the subject is generally given—and I trust I may be pardoned for still doubting that such is really the case.

In my communication I merely invited the attention of the editor and readers of the Journal of the American Medical Association, to the subject of manipulation, which all will concur with me, is surely worthy of attention, and in doing so, I had no intention of raising an issue concerning the medical teaching here, nor of reflecting invidiously on the status of surgical progress in the United States, and I shall only add in conclusion, that I regret that any of my statements have been misunderstood, and I trust that this explanation will show that my communication was dictated, not by a spirit of alienation, bnt by a feeling of friendliness and coöperation.

M. M. Louis Hutchinson,
L.R.C.S., I.L.K.Q.C.P.I., etc.

SPECIAL NOTICES.

Ashland, Neb., April 14, 1884.

Editor Journal American Medical Association, Chicago.

Dear Doctor:—The Nebraska State Medical Society will meet in annual session at 9 o'clock A. M., Tuesday, May 13, in the city of Omaha. Physicians in affiliation with the A. M. A., who may intend going West, are cordially invited to attend our meeting. Very truly yours,

A. S. V. Mansfelde, Sec.

NECROLOGY.

Bullock, Otis, M.D., of Warren, R. I., was the son of Dr. Samuel and Betsey Bullock, born in Sterling, Conn., Feb. 20, 1806; died of pneumonia, March 6, 1884. His father practiced medicine until about 80 years of age, in Rehoboth, Mass., where he died at the age of 92.

Dr. Bullock was for three years a student at Day's Academy, in Wrentham, Mass. He studied medicine with Dr. Usher Parsons, of Providence, who was surgeon of Perry's Flag Ship, at the battle of Lake Erie. He graduated at Harvard Medical College, in March, 1832. Dr. Bullock commenced practice in Warren, R. I., and for some years was a partner of Dr. Williams, the leading practitioner in the town, to whose practice he succeeded. He was a prominent and popular member of the Rhode Island Medical Society, and was rarely absent from a meeting. He was elected a Censor of the society in 1840, which position he held until his death, nearly forty-four years. He was elected President in 1866, and

served one year. He joined the American Medical Association in 1860. In 1836 he married Martha M. Randall, who died in 1837. In 1842 he married Elizabeth H. Saunders, who died in 1873. In 1875 he married Mary F. Collins, who, besides two sons, survive him. Dr. Bullock's remains were buried March 10, in South Cemetery, R. I.

W. E. S.

MISCELLANEOUS.

THE POPULAR VIEW OF PROTECTION AGAINST CONTAGIOUS GERMS.—A correspondent of the *Medical Times* says: "The wide-spread fear of contagious germs and the appreciation of the value of antiseptics seems to be more intense on the Continent than with us, if I may judge from what I saw and heard last year when on my travels. For example, the chance of inhaling tuberculous bacteria has been met by a sanitary spittoon, and the fear of absorbing poisonous matters at the other end of the body by antiseptic closet paper, both for use and placing on the seat. The former I met with in Germany under the name of 'Cellulose Closetpapier mit Salicylsäure getränkt,' and the latter in France as 'feuille hygienique de la siege des water-closets avant de sig assevir garantit de tout contact malsain et dangereux.'"

COPENHAGEN AND THE INTERNATIONAL MEDICAL CONGRESS OF 1884.—A writer in the *Lancet* gives under this head some very interesting information respecting Copenhagen. Thus, he tells us that the Danish language much resembles English, so much so that the Professor of English at the University of Copenhagen, himself an Englishman, considers the two languages to be merely two different dialects; the pronunciation is very different, but most educated Danes understand English and speak it pretty well, and in shops, restaurants, tram-cars, etc., Englishmen will often find people who understand them. Amongst well-known medical men of the past the following are worthy of mention: Ole Worm, who died in 1654, and was the first who described the ossicula intercalaria s. Wormania; Thomas Bartholin, who died in 1680, was the discoverer of the lymphatic vessels; Winslow, who died in 1760, was professor of anatomy in Paris, to which city he removed after his perversion to Roman Catholicism; Callisen, who died in 1824, was the first to perform colotomy in the left lumbar region, and Jacobsen, who died in 1843, was the first to construct a strong and useful instrument for lithotrity, and first described the tympanic nerve, which is therefore also called nervus Jacobsonii. Denmark also boasts of Oersted, the well-known discoverer of electro-magnetism.

Its (Copenhagen) university is more than four centuries old, and offers free education to all. The public lecturers are supported by the State, receiving an annual government grant. The private lecturers receive neither government grant, nor students' fees, but work entirely *honoris causâ*. There is a large, old building called "Regensen," which was built more than 200 years ago, where a hundred students live gratuitously, and receive, besides, a small grant of money every month. There are also smaller houses erected by private people for the same purpose. In addition, there are private and public funds to help the poorer students in the purchase of either books or instruments, such as microscopes, etc. The students usually enter the University at the age of eighteen and leave at the age of twenty-five. The female students of Denmark are as yet but few. They attend exactly the same lectures as the male students, and nothing is especially arranged for them. In Denmark nobody is allowed to practice as a medical man unless he has passed a certain examination at the University. The medical education is very thorough, and extends generally over six to eight years. The theoretical part is given at the University, the practical at the different hospitals, of which one, the Fredrichs Hospital, is connected with the University, so that its physicians and surgeons are always professors at the University. The medical student attends lectures on philosophy the first year, and then passes an examination on this subject. Besides preparing himself for this examination, he also studies chemistry, botany, zoölogy and natural philosophy, which are the subjects for the next examination, generally passed half a year or one year later. From this time begins the medical education proper, the students being in the hospitals as clerks and dressers during the morning, and attending lectures during the afternoon. Five to seven years after having entered the University the medical students pass examination in anatomy, with dissection, physiology, and pharmacology, and one year later the final examination in medicine and surgery, both theoretical and practical, in morbid anatomy, with necropsies, in midwifery, and medical jurisprudence, in which latter the candidate has to write a paper on a given subject. Ultimately the candidate must write a paper on some given medical, and another on some surgical, topic. He is allowed four hours for each. Much attention is paid to the practical education, the candidates being obliged to produce certificates of attendance at a certain number of hospital clinics. Every one who aspires to the rank of M.D. must prove his scientific knowledge by a work on some medical subject which is submitted to the Faculty of Medicine for approval. If accepted, it is then printed in book form, copies are distributed, and on a fixed day he must publicly defend his opinions against professors chosen specially by the University, and all others who may desire to enter the lists against him.

MATERIAL FOR CASTS.—Mr. Charles W. Cathcart, in the *Edinburgh Clinical and Pathological Journal*, has an article on the use of a composition as follows:

Strong, clear glue or gelatine	4 oz.
Glycerine	4 oz.
Water	1 oz.

He breaks the glue into small pieces, soaks for an hour in cold water, melts and adds to the warm glycerine. When thoroughly mixed, this substance can be poured into any mould, and when cool it is quite

tough and elastic. Its clear, brownish color is an objection which is overcome by oxide of zinc, 1 lb.; glycerine ½ lb.; glue 1 oz; mix the glycerine and oxide of zinc, and add the glue melted. For a flesh tint add solution of burnt sienna rubbed up in glycerine, or of vermilion in glycerine.

This material cuts with something like the consistence of skin, is elastic, and and is tough enough to hold stitches. It may be used to illustrate certain plastic operations, such as hare-lip. In making casts it is not necessary to prepare the plaster mould, other than to see that it is perfectly dry. When cold it may be *pulled* out without fear. The cost per lb. is from 1s. 6d. to 2s., and the specimens keep well.

NEW BOOKS.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT UNITED STATES ARMY, FROM APRIL 19, 1884, TO APRIL 25, 1884.

Hoff, John Van A., Captain and Assistant-Surgeon, to be relieved from duty at Alcateag Island, Cal., and to report to the commanding officer at Fort Mason, Cal., for duty as Post Surgeon. (Par 3, S. O. 45, Hdqrs. Dept. of Cal., April 16, 1884.)

Porter, Joseph Y., Captain and Assistant-Surgeon, granted leave of absence for 2 months, to take effect about May 5, 1884. (Par. S. O. 38, Hdqrs. Division of the Missouri, April 19, 1884.)

Biart, Victor, Captain and Assistant-Surgeon, granted leave of absence for one year on surgeon's certificate of disability, with permission to leave the Division of the Missouri. (Par. 2, S. O 91, A G.O., April 19, 1884.)

La Garde, Louis A., Captain and Assistant-Surgeon, granted leave of absence for one month, with permission to apply for two months' extension. (Par. 1, S. O. 91, A.G O., April 19, 1884.)

LIST OF CHANGES IN THE STATIONS OF MEDICAL OFFICERS, U. S. NAVY, FOR THE WEEK ENDING APRIL 26, 1884.

P. A. Sur con C T. Hibbett ordered to U. S. Iron-clads James River, Va

P. A. Surgeon H Aulick, detached from Iron-clads and ordered to "New Hampshire"

P. A Surgeon W. S. Dixon, detached from "Hartford" and ordered to Coast Survey Str. "Hassler"

Pr A. Surgeon F. H. Terrill, detached from "Hassler" and ordered to "Hartford"

Surgeon J. C. Wise, detached from "New Hampshire" and placed on waiting orders.

Medical Inspector W. K. Schofield, appointed Medical Inspector on Active List.

P. A. Surgeon F. S. Nash, detached from Laboratory and ordered to "Alert" (Greely Relief Expedition).

P. A. Surgeon J. H. Hall, ordered before Retiring Board.

Medical Inspector H. C. Nelson, placed on Retired List.

P. A. Surgeon S. W. Battle, placed on Retired list.

P. A. Surgeon F. H. Terrill, resigned.

P. A. Surgeon J. M. Murray, ordered to "Minnesota."

OFFICERS OF

THE AMERICAN MEDICAL ASSOCIATION

AND OF ITS SEVERAL SECTIONS 1883-4.

PRESIDENT.

Dr. AUSTIN FLINT, SR., of New York.

FIRST VICE-PRESIDENT.

Dr. R. A. Kinloch, Charleston, S. C.

SECOND VICE-PRESIDENT.

Dr. T. B. Lester, Kansas City, Mo.

THIRD VICE-PRESIDENT.

Dr. A. L. Gihon, United States Navy.

FOURTH VICE-PRESIDENT.

Dr. S. C. Gordon, Portland, Maine.

PERMANENT SECRETARY.

Dr. Wm. B. Atkinson, 1400 Pine St., Philadelphia.

TREASURER.

Dr. R. J. Dunglison, Philadelphia.

LIBRARIAN.

Dr. C. H. A. Kleinschmidt, Washington, D. C.

Place of meeting, 1884, Washington, D. C.; Time of holding meeting, first Tuesday in May.

CHAIRMAN COMMITTEE OF ARRANGEMENTS.

Dr. A. Y. P. Garnett, Washington, D. C.

ASSISTANT SECRETARY.

Dr. D. W. Prentis, Washington, D. C.

BOARD OF TRUSTEES FOR JOURNALIZING THE TRANSACTIONS.

Drs. J. M. Toner, Washington, D. C., President;
M. Moore, Rochester, N. Y.; Leartus Conner, Detroit, Mich.;
J. H. Packard, Philadelphia, Secretary;
H. F. Campbell, Augusta, Ga.; A. Garcelon, Lewiston, Me.;
P. O. Hooper, Little Rock, Ark.;
L. S. McMurtry, Danville, Ky.; J. H. Hollister, Chicago, Ill.

OFFICERS OF THE SECTIONS:

"Practice of Medicine."

Chairman—Dr. John V. Shoemaker, Philadelphia, Pa.;
Secretary—Dr. W. C. Wile, Sandy Hook, Conn.

"Obstetrics and Diseases of Women."

Chairman—Dr. T. A. Reamy, Cincinnati, Ohio; Secretary—Dr. J. T. Jelks, Hot Springs, Ark.

"Surgery and Anatomy."

Chairman—Dr. C. T. Parkes, Chicago, Ill.; Secretary—Dr. A. O. Walker, Detroit, Mich.

"Ophthalmology, Otology and Laryngology."

Chairman—Dr. J. F. Chisolm, Baltimore, Md.;
Secretary—Dr. J. L. Thompson, Indianapolis, Ind.

"Diseases of Children."

Chairman—Dr. Wm. Lee, Baltimore, Md.; Secretary—Dr. W. R. Tipton, Las Vegas, N. M.

"Oral and Dental Surgery."

Chairman—Dr. T. W. Brophy, Chicago, Ill.; Secretary—John S. Marshall, Chicago, Ill.

"State Medicine."

Chairman—Dr. Deering J. Roberts, Nashville, Tenn.;
Secretary—C. W. Franzoni, Washington, D. C

Committee on "Necrology."

Chairman—Dr. J. M. Toner, Washington, D. C.

THE

Journal of the American Medical Association.

EDITED FOR THE ASSOCIATION BY N. S. DAVIS.

PUBLISHED WEEKLY.

VOL. II. CHICAGO, MAY 10, 1884. NO. 19.

ORIGINAL ARTICLES.

ANNUAL ADDRESS.

BY AUSTIN FLINT, SR., PRESIDENT OF THE AMERICAN MEDICAL ASSOCIATION FOR 1884.

The American Medical Association has reached an age when the thoughts of one whose retrospections extend to its birth, naturally revert to the natal period of its existence. Of those who coöperated in the formation of the Association, not many now remain, and after a few more annual meetings all will have passed away.

Thirty-eight years ago, a medical convention was held in the city of New York, in compliance with a recommendation by the Medical Society of the State of New York, in 1845. In 1839, the Medical Society of the State of New York adopted a resolution recommending a national convention to be held in Philadelphia in 1840. This action of the society was without effect. In connection with the recommendatory resolution adopted in 1845, a committee of three was appointed to carry the resolution into effect, and the mover of the resolution, Dr. N. S. Davis, was made chairman of that committee. Thanks to his zeal and energy, at the time and place designated by the Medical Society of the State of New York, the convention was held, and attended by about one hundred delegates, representing medical colleges and societies in sixteen States of the Union. I can bear testimony from personal recollection to the enthusiasm which characterized that convention. The convention resolved that it was expedient to form a National Medical Association, and a committee of seven was appointed to report a plan of organization at a second convention, to be held in Philadelphia in May, 1847. A committee of seven was to report, at the same time and place, a uniform and elevated standard of requirements for the degree of M.D. Another committee of seven was appointed to report on a suitable preliminary education for the study of medicine; and a committee of seven was appointed to report a code of medical ethics.

At the convention held in Philadelphia in May, 1847, there were present 250 delegates, 40 medical societies, 28 medical colleges, 22 States of the Union, and the District of Columbia being represented. I can testify to an enthusiasm even greater than at the first convention. Resolutions reported by the several committees appointed at the New York convention were adopted. These resolutions embraced a plan of organization, a constitution and by-laws, together with the now existing Code of Medical Ethics, and the convention was merged into the American Medical Association. Thus, the birth of the Association was in 1847, and it therefore now enters upon the 38th year of its existence.[1]

What motives led to the formation of the Association? First and most prominent was a desire to promote improvements in medical instruction, and to advance the standard of professional acquirements. These were the aims stated in the call for the first convention. A more comprehensive statement was expressed in the first of a series of resolutions proposed by Alfred Stillé, and offered by Isaac Hays, as follows: "It is expedient for the medical profession of the United States to institute a National Medical Association, for the protection of their interests, for the maintenance of their honor and respectability, for the advancement of their knowledge, and the extension of their usefulness." It had become evident that for the ends expressed in this resolution the profession in this country must rely mainly on itself. Little was to be expected from State Legislatures. These bodies then, as now, were indisposed to legislate in behalf of medical education, except to charter new colleges; they were even reluctant to legalize dissections. They had not then, nor have they since the formation of the Association, recognized the promotion and diffusion of medical knowledge as legitimate objects for ample appropriations of public funds; as a rule, so far as legalized protection, sanction, and encouragement go, they have been not less considerate of irregular than of regular medical practice, and indeed, the terms regular and irregular denote a purely professional, not a legal, distinction. The State of New York, at the time of the first convention, had virtually admitted the right of any one to practice medicine; in few, if any, of the States of the Union were there legal restrictions, and in some there were no laws whatever relating to medical practitioners. Nor was much to be expected then, as now, from individuals outside of the profession. Liberality, philanthropy, and public spirit had not, and as yet has not, except in rare instances, taken a direction toward medical instruction and the advancement

[1] The annual meetings were suspended from 1860 to 1863, that is, for the years 1861 and 1862. The suspension of the meetings for these two years was owing to the civil war. It is worthy of note that the Medical Society of the State of New York, in February, 1863, adopted unanimously a resolution in favor of resuming regular annual meetings of the Association.

of medical knowledge. A conviction of the necessity for self-reliance, and a deep sense of the importance of the ends set forth in the resolution which I have quoted—these were the main-springs in the movement which resulted in the organization of the American Medical Association. The need for uniting in council members of the profession from all parts of the country, was widely felt. The feeling was catholic, not sectional. The ends had reference not to a single State, but to the United States. When Davis introduced his resolutions, at the meeting of the Medical Society of the State of New York, in 1845, the "fullness of the time had come," and in the providential order of human events, the American Medical Association came into existence. Its development and growth were rapid. It has now passed through a healthful adolescence into a mature age. It has outlived and profited by the errors and imperfections incident to youth. We have before us to-day the proof that it is replete with vitality and vigor.

I have not indulged in these reminiscences of the origin of the Association, with the intention to revive its subsequent history. As furnishing appropriate topics for my discourse on this occasion, I take for my text the preamble to the plan of organization, adopted at the formation of the Association. This preamble is as follows:

"WHEREAS, The medical convention held in the city of New York, in May, 1846, have declared it expedient for the medical profession of the United States to institute a National Medical Association; and inasmuch as an institution so conducted as to give frequent, united and emphatic expression to the news and aims of the medical profession in this country, must at all times have a beneficial influence, and supply more efficient means than have hitherto been available here, for cultivating and advancing medical knowledge; for elevating the standard of medical education; for promoting the usefulness, honor and interests of the medical profession; for enlightening and directing public opinion in regard to the duties, responsibilities and requirements of medical men; for exciting and encouraging emulation and concert of action in the profession, and for facilitating and fostering friendly intercourse between those who are engaged in it; therefore, *be it resolved*, in behalf of the medical profession of the United States, that the members of the medical convention held in Philadelphia in May, 1847, and all others who, in pursuance of the objects above mentioned, are to unite with, or succeed them, constitute a National Medical Association."

The objects of the Association are here clearly and tersely set forth. My remarks will have reference to those objects. The topics which, in connection therewith, suggest themselves, are so many and large, that, with a due regard to the length of my discourse, not a few must be omitted, and none can be fully considered.

The terms "cultivating and advancing medical knowledge," by which the first object is expressed in the preamble, imply that medicine is progressive. No one of those whom I address will deny the assertion that medicine is now progressing as it has progressed in the past, and that it will continue to progress in the future. I do not doubt that the present stage of its progress will hereafter be cited as an important epoch in its history. For the past quarter of a century, histological and clinical studies have tended to develop more and more our knowledge of the existence of specific agents in the causation of diseases. That, as regards certain diseases, these specific agents are micro-organisms, has been demonstrated. The latest discovery in this direction is that of the bacillus tuberculosis, a discovery which is the leading topic in medical literature at the present time. Recent trustworthy researches go far toward demonstrating the existence of specific organisms in pneumonia, typhoid fever, malarial fever, and epidemic cholera; and, reasoning by analogy, it is a logical conclusion that ere long a host of diseases will be proven to be parasitic. It is easy to perceive how important must be the bearings of these developments in ætiology and pathology on prophylaxis and therapeutics. A new era is about to be inaugurated in these practical departments of medicine. Professor Huxley, in his address at the International Medical Congress in 1881, uttered a prediction in these words: "It will become possible to introduce into the economy a molecular mechanism, which, like a very cunningly contrived torpedo, will find its way to some particular group of living element, and cause an explosion among them, leaving the rest untouched." I would rather say that the time will come when means will be found to destroy morbific agents outside of the body, thereby securing the prevention of diseases; and that means will be found to effect the destruction of these agents within the body, thereby arresting the course of diseases. Let us hope that the medical profession in this country will take an honorable part in the labors for the cultivation and advancement of medical knowledge with reference to these most desirable results! At all events, let us continue to recognize and apply medical knowledge, wherever it may originate!

"For elevating the standard of medical education;" these terms express the second of the objects enumerated in the preamble. At the first convention, held in 1846, a committee was appointed to report on "a uniform and elevated standard of requirements for the degree of M.D., to be adopted by all the medical schools in the United States." Another committee, at the same convention, was appointed to report on the "standard of acquirements which should be expected of young men before being received as students of medicine." These committees, at the second convention, in 1847, submitted reports which were adopted. Now, it has been charged upon the Association that its recommendations in regard to medical education have been nugatory. If, however, the recommendations embraced in these reports be referred to, it will be seen that there is less room for reproach than some may have supposed.

The committee on the requirements for the degree of M.D. reported in substance as follows: That the college terms be extended from four to six months; that candidates for the degree of M.D. shall have

attended two full courses of lectures before graduation; that three years should be devoted to the study of medicine; that a certificate of pupilage by a preceptor who is avowedly and notoriously an irregular practitioner should not be accepted; that the number of professors in medical schools be increased to seven; that candidates shall have devoted three months to dissections; that preceptors should avail themselves of every opportunity to impart clinical instruction to their pupils.

It would be absurd for the Association to renew these recommendations at the present time. The progressive advancement in medical instruction in most of our colleges has long since gone far beyond them. It is not to be doubted that the Association exerted not an inconsiderable influence in the progress which has been made in medical instruction. That there is room for further advancement, no one will deny, and it is certain that it will continue in the future as in the past, albeit not, perhaps, with a celerity to satisfy those who seem to derive gratification from the disparagement of medical education in this country. Improvements which, although steadily progressing, are to be promoted, relate to a closer union of didactic with clinical teaching, and especially to practical exercises in the investigation of cases of disease; to increased demonstrative instruction in special branches of medicine, such as histology, the microscopical and chemical examinations of morbid products, together with the fluids of the body in health as well as in disease; the physical exploration of the lungs, heart, and other organs, etc.; to a larger allowance of time, in connection with oral teaching for recitations; to the substitution of recitations, to a greater or less extent, for didactic lectures in certain departments; and to an extension of the period of medical pupilage.

The educational advantages, exclusive of those relating to college sessions, although vastly better now than heretofore, may be much extended and made more available than at present. The pupils who, between college sessions, study in the offices of medical practitioners in the country, reading such books as they find in the meager and perhaps antiquated libraries of their preceptors, accompanying the latter in their "rides," preparing medicines and making themselves generally useful, may undoubtedly pick up many facts and ideas which will become useful in after life; but it hardly requires argument to show that systematic private instruction is much to be preferred. Moreover, methodical reading and recitations are essential, not only for the information thereby obtained, but in order that the pupil may acquire, if it have not been already acquired, what may be called the art of study. There are those who, having obtained their medical education chiefly from oral teaching and demonstrations, cannot apply the mind to study by means of books, although not indifferent to the knowledge to be thus obtained, for the simple reason that they lack the ability to be acquired only by practical training.

At the present time, the most important of the means for elevating the standard of medical education, relate to the preliminary requisites for the study of medicine. The committee appointed in 1846 to report on this subject, recommended that members of the medical profession throughout the United States should satisfy themselves, before receiving young men as students, that they have acquired "a good education, a knowledge of natural philosophy and the elementary mathematical sciences, including geometry and algebra, and such an acquaintance at least, with the Latin and Greek languages, as will enable them to appreciate the technical language of medicine, and read and write prescriptions." It was also recommended that the medical colleges require a certificate of such an amount of preliminary acquirements before matriculation.

These requisites are, assuredly, neither in number nor degree, unreasonable. The need of any knowledge of the dead languages has been doubted; but when it is considered that the names of all the organs and tissues in the body, and the nomenclature of diseases, together with terms used in physiology, chemistry, materia medica, pharmacy, surgery and obstetrics, are of either Greek or Latin derivation, it is difficult to understand how the student can dispense altogether with this knowledge. The want of it must, to say the least, be a great drawback. A thorough acquaintance with these languages, philologically, or with reference to an appreciation of the literature of Greece and Rome, however elegant as an accomplishment, is by no means essential as preparatory for the study of medicine, and it may fairly be questioned whether the time usually spent in the study of the Greek and Latin authors by those who graduate in arts at our colleges, might not be given with much more profit to physics, chemistry, and the French and German languages. To the requisites recommended by the Association might be added, with advantage, knowledge of the elements of chemistry, leaving only the practical applications of this science in the different departments of medicine to be taught in our medical schools.

It must be confessed that the progress in the matter of the preliminary education of medical students, is less satisfactory than that in medical instruction. Not a few medical students are deficient in the knowledge and the mental training requisite as preparatory for the study of medicine. The fault, exclusive of the students themselves, lies in part with the medical schools, and partly with private preceptors; more with the latter than the former, inasmuch as to them, generally, applications are first made to enter upon the study. I have no wish to be an apologizer for either; there is blame on both sides, and there should be mutual coöperation in an effort to remove the greatest of the present obstacles in the way of elevating the standard of medical education.

The practical question is, what can the Association do to promote more and more the elevation of the standard of medical education? I will meet this question, in the first place, by suggesting what it is desirable should not be done.

It is not judicious to decry medical education in this country as unworthy of any commendation, and as contemptible when contrasted with the educational advantages of other countries. The low estimate in

which medical education in America appears to be held by some of our writers, is not only discouraging, but it is without any warrant from facts. Our methods of teaching have certain notable advantages above those of other countries; and in respect of effectiveness in practical branches, we have no occasion to be ashamed if comparisons be fairly made.

It is alike impolitic and unjust to depreciate, as is sometimes done in offensive terms, the medical profession of the United States. As a body, the members of our profession in this country are neither ignorant nor in any respect unworthy. The profession is honorable and honored. In no other country is the social status of its members higher. If a distinction be not always drawn, in public estimation, between true merit and either pretentious ignorance or fraudulent assumption, this is an evil by no means confined to our country; it is incident to the peculiar character of medical knowledge and to human credulity. Granting the need of a better average of professional acquirements, it is not to be effected by abuse of the profession as a whole.

Sweeping charges against medical schools of venality and deception, are not less unwise than unbecoming. As regards their maintenance, the condition of the medical schools in this country, when compared with those of other countries, is anomalous. For the most part they are unendowed, and therefore must be self-sustaining. If they cannot offer adequate inducements for patronage, they cannot exist. This condition has its advantages, but also its drawbacks. There is but little ground for the accusation of resorting to dishonorable methods to secure patronage. I may venture to assume some degree of competency to speak with confidence in regard to this matter, it having fallen to my lot to have been connected with several medical colleges, and I aver my belief that the endeavor to entice students by an expectation of easy graduation, or by any other disreputable inducements, must be rare exceptions to the rule. Granting that there are exceptions, and that some colleges may be guilty of flagrant abuses of their chartered rights, is it not more just, and in all respects better, to pursue measures for the extinction of their rights, as for rendering their degrees nugatory, than to make the evil doings of a few the ground for indiscriminate abuse, embracing colleges which are striving to do their duty to their pupils, to the medical profession and to the public?

It is injurious and an injustice to assert, as is often done, that a large proportion of those pursuing the study of medicine in this country, are governed by a desire to gain admission to the profession as quickly, as cheaply, and with as little medical knowledge as will suffice for that object. Here it may not be too presuming in me to speak with some authority, having, as a teacher for forty years, been brought into relations with many thousand medical students from the Northern, Southern, Eastern and Western States of the Union. As a class, they will compare favorably with those preparing for the sister profession or for any of the callings of life. A large proportion evince a degree of diligence and perseverance not excelled, as I believe, in any other country. I rejoice in the present opportunity to bear this testimony, based on personal knowledge, in behalf of the much and undeservedly abused American medical student.

Elevation of the standard of medical education is not to be promoted by means such as have just been adverted to. Vituperation does not supply motives for improvement. Reforms are not favored by obloquy. He who is content to do battle with the sword of ridicule, has not the spirit of a true reformer. I have no disposition to deny or to take the attitude of an apologist for defects and abuses which affect, directly or indirectly, the standard of medical education. Some of the evils most complained of might be obviated by the united action of the members of the medical profession. Much is said respecting the overcrowding of the profession by the large number of annual graduates, and this evil is attributed to the number of medical colleges. Assuming for the nonce, the fact, together with the explanation, and that the evils overbalance the advantages of an active competition among the colleges, how is the number of these to be reduced? Reliance on State legislators are likely to take away charters which have been granted, and they will probably continue to be complaisant enough to grant new charters to persistent applicants. But suppose all private preceptors were to induce their pupils not to connect themselves with colleges which are either misplaced or deficient in the means of instruction; a certain number would cease to exist, and the result would exemplify the Darwinian doctrine of the "survival of the fittest."

Again, suppose private preceptors throughout the United States were to unite in declining to either receive as pupils, or to advise entering on the study of medicine, all who lack the proper requirements, the evil of the deficiency in preliminary education would be at once removed.

I revert to the question, "What can our Association do to promote more and more the elevation of the standard of medical education?" It is to be borne in mind that, exclusive of the motives for personal improvement which appeal to its members individually, the profession must rely upon itself for whatever is to be done. The American Medical Association represents the profession of the whole country. Hitherto the Association has been content with reports, addresses, and communications pointing out existing defects in medical education, and recommending changes and improvements, the immediate adoption of some of which was impracticable. Too often a predominant spirit of animadversion has been apparent. Let a course be pursued which is more active and practical, with reference to measures for progress. Let certain measures be proposed for immediate adoption, which are within the limits of practicability. Let these measures receive the sanction and support of local Associations in the different States of the Union. Let the National Association take the initial steps and solicit conferences with, and the coöperation of, State Associations and the leading medical colleges throughout the country, with a view to agreement respecting the proposed definite measures. Let these steps be taken in a kindly spirit, with an earnest desire to harmonize different views and

interests, in order that there may be united action as regards improvements agreed upon. In this way, as we may hope, uniformity in the different States will be secured in behalf of the second of the objects for which our Association was instituted. There can be but little difference of opinion as to improvements in medical education which it is desirable should be effected; the opposing difficulties are chiefly those which interfere with uniformity throughout the United States. I venture to suggest the appointment of a standing committee on medical education, with a view especially, by means of communications with State Associations and colleges, to secure uniform action with reference to requirements for matriculation and for graduation. My purpose in the suggestion of such a committee, is not to obtain reiterated resolutions setting forth what ought to be done, but reports, at the next meeting and at subsequent meetings of the Association, of what has been actually accomplished. It is not to be expected that all desirable improvements will be at once effected. Considering the greater relative importance of preliminary requisites for the study of medicine, were these made the first objective point in the action of the committee with a satisfactory result, a very important advance would be made, and this would be likely to prove an earnest of success in effecting other improvements.

A plan for the elevation of the standard of medical education, which has been recommended by the Association, consists in making the degree of M.D. purely an honorary distinction, not rendering the graduate thereby legally qualified to practice, this qualification to be derived from a licensing board composed of examiners not engaged in medical teaching. Of this plan I forego discussion, for the reason that it would exclude the consideration of topics which seem to me more important. With no disposition to undervalue its recommendations, I will simply remark that, aside from certain intrinsic objectionable features, it is open to objection on the ground of the impracticability of securing uniformity in the different States of the Union, and because it contravenes the principle of self-reliance in matters relating to our profession.

In the language of the preamble, the third object of our Association is "for promoting the usefulness, honor, and interests of the medical profession."

I shall confine my remarks on this object to a topic which is, perhaps, at the present time, the most important as bearing upon it. I refer to medical ethics. I need not undertake to represent to this audience how manifold, delicate, and peculiar are the professional duties and relations of the medical practitioner. There is no other calling in which so much depends on the conscientiousness and uprightness of those who practice it. There is no calling in which the temptations and opportunities for deviations from rectitude are so great. In the enumeration of the attributes of the physician by Hippocrates, with "learning and sagacity" were conjoined "humanity and probity."

In order to practice medicine with proper self-respect, the practitioner must himself honor the profession, and in order that medical services shall be properly respected, the profession must be honored in public estimation. The duties incident to medical practice are often of a nature to render them menial and degrading, were they not required by a humane and honorable calling. Some one has said, with truth, that while medicine is a noble profession, it is the meanest of trades. Imbued with these sentiments, the founders of our Association, at the convention in 1846, resolved—"That it is expedient that the medical profession in the United States should be governed by the same code of medical ethics, and that a committee of seven be appointed to report a code for that purpose." A committee appointed in accordance with this resolution reported a Code of Ethics at the convention held in Philadelphia in 1847. This Code was adopted by the American Medical Association without a dissenting voice. It has remained essentially intact up to the present time, and it has been adopted by medical societies throughout the United States.

It were gratuitous to expatiate on the excellence of this Code. It speaks for itself better than any one can speak in its behalf. It has exerted a most salutary influence on the minds of the members of the medical profession in the country. It has promoted love of the profession, and self-respect as members of it, thereby contributing to its usefulness, its honor, and its true interests. I believe that a former President of this Association, Dr. N. S. Davis, uttered a correct statement in saying that in no other country are the principles and rules of medical ethics better observed than by the majority of the members of the profession in the United States,[1] and it is a reasonable conclusion that this is owing in a great measure to the influence of the national Code on the minds of the practitioners of medicine in our country. I concur with the speaker who addressed the Association from this chair, in 1882, Dr. Hooper, in the opinion that the American Medical Association, had it done nothing else than to adopt the Code of Ethics, would have been entitled to unending gratitude. I cannot forbear quoting some extracts from the address of a distinguished predecessor, the late Professor George B. Wood, in 1856: "A great benefit conferred on the profession by the Association was the preparation and adoption of the Code of Ethics." * * * * "I have no doubt that a full observance of its rules would tend more than any one thing else to maintain harmony in the profession and to elevate it in the public esteem." * * * * "I do honestly believe that to a young physician going forth into a life full of moral conflicts, the wearing of this ægis would be one of his surest defences; that next to the holy Scriptures and the grace of God, it would serve most effectually to guard him from evil."

It is only within a recent period that there have been anywhere manifestations of a disposition to change materially our National Code of Ethics, or to do away with any code. In 1882, at the annual meeting of the New York Medical Society, by a vote of 52 of 70 members in attendance at the meeting, a new code was summarily substituted for the Code

[1] Address at the Convention of Medical Editors, 1883.

of the American Medical Association. This precipitate and lamentable action has severed the New York State Society from its affiliation with our Association, and has resulted in a division of the members of the profession in the State of New York. That these results may not be permanent, must be the fervent wish of all who have at heart the usefulness, honor and interests of the medical profession.

Some of the recent opponents of our National Code object to it as antiquated, quaint, and containing useless platitudes. These objections do not call for serious refutation. They involve merely a question of taste, and the characteristics which by some are considered as blemishes, have for others a peculiar charm. Admitting that certain of the precepts of the Code are supererogatory, no one can object to them on the ground that they do harm, and if they be acceptable even to a few, wherefore should they be opposed by any?

Other objections are that the Code has, to a greater or less extent, proved inoperative, and that its rules are not enforced by means of penalties for the non-observance of them. The Code itself contains nothing in regard to penalties, nor do the By-laws of the Association take cognizance of these except to exclude from representation local societies which have not adopted the Code, "or which have intentionally violated or disregarded any of its articles or clauses." With this exception, the enforcement of ethical rules is left entirely to local societies. The fault, if fault there be, lies at the door of the latter. But, granting the fault to be ever so great and widely extended, is this a valid reason for formally repudiating obligations which are morally binding? Are the principles of morality pertaining to any of the duties of life to be ignored because immorality prevails? Are penal laws to be erased from the statutes because punishment often does not follow crime? Although few, if any, live up to the scriptural injunction to "do unto others as you would that they should do unto you," is this quintessence of religious duty to be expunged from Holy Writ? It is the salutary influence on the minds of members of the profession, in which consists the greatest potency of the ethical code for good; and I will go so far as to say that the Code were invaluable, were no penalties incurred by violations of it beyond those pertaining to the conscience of offenders.

The portion of the Code which is especially objected to, is that relating to consultations with irregular practitioners. The advocates of the "new code," so-called, in the State of New York, would permit consultations with all legally qualified practitioners of medicine. The advocates of "no code" would leave it entirely to individual judgment to decide with whom members of the medical profession should meet in consultation. After quoting the portion of the Code relating to this topic, I will ask your consideration of the views which I shall offer. The following is the article of the Code referred to: "A regular medical education furnishes the only presumptive evidence of professional abilities and acquirements, and ought to be the only acknowledged right of an individual to the exercise and honors of his profession. Nevertheless, as in consultations the good of the patient is the sole object in view, and this is often dependent on personal confidence, no intelligent regular practitioner who has a license to practice from some medical board of known and acknowledged respectability recognized by this Association, and who is in good moral and professional standing in the place in which he resides, should be fastidiously excluded from fellowship, or his aid refused in consultation, when it is requested by the patient. But no one can be considered as a regular practitioner or a fit associate in consultation, whose practice is based on an exclusive dogma, to the rejection of the accumulated experience of the profession, and of the aids actually furnished by anatomy, physiology, pathology, and organic chemistry."

The excluding clause, which is the last sentence, specifies who is not to be considered as a regular practitioner. No one, surely, will deny that a practitioner such as is specified in that clause, cannot be considered as a regular practitioner. The article does not assume to embrace a comprehensive definition of irregular practitioners. At the time when the Code of Ethics was adopted, the great majority of irregular practitioners were men who not only based their practice on an exclusive dogma, but made no concealment of their rejection of the "aids actually furnished by anatomy, physiology, pathology and animal chemistry." They made no pretension to knowledge of these branches of medicine, and they scornfully repudiated the "accumulated experience of the profession." The language of the article, which applied well enough to most of the irregular practitioners at that time, is not as applicable to those of a later date. It is not affirmed in the wording of the Code that holding an exclusive dogma is in itself sufficient for a practitioner to be considered as irregular. The language which refers to an exclusive dogma is to be taken in connection with the remainder of the same sentence. Exclusive dogmas have prevailed, to a greater or less extent, in past time, among members of the regular medical profession. Legitimate medicine places no restrictions on individual opinions; it does not assume to interfere with the utmost freedom in this regard. What is it, then, irrespective of a "rejection of the accumulated experience of the profession, and the aids actually furnished by anatomy, physiology, pathology and organic chemistry," which stamps irregular practitioners? Is it not the assumption of a distinctive name, such as homœopathic, eclectic, botanic, etc., voluntarily assumed as an announcement to the public of the adoption of a system of medicine distinct from, and opposed to, the practice of the regular profession, and on this distinction and opposition basing their claims as practitioners?

In order to make my meaning clear, let me illustrate it by examples. Within the recollection of those who have been in the profession for more than half a century, there prevailed simultaneously, for a time, two dogmas quite opposite in character, each having its ardent partisans. I refer to Broussaism and Brunonianism. Broussais and Brown were men of genius and learning, led astray by specious theo-

ries. They were honest in their opinions, and they sought to convince members of the profession, not the public, of the truth of their dogmas. Their partisans were often called Broussaists and Brunoiners; but they never assumed these names as sectarian designations. Now, had they assumed these names, making themselves known to the public as practicing Broussaism or Brunonianism, and on this ground basing their claims for practice, they would have been irregular practitioners not entitled to professional fellowship. As it was, they were not without the pale of the regular profession.

As a hypothetical example, *per contra*, suppose a graduate from a medical college of acknowledged respectability, whose professional attainments are sufficient to qualify him for membership of the regular profession, has adopted a sectarian name and allied himself with those who profess antagonism to legitimate medicine. He is, therefore, an irregular practitioner, whatever may be the particular tenet which is ostensibly the basis of his practice.

Let it be supposed that such a practitioner is desirous of being enrolled in the ranks of the regular profession. I need not say that this profession has no creed, no articles of faith, no traditional doctrines, which it imposes as conditions for membership. It enjoins no limitations of private opinion, it matters not how fantastic. In order that such an irregular practitioner as has been represented may enter the regular profession, no relinquishment of honest convictions is essential. In addition to educational and moral qualifications, the renouncement of a sectarian designation and of the hostility to the profession thereby involved, and conformity to the rules of medical ethics, are alone necessary. It is a calumny to say that persons are excluded from the medical profession on account of peculiar views, however irrational, and that conversion and recantation are essential for professional fellowship. The doors are closed to no one who has received a regular medical education, and whose conduct is governed by the rules of medical ethics.

It might prove a hazardous experiment to tamper with a Code of Ethics so complete and perfect as our national Code, and which has stood so well the test of time. Daniel Webster was accustomed to stigmatize efforts to amend the Constitution of the United States, or "attempts to tinker the Constitution." This pithy saying might be applied to propositions for altering our ethical Code. But it is safe and reasonable for interpretations of the Code to be authorized from time to time, in adaptation to circumstances as they arise; and I submit, as a recommendation, that the Association adopt resolutions embodying a more precise specification than the Code furnishes, of the grounds for refusing fellowship with irregular practitioners. This recommendation is in accordance with precedents. At the annual meeting in 1869, the Association adopted a resolution which recognized "specialties as proper and legitimate fields of practice." Herein was an authorized interpretation of the Code in adaptation to new circumstances. It was also resolved not to be "proper for specialists publicly to advertise themselves as such, or to assume a title not specially granted by a regularly chartered college." If there be the least room for uncertainty, let it be specified distinctly that the adoption of a sectarian title is not merely a violation of medical ethics, but a voluntary disconnection from the regular medical profession, and that professional fellowship is thereby not only inconsistent with self-respect, but prejudicial to the usefulness, the honor and the true interests of the profession.

I believe I do not err in saying that those objections made to the Code of Ethics which call for serious consideration, betoken either an inadequate appreciation or an erroneous construction of the Code, and therefore such objections can be removed by authorized interpretations, which being simply explanatory, without involving essential changes in the Code, are not subject to the provisions for amendments of articles embraced in the Constitution and By-laws of the Association.

I must pass cursorily over the remaining objects for which, as enumerated in the preamble to the plan of organization, our Association was instituted. The means for "enlightening and directing public opinion in regard to the duties, responsibilities and requirements of medical men; for exciting and encouraging emulation and concert of action in the profession, and for facilitating and fostering friendly intercourse between those engaged in it," furnish many topics which, if time permitted, would claim consideration.

Every member of our profession is often made painfully aware, not only of apathy but misapprehension, in the public mind, as regards our duties, responsibilities and requirements. The popular diffusion of our Code of Ethics, allowing it to speak for itself, would go far toward the removal of many errors in regard to our profession. A valuable service, not less to the public than to the profession, might be rendered by proper efforts in this direction. In this way the public may perhaps be led to understand and appreciate the rules of etiquette for which we are often held up to ridicule; our opposition to secret nostrums, and patented discoveries and improvements, and our refusal of fellowship with irregular practitioners. Recurring to the last named topic, many suppose that fellowship with those who are not of the regular profession is refused either from a false sense of dignity or from prejudice, regardless of the dictates of humanity. Now, the ethical code neither in letter nor spirit inculcates nothing in conflict with the humane exercise of our calling. This is a superfluous assertion to those familiar with the teachings of the Code. The principle of humanity underlies all its practical precepts. Quoting words which have been already quoted, "The good of the patient is the sole object in view." There are circumstances under which the higher law of philanthropy, placing in abeyance those rules of the ethical code, as well as of etiquette, which under other circumstances claim obedience, not only permits but commands members of the regular profession to bestow their professional services without stopping to ask whether a practitioner with whom chance has brought

them into association be, or be not, a "fit associate in consultation." Under such circumstances, association with an irregular practitioner, governed by a supreme regard for humanity, involves neither fellowship nor professional application, and it is to these alone that ethical restrictions apply. Let it not be conceded for an instant that there can be any antagonism between humanity and medical ethics. Nor is it difficult in particular instances to decide, practically, in what way the dictates of humanity are to be harmonized with ethical rules. Regarded in the light derived from both these sources, the path of duty is sufficiently plain. Any act honestly performed purely for a humane purpose, cannot but be consistent with the principle which underlies our admirable Code of Ethics. But it is to be added, professional association with those who, in the language of the Code, are not "fit associates in consultations" except in emergencies when philanthropy, for the time being, abolishes all restrictions, contravenes the humane objects of our profession just so far as the useful applications of legitimate medicine are thereby trammelled or curtailed. If it be inhuman under certain circumstances to decline association with irregular practitioners, it would be equally or more so, under other circumstances, to make those concessions which professional fellowship requires to practitioners who profess hostility to medical science and to the regular medical profession. The refusal of fellowship and affiliation with irregular practitioners, thus, is sanctioned, not only by a sentiment of self-respect, and respect for our profession, but by a proper regard for the dictates of humanity.

The work in the several Sections of our Association is of importance, aside from its intrinsic value as a means for "exciting and encouraging emulation and concert of action in the profession." Now that whatever is here done is speedily laid before the profession through the medium of the weekly journal, it is to be hoped that there will be a larger attendance and greater activity at the meetings of the Sections than hitherto. It is here that efforts are to be made for the advancement and diffusion of medical knowledge. On the results thereof must be based the estimation in our own country of the usefulness of the Association, and its rank as compared with sister associations in other countries. In short, we shall contribute to the true success of the Association, as we increase by our attendance and coöperation the value of the sectional work.

Our Association, both by precept and example, has aimed to facilitate and foster friendly intercourse between those engaged in the practice of medicine. The opportunities for the renewal of old and the formation of new friendships, and for social enjoyment are, in themselves, sufficient to render the meetings of the Association of great value. Let us continue to cherish this last one of the several objects for which our Association was instituted, so that, in this point of view, to the enjoyment of its meetings, may be added the pleasures of anticipation and of retrospection.

Our efforts to facilitate and foster friendly intercourse between members of the medical profession, as well as to promote the development and diffusion of medical knowledge, should not be limited to our own country. As the means of union for these objects of the medical profession of all countries, the meetings of the International Medical Congress claim a warm interest. The meeting of the Congress in London, in 1881, will ever be memorable in the retrospections of its members, and they who expect to attend the meeting at Copenhagen in August next, may anticipate much enjoyment as well as improvement. It would prove, as I doubt not, a source of great gratification to the profession of our country if the meeting of the Congress in 1887 were to be held in the United States, and I suggest the propriety of action to be taken now with reference to this desirable end. Inasmuch as an invitation should be in behalf of the profession of the whole country, and not of any particular section, it appropriately should come from the American Medical Association. If the suggestion be favorably received, it seems to me advisable that a committee be appointed with instructions to convey an invitation from this Association through its delegates to the Congress at Copenhagen. The committee may also be empowered to designate the time and place of the meeting of the Congress in 1887, and to take such other preliminary steps as may appear to the committee to be requisite.

My suggestion in regard to the International Congress is not made solely on my own responsibility, but at the instance of several well-known for their active interest in the welfare of the American medical profession. By one of the most eminent of these, I was requested, quite recently, to make the suggestion, in a letter written with a hand tremulous from the serious illness which has deprived the Association of his presence at this meeting; one whose absence is a disappointment to many who were desirous to behold once more the genial, benignant countenance which has hitherto greeted us at our annual meetings; one whose writings have made American surgery illustrious, who is revered by the many thousand practitioners who have listened to his instructions, and who is honored, not only in our own country, but in other countries, as no member of the medical profession in America was ever before honored; one admired by all who have known him, and beloved by those who have enjoyed the privilege of his friendship. I know that I speak the heartfelt sentiment of every one who hears me, and of our brethren throughout the whole country, when I address a fervent wish that Prof. Samuel D. Gross might be spared yet many years to his family, his friends, and the profession which he adorns.

Brethren of the American Medical Association:

I congratulate you on your presence at this annual meeting. It is peculiarly gratifying to meet together in this city, the Capitol of our Government, in which there is so much of interest to us as American citizens. There is also much that is attractive in a professional view. We have the opportunity of forming and renewing acquaintance with the eminent members of our profession residing in this city and vicinity. Here is the Army Medical Museum, the

largest and most complete collection in existence of the results of gunshot injuries and of the diseases of armies. It is rich in illustrations of craniology and comparative osteology; and its specimens cover the whole field of medicine and surgery. Here is also the National Medical Library, the largest exclusively medical library in the world, and, as a practical working library, the most valuable, owing to its immense collection of periodical literature, and the manner in which it has been indexed and catalogued. All praise and honor to the medical officers connected with the office of the Surgeon-General, to whom our profession and the country are indebted for the labor and skill that have made our National Medical Library and the Army Museum institutions of which we may justly be proud! Let us hope that Congress will not much longer delay in providing a commodious fire-proof building for the reception of the valuable collections which it would be impossible to replace, and which are of the greatest importance to the progress of medical science and education in this country.

The Naval Museum of Hygiene, although of recent growth, will be found to possess an interesting collection illustrating sanitary science, together with a good library. The National Museum and the Museum of the Department of Agriculture contain also much that is of interest to members of our profession.

To my congratulations are to be added my thanks for the great honor conferred on me by my election to the Presidency of the Association. My grateful appreciation of the honor is enhanced by the fact that I did not seek nor desire the office. I should have been glad had the selection fallen on one better prepared to perform the duties of a presiding officer. I can only say that, relying on your indulgence and forbearance, I shall discharge these duties to the best of my ability.

May this thirty-fifth annual meeting of the Association be characterized by harmony and good feeling! With the blessing of Providence, may its proceedings strengthen the attachment of the American medical profession to the Association, extend the boundaries of our knowledge, and promote the welfare of mankind!

ADDRESS ON PRACTICAL MEDICINE.

BY JOHN V. SHOEMAKER, M.D., CHAIRMAN OF THE SECTION ON PRACTICAL MEDICINE AND MATERIA MEDICA, MAY, 1884.

Gentlemen of the American Medical Association:

A year ago you conferred upon me the honorable position of Chairman of the Section of the Practice of Medicine, Materia Medica, and Physiology of your Society. As Chairman, it is made imperative upon me, by our By-laws, to lay before you a *résumé* of the progress made and the new discoveries announced in these branches of our science during the past year. The responsibility of this duty, in view of the numerous investigations and important discoveries by the members of the medical profession throughout the civilized world, and the steadily increasing volume of medical literature, etc., renders the task more and more difficult with each succeeding year; for as new theories arise and supplant older ones, they, in turn, will be superseded by others yet unheralded. The unbiased gleaning of what has been done is a feat of no mean proportion, and if I should not do full justice in my criticism of any particular one, or in the mention of others, I beg your indulgence in advance.

Medicine, at the present time, has a tendency to elevate itself beyond the narrow sphere occupied by it years ago. Empiricism is no longer recognized. The ultimate investigation of the cause of disease, and the remedial measures suited to it, seem the absorbing object. While our present scientific system of medicine has many followers among the sectarians, sprung from its maternal lap, it still stands proudly alone, brighter and fairer in its record than ever before. The scepticism which has arisen from heresy has had a most salutary and purifying influence on it, and has led us, again and again, to review the course we are pursuing, in order to be assured that there is no deviation from the right direction.

Sceptics hold that with all our efforts, no advance has been made upon the inroads of disease, and that mankind is as much subject to its influence as when medicine blindly groped its way. This allegation I most certainly deny. No longer are whole continents devastated by disease; no longer are epidemics the terror of nations, nor countries made uninhabitable to the human race; for with an intimate knowledge of disease and its origin, scientific medicine has adapted measures to its stay, its relief, and its extermination. And all this has been done notwithstanding population is steadily increasing, and with it, also, the danger of contamination from disease-breeding germs, multiplying at an unduly increasing ratio; that the desire for social intercourse makes itself manifest by closer congregation in localities illy suited for hygienic protection; and with it the stationary, if not reduced rate of certain classes of complaints, must certainly be regarded as a veritable triumph for medicine, and the necessity for continual effort for its advancement.

The means for making medicine more thoroughly understood and serviceable are, without doubt, the general distribution of its principles and conditions by the wide development of medical literature. A great source of satisfaction is the high standard which it has attained with its wide diffusion, thus enabling the physician everywhere to be in close intellectual communion with his fellow-workers. The time when medical knowledge was kept a family or a trade secret, was less productive of true medical advance than any other period of man's existence. With the universal spread of knowledge alone has medicine risen from empiricism, until to-day it may be called a scientific system indeed. It is a matter of congratulation that this great, and the most prominent,

association of practitioners of medicine of our country has launched a journal, which has taken the place of the time-worn Transactions, in which the valuable investigations of the members of our Association were quietly buried. Not alone has our science been advanced by the improved and increased periodical medical literature, but numerous publications on special subjects and branches have appeared during the past year, which have been largely instrumental in promulgating and advancing new theories.

It is the studious investigator, however, who, with untiring zeal and devotion, has disinterestedly employed his time in the study of health, disease, and its curative measures, that medicine has to thank for its principal advancement during the past year. The student in the laboratory, at the microscope, as well as in the actual field of devastating epidemics, is the benefactor of whom too much cannot be said in praise. While it is not our province to enumerate or name them here, it becomes certainly our duty to mention that noble hero, Dr. Thullier, of Paris, who, with the French Cholera Commission, penetrated into the very pest-houses of Egypt to serve the cause of medicine, and gave up his life there, a victim for our enlightenment. His memory should be a lasting one with physicians all over the world as a substantial monument in connection with many other great heroes in our ranks.

PHYSIOLOGY AND PATHOLOGY.

I can say but little of the progress of physiology during the past year. The field is one of vast expanse, and the observations that have been recently put forth have not, as yet, stood the test of time, so necessary in this branch of our science.

In the field of pathology and pathological research the study of the infinitesimal has attracted great attention. Humeral pathology of old has had its day. Anatomico-pathology now seems fast to lose its hold upon our workers, in view of the discovery of the constant appearance of micro-organisms as concomitants of special types of disease. Grosser lesions appear to have lost their interest and importance in comparison with the invading hosts of parasitic enemies to the organic structures. Though their presence was known for years, as has been demonstrated by older observers, we are riding now on the very crest of the billow of excitement that they are creating in medicine. *Tempora mutantur!* Will it be rash to predict a downfall of the omnipotent rule of these minute Vandals who overawe us with their menaces? That they exist there is no longer any reasonable doubt. They have been demonstrated, classified, propagated, and shown to be constant with certain features of tissue changes. Their causative influence is as yet a matter of grave doubt, and one that in accordance with close observation will probably not be soon cleared up. If all that their enthusiastic discoverers and experimenters claim proves true, medicine will resolve itself into a system of micro-botany, leading to the study of the character and habits of its subjects, and the antagonistic elements to their existence.

Of the subjects prominently brought to the attention of the profession and exciting universal interest, more than any other is that of the bacillus theory of tuberculosis and its contagious character. While the presence of micro-organisms in other diseases is being investigated and studied extensively, there is none which has as great a bearing and caused so much comment as this one. Only a few years ago Koch stood almost alone in its advocacy. Now there are numbers of unbiased observers who confirm his famous discovery. Foremost among these is Watson Cheyne, who visited Koch's laboratory for the express purpose of investigating the subject. His report fully confirms the facts set forth by the great investigator, besides demonstrating the constancy of the occurrence of bacillus in all tubercular structures, as well as the relative position of the parasitic organism to cell-structure. Similar confirmatory evidence has been produced by Pruden, Dreschfeld, West, Gibbs, Heron, Wipham, Meissen, and others, from a clinical view of the constant presence of the bacillus in the sputa of phthisis; while Charnley Smith has even ingeniously demonstrated its presence in the expiratory air of consumptives by filtering it through gun-cotton, dissolving it in ether, and then fixing it on microscopical slides for inspection.

Dr. Austin Flint, Sr., accepts the new theory as well as the ætiological character of this micro-organism when added to predisposition, leaving the subject of contagion dependent upon the causative element combined with the favorable soil for its propagation, ascribing the usual absence of contagion to a lack of predisposition, and considers the presence of the bacillus as one of the most essential elements for the diagnosis of phthisis. Drs. Janeway, Welch, and Peabody, well-known authorities on this subject, concur with Dr. Flint in his views; likewise Dr. H. C. Ernst in his contribution presented to the Massachusetts Medical Society, besides numerous other investigators, both here and abroad.

The presence of the bacillus has been observed in other tubercular lesions than the lungs: as in the mouth and soft palate, by Guttmann and Finger; in the skin by Cornil; in lupus by Demme; in the uterus by Lindsey Stephens; in the urinary tract by Rosenstein, Babés, and Cornil, as well as in rectal abscesses by Smith. Dr. Wilson Fox admits the fallacy of his former experiments, and accepts the theory of the contagious character and inoculability of the virus, and that injury to the rodents is not followed by tuberculosis, as previously expressed by him.

Now, while the adherents to Koch's theory have increased wonderfully, there are those not wanting who are open in their criticism, and opposed to the acceptance of anything like a bacterian origin of tuberculosis or other diseases. Their opposition is not based merely upon assertions or clinical evidence, but the result of years of observation and experiments conducted here, as well as at the very birthplace of the bacillus theory. Amongst those most prominently arrayed against it are Spina, of Vienna, Finkler, and Eichler, who pronounce the staining methods of Koch as fallacious and misleading, while Feltz admits his failure with cultivation by following Koch's method.

Formad, in this country, has made a most vigorous

attack upon it, and has referred the ætiology of tuberculosis to histological changes rather than to parasitic invasion, in which deduction he is supported by many eminent pathologists, such as Longstreth and others. In his denial of the contagiousness of tuberculosis he is in accord with the opinions of Virchow, Recklinghausen, Stricker, Gull, Williams, Watson, Paget, Humphrey, Richardson, Bennet, Hiram, Corson, Trail Green, N. S. Davis, H. F. Campbell, and others. Thus, it will be seen that this subject is by no means disposed of yet; and it will undoubtedly form one of the main and interesting points of our discussions at this meeting, in which some of our most prominent pathologists, practitioners and teachers have promised to take part.

The bacillus tuberculosis theory, however, is not the only one that has excited attention. The bacterial origin of other diseases has been earnestly advocated as well. Thus, a micro-organism has been found and studied by Friedländer as a micrococcus of pneumonia, possessing distinct capsules under certain conditions and at certain stages, which he verified by cultivating processes and inhalation of impregnated air, and was enabled in that way, in certain animals, to produce red infiltration of the lungs, and evolved reddish infiltration of the pleura. The capsule was easily seen by means of staining fluids, but does not exist in the cultivated micrococcus, but seems to be reproduced in the experiments upon animals, and appears to be mucin. Though reported before by Giles in the blood of pneumonic patients, where Friedländer failed to see them, they were conclusively demonstrated by cultivation and inoculation to exist. This may serve to explain the occasional epidemic form of pneumonia in certain localities. Buchanan and Russell have described cases of infective pleurisy in which micro-organisms appeared in the effusion. A bacillus of syphilis has been described by Morison, of Baltimore, as occurring in chancres, condylomata, etc., but apparently different from that described by Birch-Hirschfeld; while the micrococcus of gonorrhœa has been cultivated by Burckhart, as well as Sternberg, and successfully inoculated. Again, micro-organisms have been found and claimed as the cause of pertussis, while cases of nephritis and purpura have been attributed to the same cause, and even the vesicles of impetigo contagiosa and herpes labialis, it is asserted, contain them. A micro-organism is said to have been detected in the blood of patients ill with typhus; and Marigliano appears to confirm Klebs and Eberth as to their presence in the blood of the spleen of typhoid-fever patients. The bacillus of leprosy has again been reported by Hausen and Thin, as well as that of scarlet fever by Crooke. The discovery of the bacillus of glanders by Bonchance, Schutz, and Lœffler has been confirmed by successful inoculation. Erysipelas has been demonstrated by Fehleisen to be due to the growth of micrococci in the lymphatics of the skin, and by inoculation and cultivation he successfully introduced that affection both in animals and man. The work of Pasteur and Koch has been directed with success toward the study of the attenuation of virus; and the latter's labors, as head of the German Cholera Commission sent to Egypt and India, have been crowned by the discovery of the specific micro-organism of cholera. The constant presence of the cholera bacillus in the intestines and ejecta, seems to leave no doubt as to the important part they take in that scourge. While Prior has found a micrococcus in the coats of the intestines and stools of dysentery, and numerous organisms have been for years declared to be the cause of cholera, it is due to Koch, for his special skill in this field of research, to accord him the honor of the detection of the special micro-organism, to which may be fairly attributed the pathological changes in these structures.

That the origin of yellow fever should arise from this same cause is readily obvious, when we consider its infectious nature. Though this has been claimed to be the case by Carmona del Valle, and called by him "peronosperma lutea," there seems to be little tangible evidence for it aside from the experiments of Domingos Freire, of Rio de Janeiro, who showed, experimentally, that blood of dead yellow fever patients, inoculated into animals, caused rapid death; and that their blood had, in turn, similar effects. He attributes this to the presence of a cryptococcus, for which he proposes the name of cryptococcus xanthogenicus; and which he also claimed to have found in the earth of infected districts. While these demonstrations prove scarcely anything without proper cultivation and successful inoculation, they point, nevertheless, to a fruitful field for research.

MEDICINE.

Medicine, in a word, comprises everything relating to the healing art; necessarily we will have to give it here a closer meaning in its relation to clinical observation only. The pathological conditions, so nearly allied to it, we have treated of before. The treatment of disease we shall speak of hereafter. Hence, it remains but to call your attention to new phases of disease, of their diagnostic characteristics, and their prognostic chances.

The knowledge of nervous affections, though it has not progressed with the giant strides of other branches of disease, is steadily advancing and emerging from its mysterious enfoldings. The localization of cerebral functions, though now generally accepted, has advanced us practically but little, though the trephine has daringly opened to the neurologist the hidden regions of dura mater and gray matter. Locomotor ataxy has presented in its chronic state three diagnostic points for distinction: that of Duchenne, with the characteristic symptoms depending on the lesions of the columns of Burdach; another depending on diffuse sclerosis of the chord and medulla oblongata, although principally limited to the posterior columns of the former, differing from it by its first occurrence during puberty—sensibility not being affected until late in the disease—and that the uncertain gait and step is not increased by shutting the eyes. A third subdivision is made of the ataxy of the periphery, described by Dejerine as an atrophy of the peripheral sensory nerves.

While the treatment of the insane has so vastly improved, it is to be regretted that our knowledge of

the ætiological factors of psychical disease does not keep pace with it, and from this cause, no doubt, arises the difficulty experienced in the diagnosis of such cases, which give rise now and then to conflicting opinions in law courts, and which are interpreted to the great disadvantage of medical science. The interesting experiments of Brown-Sequard on reflex irritation, and the production by it of profound anæsthesia, bordering on catalepsy, should throw some light on the unravelled secret of hysteria and its allied affections.

The investigations and researches in the bacterial origin of phthisis would of necessity call for a reorganization of its clinical aspects. It has attracted the attention of eminent scientists, both pro and con. The bacterial development from extraneous sources would constitute it as contagious *per se*, and be in accord with the theories of its advocates; while those opposed to it have most ingeniously brought forward arguments, which, if substantiated, would upset our principles of organic law. The origination *de novo* of the bacillus, as claimed by Bouchardt, would depend on metamorphoses, no longer admitted, and certainly not understood nor explained. Guerin, in supporting his doctrine, admits its transmissibility by classifying the tubercular structures as one non-transmissible and another transmissible; although the latter he holds communicable only through putrid infection. After all, these arguments fail to meet the issue, which, in view of the wide spread of this disease, is of paramount importance, in so far as it forms not alone the indication for antiseptic treatment, but the development and propagation of the disease itself.

Typhoid fever has arrested the attention of the profession to some extent, with a view of learning the real danger hidden in it, which is now almost universally conceded to be the accompanying hyperpyrexia, giving rise to the tissue changes. Excretion of nitrogenized material, and non-assimilation of the modification of these under the antipyretic treatment can be accepted as a guide to this conclusion. The treatment by cold baths, of all antipyretics, is now thought to be the most serviceable, if we can trust to the statistics of recent investigators, as well as the thorough researches of Sassetzky in the analyses of the excreta. If, as is stated, the mortality caused by enteric fever in London was ordinarily from 15 to 18 per cent. of the population, and that it has now been reduced by means of the cold water treatment to about 10 per cent., it must certainly be regarded as a great improvement.

Of renal diseases, albuminuria has long been the subject of scientific inquiry, being considered more and more of nerve origin. Its close relation to diabetes, with mutual interchange in certain affections, has brought forward the proposition that both albuminuria and glycosuria may be produced by irritation of certain parts of the floor of the fourth ventricle. And the proposition is well established.

The hypertrophy of the muscular coat of the arterioles, and the increased tension of the vascular system, are also claimed to be due to irritation of the vaso-motor centers of the medulla. The latter especially has proved valuable in modifying the treatment of albuminuria. The neural influences seem primarily, and the renal disorganization from distension of the glomerular vessels progressive steps therefrom. That the toxic influence of certain substances, as well as severe febrile affections, is productive of albuminuria is well known, and a recent instance has been cited where it occurred after varicella. Peptonuria has been investigated and found to co-exist with suppuration from various causes, or with large exudations. Jaksch claims that it is due to the reabsorption of inflammatory products rather than to any pathological condition of the kidneys. The examination of urine for the purpose of detecting pathological products has probably further advanced during the past year than ever before. The old and common tests by nitric acid and heat are said to lack delicacy, and do not indicate albumen unless present in large quantities. The acidulated brine test, the tests with picric acid, Tanret's or potassio-mercuric, the sodium tungstate, the potassium ferrocyanide tests, in their solid or liquid form, or spread on paper for convenience sake, have no doubt their advantages, especially in point of delicacy, so that they seem an improvement on the older methods; but this very delicacy will, at times, mislead the practitioner, who, by the presence of peptones, mucin, urates, and medicinal bodies may form a hasty and erroneous diagnosis; besides, albumen might be detected as a normal constituent of the urine, when the older methods properly applied would serve as an indication of pathological change only. A question of greater importance for the medical chemist to solve is rather as to the quantity of albumen present, than to discover its probable incidental existence. The same may well be said of the new tests for sugar, such as diazobenzol-sulphuric acid, citric acid and indigo, only that they do not mislead, but serve well for qualitative tests at the bedside. For quantitative tests there will probably few outrival the older methods, or the easily applied and accurate polariscope.

The subject of myxœdema has received new impetus with our confréres abroad, both through the pathological researches of Henrot and of Kocher, in connection with the extirpation of the thyroid gland in a number of patients who subsequently showed a cretinoid condition, and the confirmation of an atrophied state of this gland in subjects of this disease. If the committee of the London Clinical Society, having this matter in charge, will solve some of the points concerned, it will shed much interesting light on its functions.

The disease known as actinomycosis, and described by Ponfick as peculiar to horses and cattle, has been exhibited by Treves in a man, whom he brought before the London Pathological Society. All stages of the disease, from minute solid growths to large suppurating and sloughing masses, were present.

The grave accusation cast against American pork by some of the European authorities makes it necessary that I should say a few words here upon the subject. Trichinosis is with us a very rare disease indeed, in comparison to its frequent occurrence in

Continental Europe. In spite of the prohibitive edict against our pork in Germany, quite an endemic of trichinosis has prevailed there of late. As there have been isolated cases reported with us, I will therefore refrain from any attempt at defence, but simply remark that the mortality from trichinosis in this country, in comparison with Germany, would lead us most certainly to discriminate in favor of our product to that of the foreign—even if we do not attribute our comparative immunity to the more civilized manner in which we partake of it than the semi-barbarous fashion of eating it uncooked. French physicians, in the Academy of Medicine, of Paris, have already given their opinion that American pork is not as dangerous as the trichiniphobist would have us believe, and recommend that the prohibition to its importation be removed.

The epidemics of small-pox, which for some years have swept over this country, and have visited almost every town and hamlet, have considerably abated, but few cases, comparatively, being reported now. The questions, if the disease has exhausted the material for its propagation, or if the vigorous vaccination insisted upon by the medical profession, has successfully stayed its ravages, are points which are not yet settled. Again the subject of a common origin of vaccinia and variola has been brought forward, and Voigt states that variola is inoculable into cows, and if used for protective inoculation with man it is equivalent, and even preferable, to vaccine, provided that the virus be far enough remote from its first source, else variola, with all its characteristics, may be developed.

In regard to scarlatina much interest has been attached to its prevalence among animals—as the horse, cat and dog. It has been claimed that contagion was carried both from them to man, and *vice versa*. The pinkeye of horses has been stated to be in many cases nothing else than equine scarlatina, readily contagious, while cases are cited every now and then where the source of the disease unmistakably pointed to the domestic feline or canine pet. Of the greatest interest herewith are the experiments of Stickler with the inoculation of the nasal mucus of horses, suffering from scarlatina, into rabbits and dogs, which produced a modified scarlatiniform exanthem, accompanied by fever and some enlargement of the glands. Blood, from a case of confluent scarlatina, afterwards inoculated in those animals, failed to bring any results. Stickler repeated the same experiments on twelve children, but failed to produce scarlatina in any of them by inoculation with scarlatinal blood, and arrived at the conclusion that the subcutaneous injection of scarlatina virus from the horse is not followed by harmful results, but that it produces a circumscribed eruption like mild scarlet fever, and that such inoculation confers an immunity from scarlatina.

The epidemic which excited the most alarm in its disastrous results, and caused the greatest anxiety as to its spread, was the late outbreak of cholera in Egypt. That country is proverbial for its filth, and, as a consequence, its prolific breeding of epidemic diseases. Although cholera has periodically visited both this country and Europe, its terrible fatality has never been felt so severely as in Egypt, which has suffered from its late outbreak there. The lack of proper drainage, and the use of water contaminated with offal and excrementitious material, are well calculated to give impetus to this disease. From the reports of Sir William Hunter and other gentlemen of the European Sanitary Commissions, we learn of the most loose and incomplete hospital arrangements, while the harshness of its quarantine enforcements arises more from individual egotism and fear than the desire to stamp out the germs of the disease, which are hatched by the stifling heat, from the filth and offal exposed everywhere to view, and offending the nostrils at every step.

Yellow fever, as usual, made its appearance in some of the Southern ports, and while it showed a tendency to a malignant character, and indeed produced great ravages in the Pensacola Navy Yard, it is due to wise quarantine laws, and to the unflinching energy of the surgeons in charge of our naval and marine hospitals, that the disease was not represented in a palliative light, and thus allowed to spread beyond its original cordon. Much praise is due to Dr. Guiteras, of the Navy, for his moral courage in facing the issue in its true light, and thus sparing the South the disastrous experiences of former years. The attempts to fight yellow fever by calling it by another name are fraught with disastrous consequences, and should under no consideration be countenanced. That it is both infectious and contagious can no longer be denied, and, if not accompanied by urinary suppression, it is a disease which otherwise shows a fair percentage of recoveries under proper treatment.

THERAPEUTICS.

It may be said of therapeutics, that while in past years they were ignored to a great extent by many physicians and scientists, they have undoubtedly now assumed new features entitling them to a prominent position. Promiscuous dosing and empirical drugging are no longer recognized, but the application of the physiological action of remedial substances to a pathological condition are the therapeutics of the present and the future.

Among the permanent remedies which have found approval during the past year, there is probably none of greater interest than what promises to be one of the most powerful and reliable antipyretics, a rival to, and perhaps surpassing in its effects as a febrifuge, quinine. It is called kairin. Although it has as yet found but little practical application in our own country, the reports concerning it from abroad are such as would make it desirable for us to give it a thorough, practical test. It may not be all its admirers claim for it, but enough has been learned to place it prominently in the class of antipyretics. It was discovered by Dr. O. Fischer, and described chemically as an oxethylquinoline hydrid hydrochloride, a coal-tar derivative. It was investigated by Filhane, Sassetzki, Knipping, Girat and Guttman, with satisfactory results, while Reigel reports adversely as to his success. Notwithstanding the favorable properties it undoubtedly possesses to reduce fever temperature, it should

be exhibited with caution, on account of its cardiac depressant action. Although it promises a remedy of the greatest value, sufficient investigation as to its physiological effect seems to be still wanting.

Another very interesting remedial substance which has been presented to the medical profession as experimented with, is the paraldehyde, a substance isomeric with aldehyde. It is asserted by Dr. Langreuter that it possesses powerful hypnotic properties, with no abnormal phenomena excepting a slight and irregular pulse. The sleep produced by it is readily induced by doses of about six grams (1½ drachms), generally giving a full night's rest, and when sleep is not produced, still a quieting influence is exercised. It is claimed for it, that it produces no cardiac depressant effect, but from its chemical source this seems doubtful. Dr. J. C. Wilson's experiments in this respect corroborate the above views. It is also claimed for it that a lethal dose suspends the functions of the medulla, and the action of the heart ceases after respiration; likewise that it acts upon the cerebral hemispheres, inducing sleepy drowsiness without preliminary excitement. While cardiac depression from it has been observed, it is said that neither nausea, depression, headache, constipation, nor other unpleasant after effects are produced by its use. It has a controlling action over some branches of the fifth pair of nerves, and seems to correspond in this effect to one of its derivatives—butychloralhydrate, or the so-called croton-chloralhydrate. While no doubt a useful hypnotic, it seems scarcely destined to supplant chloral for that purpose. Its close identity with the latter, however, therapeutically, is its antagonism to strychnine, and *vice versa*, for which property it has been studied and observed by Professor Cervella, who demonstrated that the seat of the opposing action is the spinal cord, the reflex irritability of the medulla oblongata being increased by strychnine and decreased by paraldehyde.

By far the most useful, as well as the most interesting effect produced by any new therapeutic agent given to us during the past year, is the *Abrus precatorius*, the jequirity bean of Brazil. The remarkable virtues of this drug have not alone been due to the curative effect it has exerted when applied as a remedy for pannus and other eye affections, and for which it has been reported as being a most extraordinary curative agent, but principally to the fact that in it we have pressed into our service the ubiquitous microbe, which is receiving at the present time so much attention. Sattler has proved beyond a doubt, that the watery infusion of the substance is a culture fluid, a nutrient field for certain atmospheric germs, which derive therefrom their pullulation, confirming the theory of Pasteur of the agency of ærial microorganisms in bringing about fermentation and morbid changes. That this is not mere speculation was again confirmed by the experiments of Cornil and Berlioz, who produced, by hypodermic injections of the infusion of jequirity, inflammation with suppuration and gangrene of the skin in rabbits, frogs, etc. Those animals which survived were not affected by a second operation, which has led some to the conclusion that the first had acted similar to a vaccination. In animals to which the infusion was given in only a fourth of a drop, injected into the pleural or peritoneal cavity, it caused inflammations, and the microbes were found throughout their circulation in immense quantities. A drop of their blood injected in turn in a frog set up septic infection, and caused the presence of numerous microbes, but if the bean were given as food no infection occurred.

A matter of interest in therapeutics of the past year was the investigations of DaCosta in regard to the salts of nickel, and especially its bromide. While the other salts proved of little, if any value, this bromide was found to possess the properties of the bromides generally, but in much smaller doses. It is claimed that it lowers the temperature, does not influence the pulse, nor affect the excretions; that it is a nerve sedative, without exercising a weakening or depressing influence, and of especial value in epilepsy.

The bismuth salicylate is also a new arrival among us, which has been used in the treatment of various forms of diarrhœa and typhoid fever; the latter disease, it is asserted, it will abort under favorable circumstances, but this claim needs further confirmation.

Nitroglycerine has again come to the surface, and new and striking results, as well as a larger sphere for its action has been developed, along with the closer study of its physiological action. The opinion of Robson in regard to its value in acute and chronic Bright's Disease has been confirmed by its action on the vascular apparatus. Its effect in albuminuria has been recently investigated by Bartholow, who states that it reduces the vascular tension more than any other remedy; lessens the work of the heart by removing the inhibition exercised by the pneumogastric nerve; and that by its action he has not alone seen remarkable instances of relief, but even permanent cures. In angina pectoris it seems second only to amyl nitrite; and while it does not arrest the paroxysm as promptly as the former, it possesses a curative action, and can be used to prevent future atacks. For that purpose it is given daily to restore the diminished vascular pressure. The results attained with this agent, and the study of it along with the nitrites as a class, and their effect upon vascular tension, has recently developed remarkable and interesting facts in regard to one of this class, the sodium nitrite. The dose of it had been stated as about twenty grains, given for a long period with impunity. It appears that this applied to an impure article; that the pure sodium nitrite is possessed of powerful and even toxic action, as reported by Ringer and Murrell, and the commencing dose should not exceed two grains. In connection with this subject it is proper to allude to the controversy arising from the publication of the experiments of the gentleman last named.

Dr. Murrell was severely attacked for his wanton experimentation, as it was termed, on hospital and charity patients, not alone by laymen, but also by members of his own profession. Just how these gentlemen expect to derive knowledge without "experimentation," is not obvious. Perhaps they would have preferred to have been the victims of an erro-

neously stated dose than to have the truth developed by scientific research. Dr. Murrell is entitled to the thanks of the profession for his demonstrations and important deductions, rather than virulent abuse; for with a cessation of "experimentation" the progress of medicine must also cease.

Recent investigations in the treatment of albuminuria, by Bartholow, also show the great utility of the chloride of gold and sodium in this disease, both in the subacute and chronic form. He states that "the earlier it is given the better, if structural changes are to be prevented or arrested, and its curative action will necessarily depend on the extent of the damage already inflicted on the kidneys."

It is well to mention, also, that among others, attention has been directed to the following remedies: Hyperosmic acid seems to have attracted notice, both for parenchymatous injections in tumors as well as for obstinate neuralgia. Convallaria majalis and its active principle, convallamarin, after a thorough test is, according to Robson, inferior to digitalis in its action. The digitalis group, though not definitely limited, seems to have been positively defined as contracting the blood-vessels by their effect on the involuntary muscular tissue of these organs. Hypodermic injections of pilocarpine in myxœdema are reported as being very useful. Barium chloride has been studied physiologically, and while its therapeutic value is undetermined, it is proved to possess a powerful action quite different from the calcium chloride, with which it has been classed, and its resemblance in its action to digitalis is confirmed. Croton oil has been found to consist of two therapeutically different principles, one of which represents a safe and useful laxative, while the other is stated to be a vesicant and intestinal irritant. The use of potassium permanganate, hypodermically injected as an antidote for the bite of the cobra and other venomous snakes, has again been brought forward, and though its efficacy has been doubted by some, by others it is asserted that if immediately or shortly after being bitten it is injected into the area of the wound, it will neutralize the poison, while it will not counteract it when reabsorbed and constitutional symptoms have set in. In connection herewith, Sir Joseph Frayer, who has made an extensive research into the nature of snake poison, states in a recent communication before the Medical Society of London: "The result of my experience is that, so far, no physiological antidote to snake virus is known, and that when the full effect on the respiratory center is produced, remedies are of little, if any avail; albeit, when the poison has entered in small quantities, treatment may be of service on general principles."

The vast research in the field for micro-organisms as causative elements of disease and the discoveries made therein, have given a new impetus to antiseptic treatment in every branch and affection. Antiseptic inhalations for pulmonary disease have proved of value, whether the germ theory be sustained or not. Carbolic acid and creosote are serviceable in typhoid fever, and other antiseptic agents are daily employed with equally good success. If their favorable action prove antiparasitic or otherwise, cannot at this time be ascertained, but in view of the results further investigations are indicated. Amongst the new antiseptics, naphthaline and naphthol have been mentioned as of great service; in regard to the latter, I have ascertained that if pure and properly prepared, it seems devoid of the toxic effects claimed for it.

A new feature of the greatest importance, which was first agitated by the British Medical Association, and brought before us at our last meeting, is that of collective investigation of disease. There is no denying the fact, that not alone have our statistics of disease, its ætiology, course, and termination, been very loosely collated and obtained from sources which altogether inadequately represent the condition of our country, as well as the domicils of the majority of its inhabitants, but that we have, as a consequence, no general idea as to the amount, the severity, and issue of disease, even if we take for granted that the reports of the various health officers are tolerably correct in regard to fatal results. The reports already received from our English brethren have demonstrated their value, and prompt us to a similar mode of investigation.

This system of collective investigation is also pursued in Germany, and it will, no doubt, ere long comprise all the countries which have an organized medical profession. The systematic collection of therapeutic results will alone be invaluable by showing statistically the worth of certain medicinal measures and their comparison in effects with others.

And now, in closing, I would remark that I have no new plans or propositions to offer for your consideration. The Section of Medicine continues to grow and attract more attention with each succeeding year. It is necessary for you, however, with this growth and development, to direct the attention of those entering the profession to the necessity of thoroughly mastering the details of all its different branches; above all that of general medicine, before entering into any specialty. There appears, just at this time, and it is for this reason that I refer to the subject, a desire on the part of a few physicians to gather in cliques, and, with shut doors against their fellow-practitioners, settle to their own satisfaction momentous questions in this or that special department which they affect. Such organizations are generally composed of a few medical authors and teachers and some of their friends, who think themselves immeasurably superior to the profession at large, and would create an aristocracy, as it were, in one of the most democratic of sciences and professions. Here lurks the danger to medicine as a science. When in centuries back the knowledge of special branches of medicine was kept a close secret, and transmitted as an heirloom in certain families, or hidden in the parchments of monastic libraries, the general practitioner was excluded from obtaining knowledge from these sources, and thus benefiting mankind generally, but was compelled to grope his way in darkness and trust to his own intellectual force. At that time it was thought impossible for the ordinary physician to handle the obstetrical forceps or cure favus—yet to-day both are a common practice. To that undesirable point shall we drift again if we will admit of this exclusiveness. The ten-

dency of these cliques is to keep intact their sacred circle for the use of themselves and their friends, not to study and teach by their assemblies, but to force the general practitioner to call to his aid these special oracles in every possible case.

Medicine, to be beneficial to humanity, must be open to one and all, and if its practitioners are to be excluded from medical societies and their meetings—not from a lack of knowledge and good standing—such societies have outlived their usefulness. Special studies may be made by physicians in certain directions, but the advantages of their research and study must be verified by their practical demonstration through the general practitioner. Without a thorough knowledge specialism avails little. This powerful organization should represent every branch and speciality of medicine, and its knowledge should be open to all its members. We are all entitled to the benefits derived from associated investigations. Outside organizations on special subjects will detract from the interest and advantages of our meetings, and the younger members, neglecting the general subject of medicine, dazzled by the apparent brilliancy of a select few, will wander forth to ultimately destroy their own usefulness. The American Medical Association is the representative body of the medical profession of this country, and has been organized and conducted by gentlemen who have grown gray in its service, and whose brows are adorned with chaplets most worthily won, not only at home but abroad. It is for them, and for you, my fellow-members, to control the means of disseminating our science, and not for a few, who, at best, only form but a spoke in the wheel of the triumphant chariot of our science. Our young men should learn from you that knowledge must come to them by the coöperation of their professional brethren from all parts of our country rather than from a few, who, in their exclusiveness, set themselves above the active members of the greatest and most humanitarian of all professions.

MEDICAL PROGRESS.

ANATOMY AND PHYSIOLOGY.

ANATOMICAL INJECTION OF THE BLOOD-VESSELS THROUGH THE CEREBRO-SPINAL CAVITY.—Dr. B. W. Richardson, in his *Asclepiad*, gives the curious results of some experiments made by him several years ago. He was trying to stimulate the brain directly with oxygen gas, and used for the purpose a long subcutaneous injection needle introduced into the cavity of the cranium from behind the eye ball, through the optic foramen. In his operations on animals, on opening the abdomen to expose the iliac veins and inferior cava, they were found to be filled with dark blood, then, on using his injection, almost instantly the blood in the vena cava inferior became of bright red arterial color, the color gradually extending along the vessel, until, in time, it reached the right side of the heart. This effect was produced by the use of oxygen, of common air, and of carbonic oxyde. The venous blood in the senuses of the brain and in the vena cava superior was not changed in color by the injection. Next, after dividing the vena cava and inserting a tube, coal-gas was injected in the same way, and escaped so freely from the vena cava jet that it could be lighted immediately. A drachm of mercury was made to pass in the same way into the iliac veins and lower part of the vena cava, this was repeated until the mercury reached the heart, traversed the lungs through the pulmonary circuit, reached the left side of the heart and extended into the arteries. In the process of embalming, four pints of the preserving fluid can be injected over the body through the subcutaneous injecting needle, by the cerebro-spinal cavity.

Dr. Richardson has been unable to discover, up to this time, how, from the cerebro-spinal cavity, the injected matter enter the veins so easily. It charges the plexuses of the medulli-spinal veins which lie between the pia mater and the arachnoid, but the entrance of it is obscure. No injury is traceable in the brain substance after the injection, unless undue force is used, but it is obvious that the lateral ventricles are first charged with the injection.

This leads to the almost certain influence that the cerebro-spinal fluid, which is always being secreted, finds its return current into the venous circulation in a similar manner, and that the cord and brain are thus relieved of pressure from it. If that be so, we have a ready and rational explanation of many cerebral and spinal disturbances occurring under retarded current of blood through the vena cava inferior by pressure in the vessel, or by obstruction in it in some part of its course. He gives as a case in point that of a gentleman advanced in life who was laboring under ascites. The abdomen was tense with the fluid, but the urgent and apparently fatal symptoms were cerebral and spinal. The patient was quite unconscious, breathed with deep stertor, and had frequent convulsive starts and tremors. Being in consultation, he suggested that the nervous symptom might be due to obstructed venous circulation and what might be called cerebro-spinal dropsy, and advised tapping, which was done with the result of drawing off eight pints of fluid, and restoring the patient to consciousness. He lived for nearly two years afterwards in comparative comfort, undergoing the operation of tapping several times, and sinking at last from gradual exhaustion increased by senile degeneration. Dr. Richardson thinks it probable that the vertigo which is met with in temporary hepatic obstruction, is often due to retardation of the return ascending venous current, and suppression of the cerebro-spinal secretion; as also hysterical convulsion, preceded by great distension of the abdomen from flatus, and that puerperal convulsion may be mechanically induced in the same manner, as the discharge of the cerebro-spinal fluid into the general circulation is seen to be, chiefly, at a part of the venous system where uterine pressure is most likely to prove an impediment to the ascending venous current.

EXPERIMENTS UPON THE RELATIVE RAPIDITY OF THE TRANSMISSION OF VISUAL, AUDITORY, AND TACTILE IMPRESSIONS.—M. A. M. Bloch reports to the *Jour. de l'Anat. et de la Physiol.* a series of interesting experiments upon this subject, which he sums up as follows:

1. The relative rapidity of sensorial transmissions cannot be studied by the method which consists in a voluntary response to an excitation of the senses; as it requires the coöperation of various parts of a physiological cycle, viz.: peripheric modification; nerve transmission; transformation of a sensation into perception; transformation of a perception into volition; motor transmission; muscle inertia; time lost by the instrument.

It establishes results upon an element that is unknown in its duration as well as in its essence; the transformation of a perception into volition; an individual element that is variable and modified by habit, and fundamentally is independent, as in touch, for example, of the duration of tactile transmissions, being in opposition to them.

2. The relative rapidity of transmissions of sight, sound, and touch, may be determined by noting the apparent simultaneousness of these sensations, and in studying the limits within which this simultaneousness manifests itself.

3. The interpretation of time space comprised between these limits depends upon the combined actions of the time of transmission and the duration of the persistence of the sensations.

4. Studying in each particular case the duration of the persistence of the sensations submitted to experiment, one may deduce the fraction of a second which measures the comparison sought for the comparison of sensorial transmissions.

5. Each of his experiments was composed of two parts independent of each other, and the concordance of the two results established a mutual control between these parts.

6. The comparison of vision, audition and touch, two by two, constitutes three distinct experiments; the control of each result is then proved by five other concordant results which are absolutely independent.

7. This quintuple proof of each result is not only a guarantee for the numeric value of each, but also, and particularly, a guarantee for the soundness of the theory which governs the experiments.

8. He proposes to designate under the name of *Limit of Appreciation* the sensorial error which cannot be avoided either in comparing two sensations of the same order, or in comparing two different sensations in connection with the movement of physical excitation.

9. He proposes to reserve the name of *Personal Equation* to the error of appreciation, readily modified, which results from the cycle commencing by an excitation and finishing by a voluntary movement.

10. In his last analysis he reaches the following results: Of the three sensations studied, vision is the most rapid. Then comes audition, the transmission of which is $^1/_{72}$ of a second longer than transmission; and lastly touch of the hand where the transmission continues $^1/_{21}$ of a second longer than visual transmission.

MEDICINE.

MALARIA AND THE EUCALYPTUS IN ITALY.—Consul Welsh, of Florence, reports to our Department of State (United States Consular Reports) a consideration of this subject, accompanied by a map showing the infected districts of Italy, which unfortunately is not published with the report. The map shows that Florence is not considered malarial, but its death-rate is considerable, while the deaths from typhoid fever, which term must be accepted with a very general signification, amount only to 166, the deaths from diseases of the respiratory organs and consumption amount to 1,480, or more than 25 per cent. of the total registered for the year 1882. The changes of temperature in Florence are so sudden and great, and the air so impregnated with the snow, which during the winter lies on the hills surrounding the city, that the effect on the lungs and general health of a constitutionally delicate person is most disastrous.

During the summer the days are hot and glaring, while the nights are very cool, a change of 25° F. not being unusual. During the winter piercing cold winds from the northwest, or warm winds from the south (sirocco), accompanied by rain, prevail. For consumptive patients, he recommends Pozzuoli, near Naples, the sulphuretted air of which is most beneficial, or Amalpi, on the Bay of Salerno. Both are protected from the north winds and enjoy almost uninterrupted sunshine.

Of the sixty-nine provinces into which Italy is divided, only six are considered completely free from malaria; the rest are more or less affected. Of the men composing the army, more than 10 per cent. suffer from fever during the year, and submit the State to an annual expense of about $200,000. The remedy which has been commenced is the planting and nursing of trees. The eucalyptus has been adopted as most effective. At Ventimeglia, which place was impregnated with fever in 1875, there were planted about 800 globulus eucalyptus, and in two years' time malarial fever disappeared. Great success has also attended the planting of the eucalyptus along the lines of railway and at the stations. An important nursery has been established by the Romane Railway Company, at Nola, near Caserta, and there are also many nurseries of the eualyptus due to private enterprise. Government committees having satisfied themselves that by the gradual development of groves of the eucalyptus tree, malarial fever may be, if not exterminated, to a great degree lessened, it is proposed to offer a reward, authorized by a law now before the national Parliament; for the production of the eucalyptus, which reward rates for each plant having a circumference at one meter from the ground of from 80 to 85 centimeters, 1 lire; to from 131 to 135 centimeters, 2 lire. For every centimeter over 1.35 meters, the reward will be 5 centimes.

ON GENITAL DIABETIDES.—The subject of diabetes has been especially engaging the attention of our French brethren for some time past, and their periodical literature contains much that is interesting on the subject. Prof. Fournier (*Jour. de Med. et de Chir.*), in his clinic at the Hopital Saint Louis, discusses the effect produced upon the genitals by what he calls diabetides. Diabetes acts in two ways; by the general alteration of the system, and by a local influence through the direct action of saccharine urine upon the integument. The sugar by its fermentation produces a sharp irritation of the skin, and, moreover, it favors the production of cryptogamic vegetation, which is of much importance. Among diabetics there are to be found at different points on the genital organs fatty crusts containing cryptogamic elements, which, according to Friedreich, give under the microscope the pathognomonic appearance of diabetes, and which resemble somewhat the parasite of muguet.

The various dermatoses of diabetes rarely appear suddenly; they are generally preceded by an intense pruritus, which may be of extraordinary violence, and cause perfect torture. It is particularly in women that this is most severe, being seated on the vulva, perinæum, and anus, causing loss of sleep and of appetite. It is seen from this that these symptons may occur without any cutaneous lesion on the one hand, and without any other of the marked symptoms which accompany diabetes. It should then be an invariable rule, that whenever an intense pruritus of the genitals occurs, without any lesions, the possibility of the existence of diabetes must be taken into consideration.

The first symptom observed in the woman, after pruritus, is vulvar erythema, the characteristics of which are in no way special, but which is only the first stage or the most common form—viz.: eczema. The eczema may be acute or chronic. The acute form is characterized by a marked redness extending over the vulva and perivulvar parts, producing a general turgescence, a serous weeping, local pain, intense itching, with smarting. It resists all treatment, improves a little, but is rarely cured; it has a great tendency to relapses. These variations are frequently due to the variable quantity of sugar in the urine; but after the lapse of a certain time the acute merges into the chronic form.

The chronic eczema does not occupy exactly the same seat with the acute, it generally extends further —to the groins, the abdomen, and the perinæum; its redness is darker, and is not effaced by pressure of the finger. The itching is at its height—repeated scratchings have produced a general hyperplasia of all the tissues, a true pachydermic condition, the labia majora and minora, and the different parts comprising the vulva are hypertrophied, and there is an active inflammation of all the anterior half of the vagina. Also on the mucous portions there are sebaceous crusts containing cryptogamic vegetations. So constituted, this form of chronic eczema is to a certain extent special in its character. It persists indefinitely, and is only modified in its extent. It is always susceptible to treatment, which must be prolonged and general relative to the diabetes itself, as well as local.

In man similar symptoms may result from diabetes, but they are more complex in their character. These diabetides occur on the gland under three principal forms, which have a close connection: erythematous balanitis, herpetiform balanitis, and eczematous balanitis. The first is characterized simply by erythema, with a little swelling of the meatus, limited at first, but soon extending to neighboring parts. In the second form the gland is more or less hyperdæmic, and showing little disseminated epithelial expoliations, round or oval, and resembling herpes closely. In the third form there is a true eczema of the gland, the surface of which has become epidermoid, desquamating, creased, and cracked at certain points, and the seat of a violent pruritus.

The prepuce is very often affected, particularly when it is long. In the diabetic eczematous posthitis, there is to be seen at the inferior ring a series of fissures in the shape of a crown, due to the movements of the prepuce necessary to uncover the gland. The posthitis is generally associated with balanitis, and one may say that this combination with its puffy condition, its cracks and its crown of fissures, is characteristic of diabetes. Eczema so localized is only found in this disease.

This form of balano-posthitis also often tends to the production of phimosis from the thickening and diminution of elasticity of the prepuce, as well as from the progressive narrowing and atresia of its inferior ring. Phimosis may in turn cause balano-posthitis. Then follows difficulty in urination, a more or less abundant and persistent serous discharge which is so irritating as to lead the patient to fear venereal disease, and finally a violent pruritus. In these conditions, phimosis is a marked and distinguishing sign of diabetes, and it has certain characteristics which merit attention: it is a subacute phimosis, very different from blenorrhagia; the prepuce is thick like parchment, non-elastic, immobile, without possible displacement, with sclerous atresia of the orifice, and finally, in its evolution it is chronically progressive, often taking many months or years to establish itself.

This phimosis, moreover, frequently undergoes certain complications. The infiltration may be excessively hard, and of a knotty form, giving rise to fears for a cancerous alteration, and it may produce vegetations remarkable for their rapid increase, repullulation, and the size which they may attain. The local treatment has one special indication, that of keeping the gland free from contact with the urine. When it is found to be incurable by the use of the ordinary treatment for such affections, the question of circumcision arises, but on account of the extreme risk incurred in all surgical operations upon diabetes, this should not be attempted until all traces of sugar have disappeared from the urine. There have, it is true, been successful cases, but the cases in which phymous, erysipelas and gangrenes have supervened are too numerous to warrant its attempt.

The genital organs may also in this disease be the seat of gangrenous lesions, but they are very rare.

Journal of American Medical Association.

PUBLISHED WEEKLY.

THE EDITOR of this JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information, should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE..... $5,00.
SINGLE COPIES..... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 65 RANDOLPH STREET,
CHICAGO, ILLINOIS.

SATURDAY, MAY 10, 1884.

AMERICAN SURGICAL ASSOCIATION.—This Association closed its regular annual meeting in the city of Washington, on Saturday, May 3, 1884. Its meetings, during the four days it was in session, were held in the hall or lecture-room of the National Museum Building of the Smithsonian Institute. About fifty members were present, and took a more or less active part in the proceedings. The number of papers presented was large, and, as usual on all such occasions, some of them possessed a high order of merit, while others were indifferent, or of little real value.

The two leading papers read during the last day of the session were on "Trephining for Epilepsy," by Dr. W. T. Briggs, of Nashville; and on "Extirpation of the Tongue in Cancerous Affections," by Dr. Basil Norris, of Washington. This latter paper represented the number of cases on record of extirpation of the entire tongue as 126, the results of which were given in 124 cases, claiming ninety-five recoveries and twenty-nine deaths. If this proportion of recoveries refers only to the number who recovered from the direct effects of the operation, it is probably correct. But so large a proportion of *permanent* recoveries would show that "cancerous affections" of the tongue are far less liable to reproduction, than the same class of affections in any other part of the body. The following officers were elected for the ensuing year: President—Dr. Wm. T. Briggs, of Nashville, Tenn.; Vice-Presidents—Dr. J. C. Hutchison, of Brooklyn, N. Y., and Dr. E. H. Gregory, of St. Louis, Mo.; Secretary—Dr. J. R. Weist, of Richmond, Ind.; Treasurer—Dr. John H. Brinton, of Philadelphia, Pa.; Recorder—J. Ewing Mears, of Philadelphia, Pa.; Council—Drs. H. F. Campbell, of Augusta, Ga.; Hunter McGuire, of Richmond, Va.; P. S. Connor, of Cincinnati, O.; and J. S. Billings, of Washington, D. C. Washington was selected as the place for the next annual meeting, and Dr. J. S. Billings as chairman of the local Committee of Arrangements. We regret to learn that Dr. S. D. Gross, to whom this Association is largely indebted for its first organization, was too unwell to be present.

During the meetings the Association decided to omit the annual dinner for this year. Nevertheless, some twenty of the members, including the retiring President, Dr. E. M. Moore, of Rochester, N. Y., enjoyed a banquet at Wormsley's Hotel, on Friday evening, under the superintendence of J. Ewing Mears, of Philadelphia, and L. McLane Tiffany, of Baltimore. Besides the eatables, there were the usual number of toasts and speeches, making the occasion altogether a pleasant and enjoyable one.

AMERICAN CLIMATOLOGICAL ASSOCIATION.—The members of this new organization assembled for their first annual meeting in the hall on the northwest corner Sixth and F streets, Washington, on Saturday, May 3, at 10 o'clock A. M. Though not a member of the Association, we went to the hall at the proper time, expecting to hear some good papers and discussions on topics of the highest interest. In this we were disappointed, however, as only fourteen of the forty members enrolled upon the list had made their appearance, and there being no audience but myself and a friend who accompanied me, the members present decided to devote their time to the consideration of the report of a committee on constitution and by-laws, and such matters as related to the completion of their organization, and postponed the reading of the papers until Monday morning, when it was hoped that a larger number would be present. Among those present whom I recognized as personal acquaintances were Dr. Charles Denison, of Denver; Dr. Frank Donaldson, of Baltimore; and Dr. A. Y. P. Garnett, of Washington. The first-named has a long and interesting paper on "Dryness and Elevation the Most Important Elements in the Climatic Treatment of Phthisis."

It is illustrated by maps and charts, and is based largely upon his personal observations during many years of residence and practice in Colorado. The second is to read a paper on "The Climate of Large Cities Dangerous to Consumptives," a subject of

scarcely less importance than the other, and yet one which has received less patient and accurate investigation than it deserves.

The observations made under the direction of the standing committee of the American Medical Association on the meteorological conditions of the atmosphere and their relations to the prevalence of disease, have shown that in the more densely populated parts of our large cities, hardly a trace of ozone or other active oxydizing agent is to be detected at any part of the year, while both free and albuminoid ammonia, resulting from the decomposition of organic matter, are seldom absent in the same localities. How far these conditions may favor the more frequent development and more rapid progress of phthisis in large cities, can be determined only by observations so numerous and protracted, that real causes and effects can be separated from mere coincidences. While looking at the limited number present in the meeting of the Climatological Association, I could not help thinking that all the objects of the organization could be just as well attained, at less expense, and with much better security for an audience, in connection with one of the Sections of the American Medical Association, than in a separate capacity. The special field the members propose to cultivate, namely, the relations between pulmonary diseases and climatic influences, might be prosecuted with perfect propriety in the Section on the Practice of Medicine and Therapeutics, where a good audience is reasonably certain, and from which the papers would speedily pass into the journal of the Association, and be widely distributed to the profession in all parts of the country, instead of being incorporated into a volume of Transactions to be read by very few outside of their own membership.

The same remarks apply to the Surgical Association and the Section on Surgery and Anatomy of the American Medical Association. If there should not be time to receive and consider all the papers in these Sections, it would be much more economical, both in time and money, to permit such Sections as were overcrowded to remain in session one, two, or three days after the time allotted to the general sessions of the Association, than to maintain a separate organization for each special field of professional work.

Just as we go to press the news comes of the death of Dr. D. D. Gross, the eminent surgeon and former president of the Association. His death occurred May 6, 1884.

SOCIETY PROCEEDINGS.

CHICAGO MEDICAL SOCIETY.

At the meeting of the Chicago Medical Society, held April 21, 1884, the following paper "On the Causes of Laceration of the Perinæum during Parturition, and its Prevention," was read by Philip Adolphus, M.D., Chicago:

The perinæum receives perhaps a rent in one labor, by the passage of a large head or ossified fontanelle; or possibly by a child with large shoulders. This is not sutured, and may not heal completely. In a succeeding labor, a face, or an occipito-iliac presentation, or some other unusual position of the head, renews the laceration and leaves a larger outlet.

A very *rapid delivery* through an infiltrated vulva may be *necessitated* by convulsions. Asphyxia in the child—the result of many conditions—*may require* that the shoulders, after the head is born, be *rapidly* removed whilst they are offering their *largest diameter* to the *smallest diameter* of the inferior strait.

Although the more frequent application of the forceps has made physicians expert in their use; yet laceration of the soft parts *do occur*, in the practice of young physicians, when in their *earlier cases* they use the forceps.

In difficult head and face labors also, where the forceps is used by the skillful practitioner, the perinæum may be lacerated.

Now, lacerations of the perinæum rarely heal throughout their whole extent *spontaneously*, although when carefully sutured the integrity of the perinæum is restored. In later births the scar generally stretches and yields as well as the normal tissue.

The *result*, then, of previous labors *is*, that the vast majority of all multiparæ who suffer with chronic pelvic disease, have lost one-third or two-thirds of the thickness of the perinæum, and some have merely a very thin partition between the vagina and rectum. Not a few show cicatrices of far more extensive lacerations, implicating even the anus, which have healed without operation. Very few women come now-a-days under the notice of the gynæcologist with lacerations implicating the rectum, whilst the rarest of all met with are those central lacerations of the perinæum, through which the fœtus has passed; for these lesions above all others, heal easiest.

The *frequency* of lacerations of the perinæum in general, is 15 per cent., of which 35 per cent. occur in primiparæ, and 53 per cent. in primiparæ over 30 years of age.

The *causes* of laceration are due to the *structure* of the pelvis, the *condition* of the soft parts of the mother, to *the fœtus*, or the *character* of the labor.

Primiparæ generally have the fourchette lacerated in the first labor.

Excess of energy in the *contractions* of the uterus, may be developed by a *narrow pelvis;* the head, after a tedious labor, being forced rapidly through the perinæum, by an irritable and violently excited

uterus; the patient thereby being exposed to the dangers of precipitate and tedious labors.

Any deformity of the bony pelvis, as, where the sacrum is too straight, or too near the pubis; where the coccyx is anchylosed, or where the rami of the pubes and ischia approximate too closely, may cause the head to advance too straight, or may force it too far backwards. In all such instances the proper extension of the head cannot occur, and it is pressed too powerfully against the floor of the pelvis, causing laceration.

In some primiparæ, whether thin or plethoric, especially in those who have married early or late in life, we meet a peculiar nervous or vascular excitement which disposes to rigidity of the soft parts during labor.

In these cases of "vital rigidity," and others where the elasticity of the mother's tissues are at fault, the arrest of the fœtal head at the floor of the pelvis causes the uterus to contract violently, inducing great pressure in the perinæum. The soft parts gradually yielding, the child is born; more frequently, if skilled assistance is wanting, the perinæum lacerates more or less extensively.

Now-a-days physicians and midwives are taught to interfere earlier in irritable and rigid conditions of the soft parts, before lacerations are likely to occur. The greater danger of losing the life of the child in first labors, is a sufficient reason for expediting delivery in cases of tedious labor.

The narrowness of the perinæum may not permit the head to turn well forward, and cause it to rupture, *or* firm cicatricial thickening, or syphilitic or malignant deposits may weaken it; *and* deformities of the os vaginæ and vulva from the same cause, or *any other* physical obstruction, may induce laceration.

Swelling of the vulva, from infiltration of serum, in cases of albuminuria and threatened convulsions, may induce laceration and sloughing if small incisions are withheld. These incisions into the skin and mucous membranes drain off the serum, and overcome the obstacle to labor.

Ordinary-sized heads presenting normally in these conditions of the perinæum, may induce lacerations; nay, even small heads may do so, because they pass too rapidly. The narrower the genital fissure, and the larger the head, and the more rapid its passage, the more easily the perinæum ruptures. Large heads—mostly found in boys, who are generally heavier than girls, and who have consequently large and firm skulls—increase the difficulties of any labor, especially in primiparæ, owing to the greater tonicity of the parts. But these are found mostly in multiparæ, for, according to Schrœder, "the bi-parietal diameter of the head increases quite out of proportion to the number of labors, and the age of the mother."

Large women run more danger of laceration of the perinæum, because they are generally delivered of larger children, for the weight of the child increases with the weight and age of the mother. Therefore, a multipara of stout frame and mature age will have the greatest strain on the perinæum; but even here the soft parts will have been dilated by previous labors.

The most favorable presentations for the perinæum are those of the breech. In head presentations the normal is the best. The occipito-iliac and the face presentations are the least favorable. Any other parts of the body presenting with the face increase the danger. The shoulders occasionally are too large. They are then retained at the entrance of the pelvis, and obstruct the passage of the head. The forceps will assist its passage; but the shoulders again hinder the passage of the trunk after they have gotten to the bottom of the pelvic cavity, and then rupture of the perinæum takes place.

The rapidity of the labor is important. In rapid labors, where the uterus and the accessory muscles act too violently, the head may not only tear the perinæum, but also the vagina and cervix. In these cases the shoulders may be pushed simultaneously through the lacerated floor of the pelvis. More frequently the physician causes the laceration when the labor requires a speedy termination in the interest of mother or child, or of both. For instance: after a difficult forceps labor, in cases of convulsions, in prolapse of the cord, or in cases where the cord is around the neck of the child, in tedious labors, or after profound losses of blood. The child, after the head is born, either by the efforts of nature or assisted by the forceps, is often in a state of asphyxia. It does not breathe or cry; its face is congested. Every moment is precious. The physician must deliver the trunk in order to resuscitate it.

The exhausted uterus rests awhile; the equally exhausted woman, although relieved of intense agony, cannot be induced to make bearing-down efforts; or she is still under the influence of an anæsthetic. The head and face are completely disengaged; the soft parts embrace the neck.

The child's head is placed antero-posteriorly. Rotation of the shoulders and the consequent external rotation of the head has not taken place; they are therefore at right angles with the head, in the transverse diameter of the outlet, which is the smallest diameter of the inferior tract.

Anxious to deliver, the physician gropes for the axilla, inserts his finger into it, pulls down one shoulder, then the other, delivers the body of the child, and resuscitates it. By-and-by he finds an extensive laceration of the perinæum, which might have been prevented had he tried to rotate the shoulders from the transverse into an antero-posterior position during extraction.

In his anxiety to save the child, he forgot that the head and neck of the fœtus are at right angles; that when the head disengages from before backwards at the vulva, the shoulders are situated transversely at the inferior strait, which renders it necessary that the head and body should perform necessarily the same mechanical movements of rotation and disengagements. Furthermore, the external rotation of the child, the so-called movement of restitution, is caused solely by the rotation of the shoulders.

What must be done to prevent laceration of the perinæum? Our principal means of prevention is to regulate the rapidity of the passage of the head and body of the child.

During the latter stages of labor we should endeavor to have the patient completely under control, by removing irritability and obtunding sensibility. Even the severest pains should not be agonizing, but rather stimulating. Violent bearing-down pains by stemming the feet against the foot of the bed, or pulling on sheets, should be discouraged.

The pressure of the patient's hands against those of the nurse is sufficient. Whenever the uterus contracts forcibly and the presenting part presses against the perinæum, the patient should be forbidden to bear down and instructed to open her mouth. If the patient cannot forbear doing so, an anæsthetic must be used.

The manual management of the perinæum rests on this principle, namely: to superintend the disengagement and expulsion of the presenting part, with safety to the soft parts of the mother. It is therefore expedient sometimes to assist as well as to retard the advancing part; whether it be of the vertex by extension, or the face by flexion. This principle guides the practice of all physicians, however much the minutiæ might differ. The following method has served me well:

Let the patient lie on her back, when the perinæum is distended by the head. The physician's right hand is applied to the perinæum, with the thumb near the vulva, and the four fingers pointing towards the rectum. Thus the palm of the hand covers the head from the nuchæ to the frontal bones. If the pains are too violent, he presses the occiput of the child in the direction of the coccyx, by introducing his thumb into the vulva, whilst at the same time the palm of the hand lifts the perinæum and head in the same direction.

If it is desirable to assist the extension of the head, he inserts the second and index fingers into the rectum if necessary, and presses the frontal bones towards the symphysis, whilst the palm of the fingers and hand elevate the perinæum in the same direction.

If the pains require neither expediting nor restraining, the physician has his hand in readiness to do whatever is necessary, without the slightest pressure being made on the perinæum.

The introduction of the index and second fingers into the rectum enables us to advance the head materially. By it the relations of the child's head to the perinæum can be well appreciated.

If rupture of the perinæum is imminent, owing to the violence of the pains, authorities advise that the patient be placed on her left side, and lateral incisions be made. I prefer the dorsal position, the administration of ether, and the removal of the head by forceps.

I can conceive that it might become necessary where laceration is inevitable, to make lateral incisions into the perinæum; but the timely application of the forceps will render this procedure useless; for it will save at the same time the soft tissues of the mother and the life of the child.

In applications of the forceps, the *advice* of Elliot should be followed; of introducing two fingers *deep into* the rectum, for this manœuver will impart *exact information* of the *relations* of the head and soft parts, *to the forceps*.

In narrow pelves, either the forceps or turning is indicated, *long before* the uterus would be lashed into such an excess of energy as would force the head through the perinæum.

In fact, in *all cases of first labors*, the forceps is indicated for the safety of the child, *before* the perinæum is threatened.

For the treatment of rigidity, opiates and chloral are *advisable*; they *remove* irritation and *promote* dilatation, and often render the exhibition of anæsthetics *unnecessary*. Morphia by the mouth has been given by me for years, and *by it* a timid woman can be carried through a tedious labor, *without* losing courage or suffering intensely. It obtunds the agony of the *latter stage of labor*, promotes sleep *without* abolishing consciousness, even during the short intervals of the last pains, for the renewed contractions will immediately awaken the patient.

DISCUSSION.

Dr. D. T. Nelson thought dilatation and relaxation of the perinæum usually begins long before the head of the child presses upon it. But if this process is tardy, then it may be necessary to apply emollients or fluids, to facilitate the relaxation, also give chloroform to hasten this and the labor. To expedite a labor, the perinæum should dilate, but if this is soft and succulent, then we do not resort to emollients, or perhaps the perinæum may be aided in dilating, by the accoucheur using the back of the thumb and finger.

Another observation: Corpulent women are more likely to suffer from laceration. Is it because adipose tissue tears more easily? This being true, how can this be prevented in an exceedingly corpulent patient? We should aid nature in trying to make the process of labor as nearly normal in every respect as possible.

Dr. J. H. Etheridge asked incidentally the members of the Society, if they had ever noticed the skin over the perinæum ruptured, where the rupture did not include the body of it? He then recited a case, a primipara, forceps delivery, where the skin only was ruptured nearly the entire length, from the fourchette to the rectum.

Dr. Jaggard thought there was but little more that could be added to that which the writer had stated and explained in his paper. Regarding the technique —"to support the perinæum"—this is a misnomer. Protection covers the ground more fully, and is a better term.

In Australia, some portions of France, and the United Kingdom, a patient is confined on her left side. In Germany the woman is placed on all fours, so to speak, as they reason there the child's head, then, will be in a state of flexion. The perinæum is a distensible body, and admits of the two-fold action, flexion, and substitution of the child's head. No amount of protection will preserve a perinæum from rupturing if there is malformation or infiltration of unhealthy tissue, as serous tissue or quantities of adipose in the perinæum. As one of the speakers alludes

to ephisiotomy (Hecker) says, if performed, *i.e.*, the conjoined method, may preserve it. Under the supervision of Karl Brown, of the Vienna hospital for lying-in women, during the speaker's experience the first two years with his first fifty cases, one-half of them resulted in laceration of the perinæum, but later only two cases ruptured in 100.

Dr. T. P. Seely frequently gives chloroform to quiet the nervous tendency a patient may have, and to ease her pain. This, he believes, will tend to very much lessen the danger of laceration of the perinæum.

In his practice he permits the patient to inhale it from the bottle, and does not sprinkle it on a handkerchief. By his method much less of it is used, and in this manner it can be done with much satisfaction.

Dr. J. S. Knox, not having heard all of the paper read, would only state that, in his practice of late years, to save the perinæum, where the uterine forces are exhausted and the passages dry, he uses small light forceps with a double curve. We should have complete anæsthesia of the patient. We can then extract the head easily, and by these means save the perinaeum.

Dr. C. T. Fenn. Regarding the position of a woman, the dorsal decubitus, it seems to him, is, *par excellence*, superior to all others, and then, to obtain the best results in preserving the perinæum, we should support this body with the left hand, then with the right hand placed over the patient's abdomen, and with moral influence in soothing her, he thought had much to do towards a favorable result; also to calm her by gentle measures, has much to do where there is present rigid muscular action, which is removed, and a state of relaxation will ensue. Fluids do not promote the expansibility of the perinæum, nor do ointments on the integument have much effect in this direction.

Dr. Jaggard stated further, that in Philadelphia, Boston, and New York, the left lateral position is most emphatically employed.

Dr. Adolphus concluded by saying, every physician uses emollients to soften and relax the rigidity that may be present in perinæi. He uses two fingers to keep the parts separated, and we must not permit the parts to become dry. The child, though, is primarily to be saved; the perinæum secondarily. Regarding external ruptures, he thinks they occur, but we may not notice them at the time they happen, but later, if we examine them, as in a few months, we then may notice a cicatrix. He thought Dr. Jaggard was mistaken in his statement that but two lacerations occurred in his last 100 cases that he alluded to, although he knew the doctor made the statement sincerely enough, but had he examined his patients six months after, there doubtless would have been cicatrices noticed.

BOOK REVIEWS.

INSANITY—ITS CLASSIFICATION, DIAGNOSIS AND TREATMENT. A Manual for Students and Practitioners of Medicine. By E. C. SPITZKA, M.D., Professor, etc., etc., etc. New York: Bermingham & Co. 1883.

This work, according to its preface, has been enlarged from an "essay to the dimensions of a general treatise, at the requests and suggestions of pupils and professional friends," in order to "lay special stress upon points which will prove comparatively new to most American readers," and because the author "has felt that there exists a need for a treatise, which, without being so exhaustive as to tire and bewilder the beginner and the general medical reader, shall direct attention to some of the salient points of psychiatry, etc., etc." The work appears, moreover, to be the precurser of a "larger one on insanity which the writer has in preparation, and which will appear in a few years." The work is divided into three parts, of which the first has for its subject "the general characters and the classification of insanity; the second, the special forms of insanity, and the third, insanity in its practical relations.

In the initial chapter the author, following the stereotyped programme, attempts the impossible feat of framing a verbal definition, which shall include all that is, and exclude all that is not, insanity; and with the usual result. He has, however, succeeded in framing a "definition" which, for length, circumlocution, involution and vagueness stands unrivalled. It moreover includes conditions in which every thoughtful man frequently finds himself without a suspicion concerning his sanity. In the second chapter the delusions of the insane are referred to as "perversions of the conceptional spleen," which "have had the high medico-legal position assigned to them—it is scarcely necessary to add, *erroneously*—of constituting the criteria of insanity," etc., and are subsequently designated as "*faulty ideas growing out of a perversion or weakening of the logical apparatus*, whatever that may be. Later, delusions are subdivided into "*genuine* and *spurious*," of which "the former group consists of those delusions which have been mainly created by the patient himself." The author exemplifies delusion thus: "If, for example, a medical student, as in a reported case, believes that he is suffering from spinal disease, and bases this delusion on alleged symptoms which might justify the belief, if they were not due to illusional misinterpretations and hallucinatory visions of the spinal cord,[1] he is suffering from a *systematized hypochondrical delusion*."

Still later, "the following legal definition of an insane delusion, that it is *a faulty belief, out of which the subject cannot be reasoned by adequate methods for the time being*, is (said to be) a sound one." To what, it may be asked, are these methods *adequate*, since they fail to accomplish their object? This "legal definition" must include all those holding

[1] The definition of this enigma is left to the sagacity of the students and practitioners who may perchance become readers.

religious beliefs (for example), faulty in the estimation of those who oppose them, and out of which they cannot be reasoned by methods adequate in the judgment of the reasoner, but inadequate in that of his subject.

In a subsequent chapter hallucination is defined as "the perception of an object as a real presence, without a real presence to justify the perception." It would be interesting to some, at least, of the "students and practitioners for whose enlightenment this book is written, if the writer had given the distinctive definitions of object and real presence, and had also explained how an object of perception could be other than a real presence.

On the subject of moral insanity the author's expressions are vague and inconclusive, and in relation to the "will in insanity," after advancing the proposition that "there is probably not a single case of insanity in which the will, in the widest sense, is not at some time or other in the course of the illness, more or less disturbed," he proceeds to prove that the will is supreme in its domination over actions instigated by disordered perceptive faculties.

The chapter on "the physical indications of acquired insanity," is marked by ambiguity and inconsistency, which pervades the entire work.

The chapter on "the morbid anatomy of insanity," comprising the writer's observation in this field of investigation, contains matter both interesting and valuable, although its merit is materially diminished by the discredit accorded to the work of others in the same field. Had the observations of the pathological anatomy of insanity, contained in this volume, been published as such, they would have constituted a valuable contribution to the science of psychiatry. But their utilization by means of shallow sophistries, as bases for false psychological theories, couched in ungrammatical jargon unintelligible to any but a polyglot, can serve only to confuse, mislead and discourage those whom it assumes to enlighten and instruct.

The past decade has been most prolific in neurological literature; observers have been industrious in the prosecution of investigations, and perhaps even more so in their publication. It would have been better for their own reputations and for the interests of science, had some of them, at least, been content with the former alone; it would have been better had they known that among many observers there are few thinkers, and very few teachers; that endowment with a reasonable degree of perspicacity for observation of objective phenomena, or even the additional possession of erudition adequate to record them intelligibly, by no means implies ability to estimate their significance, to compare them, nor to deduce logical conclusions from such comparison.

Few minds are trained to so great a degree of accuracy in the performance of secondary or mediate, as of primary or immediate perception, and this organic defect is the source of much, if not of most of the false theory based upon deduction from observed phenomena; hence the great advantage of the classification of intellectual labor—"*suum cuique*;" to some, the task of observation; to others, that of comparison.

FOREIGN CORRESPONDENCE.

LONDON, APRIL, 1884.

Before long, the stronger sex will have to meet the gentler on an equal footing in all the professions. The invasion of women, which is the chief event in recent university history, has advanced another step at Oxford, when congregation agreed by 100 votes against 46 to admit women to several university examinations. The girls will not yet, at least, be examined in the new schools with the undergraduates, but they will have the same papers and the same examiners, and their class lists will be drawn up on the same standard. The lady students at Cambridge have been for some time examined in this way. The opponents of the scheme, however, were divided amongst themselves; some of them arguing that as women were so notoriously inferior to men it would be unkind to subject them to the same examinations, whilst others thought that the change would be unfair to the men, because women were foreordained to be their "helpmates, and not their rivals." There were so many ladies present during the debate that many of the Dons could not gain admission.

The Marine Observatory at Granton, near Edinboro, the first of its kind in Great Britain, is now fairly launched, and will be in working order during the spring. Already many herring, cod, and other living fish are housed in cages for observation. There will be accommodation for six naturalists, and British and foreign observers with some definite object in view will be invited to use the station free. Now it is proposed to erect a marine biological observatory, on the same lines as the one at Naples, on our southern coasts, probably Torquay or Weymouth. A meeting to carry out this object is about to be held at the Royal Society. Professor Huxley will be in the chair.

Mr. William I. Nixon, house governor of the London Hospital, read a paper at the rooms of the Medical Society of London, dealing with the difficulties connected with the administration of the outdoor department of our London hospitals. The system has been in vogue for upwards of 140 years, and it is estimated that more than 1,000,000 persons, or one quarter of the population of London, were every year recipients of gratuitous medical aid. His remarks had little bearing upon the care of any but those hospitals which are supported by voluntary contributions. With a view of reducing the difficulty of too great numbers of out-patients without injuring the deserving poor, he thought it desirable that a system of inquiry should be organized. A few leading questions kindly put, not influenced by any set amount of earnings or income which the applicants might be receiving, would elicit the required information. There should be an inspection based on charitable concession. With regard to two methods which had been suggested, and in some cases adopted as remedies, Mr. Nixon considered neither just nor charitable, viz.: payments by out-patients and daily limitation of tickets to patients permitted to pass free. The first was totally unworthy of a great

charity whose existence was established, and whose lease of life was insured by its great value to the community. Charge for advice was unfair to the professional man who gave his services practically free to the institution. Charge for medicine placed the hospital in unworthy competition with the local practitioners, and, however small it might, be was a heavy tax upon the very poor.

A most entertaining volume called the "The Gold-Headed Cane," has just been published. It is edited by Dr. William Monk, F.S.A., Fellow and late Censor of the Royal College of Physicians. Most people who have visited the College of Physicians, have seen there the gold-headed cane which was carried successively by Dr. Radcliffe, Dr. Mead, Dr. Askew, Dr. Pilcairn, and Dr. Baillie, and on the head of the cane are engraved the arms of these famous men. By Dr. Baillie's widow the cane was presented to the college, and the day before the opening of the existing edifice in Pall Mall East, the cane was placed in a cupboard of the library, where it remained for more than half a century. Now it is seen in a glass case in the same apartment. In the delightful book edited by Dr. Monk, the cane is made to tell its own story. In the first five chapters, Dr. MacMichael, some time Registrar of the college, has been the cane's amanuensis. In the second period, the cane, withdrawn from intercourse from the outside world, but present where the weightiest medical matters are discussed, has its comments and meditations chronicled by Dr. Monk. The book is a sparkling epitome of the history of modern medicine. In it one reads of Dr. Radcliffe's medical attendance upon William III, about the Dutch surgeon Bidloo, about Prince Eugene, and Dr. Cheyne, and Sir Hans Sloane, and in fact, about most of the notable people of the eighteenth century. There is also some interesting talk about Dr. Conolly, the compeer of the illustrious Pinel, and who first showed in England the practicability and efficiency of the non-restraint system in lunacy.

Since the decision in the case of Dr. Price that cremation is not illegal in this country, it is proposed that a crematorium in full working order shall be exhibited at the forthcoming National Health Exhibition. The point of such an exhibition would be to familiarize people to the latest results of sanitary science. There is going to be a row of sanitary houses, and a row of unsanitary, facing each other, and it is a pity they cannot also exhibit alongside of the crematorium a section of a cemetery.

The Prince of Wales has just opened the Westminster School and Home for Nurses, an institution for the training of nurses to be employed at discretion, either in hospital nursing, district nursing in poor localities, or nursing in private families. The Prince of Wales mentioned the experience in his own family of how geatly skilful and tender nursing contributes to speedy and satisfactory recovery from illness. The committee hope shortly to have fifty nurses at their disposal, and the institution to be self-supporting. The great number of fatal and serious accidents that have happened during the past season in the foot-ball field, have given rise to a loud cry against the present rules in force in this game. At a late inquiry into the death of a student at the Royal Engineering College, a witness stated that the game was not more dangerous when played according to the Rugby rules than according to those of the Association. It is to be hoped that fresh regulations will be in force before the commencement of a fresh season.

Dr. Barnes is to be congratulated upon having at last prevailed upon the Council of the College of Surgeons to abolish their special license in midwifery and to make it part of their ordinary qualification. Previously, holding only the licentiateship of the College in Midwifery, was sufficient to qualify a person's name being placed on the "Medical Register."

G. O. M.

DOMESTIC CORRESPONDENCE.

FROM WASHINGTON.

Matters of Medical Interest before Congress. —April 21. Under instructions from the Committee on Printing, Representative Scales, of North Carolina, introduced a joint resolution into the House (which was passed) to the following effect:

Whenever the Public Printer shall have received a sufficient number of orders for copies of the reports * * * of the Medical and Surgical History of the Rebellion, * * * accompanied by the cost price thereof, with 10 per cent. additional to warrant, in his opinion, the expense of putting the plates to press, he shall cause an edition or editions thereof to be printed. Provided. That the number of copies thus at any time printed shall not exceed the number ordered and paid for in advance of publication.

April 21. Senator Call, of Florida, submitted a resolution to the Senate (which was agreed to), as follows:

Resolved, That the Committee on Public Printing be directed to report to the Senate the cost of reprinting * * * 10,000 copies of the Army Medical and Surgical History of the War, for the use of the Departments and public libraries, and the two Houses of Congress. Also to report what number, if any, of the volumes of these books are now in possession of the Government for distribution to public libraries.

April 22. The Senate Military Committee reported adversely on Senate Bill 1920, providing for the appointment of Dr. A. P. Frick as an assistant surgeon in the Army. The committee in its report gives the following letter from Surgeon-General Murray, which is heartily endorsed by the Secretary of War in his letter transmitting it to the Senate: "An endeavor to secure through Congressional legislation an appointment in the Medical Department of the Army, setting aside prescribed regulations, establishes a dangerous precedent, and one which is viewed by this office with marked disapproval. The statutes and regulations governing the admission of candidates to the Army Medical Department are the result of the

experience of years, and have been supplied by officers thoroughly conversant with the needs of the service, and have in view the perpetuation of thorough efficiency by the selection of young and vigorous men whose qualifications, both physical and professional, for the positions are rigidly scrutinized by a duly appointed examining board. No departure from the present system or relaxation, conceded to be wise and just, can but result in the demoralization of the department, and is greatly to be deprecated. The employment of doctors known as contract surgeons has heretofore been a matter of pure necessity to supplement the regular corps or to provide medical assistance for U.S. troops in emergencies, when the services of commissioned officers could not be had. As a rule they are not examined by a board as to their qualifications, but are taken upon recommendation, and the length of their service is dependent upon the emergency or circumstance which required their employment. The gradual concentration of army posts renders it now possible to dispense to a great degree with this class of doctors. In the case of Dr. Frick, there is no good reason why he should be preferred over many others who have done good and meritorious service as contract surgeons, and if the precedent is established in his case the result will be similar legislation in many other cases; by which the Medical Department will be filled by men who are rapidly passing the age of efficiency, and who in many cases are unfit for the position by lack of education and professional acquirements."

The Senate adopted the bill (S. 1559I; see page 272) to define the titles and duties of officers of the Medical Department of the U.S. Army.

April 25. Mr. Blair, from the Committee on Education and Labor, to whom was referred the bill (S. 1484; see page 272) to provide for the study of physiology, and the effect of intoxicating, narcotic, and poisonous substances upon life, health, and welfare, by the pupils in the public schools of the Territories and the District of Columbia, reported it to the Senate without amendment.

Memorials and petitions from citizens of Connecticut, South Carolina, New Jersey, and Louisville, Kentucky, have been presented in the Senate, protesting against the discriminations now made in the Army, Navy, and Civil Service appointments (excepting the Pension Office) between different schools of medicine.

THE TONER COLLECTION IN THE LIBRARY OF CONGRESS.—This collection, which was donated in 1882, and accepted by a special Act of Congress, May, 1882, from Dr. Joseph Meredith Toner, of this city, consisted of his own private library, embracing over 27,045 volumes of books, besides 12,000 pamphlets and periodicals, and contains much valuable material in the local history of States, counties, and towns, in biography, in medical science, in early imprints, etc. The last report of the Librarian of Congress, Jan. 30, 1884, shows that this donation is still being added to by Dr. Toner to a noteworthy extent; thus, in the past year he has added 470 volumes of books and 3,755 pamphlets, making the figures show 27,515 volumes and 15,755 pamphlets. Among the accessions is an extensive collection of authentic portraits of American physicians and surgeons, including many of early date, which have been fully indexed for ready reference. Mr. Spofford says further—"The frequent calls upon the Toner collection for information upon points of biography and history, as well as medical science, evince the utility of this addition to the stores of the Library of the Government."

EDITOR OF THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION:

In reading the valuable and interesting compilation of reports of cases of hydronephrosis, and tabulation of operations with results, by Dr. G. A. Staples, as published in the issues of April 12 and 19 of your journal, in the report of the interesting case, No. 49, I find two points upon which the report is inaccurate, and desire the privilege of correcting it. Upon page 422 he says: "The affection had been diagnosed by various physicians of St. Paul, St. Louis and Dubuque as tumor of the spleen, phantom tumor, etc. No therapy advised had been of service. Dr. Staples diagnosed hydronephrosis, but his opinion was not sustained by any other surgeon consulted." Lower on the same page he says: "It is proper to add that the increased flow of urine after a 'spell' had not been noticed until Dr. Staples called attention to the fact by his inquiries." As stated, during the twenty years of the existence of this trouble, a number of physicians had been consulted, of whom I was among the earlier ones. I first saw the case in 1867. At that time the attacks were less severe; rest in the recumbent position usually affording prompt relief. In the fall of 1869, the attacks having become more frequent and protracted, my attention was called to the case. After a careful investigation, I was led to believe the trouble involved the kidney. The correctness of this opinion was verified Dec. 11, 1869, when the patient, at my request (previously made) during an attack, allowed it to proceed until the tumor became perceptible, then emptying the bladder as completely as possible, she assumed a position upon her back on a firm surface, with her clothing loosened. She experienced a sense of relief, and upon rising again emptied the bladder in a fresh vessel, voiding a quantity of urine much greater than could have been normally secreted during the time involved. My diagnosis was, "obstruction of the ureter where it leaves the kidney."

I could find no history of hæmaturia or renal colic, yet the fact that assuming the position described above, with the shoulders as low, or lower, than the hips, had often afforded relief, led me to infer it might be due to a smooth calculus closing an enlarged ureter, which would be dislodged by the position described. Upon informing the patient of this diagnosis, I was asked if I could promise them a radical cure. My reply was, "that while I felt confident of being able to afford relief and probably ward off attacks, a radical cure would require an operation involving dangers that were not justified by the case at the time." Because of my unwillingness to assure

definite results, my connection with the case ceased, and it passed into the charge of a prominent homœopath, who, I was informed, diagnosed and treated it as a case of ovarian disease. Subsequently the case was under the care of Dr. N. M. Hill, who, in the spring of 1877, without knowing the details of my diagnosis, made one practically the same, and verified the fact that relief from pain was coincident with an increased flow of urine. Soon after making this diagnosis known, the doctor's services were dispensed with.

The above earlier history of the case having occurred before the writer entered upon the study of his profession, it is not surprising it should have been overlooked in the statement or notes he received from his father, Dr. Geo. M. Staples.

WM. WATSON, M.D.

Dubuque, Iowa, April 23, 1884.

MISCELLANEOUS.

CARPENTER, J. M., M.D., of New Lancaster, Kansas, was born Dec. 17, 1838, in Lockport, New York; died August 8, 1882, aged 44 years. He came to Kansas in 1857; served in the Army during the war of the Rebellion. He commenced the practice of medicine as an under-graduate in 1866, at New Lancaster, and was remarkably successful. He graduated at Miami Medical College, Cincinnati, Ohio, in the winter of 1871–'72; afterwards took post-graduate course at Rush Medical College, Chicago, Ill. He was an energetic worker in the State Society, and had attained an enviable reputation as a surgeon. He was a delegate from the State Society to the American Medical Association in 1878, and again in 1882, at Buffalo, N. Y. He died at New Lancaster, Kansas, universally lamented.

ORIGINAL ARTICLES.

ON THE REMOVAL OF NASO-PHARYNGEAL FIBROMATA BY THE GALVANO-CAUTERY, OR COLD-WIRE ÉCRASEUR.

BY E. FLETCHER INGALS, A.M., M.D., CHICAGO.

Read to the Section of Ophthalmology, Otology and Laryngology of American Medical Association, May 6, 1884.

Naso-pharyngeal fibromata usually have their origin in the periosteum which covers that portion of the base of the skull forming the roof of the naso-pharynx.

These tumors may extend downward into the mouth, forward into the nasal cavity, or upward, perforating the cranium and pressing upon the brain.

When large, they not infrequently send off prolongations into the maxillary sinus, and in some cases the frontal and sphenoidal sinuses are involved, consequently in some instances great deformity of the face results.

Owing to the obstruction thus caused, respiration and deglutition may be seriously interfered with, and in consequence of the pressure, the senses of hearing, sight, and smell are more or less impaired.

These growths are hard to the touch, and are usually rounded, having a smooth surface, slightly lighter in color than the surrounding mucous membrane; sometimes, however, and particularly when the nasal cavities are involved, these tumors are lobulated in form.

Some of them grow slowly, but in other cases they increase in size with great rapidity; and, unfortunately, they are quite liable to return after removal.

Aside from the symptoms already referred to in connection with the special senses, they may cause severe pain, frequent epistaxis, and constant catarrhal discharge. They eventually disturb the sleep, and prevent the patient from taking sufficient food; exhaustion supervenes, and ultimately, if not removed, they are liable to prove fatal.

Various forms of treatment, such as the local application of chemical agents and electrolysis, have been tried, but nothing short of a complete destruction of the growth by operative measures can give satisfactory results.

The operation recommended by surgeons, consists in tearing or gouging out the tumor after access to it has been obtained by removal of the hard and soft palate, or the superior maxillary bone, the latter being the procedure generally resorted to.

Within a few years laryngologists have demonstrated the practicability of a much safer operation, which has thus far been attended with better results than when the maxilla has been removed.

This operation is performed with the galvano-cautery, or steel wire écraseur, the loop being passed through the nostrils in some cases, and in others through the mouth and up behind the soft palate.

Within the past two years I have operated on four cases of naso-pharyngeal tumors by this latter method, and with better results than could have been obtained by excision of a part or the whole of the superior maxillary bone.

CASE I.—Fibroma. In May, 1881, I operated upon the first case of this kind which had come under my observation.

The patient, J. W., æt. 21, stated that about twenty months previous he had contracted a severe cold, since when he had been unable to breathe through the right nostril, excepting with forced respiration, and then but slightly. The left nostril had also been occluded whenever he had a cold, but at other times it had been comparatively free.

Rhinoscopic examination revealed a large ovoid tumor blocking the right posterior nares and overlying about half of the left. With the galvano-cautery écraseur I removed the larger part of the growth, and would have secured all had not the current failed me, so that I was obliged to readjust the wire, which the bleeding prevented me from doing perfectly.

Prof. I. N. Danforth made a microscopic examination of the tumor, and pronounced it a small-celled sarcoma, the most benignant of the fibromata.

A few weeks later the remainder of the growth was perfectly removed by the galvano-cautery écraseur.

Sixteen months later I found a small tumor at the seat of the old growth, about the size of a hazel nut. This I removed with Jarvis' écraseur.

At the present time, two years after the original operation, a small sessile swelling may be seen at the posterior end of the upper turbinated bone. This presents no point where the écraseur could be made to hold, and as it has enlarged very slowly, I have not attempted to cauterize it.

CASE II.—Fibroma, H.L., aged 19. Was brought me by my friend, Dr. F. E. Olney, of Warsaw, Ind. I found a large naso-pharyngeal growth, which presented slightly below the soft palate, and filled the naso-pharyngeal space.

It had been annoying him very much for twelve months by preventing nasal respiration and causing profuse discharges. The tumor was so large that I

found it impossible to pass Bullocs' canula or an Eustachian catheter through the nares. However, after much difficulty, I succeeded in passing a small, soft rubber catheter through the right nares. In doing this, all excepting half an inch of the distal end of the catheter had been kept rigid by the stylet, so that when pressure was made the flexible end insinuated itself between the growth and the palate, and was finally forced into the larynx. A string was then attached to the catheter, and by means of this an elastic band was drawn through to tie the soft palate forward; and subsequently a loop of platinum wire was drawn back into the mouth.

The loop was opened, and by patient manipulation for about three hours, it was carried up until it encircled the base of the tumor, close to the bone from which it sprang. The ends of the platinum wire were then pushed through the tubes of an electrode, which was forced back to the tumor.

The handle with which the conductors from the battery were connected was then attached, the platinum wires fixed to the ratchet, and the current turned on; but I soon found that a short circuit was established through the metallic axle of the rachet wheel. I then removed the wheel and attached the wire to a lead pencil, by means of which traction was made and the tumor rapidly cut through.

The base of the tumor was divided quicker than if the ratchet could have been used, and as a consequence profuse bleeding ensued, which, however, was checked in a short time by the insufflation of tannin upward behind the palate.

The tumor was slightly nodular in form, and measured one and one-half inches in its antero-posterior diameter, and one and three-fourths inches in its vertical diameter.

It had been cut off close to the basilar process of the occipital bone, to which it had been attached by a pedicle three-quarters of an inch in diameter.

The patient returned to his home the same evening. The cut surface healed over promptly, and for two months he seemed perfectly well, but at the end of that time Dr. Olney noticed that the growth was reappearing. It grew rapidly for about two months, when it had attained nearly half its former size, since when it has remained stationary.

The patient's general health is now perfect. The tumor will be again removed as soon as the patient can spare the time, and then the stump will be thoroughly cauterized.

CASE III.—Fibroma. J. H., aged 26, came to me during the latter part of the winter of 1882–3, complaining only of a slight cold. I noticed a peculiar lack of nasal resonance in his voice, which directed my examination to the naso-pharynx, when I found a tumor about the size of a hickory nut, which, from its position, and from the movements that could be given to it with a probe, seemed to be attached to the upper portion of the posterior border of the vomer.

With a modification of Jarvis' écraseur, half an inch of the end of which had been bent up at nearly a right angle, I passed a steel wire behind the palate and ensnared the tumor.

Up to the time when the tumor should have been nearly cut off, I had no difficulty in tightening the wire by the milled wheel, but afterward it became almost impossible to turn the wheel with the fingers. However, the wire was gradually tightened, and finally, with the aid of a pair of pliers, such as used by gas-fitters, the wheel was screwed down until the wire was released. The tumor presently dropped into the mouth, and was spat out. Upon examining the instrument, it was found that the great difficulty had been caused by the soft tissues being drawn into the end of the canula, which had been split down to the angle by the pressure. The tumor had the form of a flattened sphere, measuring one-half inch in its thickness.[1] Afterward another similar growth was detected in the posterior part of the left nasal cavity, which subsequently came down into the naso-pharynx. I have made one attempt to catch the tumor in the snare, but failing on the first trial, I was obliged to defer the operation for want of time.

CASE IV.—Fibro-Myxoma. A. P., æt 32, machinist, came to the Central Dispensary in December, 1882. He gave the following history: When two years of age, his mother noticed something growing in his nose.

Nothing was done for it until he was fourteen years of age, the growth having increased slowly in size during the interval. He was then operated on, and a large mass was removed.

He was free from the trouble for some time, but at the age of nineteen it had returned so as to necessitate another operation.

From that time until about a year before coming to me he had been free from the trouble.

Upon examination, I found a large growth completely filling the right nasal cavity, and closing the left by pressure.

It also passed back and filled about half the naso-pharynx.

The pressure caused considerable deformity of the nose. After several futile attempts to tear away the anterior portion of this tumor with forceps, about a third of it was cut off with galvano-cautery wire loops. Finally, with a modification of Jarvis' snare nearly all of the growth has been removed, so that there is now no obstruction to nasal respiration, but the treatment is not yet completed. In this case it was impossible to engage any considerable portion of the tumor at once, as the instrument could not be passed through the nose until most of the growth had been taken out; therefore, at each sitting, I removed two or three pieces about the size of filberts, and then allowed the patient to go.[2]

At the meeting of the American Laryngological Association held in New York, in May, 1883, Dr. Rufus P. Lincoln presented three cases which he had operated upon successfully by the galvano-cautery écraseur. For the sake of comparison, he also gave a tabulated statement of the results of seventy-four operations for naso-pharyngeal tumors which he had found reported.

---

[1] Dr. E. P. Davis, of this city, examined the growth microscopically, and reported it almost wholly fibrous.

[2] Dr. E. P. Davis found this to be a fibro-myxoma.

The statement which has been furnished me by Dr. Lincoln is substantially as follows:

The seventy-four operations were performed on fifty-eight patients.

Thirty-nine operations were done upon twenty-eight patients by section of the facial bones or laying open of cicatrices resulting from previous operations of the same character. Of these, in thirteen, the record ceased shortly after the operation, and the final results were unknown. Of the fifteen remaining, eight died from the operation, and in three others it nearly proved fatal, while in only four was there no return of the tumor within a year.

Seven operations were done on seven patients by scissors, knife or forceps. One of these died, five were lost sight of, or no subsequent report was made, and in only one are we told there was no recurrence within a year.

Two cases had been treated with injections of chloride of zinc, or cauterization by the same agent. In one the tumor returned, the other case was lost sight of. Three cases were treated by electrolysis. One did not recur within a year; the others disappeared. Of these forty cases, in twenty-one the history after the operation was incomplete, and probably not favorable to the operation.

Nine, nearly one-fourth of all the cases, or about one-half of those in whom the history was complete, died, and only seven remained well for one year.

Contrasting with these the cases operated upon by the ordinary écraseur, or ligation, we find that of eleven operated on none were fatal, two were lost sight of, and of those remaining there was no recurrence at the end of a year in four cases, which is a very much better showing than for the preceding operations.

Nine have been operated on by the galvano-cautery écraseur, and one by the actual cautery. None of them were fatal; two were lost sight of, and six were well at the end of a year, results infinitely superior to those of any of the other methods.

The remarkable success of this form of treatment is doubtless due to thorough cauterization of the stumps of the tumors, which has been practiced in several instances. In my own cases, the stumps of the tumors have not been cauterized.

In one there was no recurrence at the end of a year. In another there was speedy recurrence.

In the others the operation is not yet completed, and as they were dispensary patients, the disagreeable symptoms having been removed, it is probable that I will not see them again until the tumor has regrown sufficiently to be annoying.

From my experience in these cases, I believe that either with the galvano-cautery or with the steel wire écraseur the great majority of these tumors may be completely removed, and, as has been shown by Dr. Lincoln, if their bases are thoroughly cauterized with the hot wire, they are not likely to recur.

The results thus far are greatly in favor of this method of operating over that usually advised by general surgeons, for this leaves no scar, the tumors are less likely to recur, and the risks of the patient are infinitely less.

JEQUIRITY.

BY T. E. MURRELL, M.D., LITTLE ROCK, ARK.

[Read before the State Medical Society of Arkansas, at the Eighth Annual Session, Little Rock, May 30 and 31, 1883.]

Jequirity, *abrus precatorius*, is a small shrub of the order of leguminosæ, growing in tropical America, which bears a beautiful coral-like bean, commonly known as licorice bean. In Brazil the natives have a formula for making an infusion from the bean, which they use in granular conjunctivitis. According to the formula, 32 beans make about two pints of the infusion. The method of using it is to brush it on the inner surface of the lids, instil it into the eye, or apply it on compresses to the outer surface of the lids, by means of which some of it comes in contact with the conjunctiva and cornea.

The literature on the use of jequirity up to the present time is rather meager. In the *American Medical Weekly*, of January 20, 1883, there is this notice:

"Jequirity in Granular Conjunctivitis. This drug, so much vaunted of late in the treatment of granular conjunctivitis, has not yielded very good results in the hands of Dr. Ferrier. Cardoso, of Rio Janeiro, claimed to have secured excellent results by the use of a topical application of one part of the drug to one hundred of boiling water to the granulations. Wecker has had the same experience as Ferrier."

It seems that a different construction has been put on De Wecker's report of his use of it, which I have not seen, by Dr. Gruening, of New York. In the *New York Medical Record* of May 17, 1883, he says: "The gratifying results obtained by De Wecker in his cases of chronic granulation and corneal opacity, induced me to employ the infusion in a few cases of inveterate pannus." Gruening then reports two cases where he used the infusion of licorice bean with the most gratifying results. One was a man 55 years of age, and the other a girl of ten years. In ten days both were dismissed with smooth lids, free of granulations, and a total disappearance of the pannus.

Now and then one comes across a case of granular conjunctivitis that fails to yield to all ordinary or extraordinary treatment; where there exist excessive granulations and inflammatory infiltration of the conjunctiva, a dense and perhaps fleshy pannus, with intense photophobia and lachrymation, completely wearing out the sufferer, and rendering him hopelessly blind.

I had just such a case on hand when I read Dr. Gruening's paper, and at once wrote to Mr. Richard Fingerhut, druggist, 404 Fourth Ave., New York, for some of the beans. He wrote me that he sold the infusion ready prepared, and so I ordered a pint of the infusion. I used it as did Dr. Gruening, brushing it on the conjunctiva three times daily, and keeping a cloth wet with it on the eyes almost constantly.

The patient had been suffering most excruciatingly for several weeks. The pannus was so dense that he could only perceive light, the right cornea had

yielded, and was in a condition of kerato-conus, and the inflammation was of a severe type, the villi of the palpebral conjunctiva being greatly hypertrophied and engorged.

Twenty-four hours after commencing the use of the infusion, a scarcely perceptible change in the inflammatory process had begun. Forty-eight hours brought a well-marked increase of the inflammation, with beginning œdema of the lids, some increase of pain, and a beginning diphtheritic membrane on the conjunctiva. Three days' treatment increased all the symptoms, with a well-marked diphtheritic membrane covering the whole conjunctiva. A microscopic examination of it showed a fibrinous mesh filled with pus and mucous corpuscles, and young epithelia. The patient began now to complain bitterly, and insisted on stopping the medicine. I ordered it continued, with the effect of only very slightly increasing the inflammation in two more days. There now appeared a tendency to furuncular inflammation in the lids, necessitating opening at one point two or three days later, to evacuate the pus. At this period, the infusion was stopped, and a ten-grain solution of boracic acid was directed to be used freely. The inflammation rapidly subsided, and in four or five days had about disappeared. The conjunctival surface was now smooth and rather glistening, the cornea was almost totally free of vascularity, but uniformly opaque; and the patient, for the first time in many weeks, felt comfortable, and was able to sleep soundly. He was much encouraged, and so was I. No decided change in the acuteness of vision occurred, however, contrary to expectation. While the blood-vessels disappeared from the cornea, the infiltration remained. The eyes remained in *statu quo* after about the fifth day from stopping the infusion for about three weeks. The old trouble seemed to be now returning. There was a good deal of vascularity of the cornea and inflammation of the conjunctiva, with photophobia, lachrymation and ciliary neuralgia. I again put him on the jequirity, used as before. From the first, he said it felt soothing, and in twenty-four hours he experienced much relief. This could not well be attributed to the moisture, since he had been freely using water to his eyes previous to the treatment without such relief. The inflammation now began to assume a muco-purulent character, without at any time forming a diphtheritic membrane. By the fifth day, there was considerable œdema of the lids, with a free muco-purulent discharge from the eyes. The jequirity was now discontinued, and only cold water used on the eyes. The inflammation as rapidly subsided as under the boracic acid, the vascularity disappeared, and in a few days the conjunctiva was smooth and glistening. The cornea began clearing, and up to this time, about ten days from the leaving off of the infusion, vision has improved from mere perception of light to counting fingers at arm's length, with a steady and quite perceptible increase of visual power from day to day.

Before the treatment the pupils were not visible through the opaque and vascular corneæ by oblique illumination with a condensing lens. Now the whole iris is distinctly seen by the same method.

The right cornea seems to be clearing equally with the left, but owing to the excessive alteration of curvature, but little practical vision can be expected with this eye.

There is now no photophobia or ciliary neuralgia, and the patient is quite comfortable.

How long improvement will continue and when stop, and whether the granular conjunctivitis will again return, remains to be determined. From the present smoothness of the lids one would infer the absence of danger of a return.

The short history of this method of treatment in this country does not yet admit of any reliable statistics on this point.

What the peculiar principle in jequirity is that causes it to excite a muco-purulent or diphtheritic inflammation of the conjunctiva, that so rapidly subsides when the remedy is stopped, remains so far a mystery. It cannot be an irritant, since it is perfectly bland when applied to the conjunctiva, and it is only after one or two days' constant use that any inflammation is excited by it.

The infusion is a slightly opaline fluid, with a very small quantity of flocculent sediment. It has a faint narcotic smell, but I have not adventured so far as to taste it. The microscope shows the sediment to consist almost entirely of masses of rod-shaped bacteria, while throughout the fluid they are found in considerable numbers.

After a few weeks, a peculiar fungus scantily develops in it.

The finding of the bacteria was somewhat startling to me, since Mr. Fingerhut had written me that the infusion would keep indefinitely; so I wrote him to know if they were peculiar to the fluid, or accidental, or, perhaps, *the active principle!*

In reply Mr. F. wrote as follows: "Your observations are in every regard corresponding with others, hence the theory that the infusion only acts as a *lymph*, or the transplantation of bacteria. I, personally, am of another opinion, and will surrender only when all results experienced are in favor of the bacteria theory. I have reports from different parts, and although unable to form a satisfactory judgment about the cases, it seems that the majority support the bacteria theory."

In examining the diphtheritic membrane and discharges from the conjunctiva I had expected to find the same kind of bacteria as in the infusion, if they were the specific agents in causing the inflammation, but I did not succeed after very close search.

Thus stands the subject to date. From reports coming in from the proceedings of medical societies, the trial of jequirity in granular conjunctivitis is being extensively made. It is to be hoped that in it we have a remedy for that most formidable and hitherto often irremediable condition of inveterate pannus and chronic granulation of the lids.

When its method of action has been established, and its clinical uses discovered, it may be found not to act injuriously on the healthy cornea, and may prove curative of granulations in the more recent stages, thus obviating the disastrous consequences so characteristic of granular conjunctivitis.

SUPPLEMENTARY REPORT ON THE USE OF JEQUIRITY.

The above paper has been three months in the hands of the publication committee, and during that time I have had under observation the patient submitted to the jequirity treatment, and up to this writing, September 4, his lids have remained free from granulations, and but for the staphylomata, which had occurred previous to the treatment, his vision would doubtless have been quite good.

Within this time I have also treated one other case with it which is deserving of a short notice. This time I procured some fresh beans and made the infusion myself, and began its use as soon as ready.

The effect was almost immediate, setting up a purulent conjunctivitis in twenty-four hours, with great pain and œdema of the lids. Patches of false membrane appeared on the conjunctiva in thirty-six hours, and by the end of the fourth day the inflammation had run so high, and the suffering of the patient was so intense, that the applications had to be stopped. Boracic acid solution and cold water were now freely used, but the pain and photophobia continuing, an examination was made to ascertain the cause, and to my chagrin I discovered that I had a case of iritis with strong pupillary adhesions to deal with. A six grain solution of atropine was immediately applied, which, in a few minutes, produced intense pain followed by great œdema of the lids. A two grain solution was then tried with similar result. About six hours' disuse of the atropine sufficed to restore the eye to its original condition, but another application was quickly followed by the œdema of the lids and acute ciliary pains.

The jequirity in this case seemed to render the eye susceptible to atropia, as it had been repeatedly used before with no untoward effects.

In this patient there was pannus of the upper half of the cornea, with a small, central, clear-cut corneal ulcer. The keratitis was greatly increased by the jequirity, and a small onyx was formed at the lower border from gravitation of pus. In a week after stopping the jequirity the infiltration of the cornea had disappeared, it was nearly avascular and quite transparent. The granulations of the lids seemed to be entirely removed, leaving them smooth and pale. At the present writing, the patient is nearly relieved of his iritis, which will leave some posterior synechiæ, on account of his inability to bear atropia. The other eye was not treated with the jequirity; as it had rather a deep corneal ulcer with but little pannus, I feared a diffuse keratitis, a fear which was perhaps well founded, seeing the effect on the eye that was so treated.

The question as to the active agent in the jequirity which excites the peculiar form of conjunctivitis, was well proven to my mind, in this instance, not to be bacteria. The microscope showed no bacteria whatever when beginning its use, and its effect was quicker and more powerful than the preparation formerly used, which was some days old and contained abundance of bacteria. The specific agent is evidently some principle in the licorice bean, and it remains for chemistry to separate it.

April 21, 1884.

As the foregoing reports have not yet appeared in print, I will bring down to date my experience with jequirity, and give an account of some experiments I have made with it in comparison with other infusions microscopically studied.

To state in general terms, without reporting special cases, I find that the grade of inflammation is proportioned to the strength of the solution, and the freedom with which it is employed. Of the strength commonly used, and as I have used it, constantly applied with compresses wet with it, the effect is quick and reaction high, running sometimes a violent course; but if dropped in the eye, or brushed on the everted lids, three or four times daily, it induces to only a mild croupous conjunctivitis, which may be kept up for a much longer time than by the other method, and with much less suffering to the patient and risk to the eye.

Some cases of purulent corneal infiltration and severe iritis have led me to regard the cautious use of this remedy important.

I have found in several cases a return of the granular conjunctivitis after one course of treatment by the De Wecker plan, but have found them amenable to a second course, after which I have so far known of no recurrence. The milder inflammation, longer continued, seems equally as effective, and perhaps more so, and is decidedly more tolerable to the patient.

It is best to instil atropine into the eye daily while under the treatment, to guard against iritis.

I now prepare the infusion by crushing three or four beans with pincers, and having put them in a two-ounce bottle, add water, and keep them in a warm room. In twenty-four hours this is ready for use, and this amount is sufficient to treat two or three patients. The bottle should occasionally be shaken, to insure mixing. The opaline supernatant fluid contains all the strength of the infusion.

The opinion entertained by many, that the peculiar effect of jequirity is due to a bacterium, has led me to investigate this somewhat. As is known, this bean belongs to the leguminosæ, and when crushed, or in infusion, has a striking narcotic odor, more or less possessed by all the species of this order.

By way of comparison, I prepared a two-ounce infusion of jequirity and several other kinds of beans at the same time, and studied them daily for some time. Here is the result:

INFUSION TWENTY-FOUR HOURS OLD.

Jequirity—A few active rod bacteria; strong narcotic odor.
Early English pea—No bacteria; no narcotic odor.
Marrow-fat English pea—No bacteria; no narcotic odor.
Large black bean—Numerous rod bacteria, with little motion; faint narcotic odor.
Large striped bean—Rod bacteria, some sluggish, some in active motion; faint narcotic odor.
Large flat white bean—Rod bacteria, a few sluggish, a few active; faint narcotic odor.

INFUSION FORTY-EIGHT HOURS OLD.

Jequirity—Bacteria multiplied considerably, some sluggish, some active; odor unchanged.
Early English pea—An occasional rod bacterium seen in slight motion; odor unchanged.

Marrow-fat English pea—No bacteria; odor unchanged.
Large black bean—A great abundance of rod bacteria, some active, some sluggish, some in zoogloea masses; odor unchanged.
Large striped bean—A great abundance of rod bacteria, some having many joints and forming chains; odor unchanged.
Large flat white bean—Myriads of bacteria, many actively moving, but the majority formed in clusters and zoogloea masses; odor unchanged.

INFUSION THIRTY-SIX HOURS OLD.

Jequirity—Same as last examination.
Early English pea—Myriads of bacteria and micrococci; odor putrid.
Marrow-fat English pea—Myriads of bacteria and micrococci; odor putrid.
Large black bean—Bacteria in great abundance, singly and in masses; odor somewhat disagreeable.
Large striped bean—Same as the black bean.
Large flat white bean—Same as the last two.

By the next day, the three bean solutions had become strongly disagreeable from the odor of decomposition, and were opaque with bacteria and micrococci. The jequirity continued the same from day to day, there being no increase of bacteria after forty-eight hours as long as kept, and at the end of two weeks it was free of any odor of decomposition, and retained without loss the characteristic smell.

The bacteria were now less active than when the infusion was fresher, scarcely moving at all and not very numerous, in fact, they were never numerous compared with the other infusions when thirty-six hours old.

In real warm weather, the infusion of jequirity takes on a faint odor of decomposition after several weeks. From my studies I infer that,

First. The specific action of jequirity depends on some property peculiar to the bean itself, and not to the bacteria, which accidentally develop in the infusion.

Second. There is a preservative principle in the bean which resists decomposition to a remarkable extent.

Third. The infusion of jequirity is inimical to the successful development of bacteria, and restrains their multiplication.

NEW ORTHOPEDIC AND FRACTURE APPARATUS—THE UNIVERSAL SUSPENSION SPLINT.

BY DR. W. P. VERITY, CHICAGO, ILL.

[Read before the American Medical Association, meeting of 1883.]

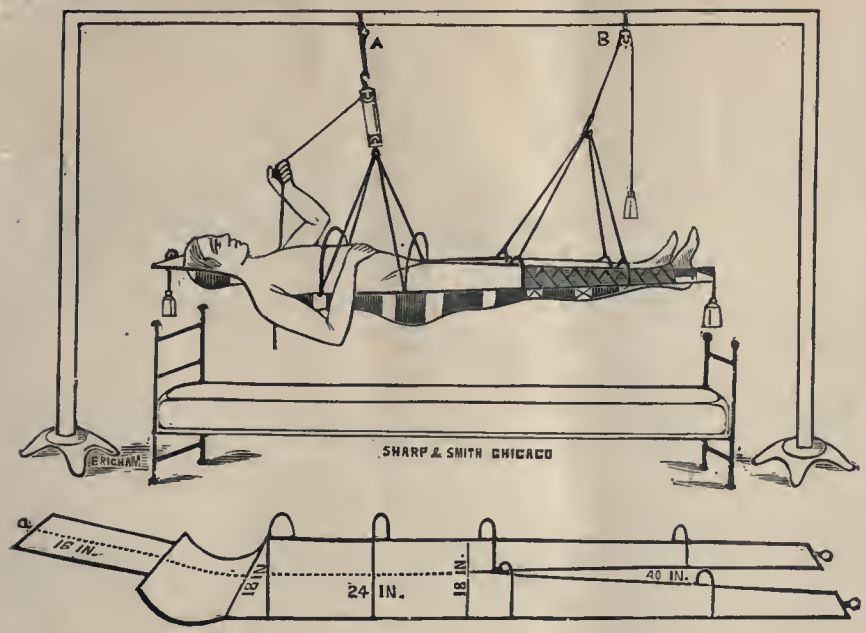
This splint can be made of gas pipe or rod iron; the first is preferable, and if it be used, one-half or five-eighths inch pipe should be employed for adults, and three to four-eighths inch pipe for children. The splint consists of a headpiece, body, extremities and arches. The arches over body should be made of material of the same size as the body of splint, and those over extremities of lesser size; arches should in all cases be twelve inches high. For children, one arch over the body and one over each extremity will be sufficient. If the adjustment be employed, the latter are unnecessary, as they interfere with its working. The dimensions may be arranged to suit the case. If the patient be five feet long, and sixteen inches broad across the shoulders, the splint should be sixty-six inches long, and twenty inches broad across the shoulders are all that will be necessary. Three sizes in practice to meet the usual emergencies.

Cut 1 illustrates the type of splint first made in 1880, which was made of rod iron.

Cut 2, the present form of splint, made of gas-pipe.

The adjustment is seldom deemed necessary, and the arm-rests at A, while convenient, can be dispensed with. The standard B, passing upward from the perineal portion of splint to a horizontal connection with the body arch, is indispensable, since it is needed to give strength to the apparatus and increased facility to the operator. As seen in cut 3, adjustment is obtained by having one joint inside of splint E, A, and one at the junction of the standard B with the rod I; the latter telescoping into the gas-pipe G, and is held at the desired point with set screw H, and this permits of any desired amount of abduction, as shown by the dotted lines. The foot-piece, of sheet iron, is constructed so as to slide upon the gas-pipe with but little friction. The rubber band, C, is tied to the foot of the splint into eyelet of set screw, which last fixes the foot piece at any desired degree of *inversion* or *eversion*. As the extremity is considerably wider at I than C, the foot-piece is easily removed by sliding in the direction of G. The foot-piece is rarely an absolute necessity.

In applying the splint, it should be suspended from the ceiling or a frame by compound pulleys, as shown in cut; common clothes line can be employed, and should be tied to the arches or sides in such a manner as to equalize the weight on the pulleys, and prevent undue strain on the joints of the splint; two compound pulleys are needed for adults; one will suffice for children. While the splint is being applied, the patient should lie on a mattress without pillows; the splint is placed over the patient without touching him at any point, and allowed to rest only on mattress. Strips of any firm cloth; canvas is the best, should now be passed under the patient, and the ends of the same should be fastened over the sides of the splint by stitches, pins, buttons or hooks. For the body it is best to use one piece, reaching from the coccyx to the cervical region. Care should be taken that the cloth is free from wrinkles. (The patient and splint should generally lie flat on mattress, and not remain for a long time elevated above it; a change of this kind rests the patient. A pillow may be placed between the head and the splint. If an extensive burn exists on the back, the patient can lie face downward on hands. If one leg only be injured, the other leg can be left free. In case the patient be of such a size as to render the splint unavailable, the mattress should be turned diagonally to the



Figures 1 and 2.

bed, and the splint applied; the bed should then be replaced by a cot). When this is done, the splint is applied.

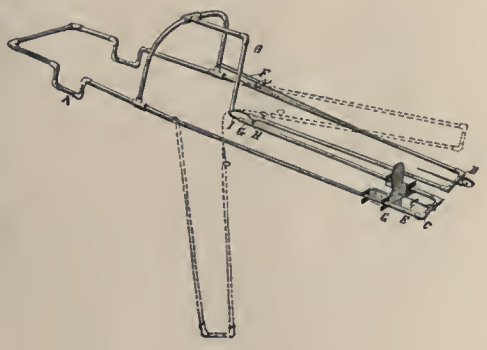


Figure 3.

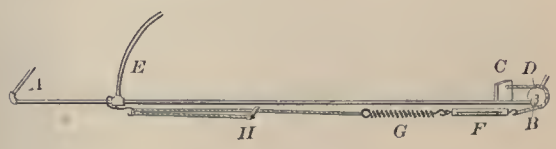
The application of the splint is almost universal. Its chief recommendations are: The ease with which it is applied, whatever be the nature of the injury; its perfect safety; the comfort experienced by the patient in the ease with which his wants are attended to by any one, without disturbance to the injured parts; the readiness with which the surgeon can rearrange dressings independently of the situation of the injury; the ease with which the bed is cleaned without discommoding the patient. The band can easily be rearranged. In a complicated case, where extensive wounds or bed-sores exist, the patient should be placed on a cot, to secure convenient access on either side; he should be raised two feet above the bed; if now the bands require change and the patient needs washing, he can be supported temporarily, but firmly and securely, by passing two pieces of leather belting two inches wide diagonally under him, which cross at sacrum, and are fastened to the sides of the splint by hooks; thus all support can be removed, and the most extensive surface carefully dressed. This done, the dressings should be arranged on the bed in the desired order of application, and then the patient let down on them, the belting removed, and the bands of support applied as at first. An air pillow can be used, and any variety of dressing; a fracture box, plaster cast, or oakum can be attached to patient or splint in the most satisfactory manner.

Extension of both extremities and head can be obtained when required. It can be secured by weight, pulley, rope and spiral spring, as shown in the following cut:



A, head part of splint. B, rope over the pulley D. C, block for adhesive plaster from lower extremity. E, body arch. F, scale indicating amount of extension. G, spiral spring. H, regulator of amount of extension. If marked counter-extension is required at the foot of splint, can be elevated with a compound pulley.

Surgical Uses.—These are numerous: In fracture of the vertebræ, pelvis, thigh, leg, or both lower extremities; resections of hip or knee; extensive burns or bed sores, etc.; operation for radical cure of hernia, it will be found of value, since the patient can readily be controlled in it.

Medical Uses.—In inflammatory rheumatism, paralysis, low fever, or any disease which renders the patient helplessly bed-ridden, and necessitates change of the patient for cleanliness, etc., the splint proves of great service.

A Derrick and Improved Suspension Apparatus for Application of Plaster Casts.—The original feature about the present is the derrick which is constructed of four hardwood strips, A, B, C, D, joined together in such a manner that the strips become parallel when folded, as indicated at E. The nature of the derrick can be ascertained from the cut. The strips should be three inches broad, an inch thick, and three feet long. In strips C and D is a slat, H, which permits of adjustment for any emergency, and is fastened with a thumb screw. The range of adjustment is indicated at E, F. The

strip B projects over D two inches, and at this point is a slat admitting a knotted rope at H, which serves for the suspension apparatus, rendering unnecessary the use of hooks, bolts, etc. This derrick can be used under almost every conceivable circumstance. It is attached by the clamp G.

THIS SUSPENSION APPARATUS, like other suspension apparatus, is used with a compound pulley, but unlike all other apparatus, is economical, easily applied, and does not incommode the patient, as there is no buckling connected with it. The method of adjustment is seen in the cut. The head piece is applicable to any person.

THE PORTABLE NATURE of the whole apparatus may be judged from cut above, which shows the whole apparatus arranged for transportation.

MEDICAL ETHICS.

BY DR. E. H. BOWMAN, ANDALUSIA, ILL.

[Read before the Iowa and Illinois Central District Medical Association.]

It is with great diffidence in myself that I presume to call the attention, and occupy any of the time of your honorable body, to the fact that, as a profession, we have a National Code of Ethics. The time was, in the not very remote ages of the past, when the profession did not have any code of morals, when every member was a law unto himself, and the majority seemed practically to adopt the Ishmaelitish tactics, involved in the patriarchal description of the progenitor of the tribe of Ishmael, viz.: "His hand is against every man," in the practice of the medical profession. As a consequence, the sense of justice, honor, and fidelity to truth (which nowhere on earth finds more fitting and appropriate lodgment than in the bosom of our profession), was, by the eternal law of self-preservation, compelled to obey the other eternal law of evolution, and formulate some of the most important principles involved by its relations with the world, and themselves, into a code of ethics. There may be men who call themselves doctors, who may be surprised to learn that the profession has any moral principles at all. And there are doubtless hosts in the outside world to whom it may be surprising news that there are any such ideas as justice, honor, and fidelity to truth, in the foundations of the temple of medicine. Let us glance for a moment at the field occupied by the science of medicine, for it is a fact that it has grown from the lowest plane of fetichism, with the grossest conceivable superstitions, into the magnificent proportions of a temple of science. Man, so far as we know, is the culmination of the great law of evolution on this planet. In him all lines of development meet and rise to the plane of the moral and spiritual being, with faculties to take in and comprehend his relations with the universe. He is the microcosm, in his own self-epitomizing the macrocosm. Our profession is the only one on earth that takes for its sphere this wonderful product of evolutionary force, in its

entirety. All other professions are limited and partial in their range and scope, dealing only with certain limited interests and faculties, in partial relation to the whole. Our profession comprises in its grasp every cause that operates on man from his lowest relations with the world of matter, up to the highest intellectual, moral, and spiritual developments and relations. There is no conceivable phase in the origin, development and termination of human life, that does not come within our sphere legitimately and necessarily. These premises being incontestably true, how apposite and indispensable, then, that we should have a code of ethics regulating or making law for all these multiform interests, in our relations with our grandest and holiest of all professions, with its members, and with all the dearest, most vital and sacred human interests and relations.

This Code of Ethics has been formulated by some of the best medical minds in the American Medical Association, and presented, with all the prestige and authority, and influence of the organization, for the acceptance, loyal adhesion to, and guidance of all worthy members of the regular medical profession. Every man who receives the degree of doctor of medicine from a school in affiliation with this highest medical authority in the nation, and for that matter in the world, is under the most binding honorable obligation to strictly conform his professional life and practice in harmony with the requirements of this Code. Let us take a succinct review of some of the leading features of our fundamental law, and see if there is any feature that a man of strict sense of justice, honor, or truth, can reasonably take exception to. And here we will say, that in our opinion, the framers of the code, while most earnestly honest and true in comprehensive regard for the dignity, integrity, honor and usefulness of the medical profession, yet were somewhat lacking in the faculty of order, and the proper or most correct sequence in treating of the profession, and its relations and multiform duties and rights. So we crave your indulgence in taking the liberty of departing somewhat from the order in which the subjects are treated in the Code, and take them up in such order as appears to us most natural and consecutive.

Passing over until we arrive at Article V, we come to the first attempt to give any definition of the profession. Section 1 of that article says: "Medicine is a liberal profession, and those admitted into its ranks should found their expectations of practice upon the extent of their qualifications, not on intrigue and artifice." This simple enunciation is far-reaching in its grasp, and goes deeply toward the eternal basis on which alone we can securely rest, and from which we can safely and surely contribute the master builder's share in the construction of "The Bridge of Precious Stones and Pearls," figured by that transcendant genius, the immortal Gœthe (whose prophetic and philosophic eye took in more than any other man had ever expressed, the full truth of the capabilities of man's development, and the relation of scientific truth thereto), in his wonderful allegorical production which he called "Das Marschen," or The Tale. This I believe he never explained during his life, perhaps for the reason that in his vast comprehension he saw that few, if any, contemporaneous minds were in the advanced stage of intellectual development to be capable of truly comprehending the truth, as from his intellectual mountain-top it clearly appeared to him. It begins to dawn, after these many years, on the advanced minds of this day, that the magnificent temple that was being formed in darkness and in the depths of the earth, and was gradually rising from "the dark profound," was intended to prefigure man in the glorious plenitude of his upward development, when the accumulation of precious stones (scientific truths) had builded the bridge which, like a celestial highway, spanned the chasms, rivers, and obstructions which imperfect development, ignorance and superstition had made or imagined in man's nature, with the "man with the lamp, whose clear radiance (reason) illumined everything on which it shone," bringing all the "disordered combinations" of soul-saving machinery into harmonious accord as ministrant servants in the upward progress of the temple where the whole world will one day worship, no longer feeling that man's nature is a wrong and a mistake, but one of the grandest notes of harmony in "the music of the spheres." And right here, at the risk of being considered in my old age a visionary enthusiast, permit me to express my profound conviction of the truth set forth in this strange form by one of the very few mountainous-minded men, whose summits pierce all the clouds of ignorance, superstition and imperfect development, and bask in the clear, eternal sunshine of truth. Man, as I said in the commencement, is the highest form of evolution known to us, or, to use a more trite form of expression, "the highest revelation which the Infinite has given of Himself on this planet; also to add my absolute conviction that the part our profession is destined to play in this grand march of humanity's upward progress will not be, cannot possibly be, a secondary one. Then, if such a destiny is before us; if we are so surely to have largely the formative hand in moulding the mighty agencies into shape, and the directing will to guide them into place, and the constructing skill to build the bridge, why should we not proudly raise our banner on high in the shape of a Code of Ethics as perfect, clean, pure and manly as human skill can formulate, and in view of the almost inconceivable magnitude of the interests committed to our keeping, and which are constantly damaged by unfaithful and recreant members, proclaim professional death to all traitors in our ranks. Why should we ever permit or sanction, or in any way wink at, the truculence which trails our grandest of flags in the mire, by joining professional hands with any of the harpies of empiricism, who befoul with falsehood every clean thing they touch? Every principle of honor and truth, it seems to me, must rise in indignant protest against such prostitution. There was in the camp of Israel of old, we are told, a character they called "Achan." He, I believe, was a Levite, and dedicated to sacred service, but he had an evil, selfish, thievish soul; so he pocketed the "wedge of gold," and filched the "Babylonish garment," which were set apart for sacred purposes, to enrich

himself and clothe his corrupt body with the rich vestments reserved for sacred use. He belonged, doubtless, to the "bread and butter brigade." We doubtless have numerous representatives of Achan in our camp, men who, like Esau, would sell their birthright, if they had any, or their soul, if they possess the article, for a mess of professional pottage. I believe, if my memory serves me, they on conviction of the traitor led him forth without the camp, and put him ignominiously to death by hurling rocks forcibly against his sinful body. Served him right. So should we be merciless. The greater the trust, the greater the crime of betrayal. The Israelites spared not the traitor who ministered in holy things. No danger of a Cincinnati mob there, exasperated to madness by the failure and perversion and debauching of all the machinery of law and justice. Swift justice is done on proof of guilt. The camp is secure and at peace, and those sympathizing with the recreant traitor, or having a proclivity of itching fingers, are at once put into a more wholesome state of mind. We should not spare even the tallest leaders. Oftentimes the more elongated the spinal extension, the weaker the column.

The age of superstition is not yet passed. Few, if any as yet, can truly say their emancipation is complete. Mankind are caught by the glamour of superstitious credulity, in the meshes of unprincipled charlatans, and are fleeced out of money and manhood. Shall we compromise with the many temporarily successful falsehoods, and be of the selfish, weak-kneed, truculent, timeservers, of the bread and butter brigade, who strike hands with empiricism? I think I can hear in every manly soul among us a most emphatic response, coming up from the manly depths of his soul, "No!" Like the dying Lawrence, rather even in prospect of defeat and death, who that is worthy would not prefer to join in with, and swell the strong cry: "Don't give up the ship!"

"Our country embraces Atlantic's wide crest,
And opens to sunset her gateway of gold."

Such width of space unavoidably gives room for wide divergence of views. It used to be the East and the West simply, but now what used to be *par excellence* the West, has become in our wonderful progress the center. From being the home of every ultraism in politics, religion, or medicine, it is rapidly evolving out of this conglomerate confusion the character of scientific conservatism. When the life of the nation was in deadly peril, and armed hosts of traitors were disputing its right to maintain its existence, the same place that now aims to pull down our professional flag, and besmirch its immaculate folds in the mire and degradation of empiricism, then got up riots in opposition to the legal and just measures of our government for the preservation of its own life. Where then were Illinois and Iowa? Was the ear of treason ever tickled with the sound of a draft riot in Iowa or Illinois? No, a thousand times no. With lavish hands they poured forth a stream of regiments, that were not hireling mercenaries, but made up of their most priceless treasures, their own noble, heroic, stalwart sons. Their blood was shed in torrents on nearly every battle-field of the war for the Union. Iowa and Illinois clasped hands across the Father of Waters, and vowed that they would not cease the fight until its beneficent current should "flow unvexed to the sea." New York has the infamy of being the worst governed city in the Union, if not in the world. It did not succeed in stopping the war or draft. To-day it presents to us another rebellion of a most destructive nature, in the shape of a treasonable war on the Constitution of our National Association. Specious and plausible arguments are produced in profusion, as all treasonable movements are thus bolstered up, to show why one stone after another may not, just as well as not, be picked out and dispensed with from our constitutional underpinning. One by one they would pick them out with the soft, traitorous cry, "it is only a little one," until finally, if we permitted the treachery, we would find our foundation gone, and the grand temple of medicine swinging in the air at both ends, ready to fall in ruin over our heads. I much mistake the stalwart, conservative sense of the medical profession of these two central sister States, if they do not again clasp hands over "The Code of Ethics" in this treasonable war, which finds its greatest encouragement in the city of draft riots. Look over the field as carefully as we may, it seems to my view very difficult, if not impossible, to find any wrong features in the Code. There is absolutely nothing that an honorable, true man would be likely to take serious exceptions to. There is nothing but what is well calculated to impress a proper man with a just view of the sanctity and exalted character of the profession of our choice. Those who make war, however speciously, upon it, are in imminent danger of finding themselves in the exact category expressed by that eminent satirist, Hudibras, when he penned his famous couplet,

"No rogue ere felt the halter draw,
With good opinion of the law."

When a member unwittingly and ignorantly transgresses any of the principles of the Code of Ethics, he deserves admonition, counsel, and instruction. But when a member intelligently and wilfully violates any of the principles of the Code of Ethics, he should be as remorselessly cut off from honorable membership as we amputate a gangrened limb to save our patient's life. Instances have doubtless occurred, and may occur again, in which such reckless disregard of any honorable principle of action is exhibited, as to justify the conclusion of moral idiocy or absolute ignorance of the existence of any moral code. Perhaps if ever, by accident, they act as if from principle, they may be the subjects of the same surprise as was expressed by the witty John VanBuren, when in the campaign of 1848 he took the stump in New York in favor of free soil. At the close of a speech he was warmly congratulated by one of the ancients on having got hold of one of the great moral principles of the age, and most urgently advised to adhere to it.

"Ah, indeed," quoth John, "I am rejoiced to learn this, for by —— it is the first moral principle I ever have been charged with possessing, and I'll stick to it like a pig to a root."

There was hope in John's case, there may be in the erring if they will only "stick to it" when they have

found out or been instructed in a correct principie. Our profession is a liberal one, in that it is an open one. It has no concealments. It does not deal in, or tolerate patents or secret formulas. It is really and truly scientific. A host of earnest, patient observers and workers in its ranks for ages have been engaged in delving in the mines where the jewels are found, and little by little, by slow accretion, they have added each his mite, until our profession now finds itself on the threshold of the most advanced and exalted position of any human, or so-called divine profession. What additions to the domain of scientific medical knowledge have ever been made by any of the cloud of empirics that have hovered like vultures on the flanks and rear of our noble army of workers? Their only work is piratical. They have not a solid, valuable fact in their possession that they have not pirated from the accumulated stores of the regular profession. And with an assurance that might put brass itself to shame, they step forward with their stolen goods, claim to be educated in the groundwork of our profession, and claim fraternal recognition for the abnormal monstrosities they are busily engaged in palming off upon an ignorant and credulous world. Let the feeble knees shake. Let the weak spinal columns succumb. Let the bread and butter brigade desert, and meekly go over and make submission to the pirates that impudently demand their allegiance. We can afford to lose all these, and be stronger, cleaner, and better for the riddance. We can part with all these, and retain our honor unsullied. But to voluntarily lower our proud ensign, would be such a humiliating acknowledgment of weakness and defeat as would require many decades to retrieve us from the dire disgrace.

Our Code of Ethics tolerates nothing but truth. It entertains no false facts. To endeavor to carry a falsehood is well illustrated in the tale of "Sinbad the Sailor," who kindly undertook to carry for a while the poor, little, decrepit, worn-out, Old Man of the Sea. When the dwarf was fairly seated astride of the sailor's neck he clutched his benefactor's throat with the grip of a giant. It ended in a struggle for life. So with us—we cannot afford to part with a single principle of our Constitution. We may think this controversy in the East over the Code is only "a little tempest in a tea-pot," but to my feeble vision its portent is of vastly greater proportions. It looked to the superficial view as if the war would be over in ninety days when Sumpter was first fired on. But Sumpter fell, and the war raged over four horrible years of carnage. Yet, nevertheless, the nation did not die. In the defection in New York at the present time we may find our medical Sumpter. But, in that event, we need to gird on our armor here in the center, close up our ranks, and with lock step, shoulder to shoulder, present an unbroken front to the pirates and traitors who would haul down our flag. Instead of lowering our national ensign, we can better afford, proudly and defiantly, to write on its gleaming folds, in golden letters, Excelsior. Truth is mighty. The eternal years are hers. We claim to be sincere devotees at her shrine. In our eager quest for jewels in the mines of truth, it is not an uncommon thing to find a spurious stone, which puts on the deceptive appearance of a genuine gem. This may deceive the unwary, and pass for a time current on the world's exchange. Its course is always brief, like all counterfeit and spurious coin. The argus eyes of scientific experts soon fasten on it, and put it through the alembic of critical analysis, when its bogus character is clearly made known, and it no longer deceives any who wish to know and follow truth. But the world, in its still imperfect development, contains a large class of those characters whom Paul, in his inexorable theology, diagnosed and prognosed thus. Says he of them—"God gave them over to strong delusions, to believe a lie, that they might all be damned, because they knew not the truth (didn't want to know it, I suppose), but took pleasure in unrighteousness." This is pretty sharp criticism from a man who was founding a new dispensation. We, in the pity of our hearts, would prefer to be in sympathy with "Auld Scotia's favorite bard," in his "Apostrophe to the De'el," when he said "O wad ye tak a' thocht an mend." Our profession is eminently scientific. Superstition is eminently unscientific; therefore there is an irreconcilable antagonism. This irreconcilable antagonism inevitably leads to an "irrepressible conflict." The hosts of empiricism, or unscientific medicine, are always ranged under the somber, gloomy folds of the banner of "the Giant," who, in "The Tale," represents Superstition. His power was always greatest when the light was weakest. So the course of empiricism is always flourishing in exact ratio with the ignorance or superstitious credulity of the community. Our calling seems destined to encounter, fight, conquer, and finally explode every form and phase of medical falsehood. This is in accord with a universal law in development which seems to require that every conceivable form of error and wrong, from want of conformity through ignorance, or departure through viciousness, should be demonstrated, that in the end mankind may intelligently and wisely choose and follow truth as the enduring good— the only safe, certain way to true, enduring happiness and prosperity. In conclusion, Mr. President and gentlemen, oppressed with a vivid sense of the magnitude and importance of my theme, I feel constrained to apologize to you for the very inadequate, hasty, and imperfect manner in which it has been presented for your consideration. I did at first intend to pass in review the entire Code, by article and section, but the more I reflected, the more it grew upon me, until I saw that a book would be required to contain all that might be, or perhaps ought to be said. So, in the brief space of a paper before you, I thought the presentation of the more general features might be more acceptable. With your kind permission I desire to state a few of the points I wished to take:

1. Our profession is the highest and holiest of any on earth.

2. That it brings us constantly into connection with the laws and vital forces of the universe.

3. That man is the highest product of those laws and forces.

4. That our profession includes for its field man in his entirety.

5. That it is necessarily required to investigate and understand every cause that operates favorably or unfavorably on man.

6. That in order to successfully perform the responsible duties involved, the highest scientific education attainable is imperatively required.

7. That as we are daily made the repositories of confidence in the most delicate and sacred of human relations, our profession is bound to a higher and more perfect standard of manly character than is required of any other profession.

8. That as our sphere is man in his entire nature, and we are thus brought necessarily into intimate connection and knowledge of the laws of his being, our profession is inevitably destined to take precedence of all other professions, and lead in the van of the grand army of human progress.

9. That humanity is perfect, and beautiful, and valuable, just in proportion to its absolute conformity to universal law in the conception, growth, and development of the human being.

10. That it is the mission of our profession to develope the knowledge of all the laws of man's organization, and teach them to all mankind.

11. That, under this teaching, the tide of humanity will rise higher and higher in the scale, until a nobler, more intellectual, a purer, better race, more efficient for all beneficent enterprise, will be developed on and dominate the earth, than has ever yet peopled and governed it.

THROMBALLOSIS.

BY GEO. N. MONETTE, M.D.

The phenomena typical of thromballosis (and embolism), in contradistinction to apoplexy, coincident with rupture of a cerebral vessel, are of a more pronounced and complicated character than those of apoplexy.

Although apoplexy, in the aged, may be more rapidly fatal, yet an embolism may complicate with diversified phenomena, and the patient may linger for a long time.

The differentiating feature being that in embolic cases the pressure upon brain tissue is from within outwards, but circumscribed by the limits of the dilated vessel, and not diffused over the adjacent tissue, similar to *extra-vascular*, as occurs when rupture of vessel takes place, thereby causing extensive circumjacent pressure and obliteration of cerebral function; often profound coma, or *bona-fide* apoplexy is caused.

We know that the predisposing cause of apoplexy is an atheromatous degeneration of the internal coat of arteries, *vice-versa*, in thromballosis the pathology is induced by an endarteritis or phlebitis, yet the inflammatory phenomena are really not acute enough to attract serious attention in some cases.

Very recently, several cases of thrombus and embolism have come under my observation and treatment, as I was able to interpret the symptoms.

Case. I. Will S., aged 23 years, a wild and dissipated character. Had had syphilis, but was treated some time prior to my attendance upon him. I found him with an acute diarrhœa, induced by drastics. Associated with this were aphonia and unilateral paresis, which yielded gradually to quietude and alkaline treatment (pot. iod.) Motive coördination was almost wholly regained after a fortnight. When acute unilateral facial paralysis and contraction developed, I added strychnine to the compound, with success.

In connection with the treatment of this series of cases, I must not overlook the inestimable advantages derived from the internal administration of ergotine. So, in the foregoing case No. 1, I ascribed much of the benefit acquired to the joint efficacy of ergotine.

Some weeks subsequent to the manifestation of the unilateral facial paresis and its relief, the young man developed violently insane and murderous features; intensely irascible and as suddenly humiliated, and ultimately morose and subdued. These paroxysms of insane violence (sometimes alternated by fits of immoderate laughter, conveying an hysterical nature) continued up to his demise, which was resultant upon an attack culminating in apoplexy. No post-mortem could be obtained. He survived his incipient malady about six months. Syphilis may have been a potential factor in the predisposition of such a lesion, superinduced by hypercatharsis. I have observed numerous developments of a similar nature with no specific taint.

Case II. Mrs. ——, aged about 31 years, mother of several children (all healthy); of prior good health. Catamenia regular; devoid of uterine disorders. She was addicted to the use of patent cathartics, and was suffering from the violent effects of the same when I was called.

I found her with an unilateral transient paresis, with loss of motion. Modified sensation. No perceptible diminution of surface heat or of temperature, save of podalic extremities. There was some contraction of the facial muscles, also an irrepressible disposition to alternately immoderate paroxysms of laughter and grief, resembling hysteria. In view of the pathology of the case, as I appreciated it, I adopted the *nihil* treatment for several days when, I ordered the following:

℞. Potassii iodidi.....3ij.
Liquoris potassi arsenitis...3ij.
Ext. ergotæ fluid.....
Tinct. Gentianæ āā..... ℥i.

Sig. Teaspoonful every 4 hours.

which was continued for several weeks, when she recovered sufficient strength to walk about with the support of chairs, railing, etc.

Her general health continued good for about a year, when I was called again. I observed a recurrence of the identical hysterical phenomena, with exaggerated sensations and some tingling in the affected side (left), which alarmed her. I ordered an enema of chloral (ʒss) potassii brom. (ʒj) for the night. Upon my next visit I renewed the prescription for her former illness, which proved beneficial as formerly.

Case III. A gentleman was aroused during the night and found his wife in convulsions. I was called,

and saw her still comatose, yet emerging somewhat from the seizure, with an occasional respiratory stertor, and as often relapsing into an apparent respiratory indolence. I saw no hope for her recovery. She died within four hours. She was *enciente* (about three months). Her husband related that she used cathartics immoderately, with the consequent perversion of her assimilative energies.

I ascribe the phenomena of these cases to *hypercatharsis*, provoking malassimilation, anæmia, hydræmia, ultimating diversely in each case as above reported.

No. 285 Camp St., New Orleans.

MEDICAL PROGRESS.

MATERIA MEDICA AND THERAPEUTICS.

The Surgical Uses of Subcarbonate of Iron.—Dr. N. Timmermans (*Journal de Medicine, Bruxelles*) recommends the use of this agent in the treatment of constitutional and local ulcers, recent or suppurating wounds, and in erysipelas. He uses it in ulcers, by first washing the ulcer thoroughly with warm water, by lotions or irrigations, dries the surface with fine linen or charpie, and then covers the surface and borders of the ulcer with a layer (1 to 3 millimeters) of the powdered subcarbonate of iron, holding it in place by charpie, a compress and a bandage. The first few days it is renewed three and four times a day. If there is an abundant secretion, it mingles with the powder and forms a crust, under which the pus forms, and nullifies the action of the drug.

After several days of application, the ulcer, which had been pale, grayish, with a few vascular granulations or none at all, and furnishing a sanious, ichorous, fetid pus, in greater or less quantity, becomes changed in appearance; healthy pus shows itself, the borders which before were puffed out have now flattened out, and the base is filled with small, red, vascular granulations. A slight pellicle, like a delicate bluish line, appears along the borders, and invades by degrees, and by successive concentric zones, the whole of the loss of substance.

This application is ordinarily painless. But when the ulcer is the seat of a certain inflammation, the pain caused by its use becomes intolerable, and the inflammation must be subdued by the ordinary means before proceeding to its use. Sometimes this pain is due to impurities in the drug, such as sulphate of iron, and the sulphate and carbonate of soda. Varicose ulcers are the most painful on the application of this preparation, and the callous ulcers give the best results from its use, a cure being generally completed in from twenty-five to thirty days. The fungous ulcer also yields readily to treatment. The only cases in which there is absolute want of success, is in those where the ulceration of the subjacent derm is so advanced (scleroderma deuteropathic) that the conditions of the circulation have changed.

The powdered salt of iron, so applied, absorbs the pus, and exercises a certain degree of constringing power, which moderates or arrests the secretion. It is an excitant, acting like a foreign body; it modifies the atonic surface, stimulates and revives its vitality. But its prime force lies in its capacity for establishing an electrical current, and thus stimulating the ulcer.

On Bromide of Cadmium.—Dr. Roux (*de Brignoles*) has attempted to give bromide of cadmium for an antispasmodic in two cases of epilepsy. He records (*Marseille Medical*) the result as producing immediate and abundant vomiting. He used bromide of cadmium 5 grammes, distilled water 300 grammes; a tablespoonful as a dose. He naively says that he desired to try the medicine on himself, and took, as a prudent man, only a half of a coffeespoonful, when it produced as much upon him as if he had taken a grain of tartar emetic, which salt always has a very energetic effect upon him. His second case was that of a young girl, and he modified his prescription so far as to add bromide of sodium 5 grammes to the mixture, but the result was the same. In this case, however, there was no return of the epileptic attacks for six months.

Dr. Roux is content to class this drug simply as a very energetic emetic.

On Resorcin in the Treatment of Pertussis.—Dr. Moncorvo, of Rio de Janeiro, concludes an interesting article on this subject as follows:

1. Pertussis, the nature of which has been for so long a question for various interpretations, as regards its genesis, seems to-day to be ranked among the parasitic diseases, according to the latest clinical observations and microscopical researches.

2. The disease appears to be attributed to the presence of micrococci, which proliferate in great numbers on the mucous membrane of the supra-glottidian region of the tongue, by infiltrating the epithelial cells, which seem to be the seat of selection for their proliferation.

3. The resorcin applied directly upon the laryngeal mucous membrane, is successful in every case in which it has been employed in diminishing quite rapidly the number of paroxysms of coughing, which also lose their intensity, causing, in fact, after a short time a cure independent of all other medicinal agents.

Dr. Moncorvo employs concurrently the classic treatment of catarrh, when it is necessary, as ipecac, for example. But the painting with resorcin constitutes his true curative treatment. This is applied every two hours to the orifice of the glottis by means of a brush with a long handle.

The following is the formula used:

Resorcin, chemically pure.. 1 gramme.
Distilled water.....100 grammes.

From the numerous observations recorded by Dr. Moncorvo, it appears that the paroxysms of coughing diminish rapidly, and cease entirely in from twenty days to a month.—*Moniteur Therapeutique, Marseille Medical.*

The Hypodermic Use of Kairine.—Dr. Queirolo (*Gazzi degli Ospitali; Bull. Gen. de Therap.*) finds that kairine, used hypodermically, produces a more rapid, enduring, and greater lowering of the temperature than when taken internally.

To obtain this result the kairine is not required in as large or as frequent doses as when taken internally.

The hypodermic administration is exempt from any general inconvenience or local disturbance.

On the Treatment of Syphilis by Thallium.—Dr. Rabuteau having published in his last, fourth edition (1884) of his *Traité elémentaire de therapeutique et de pharmacotogie*, some references which were favorable to the use of this new drug in syphilis; as he used it in the form of an iodide and in one fifth the dose of mercurial iodides, Drs. Pozzi and Courtade, of the Hopital de Loureine, who were associated with Rabuteau in attemping to utilize the drug, give their views, based upon eight cases, as follows (*Gazette Medicale de Paris*):

1. Iodide of thallium is an alterative.

2. It has produced a certain degree of amelioration in syphilitic affections, but this relief might also, with propriety, be attributed to proper attention to hygiene, etc.

3. It becomes absorbed into the system, as is shown by the alteration of the gums, and its presence in the urine.

4. Mercury remains in the first rank in the treatment of syphilis, and thallium takes its place far behind it, even if the relief afforded can be attributed to it.

Etherization by the Rectum.—M. Daniel Molliere (*Lyon Medical*) relates that for the idea of using ether in this way, he is indebted to Dr. Axel Tversen, of Copenhagen, who, upon being shown around the Hotel Dieu by him, asked what anæsthetic was preferred, and whether it was used by the mouth, or by the rectum. Struck with the remark, and its explanation the next day, M. Molliere applied ether by the rectum with the aid of a double-tubed flaçon and Richardson's atomizer in the case of a girl of twenty years of age, to assist in the removal of a tumor in the parotid region. Ten minutes passed before she showed any signs of absorption of the drug. Then she said that she tasted the ether very decidedly, and her breath gave a marked ether odor. She began to hesitate in her speech, and a few drops of ether being applied to the nose, she fell into a profound sleep. The quantity of ether absorbed was insignificant. The patient having taken a plate of soup before its use, vomited in consequence, on her awakening, but there was no fatigue or nausea following.

A second case was that of a woman, forty years of age, etherized for the removal of a tumor filling the antrum of Highmore. A rubber tube of the size of the finger was introduced into the rectum and connected with a vessel of ether, which was placed in another vessel filled with water at about the temperature of 122° F. The ether entered in ebullition, and in about five minutes the patient came under its effects, with a marked ether odor from her mouth. A few grammes of ether on a sponge, applied to the face, produced complete anæsthesia. There were no bad effects on awakening, no nausea or vomiting; only a slight excitation common with ordinary anæsthesia.

The third case was that of a robust girl of nineteen years, who suffered from a necrosed phalanx which had to be removed. She, lying upon her side, talked freely and pleasantly while the ether was bubbling up in her rectum. Presently she stopped talking, closed her eyes, and slept peaceably, and the operation was performed. The ear applied to the abdomen heard the crepitus of the bubbles of ether. The nostrils exhaled an odor of ether. The awakening was perfectly natural. The quantity used was about ten grammes.

The fourth case was a robust man, to be treated by stretching the sciatic nerve. He had been a soldier for twenty-five years, and was in the habit of drinking his quart of white brandy daily. His anæsthesia was complete, without any period of excitation, which is remarkable in an alcoholic subject.

Two other similar cases are recorded, and M. Molliere considers that this mode of administering ether is destined to be of great service, in suppressing the period of excitation, in allowing of an exactitude of dosage, in reducing the quantity to its minimum, and in giving great freedom to the surgeon in operations upon the face.

OBSTETRICS AND GYNÆCOLOGY.

On the Use of Sulphate of Copper in Obstetrics.—Dr. A. Charpentier, in a communication to the Paris Academy of Medicine (*Archives de Tocologie*), refers to the comparative value of certain medicinal agents in the antiseptic treatment of confinement, such as carbolic acid, bichloride of mercury, salicylic acid, permanganate of potash, chloral, etc., etc. The object to be attained is to find an agent that will fulfil certain conditions, such as:

A decided antiseptic, of ready preparation, not causing any risk to the woman, any danger of intoxication when administered for a prolonged period of time; its management easy and inoffensive to the patient, physician, or attendants; not injuring linen, cloths, napkins, etc.; if possible, inodorous; and, finally, of a moderate cost.

Of these substances, carbolic acid is no longer used by the French obstetricians. The sublimate is the agent most used to-day in the lying-in hospitals. This latter agent has decided advantages over carbolic acid; it is without odor, and its antiseptic action is much more energetic, but it has its inconveniences and dangers. Carbolic acid, to be really of use as an antiseptic, must be given in strong solution, and in addition to the disagreeable odor, which is offensive, it may be also dangerous. All obstetricians have noticed, after seven or eight days of continued use of solutions of carbolic acid, erythemas,

and vulvar and vaginal lesions, which render them painful to patients; but we have the further testimony of a number of surgeons to show that the absorption of carbolic acid may produce symptoms so serious as to endanger the lives of patients.

Corrosive sublimate is naturally preferred to carbolic acid from its want of odor and its ready solubility in alcohol and chlorhydrate of ammonia. But it has also its objections; it irritates the skin, which becomes as hard as if tanned, and it is frequently badly tolerated by patients in whom it produces pain, erythemas, and very marked eruptions upon the genitals. Eight cases are referred to, in one of which it was thought that erysipelas of the arm existed, another case was affected with gingivitis, and in another, a case of Stadfeldt's, the death of the patient was attributed to an intra-uterine injection of a solution of sublimate, 1 to 1,500.

Sulphate of copper, Dr. Charpentier tells us, he was induced to try, after learning of the laboratory experiments with that agent by Pasteur. The solution used was a 1 per cent. heated to a temperature of 96.8° to 100.4°, applied as follows:

1. During pregnancy, all the women in the waiting wards who presented any symptoms of leucorrhœa, however slight, received each day one or two vaginal injections. Not one of the children born of these women showed any signs of ophthalmia. Every student who examined or handled these women, first washed his hands in the solution.

2. During labor, every student or midwife called to direct the labor was required, after a careful washing of the hands with soap and use of the nail brush, to wash the hands with the copper solution before making an examination. So long as the labor lasted, the woman was submitted, every two or three hours, to a vaginal irrigation with the copper solution. This was the morely strongly insisted upon in cases of premature rupture of the membranes, of dead and macerated fœti, malpresentations, etc. All manual or instrumental interference was always preceded by a copper vaginal injection, and a washing of the hands and instruments with the same.

3. During delivery. If the delivery was natural, it was followed by a single vaginal injection, and left to the ordinary treatment. In four cases of incomplete abortion where the membranes were retained, and septicæmia was threatened, the copper solution was used in vaginal and intra-uterine injections, with the result in each case of a complete, rapid and radical cure. In three of these cases the temperature descended in twenty-four hours, from 104° to normal, and the pulse returned to its normal frequency after three injections. In one case it required five intra-uterine injections to produce the expulsion of the contents of the uterus. Once the first injection produced suddenly uterine contractions and a marked hæmorrhage. Again, the fourth injection was followed immediately by a nervous attack with almost complete loss of consciousness, paralysis of the tongue, and contraction of the limbs, but this could not be attributed to the sulphate of copper alone, for the same symptoms occurred in another patient, some time previously, after the use of a solution of the sublimate. In the cases of delivery at term, each patient receives afterwards a vaginal injection, which is replaced by a uterine injection in those who have undergone any manual or instrumental operation, where labor has been prolonged, who have been delivered of dead or macerated fœti, where the amniotic fluid is colored by the meconium, and in cases of malpresentation. In one case where free hæmorrhage occurred after delivery, one vaginal injection, followed in a few moments by a tampon of wadding soaked in the solution, stopped the flow. Another case of hæmorrhage which had resisted the use of ergot and hot water injections, was checked instantly by a cold uterine injection.

4. During the confinement which follows delivery. Here, if everything is regular, the application is restricted to washing the vulva at least four times in twenty-four hours, and the application of a compress wet with the solution to the genital organs. If there occur, however, the slightest signs of infection, chilliness, elevation of pulse, of temperature, tendency of the lochiæ to become fetid, or sensitiveness of the abdomen, the vaginal injections are used; if at the end of several hours no relief is afforded, intra-uterine injections are used.

This vigorous application of antiseptic treatment followed 12 deaths out of 397 labors within six months, which were attributed to septicæmia; for a month afterwards, under the use of carbolic acid, the mortality was suppressed, but slight phlebitis, phlegmasia alba dolens, and ophthalmias in the newly born, showed the existence of a morbific influence; then three women died, one after the other, within a space of five days. The sulphate of copper treatment, as detailed, was then established, and kept up for three months in 212 labors, with no deaths and no complications worthy of note. Whether used as a vaginal or intra-uterine injection, the solution of sulphate of copper never produced any pain, immediate or consecutive, even when there existed vulval or vaginal erosions. In one case, through a mistake of a pharmacist, a ten per cent. solution was employed without any discomfort. Dr. Charpentier sums up his conclusions with regard to it as follows:

1. Sulphate of copper in 1 per cent. solution, is an antiseptic of the first order.

2. It combines astringent and coagulating properties, and may yet be substituted as a hemostatic for the perchloride of iron, over which it has the advantage of not soiling the linen.

3. Its use may be continued through the first eight or ten days following delivery, repeated frequently during the twenty-four hours, without other effect than a rapid amelioration.

4. Surgeons especially should test this antiseptic, which, in a number of cases, particularly in one of voluminous thrombus of the vulva, assisted in a rapid cure without the discharge of any pus. In one case of fetid abscess of the urethro-vaginal track, it suppressed in twenty-four hours all the fetidity and general symptoms of putrid infection, which carbolic acid solutions had failed to do.

SURGERY.

FIBRO-PLASTIC CANCER OF THE PENIS.—Dr. J. Lopez Alonas (Correo. *Medico Castellano*, Madrid) reports this case as occurring in a priest, 58 years of age, of a sanguine temperament, excellent habits of life, and with no hereditary antecedents. For about six years, the tumor, of the size of a grain of corn in the beginning, developed by degrees until the penis disappeared almost entirely, showing in its stead a rounded tumor of the form and dimensions of a cauliflower, formed by little soft lobules, adherent to the deeper parts of the organ, and separated from each other by a soft substance. The penis served as a peduncle to the tumor, which presented deep ulcerations at various points, with indurated edges that bled freely and discharged an abundant quantity of a thick, grayish, purulent fluid of a fetid odor. The meatus urinarius was found at the inferior portion of the neoplasm, and the urethra was not ulcerated. The amputation of the penis at its root was effected by the linear constrictor—the urethra being protected by a rubber sound—to prevent its narrowing during cicatrization, which took place within ten days after the operation without any serious drawbacks. The detached tumor weighed 972 grammes.—*Revue Medicale.*

A CASE OF NECKLACE SWALLOWING.—Dr. Dujardin (*Journal des Sciences Medicales de Lille*) records the case of a child seven years of age which swallowed a necklace of steel beads, weighing about 17 grammes. The interesting part of the case consisted in the perfect detection of the location of the necklace by the use of the induction balance. After placing one of the two groups of bobbins at different parts of the abdomen, the telephone responded only over the region of the stomach. The response was very feeble in the neighborhood of the umbilicus, but attained its maximum of intensity at the left hypochondriac region, over the great pouch of the stomach. There seem to have been no bad effects from the accident. For several days the stools were very black, but they soon resumed their normal color, due probably to the fact that the beads were covered by a layer of mucus which prevented their direct contact with the gastric juices and alimentary substances.

MEDICINE.

HEAT AS AN ANÆSTHETIC IN BURNS.—Dr. Silverio Dominguez (*Anales del Circulo Medico Argentino*) finds that when small superficial burns, such as often occur upon the fingers, are approached as closely as possible by the body which has produced the burn, or by a lighted match, which is kept there for a time, the pain ceases. The pain increases very much for a moment, and then ceases entirely. In these burns there is an instantaneous elevation of temperature, which is not sufficient to produce a disorganization, as it hardly produces an effacing of the wrinkles of the epidermis, but it increases the sensibility to the amount of positive pain by the irritation of the peripheral nerve extremities. Under these circumstances, the close approach of a heated body increases the pain greatly for the first few moments, and then, having arrived at its maximum, the pain disappears, and nothing remains but a sensation analogous to that of a foreign body, which is probably due to the slight modification undergone by the cutaneous surface.

The sensations of contact, and of pressure, are placed on a scale better graded than the thermic sensations. By increasing contact, pressure is produced which, to a degree, produces pain, in consequence of an alteration or disorganization of the nervous extremities; this pain disappears on the increase of the pressure. Undoubtedly, a very low temperature would produce the same effect, but it is not so readily applied. We may say, then, that the pain of a burn may be made to disappear by the application of heat or cold, and that the pain from a similar lesion produced by low temperature may be made to disappear in the same way.—(*Revue Medicale.*)

A READY MEANS OF DETECTING ALBUMEN IN THE URINE.—M. Hoffmann (*Semaine Medicale*) has strips of paper prepared for this purpose, by dipping them into a mixture consisting of a solution of corrosive sublimate 1 to 20 parts of water, and iodide of potassium 1 to 2 parts of water, in equal quantity. When dried, the paper can be carried to the bedside, and dropped into the specimen of urine, and if albumen be present a precipitate will immediately follow. To produce this reaction the urine must be acid, and to make sure of this, a strip of paper which has been soaked in a solution of citric acid is first placed in the urine.

ON THE TRANSMISSION OF TUBERCULOSIS BY MILK.—Either the recent experiments made by the inoculation of various substances in connection with the germ theory of disease, are making wonderful and rapid strides in advance in medicine, or many of us are being greatly deceived. M. H. Martin (*Jour. de Med. et de Chir.*) thinks he has demonstrated by a series of inoculations of milk in guinea-pigs, that the milk ordinarily consumed in Paris is susceptible of communicating tuberculosis. Out of nine inoculations, three were positive in this result, and he advises that milk be always boiled before using. But he considers that when taken into the alimentary canal, a lesion is necessary to admit the entrance of the morbid germ.

LUSK says: "The indiscriminate use of intra-uterine injections has been followed by an increased mortality invariably." He refers to their use in the puerperal state.—*Detroit Lancet.*

IT is stated that among the Piute Indians a doctor who loses three patients, one after another, is shot by the tribe. There is some encouragement for medical men there to exercise all their skill.—*Detroit Lancet.*

Journal of American Medical Association.

PUBLISHED WEEKLY.

THE EDITOR of this JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information, should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE..... $5,00.
SINGLE COPIES..... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 65 RANDOLPH STREET,
CHICAGO, ILLINOIS.

SATURDAY, MAY 17, 1884.

GROSS, SAMUEL D., M.D., LL.D., of Philadelphia, was born near Easton, Northampton Co., Pa., July 8, 1805; died at his residence in Philadelphia, May 6, 1884. His literary and classical education was obtained at the Wilkesbarre Academy, and the high school, Lawrenceville, N. J. Having selected medicine as the pursuit of his life, he began the study of it in his native place with Dr. Joseph K. Swift, and subsequently for some two years he was a student in the office of Prof. George McClellan. After attending the usual course of lectures in the Jefferson Medical College, he received the degree of M.D. in 1828. Dr. Gross began practice in Philadelphia; he was fond of study, industrious, and stable in his purposes, and being resolved to succeed in his profession, occupied his spare time in extending his medical researches and in editing or translating medical papers and works from the French and German. He published in 1838 a work on "General Anatomy," and "Operative Surgery," in 1829; in 1830 "Anatomy, Physiology, and Diseases of the Bones and Joints," in which adhesive plaster is recommended in making extensions; shortly after, a small work on obstetrics, and a work of much value, based on experiments and original observations, "On Wounds of the Intestines." Work on "Elements of Pathological Anatomy," which was the first work of the kind in the English language. A paper on Foreign Bodies in the Air Passages was published as early as 1850. Dr. Gross early established a reputation for close and accurate observation with a comprehensive knowledge of anatomy and pathology.

In 1833, he was invited to become Demonstrator of Anatomy in the "Medical College of Ohio," at Cincinnati. After filling the position for two years, he was elected to the chair of Pathological Anatomy in the "Cincinnati Medical College." He delivered the first course on "Morbid Anatomy" ever delivered in this country. After a residence of four years in Cincinnati he removed to Louisville, Ky., where he resided and practiced his profession with increasing reputation. He had been elected to the chair of Surgery in the "University of Louisville." Here was the theater in which his great powers were brought prominently before the profession and gained a wide and appreciative recognition. In 1850, on the retirement of Valentine Mott from the chair of Surgery in the Medical Department of the University of New York, Dr. Gross was elected to the position. He delivered one course of lectures, but at the solicitation of his former colleagues, he returned to his previous position in Louisville. In 1856, when the failing health of Prof. Muter induced him to retire from the chair of Surgery in the Jefferson Medical College, Prof. Gross was elected to the position, and he returned to his native State. For one-quarter of a century he filled the position in the most satisfactory manner and with increasing reputation, and the advancement of the popularity of the college. Admonished by increasing years, in 1882 he retired from the chair of Surgery with the best wishes of the Trustees and Faculty, and had the satisfaction of seeing his son inducted to the position. Although a pleasing lecturer, and an excellent teacher, which accurate knowledge and a good address enabled him to use with effect and rare ability before a class, and in the operating room, still it is probable that his fame will rest largely upon his high moral character and his operative skill and literary labors, rather than upon that of a teacher. It is probable that his system of surgery, which he has revised and enlarged, is to-day the work of the highest authority on surgery in this country. Prof. Gross has received the highest honorary testimonials and honors from foreign universities, from Oxford, from Cambridge, and from the University of Edinburgh, in Scotland, and from other foreign societies and institutions of learning. He has also been equally honored by the scientific, literary and medical institutions throughout the United States. In 1867 he was elected President of the American Medical Association; in 1870, President of the Pennsylvania State Medical Association; and in 1876 he was elected President of the International Medical Congress, which met in Philadelphia that year. Prof. Gross was largely influential in founding

the Pathological Society of Philadelphia, the Philadelphia Academy of Surgery, and the American Surgical Association. He was a member of the Philadelphia College of Physicians and the Philadelphia County Medical Society. It would fill pages to enumerate all the societies to which he belonged. He was a warm supporter of medical organizations, and attended meetings of the American Medical Association in 1858, 1866, 1867, 1868, 1870, 1872, 1874, 1875, 1876, 1877, 1878, 1879, 1880, 1881 and 1883.

Prof. Gross was popular with the profession, and widely known throughout the United States and Europe. Scarcely a foreign medical man of note visiting America but paid his respects or brought letters of introduction to Dr. Gross. He was hospitable in the highest degree, social and entertaining. At his table and in his parlors were to be met on almost any day the notables in social and professional life. He retained to the last his relish for society and his power of literary work. Within a day or two of his death a paper of his, "On Wounds of the Intestines," was read in the American Surgical Association by his pupil and friend, Prof. Richardson; and another, after his death, before a Section of the American Medical Association, by Prof. Theophilus Parvin. An autopsy was made, in obedience to an oft-repeated injunction to his children, that the cause of death might be obtained beyond a question. He also left a request that his remains should be cremated, which injunction was respected, and the incineration accomplished at the Lemoyne furnace, in Washington county, Pennsylvania, on the 8th of May, 1884. Funeral services were held at his residence before the remains were sent to the crematory. The ashes of Prof. Gross were taken to Woodland Cemetery, and laid by the side of the remains of his wife. Dr. Gross leaves four children, two sons and two daughters. His sons, S. W. Gross, M.D., and A. Haller Gross, Esq., of the Philadelphia bar. His daughters are married, one to Dr. P. J. Horwitz, ex-Surgeon-General of the United States Navy; the other to Benjamin Horwitz, Esq., of Baltimore. As the duty of preparing a proper memoir of Prof. Gross has been referred to a committee by the American Medical Association, this hasty sketch is presented for immediate use, to answer the expectations of the readers of the JOURNAL. J. M. T.

THE THIRTY-FIFTH ANNIVERSARY MEETING OF THE AMERICAN MEDICAL ASSOCIATION.—This truly representative organization of the medical profession in our country, closed one of its most successful and enthusiastic annual meetings in Washington about 1 P. M., on Friday, May 9, 1884. It was successful in the unusually large number in attendance, there being more than 1,200 regularly registered members present, including representatives from nearly all the States and Territories of the Union. It was eminently successful in the amount and quality of work done. Through the active interest of the President of the Association, the repeated notices and explanations in the JOURNAL, the officers of most of the Sections had been induced to act more directly in concert with the Chairman of the Committee of Arrangements in securing an ample supply of good papers for each Section, with more systematic and interesting provisions for discussion, than at any previous meeting. If there was any exception to this remark, it was the Section of State Medicine, which appeared to have very few papers on its programme. The principal defect in the general preparation of the programme, was in not completing it in time to have it published in the JOURNAL, at least two or three weeks before the time of meeting. The By-law of the Association requires that the Chairman of the Committee of Arrangements shall be notified of the title and general contents of all papers intended for presentation in any of the Sections on or before the first day of April of each year, for the express purpose of enabling him to have the programme ready for publication sufficiently in advance of the meeting, that members may be prepared to consider and discuss intelligently the papers presented in every Section. Through the prompt and persevering activity of the Chairman of the Section on Practical Medicine and Materia Medica, the programme for that Section was completed and published in the JOURNAL three weeks before the meeting, giving not only an attractive list of papers, but the names of eminent men who would lead in the discussion of those deemed most important.

The result was, that the attendance upon this Section was full, and the most lively interest maintained in every session from the beginning to the end; while the other Sections, whose programmes were completed only in time for distribution at the opening of the meeting, had a much smaller attendance. The Chairman of the Committee of Arrangements used every legitimate means to induce those intending to present papers to send him notices of the same within the time specified in the By-law, but the dilatoriness of those who should be most interested in the matter, induced him to keep the programme open until the 24th of April, leaving only time to have it printed for distribution after members would be on their way to the meeting. The only cure for

this evil will be a rigid enforcement of the By-law requiring all who propose to present papers or reports, to forward them or their titles and contents to the Chairman of the Committee of Arrangements, at least *one month* before the time of the meeting of the Association. An active coöperation of the officers of the Sections will greatly aid in accomplishing this. The meeting just closed, was not only successful in the number of members in attendance, and the quantity and quality of the scientific and practical work done in the Sections, but equally so in the character of the general sessions of the Association. The Committee of Arrangements had performed its work with rare good judgment and ability; and the welcoming address of the Chairman, Dr. A. Y. P. Garnett, was eloquent in style, appropriate in matter, and judicious in length. The President, Dr. Austin Flint, so well known throughout the medical world as an eminent author and teacher, on taking the chair was received with enthusiastic demonstrations by the assembly, which closely filled both the large audience room of the church and the spacious galleries. As every one expected from his well-known ability, his address was admirable in its tone, appropriate in the selection of topics discussed, eloquent in its style, and dignified in the manner of its delivery. It was listened to with the most marked attention, and its recommendations promptly taken under consideration. The address in full, however, was given to our readers in the first issue of the JOURNAL after its delivery, (May 10), and speaks for itself. The allusion in the address to Prof. S. D. Gross was in perfect accord with the feelings of the audience, and when the dispatch came back from Philadelphia saying that the Nestor of American surgery had expired during the hour the address was being delivered, it caused a feeling of sadness to pervade every heart. The addresses of the chairmen of the several Sections so far as they were read, were characterized by a fair degree of ability; but their number and the length of some of them rendered it impracticable to have them all read in the time allotted to the general sessions of the Association, and allow time for the transaction of any other business of importance.

In consequence, three of these addresses were only read by title on the last day, and referred for publication. It is apparent that some change must be made in regard to these addresses in the future. Either the writers must be required to adhere strictly to the requirements of the By-laws, which would necessarily render them short, or their number must be reduced. But this topic, in connection with a proposed change in the mode of electing the officers of the Sections, will be referred to more at length hereafter.

The social entertainments were numerous and of the most attractive character. Besides several elegant private entertainments, the members of the Association, and those accompanying them, were cordially received on the first evening by the President of the United States in the Executive Mansion; on the second, an elegant banquet was tendered by the Medical Association of the D. C.; on the third, the Corcoran Art Gallery was illuminated and a reception given by W. W. Corcoran, Esq.; and on the fourth the members were very cordially received in the Capitol, which was illuminated for the occasion, by Senator Edmunds, President *pro tem.* of the Senate, and Mr. Carlisle, Speaker of the House, and at the Army Medical Museum by Surgeon-General Murray and his Staff. The place selected for the next meeting of the Association was New Orleans, and the time the last Tuesday in April, 1885. The full list of officers elected for the ensuing year may be found on the last page of the present number of the JOURNAL.

SOCIETY PROCEEDINGS.

PLASTIC SURGERY.

BY PROF. A. C. POST, NEW YORK.

At the regular meeting of the District Medical Society for the county of Hudson, at Jersey City, N. J., April 1, after the routine business had been disposed of, Prof. A. C. Post, of New York, delivered a very instructive and interesting lecture, illustrated by diagrams, paintings, drawings, and photos, showing the results in rhinoplastic, blepharoplastic, cheiloplastic and heteroplastic operations in *Plastic Surgery*. Prof. Post said: By this term is understood the branch of the healing art, which aims to supply deficiencies on the surface of the body, resulting from congenital malformation, from traumatism or from disease. The term plastic is derived from the Greek verb πλαστικος, —I form. Plastic operations consist in the detachment of flaps from neighboring or distant parts, and uniting them with the surface and edges of the vacant space which is required to be filled. The term anaplastic is sometimes employed, the prefix *a va* signifying up, and the term implying the forming or building up of the parts to their proper level. The term autoplastic conveys the idea that the transplanted parts are derived from the patient himself. The term heteroplastic signifies that the new tissue is derived from another person, or from an inferior animal. Blepharoplastic operations are those which are performed to repair defective eye-lids. Rhino-plastic operations are for defects of the nose. Cheilo-plastic,

for those of the lips. Prosoplastic, for those of the face in general.

In most of the operations for the repair of lost or defective features, the transplanted flap is left attached by some part of its circumference to the part with which it was naturally connected until it has acquired a vital union with the new parts to which it is artificially attached. The portion of the flap which retains its natural connection is called its neck or peduncle. There are three methods of transplanting pedunculated flaps, known as the Italian, the Indian, and the French methods. Plastic operations were performed by the ancient Egyptians, Greeks and Romans. In modern times Bianca performed a rhinoplastic operation in Sicily, in 1442. In 1597 Gaspar Tagliacossi, Professor at Bologna, published at Venice a book entitled "De Curtomm Chirurgia per Insitionem." In this book he gave a detailed account of his operation for the restoration of lost noses and other features. This book acquired a world-wide celebrity. The mode of operating consisted chiefly of the transplantation of flaps from the integuments of the arm, the hand being firmly bandaged to the head during the process of union. Fabulous accounts of his operations were published, representing the excision of flaps from a poor man nater, to supply the deficiency of a rich man's nose,a nd it was asserted that the vitality of the new nose depended on the life of the person from whom it was taken. A story is related of a nobleman whose nose was formed from the integuments of a Florentine peasant, and which retained its vitality for a number of years. Suddenly, without any obvious cause, the nose died and became a putrid mass. On inquiry, it was ascertained that the death of the nose coincided with that of the peasant from whom the material for its construction was obtained. Butler, in his Hudibras, alludes to such fabulous rumors, when he writes: "Thus learned Taliacotius from the brawny part of porteis bum cut supplemental noses, which would last as long as parent breech, but when the date of nock was out, off dropped the supplemental snout."

This mode of repairing defective parts by transplanting flaps from remote regions, is called the Italian or Taliacotian method. The mode of operating by transplanting flaps from adjacent parts, and twisting the peduncle so as to bring the flap into its proper position, is known as the Indian method, having long been practiced in Hindostan, and having been made known to European surgeons about the close of the eighteenth century. It had long been the custom of native tyrants of India to mutilate their rebellious subjects by cutting off their noses, and as "necessity is the mother of invention," the persons who were mutilated exercised their ingenuity in finding a remedy for the disfigurement resulting from the mutilation. The operation for this purpose was not performed by physicians, or surgeons, but by a class of artisans who were engaged in pottery. The Indian operation for the restoration of lost noses consisted in freshening the edges of the space from which the nose had been excised, and cutting a flap from the integument of the forehead, and twisting its peduncle so as to bring the flap into the position of the nose and fixing it so as to secure union with adjacent parts. The same principle is applicable to the restoration of other features besides the nose. The Indian operation of rhinoplasty was performed in London in 1803, but the first operation was unsuccessful. The first successful operation in Europe was performed in London in 1814, by Mr. Carpul. The operation has since been performed many times by surgeons in different parts of Europe and America. The resulting operation has been quite satisfactory, when enough of the original nose has remained to support the transplanted flap in its new position. But in cases in which the nose has been entirely destroyed, the new organ is an imperfect substitute for the old one, presenting a flattened or depressed appearance. But even in these cases, the new nose is a decided improvement on the cavernous depression which preceded its formation.

The French method of performing plastic operations consists in cutting flaps in the vicinity of the defective part, and gliding them into position without twisting the peduncle to any considerable extent. The Italian method of restoring lost features, by transplanting skin from remote parts, is now very seldom resorted to, except in those cases in which there is no available material in the immediate neighborhood. The Indian method is often employed, and yields very excellent results. In many cases, where the nose or the eyelid is the feature to be repaired, it is the only available method. The French method, by gliding the flap into its place, without twisting its peduncle, is the best operation in cases in which it is applicable, especially in supplying deficiencies of the lips and cheeks. The principal difficulty to be contended with is the tension of the flap when it is brought into its new position. This difficulty may, however, in most cases be obviated by giving a decided curve to the peduncle of the flap. In the performance of plastic operations, certain facts have been observed, to which it is proper to direct your attention. On making the first incisions the flap becomes pale, but afterwards the parts adjacent to the connecting medium assume a redder color. Dark bluish spots or streaks are often found scattered through the flap. Blood spouts at first from the arteries at the edges of the flap, and afterwards fibrine is effused. The flap contracts considerably, and is disposed to turn inwards; it also acquires an increase of thickness. These changes are most distinctly perceptible in young persons of healthy constitutions. The flap loses all sensibility, except at the extremity by which it is nourished, and even there the sensibility is but slight.

The flap should be one-fourth or one-third longer than the space which it is designed to fill, and a wide bridge should be left, connecting it with the adjacent part. The flap should contain not only the skin, but a considerable thickness of the subjacent parts, so as to afford a good vascular supply. It is highly important that it should be easily held in position, as any considerable tension will be likely to hinder its adhesion to the adjacent parts. In cutting the flap it is well to make a pattern of oil-silk, or other suit-

able material, of the size and shape of the space to be filled, and to use this pattern as a guide in making the flap. In fixing the transplanted flap in its new position, one or more pin sutures may be advantageously employed. These should include nearly or quite the whole thickness of the flap, and the points of entrance and the exit of the pins should be at least eight or ten millimeters from the edges of the wound. Numerous sutures of fine black silk should be employed to secure a perfect apposition of the edges of the wound. The spaces between the sutures should not exceed two or three millemeters. Black silk is preferable to white, as being less irritating and being more easily seen. The fineness of the silk is indicated by the letter O on the spools. In introducing the sutures, if the edges of the wound are of unequal thickness, the needle should be introduced more superficially on the thicker side. Before closing the wound, it may be freely irrigated with a solution of mercuric bichloride, eight grains to a pint. After applying the sutures, there is no occasion for applying bandages or plasters, but the surface may be freely exposed to the air. When the flap is congested, cold water dressings may be applied. On the ninth or tenth day all inflammatory swelling has generally subsided, and the cuticle cracks and peels off. When the flap has been taken from the hairy scalp, the hairs after a time will grow, and they may from time to time be plucked with forceps. The growth of hair may be diminished by the free application of lime-water, or a solution of mercuric bichloride, or the hair bulbs may be destroyed one by one by a galvano-cautery. In blepharo-plastic operations, when the eyebrow has been destroyed, it may be replaced by a flap from the hairy scalp, the hairs being allowed to grow over a space corresponding with the eyebrow, those above and below being plucked or destroyed. When I first restored the eyebrows in this way, I supposed that the practice was original with myself, but was afterwards informed that I had been anticipated by Dr. Pancoast, of Philadelphia.

To give proper shape to the newly formed feature it is often necessary to excise here and there small portions of the newly transplanted integuments. This may be done without hesitation, as wounds in recently transplanted integument heal by the first intention and with great rapidity, much more so than wounds in other parts. This observation was made by Dieffenbach, and I have often verified it in my own practice. When these wounds are allowed to granulate they bleed freely at first, and the blood is very bright and liquid. The wound appears pale, and the edges are scarcely inflamed; there is little or no suppuration, and the exuded blood forms a scale or scab, which after a while falls off, leaving the wound healed. When it becomes necessary to separate the edge of the flap from its new attachment, it never heals by the first intention, but always goes through a tedious process of granulation. Sensation is very slowly developed in transplanted parts. Many months, for example, elapse before a new nose transplanted from the forehead becomes sensible to pain. Sensibility is first restored near the line of union with the adjacent parts. The newly formed feature does not begin to perspire, nor to form thick pus when wounded, before twelve months. There is much difference in different cases in the power of withstanding cold possessed by the transplanted part. A patient, for whom Dieffenbach made a new nose, was attacked with jaundice eighteen months afterward. The whole body, with the exception of the nose, was of a deep yellow color. When the patient was warm the nose was white, when he was cold it was of a dark-bluish hue.

The treatment of cicatricial contractions is a matter of great importance. It is not safe to include cicatricial tissue in flaps which are to be transplanted, or to raise it to any considerable extent from the subjacent parts, as it almost invariably sloughs when it is so treated. But it may be freely divided, and a flap of healthy skin may be united with its divided margin with a good prospect of union by the first intention. It may be divided into narrow segments by incisions crossing each other at short intervals, and may then be put upon the stretch, and it will not slough if sub-based attachments be not interfered with.

Certain special modes of operating, which have been introduced by different surgeons, are worthy of attention.

Dieffenbach introduced an important improvement in treating the deformity occasioned by the loss of the nasal septum from syphilitic disease, and the sinking of the remnants of the nasal pyramid into the cavity. He made longitudinal incisions dividing the nasal pyramid into five strips, attached above and below, and raised them to their proper position, fixing them with pins and sutures.

T. Wharton Jones, in certain cases of ectropion, made a deep triangular flap, the base of which was formed by the margin of the everted lid, and bringing the margin of the lid into its normal position, caused the apex of the flap to recede widely from the part from which it was taken, converting the shape of the wound from the letter V to Y, and fixing the flap in its new position by sutures. This ingenious operation is applicable to other parts besides eyelids.

Burow, a German surgeon, introduced a new operation for certain deformities of the lips, in which there is a great deficiency in the lower lip and a relative superfluity in the upper lip, or *vice versa*. He took out a triangular portion from the diseased lip, the base of the triangle corresponding with the vermilion border, and extending on one side to the angle of the mouth, and extending the line of the base by an incision into the cheek, he excised another triangle, with its apex in the opposite direction, and uniting the opposite sides of the two triangles by sutures, restored the symmetry of the mouth, lengthening the shortened margin of one lip, and shortening the superfluous margin of the other.

In all cheilo-plastic operations, it is important that the margin of the newly-constructed lip should be invested with mucous membrane. When a flap has been transplanted from the cheek, the mucous membrane should be drawn over the margins and attached to the skin by fine sutures.

When there is no healthy mucous membrane for the purpose, the skin itself may sometimes be inverted over the margin.

Within the past fifteen years, a new mode of supplying deficiencies of integument upon the surface of the body has been introduced, viz.: transplanting thin portions of skin without peduncles upon recent wounds, or upon granulating surfaces, and maintaining them in position by plasters or bandages. The name skin-grafting, or epidermic grafting, has been applied to this process. It is somewhat analogous to the process of budding or grafting fruit trees. The practice was introduced by Reverdin, a French surgeon, in 1869. Reverdin was at that time interne in one of the French hospitals. He shaved off very thin portions of integuments of the size of a grain of rice, and applied their raw surfaces to the denuded or granulating surface of the part which he wished to invest with new skin. Close apposition was maintained for a number of days, and on removing the dressings, it was found that some of the grafts had acquired a vital union with the surface upon which they had been placed, and from each one of these points there was a radiated growth of new skin. This has now become an established practice in surgery, and it has become a valuable addition to our resources in cases in which there has been an extensive loss of skin. The practice has been modified by Lee, Ollier, and Poucet, who successfully transplanted larger portions of skin, in some cases larger than a silver dollar. In grafting portions of skin without peduncles, a very different course is to be pursued from that which is adopted in the transplantation of pedunculated flaps. Instead of including a considerable thickness of subcutaneous tissue, the part to be transplanted should be cut very thin, never including any subcutaneus tissue, and often including less than the whole thickness of the skin. This mode of grafting has the advantage that it can be applied where there is no available sound skin in the vicinity of the part which is to be restored, and that the new material may be obtained from parts of the body which are covered by clothing, so that the patient will not be disfigured by the cicatrices which follow the excision of the flaps. On the other hand, it has the disadvantage that it does not provide a flap of considerable thickness, such as is required for the restoration of the lips, where the skin must be lined with mucous membrane to perform its functions in a satisfactory manner.

The operation is a useful one under some circumstances, but it is not likely to supersede the transplantation of pedunculated flaps.

After Prof. Post's able discourse, the subject was thrown open to the Society for discussion.

Dr. Quimby remarked that the subject of plastic surgery belonged to that branch of the healing art which did not, as a rule, come under the notice or occupy the attention of the general practitioner. But it is a difficult, intricate, and important branch of surgery, and as we increase in population, and advance in civilization, it will, of necessity, become more important, and should engage the general attention of surgeons more in the future than it has in the past. Having paid some attention to plastic surgery, Dr. Quimby said he would like to make one or two observations:

1st. The reason, he thought, some surgeons failed in their plastic operations, was because there was not sufficient amount of care taken in relieving the affected parts operated upon from all tension. 2nd. He had witnessed one or two failures in these operations, because due regard, he thought, was not exercised in having the flap to be transplanted thick enough, and its peduncle large enough to preserve its vitality. When the flap is cut too thin, or the peduncle too small, and where there is too much tension, sloughing is sure to follow. A unanimous vote of thanks—of the Society—was tendered Prof. Post for his exceedingly instructive and valuable lecture, after which the Society adjourned.

J. A. EXTON,
Sec'y. Hudson Co. Dist. Med. Society.

CHICAGO MEDICAL SOCIETY.

Continuation of the proceedings *of the regular meeting*, April 21, 1884:

Dr. E. C. Dudley was to have read the report of a case of removal of a uterine myoma weighing 35 pounds. The patient was operated on five weeks since, and is gradually recovering. He promised to report the case to the society sometime during the next month. He would therefore report a case this evening in which he had operated to-day. The operation was for the removal of a cyst from the abdominal cavity. The specimen was presented for examination, and consisted of a polycystic tumor, of which the history is unique. The uterus and tumor were disconnected. Ten years ago the patient first noticed this tumor, when it suddenly disappeared. It developed again, and for years it has every three to six or sometimes eight weeks disappeared rapidly, followed, as the patient stated, by a very copious evacuation of urine; she would void a pint every half hour, amounting to a gallon or more in twelve or fifteen hours. It has ruptured repeatedly within the abdomen. Several gentlemen in the profession had been consulted by the lady before she called upon him. Such cases may very easily be confounded with hydronephrosis. There were in all fifteen or twenty cysts. The tumor was two-thirds as large as an adult head, and each cyst contained a yellow viscid fluid. The pedicle is small, and the operation of removal was easily effected. There are numerous cicatrices on the outside of the cyst walls, showing where rupture had occurred at different times, while on the inside there is developed a large colloid excrescence, which I here show you, although I have not examined it with the microscope. I am sure a histological examination would result in showing it to be an endogenous colloid growth. The development is not malignant.

In relation to its adhesions, no reliance could be placed on this, as there were no adhesions. In three hours after the operation the patient's pulse was 70, strong and full, and the temperature normal. The case shows that the fluid within the abdomen when

the sacs ruptured was innocent or non-irritant, and did not at any time induce peritonitis.

Dr. G. F. Lydston asked the author if he thought the colloid growth would be apt to return in another portion of the patient's system?

Dr. J. H. Etheridge asked if there were any communication between the cyst and bladder?

Dr. D. A. K. Steele reported a case of tumor occurring in a young woman, that disappeared spontaneously in a similar way as the one reported above. That it developed again, and he tapped it, when there was discharged clear ovarian fluid. He understood that it had filled again, and then disappeared the third time.

Dr. Dudley said the first question was an important and interesting one. He thought internal cancer, if thoroughly removed, is less liable to return than when removed elsewhere—by this he meant where the cancerous tissue develops within or internal to a cyst. If an ovarian tumor containing cancerous development is removed, neither will return as that of a cancerous breast is apt to do.

This case I have reported contains within the cystic wall colloid tissue. Had a cancer been without the wall, the history would have been quite different.

In answer to Dr. Etheridge, in none of the cysts was there any rupture communicating with the bladder. There was no solution of continuity or rupture or cicatrix of the bladder. Rupture of polycystic or monocystic tumors is not common, and this peculiarity occurring in the case which I have cited is the principal reason of my presenting it. When a cyst ruptures, the fluid is eliminated or absorbed, *i. e.*, the peritonæum will carry it off, and the fluid is not infectious in the least, as has often been demonstrated.

Dr. R. Tilley asked if the urine was examined microscopically? he was answered negatively.

Dr. Charles W. Purdy then read a practical paper, and demonstrated the reaction with the new urinary papers, for albumen and sugar in urine. These test papers were prepared by Parke, Davis & Co., and he thought were the most reliable of anything of the kind that had ever been presented. The following is an abstract of Dr. Purdy's paper:

After stating the very deep importance of additional light on the pathological condition of the urine, and the subject of urinalysis generally, the author proceeded to cite what is required from us by the leading life insurance companies in this direction, and furthermore, that the day is already dawning when no reputable surgeon can afford to employ the knife or chloroform without previous observation of the same precaution. The very ablest diagnosticians repeatedly overlook the presence of an interstitial nephritis, that may begin its march silently and stealthily, when the disease is yet within range of medication. The new method of investigation has practically revolutionized the old system of urine testing, and contains so many advantages over the old methods, that we are warranted in giving it more than a passing notice.

First, then, the four solutions—ferrocyanic, picric, iodo-mercuric, and tungstic, produce the most efficient tests in paper form. As all are very soluble salts, the papers can be heavily charged with each of these solutions.

Experience demonstrates that these tests possess the elements of rapidity, simplicity and accuracy to a degree not approached by the nitric acid or any method at present known, and the precipitates that any of these papers will produce, as Dr. Oliver observes, "in ninety-nine cases in one hundred are albuminous," and if *the one precaution alone of heating* afterwards is observed, the precipitate remaining *is positively albuminous.*

The mercuric iodide test first claims our attention as the most delicate of all, as an albumen precipitant. This test, in addition, is a most sensitive one for alkaloids, hence, if a patient is taking quinine, it will produce a haze in the urine, at first sight much resembling albumen, but the haze is a uniform turbidity in the case of the alkaloids when in the urine, *which does not break up into flocculi or settle to the bottom,* as in the case of albumen. Gentle heat will of course clear up this turbidity. The oleo-resin balsam copaibæ is not thrown down by mercuric iodide in the absence of an acid, but it precipitates peptones, if present in the urine, and is redissolved by heat.

Picric acid papers throw down alkaloids, also peptones, and occasionally urates, if present in the urine, the latter in excess. The picric, unlike the mercuric test, throws down oleo-resins, even in the absence of an acid, as a dense opacity; this dissolves on boiling, and reappears on cooling.

The tungstic papers differ from the picric and mercuric in the important particular that they will not cause precipitates with alkaloids, but, like the two latter, in the absence of an acid, they will not precipitate oleo-resins.

The ferrocyanic papers are likely to prove the most valuable of the series, being the least liable to error. So far as at present known, they throw down precipitates with no bodies usually met with in the urine save albumen and urates; the latter may be avoided by first diluting the urine with an equal bulk of water. This, then, is the only known test which will detect serum albumen in the urine positively without heat.

The citric papers accompanying these tests are destined to cover a wider range of utility than the mere previous rendering of the urine acid, and clearing up phosphatic turbidity. These test papers will also differentiate the forms of albumen in urine, whether it be serum albumen, or where it may be associated with an acid, or whether it may be associated with an alkali, (called alkali albumen). With such agents as the mercuric and tungstic tests, one part of albumen to twenty thousand (20,000) may be detected.

The mode of using the paper tests for albumen was then discussed, which evoked much interest from those present. Urine, if turbid, should not be submitted to any test if we expect to gain any accurate information. If the urine is not clear when voided, it should be filtered. If this does not clear it, a fourth of its bulk of liquor potassa may be added, then warmed and filtered. If still not perfectly clear, one or two drops of the magnesium fluid, (magnesia sulph.,

ammon. carb. āā parts i; aqua destillat, parts viii; liq. ammon. pur parts i), may be added, then warmed again and filtered. Then proceed with the suspected urine. Its reaction is first noted with litmus paper. Then the various procedures and steps are taken to ascertain whether albumen may be found with the above-named reagents.

In testing for sugar, all agents employed are either caustic alkalies, or bodies associated with an alkali. We may meet with a case of saccharine urine of exceptional acidity, rendering it necessary to add an extra paper of soda carbonate. Fehling's test becomes unreliable if kept too long, and all solutions used in sugar testing become unsuitable and unreliable. One of the tests for sugar is the copper test paper (made after the method of Trommer), and a soda carbonate paper; one of each are introduced into a test-tube containing 30 minims of urine, and heated to boiling. If sugar is present, the usual reaction will be observed.

Picric acid test papers possess the advantage that they may be used in testing for both sugar and albumen. Used with the soda carbonate paper, the picric, upon boiling with urine, assumes a dark color if sugar be present.

The indigo carmine test for sugar is the most striking and beautiful in reaction of any of these tests. When the indigo carmine is heated with soda carbonate and a solution of glucose or saccharine urine, the blue color is converted gradually into violet, then into various tints of red, and finally into yellow. This method is as follows: Place in a test-tube containing 30 minims of water a paper charged with the carmine of indigo, and one of the soda carbonate, heat till the indigo is discharged into the water, then add one or two drops of the suspected urine and apply heat. If sugar is present, the blue quickly changes to a violet tint. This in turn deepens, and passes into purple, which next shades into reddish purple, followed by various tints of red. These quickly merge into orange red and orange, and at last the solution becomes of a straw color, and the paper assumes a yellow color. The compass of this wonderful color reaction embraces all the prismatic colors save that of green, and their kaleidoscopic play before the eye of the observer in testing is one of most exquisite beauty.

It will be noted, on standing the tube aside, that these colors slowly return in the inverse order in which they appeared, especially in the upper part of the tube, which is due to reoxygenation through atmospheric contact. This may be hastened, as well as diffused through the whole tube, by constant agitation, or entirely stopped by filtering and corking the tube at any color. The tint reached in any particular case depends upon the quantity of glucose present in the urine. It may stop at any of the colors reached, but made to proceed to yellow by adding more glucose to the solution, *and upon this fact depends the working of the* QUANTITATIVE *tests for sugar in paper form*, which is deferred until another time.

In the discussion, Dr. G. C. Paoli spoke of the information on this subject that a writer advanced last year, and published in one of the British medical journals. I desire to state, also, that another test for albumen is in placing a crystal of metaphosphoric acid as large as a small pea in the suspected urine, and if albumen is present, will be followed by the usual reaction, and further, that a crystal of pure carbolic acid used in the same manner, is also a sure test for albumen. He had heretofore been content in using concentrated nitric acid, chemically pure, as a sufficiently reliable reagent for albumen, which is so well known as to not require further detail.

The hour being late, the society then adjourned.

L. H. M.

BOOK REVIEWS.

THE DISEASES OF CHILDREN. A Handbook for Practitioners and Students. By ARMAND SEMPLE, B.A., M.B.; M.R.C.P., London. Physician to Northwestern Hospital for Children. New York: G. P. Putnam's Sons, 1884. Pp. 352.

The small size of this work and the great extent of the subject it covers, has rendered condensation and brevity of style a necessity. It is true that the whole subject has been traversed in its pages, but in many instances in a fashion extremely unsatisfactory to the reader.

In the discussion of the diseases of the spinal cord and its membranes, all mention of *treatment* is omitted from the sections devoted to "spinal irritation," "spinal hæmorrhage," "myelitis," "spinal meningitis," and "hydrorachis." For these five affections, the important question of treatment is dismissed with the following brief paragraph at the foot of the last page in the chapter:

"Treatment of Spinal Diseases.—In acute inflammation of the spinal cord, the patient must be kept in the recumbent position. The prone position is also very useful. Ice may be constantly applied along the spine; blisters, or an issue on each side of the spine have been recommended, or even a few leeches. The value of drug medication is doubtful, but in spinal affections of rheumatic origin, iodide of potassium and colchicum may be employed with advantage. Belladonna, conium, and ergot, are by some considered to act beneficially when the cord is involved."

Not less curtailed are the descriptions of many of the most common and important diseases, so that the book can only claim to be a compend at best. With the exception of a few minor inaccuracies, the work has been carefully done and is fairly creditable, but displays no great originality of thought or investigation.

A MANUAL OF OBSTETRICS. By A. F. A. KING, M.D., Professor of Obstetrics in Columbian Univ., Washington, D. C., and in the Univ. of Vermont, etc. Second Edition. Philadelphia: Henry C. Lea's Sons & Co., 1884. Pp. 338.

This is a text-book for students. The author has compiled with good judgment from Leishman, Play-

fair, and Lusk, a fair outline of the essential principles of midwifery, and has done his work so well that graduates as well as students will find the manual a convenient one.

It is, however, confessedly a work for beginners. Its discriptions are terse and clear, its directions bluntly stated, without unnecessary explanations.

The use of short paragraphs with capitalized headings, makes reference quick and certain, and aids the memory of the learner in preparing for examinations. This is a type of book now becoming quite common in America, an admirable type too, for the purpose intended.

ECZEMA AND ITS MANAGEMENT. A Practical Treatise Based on the Study of Three Thousand Cases of the Disease. By L. DUNCAN BULKLEY, A.M., M.D., Attending Physician, New York Hospital Skin and Venereal Diseases, etc., etc. Second Edition G. P. Putnam's Sons, New York.

Dr. Bulkley, in the second edition of his valuable treatise, has made no radical changes in form or contents. The book still remains, as the author expresses it, "a personal one," representing his own experience, with data of many hundreds of cases from private practice. It covers, nevertheless, all the ground of a complete treatise on eczema thoroughly and systematically, and embodies avowedly the views of prominent dermatologists as well as those of the writer.

Statistics are furnished of 3,000 cases. Separate chapters are devoted to the nosology of eczema, to its pathological anatomy, to its diagnosis, to its treatment, and to its special localities.

A copious general index and a complete formulary are appended, making the treatise one of much practical utility to the practitioner. It will be received with favor by the profession, and serve a useful purpose in supplying a thorough and tangible summary of modern investigations of this protean affection, a knowledge of which really constitutes a key to the whole specialty of dermatology.

DOMESTIC CORRESPONDENCE.

FROM WASHINGTON.

MEDICAL MATTERS BEFORE CONGRESS—THE BUREAU OF ANIMAL INDUSTRY—PROVISIONS OF THE PLEURO-PNEUMONIA BILL AS IT PASSED THE SENATE.—April 29.—As amended and passed by the Senate, the bill providing for the establishment of a Bureau of Animal Industry and the extirpation of contagious cattle diseases, provides, that the Commissioner of Agriculture shall organize in his department a Bureau of Animal Industry, with a chief, who shall be a competent veterinary surgeon, and who shall investigate and report the condition of the domestic animals of the United States, and the causes of contagious, infectious, and communicable diseases among them. He shall also collect such other information on these subjects, as may be valuable to the agricultural, or commercial interests of the United States. For the purposes of the Bureau, the Commissioner of Agriculture is authorized to employ a force, not to exceed twenty persons at one time. The salary of the chief of the Bureau is fixed at $3,000; that of the clerk at $1,500. The Commissioner is to appoint two competent agents, who shall be practical raisers of, or men experienced in, commercial transactions affecting live stock, who shall report the best manner of transporting and caring for animals, and the means to be adopted to suppress and extirpate pleuro-pneumonia and other dangerous contagious or communicable diseases. The compensation of such agents is fixed at $10 per day.

The Commissioner is to prepare, as early as possible, such rules and regulations as may be necessary to extirpate the diseases named, and certify such rules, etc., to the executive authority of each State and Territory, and invite the coöperation of such executive authority in the execution of the Act of Congress. When the rules, etc., shall have been accepted by such executive authority, the Commissioner may expend in the State so accepting so much money as may be necessary for the purpose of the investigations contemplated by the act, and for such disinfection and quarantine measures, as may be necessary to prevent the spread of the disease from one State or Territory into another.

In order to promote exportation of live stock, special investigation shall be made as to the existence of contagious diseases along the dividing line between the United States and foreign countries, and along the transportation lines from all parts of the United States to ports from which cattle are exported, and reports made to the Secretary of the Treasury, who shall coöperate with the State and municipal authority, corporations, and persons engaged in transportation of neat cattle by land or water, in establishing regulations for the safe conveyance of the cattle, and preventing the spread of disease; and the Secretary of the Treasury is authorized to take such steps as may be necessary, not inconsistent with the act, to prevent the exportation of cattle affected with any contagious disease, especially pleuro-pneumonia. Transportation companies are forbidden to transport cattle affected with any contagious disease from one State or Territory to another, but the so-called splenetic or Texas fever is excepted from the category of communicable diseases, so far as regards the transportation of the cattle to market. Violation of the act by railroad companies or vessels is declared a misdemeanor on the part of the manager or captain, punishable by fine not to exceed $5,000, or by imprisonment not to exceed one year, or by both. It is made the duty of the United States District Attorneys to prosecute the cases.

The sum appropriated for the purposes of the act is $150,000. The Commissioner of Agriculture is required to report annually to Congress a full account of the operations of the bureau, a list of all persons employed, their compensation, etc.

The third annual Commencement of the Washington Training School for Nurses took place on May

2, when four skilled women were graduated. Addresses were made by Prof. D. W. Prentiss, M.D., the President of the Board of Trustees, Dr. P. J. Murphy, Surgeon-in-charge of the Columbia Hospital for Women, and Dr. W. W. Godding, Superintendent of the Government Hospital for the Insane.

The graduating exercises of the medical department, University of Georgetown, took place on April 30. Diplomas were conferred by Rev. S. J. Doonan, S.J., President of the University, on the following graduates: Dexter A. Smith, Illinois; J. Paul Chambers, Pennsylvania; Thomas W. Burke, Ireland; and D. Percy Hickling, George E. Harvey, Carroll M. Rawlings and B. F. Madison, District of Columbia. The valedictory address was delivered by Dr. Dexter A. Smith, of the graduating class. The address to the graduates was made by Prof. M. C. Ellzey. Dr. Joseph Taber Johnson then presented a prize valued at $75 to Dr. Dexter A. Smith for passing the best examination; a prize, consisting of a case of surgical instruments, to Dr. John B. Hawes, of California, and a set of post-mortem instruments to Dr. J. W. Morgan, of the District of Columbia.

The American Surgical Association completed its sessions on May 3. The meetings were held in the National Museum, and some forty members were registered. A telegram of sympathy was sent to Prof. Gross. Almost all of the papers published in the official programme were read and discussed. Private receptions and an informal dinner constituted the entertainments.

MISCELLANEOUS.

NERVOUS SIALORRHŒA.—M. Gilles de la Tourette (*Revue Medicale*) records the case of a patient in the service of M. Charcot, who for some time had suffered from nervous and cerebral symptoms, and who was suddenly attacked with a sharp pain in the parotid region, which was immediately followed by an abundant secretion of saliva, which was clear and viscid, presenting all the characteristics of parotid saliva. This sialorrhœa followed the same oscillations as the pain, diminishing with it and increasing with the neuralgic exacerbations. In twenty-four hours there was a discharge of twelve hundred grammes of liquid, much more than has been noted in pathological cases or after the use of sialogogues. One peculiarity was that physical and chemical examination showed this fluid to be purely the secretion of the parotid gland. It is absolutely impossible by means of jaborandi, or other sialogogues, to disassociate the various glandular secretions in salivation. Another point is that the saliva was loaded with white corpuscles, and the epithelial cells of the mucous membrane of the mouth, but contained no trace of the caciliform cellules of the glandular crypts. These hypercrinic disturbances in the course of neuralgic attacks are in no ways new—the discharge of tears and nasal discharges are among the prosopalgias—but such an excessive secretion with a moderate neuralgia, has not before been recorded. Recognizing the neuropathic condition of the subject, we are justified in determining the cause as in the manifest disturbance of the nerve centers.

A case of an ataxic, reported by Archibald Wilson, in the *France Medicale*, presents certain resemblances to the one just referred to. This latter patient presented symptoms that were very characteristic of his trouble, such as a want of coördination in walking, loss of the patella reflex, fulgurating pains, etc. Besides which, he had a modification of the cutaneous sensibility, and attacks of suffocation which were indicative of laryngeal affection. He also suffered from sudden crises of salivation and of urination which occurred without any appreciable cause. M. Feré designated them as perfect diarrhœas, occurring from some nervous influence exercised upon the spinal cord.

AMERICAN NEWSPAPERS IN 1884.—From the edition of Messrs. Geo. P. Rowell & Co.'s American Newspaper Directory, now in press, it appears that the newspapers and periodicals of all kinds at present issued in the United States and Canada reach a grand total of 13,402. This is a net gain of precisely 1,600 during the past twelve months, and exhibits an increase of 5,618 over the total number published just ten years since. The increase in 1874 over the total for 1873 was 493. During the past year the dailies have increased from 1,138 to 1,254; the weeklies from 9,062 to 10,028; and the monthlies from 1,091 to 1,499. The greatest increase is in the Western States. Illinois, for instance, now shows 1,009 papers in place of last year's total of 904, while Missouri issues 604 instead of the 523 reported in 1883. Other leading Western States also exhibit a great percentage of increase. The total number of papers in New York State is 1,523, against 1,399 in 1883. Canada has shared in the general increase.

List of Changes in the Stations of Medical Officers, U. S. Navy, for the Week ending May 10, 1884.

P. A. Surgeon C. W. Gravatt, detached from Naval Hospital, Chelsea, and ordered to U. S. Str. "Michigan."

P. A. Surgeon G. E. H. Harmon, detached from "Michigan" and granted leave of absence.

Assistant-Surgeon T. M. Edgar, ordered for examination preliminary to promotion.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department United States Army, from May 3, 1884, to May 9, 1884.

Webster, Warren, Major and Surgeon, granted leave of absence for six months, from April 29, 1884, on account of sickness. (Par. 5, S. O. 103, A. G. O., May 3, 1884.)

Sternberg, Geo. M., Major and Surgeon, now at Governor's Island, New York Harbor, ordered to repair to this city (Washington, D. C.) to represent the Medical Department of the Army at the annual meeting of the American Medical Association, to meet on May 5, 1884, and on adjournment of the Association to return to Governor's Island. (Par. 2, S.O. 103, A. G. O., May 3, 1884.)

OFFICERS OF

THE AMERICAN MEDICAL ASSOCIATION

AND OF ITS SEVERAL SECTIONS, 1884–5.

PRESIDENT.

Dr. H. F. CAMPBELL, of Georgia.

FIRST VICE-PRESIDENT.
Dr. J. S. Lynch, of Maryland.

SECOND VICE-PRESIDENT.
Dr. S. D. Mecer, of Nebraska.

THIRD VICE-PRESIDENT.
Dr. J. H. Parsons, of New Hampshire.

FOURTH VICE-PRESIDENT.
Dr. H. C. Ghent, of Texas.

PERMANENT SECRETARY.
Dr. Wm. B. Atkinson, 1400 Pine St., Philadelphia.

TREASURER.
Dr. R. J. Dunglison, Philadelphia.

LIBRARIAN.
Dr. C. H. A. Kleinschmidt, Washington, D. C.

Place of meeting, 1885, New Orleans, La.; Time of holding meeting, last Tuesday in April.

CHAIRMAN COMMITTEE OF ARRANGEMENTS.

ASSISTANT SECRETARY.
Dr. W. H. Watkins, Louisiana.

BOARD OF TRUSTEES FOR JOURNALIZING THE TRANSACTIONS.

Drs. J. M. Toner, Washington, D. C., President;
M. Moore, Rochester, N. Y.; Leartus Conner, Detroit, Mich.;
J. H. Packard, Philadelphia, Secretary;
H. F. Campbell, Augusta, Ga.; A. Garcelon, Lewiston, Me.;
P. O. Hooper, Little Rock, Ark.;
L. S. McMurtry, Danville, Ky.; J. H. Hollister, Chicago, Ill.

OFFICERS OF THE SECTIONS:

"Practice of Medicine."
Chairman—Dr. H. Didama, New York; Secretary—Dr. J. M. Garland, Massachusetts

"Obstetrics and Diseases of Women."
Chairman—Dr. R. S. Sutton, Pennsylvania; Secretary—Dr. J. T. Jelks, Hot Springs, Ark

"Surgery and Anatomy."
Chairman—Dr. Duncan Eve, Tennessee; Secretary—Dr. E. B. King, Pennsylvania.

"Ophthalmology, Otology and Laryngology."
Chairman—Dr. J. A. White, Virginia; Secretary—Dr. Eugene Smith, Michigan.

"Diseases of Children."
Chairman—Dr. J. H. Pope, Texas; Secretary—Dr. S. S. Adams, D. C.

"Oral and Dental Surgery."
Chairman—Dr. W. W. Allport, Chicago, Ill.; Secretary—

"State Medicine."
Chairman—Dr. E. W. Schaefer, Maryland; Secretary—J. M. McCormick, Kentucky

Committee on "Necrology."
Chairman—Dr. J. M. Toner, Washington, D. C.

ORIGINAL ARTICLES.

AMERICAN MEDICAL ASSOCIATION.

THIRTY-FIFTH ANNUAL MEETING, HELD IN WASHINGTON, TUESDAY, WEDNESDAY, THURSDAY, AND FRIDAY, MAY 6, 7, 8, AND 9, 1884.

TUESDAY — FIRST DAY.

The meeting was called to order in the Congregational Church, at the corner of Tenth and G Streets, at 10:30 A. M., by the Chairman of the Committee of Arrangements, Dr. A. Y. P. Garnett. After prayer by the Rev. William A. Leonard, D.D., the Chairman introduced the President of the Association, Dr. Austin Flint, of New York. The Vice-Presidents, Dr. R. A. Kinloch, South Carolina; Dr. T. B. Lester, Mo.; Dr. A. L. Gihon, U. S. N.; Dr. S. C. Gordon, Me.; the Permanent Secretary, Dr. W. B. Atkinson, Pa.; the Assistant Secretary, Dr. D. W. Prentiss, D. C.; the Treasurer, Dr. R. J. Dunglison, Pa.; and the Librarian, Dr. C. H. A. Kleinschmidt, D. C., were also present.

Dr. Garnett addressed the Association as follows:

GENTLEMEN OF THE AMERICAN MEDICAL ASSOCIATION:

Through the favor of your suffrages at our last meeting, I find myself occupying the position which imposes upon me the pleasant duty of tendering to you, on behalf of the medical profession of Washington, our welcome to this the capital of these United States; and sincere and honest as my words of welcome are, you will find, I am sure, in the more intimate association that will follow this formal reception, that words are weak to express the cordiality of our greeting.

You have come to a place of eminent and renowned gatherings, for here the supreme interests of our whole country are studied and discussed by its larger intellects, in order to the discovery and enforcement of those political and constitutional laws which shall best establish and maintain the well-being of the Republic. And surely it is a fit place for your meeting, for no laws devised by human wisdom can be more important to humanity than those laws of life upon which rests the "*salus populi*"—laws to the study and comprehension of which, in their truest and most literal sense, your time and labor are devoted; and in no department of human effort has there been needed or has there been found keener, broader, more conscientious intellect than has been exhibited in the long historic growth and in the recent rapid development of medical science.

For the wise and stable government of a nation, as well as for the comfort of domestic life and the success of humble labor, we recognize no more important and necessary condition for him who executes the work, and for those who are to profit by it, than the preservation of that "*mens sana in corpore sano*," which it is the highest effort of our profession to secure.

There is, perhaps, in our profession one advantage possessed by no other deliberative body which is called to consult for interests as wide as the whole country. We may come—indeed, we doubtless do come—with some stubborn prejudices and fixed opinions; but we are not affected by sectional interests, nor by party ambitions; we have no constituencies to whom we are responsible; we move in a higher plane, and are answerable alone to the dictum of scientific truth. The truths we discover cannot be patented for individual use, nor converted into practical profit by huge monopolies. The remedy discovered by one man's patient and laborious study is the possession of all, and is carried by the country doctor in his saddle-bags to the humblest log cabin in the remotest settlement as freely as it is given by the great practitioner in the homes of the wealthy and powerful.

Contemplating the vast and varied field from which our information is derived, the thought comes to me—if I could sketch only the past year of the professional life of those who are met here to-day, what a multitude of profound and perplexing problems, what strange illustrations of the mysterious laws of life, what startling and apparently inexplicable exceptions to those very laws, what new suggestions as to function and organ—what uncertain but hopeful premonitions of wider and richer discovery would I have to lay before you.

Let us consider, too, the tone and temper of that spirit of inquiry in which our experience has trained us. For ours has not been the investigation of merely material facts; we have studied the finer tissue of nerves and the coarser tissue of muscles, but we have seen the one quiver and the other waste under influences beyond the analysis or control of medicine; we have seen the strong and active mind broken and palsied by disease of the body, and we have seen the mind control, and shape, and stamp its will upon the body, until, to the uneducated intelligence, as in those strange but well authenticated cases of the

stigmata, a very miracle seemed present. We have seen the painful evidence of that terrible truth, that often vice itself is disguised congenital disease. We have stood on the very border of life and of death—but we have never seen beyond. We have seen man as he is seen by no one else; we have seen him in his moments of highest heroism and of abjectest cowardice, of sublimest self-sacrifice and of basest selfishness; we have witnessed at the bedside the pleading hope, which is man's intensest prayer, and the defiant despair, which is his bitterest curse. What, in comparison to such experience, I ask is the knowledge of human nature acquired in the confidential council chamber of the lawyer, or learned in the secrecy of the confessional, even when remorse wrings truth from the penitent?

And yet does our daily experience force us to recognize with humility that beyond all our knowledge there are experiences we cannot understand, laws we cannot explain or regulate, and powers and influences which we cannot control.

We have also been taught *that* sympathy which familiarity with human suffering always excites in the mind of the true-hearted physician, and which enables him to determine more accurately the true condition of his patient than the conclusions of a purely cold intelligence.

And should we not be taught by the mental, moral and physical relations which these experiences bring before us, an abiding faith in the wisdom of that Being who has made the ministry of pain and death a part of His divine administration in nature, and in nature's order of animate life?

With these convictions of our duties and responsibilities, no language of mine can exaggerate the value and importance of these periodical gatherings, when we meet to compare experiences, to exchange counsel, and to contribute what each of us can to broadening and extending the power of medical science.

For of that power it can be said, as can be said of no other, that it has in it no faculty of oppression—that it is not sought, but freely and gratefully given, and that it cannot be exercised without doing good to others.

He offered the following report of arrangements:

The Committee of Arrangements, having executed the duty for which it was created, beg leave to submit the following report:

After a careful inspection of the various public edifices available for our use in this city, it was found that the Congregational Church, in which we are now assembled, possessed the largest seating capacity, together with three capacious rooms suitable for the meeting of the Sections. It was accordingly selected as the most eligible building for our meeting. We have also secured for the Surgical Section, and for the accommodation of the Judicial Council, capacious apartments in the Armory Building, on G street, diagonally opposite this church.

For the meeting of the Section on State Medicine, and that on Dental and Oral Surgery, we have been compelled to select the hall on the south-east corner of Sixth and F streets, being less accessible on account of the distance from this point. With regard to effecting arrangements with the various railroads for the reduction of rates, we beg to say that the most active and energetic measures were adopted early in the year to accomplish this purpose. Correspondence was had with the officials of all the trunk lines, but owing to the delay on the part of those having the power to act in this matter, we have only been able to effect final arrangements within the past three weeks. The following terms have been agreed upon, and the statement sent to the Secretary, Dr. W. B. Atkinson, some three weeks ago, together with a price list of the hotels and principal lodging-houses of Washington, in order that the information might be given to the medical public:

1. The Virginia Midland railroad will issue round trip tickets from all through points at 4 cents per mile one way, for the round trip; local points, 4½ cents per mile one way for round trip.

2. Boston, Norfolk and Baltimore steamship line, Boston to Washington, $9.50; round trip, $19.

3. Trunk lines east of St. Louis, Chicago and Cincinnati agree to return delegates at one-quarter lowest unlimited rate.

4. Trunk lines west of St. Louis and Chicago agree to return delegates at one-third regular rate.

5. Atlantic Coast lines have agreed to issue round trip tickets at reduced rates from various points.

6. Pennsylvania railroad and Baltimore & Ohio railroad will issue round trips from New York City $9.80, Philadelphia $6.10, Baltimore $1.60.

7. The Southern Association, embracing the territory south of the Potomac and Ohio and east of the Mississippi, excepting the Virginia Midland and Coast line, refuse to reduce rates.

PROGRAMME FOR TUESDAY'S RECEPTIONS.

We are gratified to announce that there will be a reception by the President of the United States at the Executive Mansion from 8:30 to 10:30 p. m. Reception by Mr. and Mrs. Leiter, No. 1500 Twentieth Street, Northwest, from 9 to 11 p. m.

Wednesday.—Reception and entertainment by the medical profession of Washington at National Rifles' Armory, 920 G Street, Northwest, from 9 to 12 p. m.

Thursday.—Illumination of the Corcoran Art Gallery, and Reception by Mr. W. W. Corcoran and Board of Trustees, from 8 to 10 p. m.

Reception by Commissioner and Mrs. Loring, No. 1521 K Street, Northwest, from 9 to 11 p. m.

Reception by Mr. and Mrs. W. T. Hildrup, No. 1 Iowa Circle, from 9 to 11 p. m.

Reception by Chief Justice Morrison R. Waite, No. 1415 I street, Northwest, from 9 to 11 p. m.

Friday.—Reception by the Surgeon-General, U. S. A., and Staff, at Army Medical Museum, Tenth Street, between E and F Streets, Northwest, from 8 to 11 p. m.

Reception by Hon. George F. Edmonds, President *pro tempore* of the Senate, and Hon. John G. Carlisle, Speaker of the House of Representatives, in the Marble Room, Senate side of the Capitol, at 8 p. m. Illumination of the Capitol from 8 to 10 p. m.

At the suggestion of our honored President, invitations were sent to several of the most distinguished

physicians and surgeons in Europe, inviting their attendance or any contribution of papers which they might feel disposed to make at the present meeting.

Several responses were received and one paper sent as a contribution, by Mr. A. Pearce Gould, F.R.C.S., of London. If it is the pleasure of the Association these letters will now be read.

The Chairman of the Committee of Arrangements embraces this opportunity to call attention to the flagrant and unexcusable manner in which the By-laws relating to the time of reporting titles of papers to be read before the Sections, and other matters to be included in the programme, has been disregarded.

The embarrassment to the committee occasioned by such neglect on the part of those who prepare papers, can only be appreciated by the unfortunate individual who is subjected to it, and he therefore earnestly hopes that some means may be found to enforce the law in this regard and spare the patience of his successor. More than one-half of the matter to appear in the programme was reported to the committee after the 1st of April, notwithstanding a notice had been published in the official journal two months before, calling attention to the By-law on this point. He further begs leave to suggest that the office of Assistant Secretary (which at present seems to be a superfluous one) be more specifically defined and its duties clearly and intelligently designated.

In closing this report, the Chairman begs to express his grateful acknowledgments to the whole committee, for its hearty coöperation and support, but especially does he desire to return his thanks to the chairmen of the several sub-committees for their active and efficient assistance in prosecuting this vexatious labor of love.

COMMUNICATIONS acknowledged by Dr. Garnett from A. Pearce Gould, F. R. C. S., of London, and from other eminent medical men of Europe, which on motion were received and filed.

THE REGISTRATION.—The Secretary read the list of registered delegates up to the time of the morning session, having been called to order, the whole number being 590. On motion of Dr. J. M. Toner these were confirmed.

INVITED GUESTS.—Dr. J. H. Trumbull, of South America; Dr. Jonas A. Marshall, of Massachusetts; Dr. F. R. Garloch, of Wisconsin, and the members of the Medical Association of the District of Columbia, not already members, were invited to seats in the meeting.

A LETTER FROM DR. JOHN L. ATLEE, of Pennsylvania, an ex-President of the Association, expressing his regret at being unable to attend the meeting, was read by the Secretary and ordered to be entered on the minutes.

Vice-President Dr. R. A. Kinloch occupying the chair, the President then delivered the annual address.

On motion of Dr. Toner, thanks were tendered to the President for his address, and a copy was requested for publication.

On motion of Dr. Toner the following was adopted:

WHEREAS, it has come to the knowledge of the American Medical Association, that one of its former Presidents, and a surgeon of world-wide reputation, and whom we miss among us, is at this time confined to his room by serious illness. Therefore be it

Resolved, That the American Medical Association extends Prof. S. D. Gross its heartfelt sympathy in his suffering, and expresses its earnest hope for his speedy and complete recovery, and many years of usefulness in the profession he has so signally adorned, and for the enjoyment of the well-earned reputation he has won throughout the world.

Resolved, That a copy of these resolutions may be conveyed by the Secretary to Prof. Gross.

On motion of Dr. A. L. Gihon, of the U. S. Navy, that portion of the President's address referring to Professor Gross was ordered to be telegraphed to him at once, as an appropriate form of expression of the sentiments of the Association.

Dr. T. G. Richardson, of La., stated that he had only recently come from the bedside of Dr. Gross, who, when asked whether he had any word to send to the Association, said, in a feeble voice: "Give them my love."

On motion of Dr. L. A. Sayre, of New York, the resolutions offered by Dr. Toner were ordered to be telegraphed to Dr. Gross. And, on motion of Dr. W. L. Schenck, of Kansas, it was further resolved that the expression of love on the part of Dr. Gross toward the Association be acknowledged and reciprocated.

The Secretary read the following telegram from Dr. W. O. Baldwin, of Alabama:

PASS CHRISTIAN, MISS., MAY 5, 1884.

Dr. Austin Flint, Sr., President Am. Med. Ass'n, Washington:

I deeply regret my inability to be with you; my failure to attend is due wholly to ill-health. You know how sincerely my heart is with you. May God prosper the good work. I am banished here on account of poor health.

W. O. BALDWIN.

On motion, it was ordered to be entered on the minutes.

On motion of Dr. Sayre, that portion of the President's address suggesting that the International Medical Congress be invited to meet in this country in 1887, was referred to a special committee of five, of which Dr. Billings should be the chairman.

Several resolutions were offered regarding that portion of the President's address relating to medical ethics, for which the following, by Dr. Ferguson, of New York, was finally substituted and adopted:

Resolved, That that portion of the President's address referring to the subject of medical ethics be referred to a committee of seven, to report upon the recommendations therein contained as speedily as possible.

The titles of several papers not on the printed list were then read, and, on motion, they were referred for reading before the appropriate Sections.

Dr. A. Blumberg, of Pennsylvania, and Dr. B. F. Shreeve, of Iowa, were invited to seats in the meeting, and the session was then adjourned until Wednesday at 10 A. M.

WEDNESDAY—SECOND DAY.

The meeting was called to order at 10 a. m. by the President. A prayer was offered by the Rev. W. A. Bartlett, D.D.

The President formally announced the death of Professor Samuel D. Gross, of Philadelphia, and appointed the following committee to take such action as it might think proper in the matter: Dr. T. G. Richardson, of Louisiana; Dr. L. A. Sayre, of New York; Dr. J. H. Packard, of Pennsylvania; Dr. F. H. Hamilton, of New York; Dr. Moses Gunn, of Illinois; Dr. W. T. Briggs, of Tennessee; and Dr. I. M. Hays, of Pennsylvania. On motion of Dr. H. C. Ghent, of Texas, the President of the Association was added to the committee as its chairman. The Secretary read the following dispatch from Dr. Samuel W. Gross:

PHILADELPHIA, PA., MAY 6, 1884.

Dr. W. B. Atkinson, Secretary American Medical Association, Washington, D. C.:

The resolution and extract received too late. Convey to the Association the warm thanks of the family for its great kindness and consideration.

S. W. GROSS.

On motion this dispatch was ordered to be entered on the minutes.

Dr. Garnett, of the Committee of Arrangements, presented some protests, which were referred to the Judicial Council.

On his motion, Dr. C. D. Alton, of Connecticut, and Dr. A. W. Adair, of Iowa, were invited to seats.

The Permanent Secretary called the roll, and announced as the Committee on Nominations:

Alabama, Jerome Cochrane; Arkansas, P. O. Hooper; California, F. W. Hatch, Sr.; Colorado, Jesse Hawes; Connecticut, G. L. Porter; District of Columbia, J. W. H. Lovejoy; Dakota Ter., Hector Galloway; Delaware, W. Marshall; Florida, R. B. Burroughs; Georgia, W. F. Holt; Illinois, E. P. Cook; Indiana, T. B. Harvey; Iowa, H. C. Huntsman; Kansas, F. F. Dickman; Kentucky, W. H. Wathen; Louisiana, T. G. Richardson; Maine, F. C. Thayer; Maryland, J. S. Lynch; Michigan, H. F. Lyster; Mississippi, B. A. Duncan; Minnesota, D. Leasure; Massachusetts, Chas. A. Savory; Missouri, N. F. Essig; North Carolina, C. J. O. Hagner; New Hampshire, J. W. Parsons; Nebraska, S. D. Mercer; New Jersey, Jos. Parrish; New York, J. W. S. Gouley; Ohio, W. M. Beach; Pennsylvania, J. B. Murdock; Rhode Island, Jas. H. Eldredge; South Carolina, Wm. Huger; Tennessee, Duncan Eve; Texas, J. H. Pope; Vermont, Henry D. Holton; Virginia, Alex. Harris; W. Virginia, Geo. Beard; Wisconsin, Wm. Fox; U. S. Army, J. R. Smith; U. S. Navy, N. L. Bates; U. S. Marine Hospital, Walter Wyman.

The President appointed the following general committee on his annual address: Dr. N. S. Davis, Dr. W. W. Dawson, Dr. W. T. Briggs, Dr. T. F. Prewitt, Dr. D. W. Stormont, and Dr. H. B. Ransom. As the Special Committee, he named the following gentlemen: Dr. J. S. Billings, Dr. L. A. Sayre, Dr. R. H. Fitz, Dr. I. M. Hays, and Dr. H. F. Campbell.

The committee appointed to frame resolutions in favor of securing more competent medical and sanitary service on board trans-oceanic passenger vessels reported, through its chairman, Dr. A. N. Bell, of New York, that a bill had been prepared and presented to Congress which covered the matter.

Dr. T. D. Keyser, of Pennsylvania, made some remarks on the subject, and on motion of Dr. Foster Pratt, of Michigan, these points were referred to the committee, which was continued.

Dr. Irwin, of Canada, by invitation, made some remarks on the subject.

Dr. Gihon asked that Dr. Irwin formulate his ideas.

On motion of Dr. Foster Pratt it was

Resolved, That the Report of Progress by the Committee be accepted, that the Committee be continued and instructed to report upon the condition of the subject at the next session of the Association; also,

Resolved, That the American Medical Association now in session urge upon Congress through the respective Committees on Commerce of the Senate and House of Representatives the necessity of suitable and efficient legislation, to promote the well-being of emigrants to this country, and to protect our public health.

Dr. J. V. Shoemaker, of Pennsylvania, Chairman of Section on Practice, delivered his address.

On motion of Dr. W. Brodie, of Michigan, it was referred to that Section.

Dr. T. A. Reamy, of Ohio, Chairman of Section on Obstetrics and Diseases of Women, delivered his address.

On motion, the address was referred to that Section.

On motion, Dr. LeBaron Botsford and Dr. L. Stevens, of Canada, and Dr. J. W. Hanna, were invited to seats with the Association.

On motion of Dr. Henry H. Smith, of Pennsylvania, seconded by Dr. P. D. Keyser, of Pennsylvania, and Dr. J. C. Dalton, of New York, the following was adopted:

WHEREAS, It appears that an effort is being made to restrict, by legislative action, the practice of investigation in medical science by experiments on animals; and

WHEREAS, In the opinion of this Association such restriction is not needed for the guidance of medical men in their investigations, and would be an injury and a hindrance to the pursuit of medical knowledge and the improvement of the medical art; therefore

Resolved, That a standing committee of seven be appointed by the President of the Association, to be known as the "Committee on Experimental Medicine of the American Medical Association," charged with the duty of opposing, by all legitimate means, any interference with the progress of medical science by unwise or ill-considered legislation.

The President appointed as the Committee: Dr. H. C. Wood, of Pennsylvania; Dr. Wm. Pepper, of Pennsylvania; Dr. Jas. Tyson, of Pennsylvania; Dr. C. Johnson, of Maryland; Dr. J. C. Dalton, of New

York; Dr. A. Flint, Jr., of New York; and Dr. J. S. Billings, of United States Army.

Dr. LeGrand Atwood, of Missouri, on behalf of the St. Louis Medical Society, presented a paper objecting to the practice of physicians connected with colleges, etc., advertising, etc.

The matter was referred to the Judicial Council.

Dr. D. Benjamin, of New Jersey, offered the following:

Resolved, That this Association earnestly urges upon all American medical colleges the necessity of elevating the standard of education at least so far as to require a preliminary examination; a three years' course; a register of attendance, and practical demonstrations of diagnostic skill.

After much discussion, a motion to lay it on the table was lost, and after some further discussion, the resolution as offered was adopted.

On motion of Dr. J. H. Packard, of Pennsylvania, certain amendments to the Constitution and By-laws offered at Richmond, were made the special order for Thursday, immediately after the addresses for that day.

The Permanent Secretary read an invitation from Prof. Baird of the United States Fish Commission, for the members of the Association to visit the institution and observe the hatching of shad, which, on motion, was received with thanks.

On motion, the Association adjourned until Thursday, at 10 A. M.

THURSDAY—THIRD DAY.

The Association was called to order by the President at 10 A. M., and prayer was offered by the Rev. W. Paret, D.D.

On motion of Dr. J. M. Taller, it was

Resolved, That the records of the meeting held at St. Paul, in 1882, be so corrected as to show that the organic law was then so amended as to leave the date of meeting of the Association to the Nominating Committee.

The President appointed the following committee to nominate trustees of the Journal to fill the vacancies occasioned by expiration of term: Dr. E. D. Ferguson, of New York; Dr. W. T. Briggs, of Tennessee; Dr. J. E. Reeves, of West Virginia; Dr. T. F. Prewitt, of Missouri; Dr. George Peck, of the navy; and Dr. D. W. Stormont, of Kansas.

The committee appointed to urge the provision of commodious and fire-proof buildings for the Army Medical Museum and the Library of the Surgeon-General's Office reported that a memorial to Congress recommending that $5,000 be appropriated for the improvement of the museum had not been acted upon in the committee of Congress; but that the committee had reported favorably to an appropriation of $10,000 for the library. The report was accepted, and the committee continued.

Dr. George M. Sternberg, U. S. A., offered the following:

WHEREAS, We recognize our responsibility as guardians of the public health, and the fact that it is better to prevent than to cure disease; and.

WHEREAS, Intelligent measures of prevention require an exact knowledge of the causes of disease, which exact knowledge has not yet been obtained for a majority of the infectious and pestilential maladies which afflict the human race; and

WHEREAS, The extension of our knowledge in this direction calls for the persistent and intelligent efforts of men specially trained for such investigations, and brings no pecuniary reward; and

WHEREAS, The Congress of the United States has heretofore made liberal appropriations for scientific investigations relating to geology, natural history, the diseases of domestic animals, etc., all of which are evidently secondary in importance as compared with the subject herein referred to; therefore, be it

Resolved, That we earnestly petition the Congress of the United States to make suitable appropriations for the prosecution of scientific researches relating to the cause and prevention of the infectious diseases of the human race, to be expended under the direction of the National Board of Health, and that the permanent detail of one medical officer of the army, and one of the navy, be authorized for the prosecution of researches of this nature.

Resolved, That a committee of five members of this Association be appointed to present copies of this resolution to the Speaker of the House of Representatives, to the President of the Senate of the United States, and to the Chairman of the Committees of Public Health of the House and of the Senate.

On motion the resolutions were adopted, and the President appointed the following named gentlemen to constitute the committee: Dr. Sternberg (Chairman), Dr. Albert L. Gihon, U. S. N.; Dr. I. M. Hays, Pennsylvania; Dr. J. C. Dalton, New York, and Dr. J. E. Reeves, West Virginia.

Dr. Keller, of Arkansas, offered some resolutions on cremation, but was ruled out of order.

Dr. J. S. Billings, of the Committee on International Medical Congress, presented the following:

The Committee to which was referred that part of the President's address, relating to the proposed meeting of the International Medical Congress in the United States, in 1887, has the honor to report that it has conferred, so far as the limited time at its disposal would allow, with leading members of the Association, representing all parts of the country, and that the sentiment appears to be practically unanimous in favor of carrying out the suggestions made by the President.

The Committee accordingly respectfully submits the following resolutions with the recommendation that they be adopted by the Association:

Resolved, 1. That a Committee of seven, of which Dr. Austin Flint, the President of this Association shall be a member, shall be appointed by the President.

2. It shall be the duty of this Committee to extend in behalf of the medical profession of the United States to the International Medical Congress, about to meet at Copenhagen, a cordial invitation to have the next International Medical Congress meet at Washington, D. C., in 1887.

Resolved, 2. That the Committee shall elect its

own officers, and that, in case the invitation is accepted, it shall proceed to act as an Executive Committee, with full power to fix the time and to make all necessary and suitable arrangements for the meeting of such Congress, and to solicit funds for this purpose.

3. That the Committee shall have power to add to its membership, to perfect its organization, and that to meet the preliminary expenses of printing, postage, etc., the chairman of this Committee is authorized to draw upon the Treasurer of this Association for an amount not exceeding four hundred dollars.

(Signed.) J. S. BILLINGS,
L. A. SAYRE,
I. MINIS HAYS,
H. F. CAMPBELL.

R. W. Foster not present.

On motion the report was adopted.

Dr. J. M. Toner, on behalf of the Board of Trustees, then presented their report and the report of the editor, Dr. N. S. Davis.

REPORT OF THE BOARD OF TRUSTEES.

The Board of Trustees of the American Medical Association, for journalizing and publishing its transactions, beg leave to lay before the Association the following report of their operations for the year:

It is well known to the Association that after much deliberation, and various reports by special committees to whom the consideration of the question of journalizing its transactions had been at different times referred, finally in June, 1883,

"*Resolved*, That the interests of the Association would be promoted by the publication of its transactions in a weekly medical journal under its own control, instead of an annual volume as heretofore, provided it could be done without involving pecuniary embarrassment, or so far engrossing its funds as to prevent the annual encouragement of original investigations by its members."—JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Vol. 1, p. 4.

A detailed account of the plan and scope of the journal, and its probable cost per year, was given in the report referred to, as well as its place of issue named.

The place of publication, however, was determined by competitive bids from reliable publishing houses in several of the large cities, and A. G. Newell, publisher, of Chicago, being the lowest, the contract was awarded to him.

By a fortunate coincidence, the editor selected resided in the same city.

One of the resolutions accepting the report, changing the form of publication, and giving effect to its provisions and recommendations, is in the following language.

"*Resolved*, That the Board of Trustees are hereby instructed to proceed with the publication of the Journal of the American Medical Association, at as early a day as is practicable, to take the place of the annual volume of transactions, and that the duties formerly devolved upon the Standing Committee of Publication be transferred to the Board of Trustees, and that the Secretaries of the Association, during or immediately after each annual session, be required to transfer to the editor of the JOURNAL the record of proceedings, addresses, and all written reports of committees and officers, papers and contributions, that may be referred for publication, either in general sessions or in any of the Sections.

The Board of Trustees first organized at St. Paul by electing officers, and made their report recommending the establishment of the JOURNAL at Cleveland, in June, 1883, from which we just quoted.

Dr. N. S. Davis, the veteran projector, steadfast friend, and wise promoter of the best interests of the American Medical Association, was unanimously selected by the Board as editor of the JOURNAL.

The report was comprehensive, and outlined the plan upon which the JOURNAL was to be conducted, and the class of advertisements to be admitted, which has been adhered to. A constitution for the government of the Board of Trustees was drafted and adopted at the Cleveland meeting.

The rule laid down in the report relating to advertisements is in the following words: "Advertisements from all medical educational institutions and hospitals open for clinical instruction, from book publishers, pharmaceutists, instrument-makers, and all other legitimate business interests. But all advertisements of proprietary, trade-mark, copyrighted or patented medicines should be excluded. Neither should any advertisements be admitted with one or more names of members of the profession as indorsers, having their officinal titles or positions attached.

"In other words, no advertisements should be admitted which fairly contravene, in letter or in spirit, the principles of the National Code of Ethics."—JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Vol. I, p. 6.

This regulation is a wise restraint, tending to elevate the dignity of the JOURNAL; but it, at the same time, deprives it of a considerable revenue.

A weekly issue of 3,500 copies, containing the papers recommended by the Association for publication and original contributions, such as are usually admitted to first-class medical journals, was begun in July last, and mailed to members, subscribers and exchanges.

The number printed was slightly in excess of the number of members and subscribers, so as to have a residue on hand, and the number has consequently been gradually increased until the issue has reached 3,800.

The character and appearance of the Journal is familiar to all. That the publication of the transaction in the weekly JOURNAL form has proven more acceptable to the members than the annual volumes, is manifest.

The proceedings and papers of the Association can now reach the members within the first quarter after the meeting, and besides, the Journal furnishes six times as much reading matter during the year, including the latest medical news and progress in medicine, as was given under the old method of publication.

The enterprise was at the start something of a financial venture, and like most new departures has been more or less hampered for want of funds.

It is gratifying to find, however, that by this method of publication increasing interest has been aroused among the old members of the Association.

The remarkable increase in the income of the Association may be taken as the indubitable evidence of approbation.

This is made apparent when we contrast the total increase of the Association from annual dues of members and sale of transactions for a series of years with the past ones.

The Treasurer's account shows the following receipts for the respective years:

Namely 1877, reported at Buffalo in 1878..	$ 5,439.75
" 1878, reported at Atlanta in 1879	5,483.16
" 1879, reported at New York in 1880	3,879.34
" 1880, reported at Richmond in 1881	7,409.89
" 1881, reported at St. Paul in 1882	3,304.00
" 1882, reported at Cleveland in 1883	4,535.30
" 1883, reported at Washington in 1884	13,017.25

From subscriptions, sale of Index, and advertisements to May 5, the income for the year ending with this meeting, you will observe, shows a very marked increase of funds, nearly double that of any former year, and will be further augmented by assets due the JOURNAL, and payable at the end of this quarter.

What the amount may aggregate at the end of the year cannot now be stated with exactness.

But the editor in his clear and comprehensive report on the management and prospects of the JOURNAL to this Board, however, gives a close approximation to the amount of assets at the close of the publication year, which will appear farther on.

Dr. Dunglison reports, May 5, that the sources and amounts of income for the year 1884 on hand from last year	$ 903.95
Received during the past year from sale of Index	198.00
From members and delegates at Cleveland	5,008.75
And from the office of publication, from subscriptions, advertisements, etc	7,810.50
Total	$13,921.20
The expenses incurred in publishing the JOURNAL for the first three quarters of the year and the three first numbers of the last quarter, and already paid from the treasury on vouchers properly signed	$8,808.66½
Drawn on account of editorial work	752.12
Total amount drawn from the treasury on account of the JOURNAL, on the order of the Editor, countersigned by the President of the Board of Trustees, is	$9,560.78½

It will require about $1,800 to complete the publication of the last quarter of the JOURNAL, and there is due the editor for the year's salary $5,247.88.

The treasurer's statement just referred to shows that there remains in the treasury, May 5, 1884, $2,212.07. The assets from unpaid subscriptions, and from contracts for advertisements which fall due at the end of this quarter, and which are deemed perfectly good, will yield a sufficient sum to complete the volume.

The year will therefore, we believe, close with a surplus in the treasury over all expenses, including Editor's salary, of about $500.

The Editor's report furnishes important data to the Board, and will also give desirable information to the Association, and is, therefore, incorporated as a part of the report of this Board of Trustees to the Association. I now request that if present, the Editor, Dr. N. S. Davis, may read his report for me.

REPORT OF THE EDITOR TO THE BOARD OF TRUSTEES.

When the undersigned entered upon the discharge of his duties, and the Board of Trustees adjourned at the meeting in Cleveland the first week in June, 1883, it was understood that the actual number of members of the Association and subscribers to be supplied with the JOURNAL would not exceed 2,500, and that 1,000 extra copies would be sufficient to afford a moderate number each week to be used as specimens for inviting more subscriptions, and leave a sufficient surplus to supply any additions that would be made through the year. Consequently, Mr. A. G. Newell, successor to the firm of Tucker, Newell & Co., to whom had been awarded the contract for publishing the JOURNAL, was notified to be in readiness to commence such publication on the 1st day of July, 1883, and the manuscript for the first number was placed in his hands in time for issue at that date. But the many incidental details required the adjusting of forms, apportioning new type to the wants of medical writing, the arranging of printed mail lists, and organizing of folders, stitchers, wrappers, etc., actually delayed the first issue to the middle of July. And the same causes prevented the regaining of prompt issues on time for the first three months. These embarrassments were greatly increased by the inefficiency of the foreman of the printing department both in arranging his forms and in making the corrections marked by the proof-reader.

By the exercise of much patience, however, all these obstacles were finally removed, and the establishment secured the services of a very competent foreman, a fairly well-skilled proof-reader, and a well-drilled corps of folders, wrappers, and mailers, under whose hands the JOURNAL has been mailed with almost uniform regularity on the day of its date (Saturday of each week) for the last four or five months.

Circulation.—Before the time for issuing the fourth number it became apparent that more than 3,500 copies would be required each week, if any were to be used, either to supply extras to writers or for samples to other parties.

Accordingly, the number issued each week was increased to 3,800, and has been continued at that rate until the present time.

The first three-quarters (nine months) of the Jour-

nal year closed March 31, 1884. Up to that time the total number of names received from the Treasurer, as members having paid their dues and entitled to the JOURNAL, was 2,069.

In addition, there had been received 1,202 names of subscribers, a large part of them by *pledge*, before the issue of the first number of the JOURNAL.

In addition, further, 165 copies are sent each week to exchanges and correspondents at home and abroad, making the total regular weekly circulation at the present time 3,436, of which 3,271 are to members of the Association who have paid their dues for the current year and to actual subscribers. Of the 1,202 of the latter class, 650 have already paid their subscriptions at this office, leaving 552 still unpaid. Some remittances are being received from these daily, with a prospect that very nearly all will be paid before the end of the JOURNAL year. It is thus seen that the actual circulation of the JOURNAL has considerably exceeded the estimates made at the last meeting of your Board.

Advertising.—Coincident with the issue of the first number of the JOURNAL, a circular letter, accompanied by a card containing a scale of advertising rates, and explaining the merits of the JOURNAL as an advertising medium, was sent to the officers of medical colleges, drug manufacturers, instrument-makers, etc., soliciting patronage. As nearly all the annual medical college advertising is placed in May and June, it was too late in the season to secure more than a very few advertisements from that source. A few of the larger and better class of drug manufacturing firms promptly responded with page advertisements, payments to be made at the end of each quarter. Many offers of advertisements were received from advertising agents and business firms, but of such a character as were precluded from acceptance by the rule adopted by the Association. Still the advertising patronage has slowly increased. During the month of March, another circular letter was sent to nearly all the medical colleges in the country; and in consequence several good advertisements have been received during the last few days.

Notwithstanding the restrictions already alluded to, the amount received on account of advertisements up to March 31, was $809.50. The amount due at that date, but not paid, for advertisements during the third quarter, $1,000, and there will accrue during the fourth quarter more than $1,200, making the total from advertising department during the first year at least $3,000.

Total income first 9 months.—From the foregoing facts it will be seen, that, counting the 2,069 members whose names have been forwarded to the publication office by the Treasurer, as having each paid $5, the aggregate receipts by the Treasurer from that source up to the end of the third quarter of the JOURNAL year is $10,345. The actual receipts from subscribers at the office of publication, up to same date, is $2,293; and from advertising $809.50, making the total at this office $3,102.50, all of which has been paid into the treasury, and receipts taken ere for. This makes the *supposed* total receipts on account of the first three-quarters of the JOURNAL year $13,447.50.

In the 650 subscribers reported to have paid at the office of publication, are included 52 who have paid since the 31st of March, and 37 whose subscriptions net only $4, each on account of the deduction of 20 per cent., or $1, commissions to book and periodical dealers who procure subscribers; and 170 at the same rate furnished in one bundle to the Surgeon-General's office, for the use of the medical department of the U. S. Army, and on which there is unpaid the last half year, amounting to $340, and which will be paid at the end of the fourth quarter.

These facts will explain the difference between the nominal proceeds of 650 subscribers reported to have paid, (but 170 of which had actually paid only for the first half of the year), and the sum reported to have been actually received up to March 31, 1884.

Additional receipts to be expected during the fourth quarter.—In regard to the income that may be expected during the fourth and last quarter of the JOURNAL year, I think the $340 from the medical department of the United States Army, and the $2,000 from advertisers, may be considered entirely reliable. From the 552 subscribers who have not yet paid, there is due $2,760; which added to the other sums named would make an aggregate of $5,100. If we add this to the actual receipts of the first *three-quarters*, it will make the total income of the Association on account of membership fees and subscriptions, etc., for the JOURNAL year, $18,547.50.

Expenditures.—The total amount drawn by orders on the Treasurer of the Association and approved by the President of your Board, for the payment of publication expenses, as by contract with the printers, and for cuts, stereotype plates, clerk hire, U. S. postage bills and expressage for the first quarter was $3,152.98; for the second quarter, $2,348.24; and third quarter, $2,670.04; making a total of publication expenses for the first three quarters of $8,171.26. Estimating the publication expenses of the fourth quarter nearly the same as the third, viz.: $2,720, it would make the total publication expenses of the JOURNAL for the first year $10,891.25. There has been drawn from the treasury on account of editorial work during the first three quarters of the year $721.63. If we add this to the total publication expenses for the year it makes an aggregate of $11,612.88.

This is $1,834.62 less than the total actual receipts of the first three quarters of the JOURNAL year, and $6,134.62 less than the total receipts, with the estimated income of the fourth quarter added. If we deduct from this the unpaid balance of the $6,000 appropriated to the editorial department, namely $5,278.37, it would leave a balance or surplus in the treasury as the result of the first year of journalistic work of $1,656.25. If we make the liberal allowance of $1,000 for the necessary current expenses of the Association for the year, there will still be a balance of over $500 in the treasury.

There is a reasonable certainty, therefore, that the aggregate receipts for the year will pay all the expenditures belonging to the publication of the JOURNAL,

and leave a surplus sufficient to meet all the necessary current expenses of the Association.

JOURNALS on hand.—Immediately after the close of the first volume of the JOURNAL, we requested all members and subscribers to examine their files and inform us at once of any missing numbers, and we would supply them without additional charge. This brought a considerable number of applications, all of which were supplied, consequently if there are any whose volumes are still incomplete, it is their own fault. Owing to the printing of only 3,500 of the first numbers, and the sending out of some as sample copies, numbers two, six and sixteen of volume one are exhausted. Of the remaining numbers of that volume, there remain on hand about fifty copies of each. Of the numbers thus far issued of volume two, between two and three hundred of each have been carefully reserved to supply such new members as might come in at the present annual meeting in Washington, and desire the volume complete.

It is proper I should state in simple justice to the present publisher of the JOURNAL, that he has faithfully adhered to his contract in every particular. The paper furnished has been very uniform in quality, and every effort has been made to correct defects, whether in the skill of employes or in the lack of material, and the improvements made during the past six months have been too marked to be denied by any impartial reader. He has enlarged his room accommodations, furnished additional type as needed, and within the last few days put in an additional press. And should the publication be continued in his hands, he will cheerfully and promptly remedy any other defects and make any change in the style or arrangement of the JOURNAL that may be desired by its managers. The experience of the present year having demonstrated a fair financial basis for the JOURNAL, the editor could safely begin the next volume with two or three additional paid correspondents in Europe, and one in each of the chief medical centers in our own country. He could use a moderate sum in payment for important reporting, and for papers containing the results of original investigations. In a word, he could double the amount hitherto paid for such work, and at the same time feel some confidence that in devoting more of his own time and thought to improvements in every department of the work he would not be without a fair financial remuneration. It is thus the enterprise can and will grow in all its relations from year to year, provided there is sufficient stability in the management to make the experience of each year available for improvements in the next. That the JOURNAL has already exerted a very important influence in diffusing a better knowledge of the plan of organization, by-laws, and ethics of the Association, and in correcting errors and mischievous misrepresentations, we have the testimony of several of the most eminent men in the profession. But its proper work in these directions is only just begun.

The fact that nearly all the reports and papers referred for publication were printed during the first three months of the JOURNAL, and that there has been no lack of good original contributions during the remaining part of the time, shows that it is exerting a strong influence in encouraging more active investigations and attracting more attention; while financially it has caused more than double the number of members to pay their annual dues and retain their membership than had paid in any one of the past five years. At the same time, it has received one-third of its patronage from outside of the membership of the Association. Much the larger part of this has come from the profession located in the States west of the Alleghany mountains, where the field for the circulation of a large weekly journal is less occupied than in the New England and Middle Atlantic States.

But having stated as briefly and clearly as possible the development and status of the JOURNAL thus far, I leave the important enterprise in your hands, knowing that it will receive your most full and careful attention. All of which is respectfully submitted.

N. S. DAVIS,
Editor JOURNAL OF AMERICAN MEDICAL ASSOCIATION.

Chicago, May 1, 1884.

The editor's report, here presented, shows the financial condition of the JOURNAL to be in a satisfactory condition.

The Treasurer's report has been audited and found to correspond with the vouchers and orders of the Association upon the Treasury.

The JOURNAL has been, we believe, conducted with economy, ability and judgment, and the best interests of the Association kept steadily in view, and its dignity maintained with rare discretion.

It is confidently expected that the experience gained during the last year, with the assured increase of funds, will enable the Board of Trustees and more especially the editor to greatly improve the JOURNAL.

Greater experience in the work and a clearer comprehension of the requirements of the JOURNAL, with more trained and able contributors employed and liberally paid, and the whole available revenue of this enterprise put into the JOURNAL, will, before the end of the next year, place it in the front rank of medical periodicals.

Dr. N. S. Davis, April 11, 1884, by a letter to the Board, tendered his resignation as editor to take effect June 30, which would be at the end of the second volume of the JOURNAL.

His letter is as follows:

APRIL 11, 1884.

To the Trustees of the American Medical Association for Journalizing its Transactions:

MESSRS.:—As the time is near at hand when you are to meet for considering the important interests confided to you, and desiring to relieve you from all possible embarrassment from personal considerations, I hereby tender my resignation of the position of editor of the JOURNAL, to take effect at the close of the present volume, June 30, 1884.

Yours truly,

N. S. DAVIS.

After a very careful canvass of the best interests of the JOURNAL, including propositions for a change of the location of publication and an available and unex-

ceptionable editor, a vote of the Board with but one dissenting voice requested Dr. Davis to withdraw his letter of resignation, to which Dr. Davis makes the following reply:

To the Board of Trustees for Journalizing the Transactions;

In presenting my resignation of the position of editor of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, one month since, to take effect at the end of the JOURNAL year, I was actuated by a sincere desire to be relieved from so onerous an amount of labor on the one hand, and on the other, an equal desire to relieve the members of the Board from all merely personal considerations while considering questions of future policy. But the same motives and impulses which constrained me to yield to your invitation to accept the position one year since, equally impel me now to yield to your nearly unanimous request that I withdraw the resignation tendered. I therefore defer to your judgment, and will diligently strive to make the JOURNAL better in the year to come than in that which has passed; but at the end of that time must positively withdraw from a position involving so much labor and responsibility.

Yours truly,

N. S. DAVIS,

Editor of JOURNAL OF AMERICAN MEDICAL ASSOCIATION.

WASHINGTON, MAY 7, 1884.

The Board has therefore secured the services of Dr. N. S. Davis as editor for the coming year. Bids for the publication of the JOURNAL for this year were solicited from leading publishing houses. We had bids from New York, Philadelphia, Detroit, Washington, Portland and Chicago.

The most favorable bid, however, was found to be from the present publishers. It has therefore again been awarded to A. G. Newell, of Chicago.

All of which are respectfully submitted by direction of the Board.

J. M. TONER, Prest. Board of Trustees.

Dr. J. H. Packard, of Pennsylvania, presented a minority report.

Minority Report of the Trustees of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, made to the Association at Washington, D.C., May 8, 1884.

In presenting a minority report to the Association, I obey a strong conviction that in no other way can I fulfil the duty resting upon me as one of the trustees of your JOURNAL. I do so in no unfriendly spirit toward my colleagues, and without in any way reflecting upon them. I have no hostility toward the present editor of the JOURNAL, whose long and eminent services in the counsels of this body are too well known to admit of even momentary question. Still less can I be suspected of a desire to hamper or weaken an enterprise in which my interest has been for the last four years most warmly enlisted, and, I think, amply shown. Perhaps I need hardly pause to deny the imputation of any personal motive, or of captious fault-finding.

From the report of the majority of the Board of Trustees, it would appear that the Association is able this year to meet the expenses incurred by it in the publication of the JOURNAL. Yet I am in possession of an official letter to me from the President of the Board, dated since the beginning of the year, in which it is stated that the editor has abstained from drawing his salary, and that we count upon his so abstaining for some time to come. Unless this statement is no longer correct I cannot but express to the Association my disapproval of such a state of affairs.

It is not, however, in regard to the financial part of the matter that I feel called upon to dissent from the report offered by my colleagues. What I am constrained to say is, that the JOURNAL has not, in my opinion, approached anywhere near the standard of what the organ of the associated medical profession of the United States should be. I am well aware that there are difficulties attending the inception of such an enterprise, but the defects of the JOURNAL are not of this kind, nor have they in any sense become less marked in the nine months of its existence. I submit that the object of its establishment was not the mere "Journalizing of the Transactions," not the spreading out of the minutes of the Association, and of the papers read before it, over a year; the object was the setting up of a strong, wide-awake, high-toned periodical, well-found in every respect, which should be a medium of communication between the members of the profession all over the United States—the non-sectional, non-partisan organ of the Association, which should enable it to more efficiently carry out the aims of its organization and maintenance. Such was certainly the scheme contemplated and advocated in the reports presented by myself, and especially in the first one, read at Richmond in 1881. It is true that at the outset there was a certain timidity in the movement, and a hesitation in striking out boldly from the shore. But the faith was there, and only needed development.

Such a journal as we require can only be carried on, I assert, by a thoroughly trained corps of qualified editors, acting together in such a way that the work should go on without a perceptible break, even if one or more of them should, in the chances of life, be disabled. It can be best done where there is ready access to large libraries, and to all the current literature of the day, and where there is constant opportunity for securing the best auxiliary work. Such contributions to its pages, like all others, should be properly and liberally paid for.

Facilities for the mechanical execution of the work are also essential, as its real success depends largely upon the accuracy of and elegance of the printing, press-work, and general make-up, as well as the punctuality of its issue and distribution.

None of these requirements seem to me to have been adequately met or possessed by the JOURNAL of the Association as heretofore conducted, and due respect for the interests of the Association compels me to state this as my sincere and deliberate judgment.

The limited time at my disposal, with many interruptions, must be my excuse for the brevity and, perhaps, the abruptness with which my views have been offered, but I trust I have made them clear.

I beg to recommend that the resignation of Dr.

Davis as editor should be accepted, and that the publication-office of the JOURNAL be transferred to some eastern city,—Washington, Philadelphia, or New York. All of which is respectfully submitted.

JOHN H. PACKARD,
Trustee.

The President decided that the majority report must first be considered.

Dr. Kinloch made the point of order that the minority report should first be considered.

Dr. A. Garcelon, of Maine, appealed from the decision of the chair, the appeal was taken and the decision was reversed.

A motion was then made that the minority report be laid on the table.

On this motion the ayes and nays were demanded; while this was pending, the Committee of Nominations offered their report, which was received:

OFFICERS ELECTED FOR 1884—85.

President, Henry F. Campbell, Georgia; First Vice-President, Jno. S. Lynch, Maryland; Second Vice-President, S. D. Mercer, Nebraska; Third Vice-President, J. W. Parsons, New Hampshire; Fourth Vice-President, H. C. Ghent, Texas.

Time and place of meeting, New Orleans, last Tuesday in April, 1885.

JUDICIAL COUNCIL.

To fill vacancy, 1886, J. K. Bartlett, Wis.

To fill vacancy caused by expiration of term of service, John H. Murphy, Minnesota; J. M. Toner, District of Columbia; W. Brodie, Michigan; H. D. Holton, Vermont; A. B. Sloan, Missouri; W. B. Ulrich, Pennsylvania; Wm. Morrow Beach, Ohio.

Secretary—W. B. Atkinson, Pennsylvania.

Assistant Secretary—W. H. Watkins, Louisiana.

Treasurer—R. J. Dunglison, Pennsylvania.

Librarian—C. H. A. Kleinschmidt, District of Columbia.

SECTIONS.

Practice of Medicine—Chairman, H. D. Didama, New York; Secretary, G. M. Garland, Massachusetts.

Obstetrics and Diseases of Women—Chairman, R. Stansberry Sutton, Pennsylvania; Secretary, J. T. Jelks, Arkansas.

Surgery and Anatomy—Chairman, Duncan Eve, Tennessee; Secretary, C. B. King, Pennsylvania.

Ophthalmology, Otology and Laryngology—Chairman, Jos. A. White, Virginia; Secretary, Eugene Smith, Michigan.

Diseases of Children—Chairman, Jno. H. Pope, Texas; Secretary, S. S. Adams, District of Columbia.

State Medicine—Chairman, E. W. Schæffler, Missouri; Secretary, J. M. McCormick, Kentucky.

Oral and Dental Surgery—Chairman, A. W. Harlan, Illinois; Secretary, J. Ewing Mears, Pennsylvania.

State Medicine—Arkansas, Jas. A. Dibrell, Sr.; Alabama, R. D. Webb; California, Dr. F. W. Hatch; Connecticut, Dr. C. W. Chamberlain; District of Columbia, Dr. Smith Townsend; Georgia, Dr. J. P. Logan; Illinois, J. H. Rauch; Indiana, E. S. Elder; Iowa, W. S. Robertson; Kansas, H. D. Hanawalt; Kentucky, J. A. Ireland; Louisiana, S. E. Chaille; Maine, T. A. Foster; Maryland, J. A. Stewart; Massachusetts, Dr. Warner (Boston); Michigan, Dr. Foster Pratt; Ohio, Dr. R. Harvey Reed; Vermont, Dr. E. F. Upham; Minnesota, Dr. Talbot Jones; Missouri, T. F. Prewitt; Delaware, L. P. Forward, (surg.); U. S. N., N. L. Bates, (med. inspector); U. S. M. H., H.W. Austin; N. H., E. E. Graves; Wisconsin, J. K. Bartlett.

Committee of Arrangements—Samuel D. Logan, M.D., Chairman; S. E. Chaillé, M.D., E. S. Lewis, M.D., Joseph T. Scott, M.D., W. G. Austin, M.D., W. H. Watkins, M.D., J. P. Davidson, M.D., J. A. G. Fisher, M.D., Geo. W. Lewis, M.D., B. A. Pope, M.D., W. C. Wilson, M.D., M. Schuppert, M.D., Geo. J. Friedrichs, M.D., F. Loeber, M.D., D. Jamison, M.D., G. K. Pratt, M.D., L. F. Solomon, M.D., J. H. Bemiss, M.D., Geo. Lawrason, M.D., G. U. Gaudet, M.D., Sam'l M. Bemiss, M.D., C. J. Bickham, M.D., Chas. Turpin, M.D., Jno. Carter, M.D., A. W. DeRoaldes, M.D., S. S. Herrick, M.D., W. S. Mitchell, M.D., E. T. Shepard, M.D., E. Souchon, M.D., T. D. Layton, M.D., T. S. Dabney, M.D., S. R. Olliphant, M.D., Edward Harrison, M.D., A. B. Miles, M.D., Joseph Holt, M.D., P. B. McCutchon, M.D., F. H. Parham, M.D., G. B. Underhill, M.D., Stanhope Jones, M.D., E. Chassaignas, M.D., R. Dell'Orto, M.D.

On motion of Dr. Brodie, the report as read was unanimously adopted.

After much discussion as to the calling of the additional names on the register prior to the call of the ayes and nays, the President decided that this list need not be called.

The Permanent Secretary then called the roll.

The minority report of the Board of Trustees was laid on the table by 191 ayes to 74 nays.

The majority report was then adopted.

Dr. N. S. Davis, Chairman of the Committee on Meteorological Conditions and their Relations to the Prevalence of Acute Diseases, read his report.

On motion, the report was accepted, with a recommendation for its publication in the JOURNAL.

Dr. Davis reported, with regard to the Collective Investigation of Disease Committee, that a proposition from a similar committee of the British Medical Association be accepted; that a central general committee of this Association, consisting of seven members, be appointed by the President to carry it into effect, with power to appoint a sub-committee in each State, either directly or through the State Societies, to correspond with the same committee of the British Medical Association, and report annually to this body; and that a sum not to exceed $300 be appropriated for the use of the general committee, to prosecute the work.

On motion, the report and recommendations were adopted.

Dr. Davis, on behalf of the Judicial Council, reported:

REPORT OF THE JUDICIAL COUNCIL.

1st. In the case of Dr. S. S. Goode, who presented credentials as a delegate from the Somerset County (Pa.) Medical Society, it was decided that said Society was not entitled to representation in this Association, for the reason that it had never been recognized by representation in the Medical Society of the State of Pennsylvania, such recognition being necessary under the constitution of this Association.

2nd. In the case of H. G. Sherman, whose registration as a delegate from the Cuyahoga County Medical Society, Ohio, was protested against, after a partial investigation the protest was withdrawn, and the registration permitted to proceed. Some facts were developed during the investigation rendering it probable that said County Society had not been, in the past, as faithful in requiring its members to observe the rules of ethics, as would be desirable if it remains a constituent of this body.

3rd. In the case of Dr. D. W. Day, which was originally adjudicated at the meeting in St. Paul, and a petition for a rehearing made by the defendant, on the ground of having new evidence to present, the Council, after an examination of all the new evidence on both sides, unanimously decide that such testimony does not justify a re-opening of the case.

On motion, Dr. C. T. Parkes, Chairman of the Section on Surgery and Anatomy, was requested to read his address by title, and it was referred to that Section.

On motion, the address on State Medicine was made the first order of business on Friday.

On motion, the Association adjourned until Friday, at 9 A. M.

FRIDAY—FOURTH DAY.

The President called the Association to order at 9 A. M.

Dr. J. C. Dalton, of the Committee on Experimental Medicine, reported as follows:

Supplementary resolutions reported by the Committee on Experimental Medicine.

Resolved, That the Committee on Experimental Medicine be empowered and instructed to add to its numbers and efficiency by the election of associate members from different States, and that it report to this Association at its annual meeting any matters relating to the subject of Experimental Medicine which may need the consideration and action of the Association.

Resolved, That in view of the attempts which have been or may be made to obstruct by restrictive legislation the progress of experimental medicine, this Association desires to express its earnest conviction that experimentation on animals is a most useful source of knowledge in medical science; that it is the means by which many valuable discoveries, both practical and scientific, have been accomplished; that its direction and supervision can be properly entrusted only to members of the medical profession, and that its restriction and prohibition by law would inevitably retard the advancement of medical science and the improvement of the medical art.

On motion, the report was unanimously adopted, and the committee was continued.

A question arose as to the report of the names for Trustees by the Committee on Nominations, as it was the duty of a special committee appointed by the President to name the Board. After some discussion, on motion of Dr. Pratt, the names presented by Dr. Ferguson, chairman of the special committee, were approved. These were the same as named by the Committee on Nominations. (See their report.)

On motion of Dr. Eugene Grissom, of North Carolina, it was agreed that in the future the Trustees should be nominated by the Nominating Committee.

Dr. Packard moved to take up the amendments offered at St. Paul, and after some discussion they were made the special order after the address on State Medicine.

The President announced that the committee on the late Prof. S. D. Gross had not been able to meet, and, on motion, the committee was continued with power and unlimited time.

Dr. Davis, of the Committee on Suggestions, in the address of the President as to the Code of Ethics, reported that no action was deemed necessary at this meeting, and asked permission on his own part to offer a resolution, as follows:

WHEREAS, Persistent misrepresentations have been and are being made concerning certain provisions of the Code of Ethics,

Resolved, That the President appoint a committee of *five*, of which he shall himself be a member, to report at the next annual meeting of the Association such explanatory declarations on the subject as they deem proper.

On motion, the resolution was adopted.

Dr. P. O. Hooper, Chairman of Committee on Nomination, stated that Dr. J. Ewing Mears, of Pennsylvania, not having been present, his name would be withdrawn as Secretary of Section on Dental and Oral Surgery; and Dr. Harlan, Chairman elect of that Section having declined, he offered as Chairman,

Dr. W. W. Allport, of Illinois, and as Secretary, Dr. E. C. Briggs, of Massachusets, which were agreed to.

On motion, the Committee on the President's address, Dr. Davis, Chairman, was discharged.

Dr. D. J. Roberts offered certain resolutions from the Section on State Medicine, which was declared not in order at present.

Dr. Roberts, Chairman of that Section, then read his address.

On motion, the address was referred to that Section.

By request, Dr. T. Antisel, of District of Columbia, was placed on Section of State Medicine, vice Dr. S. Townsend; and Dr. J. L. Cabell, of Virginia, in place of Dr. Chancellor.

The President announced the Augmented Committee on invitation to the International Medical Congress as Dr. A. Flint, New York; I. M. Hays, Pennsylvania; L. A. Sayre, New York; C. Johnson, Maryland; G. Engleman, Maryland; J. M. Brown, U. S. N.; J. S. Billings, U. S. A.

On motion, the President-elect Dr. H. F. Campbell was added.

Dr. Packard then called up the amendments on Members by Application.

The amendments referred to are as follows:

"Dr. J. H. Packard, of Pennsylvania, offered amendments to the Constitution contemplating changes in the plan of organization of the Association.

"Regulation II, Paragraph 1, to read as permanent members or members by application.

"Regulation II, after eighth paragraph add:

Members by application shall consist of such members of State or County Societies, certified to be in good standing by the President and Secretary of said societies, as shall make application in writing for admission. They shall simply have the right to receive the JOURNAL on the same terms as other members.

"Regulation IV, Paragraph 6, strike out all from "See," in line 7 to "and" in line 9.

"Regulation V, Paragraph 3, after "published" insert "in such manner as the Association may direct."

"Regulation VI, line 4, strike out 5, and insert 10. Second paragraph, lines 4 and 5, strike out all after "publication," to and including "Association," and insert "publication."

See TRANSACTIONS, Vol. 32, p. 51, 1881.

After much discussion by Drs. Toner, Pratt, Kinloch, Billings, Brodie, and others, on motion of Dr. Kinloch, the amendments were taken up for immediate consideration.

Much discussion having ensued, the previous question was called for and sustained, and the amendments as read were adopted by a large majority.

Dr. C. H. Von Klein, of Ohio, offered the following amendments:

Proposed Amendments to the Constitution, offered by Dr. Carl H. Von Klein, of Ohio.

WHEREAS, A higher grade of preliminary education among physicians, has been urged from year to year, without any action being taken, and

WHEREAS, This Association has the power to secure this much desired object—the following Amendments to the Constitution are proposed:

I.

No person who shall hereafter graduate from a medical college where literary education is not a prerequisite to such graduation, shall be eligible to be a delegate to the American Medical Association.

II.

All delegates to this Association, as a part of their credentials, shall present certificates from the County, District or State Associations they represent, showing from what medical college and when graduated, but this provision shall not apply to delegates from the Army and Navy.

These lay over for one year.

Dr. J. M. Keller, of Arkansas, offered the following:

Resolved, That in our large cities in the very near future, if not now, cremation of the dead will become a sanitary necessity.

Two years ago, after careful and deliberate thought for years on the subject, I offered a resolution at the meeting of the American Medical Association at St. Paul, embodying the idea that in the very near future cremation or incineration of the dead would become a sanitary necessity. Knowing, as I well did, that it would meet with a very strong opposition from many who had never given the subject a thought, I was not astonished to find the hands and voices of a number raised in horror at hearing it read, and, instead of asking any decisive action by the Association, I thought it best to let it lay over for a year, and, therefore, simply asked its reference to the Committee on Hygiene, thus accomplishing all I desired, to-wit: The bringing of it before the minds of the people, feeling fully confident that it needed only to be seriously thought of to secure sooner or later the earnest support not only of men of the medical profession, but thinking men and women of all professions and creeds. In order to give an opportunity for more thought on the subject, it was referred again to the same committee at Cleveland a year after, although many who would have opposed it violently when first offered, had become its advocates, and were anxious that it should be put upon its passage, that they might lend their earnest support to it.

Not only have I watched and noticed its increasing popularity with physicians, but the same is true with the masses, not only in this country, but in Europe, for only recently we find the subject warmly advocated in the British Parliament, just after it had been tested in the courts in the case of a Welshman, who for cremating his dead child, was arrested and tried, and acquitted, the court deciding that there was nothing contrary to law in the act.

Having been thus decided, the subject needs now only to be discussed in three aspects—hygienic, religious or sentimental, and economical. The custom of burying the dead contaminates the earth, its waters, and the air we breathe. Germs buried with the body do not die with it, but rather increase, and

it is claimed do not become innocuous under twenty years, if ever, and thus live on to reproduce disease and pestilence. If it be true—and there can be no question about it—that in the atmosphere of graveyards there is three-fold more carbonic acid gas in the atmosphere than away from them, what must be the extent and amount of the deadly poisons emanating from our public cemeteries, where from 20,000 to 100,000 corpses lie at all times in complete putrefaction. Take our largest Southern city, New Orleans, where the dead, if buried at all, are scarce covered with earth, and say if you can for a moment doubt the fact that most, if not all, its unhealthiness is due to the noxious exhalations constantly emitted from her thousands of decomposing, putrefying dead bodies, that are daily multiplying. Think of it, and imagine, if you can, the evils and ills being constantly engendered, every moment of time impregnating the air and water which her people breathe and drink.

How would it be if incineration were to take the place of such disposition of the dead? Instead of the constant generating disease and pestilential vapors as long as time lasts, decomposition would hardly have commenced before it would be forever destroyed, and instead of a mass of offensive putrefaction remaining indefinitely, the crematory would give back to living friends a few pounds of pure, clean, snowy ashes, to care for as their love and affection might prompt.

I am not aware that there is any expressed law or rule in any religious sect or denomination, but rather incline to the opinion that we who have favored it, and dared express our convictions, only feared that such obstacles might stand in the way of having it become the rule and custom, instead of the present horrid and repulsive and filthy one of burial, and each day I feel more and more assured that it will take but a few years for all objections to die out, when we will hear it advocated alike from Protestant and Catholic pulpits.

In the Campo Santo, the chief cemetery in Rome, and almost adjoining the church in which the last pope lies entombed, there stands a crematorium where, for years, numbers of incinerations have been made. May the time soon come when we will see one standing in lieu of each burying ground in the world. The process is but the simplest, quickest plan of reducing the corpse to its constituent elements, without leaving one vestige or mark of anything offensive or injurious to the living. It is strictly in conformity with nature's laws, and does, in a few moments, what putrefaction after burial fails to do in twenty years, if ever. Some will say that it is a relic of barbarism. No more than is our burial, for both were customs with the ancients, and equally practiced.

Ignorance and fanaticism can have no tenable objection to it because of the resurrection, for when the last trump shall sound, which will call upon the graves to give up their dead, so will the urn in as quick obedience give up its ashes—the first the putrid excrement and decay of worms, the latter its handful of white ashes.

The Great Creator will ask no man's assistance in accomplishing that work. His power, which can make the earth and sea give back their dead to life, will as surely revivify the ashes in the urn. When life ceases, decomposition begins, inexorable in its laws, and hideous and horrible to contemplate, even to the beasts of the field, in all its different phases of decay. Slow, offensive, repugnant and dangerous in its every step.

Cremation or rapid combustion dispels from death all these horrors, and strips the grave of its terrible mysteries. It quickly gives back to us all that is not offensive of our dead loved ones, to be placed, if you please, in some public temple to be built for the purpose, or else placed in urns of plain or costly, but durable material, to deposit in some consecrated niche in our own homes, there to be kept fresh and green with the cedars and the lilies, and not as custom now forces it, into the earth, away from home, exposed alike to the snows and storms of winter and the scorching suns of summer, and mayhap some day to be exhumed by the plowshare of the farmer or the spade and pick of the builder, a common but revolting scene, bound to grow more frequent as estates descend and change owners, and cities grow.

The thanks of the Society were voted Dr. Kellar, and on motion the resolution was referred to the Section on State Medicine.

Dr. Foster Pratt offered the following amendment:

That the By-laws be amended so as to provide that each Section shall nominate its Chairman and Secretary—all other nominations to be made as now, by the nominating Committee.

Laid over for one year.

On motion of Dr. Pratt, it was

Resolved, That the publishers of the JOURNAL be requested to publish, in pamphlet form, the minutes of the Association, together with its Constitution, By-laws and Code, for distribution to each member of the Association at each next succeeding meeting.

On motion of Dr. Brodie, it was

Resolved, That the Committee of Arrangements and the Secretary of the Association be requested to provide for future meetings a system of registration, whereby delegates and members can send in advance or hand in their credentials, certificates, fees, etc., and obtain their cards of membership at their convenience. Also that they shall provide for the prompt publication each day of the names of the members and delegates present.

On motion of Dr. D. J. Roberts, it was

Resolved, That the thanks of this Association are hereby tendered to the Museum of Hygiene of Navy Department of the United States.

Resolved, That this Association earnestly recommends to the United States Senate and House of Representatives, that this museum be placed upon a permanent basis, by such legislative enactments and appropriations as are justified by so important a movement in behalf of the best interests of our whole people.

Resolved, That this Association does most earnestly recommend, that a permanent and suitable

home be prepared at the earliest possible day for this museum.

Resolved, That the Permanent Secretary of this Association be directed to forward a copy of these resolutions to the Secretary of the Navy and to Surgeon-General Gunnell.

Dr. J. Cochran, of Alabama, offered the following:

Resolved, That it is the sense of this Association that it is not expedient for the Nominating Committee to nominate any of its own members for any of the offices of the Association.

After much discussion, on motion of Dr. J. B. Murdoch, of Pennsylvania, it was laid on the table.

Dr. D. J. Roberts then offered the following:

Dr. F. Pratt, of Michigan, offered the following resolutions, which were unanimously adopted at the Section on State Medicine, held May 7, 1884:

Resolved, That we earnestly urge upon Congress the importance of efficient legislation to so regulate immigration as to exclude from our soil the so-called "defective classes" of all nations.

Resolved, That the Chairman of this Section be instructed to report the foregoing to the Association, with the recommendation that it be adopted.

A motion by Dr. A. Garcelin, of Maine, to lay it upon the table was lost, and the original motion was then adopted.

On motion all the reports in the programme were postponed until the reading of the addresses.

On motion these addresses were ordered to be read by title and referred for publication.

Dr. J. Chisolm, Chairman of Section on Ophthalmology, etc.

Dr. Wm. Lee, Chairman of Section on Diseases of Children, etc.

Dr. T. W. Brophy, Chairman of Section on Dental and Oral Surgery, read the titles of these addresses, and they were referred for publication.

Dr. Toner announced that his report on Necrology had been published in the JOURNAL from time to time.

On motion his report was accepted, and the plan was continued.

On motion the secretaries of Sections were permitted to report to the Permanent Secretary.

The Section on State Medicine presented the following:

WHEREAS, There is apparently among the people a movement to secure a more thorough education of persons who offer themselves as practitioners of medicine, by demanding statutory enactments providing a standard of qualifications; and

WHEREAS, It is desirable and important that there should be uniformity in the legal standard of qualifications adopted by the several States of the Union in this behalf; therefore

Resolved, by the American Medical Association, that it is recommended to the organizations in the several States represented in this Association, that they use their influence in their respective States to secure the passage of laws that shall require all persons who enter the profession of medical practitioners to first pass a satisfactory examination touching their knowledge of medical history, anatomy, histology, physiology, animal chemistry, pathology, pathological anatomy, ætiology, semeiology, mechanical surgery, mechanism of parturition, botany, hygiene, and medical jurisprudence.

On motion, the resolutions were adopted.

Dr. C. Lester, of Pennsylvania, of the Section on Ophthalmology, etc., presented the following:

Resolved, That the Section on Ophthalmology, etc., requests the Association to consider the advisability of dividing the Section and forming two, one consisting of Ophthalmology alone, and one consisting of Otology, Laryngology and Rhinology.

It being an amendment, laid over.

The Permanent Secretary read the report of the Treasurer.

REPORT OF THE TREASURER.

The Treasurer has the honor to report a balance in the Treasury, at this date of $2,212.07. The sources of revenue during the past year differ from those of previous years, in the fact that subscription to the JOURNAL of the Association and payments for advertisements therein, have been added to the usual routine report of amounts received for annual dues. This subject, however, will doubtless enter as an interesting feature into the Report of the Trustees of the JOURNAL, and need not, therefore, be dwelt upon at this time.

In previous reports of the Treasurer, allusion was made to a prevalent misconception and misconstruction, on the part of permanent members, of that paragraph of the By-laws of the Association, which provides that membership will be forfeited after non-payment of the annual dues of three years for three successive years. Whatever may have been originally contemplated in this provision, the fact is undoubted that many of the members understand it to give them liberty to pay triennially dues which are particularly stated to be annual. Hundreds of members pay their dues but two years out of every three, and expect to resume their membership in good pecuniary standing at their option, provided they do not allow three non-paying years to elapse; in the honest belief that this single payment is all that is required of them in the By-laws. Other members of the Association contend that the assessments for two or three successive years, are alway due until all of them are actually paid, and that a single payment for an assessment for one year, where two or three years' payments are due, should be credited to the first year only, and not to the last. A resolution expressive of the proper construction of this paragraph of the By-laws, is undoubtedly a desideratum for the information of the members generally, and for the guidance of the Treasurer in his correspondence with them, so that his action may be just to the Association and in no wise ungenerous to those who may be prevented from various circumstances from punctually remitting the assessments annually due from them.

RICHARD J. DUNGLISON, Treasurer.

May 8, 1884.

On motion of Dr. Brodie, the report was received, and it was agreed that a continued annual payment is essential to continuance in permanent membership.

The Permanent Secretary read the report of the Librarian, which was accepted, and referred for publication.

Dr. J. C. Greene, of New York, offered the following, which was adopted:

WHEREAS, The first edition of the Medical and Surgical History of the War of the Rebellion was long since exhausted, and so distributed by the different representatives in Congress at the time the several volumes were issued;

WHEREAS, A large number of physicians and surgeons desire to obtain the work in its entirety, as is shown by the inquiry being so often made for it of Congressmen and others;

WHEREAS, The third volume of the Medical History has not been printed, which is necessary to complete the entire work;

Resolved, That it is the desire of the American Medical Association to have the third medical volume issued at the earliest possible date; also, that Congress be respectfully requested to issue a uniform *edition* of the work known as the Medical and Surgical History of the War of the Rebellion, at cost, including the usual 10 per cent. addition; therefore

Resolved, That the Secretary be requested to furnish a copy of this preamble and resolution to the President of the Senate and Speaker of the House of Representatives.

On motion of Dr. Wm. Morrow Beach, of Ohio, it was

Resolved, By the members of the American Medical Association, that it is important that proper legislation be had at this session of the National Congress for the ultimate extermination of the disease among domestic animals known as pleuro-pneumonia.

Resolved, That copies of this resolution be forwarded by our Secretary to the President of the Senate and Speaker of the House of Representatives.

Dr. Flint then introduced Dr. H. F. Campbell, President-elect, who addressed the Association, thanking the members, etc.

On motion of Dr. Garnett, it was

Resolved, That the thanks of this Association are due to the Hon. Frank B. Conger, Postmaster of Washington, for the courtesy he has shown in establishing a branch of his office in such close proximity to this hall.

On motion of Dr. W. Brodie, the following was adopted:

WHEREAS, It is desirable that a correct and full report of the proceedings of this Association should appear in its JOURNAL, therefore

Resolved, That the Board of Trustees of the JOURNAL be, and they are hereby, authorized to procure a stenographic report of the proceedings of each meeting.

On motion of Dr. W. J. Herdman, Michigan, it was resolved that,

Recognizing the important and valuable character of the contributions to medical science contained in the Medical and Surgical History of the Civil War, and with the view of increasing its usefulness by a wider distribution of that information than is now possible, since the edition published has been exhausted, be it

Resolved, That the members of this Association do most earnestly recommend the passage of the joint-resolution now pending before Congress, providing for the reprinting of 25,000 copies of this History.

Resolved, That copies of the foregoing resolution be furnished, by the Permanent Secretary, to the Speaker of the House of Representatives and the President of the Senate of the United States.

Dr. C. H. Von Klein, of Ohio, offered the following, which was unanimously rejected:

WHEREAS, The members of the American Medical Association are composed of all nationalities, denominations, sects and creeds, and

WHEREAS, Many of its progressive and scientific members are skeptics, materialists, etc., and

WHEREAS, The principles of the Association are to give equal rights to all its members, and

WHEREAS, The custom of opening the annual sessions with prayer, by the clergy of some denomination, is an imposition on many of the members, therefore

Resolved, That the custom of opening the sessions of the American Medical Association with prayer be abolished.

On motion of Dr. C. A. Rahter, of Pennsylvania, the following was adopted:

WHEREAS, The medical museum and library is the most extensive and valuable in the world, representing an almost incredible amount of patient labor; and

WHEREAS, A complete catalogue is necessary to the practical utilization of this wonderful collection of valuable information by the medical profession; and

WHEREAS, The present building is unsafe and wholly inadequate for the proper and safe care of this priceless collection; therefore

Resolved, 1st. That we earnestly request Congress to make provision at once for the safe and proper care of the medical library and museum.

2d. That in the judgment of this Association the necessary provision for the early completion of the index catalogue should be made, and that an additional number of the completed volumes be issued by the Government Printing Office, and offered by sale to the profession.

3d. That copies of these preambles and resolutions be transmitted to the proper Congressional Committee.

On motion of Dr. D. Leasure, of Minnesota, it was

Resolved, That this Association most solemnly protests against any of its members committing it by implication, to the endorsement of any of the many polypharmacal compounds and mineral waters thrown upon the market by private individuals or corporations, by signing certificates as to their value as remedial agents to be used as advertisements.

The Permanent Secretary read the following:

At a stated meeting of the West Philadelphia Medical Society the following resolutions, presented by Dr. John H. Musser, were adopted:

WHEREAS, The dignity, the honor, and the power for doing good of the medical profession can only be maintained by the individual members conducting themselves in relation to one another and the public, with the dignity and honor of gentlemen, and

WHEREAS, The noble and beautiful Code of Ethics of the American Medical Association is expressive of such virtuous and honorable sentiment,

Resolved, 1st. That we, members of the West Philadelphia Medical Society, look with regret and abhorrence upon the attempt of certain mercenary men to destroy those principles which for 48 years have been cherished and protected by the noblest and most honorable men of the medical profession.

2d. That we solemnly reiterate our faithfulness and allegiance to the principles maintained in the Code of Ethics which we are pledged to abide by.

3d. That we will not encourage such a travesty upon honor by consultation with the physician who stoops to alliance with quackery, or by directing students to those colleges which abide by such false principles.

4th. That a copy of this earnest expression be transmitted to the County and State Societies, and to the American Medical Association to which we hold allegiance, and to the *Philadelphia Medical Times*, and to the *Philadelphia Medical News*.

ATTEST: JAS. HENDRIE LLOYD,
Secretary West Phila. Med. Soc.

S. W. Cor. Walnut and 40th Sts., Phila., May 7,'84.

Dr. F. E. Daniel, of Texas, offered the following, which was adopted:

In consideration of the very innocent appearance and liability to deceive the ignorant and unwary, of an article of common domestic use, to-wit: The preparations of caustic potash, known as "Concentrated Lye," and "Star Potash Ball;" and in view, further, of their dangerous and death-dealing character, and the fact that many deaths and accidents occur in consequence of the want of discrimination in and restriction of the sale of such article,

Resolved, That the Association in convention assembled do earnestly recommend to the National Congress, or to the Legislatures of the several States, the passage of such laws as shall class all such articles as *poisons*, and shall require the same discriminations as to their sale as are now applied to other articles of a deadly nature.

The present Secretary presented the following for the New Jersey State Medical Society:

Office of Corresp. Secy.,
N. Jersey State Med. Soc.,
Trenton, N.J., May 7, 1884.

Wm. B. Atkinson, M.D., Sec. Am. Med. Assoc.

DEAR SIR:—I herewith forward to you a copy of the "Report on Preliminary Education," prepared by the Committee, and presented to the Society of the State of New Jersey at its annual meeting in 1883.

It was then ordered to be printed, and will come before the Society at its ensuing meeting in June next for adoption.

As it coincides with the suggestions made by your President, Austin Flint, M.D., in his address, will you present it to the Association that it may receive therefrom its sanction and approval, as requested in recommendation 4, page 6.

Yours very truly,
W. ELMER, Jr.,
Corresp. Sec. N. J. S. Med. Soc.

Report to the Medical Society of New Jersey of Special Committee on Preliminary Education, made at its annual meeting, June, 1883.

The Committee appointed at the last annual meeting of the Medical Society of New Jersey to present "a plan for putting into effect the suggestions made by the President in regard to the curriculum of medical study," respectfully report:

That they have bestowed much thought on the subject committed to them. They find it environed by many and grave difficulties. The resolution, in its full scope, would require the revision of the whole subject of medical education. For the execution of a task so extensive and radical, your committee feel that they have not the time, the facilities, nor the necessary ability; and it is apparent from the tenor of the address which gave occasion for their appointment, that the preliminary training to be required of persons contemplating the study of medicine in this State, was the matter whose importance the learned speaker desired to impress upon the Society. To this your committee propose to limit their consideration.

It is not necessary for your committee to enter upon an elaborate argument to prove the importance of the measure contemplated. It has been the theme of eloquent exhortation and discussion in our own and other societies, and it was ably and forcibly presented in the address to which this Society listened at its last anniversary. The appointment of the committee presupposes a conviction, in the minds of the constituency, of the weighty nature of the subject-matter of the address, and that the time had come for practical action to realize its wise suggestions. The duty of your committee will be sufficiently discharged by a statement, as brief as the case will admit, of the conclusions to which they have been led by the best thought they have been able to give to its contemplation.

It would be comparatively easy to define what your committee deem an essential preparation for a course of medical study, and submit such a plan, in general terms, as in their judgment would best insure it; but its practical execution must depend on the cordial coöperation of so many and so various agencies, influenced by so many and so various motives, that your committee, were they guided by their first impulses, would shrink from the formidable task. A plan, to be effectual, will require the assent and the hearty effort of the individual members of the profession, not only in our commonwealth, but in all the States of our national Union. The several medical organizations, national, state and local, must employ their power and influence to enforce and sustain individual action, and the medical colleges conform to the demand, which would then be imperative, to limit admission to their privileges to applicants having the

qualifications that the profession, by its authorized exponents, shall have determined to be necessary for the maintenance of a proper standard.

The duty of your committee is two-fold. 1st. To indicate a proper curriculum of preliminary preparation to be exacted of every person applying to be received as a medical student under the care of a member of the profession in this State; and, 2nd. To recommend suitable measures to secure such preparation.

The uses of a preliminary education to medical study are: 1st. Those which are common to all departments of intellectual labor, and are fitted to discipline the mental faculties so as to prepare them for profitable study, and their right exercise in the processes of observation, discrimination, analysis, deduction and reason; and, 2nd, those which will store the mind with a sufficient knowledge of the branches of science and learning that are cognate with, and essentially preparative to those that specially pertain to the medical profession.

No one who estimates properly the profound and intricate subjects of medical study can doubt the indispensable necessity of bringing to their contemplation vigorous minds, sharpened by habits of nice perception, careful observation, patient, untiring investigation, absorbing abstraction and concentration, a calm and imperturbable judgment, and a conscientious devotion to truth. There is no profession whose pursuit requires greater maturity or more systematic method; none, in the preparation for which there is greater need for the culture best fitted to develop these indispensable qualities.

Much as has been discussed the question of education best adapted to this kind of culture, it is now generally conceded that the curriculum of study adopted by our higher colleges and universities is that on which is to be placed the most reliance. Your committee would therefore recommend that all persons contemplating the study of medicine be advised to a preliminary college education, and that the possession of a diploma from a well-equipped college or university be regarded as the best evidence of fitness. The objection so often advanced that this course exhausts so much time and incurs so much expense as to put it out of reach of many meritorious young men, well fitted by natural endowments for the functions of the medical practitioner, is effectually answered by the consideration that the responsibilities of a physician, to whom is entrusted the care of human life, are too great to be undertaken by those who have not, or cannot obtain, the means to fit themselves in the best possible way for the duties they propose to assume. Incompetence may be tolerated in pursuits which are resorted to for mere maintenance or pecuniary profit. The consequences will inure to the presumptuous pretender, and affect the material interests of those who employ him; but it will not do here. Ours is a profession whose aim is, or ought to be, higher than mere physical subsistence or sordid pelf; and the consequences of incompetency touch the public health and life itself. He who conscientiously and from worthy motives aspires to it, if unfavored by fortune, will willingly submit to privations and struggles—themselves disciplinary and invigorating—to secure to himself the facilities he needs; and these are now, through college scholarships and educational institutions maintained at the public expense, brought practically within the reach of the laudably ambitious and deserving, who earnestly desire and seek them.

In cases where the evidence of preliminary education in a respectable college or university is not presented, your committee are of opinion that an equivalent or near approximation to it should be exacted, and that the applicant should produce a certificate of a complete course in a reputable academy or high school, in which are taught, in addition to the English, classical and mathematical branches required for admission to our most advanced colleges, intellectual and moral philosophy, rhetoric, logic, descriptive and physical geography, and the elements of physics, chemistry and natural history, including botany and zoology.

In default of either a college diploma or academic certificate, as above defined, the applicant, before being taken under the care of a physician for medical instruction, should be subjected to examination and approval by a competent censorship, appointed under the authority of the State Medical Society and composed of gentlemen of recognized capacity and scholarship, in the branches of science and learning indicated in the certificate to be required of the academic or high-school graduate.

The question now recurs, what measures shall be taken to secure the attainment of these ends.

So far as our own State is concerned, it will be indispensable that every member of every district medical society be brought into harmonious concurrence, in sentiment and action, with the measures that shall be adopted. Your committee would therefore recommend:

1st. That the State Medical Society make such amendment of its By-laws as to provide for the appointment of one or more boards of examiners, as it shall deem expedient, to pass upon the credentials of all persons contemplating the study of medicine in this State; and to examine such persons as fail to present a diploma from some reputable college or university, or a certificate of a completed course in a reputable academy or high school, in which are taught the branches specified in the foregoing part of this report, in the following branches of science and learning, viz.: English language and literature, and history; mathematics, including arithmetic, algebra and geometry; Latin language, including its grammar, and ability to translate with facility three books of the commentaries of Cæsar, two orations of Cicero, and two books of the Æneid of Virgil; Greek language, including its grammar, the Anabasis of Xenophon, and two books of the Iliad of Homer; intellectual and moral philosophy, logic, rhetoric, descriptive and physical geography, and the elements of physics, chemistry and natural history, including botany and zoology.

2d. That the State Medical Society send down to the District Medical Society a requisition to add to their By-laws a provision making it a condition of

membership that every physician, belonging to or coming into it, obligate himself to receive no person under his care as a student of medicine without a certificate of a board of examiners, appointed under the authority of the State Medical Society, that the applicant has exhibited a satisfactory diploma or certificate of the character defined in this report, or that he has been examined, with approval, in the several branches of learning and science heretofore specified.

Your committee are not prepared to give an opinion on the question whether the proposed censorship should be committed to one or two boards. Considerations of convenience and economy would suggest the institution of a board in connection with each of the District Societies, and a resolution has already been adopted by this Society, imposing on them the duty of appointing a committee of similar character, invested, however, with more limited functions. Other considerations would favor a single board, or at most three boards, one in the central and one each in the northern and southern parts of the State. Among these is the greater probability of securing the services of competent examiners, governed by a stronger sense of responsibility and less liable to be biased by local influences. It is worthy of consideration, also, whether it might not be advantageous, in constituting the examining board or boards, to select for one of its members some gentleman of acknowledged scholarly attainments not belonging to the profession.

Your Committee have felt some hesitation in recommending the extreme penalty of professional non-intercourse and disbarment from membership, in the case of physicians who may wilfully disregard the regulations that may be adopted; but so vital do they believe effective enactments on this subject to be, and so futile if put into partial execution, that they are constrained to propose them, cheerfully leaving it to the wisdom of the Society to decide upon their expediency.

But, whatever be the action taken in our own Society, as has already been intimated, nothing short of coöperation of other medical organizations, national, state and local, and of the medical colleges, can avail fully to accomplish the great result desired. Take what steps we may, if persons from other States, where like provisions do not prevail, continue to be received without evidence of preliminary preparation and, after courses of professional instruction necessarily superficial, and an examination sustained through cramming, sent forth in myrmidons, armed with diplomas by scores of medical colleges, good, bad, and indifferent, what is to hinder invasion into our borders of half-educated men from abroad, to enjoy privileges denied to our own citizens, and to prey upon the health and lives of our own people? Your Committee, therefore, recommend:

3. That the action of this Society be communicated to the medical societies of the several United States, with a request for their coöperation with this Society, by the adoption of these or similar measures to secure the ends sought to be attained by this Society.

4. That a similar communication be addressed to the National Medical Association, asking its approval and recommendation to the State Societies, with the request that it use its power or influence to induce medical colleges in affiliation with it to receive, or at least grant diplomas to no students without satisfactory evidence of the preliminary training required in the regulations herein proposed.

The foregoing suggestions and recommendations are presented by your Committee with great deference, as the product of much deliberation and careful thought. They can hardly expect that, on their first presentation, they will meet with unanimous concurrence. They are doubtless susceptible of improvement from the wisdom of the Society. By some, the requirements may be considered too exacting. Others will probably concur with the members of the Committee itself, in the opinion that the curriculum presented omits many studies that are essential to a well-rounded, liberal culture, such as ought reasonably to be expected of members of a learned profession. They have defined the minimum, not the maximum, of attainments which it should be the aim to reach.

The time is coming when mediocrity will not be tolerated. Public education has so elevated the common mind that it will not much longer be incapable of distinguishing between real science and boastful pretension; when self-assertion, plausible manners, an imposing presence, a pompous vocabulary or its opposite, coarse jocularity, and the show of learning without the substance, will cease to be the passport of popular confidence. The standard of scholarship and scientific knowledge in all the so-called learned professions must be raised if they would not fall into merited contempt. Let us see to it that the title of "Doctor," with which common parlance has invested the physician, be a deserved distinction, not a meaningless misnomer. The movement now contemplated is a step in the right direction. It may be difficult of accomplishment; but, if the profession is true to itself, in its personality and in its corporate organizations, there is no reason to despair of success. The Medical Society of New Jersey—the oldest of the sisterhood of medical societies on the continent—may appropriately give impulse to a movement which, if successful, will crown the profession with honor, and add new lustre to her ancient renown. If, unfortunately, through want of coöperation, the effort end in disappointment, she may lament the infatuation of others, while she consoles herself with the assurance of an ancient critic, that "in great attempts 'tis noble even to fail."

Respectfully submitted,

S. H. Pennington,
Wm. Elmer, Jr.,
Alex. Rogers,
Committee.

On motion, it was received.

Dr. Le Grand Atwood presented the following for the St. Louis Medical Society which, on motion, was referred to the Judicial Council.

Memorial sent up from the "St. Louis Medical

Society" to the "American Medical Association," upon the subject of medical colleges advertising.

LEGRAND ATWOOD,
JAS. M. SCOTT,
R. M. JOURDAN, } Com.

If it is reprehensible in an individual physician to resort to public advertising, it certainly is none the less objectionable in an association of medical men. It cannot be that the enormity of the offense is diminished by combination, nor can a collegiate shield justly protect from censure those who, individually, would not thus offend.

The condemnation which inevitably awaits one who advertises, cannot consistently be withheld from others equally as culpable, who are associated in the perpetuation of a precisely similar infraction.

We can but believe that honorable professors of respectable medical colleges recognize this evil, and are individually and collectively opposed to its existence and perpetuation.

There can be no doubt that the efficacy of such advertisements as are contained in college announcements, and the individual reward consequent upon public notification of professorships, has led to the unfortunate multiplication of medical schools, with consequent reduction of rates, shortening of terms, and lowering of the requirements for graduation, whereby both the profession and the public are injured.

Ambitious and deserving men, unappreciated by the community and anxious for immediate recognition and reward, observe the success of inferior physicians connected with medical institutions, and, attributing their preferment to the widespread publication of their connected specialties and professorships, establish clinics or dispensaries, advertise that they will treat the poor gratis, and in this unprofessional manner seek success. As this course renders the *individual* amenable to discipline under the Code, common justice demands similar censure and condemnation for a college faculty in like manner transgressing.

It may be taken for granted that the corps of every respectable medical school is composed of men who consider themselves bound by the requirements of the Code, and who are ready to apply its provisions in preservation of professional honor; yet the annual circular and the daily announcement of each medical college conveys to the public, far and near, individual advertisement over signature and location of a specialty, and professional proficiency in that specialty, to the injury of less favored medical brethren. And not only is this advantage thus obtained, but, by the same means, the entire faculty is glorified in its published connection with an institution of learning, in which the facilities for obtaining instruction are set forth in glowing terms, with pictorial illustrations of the college building; its amphitheater, its laboratory, its dissecting-room and its free dispensary, where the clinical professors treat so many cases of disease and perform so many surgical operations, thus violating the Code by advertising, by advertising specialties, by circulating hand-bills, and by virtually announcing that the poor are treated gratis.

Whenever the equality of rights and duties of medical men is disregarded, and the restrictions of the Code which limit and protect us in our relations to each other, to the profession and to the public, are annulled by reason of fictitious claims to license or favor, the organic law will cease to inspire respect or obedience.

After some discussion, on motion, this was referred to the Judicial Council.

The Permanent Secretary read the following list of foreign delegates:

Drs. J. W. S. Gouley, E. C. Harwood, H. D. Didama, C. C. Wycoff, Fred Hyde, N. C. Husted, G. T. Stevens, and J. C. Hutchison, New York; S. C. Gordon and T. L. Estabrook, Maine; S. J. Jones, of Illinois; E. M. Dent, and J. F. Gabriel, Virginia; C. E. Vaughn, and H. O. Marcy, Massachusetts; J. V. Shoemaker and W. H. Daly, Pennsylvania; W. A. Hobday, of Illinois; H. P. C. Wilson, Maryland; D. W. Prentiss, L. Friederich, and S. C. Busey, District of Columbia; J. M. Browne, U. S. Navy; J. S. Billings, U. S. Army; Edward Borck, Missouri; T. J. Gallagher and A. M. Pollock, Pennsylvania; C. Deveny, Illinois; C. Johnson, Maryland; Austin Flint, New York; H. F. Campbell, Georgia. Delegates to the Canadian Medical Association, W. S. Tremaine and E. N. Bush, New York; W. Brodie and H. O. Walker, Michigan. British Science Association, W. Brodie.

On motion of Dr. T. H. Nott, of Texas, the following was adopted:

WHEREAS, It has pleased Almighty God to take from us our beloved brother, J. Marion Sims, and translate him from the pinnacle of his earthly fame to a throne above, therefore be it

Resolved, That we keenly feel and deeply deplore our loss and extend our heartfelt sympathies to his bereaved family, to suffering women and to the rest of our profession.

On motion of Dr. A. L. Gihon, it was

Resolved, That a Committee of seven be appointed to report next year on the subject of the erection of a monument to Dr. Benjamin Rush, in Washington.

Committee { A. L. Gihon, U. S. Navy,
Dr. Henry H. Smith, Pennsylvania,
R. A. Kinloch, S. C.,
S. C. Gordon, Maine,
Geo. H. Rohe, Maryland,
J. H. Murphy, Minnesota,
M. H. Henry, New York.

On motion of Dr. Brodie, of Michigan, a resolution of general thanks to all committees, persons, and institutions, who had extended courtesies to the Association, was adopted.

Dr. Garcelon, of Maine, offered a resolution of thanks to the President, which was put by the Secretary and carried.

Dr. Flint gracefully thanked the Association for their courtesy and kindness.

The Association then adjourned.

WM. B. ATKINSON,
Permanent Secretary.

THE

Journal of American Medical Association.

PUBLISHED WEEKLY.

THE EDITOR of this JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information, should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE..... $5,00.
SINGLE COPIES..... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 65 RANDOLPH STREET,
CHICAGO, ILLINOIS

SATURDAY, MAY 24, 1884.

OFFICIAL RECORD OF PROCEEDINGS.—We give a large part of the space usually devoted to papers and original contributions, to the official record of the proceedings of the thirty-fifth annual meeting of the National Association, in the present number of the JOURNAL. It contains many items of interest, and some that should receive the careful attention of every member. To the latter belong the initial steps for so changing the mode of registration at the opening of each annual session, as to avoid the very uncomfortable crowd and delay around the registration table during all the morning of the first day of the meeting. To remedy this, it has been proposed that the Permanent Secretary place the blank certificates for members and delegates to fill up and sign as the initial step for registration, within easy reach of all who may need them. The member or delegate can fill and sign the certificate carefully and enclose it with his credentials from the society he represents, if a delegate, and the $5 for annual dues, in an envelope, and pass it to the Permanent Secretary or the Chairman of the Committee of Registration, and go his way.

The registration officers enter his name on the registry, credit his money, fill up his card of membership and invitations, place them in an envelope as usual, and deposit the envelope within reach of the member at any subsequent part of the day. It is quite possible that such an arrangement can be rendered safe and practicable, and thereby obviate one of the chief annoyances connected with the annual meetings of the Association. Under the present By-laws, it is made the duty of the Secretary to read the roll of members, as registered, in open meeting, which usually occupies a tedious amount of time at a stage of the proceedings when all present are expecting to hear the President's address. For a full audience to sit and listen to the monotony of reading 1,000 or more names, is at any time tedious, and doubly so at the opening of an annual meeting, when all are expecting something of special interest. It was suggested at the recent meeting, that the names as registered, should be simply posted on bulletin boards where they could remain subject to the inspection of members during the whole time of the annual meeting.

Another subject for consideration is the amendment to the By-laws proposed by Dr. F. Pratt, of Kalamazoo, Mich., for giving each Section the privilege of electing its own officers, instead of having them nominated by the Nominating Committee.

It is claimed that the members accustomed to work in any given Section, are much more familiar with the men who would make good officers for that Section, than the Nominating Committee, constituted of one member from each State represented, can be; and were it known that promotion to the Chairmanship of a Section depended upon the choice of the members in attendance, it would induce a larger and more uniform attendance and thereby give more stability and efficiency to each Section organization. If the change is made, the time for each Section to elect its officers should be on the third or fourth day of the annual meetings, after the previous sittings have shown who are present and interested in the work of the Section, and those elected should serve during the succeeding year. While a new Chairman should be elected each year, whenever a good Secretary is found, he should be reëlected from year to year, as long as he can be induced to serve. A thoroughly competent Secretary, conversant with the rules governing the action of the Sections, will always add 50 per cent. to the practical value and interest of each year's work. Let the subject be well considered before the next meeting, when the proposed amendment will come up for final action.

UNIVERSITY OF PENNSYLVANIA.—At the annual commencement of the Medical Department of the University of Pennsylvania, held May 1, 1884, the graduating class, numbering 101, presented the University with a full-length portrait of Prof. Alfred Stille, who has filled the chair of Theory and Practice of Medicine during the last quarter of a century with signal ability.

CORRECTION.—In this JOURNAL for the 5th of April was a letter from Paris, in which the following expression occurs in the seventh line from the top of the letter: "But the class of phthises *without* bacilli are according to Prof. Sée the only true phthises." It should have been: "But the class of phthises *with* bacilli are according to Prof. Sée the only true phthises."

SCARLET FEVER SPREAD BY ICE.—The secular papers are responsible for the following statement: "There is an epidemic of scarlet fever in Gloucester City, on the Delaware River. Its rapid spread was caused by an undertaker throwing ice which had been used on a scarlet fever corpse into the street near a school. The ice was picked up and eaten by the children." Will a reliable physician in Gloucester City inform us whether there is any truth in the foregoing paragraph?

JUMPING THE ROPE.—This favorite exercise, especially among girls at school, is evidently capable of being carried to a dangerous excess. At Lima, Ohio, recently, a girl fourteen years of age is reported to have jumped the rope 250 times without interruption. In about twenty minutes after she fell into an unconscious condition, and died in a little less than three weeks.

MICHIGAN STATE MEDICAL SOCIETY.—The Twentieth Annual Session of this Society will be held in Grand Rapids, Michigan, commencing June 11th, 1884. For further information apply to G. E. Ranney, M.D., Lansing, Michigan. We would respectfully suggest to the members of this Society the propriety of so changing its plan of organization as to make it a representative body, and thus place it more in accordance with nearly all the other State medical societies, and with the National Association.

A FULL REPRESENTATION.—Thirty-four members of the profession in this city attended the recent meeting of the American Medical Association in Washington. Twenty-six were delegates from the Chicago Medical Society, and the remaining eight either delegates from the Illinois State Society or permanent members.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.—At a recent meeting of this Society, Dr. J. M. DaCosta was elected President, in the place of Dr. Samuel Lewis, resigned.

OFFICERS OF STATE MEDICAL SOCIETIES.—At the annual meeting of the Arkansas State Medical Society, held at Little Rock, April 30, 1884, Dr. T. W. Hurley was elected President; Dr. W. B. Hart, Vice-President; and Dr. W. P. Gibson, of Little Rock, was reëlected Secretary.

AT the annual meeting of the Texas State Medical Society, held at Belmont, Tex., April 22, 1884, Dr. H. C. Ghent, of Belton, President; Dr. E. F. Becton, of Sulphur Springs, First Vice-President; Dr. H. H. Darr, Second Vice-President; Dr. M. Matkin, Third Vice-President; Dr. W. F. Burtof, Secretary; and Dr. F. Larendon, Treasurer.

MINNESOTA STATE MEDICAL SOCIETY.—The next annual meeting of the Minnesota State Medical Society will be held in Stillwater, on Thursday and Friday of the first week in June, 1884. A full meeting is expected.

OHIO STATE MEDICAL SOCIETY.—The thirty-ninth annual meeting of this Society will be held in Columbus, Ohio, on the 10th, 11th, and 12th of June, 1884. Dr. H. F. Sharp, of London, Ohio, is the Secretary.

SALICYLATE OF SODIUM IN PREGNANCY.—Dr. Balette, of Paris, reports four cases of pregnant women to whom *large doses* of the salicylate of sodium were given, in two of which abortion followed. The announcement would have been more satisfactory if the actual size of the doses had been stated, as moderate but efficient anti-rheumatic doses have been freely administered to many women in various stages of pregnancy without any evil effects.

SHIP OWNERS AND MARINE HOSPITAL SERVICE.—The following, from the Detroit *Lancet* of recent date, is worthy of serious thought:

"The ship owners and sailors have had bills introduced into Congress repealing the tax upon sailors for the support of the Marine Hospital Service, and ordering that the same be supported by the government. We would like to see the tax and hospitals both abolished. This entire service is an anomaly in our plan of government. There is no more reason why there should be a series of hospitals for the care of sailors supported by the government, than that the government should have hospitals supporting railroad men, or the factory operators, or any other class of laboring people. Since the government does not do this for all classes, we object to any discrimination in favor of any class. We already have a navy medical service, to care for all the sick sailors in

the service of the government. This suffices. Were it needful for the government to extend aid to any class on the water, it were best done by this service. But there is no need whatever. The sailor would be better cared for, and be trained to make a better citizen, if he were treated like all other classes of citizens. This matter is one of importance, but it will scarcely receive the attention it demands while the government department, to which it belongs, deems it of such value in enabling it to exert a powerful influence toward the accomplishment of its purposes. In short, so long as it has so large a patronage at its disposal it will have vigorous defenders; for who will not fight for his bread and butter, and find weapons of offense and defense? The reform in this matter must come from those whose interests are not interfered with by the abolition of this service."

SOCIETY PROCEEDINGS.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Thursday, May 1, 1884. The President, R. A. Cleemann, M.D., in the chair. Dr. Henry Beates, Jr., read a report of a case of

CYSTIC LEIOMYOMA UTERI,

the fluid of which contained the Drysdale corpuscle and other characteristics of typical ovarian cystoma. The early history of this case, owing to the inability of the patient to state with precision a few minor details, is somewhat incomplete, yet sufficient accuracy is available to supply a clear unequivocal clinical record, and distinctly demonstrate that the Drysdale corpuscle, where found in considerable number in fluid derived from the abdominal cavity, is not pathognomonic of cystoma ovarii.

Mrs. L., æt. 51; housewife; a mother; noticed four years prior to admission to the Philadelphia Lying-in Charity Hospital a lump in the lower abdominal region. The menopause had not yet occurred. The tumor was round, painless, and occasioned no inconvenience. Its development was comparatively slow, and not till it had attained large dimensions did it occasion constitutional derangement. When admitted the patient was markedly asthenic, and suffered from mechanical dyspnœa, gastric irritability, sub-acute proctitis and pyrexia; the temperature ranging from 99° to 100.5°.

The facies ovariana and the peculiar atrophy of the soft tissues of the supra-thoracic region, so constant an attendant upon ovarian cystoma, were present in conspicuous degree.

The notes of measurement are unfortunately lost, but an estimate of the size can be formed when it is remarked that the tumor completely occupied the abdominal cavity, everting the xiphoid cartilage and inferior ribs bulging far over the lumbar regions and extending over the pubes down and between the thighs. The circumference at its largest portion was about 51 inches. The superficial abdominal veins were conspicuous, and the cellular tissue from the mammary zone to the feet very edematous. Palpation and percussion detected and revealed signs of ovarian cyst. The fluctuation was more perceptible in the longitudinal than transverse diameter. In the sub-hepatic region a decided resistance to pressure was noticeable, dependent upon a thickening of the cyst wall. This mass was attached to the liver at the outer two-thirds of the inferior border. At the inner third there intervened a space which emitted a percussion tympany, the note being that of colic resonance. The urine afforded negative evidence. As the asthenia was so profound it was deemed advisable to tap the cyst in order to obtain an opportunity of improving the general strength and rendering ovariotomy bearable. Dr. Albert H. Smith, who had charge of the case, tapped, employing the ordinary curved trocar and canula used in tapping per rectum the urinary bladder, and withdrew twenty-seven pints of a dark, muddy-brown grumous fluid, possessing a neutral reaction, specific gravity 1018, and containing blood and par-albumen. Microscopically I found red blood-corpuscles, leucocytes, endothelium in various degrees of retrograde metamorphosis, *i. e.*, the corpuscles of Bennett, Nunn and Gluge, the ovarian cell of Drysdale, cholesterine and amorphous detritus. It did not coagulate spontaneously. These microchemical properties, coupled with the physical signs, determined a diagnosis of ovarian cyst. The grumous character of the fluid and the existence of the sub-hepatic mass inclined to the belief that we were dealing with a cyst in which carcinosis had become established, and that either metastasis to the liver occurred or there co-existed carcinoma hepatis. The idea of ovariotomy was abandoned and analepsis instituted, with the effect of improving the general condition sufficiently to enable her being removed to her home, where she remained under the care of Dr. L. Brewer Hall. In about five months the tumor had refilled, and during my absence Prof. James B. Walker, at Dr. Hall's request, tapped the second time. The fluid was clear and presented the appearance of ovarian fluid. In the winter of 1882 I tapped a third time, employing an aspirator. The gentleman assisting me inadvertently applied the exit nozzle of the air-pump to the vacuum jar, and when the trocar was introduced there occurred an inflation of the cyst. The air apparently inflated a series of variously sized cysts that were arranged circumferentially and emitted percussion notes of different pitch from this circumstance, which occasioned no evil consequences, we concluded that there existed a number of small cysts, communicating with the principal. As the evacuation of the fluid progressed the umbilical region sunk in, disclosing a circumferential mass, presenting the appearance of a wreath, as it were, underlying the abdominal parieties. This ridge could be firmly grasped and moved to a limited extent. This peculiarity determined me to carefully examine the fluid. I also had Dr. Formad examine it, and he pronounced it ovarian. The class at the University of Pennsylvania was supplied, and the ovarian cell of Drysdale demonstrated. The cyst refilled more rapidly, and I tapped a fourth time, removing a large bucketful of

clear fluid, containing the same corpuscle in greater number than previous specimens: large flakes of coagulated lymph were also evacuated. The circumferential mass had undergone great development, as had also the sub-hepatic induration. The re-accumulation of fluid was more rapid and the deterioration of health steadily progressing. Death terminated suffering about six years after the first manifestations. During the last days of the patient's life Professor Walker, in the absence of Dr. Hall, was in attendance. His letter details the mode of death and results of autopsy: "Mrs. L. died on the Sunday night after your departure. Her bowel trouble rapidly disappeared, but the symptoms of cerebral anæmia deepened, with hallucinations and convulsions until death.

"At the autopsy the tumor was found to have membranous walls over an area of nine square inches above the navel in the middle line, elsewhere the cyst wall was thick as per sample. In some localities, notably in the hypochondriæ, the wall was quite thick. Firm attachments existed over the anterior wall of the sac with the parietal peritonæum, and the intestines were carried far up under the liver and stomach, and were attached to the tumor. The liver was also attached. The entire abdominal cavity was occupied with the tumor, and it dipped into and occupied the pelvis. No attachments existed at the sides nor behind. The uterus was forced downward. One ovary, the right, was normal and attached loosely to the pelvic brim. The other is presumably occupied by the tumor. The cavity of the tumor was occupied by a brownish gelatinous fluid, resembling soft soap; it was transparent, but had a sediment consisting of detritus from the inner wall of the sac. There was but one cyst, and the entire interior was similar in its lining, being apparently undergoing erosion. The contents of the cyst measured over a Yankee bucketful. As the tumor was too immense to even contemplate removal, and as the variably thick wall was everywhere similar save in the pelvic portion, which was darkened from hypostatic congestion, I removed the uterus and the portion of the tumor immediately surrounding it, extending the section through the cyst wall." (This specimen was presented to the society.) Sections for microscopic study were prepared from different portions of the cyst wall and were all demonstrative of leiomyoma. Those from the sub-hepatic portion resembled spindle-celled sarcoma, but were clearly differentiated by the elongated nuclei and want of sarcomatous relationship of cells to capillaries. The identity of the clinical phenomena of this neoplasm with those of ovarian cyst is a matter of special attention. In the early stage a marked peculiarity consisted of the sub-hepatic enlargement and induration; a morbid resistance to pressure noticed in the inferior lumbar regions after the first tapping, and attributed to the edema, is now seen to have depended upon a thickening wall, which at that time was insufficiently developed, save in the hepatic region, to attract special attention. That all doubt regarding the nature of this neoplasm may be removed, attention is directed to the left ovary, which has undergone marked atrophy and is to be seen in the specimen. I submitted some sections to Dr. Formad, who pronounced them ovarian. The origin of the cyst from the fundus uteri is evident upon examination. With the facts before us, I think it is conclusively proved that the ovarian corpuscle of Drysdale, while a valuable aid to diagnosis, does certainly not possess pathognomonic value.

Dr. DRYSDALE regretted that Dr. Beates had not sent him a specimen of the fluid received from this tumor, especially as he had more than one opportunity of doing so. While having the highest regard for the opinion of the gentlemen who examined it, still, so many errors had been made in these investigations that it would have been a satisfaction to him to have examined it himself. But, apart from this regret, he considered it by no means proven that the cyst in question was not ovarian. The portion of tumor left attached to the uterine wall in the specimen resembled a closely adherent ovarian cyst, such as he had met with repeatedly. The little mass lying close to the uterus, described as an atrophied ovary, did not present any resemblance to an ovary, nor did it occupy the usual position of that body. In the description no reference had been made to the color of the tumor, which has an important diagnostic value, the uterine fibro-cyst being usually livid or purplish in color, while the ovarian had a white, pearly hue. It was especially in cases like that of fibro-cyst of the uterus where the importance of the ovarian cell in diagnosis was well marked. In his investigation of these tumors he had never met with the cell which he had described as ovarian. Mistakes were very easily made in the differential diagnosis of such tumors, and in fact in many cases the diagnosis could not be established except by the examination of the fluid or by opening the abdomen. For want of this examination of the fluid he had seen Spencer Wells make the abdominal section to remove a tumor which he had diagnosticated as ovarian, but which proved to be uterine. Dr. Marion Sims had sent him on three different occasions, and without telling him that they were from the same patient, specimens of fluid which he thought was ovarian, obtained from a cyst in the abdomen. Dr. Drysdale assured him that the fluid was not ovarian; but, after the examination of the last specimen, Dr. Sims still doubting, determined to operate, and found a uterine fibro-cyst. The history and all the characteristics of the tumor described this evening were ovarian, and the specimen and autopsy were not sufficient to establish the diagnosis of uterine cyst.

Dr. B. F. BAER remarked that the specimen seemed to be a section of a fibroma arising from the uterus, but it is too small to be satisfactory or to prove its origin. His personal experience has taught him the diagnostic value of the Drysdale corpuscle. When Dr. Formad reports finding this cell in the fluid removed from an abdominal tumor, he feels strengthened in his diagnosis of ovarian cyst. He has not trusted to the cell alone, but has been greatly influenced by its presence or absence in making up a diagnosis in doubtful cases. In every instance in which Dr. Formad has reported finding the ovarian

cell, operation has proved the tumor to have been of ovarian origin. He would like to ask Dr. Drysdale if he still considers the cell pathognomonic.

Dr. DRYSDALE still believed in the pathognomonic value of the ovarian cell. In his investigations he had met with but one exception to the rule, and that was in renal cysts. To prove that the cell could be relied on to establish a diagnosis he would give one or two instances where it was impossible to do this except by its aid. In a review by Dr. Harris of the "Transactions of the American Gynecological Society" in the *American Journal of Medical Sciences*, will be found this statement: "On one occasion Prof. D. Hayes Agnew gave Dr. Drysdale a fluid for examination in which he found the characteristic cell. Upon stating what he had found to Dr. Agnew, he was told that the fluid had been taken from the abdominal cavity; upon which he immediately said that the fluid must have escaped from an ovarian cyst, for it was ovarian. In this he was correct, as the cyst had a small hole in it, as if made with a punch, and the fluid had escaped as claimed." In another case, Dr. D. received a letter from Prof. Matthew D. Mann, of Buffalo, N.Y., with a specimen of fluid consisting of eight or ten drops, which the doctor stated was all that he could obtain by aspiration. The tumor had been diagnosticated by other surgeons as one of uterine fibroma, and consisted of a large, solid mass, which filled the pelvis and abdomen as high as the umbilicus. The history and symptoms all pointed to a uterine fibroid, and the patient was in such a precarious condition that an exploratory operation was considered unjustifiable. An examination of the fluid by Dr. D. showed the presence of the ovarian cell. This determined Dr. Mann to operate. He found two ovarian tumors, which he removed successfully, and the patient recovered. "Without the microscope no certain diagnosis could have been made except by resorting to an exploratory incision." These cases, and he could give many others like them, were sufficient to show the diagnostic value of the cell.

Dr. BEATES remarked that it was a matter of extreme regret to him that Dr. Drysdale did not have an opportunity of examining the fluid; it was due to the fact that the neoplasm was regarded as ovarian, and the specimens of fluid were not preserved. At the autopsy the growth was presumed to have arisen from the left ovary, and none of the fluid was kept. Later study of the specimen disclosed the amygdaloid mass situated in an atrophied membranous structure closely approximated to the uterus. The microscopic examination of this determined its ovarian character to the mind of Dr. Formad, which conclusion dissipated a doubt in my mind, and confirmed my belief of its being the left ovary. I thoroughly appreciate the strong probability of error, liable to occur in positively diagnosticating by differentiation the Drysdale corpuscle from similar bodies, as the pyoid body of Lebert, but the fact that treatment with acetic acid only had the effect of rendering the whole corpuscle very slightly clearer, and disclosed no nucleus, that ether added to the fluid and the mixture, thoroughly agitated for several minutes, had the effect of simply rendering the corpuscle paler, convinced me that the bodies were the corpuscles in question. There is, by very extended experience, developed a capacity to differentiate by a varying degree of opacity. Dr. Formad believed these corpuscles to be those of Drysdale. The striking phenomenon, if this be an ovarian cyst, is in the fact that primarily it was purely cystic, typically so, and that during the last year of its existence the cyst wall, throughout its posterior, seven-eighths assumed a myomatous development. If this did not occur, the myomatous wall must have originated at the fundus uteri, and gradually permeated the cyst. Either of those processes is almost incredible, and certainly exceptional to known clinical facts. The true uterine origin must not be forgotten. That a proper conception of the tumor may be formed, it should be compared to a large pumpkin, with a wall varying in thickness from one to three inches. For an area of about nine square inches at the umbilical region the ordinary cyst-like structure formed, as it were, a drum head. This wall is not fibromatous, but purely myomatous. Dr. Goodell has seen this patient, and diagnosticated the tumor as ovarian.

Dr. B. F. BAER exhibited a specimen of hypertrophied uterine mucous membrane. R. H., æt. 30; married twelve years; sterile; puberty occurred at age of twelve; slight dysmenorrhœa from the first, and since her marriage the difficulty has been increasing, so that during the last few years the pain has been very severe. The menstrual flow, which has always been rather profuse, especially since her marriage, has for more than a year been irregular in time and quantity; sometimes it continues two weeks very freely, when she would be so prostrated as to be compelled to remain in bed to regain strength. She complained of a severe, sharp pain in the region of the left ovary, radiating to the groin and anterior part of the thigh, and to the præcordial region and side of the head to the top-head. She had great dragging in the pelvis, and pain in the sacral region. During her periods, the mammary glands would swell and become very tender and sore. Coition had been rendered almost intolerable on account of pain during the act, and because it increased the pain in the left ovarian region and induced a sensation of nausea and faintness. She had such dread of sexual congress, that an interval of months would sometimes elapse between the acts. Her weight had decreased from 146 to 127 pounds, and her appetite and digestion were poor.

Examination showed the cervix uteri to be near the vaginal orifice, somewhat elongated and conical. The os was patulous, the body of the uterus very much hypertrophied and retroverted. The left broad ligament was contracted, and the corresponding ovary prolapsed, larger than normal and very tender to pressure. The sound indicated a uterine depth of three and one-half inches, and the cavity was large and soft. The organ was mobile. Ether was administered, the cervix dilated by means of Ellingen's dilator, and the endometrium was carefully curetted, removing a large amount of the most enormously hypertrophied mucous membrane. Nitric acid was applied. Under a regulated diet, with

rest, complete relief followed, with freedom from hæmorrhage and pain.

Dr. W. H. PARISH would like to hear the result in Dr. Baer's case after the lapse of three or four years. Two or three years ago he had reported before this Society a similar case, in which after dilation by sponge tents, he had removed a large quantity of endometric growths, and applied nitric acid. The treatment was followed by an apparent cure, which lasted for some months, after the lapse of which the previous condition returned. The same treatment followed by relief, and subsequent relapse has been repeated several times. Good microscopists have pronounced the growths benign. Dr. Goodell has, however, given it as his opinion, that it will ultimately become malignant. Dr. Parish has been gradually coming to the same opinion.

Dr. BEATES has treated a woman, æt. 33 years, who suffers from ante-flexion of the uterus, menorrhagia, and granulations of the endometrium. The microscopic appearance is benign. After treatment, by means of the curette and nitric acid, no hæmorrhage occurred for four months; the treatment was repeated, a laceration of the cervix was closed, and seven months later the patient became pregnant, abortion occurred at two and a half months, and the granulations and hæmorrhages have returned.

Dr. BAER remarked that these cases are very common, they are seen every week at the clinic. They are usually benign, but sometimes become malignant from loss of blood and a run-down condition of the system. Adhesions or some other obstacle to the free return of the venous blood from the uterus may exist, or the ovaries may be diseased, and these causes will bring on the relapse, no matter how perfect the relief may be. In many cases the cause is flexion, the effect is sterility. It is an exaggeration of a purely physiological process. It may be benign in its incipiency, but may become malignant later on.

W. H. H. GITHENS,
Secretary.

DOMESTIC CORRESPONDENCE.

THE MEDICAL ASSOCIATION OF THE STATE OF ALABAMA TO THE NEW YORK STATE MEDICAL ASSOCIATION.—At the annual meeting of this Association, at Selma, Alabama, April 9, 1884, Dr. William O. Baldwin, of Montgomery, introduced the following resolutions:

Resolved, 1. That the members of the Medical Association of the State of Alabama have watched with deep interest the progress of the struggle which for the past two years has been going on in the New York State Medical Society; between the advocates of the ancient and established ethics of the medical profession, as embodied in the Code of Ethics of the American Medical Association, and heretofore recognized and observed by all physicians of reputable standing in all the countries of the civilized world, on the one hand; and on the other hand, the advocates of the so-called "New Code," or New York Code, which in effect proposes to degrade the medical profession by opening the way for professional association with irregulars and charlatans;

Resolved, 2. That all hope of the prevalence of wise and conservative councils in the New York State Medical Society having been dissipated by its action at its recent session in Albany, no honorable course was left for the adherents of the established ethics except that which they have chosen to pursue, namely, to separate themselves from the demoralizing movement which they are unable to control, and to organize themselves into a new association for the maintenance of the honor and dignity of the profession in their State.

Resolved, 3. That in doing this these men, Flint, senior and junior, Gouley, Didama, Squibb, Rochester, Sayre, and their associates have earned for themselves the thanks of the medical profession of the whole country; and we extend to them our hearty congratulations and fraternal good will.

Resolved, 4. That in order to signalize still further our appreciation of their recent action, a copy of these resolutions, with the greetings of this Association, be forwarded by our President to Dr. H. D. Didama, of Syracuse, the President-elect of the New York State Medical Association, wishing them prosperous fortunes and abundant success in the further development and fruition of their noble work.

Resolved, 5. That a copy of these proceedings be also forwarded to the *Medical News* and *Gaillard's Medical Journal*, with a request that they be published.

NEW YORK STATE MEDICAL ASSOCIATION.—The council of the New York State Medical Association receives with gratification the greeting of the Medical Association of the State of Alabama.

Though conscious of integrity of purpose in founding our new Association, and with full faith in the wisdom and utility of its establishment, still words of encouragement and approval from those who view the contest from afar are specially cheering.

It is the desire of the council, by unanimous vote, that the thanks of the New York State Medical Association be sent to the Medical Association of the State of Alabama for the resolutions relating to the organization of the New York State Medical Association, and to the protection of the honor of the profession in the maintenance of the National Code of Ethics.

Done at the session of the Council, held May 7, 1884.

E. D. FERGUSON,
Corresponding Secretary.

THE Medical College men in Cincinnati object to any law which will compel the re-examination of their graduates by gentlemen unconnected with any college.

THE Medico-Chirurgical College of Philadelphia lost by death two members of its faculty during February, viz., Dr. Frank O. Nagle, of typhoid fever, and Dr. George P. Oliver, of apoplexy.

NECROLOGY.

Byford, William H., Jr., M.D., was born January 21, 1850, at Mount Vernon, Indiana; died at his residence in Minneapolis, Minn., October, 1883. He was the son of Prof. Wm. H. Byford, of Chicago, Ill. His early boyhood was spent in Evansville, where his father removed during his infancy.

In the fall of 1857, the family went to Chicago, Ill. There he attended private and public schools until his fourteenth year, when he was sent to Racine College. After remaining two years in the primary department of that institution, he went to Berlin, Prussia, to complete his education. Besides his regular course of instruction there, he acquired a thorough knowledge of the German and French languages under the supervision of Dr. Doebbelin, with whom he visited the Exposition at Paris, during the year 1867.

Leaving Berlin in 1868, he took an extensive tour through Europe, returned home to study law, and was admitted to practice in the courts of Illinois in the year 1870. Soon after entering the practice of law, he brought upon himself a slight pulmonary hæmorrhage by over-exertion in a gymnasium. This was the first of a series of such attacks, which brought prostration, and compelled him to give up his profession, and travel in the South; and finally to settle in Denver, Colorado, where his health so improved that he was able to study medicine with Dr. Denison during the last year of his residence there. He then returned to Chicago, entered the Chicago Medical College, and graduated in the spring of 1878. But the climate of Chicago soon began to develop his pulmonary troubles, which led him to remove to Faribault, Minnesota, with the hope that the dryer and more invigorating climate of that State would better agree with his condition. But the long rides, great exposure and unavoidable irregularities that attend the duties of the physician in small towns, rendered it impossible for one of his infirmities to continue in active practice there.

About this time the prosperous and already populous city of Minneapolis, with its brilliant outlook, attracted his attention, and he decided upon it as his permanent home, and removed there in October, 1881.

Before leaving Chicago he gave evidence of the solid acquirements and sound judgment which afterward showed themselves as leading qualities in the practice of his profession. In Faribault he became distinguished among his medical friends for his clear insight into intricate cases, and the steady confidence with which he inspired his associates in consultation.

His popularity there was very gratifying to his friends, and his patronage was limited only by his physical inability to attend his numerous calls.

While in Minneapolis he was brought prominently into notice by those same qualifications which had marked his short professional career in Southern Minnesota, and peculiarly exhibited his aptness in the work he had undertaken.

He accepted the chair of Physical Diagnosis from the trustees of the Minnesota College Hospital, and gave the greatest satisfaction in that position.

He was a member of the Society of Physicians and Surgeons, and of the State Medical Society, at Minneapolis. F. A. Dunsmoor, Minneapolis.

ORIGINAL ARTICLES.

GUN-SHOT WOUNDS OF THE SMALL INTESTINES.

BY CHARLES T. PARKES, M.D., PROFESSOR OF ANATOMY IN RUSH MEDICAL COLLEGE, CHICAGO, ILL.

[Address of the Chairman of Section on Surgery and Anatomy.]

MR. PRESIDENT, AND GENTLEMEN OF THE AMERICAN MEDICAL ASSOCIATION:

The subject-matter of the remarks to be presented this morning was suggested to me by an article published in the *British Medical Journal* in 1882, from the pen of "that good man among men, and great man among doctors," J. Marion Sims.

The article in question was an appeal for operative interference in penetrating gun-shot wounds of the abdomen, in lieu of the "expectant treatment" so universally accepted and adopted by the profession, and which, in a few seemingly well authenticated instances, has led to recovery.

The appeal was uttered in behalf of the vast majority on the side of fatality attending these cases, and was based upon the deductions to be drawn from the recoveries following operations for diseases affecting the viscera of the abdomen and pelvis, during which the most terrible injuries have been inflicted upon the contents of these cavities—the peritonæum exposed for hours, as well as brought in contact with all kinds of foreign and usually irritating substances.

It is scarcely necessary for me to affirm in your presence the fact that, with few exceptions, the older writers and surgeons advocate the "expectant treatment" in the management of these injuries, while the younger writers and surgeons favor operations, pinning their faith upon the wonderfully favorable results attending the practice of Listerism, the purest of antiseptic surgical methods.

During the past few months I have instituted and carried out, with the valuable assistance of Mr. J. McDill and Drs. Anthony, Freer and Bolles, a series of experiments for the purpose of ascertaining the results to be obtained by immediate operations after these wounds, with the hope that the relation of the attending circumstances and events would be interesting as well as useful, by adding to the data now in our possession other data, from which may be determined more intelligently the course of action to be adopted when these cases come under our charge for treatment.

No attempt will be made to review the great question of penetrating gun-shot wounds of the abdomen, which would lead me beyond the scope of the paper. Nothing but a fair recital of the history of the experiments, with some application of the conclusions to be drawn therefrom, will be undertaken. With this intent in view, there will be presented to you the accompanying phenomena, the manner of treatment and results of thirty-seven intentional gun-shot wounds of the abdomen, confining my attention entirely to my own observations, and exhibiting to you such specimens as I have been able to preserve, taken from the animals; both of those which died, and of those which were sacrificed, after recovery, to obtain the specimen. Experiments of like nature have been made upon animals by very many surgeons, previous to the application of their convictions of the necessity of certain procedures to relieve disease or the effects of injury in the human body.

No preparation of the animals selected for experiment was made, either as to choice of physical condition or surrounding circumstances, except that they were anæsthetized previous to being hurt. The wounds were produced by the ordinary Smith and Wesson revolver of 22, 32, 38 and 44 caliber, and by the 22 caliber rifle. The shots were given at short range, so the damage done by the bullet fairly represents the injury met with, either in military or civil practice, as the results of shots from the firearms now in use.

At first, no attempt was made to give a definite direction to the course of the bullet, other than that it should perforate the abdominal cavity. The results soon confirmed the fact so well known, that the larger number of patients suffering from such wounds never come into the hands of the surgeon, their injuries proving rapidly fatal.

This ending, we can readily understand, must be a common one, when we bear in mind the construction and nature of the viscera contained in the cavity, especially their great vascularity, having vessels of immense size supplying them with, and carrying away from them, the blood necessary for their nutrition and the performance of their special functions; not to mention the main systemic artery and vein coursing through the cavity in a position rendering them readily liable to perforation, death following speedily.

It was also soon ascertained that a severe perforating and lacerated bullet wound of the viscera, such as of the kidneys, of the spleen, and of the pancreas,

could not apparently be treated successfully in any other way than by an absolute removal of the injured organ; and notwithstanding the reported successful removal of almost every important organ of the abdomen by one surgeon or another, the conclusion was reached that some of these organs must be left *in situ*, in order that the functions of life may be carried on.

Hence we were compelled to exert such control over the course of the missile, as to have it produce a wound of the nature of those likely to come, and actually coming, under the care of the surgeon; so that the injuries became those confined to perforations and injury of the intestinal tube, with occasionally the injury of some of the larger special organs.

It will not be amiss to recall to your minds, very briefly, some of the triumphs of abdominal surgery, and more especially to impress the fact that shot wounds of the cavity and contents present many questions of prime importance which are not met with in, and do not complicate, ordinary operations for disease or injury with any free, external wound.

The removal of the spleen for acute wounds nearly always results in recovery; so also one kidney has been removed successfully, either for disease or injury, often enough to place the operation of nephrectotomy among the list of justifiable undertakings.

Again, wounds of the intestinal tube of all degrees of severity, up to complete division by the resection of portions of the entire caliber thereof, have been successfully treated by surgeons, as is proved by the experimental researches of Dr. Traverse, the eminent Prof. S. D. Gross, Dr. Bell, and others, and confirmed by the experience of many surgeons during operations upon the human being for diseases of these cavities. Still, in each of the examples mentioned, the circumstances were entirely different from what is found present in perforating gun-shot wounds of the abdomen. In the former, the peritoneal cavity was clear of blood and other extraneous substances; the prevention of their entrance entirely under the control of the operator. In the latter, blood in large amounts was always found present; and the peritonæum was smeared with the contents of the intestinal tube, necessitating prolonged efforts to secure a cavity clear of all hurtful substances. Of necessity, the latter cases would be least likely to escape the probabilities and dangers of subsequent inflammation of the serous membrane.

Primary resection of portions of the intestinal tube, or entire removal of separate organs, are operations comparatively easy of performance, and are not necessarily attended with any damage to or exposure of any other portions of the abdominal cavity, outside of the immediate proximity of the site of the operation.

Extravasation and hæmorrhage should be entirely prevented and controlled; and the peritoneal sac can be maintained perfectly clean during the time of, and after, all the procedures required by the operation.

After gun-shot wounds, besides the resection or removal of any special organ required, there is great shock, and prolonged manipulation is necessary to obtain a proper cleanliness.

The recital in detail of each experiment would be tiresome and occupy too much time, so that your attention will be called only to the more important facts and circumstances determined by them.

There will be published with the paper a somewhat extended account of each experiment, from which individual inferences may be drawn. In addition, a short *résumé* of the entire work will be given further along.

First comes the question of hæmorrhage and damage to blood-vessels, as this is primarily the most common and certain cause of death, and demands the surgeon's first attention. In its excessive amount, occurring rapidly and suddenly, is to be found the explanation of the cases which are immediately fatal. This result will surely happen when the largest arterial trunks are severed by the bullet; further, its copiousness and persistency of flow, even when none but very small blood-vessels are divided, involve a matter of serious concern, if not a fatal issue, either from the amount of blood lost, or in predisposing to septic processes from blood decomposition.

There is a remarkable persistency in the flow of blood following the severance of vessels in the abdominal cavity, perhaps dependent upon the laxity of the tissues through which these vessels course, the absence of pressure from surrounding soft parts, and the lack of the peculiar influence of the atmosphere, either from its weight or clot-producing power.

When the abdomen is opened immediately after the transit of a bullet, its cavity is found to contain a large amount of blood, the quantity, of course, being in proportion to the size of the vessels wounded, but always a disproportionately large amount, no matter what their caliber; further, the flow is still going on from vessels of all sizes. There seems to be slight disposition to the formation of an obstructive clot in the mouths of the smaller ones, and slow retraction or contraction of the walls of the larger.

Bleeding stops only when the heart ceases to beat in a faint from excessive loss, or when the amount of blood is so large that by its bulk, and weight, and distension of the abdominal walls, it makes pressure sufficient to occlude the open vessels.

The conditions are very quickly altered after air is admitted through the abdominal section. Clots rapidly seal up the smallest vessel; the smaller arteries spurt less forcibly and soon cease beating; the larger ones contract and retract, just as occurs in the wounds of soft parts in other regions of the body. This is in accordance with, and corroborative of the experience in hæmorrhages occurring in abdominal surgery in the human being. Few of us have failed to see cases like this: a patient dies suddenly, with all the symptoms of acute prostrating hæmorrhage; post-mortem examination shows the abdominal cavity filled with blood; the blood is carefully cleared away in the search for the source whence it came; and when this is found, it is a matter of astonishment that such a vast amount of blood could come from so small a vessel. Perhaps it is a small vein of the ovarian venous plexus, or a minute vessel in the thin-walled sac of an extra-uterine fœtation, or the partially closed vessels in the shrunken stump of a

recently removed ovarian or other tumor, or some recently divided adhesions, all of them vessels which, in any other part of the body, would be no item of concern to the surgeon, or need any of his special care to prevent bleeding from them.

The lesson taught by these facts is of imperative importance in all operations upon these cavities; and even if mastered, loses nothing by reiteration. Excessive hæmorrhage being certainly the principal cause of speedy death in severe gun-shot wounds in this region of the body, where evidences of its presence are plainly exhibited, there can be no hope whatever of saving the lives of any of the wounded except by immediate abdominal section. This alone, by admitting air quickly, staunches the fast flowing current, and gives time for the application of the ordinary rules of surgery for the prevention of hæmorrhage.

In order to be safe from subsequent trouble, every divided blood-vessel must receive the surgeon's attention, occluding clots must be thoroughly sponged away, and in their stead must be placed the ligature or the sear of the actual cautery. If left without this restraint, and the abdominal opening be closed, the same conditions are restored as existed previous to the section; and as reaction comes on, bleeding will surely recur, and in large amount, leading to death from this cause alone, or furnishing a frequent source of septicæmia.

This fact again is corroborative of the experience of ovariotomists, the most successful being those who take the greatest pains to staunch all bleeding before closing the abdomen.

Following a resection of three or four inches of bowel and a ligation of two large subdivisions of the mesenteric artery wounded by the bullet, there occurred a mortification of several inches of the entire intestine above the site of resection. The mortified part corresponded with the distribution of the arteries wounded and ligated. This assuredly was an important fact to know, if at all likely to occur as the result of wounds of these arterial branches; even its accidental occurrence is a circumstance to be remembered. Its occurrence would surely add largely to the gravity of the cases in which it happened, probably necessitating a resection of a portion of the intestine corresponding to the area of distribution of the wounded vessel. The great freedom of anastamosis between the mesenteric arteries rather argues against their wounds being followed by any such hazardous result; still, the case recorded above required explanation. Two experiments were performed in order to determine whether destruction of the arteries alone was sufficient to lead to such mortification.

Both demonstrated that a closure of two or three of the largest subdivisions of the main mesenteric vessel was not in itself sufficient to produce death of the portion of intestine supplied by them. The experiments were as follows: an animal was anæsthetized, and the abdomen opened. A sufficient length of bowel was drawn through the opening to allow of the ligation of two large sets of vessels adjoining each, the ligatures including vein and artery. The parts were returned to the abdomen and the latter closed. At the end of thirty-six hours the wound was reopened. No very noticeable change was found in the intestine; pulsation had returned in the ligated vessels beyond the ligature. The external wound was again closed. The animal recovered in a few days so as to be as lively as ever.

A second animal was etherized, and a ventral section made. Three large vessels were ligated (veins and arteries), before their division into any branches. These three vessels lay parallel with each other. A ligature was also thrown around the anastomosing branch near the intestine which connected with a fourth larger vessel. There followed immediately very marked whitening of the bowel. The parts were returned and the wounds closed. The animal recovered promptly from the effects of the ether and the immediate effects of the operation.

It remained quite well for six days, when it grew ill. The wounds were reopened. Pulsation had returned beyond the ligature. There was no sloughing or mortification of the intestine. It was congested slightly and seemed paralyzed, and was of wider caliber opposite the distribution of the ligated vessels; this was the only change. There was a great deal of very offensive matter in the peritoneal sac, and notwithstanding the high grade of inflammation, there was no adhesion of intestinal folds except at one point. Here there was found a perforation of the intestine. Out of the opening there protruded a piece of wood which, upon being pulled out from the cavity of the intestine, was found to be four inches long, and connected with a large mass of twine. This had evidently been swallowed by the animal, and had gotten along safely enough until it reached the inactive portion of the tube corresponding to the seat of operation, where it was forced through the tube by the strong contractions behind it. Unfortunately, the animal was killed by the ether during the examination. Aside from this accident, the animal had a good chance of recovery.

The complication of a complete resection of the bowel, with a ligation of two or more vessels, is the only explanation to be given of the case where mortification occurred. The experiments prove that such result does not follow simple closure of the vessels by ligation.

The second item to be considered refers to the course of the bullet and the character of the damage done by it. Nothing can possibly be more uncertain and erratic than the track of the missile through the body. A contracting muscular fiber, an edge of fascia, the elasticity of the skin, a surface of bone, or a distended knuckle of intestine, each and all of these at times present obstruction sufficient to divert it from the direct line of its flight. It is certainly astonishing what very extensive and severe lacerations of the intestine are produced by so small a bullet as one of caliber No. 22, Fig. 1; the entire circumference of the bowel at some points being mangled beyond recognition; again, it is equally surprising how minute are the perforations made by the large No. 44, Fig. 2. As a rule, the larger the calibre of the bullet the larger the wound.

Figure 1.

An estimate of the direction of transit, based upon the points of entrance and exit, is purely conjectural, and furnishes no standard whatever by which we may judge of any supposed injury to any organs known to lie in such course. In one experiment, the bullet made four openings through the abdominal walls, and did no damage other than contusion of two knuckles of the small intestine and gouging the serous membrane.

The animal had a remarkably deep furrow along the course of the "linea alba." The bullet entered the right side of the abdomen obliquely, two inches from the mid-line, perforated its walls, and coursing to the left, furrowed the peritonæum in its passage; was evidently deflected outwards, immediately before reaching the linea alba, by a knuckle of intestine, which it contused slightly.

Here it made its first exit through the walls, passed to the left side of the mid-line, again perforated the abdominal walls, and, furrowing the peritonæum upon the left side, finally made its second exit through the abdominal walls three inches to the left of the linea alba. Near its place of final exit, a second knuckle of intestine was found badly contused. The contusion was so severe and extensive that it was thought best to resect a length of one inch. The animal recovered.

In a second instance, the bullet entered the cavity about two inches to the right of the linea alba, on a line with the umbilicus, with a direction upwards and to the left side. It made its exit nine inches to the left of the mid-line, and just at the lower edges of the last rib. On opening the abdomen the stomach was found greatly distended, entirely concealing the other viscera from view, and presented two large perforations in its walls about two inches apart, from which some blood, mucus, and food were found running into the peritoneal sac. The wound to the right, in the stomach walls, was the smaller, and situated directly opposite the entrance perforation in the abdominal wall, having the same direction. The wound to the left in the stomach walls (two inches to the left) was the larger, very ragged, and had evidently been made by the bullet deflected forward at its first entrance into the stomach. After leaving the stomach the bullet impinged upon the inside of the abdominal walls just to the left of the mid-line, and then, instead of perforating them at that point, was again deflected upwards and to the left, merely furrowing the peritonæum along the remainder of its course to the point of exit mentioned. The wounds of the stomach were inverted, as it were, into the cavity of that organ, by bringing its peritoneal surfaces surrounding the wounds in contact with each other by means of the continued catgut suture. The abdomen was carefully cleansed of blood, etc., and the wounds in the walls closed in the ordinary way. The animal speedily recovered from the injury, without any uncomfortable symptoms. During recovery from the effects of the ether, the animal vomited considerable quantities of blood, giving an additional evidence of the perforation of the stomach.

There were two cases where the bullets perforated the abdominal walls, and in their transit did no injuries to the viscera, in which the points of entrance and exit were five and six inches apart. In each instance the only damage done was a furrowing and laceration of the peritonæum along their entire courses, the blood from the track of injury falling into the abdominal cavity. In one experiment, the bullet failed to penetrate the abdominal walls and was subsequently dissected from between the muscles. On opening the cavity, quite a rent was found in the spleen opposite to the seat of external bullet wound, from which blood was freely flowing. There was neither abrasion nor perforation of the peritonæum. This case may suggest the probable cause of death in some fatal cases from non-perforating wounds. The laceration was evidently caused by concussion alone.

Other instances might be cited to illustrate the exceedingly great uncertainty as to the course taken by the bullet, and as to the organs probably impaired. They would also confirm the possibility of perforations of the walls without accompanying injury to the contents of the abdomen. Still, no instance was shown of failure to produce a wound thereof when the bullet's course lay among the intestines. Their safety followed deviation by glancing.

The wounds of the intestine may be many in number and situated very near to each other (Fig. 2) so

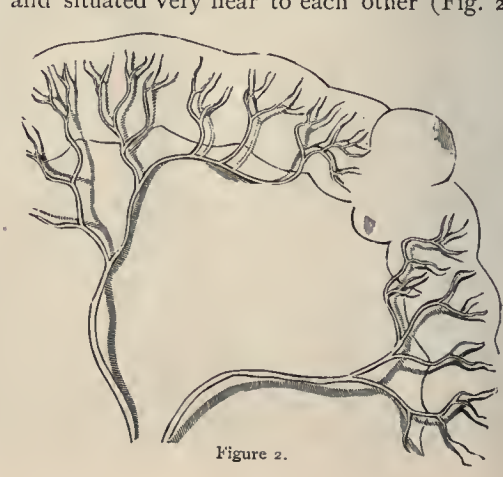

Figure 2.

that one resection including all the openings will constitute the only operation that furnishes relief.

Again, the openings may be few in number and widely removed from each other; and if each wound is large, and the damage to the tube extensive, such as is usually produced by a 32, 38 or 44 caliber bullet, three or four resections are necessary. The latter are the most difficult cases to manage and most fatal in their results. The position of the points of entrance and exit of the bullet in the intestine is subject to immense variety, even in simple cases. It may involve only the top of a knuckle of intestine, merely opening the cavity thereof. The points may be so near each other that only a half inch or less of intestinal wall separates them from each other. (Fig. 1, a.) The bullet may merely cut off the mesenteric junction opening into the cavity more or less freely. The intestine is often perforated transversely near the middle, or longitudinally; in the latter case the bullet, entering at one point, courses along in the cavity of the tube for some inches, and then makes its exit.

All of these varieties depend upon the situation of the intestinal folds with reference to each other at the time of the transit of the bullet. One case showed 10 complete perforations in 18 inches of length of the ileum. Fig. 3.

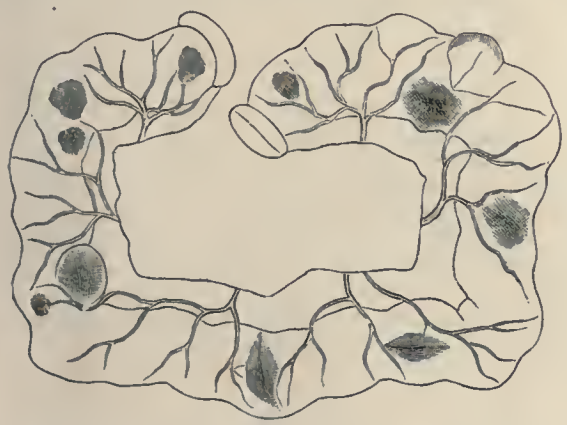

Figure 3.

Extravasation of the contents of the tube was present in every instance where there existed the slightest degree of perforation. These contents were forced out into the peritoneal cavity, or on to the surface of the intestines, if the wound was large, by the bullet itself, and the normal tonic contractions of the bowels; and, if small, perhaps by the latter alone. This facility of extravasation agrees with my experience in wounds of the intestine in the human being. I have personal knowledge of two instances in which the medium-sized aspirator needle was employed to relieve tympanitic distension of the tube, with success so far as getting rid of the gas was concerned, and giving great temporary comfort to the patient. Death ensued from the disease. Post-mortem examination in each case demonstrated the presence of fæcal extravasation at the seat of the needle puncture. It would not be an arduous task to collate instances of this accident in the practice of others, where this plan has been adopted. It is difficult to understand how any other result could follow a perforation, if there be contents at the seat of the puncture, when we remember how strong and constant is the action of the circular muscular fiber. It is stated that the protrusion or eversion of the mucous coat, which ensues very rapidly after complete division of the walls, acts as an immediate stopper to wounds of small size, say one-eighth of an inch in diameter. This may be true in incised wounds, but it was not shown to exist in a single one of the several hundred perforations coming under my inspection as made by the bullet. The latter tears away and lacerates the parts through which it passes, and perhaps paralyzes the muscular fibers in its immediate neighborhood, but whatever the cause, there was no instance in which the eversion of the mucous membrane was sufficient to prevent extravasation.

Recognizing the very deleterious influence of this material upon the peritoneal membrane, this fact of the great certainty of extravasation adds another point to the argument in favor of abdominal section in these cases, as furnishing the only means by which this source of trouble can be absolutely eliminated.

As part of the extravasated material from the wounds of the intestine, it was an exceedingly common thing to find intestinal worms of all kinds, and in large numbers, protruding from the rents or free in the serous cavity.

In the treatment adopted during these experimentations, it was found necessary to make an extensive external incision, freely exposing the abdominal cavity, in order that all the viscera might be thoroughly and carefully examined, and every wound brought within reach. In a majority of instances the median line gave space enough, in two the bleeding vessels could not be reached without a lateral prolongation toward the flanks.

There was no reason to suppose that the extent of the incision added very much, if at all, to the gravity of the operation. After opening the abdomen, the intestines were all turned out, critically examined for perforation or contusion, the situation of these fixed, and the hæmorrhage therefrom controlled by means of the snap forceps, after which wounds of special organs were sought for. If the substance of the spleen or the kidney was found perforated, the organ was immediately removed after ligating its blood-vessels, the stump being returned to the abdomen. If slight lacerations only at some point on the surface had been produced, these were closed by bringing peritoneal surfaces of the organ over the wound by means of the continued suture.

The peritoneal sac was then carefully and thoroughly cleared of blood and other extraneous substances by repeated sponging or irrigation. The intestines, which during this process had been protected by being enveloped in towels wrung out of warm water, were now cleanly sponged, while all unwounded portions were returned to the abdomen.

It seems to be of little consequence whether or not the intestines be returned to the cavity in any definite order — in fact, it is doubtful whether they are ever returned precisely to the same positions they originally occupied before being disarranged during

the operation. Still, some care must be used in order to avoid the accident which happened in one experiment. After the divided ends of the intestine had been united, it was found that during the manipulation one of the ends had in some way been passed through an opening in the divided mesentery, so as to produce a figure of eight convolution in the tube. It was left in this shape. The animal recovered, and I have the specimen with me to demonstrate the perfectness and security of the union in the intestine at the place of reunion. The animal was sacrificed to secure the specimen six weeks after the operation. The abdominal cavity was quite free from evidences of inflammation, except where the misplaced folds lay in contact with each other. At this point slight peritoneal adhesion had formed between them.

Where several wounds occurred rather close together, severe enough to destroy a considerable portion of the integrity of the bowel, one resection was made to include all of them, even when the length of intestine removed measured ten inches or more. Where the points of injury were widely separated from each other and extensive damage done at each point, several resections of a length of the tube just sufficient to include the injured portions were made.

In the former case, in which several inches, or more, of the tube were taken away, the mesentery was ligated as close as practicable to the intestine (Fig. 3), in sections corresponding to the number of blood-vessels going through it to the resected portions. The mesentery was then divided close to the intestinal wall. After this, the tube itself was separated, and the wounded portion removed. One artery, always needing ligation, was found in the divided ends at the point of junction of the mesentery with the intestine. Before the final division of the intestine, its contents were pushed back out of the way, compression exercised upon its walls by a pair of forceps or a temporary ligature, in order to prevent extravasation of its contents through the divided ends. The mark of constriction made by the forceps or ligature, used to close the lumen of the bowel, was to be plainly seen several days after the operation. The safest compression can be made by an assistant's fingers. Results soon demonstrated the paramount necessity of carefully selecting the place for final division of the intestine, in order to avoid sloughing of the edges approximated together, the results being best in those cases where the division was made close to the point at which any given mesenteric artery approached nearest to the intestine, as compared with those where the cut was made in the intervals between any two branches of these vessels, and this was seemingly dependent on the better supply of blood belonging to the former cases. Immediately after division of the intestine, there followed an instantaneous, regular and considerable contraction of the caliber of the tube (Fig. 4, a), close up to the divided edge, caused by the action of the circular muscular fiber. The diameter was often diminished more than half by this contraction. This persisted for a time, but was soon followed by an eversion of the mucous membrane, which rolled out and over the constricted portion in a remarkable manner. (See Fig. 4, a, b and c.)

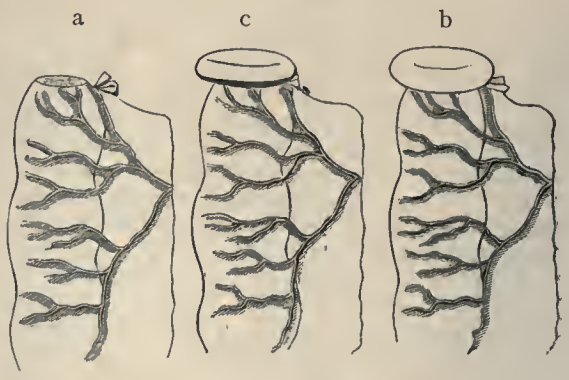

Figure 4.

This protrusion of the mucous membrane forms a serious obstacle to easy and close approximation of the ends of the bowel in the efforts to bring them together by sutures; and, when turned into the bowel during such procedure, diminishes its caliber considerably, although it was not demonstrated that the obstruction was ever sufficient to prevent the passage of the intestinal contents. Several efforts were made to get rid of it, and overcome the seeming delay caused by its presence, but all these were finally abandoned.

It was pared away with the scissors; it was dissected up from the other coats for a quarter inch from the edges, but the conclusion was finally reached that instead of being a harm, its presence was useful in giving support, protection, and perhaps vascularity to the freshly sutured edges; at least, in all instances where it was removed, the stitches were found torn out and union defeated; in no instance where it was left entire did there fail to be union in some part, and no sutures gave way when properly applied.

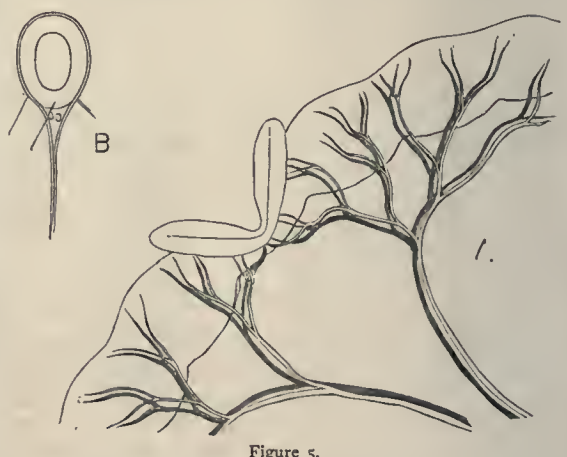

Figure 5.

In all instances where a perforation was severe enough to require a resection of the wounded part, it was found advantageous to leave, if possible, a strip of the bowel near the mesenteric junction (Fig. 5 A), taking out the wounded portion by means of a "V"-

shaped incision. The part left acted as a support to the wound, avoided division of the blood-vessels at this point, opposed the action of the longitudinal fibers, and in no instance in which this plan was adopted was there any appearance of separation of the wound or any displacement of stitches. In perforations through the stomach, the wound did well after drawing the peritoneal surfaces some distance from the edges thereof, over it, by means of the continued suture, thus converting it into a linear wound (Fig. 6 A). The same plan was adopted with success in abrasion and small perforations in the small intestines. (Fig. 6 B.)

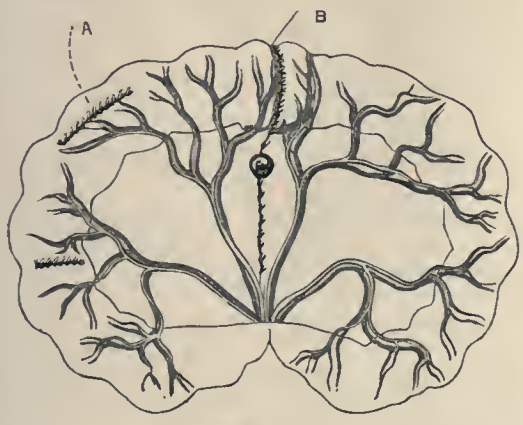

Figure 6.

This way of treating the bullet openings in the bowel is susceptible of much wider application than would appear possible at the first glance. I am quite well satisfied that it will safely take the place of excision in not a few cases of quite severe injury. The torn edges of the wound can be turned in, and peritoneal surfaces fastened together, even in large wounds, with perfect confidence in the result of safe and secure adhesion following.

It seems probable that by far the greater number of successful cases will follow a single resection, even if that include a number of perforations, and involves eight or ten inches of bowel, in comparison with those cases where several excisions are made of wounded portions widely separated.

Perforations passing through the mesenteric surface of the intestine were found the most difficult to treat, and even if slight, seemed always to require a complete excision. A partial excision of this surface of the bowel resulted in an acute-angled elbow which never did well.

The point of attachment of the mesentery with the bowel, will usually be found the most troublesome to manage, in applying the sutures in restoring a complete division. (Fig. 5, B.) It is quite difficult to so place the sutures as to secure a perfect reinversion of the mucous membrane, to bring serous surfaces fairly in contact with each other, and to get a sound junction. The difficulty arises apparently from the manner in which the folds of peritonæum separate from each other before passing on to invest the bowel, leaving a little triangular interval filled with loose connective tissues, fat and blood-vessels. Now, if the suture fails to include the muscular coats of the intestine as well as the peritonæum at this point, the junction will surely give way and extravasation result. To make this point secure, the greatest possible care must be taken in placing at least three sutures, this number being usually quite enough to include the troublesome area, and these should always be the first sutures applied. In placing the remaining sutures to complete the junction after placing the three sutures mentioned, at the mesenteric surface, it assists materially in the ease of application, saves time, and especially avoids trouble from the everted mucous membrane, to apply one at the most convex surface, and then one half way down, on each lateral surface. After this is done, the remainder can be introduced easily and rapidly. If introduced in a regular series, one after the other, all the way around, it is a very slow process; the mucous membrane is always in the way, the needle openings in the intestines are apt to be uneven, and it is altogether the poorest plan of proceeding. The advantages mentioned as gained, by taking the course suggested, are certainly all of them items of importance, and have some bearing on the result. At best, these procedures will be found very prolonged and tedious. The material used by me for sutures was silk and catgut — the latter for the continued, the former for the interrupted ligatures. No. 1 catgut; No. 2 silk. The needles were the full curved round needle, or ordinary straight sewing needle; the latter is the best. The sutures were introduced about the third of an inch from the divided edges, made to include the peritoneal and muscular coats, and brought out just free of the edge on one side, and were then reintroduced close to the edge, and made to include about the same amount and kind of tissue on the other side, being very sure not to allow the needle to pass into the intestinal cavity. Howse, of London, proved conclusively in his cases of gastrotomy, that the fact of entrance of the needle into the cavity of the tube, carrying the thread with it, made the difference between success and failure, cases dying from peritonitis and extravasation when the entry occurred, and recovery following when the thread included only the peritonæum and muscular coats.

Again, the everted tissue should be turned in before introducing the needle, so that it will pass through the rim of constriction. If entered too far away from the divided edge, too much tissue is turned into the intestine. When the mucous membrane was turned in, and the suture tightened, two broad surfaces of peritonæum were brought in contact. This you will recognize as Lembert's suture (Fig. 6, B), with one change. Lembert directs that only one and one-half line in width of tissue should be taken up by the suture. This amount of tissue will do very well in the closure of small slits, for which it was intended, and to which it was applied; but complete resection needs a much firmer hold to withstand the strain of peristaltic movements. *The fact is that it makes no difference whatever what kind of suture is used, so that the principle of positively securing the application of two broad surfaces of peritonæum in contact with each other is certainly carried out. Jobert's,*

Gely's and Czerny's double row of sutures were all given a fair trial, but none of them resulted as well as this. It never failed to be followed by good union when properly applied, with peritoneal surfaces brought together around the entire circumference of the intestine.

The greatest number of mishaps followed drawing the sutures too tightly, which, if done, leads to death of the applied edges, and, of course, to failure. They must be drawn only sufficiently close to bring the surfaces fairly in contact, the subsequent swelling from obstructed circulation will hold the surfaces firmly together until glued to each other by the rapidly forming adhesive material.

The interval left by the incurving of the edges of the bowel, immediately after the completion of the operation, was found entirely obliterated, and the sutures covered up by effused lymph at the end of twenty-four hours. In one or two instances where very small openings had been made in the bowel, they were occluded by passing a suture around the perforation, a short distance from its margin, pushing the wound into the cavity of the intestine, and then by tightening the suture the peritonæum was drawn together over it; a very satisfactory plan of procedure where circumstances will permit its application.

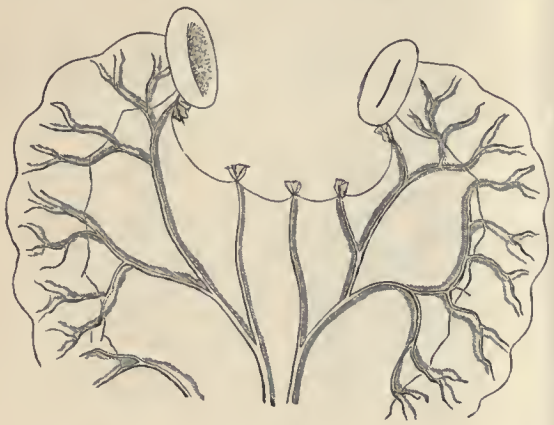

Figure 7.

The question of the proper disposition to be made of the divided mesentery, after removal of some length of the intestine, is an important one to decide. No plan adopted proved entirely satisfactory. Previous to separation it was ligated in sections (see Fig. 7); the part beyond ligature is apt to mortify and thus prove a focus for fatal inflammation. The tissue of the mesenteric membrane is not very vascular, and the vitality of the distal portion of the stump is seemingly best provided for by causing it to adhere to surrounding vascular parts.

In some cases the stumps were left free in the abdominal cavity; these all did badly, each showing mortification. In others the different sections were all included in one suture and then stitched to the bowel at the seat of operation, making as nearly as possible a continuous surface of mesentery.

These did much better, there being few instances of sloughing. When sloughing occurred, it seemed to be dependent upon and follow a too tightly fastened ligature. This method above mentioned of treating the divided mesentery, is useful in another way; it gives support to the bowel at the point of resection, maintains the intestine in proper position by preventing bending, and also leaves fewer raw surfaces free in the serous sac. This last, a condition acknowledged to be the frequent source of serious trouble from faulty adhesions to surrounding organs, and from furnishing points from which septic absorption takes place.

A plan of dividing and treating the intestine and mesentery has been suggested to me as a possible improvement on those already noticed. This is to make the separation through the intestinal walls three-eighths of an inch on either side of the mesenteric attachment, tear away the mucous lining of the retained strip of bowel, and draw the peritoneal surfaces thereof together by the continued stitch. This would avoid division of the blood-vessels going to the bowel, do away with the necessity of using ligatures, and leave no raw surfaces free in the abdominal cavity. The opening formed by the folding together where the bowel-ends are united, should be closed by the continued suture.

Bleeding from slight lacerations of the spleen, kidney or liver, can be controlled with actual cautery lightly applied, perhaps the very best method to adopt. If the wound is a complete perforation of the body of the organ, the hæmorrhage is very great, rendering extirpation of the entire organ apparently the only sure way of surmounting the difficulty.

Quite frequently the entire mass of the greater omentum seemed to require removal. The bullet in transit not only perforated it here and there, but passed along between its folds as well, leaving injured tissue and blood-clots of considerable size in its track. These clots disseminated themselves in the meshes in such a way as to entirely prevent their removal without tearing the tissue to shreds. When this condition was present in any degree the mass was amputated, after ligation, in sections. In a few instances these stumps gave rise to trouble, either from recurring hæmorrhage or mortification of the distal end.

In the after treatment it was often necessary to administer morphia to secure quiet. Very careful attention must be paid to the amount and kind of food given for some time after apparent recovery. One experiment resulted in failure after the lapse of three weeks from date of operation. The animal was lively, running about as freely as ever, all the functions normal, and the external wounds all healed, when it suddenly sickened and died, having tetanus accompanying rupture of the intestine, several inches above the seat of resection. Post-mortem examination showed masses of food and grit and greasy cloth, occluding the intestine, and distending it so enormously that rupture was produced; the tube at the seat of operation was patulous and nearly of usual size. This animal was lost solely through neglect in the matter of feeding. Milk alone was given in all other cases for some weeks after operation. Certainly this is a matter of great importance,

and suggestive of the proper care to be given after all such operations. Extreme emaciation occurs during the first week following the operation, and, if there is shown any likelihood of recovery, there follows a voracious appetite, which should be very sparingly gratified.

The circumstances under which these experiments were done, were such, that it was absolutely impossible to carry out full antiseptic appliances. The external incision was treated with iodoform and oakum or absorbent cotton, and with two exceptions healed by first intention.

The bullet wounds through the abdominal walls were not probed nor disturbed in any way. Occasionally, when large and much contused, iodoform was poured on them. In only two instances did they suppurate or give rise to any trouble whatever, crusting over and healing rapidly. This result clearly enforces the rule of not disturbing the track of a bullet through the soft parts, unless the most urgent reasons call for interference. The damage of a serious nature is not in the abdominal walls, but in the cavity; the nature of it can be better ascertained and the most satisfactory treatment adopted, after section through the linea alba, rather than by enlargement of the wound of exit or entrance, if any surgical interference be instituted.

In gunshot wounds of any part of the body, it is not the injured muscular tissue or fascia that causes grave concern, but the torn arterial trunk, or severed nerve, or fractured bone made by the missile, and here, too, incisions out of the course of the bullet track often furnish the best exposure of the parts for manipulation.

None of the wounds of entrance were perpendicular to the surface of the abdomen. All were more or less obliquely directed through the component tissues of the walls, so that they were valve-like in character and tended to close spontaneously. None of the cases presented any extravasation of the contents of the intestines through the external wounds, notwithstanding the lacerations of the tube were often very extensive, and considerable quantities of fæcal matter were found in the peritoneal sac. The conclusion naturally follows, that the discharge of such matters, through the external openings, is not of frequent occurrence after the wounds under consideration. The absence thereof is far from being proof of the non-occurrence of perforation of the intestine.

It can scarcely be expected that extravasation through the wounds in the abdomen will often happen as an immediate occurrence. This is most likely to occur, if present at all, several days after the injury, following adhesion of the bowel to surrounding parts, and the accumulation of considerable quantity of matter.

There is no reason to suppose that interference with the adhesions to be met with in operations, done some time after the injury, would be followed by any worse consequences than that which follows their disruption during the performance of operations for ovarian or other tumors. The hazard supposed to attend their severance is certainly exaggerated. With a clean cavity, they will do equally well in all cases.

These experiments have not developed any data which will aid in the positive diagnosis of the severity, or extent, or kind of injury done to the viscera, or render such diagnosis less difficult than heretofore, previous to abdominal section.

They go a step in advance of this by supporting the assertion that it is absolutely useless to expect immunity from perforations of the intestines when the bullet has traversed the cavity. It seems, and is infinitely more reasonable to subject a patient to the slight risk of an abdominal section, showing unwounded intestines, than to allow him to pass through the fearfully deadly peril of wounded intestines unrelieved, on the barren supposition that they may have escaped injury.

Some uncertainty as to its necessity is likely to arise, except in those cases showing extravasation of the contents of the bowels, or those where the free loss of blood, as indicated by the usual symptoms accompanying such accident, calls for aid. When doubt exists, and a critical condition of the patient argues severity of lesion, abdominal section surely seems to promise relief that can come in no other way. Exploratory incision of the abdominal walls has been done so often, and with so little hazard, as to entitle it to be classed as a procedure in itself almost destitute of danger. Such a conclusion is certainly supported by the results developed during these trials. The rule was, no trouble whatsoever from this incision.

No deduction can more justly or positively follow, as the result of these experiments, than that an incision *de novo*, through the linea alba, is the best method of procedure in the treatment of the class of wounds under consideration; a plan far preferable to enlarging either of the openings made by the bullet. It at once gives command over the entire cavity; therefore any lesion likely to result in harm is far less liable to be overlooked; it is the least vascular part of the walls; incisions thereof are more easily and perfectly co-aptated than elsewhere, heal readily and soundly, and as a consequence, the oncoming cicatrix is less likely to be followed by ventral herniæ.

Thirty-nine (39) animals were used in these experiments, exclusive of those dying from the effects of the anæsthetic. Two of the thirty-nine were used to demonstrate the effects of closure of the main branches of the mesenteric artery upon the nutrition of the intestines. Of the remaining thirty-seven (37), three cases died immediately after the shot or from the effects of profuse hæmorrhage; one having a division of the aorta just below the mesenteric artery; the second had a large laceration of the kidney, with a wound of the renal artery; the third, a laceration of both kidney and spleen. One case, No. 4, had tetanus three weeks after operation, and is given a special position, simply owing to the presence of this condition as a complication in the case. The post-mortem examination, as already mentioned, developed other conditions which would have caused death, and which were no doubt the cause of the tetanic

convulsions. Twelve of the remaining cases died inside of twenty-four hours, either from severe primary or recurring hæmorrhage, and the effects of the very extensive character of the wounds. Two out of this twelve (12) were cases requiring removal of the pregnant uterus, accompanied with many perforations of the bowel; death in both occurred from secondary hæmorrhage from uterine stumps—the ligature having slipped. Three (3) more had slight lacerations of the spleen and numerous perforations of the intestine. The spleen was removed and several inches of the tube excised in each case. In three (3) others, from twelve to twenty inches of the bowel was excised, and many arterial trunks severed. One of the twelve (12) had rapid mortification of five or six inches of the entire caliber of the bowel, apparently dependent upon the division of two large mesenteric arteries by the bullet, and also the resection of six inches of the intestine. The remaining three (3) of the number dying inside of twenty-four hours, are classified as having died of shock. On all of them the damage done by the missile was of excessive severity. The bullet was of large size, (38 or 44 caliber) and the fire-arms possessing great penetrating and lacerating power. There was not manifested in any case any recognizable evidence of shock aside from that following great loss of blood. The transit of the bullet made no noticeable impressions upon the pulse or respiration. In every instance where signs of severe prostration became manifest, through change in respiration or weakening of pulse, there was found profuse hæmorrhage to account for such condition. I am inclined to infer that the cases are exceptional indeed, in which purely nervous shock will give rise to symptoms severe enough to mislead one to perform an unnecessary ventral section; rather, when severe constitutional manifestations follow the passage of a bullet through the abdominal cavity, good cause for them will be found, as soon as the cavity is opened, in wounded viscera or blood-vessels, and this course will often be the only possible way of either actually saving life or even prolonging it. None of these twelve cases could possibly have lived longer than twenty-four hours after the injury received. Most of them would have died much sooner without the control of hæmorrhage, alone made possible by the opening.

Two cases of the series were subjected to the expectant treatment. These cases were chosen because their injuries did not seem very severe; the hæmorrhage was not great, and the prostration not extreme. Both died; the first in one day; the other lived five days. Post-mortem examination showed extensive extravasation of the contents of the bowel and septic peritonitis.

In one case an attempt was made to establish an artificial anus. The wounded intestine was resected, and the ends fastened to the edges of the abdominal incision. The animal died of septic peritonitis in three days. This trial was made early in the experimentation, before any definite plan of procedure had been settled upon. This is the only experiment that has given rise to any regret, for I feel satisfied that, with a fair junction of the bowel and a clean abdomen, the animal would have been saved.

Eighteen of the thirty-seven (37) have thus far been accounted for; of the remaining nineteen (19) ten (10) died, and nine (9) recovered.

The ten fatal cases lived from three days to three weeks. Peritonitis from one cause or another seemed to be the precursor of death. In six of them, mortification of the ligated stumps of the divided mesentery, together with mortification of the edges of the recently united bowel, were present. In the one that lived three weeks, death was the result of intestinal obstruction, caused by the adhesion of a fold of the intestine to the stump of mesentery left free in the cavity. An acute flexure was produced at the point, against which the contents of the bowel had accumulated in large quantity. A rupture was found above this mass, through which extravasation had taken place. The inflammation was so intense that everything was matted together, and the specimen so horribly offensive it could not be preserved. There was no separation at the point of operation on the bowel; it was thicker here than elsewhere; but full distension with water was allowed without leaking. All of these cases demonstrate conclusively the necessity of great care in the manner of dealing with the divided mesentery, and in the application of the sutures which bring the separated bowel-ends together. The remaining four furnished evidence of separation of the recently united parts of the intestine at the mesenteric junction. In all of them the thread failed to include the muscular and fibrous coat of the bowel, holding only the peritonæum. The result was extravasation, and death followed.

It may be a matter of surprise to you that the percentage of successful cases presented is so small—nine out of nineteen—so few out of so many. To me, knowing well the extremely adverse circumstances under which these experiments were performed, it is a matter of astonishment to have so many recoveries included in so few cases. It is suggestive to remember that all the recoveries followed the use of Lembert's method of bringing the peritoneal surfaces together, while in many of the failures, trials were made of other methods. Full six weeks have gone since the last case followed by recovery was subjected to operation. The first favorable case was treated four months ago. None of the animals present evidence of being other than in their usual health. The longest resection of intestine among the recoveries measured over six (6) inches and included four (4) perforations.

It is scarcely possible to do work of any kind under more disadvantageous surroundings than accompanied the performance of these experiments. The operative work was carried on, and the animals kept in the prosector's room of a medical college during the winter season, in the midst of the odds and ends and bad hygienic conditions of such a place. No better accommodations could be secured. The labor has been purely one of experimental inquiry, and not a striving after recoveries, implying a choice selection of attending circumstances and special preparations to that end; therefore I judge it proper

and fair to claim the results as satisfactory. These results certainly indicate that a better showing is likely to follow where more satisfactory control can be had over both patients and surroundings, than was present during these examinations.

They clearly demonstrate that a hopeful expectation of recovery may be entertained after operation, and suggest the nature of the injuries produced, what accident to avoid, and what treatment to adopt.

My confidence in coming before you with no better record is assured, when I remember that all of you are well aware of the great mortality of these injuries, under all circumstances. It must be large, surely, when Dr. Otis, in the surgical history of the war, says the authenticated cases of recovery can be counted on the fingers of one hand. It can not be said that operative interference in these cases has as yet an established position. Still, perhaps Dr. J. Marion Sims looked with prophetic eyes upon the future, when he closed the article already referred to with the following words: "I have the deepest conviction that there is no more danger of a man's dying of a gunshot or other wound of the peritoneal cavity, properly treated, than there is of a woman's dying of an ovariotomy properly performed. Ovarian tumors were invariably fatal till McDowel demonstrated the manner of cure, which has now reached such perfection that we cure from 90 to 97 per cent. of all cases. And by the application of the same rules that guide us in ovariotomy to the treatment of shot wounds penetrating the abdominal cavity, there is every certainty of attaining the same success in these that we now boast of in ovariotomy."—*British Medical Journal*, March 4, 1882.

In a rather quaintly-written but richly-laden book on surgery, by Herr L. Heister, Professor, etc., written in 1739, there occurs this passage:

"When the intestines are wounded but not let out of the abdomen, and therefore their wounds are out of reach, the surgeon can do nothing but keep a tent in the external wound, according to the rules laid down at chap. V, and after this bleed the patient if his strength will admit of it, advising him to rest, eat abstemiously, and to lie upon his belly; the rest is to be left to Divine Providence and the strength of his constitution. But the question may be asked here whether a surgeon may not very prudently, in this case, enlarge the wound of the abdomen, that he may be able to discover the injured intestine and treat it in a proper manner. Truly I can see no objection to this practice, especially if we consider that upon the neglect of it certain death will follow, and that we are encouraged to make trial of it by the successes of others. Sacherus, in Programmate Publico, Lipsiæ, ed. 1720, mentions a surgeon who performed this operation successfully."

A period of 100 years and more has rolled away since Dr. Heister published his belief and reported recovery, to the time when Dr. Sims expresses his convictions—over a century of doubts, timidity, uncertainty, and gloomy misgivings, lightened only occasionally by some bold and resolute assertions. The future asks for action, and it is not unreasonable to assert that careful trials will accomplish successful results.

Avoiding any spirit of dictation, it seems proper to tabulate the following conclusions as an outgrowth of the experiments:

1st. Hæmorrhage following shot wounds of the abdomen and the intestines, is very often so severe that it cannot be safely controlled without abdominal section; it is *always* sufficient in amount to endanger life by secondary septic decomposition, which cannot be avoided in any other way than by the same treatment.

2nd. Extravasations of the contents of the bowel after shot injuries thereof are as certain as the existence of the wound.

3rd. No reliable inference as to the course of a bullet can be made from the position of the wounds of entrance and exit.

4th. The wounds of entrance and exit of the bullet *should not be disturbed* in any manner, except to control bleeding or remove foreign bodies when present. They need only to be covered by the general antiseptic dressing applied to the abdomen.

5th. Several perforations of the intestines close together require a single resection, including all the openings. Wounds destroying the mesenteric surface of the bowel always require resection.

6th. The best means of uniting the wounded intestine after resection is by the use of fine silk thread after Lembert's method. It must include at least one-third of an inch of bowel tissue, passing through only the peritoneal and muscular coats, never including the mucous coat. The everted mucous membrane must be carefully inverted, and needs no other treatment.

7th. Wounds of the stomach, small perforations, and abrasions of the intestine, can be safely trusted to the continued catgut suture.

8th. Every bleeding point must be ligated or cauterized, and especial care devoted to securing an absolutely clean cavity.

9th. The best method of treating the stumps of divided mesentery is to save the mesenteric surface of the bowel as above indicated.

10th. *Primary abdominal section* in the mid-line gives the best command over the damage done, and furnishes the most feasible opening through which the proper surgical treatment of such damage can be instituted. Farther, its adoption adds but little, if anything, to the peril of the injury.

11th. Is not the moral effect of the assurance to the patient, that he will be placed in a condition most likely to lead to his recovery, a good substitute for the mental depression accompanying the general and popular conviction that these wounds mean certain death?

EXPERIMENTS ON GUN-SHOT WOUNDS OF THE ABDOMINAL CAVITY.

Appended to Dr. Parkes' Address.

EXPERIMENT No. 1.

Wednesday, November 14, 1883.—Long, lean and lank setter; about 30 lbs.; in rather poor condition. Etherized with common ether and shot through abdomen with a No. 32 cal. ball, which passed directly through anterior wall to the innominate bones. Upon opening abdomen found ileum perforated about the middle and at the ileo-cæcal valve, and slightly grazed at another point. Extravasation of intestinal contents at each perforation. Some entozoa. The two perforated regions were resected and continuity of ileum re-established by Lembert's intestinal stitch. The grazed portion was closed by continued suture. Intestines washed with a feeble solution of carbolic acid, and returned to abdomen; and the external wound closed by two sets of sutures, one set through muscular walls, including peritoneum, and the other uniting the skin. Drainage tube inserted, and wound dressed antiseptically with gauze, cotton, etc.

Entire operation lasted about one hour, and conducted antiseptically, abdomen being shaved, washed and irrigated with carbolized solution, etc. The animal waked considerably shocked. Gave rectal injection of alcohol and water (1-2 1-2) about 3 drachms, and in half an hour gave 10 drops of laudanum. The dog seemed very bright. At 6 P. M. was considerably weakened; respiration very rapid, with much febrile excitement. About three-quarters of a pint of warm milk per stomach-tube, twelve drops of laudanum, and about a quarter-grain of morphia hypodermically. Tied him under register well bedded in a large comforter, and covered him with a coat.

Thursday, November 15.—Dog died between midnight and morning. Post-mortem. Abdomen filled with bloody serum and intestines inflamed and badly smelling; kidneys a bright blue, and rectum filled with hardened fæces. Dog had vomited during the night a quantity of hair and some pieces of cartilage, etc. Died of shock. Wounds of intestine well agglutinated.

EXPERIMENT No. 2.

Friday, November 16.—The ball (32) severed the aorta.

EXPERIMENT No. 3.

Saturday, November 17.—(Ball 32 Cal.) Dog etherized, shaved and shot very near abdominal margin. Upon opening abdomen (incision 3½ inch), but one loop of gut was found perforated. This was excised, and the continuity of intestine restored by eighteen individual silk stitches, which brought serous surface to serous surface, the greatest difficulty being encountered at the mesenteric attachment to the gut on account of the fat which lay between the two layers of peritonæum and adherent to the gut itself. Extravasation of intestinal contents. Tape worm.

Wound closed with heavy silk and dressed antiseptically. Gave 15 gtt. laudanum at night.

November 18.—Animal seems bright, but disposed to remain quiet, drinks plenty of water and urinates freely. Respiration hurried and febrile action high.

November 19.—Seemed very well, and partook of some milk during morning, but began vomiting in the P. M. a sour, watery and greenish fluid. Gave per rectum about ¼ grain morph. sulph. at night, and left him sleeping comfortably.

November 20.—Seemed quite lively and comfortable, the dressings having been removed the day before and a large body bandage applied. About 11 A. M. seemed rather tired, and vomited large quantities of the same sour fluid as before; would not eat meat or drink milk, but drank water freely. Gave about ⅜ grain morph. sulph. hypodermically, and during the P. M. he seemed extremely sleepy and much disposed to lie down flat, but is nervous and easily alarmed by sudden noises, etc., etc. This condition lasted all day, and suppose it is the effect of the morph.

November 21.—Died during night. Post-mortem showed a separation of the resection which had evidently first torn out at the mesentéric attachment. Extensive peritonitis, intestines being agglutinated together and abdomen filled with fluid blood and fæces.

EXPERIMENT No. 4.

November 23.—(Ball cal. 32.) Very large dog, weight about seventy-five pounds. Upon opening abdomen found a section of intestine for about six inches perforated in several places, the ball apparently having skipped along inside of the gut; at another place the free edge was shot off and other portions of the ileum grazed three times. The middle section was resected entirely, and closed perfectly; the shot edge was closed by trimming edge or side of the tube of intestine by a "V"-shaped cut towards the mesenteric attachment, and that also was closed fairly well. This was close to the left end of the pancreas. Each opening showed extrusion of contents. Many worms.

The operation lasted two hours, abdominal wound closed by two sets of sutures, one set through the muscular walls, the other bringing the skin in contact. Wound was covered with cotton and bandage applied. Gave 20 gtt. deod. tincture opium and a little water. Seemed to be doing well all P. M., and at night at six o'clock gave about twenty gtt. more of the opium, and left some water where he could get it.

November 24.—Dog still alive and very thirsty, but vomits the water soon after drinking; gave another dose of opium at night.

November 25.—Bandages have not been changed.

November 26.—Changed dressings; dog seems bright. Gave pint of milk; also opium, which he drank readily, but soon vomited. Gave more milk about noon, which he retained... In the afternoon he seemed much weaker. Gave deod. tincture of opium gtt. 20 at night.

Still lives, but is not strong. Lies in any position in which placed and seems quite prostrated. Opium as before seems to revive him; he refuses milk, but

drinks freely of water, which the stomach promptly rejects. In the afternoon, being no better, removed dressings, and although wound was quite healed made an opening for a medium-sized drainage-tube and let out about a quart of bloody serum; re-dressed the wound after injecting a weak carbolized solution of warm water into abdomen through tube. Gave a rectal injection of alcohol and water (1–2 1–2) warm and gtt. 20 of opium. Is getting very poor, but respiration is regular; pulse very weak and rapid.

November 28.—Gave enema of soapy water very weak. Washed out wound and inserted short drainage-tube and fresh bandages. About eleven o'clock had a passage from bowels of a large quantity of black, tarry, and badly smelling fæces, result of injection per rectum. At 2 p. m. was very weak. Gave enema of whisky and milk, warm, about 2 oz., and made a stew of small bits of beef and milk in whisky, which he ate greedily. Gave milk and whisky per rectum every three hours, also Valentine's extract of meat.

November 29.—Seems much stronger; had a semi-liquid passage from bowels. Gave enema every four hours of Valentine's extract, milk and whisky; and also fed pieces of raw meat in milk.

November 30.—Steady improvement; another passage which evidently came from above seat of operation. Fed him on raw steak, and gave whisky per rectum every four hours. Sutures through integument have ulcerated their way out; were removed and dog allowed to lick his wound, as he promptly tears off all bandages.

December 1.—Feeding as before, with steady improvement.

December 2.—Another passage from bowels during night. Gave meat, about one-half pound every three hours, which he eats greedily; marked improvement daily in strength and appearance.

December 3.—Same improvement.

December 4.—Sent dog down stairs in basement.

December 10.—Alive and apparently in perfect health. External wound closed completely.

December 11.—Seems sick; refuses to eat; howls at night.

December 12. Has marked symptoms of tetanus, and is in a state of rigidity with episthotonos.

December 13.—Died, and post-mortem showed an obstruction of intestine by a large mass of meat or a collection of various substances of a gritty consistency which completely obstructed and occluded bowels for some distance. The bowel was opened above this, and abdominal cavity filled with intestinal contents, and organs all adhered, as result of peritonitis; resection wound quite strongly united. Dog died from careless feeding and obstruction following adhesion of knuckle of intestine to omental stump.

Experiment No. 5.

Monday, November 26.—(Ball cal. 32). Medium-sized, well-conditioned and sturdy dog. Shot passed through a six-inch piece of intestine, making several perforations. Much fæcal matter free in abdomen, some opposite each opening. Many tapeworms.

November 27.—Made a resection of but one piece six inches in length, including both wounds. In this instance the larger silk sutures were used. After the continuity of the intestine was restored there was a great deal of bleeding from the interior of the abdomen, the origin of which could not find, but allowing the air to reach into all parts of the abdominal cavity, it ceased after considerable loss of blood. A portion of the omentum being filled with blood, it was ligated and removed. In closing abdominal wound was obliged to tear away a certain amount of fat which was closely adherent to interior wall of abdomen, along the line of the wound, in order to introduce sutures so they would not include the fatty mass. Introduced two drainage-tubes, and applied large pad of cotton. Gave some opium, about gtt. 15. P. M. dog seemed considerably shocked, but was quite thirsty. At night gave more opium.

November 17.—Cotton was soaked with fluid from drain-tubes. Removed dressings, and, upon getting him upon his feet, a small quantity of fluid escaped. In the evening washed out the abdomen with a warm solution of carbolic acid, about ½, and applied dressing of gauze. During the day he vomited considerable milk and water which he had drank, and was evidently very weak. Gave about gtt. 20 of opium at night. Died at 8 A. M. on November 28. Post-mortem showed that sutures had parted at mesenteric edge, and death was from peritonitis. Mortification of edges of resection.

Experiment No. 6.

December 5.—(Ball cal. 32). Died of hæmorrhage, after being shot from wound of renal arteries, the ball perforating one kidney. Several perforations of the small intestines, all of them showing extrusion of contents. One large, round worm free in cavity.

Experiment No. 7.

December 7.—Died under ether.

Experiment No. 8.

December 7.—(Ball cal. No. 32). Ball opened one of the mesenteric arteries, and after resecting three pieces of intestine, and closing wound nicely (every perforation showed fæcal matter, worms, etc.), she died in less than nine hours from the shock. Great loss of blood; died of loss.

Experiment No. 9.

December 10.—(Ball cal. 32). Gave morphine hypodermically at 9 A. M. Medium-sized female dog. Anæsthetized at 9 A. M., and shot at 9.30, first shot simply going through abdominal walls, second shot higher up and perforating spleen. Operation began at 10.15. Found abdomen full of blood, fæcal matter, and some worms. Removed spleen and large mass of omentum; ligated and removed one piece; resected about three inches in length, perforated in two places. Much hæmorrhage; operation concluded at twelve. Gave opium and whisky; much shocked. Died.

EXPERIMENT NO. 10.

A well-nourished bull-dog (female), about twenty-five pounds in weight. Was anæsthetized about 9.15 A.M., and then shaved over the abdomen. Was shot at 9.45 by a 32-100 caliber revolver just posterior to the umbilicus, the bullet entering on the right side about three inches from the median line, the point of exit being in the corresponding situation on the opposite side. On opening abdomen found animal pregnant. There was one wound through the right cornu of the uterus, rupturing the membranes of one fœtal dog, and allowing the escape of the amniotic fluid into the peritoneal cavity. One of the smaller mesenteric arterial branches was cut, and the small intestine perforated in one place. The abdomen contained considerable blood on opening immediately after the shot, and there was slight extravasation of fæcal matter from the gut at openings. The vagina and uterine ligaments were ligated by single carbolized silk ligatures, and the large gravid uterus removed. The hæmorrhage in the mesentery having been checked, the wound in the intestine was resected, about two inches being removed. The free ends were united with the interrupted silk ligature. The peritoneal cavity was sponged out and washed with slightly carbolized warm water. The external wound was united with about ten silk ligatures, and dressed with iodoform and gauze, the whole being covered with oakum and bandaged. About half a grain of morphia was administered hypodermically; and at twelve the dog was allowed to come from the influence of ether. She showed marked symptoms of shock, but rallied in the afternoon. She died in the night. Post-mortem revealed hæmorrhage from the uterine stumps, and some peritonitis commencing.

EXPERIMENT NO. 11.

A full-grown, healthy-appearing dog. Etherized at 9.30 A. M. Abdomen shaved and cleansed. Was shot at 10 A. M., still under the influence of ether, the bullet from a 32 S. & W. revolver passing transversely through the lower part of abdomen. Was placed on table and kept partially anæsthetized until 10.45. The animal then presented signs of extreme loss of blood, feeble respiration and heart action, cold extremities, pallid gums, etc. Abdomen was opened by large crucial incision and found to be filled with blood. Bleeding was ascertained to come from a divided mesenteric artery, and was readily checked by ligature. Clots were turned out, and two wounds of small intestine found. But slight extravasation of contents of bowel into the cavity, still some matter and worms found at openings. The intestine was resected at the site of each wound, about three inches being removed in each place. The cut ends of each were then united by about twelve interrupted silk sutures, so placed as to bring peritoneal surfaces in apposition. Intestines were then returned to their place, the cavity sponged out, and the external wound closed tightly with silk sutures. This was finished at twelve o'clock, the dog appearing moribund at its close, and remaining in a condition of collapse for about three hours. Reaction then took place, and he was able to stand and walk about. Second day took some milk, which was vomited at once. This was repeated at intervals during second and third days. Dressings were changed on third day. No discharge from wound. On fourth day vomiting was increased, and was fæcal in character. Dog too weak to stand. Dressings changed again and wound found to be discharging purulent fluid. Died at 4 P. M. on fourth day. Post-mortem showed sero-purulent exudation in abdominal cavity, intestines glued together by adhesive lymph, wounds uniting well, and occlusion of the bowel in the neighbourhood of one of them, from its having been sharply folded upon itself and bound in the position by the inflammatory exudate.

EXPERIMENT NO. 12.

December 27, 1883.—The bullet, 32 cal., entered the abdomen on a line corresponding to the junction of the anterior and lateral surfaces of the abdomen, just in front of the hind leg, its point of exit on the other side being on the same line a little above the umbilicus.

On opening the abdomen it was found that the lower part of the jejunum was cut in two places within two inches of each other, and that there was considerable blood in the peritoneal cavity from these cut surfaces, there being no mesenteric vessels cut; also fæces and worms.

Both wounds were included in the part excised, and the cut ends of the intestine were fastened together by three sutures, and then stitched to the abdominal parieties, thus forming an artificial anus.

Considerable shock was experienced, and owing to a desire to hasten the operation, the peritoneal cavity was not as carefully sponged as it should have been.

The dressing consisted of iodoform, protective and oakum. Of tinct. opii. deod. gtts. 20 were given by the mouth. The operation lasted two hours. On the following day he took a little nourishment; there was no tenderness, but some pus was squeezed from the point of exit of the bullet, the dog lying on that side.

Next day about one-half ounce of pus was forced from the point of exit of the bullet, the dog lying on that side, and by turning him onto the other side an equal amount was obtained from the point of entrance, but there was no suppuration from the wounds themselves.

He took a little nourishment and seemed to be in good condition, respiration being normal and pulse regular. He had a free urination from the bladder, and soft stools were passed from the artificial opening. He died during the night. Post-mortem revealed a large amount of septic material in the peritoneal cavity.

EXPERIMENT NO. 13.

Saturday, December 29.—(Ball caliber 32.) Medium-sized, middle-aged female dog. Gave with the anæsthetic about $\frac{3}{8}$ grain of morphia hypodermically after shot. Abdomen found full of blood; seat of hæmorrhage found at one of the points of perforation, of which there were two; from these issued fæcal matter, gas and worms; a medium-sized mesenteric artery having been shot off. All the intestines were drawn out of abdomen for examination,

and it was found necessary to resect two portions which were a considerable distance apart, both places closing neatly and perfectly. Abdomen washed out and external wound closed by one set of sutures and a large pad of oakum laid over and held in place by roller first, and over all a many-tailed bandage. Gave 25 gtt. laudanum.

December 30.—Dog got loose during night and was running around very briskly; room very cold and disagreeable. (On the afternoon of the day of operation some person had opened the doors and windows and exposed the animal to a strong, cold draft for about two and one-half hours.) In the evening gave hypodermically morphine, when she vomited for first time and seemed very weak.

December 31.—Seemed lively and well all day; gave milk, which she would drink but could not retain. About noon gave an enema of Valentine's extract, and in the evening left a pan of milk.

January 1, 1884.—She seems as well as ever, but the floor of the room was profusely decorated with vomit. The milk was all gone. Gave an equivalent of an ounce of whisky, of alcohol and water per rectum, and left a supply of water, as she seemed very thirsty. Bandages changed for the first time since the operation. There had been but little discharge and the wound was in good condition. Applied a large pad of oakum and a wide roller as before.

January 2.—Seems quite exhausted. Gave alcohol and water (1-2 1-2) per rectum about four or five times a day in quantities of about 1 ounce; has a diarrhœa and vomits.

January 3.—Diarrhœa continues, but no vomiting. Has some appetite, and gave raw meat (steak) chopped fine, every two or three hours; also fresh milk, which she drinks readily.

January 4.—Seems quite well, and hungry; fed regularly and removed all dressings; wound in good condition. Removed all stiches and did not apply dressing again. Appetite good.

January 5.—Dog is seemingly well; has a voracious appetite. Much wasted in flesh, but appears strong.

January 6, 7, 8.—Fed her upon milk; also meat chopped fine and raw.

January 9.—She seemed well enough to be sent down cellar, where she continues gaining strength and flesh.

January 15.—Is perfectly well. Recovery.

Experiment No. 14.

January 9, 1884.—This dog was allowed some milk a short time previous to the operation, hence his stomach was distended.

The first bullet (32 calibre) grazed the abdomen walls, not entering the peritoneal cavity.

The second entered on a line corresponding to the junction of the anterior and lateral surfaces of the abdomen, a short distance in front of the hind leg, coming out a little nearer the median line, and two inches nearer the front leg.

On opening the abdomen it was found there was some hæmorrhage, mucus and particles of food in its cavity and on surface of stomach, and that the lower part of the stomach was wounded, the point of exit being two inches from the point of entrance, passing through the whole thickness of the stomach. There was no wound of the gut. The peritoneal surfaces were drawn together with cat-gut, by inverting the edges and using the continued suture.

Great care was taken in the *toilet de peritonie*. Immediately after closing the external wound he vomited half a pint of blood, mucus and milk. Time of operation was one hour and a half. Then he was given tincture of opii deod. gtts. xx.

The wound was dressed with iodoform, protective and oakum.

On the tenth was given nothing except a little water. On the eleventh he was given a little milk, which caused some disturbance. On the sixteenth the stitches were removed and no dressing applied, there being but slight discharge from the wound made by the incision and none from the bullet wounds. Recovered.

Experiment No. 15.

Small dog, female, was anæsthetized and shot at 10:30 a. m. (S. & W. revolver, 32 calibre.) First wound passed through abdominal muscles only. Shot again immediately, bullet this time passing transversely through middle of abdomen. Opening made at once by linear incision. But little blood in cavity. All bleeding stopped upon exposure of intestines to air. Five wounds of small intestine found, all showing extravasation of contents. Two resections of five inches each were made to include all wounds. Cut ends were united by a continued cat-gut suture in each place. Intestines returned and abdominal incision united by silk sutures, after thoroughly washing out cavity by 2 per cent. solution of carbolic acid. The operation was finished at 10:30 a. m. Dog was laid in a warm place, apparently suffering but little from shock. External wound dressed with iodoform, covered by protective carbolized gauze, tow, and a bandage. Animal died in about twenty hours. Was not given any food or medicine in that time. Post-mortem showed some small blood-clots about the wounds in the intestine. No serum or other fluids in cavity, and no signs of peritonitis. Death from shock.

Experiment No. 16.

A dog of uncertain breed, about 20 pounds in weight, was shaved over the abdomen and anæsthetized at 10 a. m. Was shot in the abdomen in front of umbilicus, the bullet entering on the right side and coming out on the same side about two inches nearer the median line, not entering the abdominal cavity or wounding the peritonæum. Was shot again, the bullet entering on the right side, external and posterior to the first, and coming out on the opposite side, about two inches from median line. The calibre of the revolver was 32-100. Upon opening the abdominal cavity the peritonæum was found to be plowed across between the wounds of entrance and exit, and the spleen to be slightly nicked, the bullet having skirted the abdominal walls. The only hæmorrhage was from the external wounds and the spleen and track of bullet. The spleen was removed, its

peritoneal connections being ligated by five silk ligatures. The small intestine was resected, about four inches being removed. The abdominal cavity was washed with warm carbolized water. The external wound was sewed up by about ten sutures. The dog came from under the influence of ether at 11:30 A.M. The wound was dressed externally with iodoform and oakum, and fifteen drops of deodorized tr. of opium administered by the mouth. A curious phenomenon was observed upon cutting out the spleen. The stomach and intestine became distended enormously with gas, extruding from the abdominal cavity and covering a large area of the operating-table. They were with difficulty returned with steady pressure. The dog died in the night from shock and hæmorrhages from splenic stumps.

EXPERIMENT No. 17.

January 23.—(Ball cal. 32.) Good-sized coach dog. Bullet passed through abdominal walls without wounding intestines and just entering the peritoneal cavity, as was found after opening abdomen, the point of entrance and exit being on either side of the middle line and five inches apart. Removed the major portion of the greater omentum and also resected about six inches of the ileum and closed the wound by five sutures, the external wound being but two inches long.

January 24.—Seems inclined to be quiet all day; had defecated during the night and urinated very little; drinks but little water, and does not vomit it. Is by nature a very frisky dog, and do not think his extreme quiet very favorable.

January 25.—Seems quiet; no bloating of abdomen; removed bandages; re-applied dressings. Refused milk all day; also water.

January 26.—Gave small quantity of milk in the afternoon; re-applied the dressings which had been removed the day before; found the bullet-wounds much puffed up, and that the stitches had slipped in two places, leaving a hole opening into abdomen large enough to admit little finger. The portion of intestine viewed through opening in external wound looked red and inflamed, but not badly so; little running from the wound. Filled it with iodoform and applied pad of oakum.

January 27.—Gave about one-half pound of meat and a quart of milk; seemed to be ready to get well.

January 28.—Fed meat and milk during day, and he seems to be rapidly getting well.

January 29.—Wound gaping, but discharged him to the cellar. Recovered.

EXPERIMENT No. 18.

January 25, 1884.—This dog, a black and tan bitch, having been shaved the day before, was anæsthetized and shot.

The bullet, 32 caliber, passed directly through the abdomen about its middle, piercing the gravid uterus in two places, and cutting the gut longitudinally. No large vessels were cut. The uterine attachments were ligated *en masse* and the uterus removed. Contents of bowel found at site of wound in intestine.

During the time that an excision of the gut was being made, a profuse hæmorrhage occurred from the uterine stumps, before they could again be ligated by passing a suture through and ligating one-half at a time, the animal was almost exhausted from hæmorrhage.

The excision of the gut was then completed, and the cut ends stitched together with silk. The peritoneal cavity was then thoroughly washed out with slightly carbolized warm water, and the external wound closed. The dressing consisted of iodoform, gauze and oakum.

Of tinct. opii. deod., gtts. xx were given. Death occurred within ten hours after the operation, from effects of the hæmorrhage.

EXPERIMENT No. 19.

Dog was full-grown and apparently healthy. When the abdomen was exposed by shaving, two small abscesses, each the size of a filbert, superficially seated and non-inflammatory, were discovered. They were not disturbed. The animal was anæsthetized at 8:30 A. M., and at once shot through the middle of abdomen with a 44 caliber revolver. The dog was placed upon the table, and a linear incision of about three inches made in the median line. It was there found that the ball had glanced upon the abdominal muscles, and instead of going through the mass of small intestines, had been deflected so that it just entered the peritoneal cavity beneath the linea alba, traversed the cavity for about an inch, producing a contused wound of a fold of intestines, and then entered the abdominal parietes to make its exit opposite the wound of entrance, about two inches from the linea alba. Only a small amount of blood was found in cavity. Although none of the intestines were wounded, a resection of about two inches from the middle of the ileum was made. The divided ends were united by about a dozen interrupted silk sutures. The cavity was washed thoroughly with a 1 per cent. sol. of carbolic acid, the intestines returned, and stitches were being placed in external wound, when the abdominal cavity was found to be filling with blood. Source of the hæmorrhage was found to be a branch of mesenteric artery at the site of the resection, which had commenced to bleed as soon as circulation was restored by warmth of abdomen. A ligature was applied, the intestine returned and the cavity again thoroughly washed out. The external wound was now closed by silk sutures, the wound dusted with iodoform, and dressed by applying a few thicknesses of carb. gauze, covering this with a mass of tow and a bandage over all. Animal appeared to suffer but little from shock. On morning of second day was given ¼ grains morphia with 1-100th grain atropia by the mouth.

On third day appeared greatly prostrated, vomited at intervals, and a muco-purulent discharge was noticed coming from nostrils and eyes. Vomiting ceased on fourth day. Prostration and evidence of fever kept up to the morning of fifth day, when improvement began. Discharge from nostrils continued about ten days. On the fourth day a small quantity of milk was taken and retained. Loose discharge from bowels on fifth day, slightly colored with blood. A rectal injection of alcohol; water was

given on the sixth day. Dressings changed for the first time on sixth day. Wound appeared healthy and united in its deeper portions. Some pus from superficial part of wound from this time on, the dog ate milk regularly, and had regular and normal passages from bowels. On ninth day sutures were removed from external wound, which had entirely closed. On the thirteenth day, February 10, 1884, dog is apparently perfectly well; has been eating regularly of raw beef, and has begun to gain in flesh. On the evening of thirteenth day dog was well. Recovery.

EXPERIMENT NO. 20.

February 2.—(Ball cal. 32). Died from ether before any incision was made.

EXPERIMENT NO. 21.

A strong black dog, about 20 lbs., was shaved over the abdomen and then etherized at 9.15 A. M. Was shot with a 38-100 caliber revolver through the abdomen about opposite the umbilicus; and five inches to the right of the median line, the point of exit being in a corresponding situation on the opposite side. Upon opening the abdominal cavity such a large amount of blood was found that it was necessary to enlarge the incision by a cross cut. A large mesenteric artery was found to be cut and was ligated. Another smaller one was treated in the same way. There were two wounds in the small intestine close together, about six inches intervening between them. Extravasation of contents from both. One was perforating and the other nicking the gut on the mesenteric side. Eight inches were removed, and the free extremities of the intestine united by interrupted silk sutures. There were three other wounds nicking the intestine which were sewed in the same manner without resection. The end of the cæcum, which is peculiarly shaped in dogs, was shot off. Stained mucus and some shreds at the opening. This was sewed, turning the cut end in. The spleen was cut in one place, which was left with one deeply-planted suture. A large fold of omentum was ligatured and removed. The abdomen was thoroughly washed with carbolized water, and the external wound united with about fifteen sutures. It was then dressed with iodoform and oakum, ½ ounce of alcohol and 15 gtts. of deodorized tincture of opium were administered per rectum, and at 12.15 the dog was allowed to come from the influence of ether. The same amount of alcohol and opium were administed as before at 6 P. M. The dog died during the night. Post-mortem revealed no evidence of inflammation, and some slight bleeding from the spleen. The sutures in the intestine were in good condition. The piece of gut, about eight inches long, supplied by the mesenteric artery, which was cut by the bullet, was found to be completely mortified.

EXPERIMENT NO. 22.

February 12, 1884.—(Ball cal. 32). Brindle bull dog. No attempt to sew up the holes in the intestines, of which there were about twenty. Died the day following. "Tilley's anæsthetizer." Every opening showed evidence of extrusion of contents.

EXPERIMENT NO. 23.

February 28, 1884.—Tilley's anæsthetizer. Died before operation from effects of ether.

EXPERIMENT NO. 24.

February 28, 1884.—(Ball cal. 44). A short, strong, Spitz dog. Bullet wounds of entrance and exit 4 in. apart. Intestine perforated in four places and abraded in one spot. Intestinal worms free in abdomen. Tape worms protruding from perforations.

Extravasation of contents of the bowel. No arteries divided by bullet. Resected one piece, (including three perforations) 12 in. in length. Removed a V-shaped piece including the fourth perforation, and inverted the serous surfaces by interrupted sutures, the same as in complete section. The apex of the V (pointed to the attached border of the bowel) controlled the oozing from the abraded spot by small suture passed across the mesenteric side of abrasion, the abrasion being the size of a copper cent, and on the side of intestine. Washed the intestines and abdomen cavity as clean as possible by stream of weak carbolized and pretty warm water from the irrigator; closed abdomen wound by five deeply-placed sutures about one-third inch apart; gave hypod. of one-fourth grain of morphia. Shock and little loss of blood. Omentum also removed.

February 29.—In morning seemed very lively and bright; gave some water, which was immediately rejected by stomach. During morning vomited foul-smelling fluid and two large chunks of meat. About 10 A. M. gave hypod. of one-half grain morphia; in very few minutes he laid down and began to whine as though in pain, and threw up large quantity of offensively-smelling fluid. Died about 3 P. M.

Post-mortem.—Abdomen showed evidence of intestinal extravasation, all organs being bound together by peritoneal inflammation; extravasation of blood beneath peritoneal covering of intestines, and small clots adherent all along the length of ileum. The stumps of ligated mesentery and omentum were black. The seat of the operation showed adhesion of the serous surfaces, and water could be forced through the excised piece which was taken out by a cut six in. to each side of the stitches, without any leaking at seat of operation. The spot of abrasion was swollen and blue, and there had been a little hæmorrhage from it. The intestines generally were contracted, glued together, and pressed into prismoidal and other shapes. Stomach empty.

EXPERIMENT NO. 25.

February 28, 1884.—(Ball cal. 44). "Tasso." Bullet under skin opposite to point of entrance. Intestine riddled in about four places, for which a complete section 20 in. in length was removed and was nicely adjusted; another hole in the ascending colon was closed on each side by the continuous suture; the tip of the spleen being shot off, to arrest hæmorrhage a ligature was passed around proximal side of wound tight enough for that purpose, but yet not enough to cause death of the spleen tissue beyond ligature. The stumps of ligated mesentery being gathered upon a suture, were united to intestine near or about at the seat of the approximation of the divided ends; omen-

tum removed; gave rectal injection of alcohol and water ½ ½ about. Each opening in bowel had more or less of the contents around it.

February 29.—Seemed very quiet all the morning, and was quite indisposed to move. Towards noon, gave him, about 11 o'clock, about 1 oz. of alcohol and water ½ ½ per rectum and some water to drink, which was at once vomited. Seemed very tired all day, and disposed to lie stretched out before the heat of the register, and his breathing was entirely thoracic and by means of the cervical muscles. At 6 P. M. gave hypod. of morph. gr. ⅜, and left water where he could drink.

March 1.—Seemed very weak all day; gave hypod. of morph. ½ gr. twice, the last at night. About noon gave rectal injection of alcohol and water.

March 2.—Still alive, but very cold; listless and indifferent; gave morph. in A. M., and tied him up in blanket. Returned at nine P. M., and poor "Tasso" was in rigor mortis. I think the exposure to cold during the day (Sunday) which was a very wintry day, was in great measure the cause of his death. He refused to drink any milk during the day, and also seemed to have lost his thirst for water.

Post-mortem March 4.—Extensive peritonitis present; no separation of the united intestine to be found at the seat of operation.

EXPERIMENT No. 26.

March 3.—(44 cal. cartridge). Large, fat and old bitch. Used Frank Gould's revolver, 44, and upon opening the abdomen, found four large rents in the intestines (every one of which showed extrusion of contents and some worms) at a considerable distance apart, and a very profuse hæmorrhage from the wound of exit, which was not discovered until the resections were made, of which two included the wounds in the gut, which was about shot off, and much bleeding took place before they were found and ligated. The animal was so fat and boggy that it it was with the greatest difficulty that hæmorrhage could be controlled, and the beast was old and presented signs of cataract in both eyes. The bladder was greatly disturbed, and the structure of the intestines themselves seemed "sleazy," and the sutures tore out with readiness upon slight traction. Cleansed out abdomen as best we could by thorough washing, but a little bleeding was going on when the wound was closed in the abdomen, and the operation given up as a bad job of one-half hour's duration.

March 4.—Found dead.

EXPERIMENT No. 27.

March 4.—(44 cartridge). Medium-sized dog; died from shock on night of 4th.

EXPERIMENT No. 28.

March 6.—(Ball cal. 22, revolver). Very small, black and tan dog. Shot him with a 22 cartridge, and had to use three shots before could get a good perforation and but little bleeding. Resected a piece around the bullet-hole of ¾ inches long, cleaned abdomen and closed tightly; gave morph. gr. ¼.

March 7.—Seemed very bright.

March 8.—Gave little milk and morphia in evening.

March 10.—Milk.

March 11.—Sent down cellar to be fed on milk.

March 12, 13.—Very hearty, and eats ravenously of milk and very little meat.

March 14, 15.—Doing nicely. Recovery.

EXPERIMENT No. 29.

March 6.—(Ball cal. 44). Large, strong dog. Used 44 cartridge. Found the abdomen full of blood; spleen perforated, and intestines wounded in three or four places. From these issued fæces, gas, etc. Removed spleen, omentum, and resected about 12 in. gut, including all the holes but one, which was sewed up by continuous stitch. The animal having lost nearly all his blood by this time, and as death was sure to ensue, one of the mesenteric arteries was ligated to ascertain results.

March 7.—Found dead in morning.

Post-mortem.—Intestine black, but the animal had evidently not lived long enough to get any positive mortification of ligatured part, or any interesting appearance at all.

EXPERIMENT No. 30.

March 10.—Tilley's Inhaler. Large chandler bitch. Killed by ether.

EXPERIMENT No. 31.

March 10.—Tilley's Inhaler. Large Hastman dog. Killed by ether.

EXPERIMENT No. 32.

March 10.—(Ball cal. 22, rifle). Medium-sized bitch. Found three mesenteric arteries severed, and intestines riddled in many places and far apart. Perforations showed fæcal matter and tapeworms. Stopped bleeding and returned intestines without closing the perforations, and closed abdomen. No dressing but iodoform (C. T. P.). Spleen also removed, being perforated.

March 11.—Still alive, and sent down cellar.

March 13, A. M.—No better.

March 14, 15, A. M.—Vomiting, and refused food.

March 18.—Dead. Peritonitis septic. Pockets of fæces.

EXPERIMENT No. 33.

March 10.—Small dog (yellow). Shot with 22 cal. rifle. Three perforations of small intestine, showing fæcal matter. Removed a 4-in. piece in two places, and brought ends together very closely; stitched mesenteric stumps to attached border of intestine. Removed omentum, tying tightly, and also putting in three side stitches connecting sides of stumps on each side of ligation with one another.

March 11.—Alive, but feverish and vomiting.

March 12.—Died. Separation at seat of operation, and stumps mortified. See specimen. Fæcal extravasation.

EXPERIMENT No. 34.

March 12.—(Ball cal. 22 rifle). Old, mangy bitch. Died under ether, Tilley's Inhaler. Perforation showed extravasation of contents, fæcal matter and worms.

EXPERIMENT No. 35.

March 12.—Medium-sized, short-haired, yellow

cur (white nose). Shot with 22-ball rifle. Upon opening the abdomen, found blood flowing from a rent in the side of spleen. This organ was three times the normal size, but no holes in the intestines anywhere, and no hole could be found in the abdominal wall on either side. The bullet lay next the abdominal muscles, and was cut out from the wound of entrance. Free bleeding from the laceration in the spleen, which was controlled by a continued suture. Resected six inches of intestine and closed abdomen. Also omentum removed. Iodoform and oakum dressing; gave morphia.

March 13.—¼ gr. morph. A. M.; very weak P. M.

March 14.—Morph. A. M.; very weak P. M. Temperature 102.

March 15.—Re-opened, but found intestine in solid mass and filled with badly-smelling fluid. Washed out as best I could and reclosed. Seat of operation showed mortification on one side, and stumps of mesentery also were black and soft.

March 16.—Still alive. Morph. gr. ¼.

March 19.—Dead. Found intestinal worms in abdominal cavity.

Experiment No. 36.

March 12.—Short, black, stumpy and very fat dog. Fired four 22-balls at the animal before was sure that any had entered. Found abdomen full of blood; two perforations five inches apart, and two mesenteric arteries shot off near the gut. Each perforation showed extravasation, fæces and worms. Ligated the arteries; resected one piece, including both holes; sponged out abdominal cavity; removed omentum, also a large quantity of fat which hung to the inner wall of the belly, and closed wound. Iodoform and oakum dressing; gave morphia.

March 13.—Quite bright. Morph. A. M. and P. M.

March 14.—Dead. Post-mortem. Found considerable peritonitis and mortification of the ends of the intestines where they were stitched together. The stumps of mesentery and omentum also showed signs of mortification.

Experiment No. 37.

March 13.—Medium-sized brindle bitch. No. 22-ball rifle. Resected one piece six inches having two holes; removed omentum very little; hæmorrhage; gas and fæces from wounds; temperature $98^{2}/_{5}$ at close of operation.

March 14.—¼ gr. morph. A. M. Temperature $102^{2}/_{5}$. Morph. P. M.

March 15.—¼ gr. morph. P. M.; temperature $102^{2}/_{5}$.

March 16.—Morph. P. M.; temperature 102.

March 17.—Gave milk and morph. P. M.

March 19, 20.—Gave milk and morph. P. M.; seems well.

April 22.—Perfectly well; recovery.

Experiment No. 38.

March 13.—Medium-sized yellow dog (with bare spot on tail). No. 22-ball rifle; found one lateral hole which closed by continuous suture, and three holes which were included in one piece which was cut in half by mistake; two arteries gave some bleeding, but were ultimately controlled. Contents of bowel found at each wound. Abdomen closed while yet there was some oozing from the wound, which ceased when bandages were applied; omentum removed.

March 14.—Very weak and much prostrated. Refused to lie down, and can stand with difficulty on his feet. Gave morphia ⅜ hypodermically, morning and evening.

March 15.—Found dead. Post-mortem. Mortification at seat of operation, and escape of intestinal contents.

Experiment No. 39.

March 14.—(Ball 22-cal. rifle.) Medium-sized brindle dog (wolf face); found three ragged holes. Resected one piece which included all openings, the piece being seven inches long; closed neatly, the omentum being removed also (many tapeworms and considerable fæcal matter from openings), then washed clean by irrigator. The entire ileum was inspected and sponged off, and returned to abdomen. Spleen also pulled out and inspected; gave morphia and dressings of iodoform and oakum.

March 15.—Some shock; morphia.

March 16.—Morphia P. M. only.

March 17.—Morphia P. M. only.

March 19.—A. M. morphia, stercoraceous vomiting, and seems very sick; P. M. is evidently dying.

March 20.—Vomiting has stopped, and seems much better. Died in the evening. P. M. Septic peritonitis. Post-peritoneal abscesses.

Experiment No. 40.

March 14, 4:45 P. M.—A young, black, bitch pup; anæsthetized and abdomen opened without shooting; ligated a mesenteric artery and closed wound to be re-opened to-morrow P. M. and resect the part supplied by ligated vessel; gave morph. 3-8.

March 15.—Opened her at 3 P. M. in presence of Prof. Parkes. Intestine supplied by the ligated artery seemed softer than normal and its mesentery showed inflammatory exudate considerable effusion; closed wound, gave morphia at night.

March 16.—Gave morphia, gr. ¼.

March 17.—Sent down stairs.

March 19.—Seems quite well.

April 22.—Perfectly well. Recovery.

Experiment No. 41.

March 19.—(Ball 22 cal. rifle). Medium-sized young bitch (black). Found one abrasion which closed up by continued suture and the intestine in another place was about shot off; fæcal matter scattered all about, worms divided; resected the piece about one inch long; irrigated the abdomen cavity; removed omentum and then found a hole or rather the tip of the spleen shot off which bled some and was controlled by two interrupted sutures; gave morphia, gr. ¼, and applied dressings.

March 18, 19.—Morphia, gr. ½.

March 20.—Seems bright, but very quiet.

April 22.—Quite well. Recovery.

Experiment No. 42.

March 19.—Twenty-two ball rifle (brindle, white bitch). Found one abraded edge and one hole through free edge of ileum, from which contents

issued. Closed one by continued suture and resected across the hole by cutting out a ¾ inch piece. Did not remove omentum. Gave morphia ⅜ and applied dressings.

March 18 and 19.—Morphia. Seems to have a paralysis of left fore-leg since operation and for two days past seems to be salivated.

March 20.—Better.

April 22.—Well. Recovery.

EXPERIMENT No. 43.

March 20.—(Stub tail). A small ½-breed terrier dog. Twenty-two ball rifle. Found two perforations and one abrasion, extravasation of gas and stained mucus and shreds of matter from openings going through mucous coat. Made a resection including all three wounds, the excised piece being six inches long, closed very snugly and connected the ligated mesenteric stumps with the attached border of intestine by a single ligature passing through both stumps (but two sets of vessels having been ligated) and both sides of the mesenteric borders of the united ends of the gut; removed omentum and irrigated abdomen cavity freely with a 1 per cent. of carbolic acid solution. Dressings, oakum and iodoform; gave morphia, ¼. Recovery.

EXPERIMENT No. 44.

March 20.—A young, shaggy, cur dog opened without shooting, and litigated three sets or branches from the superficial mesentery artery, close to the main artery, and also a good-sized anastomatic connection with an adjoining vasa intestine tenuis, which ran parallel with and along the attached border of the bowel. The intestines supplied by the vessels blanched immediately. Closed abdomen; gave morphia, gr. ¼; applied dressings. Recovered.

Died subsequently from ether during examination as to result of above operation six days after it. Found intestine perforated by stick of wood four inches long, rolled in twine. Had removed it, and was about to sew up wound when ether killed him.

EXPERIMENT No. 45.

March 20.—A good-sized spaniel dog (old). Stopped breathing once from ether before shooting. Shot with a rifle twenty-two ball. Found the abdomen full of blood, two arteries having been shot off and the ileum perforated in four places; from each contents extruded, two being so near together and the wounds so great as to almost carry away an entire segment of the bowel, necessitating a removal of about twenty inches. Much bleeding, which took about half-an-hour to control, being from the ligated stumps and bullet-wounds; the tissues were very brittle, and so loaded with fat as to make the operation difficult. Died in one half-hour after closing abdomen wound.

PNEUMONIA.—Professor Purjess, of Buda-Pesth, claims to have found the Micrococci of Friedländer in other diseases besides pneumonia; and consequently denies the infectious character of the latter disease.

MEDICAL PROGRESS.

MEDICINE.

A NEW METHOD OF TREATING NOCTURNAL INCONTINENCE OF URINE.—J. F. Anderson, L.R.C.P., gives us in the *Australian Medical Journal* what is certainly an original method of treating nocturnal incontinence of urine. He places a battery at the head of the bed, attached to the poles of which are two long insulated wires, that pass underneath the pillow and down the patient's back, terminating in two small exposed copper loops placed a little distance apart on the perineum. One of these wires, before reaching the perineum, is brought round to the pubes in front, and there passes down inside a small India-rubber bag, shaped like the upper part of an ordinary male urinal, but closed at the bottom. At the lowest part of the bag this wire is filed clean through, leaving the two metallic ends exposed, and about an eighth part of an inch apart. Into this bag the penis of the patient is put.

Now set the battery in action, and let the patient go to sleep. So long as the bag is empty no current passes, but let the smallest drop of urine be voided, it immediately passes to the bottom of the pouch, fills the interspace between the filed ends of the wire, and so completes the current, the current passing through the body of the patient from one copper loop to the other; immediately the perineal muscles contract and the patient is awakened.

SURGERY.

TRAUMATIC CEREBRAL ABSCESS EVACUATED THROUGH THE NOSE; RECOVERY.—*The Lancet* gives us a reference to the report of Dr. Tassi to the Royal Academy of Medicine of Rome, who presented a patient, who, three months previously, had sustained a comminuted depressed fracture of the skull in the left frontal region. The patient, F. B., from Civita Vecchia, was a robust railway engine-driver. The blow had been inflicted with a sledge-hammer; and the extensive comminuted and depressed fracture was complicated with diffuse hæmatoma and very serious cerebral symptoms; loss of consciousness, high fever, paraplegia, and paresis of rectum and bladder succeeded. Antiphlogistics and counter-irritants were employed, and the propriety of trephining was discussed. Some sero-purulent fluid escaped through the center of the wound, which admitted a probe for a considerable distance into the cranial cavity. The symptoms of cerebral irritation and compression increased, the limbs became contracted, divergent strabismus and priapism ensued, and the speech was monosyllabic and unintelligible. The seventieth day after the injury, sero-purulent fluid suddenly burst from the left nostril, and continued for four or five days, amounting in the aggregate to several ounces. As the discharge progressed, the symptoms of irritation and compression decreased. The patient first recovered consciousness and speech, then sensitive and motor power. In the course of fifteen days, all the

functions of organic life were restored to the normal standard, and in three months from the date of injury, the patient was able to return to work.

ANATOMY AND PHYSIOLOGY.

On the Movements of the Brain Within the Cranium.—M. J. Luys has made a long and interesting communication on this subject to the Paris *Académie de Médecine* (*Bulletin*), in which he gives the results of his experiments as follows :

1. The brain is not as immovable in its cranial box as one is led to believe. Besides the intrinsic movements, due to its expansion and contraction, it has also certain movements which are independent of these.

2. When a man passes from the dorsal decubitus to the abdominal decubitus, his brain follows the movement and glides gently from behind forwards, simply in agreement with the force of gravity and aided by the yielding of the arachnoid membrane whose physiological purpose is naturally explained in conformity to that law of anatomy which prevails wherever there is movement in the economy, as there is a serous membrane to facilitate that movement.

3. When the body is in the vertical position, the cerebral mass settles down and recedes from the cranial vault, to a degree amounting in the cadaver to about 5 to 6 millimeters, slightly less in the living subject.

4. When the body assumes the lateral decubitus, the cerebral mass follows the law of gravity, the superior lobe presses lightly upon its congener over the falx cerebri, which offers but little resistance.

5. The cephalorachidian fluid may modify these movements a little, but does not overcome them, for there is always in the normal condition a space between the cranium and the encephalic mass.

Admitting these facts he applies them in explanation of certain physiological and pathological conditions.

The change of position from the horizontal to the vertical causes by increased pressure of the brain downwards, a change in the vessel trunks of the circle of Willis, a partial obliteration and a consequent condition of general ischæmia for the superior regions. In this way he explains the vertigo that affects some persons on assuming the erect position after lying in bed for a length of time. This also in his opinion serves to stimulate the organic sensibility of the cerebral tissue, to awaken the brain after a night's sleep, for example. In pathology he ascribes the severe cephalalgia which accompanies meningitis as due to the movements of the brain influencing the inflamed and sensitive surfaces of the serous envelope.

MATERIA MEDICA AND THERAPEUTICS.

Etherization by the Rectum.—An editorial in the *Boston Medical and Surgical Journal* gives the experience in Boston of the use of this method as showing that if there are advantages there are also grave objections to the method. In many cases the effect has been out of proportion to the amount of ether used, as it continues to be absorbed after anæsthesia was already complete until it became profound, sufficient in certain cases to cause anxiety. In these cases in which the insensibility grows deeper and deeper, it is impossible to withdraw the anæsthetic. A rectal tube fails to evacuate any sufficient quantity of gas, and one can only have recourse to stimulants and general measures until the effects have passed away. This prolonged effect has followed the smaller doses, and in patients where there was no reason to expect such results. These cases have not rallied easily. In doing away with the local difficulties about the air passages, other local difficulties have shown themselves in the rectum and bowels. The diarrhœa has, in some cases, been marked, and occasionally blood has been passed in sufficient quantities to prove serious, while the vomiting has been in these same cases quite as severe as in patients anæsthetized in the usual manner. In addition, certain cases have proved quite intractable to the new mode of administration within any reasonable time, and inhalation has been added.

From New York comes the account of a case in which two ounces were administered to a child of eight months, in which bloody discharges and death occurred the following night.

The present experience has been sufficient to formulate the following rules, which should guide any one desirous of using the new method, until further experience modifies them :

Rectal etherization should be reserved for cases in which there is some special objection to the administration by inhalation.

It should be made use of only with robust adults.

In general, two ounces should be regarded as a sufficient dose. That dose should be exceeded only with great caution.

When insensibility is fairly established the administration should be stopped.

MISCELLANEOUS.

Dr. Morell Mackenzie's Diseases of the Throat and Nose.—The second volume of this work, which was on the eve of publication, was burned at a fire in a London book-publisher's establishment, and, had not one copy fortunately been in the possession of the author, four years of unremitting labor would have been entirely lost; but the reprint will be carried out by the publishers, Messrs. Pardon, as rapidly as possible, and the volume will, it is hoped, be brought out in three or four months.

Russian Medical Literature.—Dr. Max Bach, in the *Deutsche Medicinische Wochenschrift*, gives to Russia seventeen medical journals, a few of which are confined to special subjects, such as psychiatry, and neurology, medical jurisprudence, military hygiene, etc. In addition to this, the transactions of several medical societies, and numerous theses, besides independent works and brochures, it may be estimated that nearly a thousand independent medical productions are annually printed in Russia.

THE

Journal of American Medical Association.

PUBLISHED WEEKLY.

THE EDITOR of this JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information, should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE..... $5,00.
SINGLE COPIES..... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

CHICAGO, ILLINOIS.

SATURDAY, MAY 31, 1884.

MEMBERS BY APPLICATION.—At the last meeting of the National Association action was taken for amending the constitution in such manner as to provide for the admission of members by application, in addition to the previous methods, as may be seen by reference to the minutes as given on page 573 of the present volume of the Journal (No. 21, May 24, 1884). Under the new provision any member of a State, County or local society, recognized by representation in the American Medical Association, who is himself in good standing in the local society to which he belongs, may become a member of the National Association, by making application in writing, and accompanying such application by a certificate of his good standing, signed by the President and Secretary of the Society to which he belongs, and the payment of five dollars membership fee. The amendment adopted does not specify the officer of the Association to whom the written application, certificate of good standing and fee, should be sent. But as the Treasurer is the proper officer to receive all membership dues, and to keep a record of all who retain their membership by continuing to pay the annual fee of five dollars, it would be better if all papers and money relating to applications for membership in the manner specified above, should be sent directly to the Treasurer, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa. Members by application will hold the same rank as other permanent members. They will be entitled to receive the Journal of the Association, attend the annual meetings, and retain their membership so long as they continue to pay the annual dues and comply with the regulations and requirements of the Association, but without the right to vote; the latter being reserved for delegates only.

ILLINOIS STATE MEDICAL SOCIETY.—This Society held its thirty-fourth annual meeting in this city, commencing on Tuesday, May 20, 1884, and continuing until Thursday evening following. The attendance was large and the meeting a profitable one. The full report of the proceedings, which had been prepared for this number, must be deferred until the next, on account of the unusual space occupied by the address of the Chairman of the Section on Surgery and Anatomy in the American Medical Association. The reports and papers read were, in most cases, well prepared and appropriate. As everywhere else, the idea of germs as efficient causes of disease, and germicide remedies, pervaded a large part of the papers and discussions; and it was noticeable that some members economized their materials and labors by favoring the State Society with the same matter that had previously been brought fully before the profession through local societies and medical journals. The profession of the city gave the State Society an elegant banquet at the Grand Pacific Hotel on Wednesday evening, which was enjoyed in a high degree by the large number in attendance.

DELEGATES TO THE INTERNATIONAL CONGRESS.—To the list for delegates for the International Medical Congress at Copenhagen and other foreign societies, appointed at the recent meeting of the American Medical Association, and published in the minutes of the meeting in the JOURNAL for May 24, the name of Dr. G. M. B. Maughs, of St. Louis, Mo., should be added.

A PRIZE FOR MORE LIGHT ON THE BACILLUS.—A Fellow of the Linnæan Society, of New South Wales, offers a prize of £100 for the best essay on "The Life-History of the Bacillus of Typhoid Fever." The essays must be written in the English language, and delivered at the Society's office on or before the 31st of December, 1884.

EDUCATIONAL PROGRESS.—The Faculty of the Medical College of Ohio has adopted the rule to subject all applicants for admission to the college, to an examination on their preliminary or general education, except such as present a diploma or other evidence of sufficient literary attainments.

APPOINTMENTS.—Dr. William H. Welch, of New York, has been elected Professor of Pathology in the Johns Hopkins University, Baltimore. Dr. Thomas A. McBride has been elected Professor of Mental and Nervous Diseases in the New York Polyclinic. Sir William Jenner has been re-elected President of the Royal College of Physicians, of London.

DELAWARE STATE MEDICAL SOCIETY.—The ninety-fifth annual meeting of this Society will be held in Wilmington, Delaware, on Tuesday, June 10, 1884, in the lecture-room of Masonic Temple. This is one of the oldest State Medical Societies in the country. Dr. J. A. Draper, of Wilmington, is Chairman of the Committee of Arrangements, and Dr. G. W. Marshall, Milford, Delaware, Secretary.

PAYING A PREMIUM OR A COMMISSION ON MEDICAL STUDENTS.—According to the newspapers, St. Louis has a medical college (Eclectic) which for business enterprise is likely to rival its neighbor of free scholarship fame in Louisville. It offers its agents $12.50 commission for every student who will pay the regular lecture-fee of $75, and $25 as commission for each full scholarship sold at $150. It will take such commissions a long time, however, to overtake free scholarships and skilled letter-writers.

BOOK REVIEWS.

MEDICAL EDUCATION AND THE REGULATION OF THE PRACTICE OF MEDICINE IN THE UNITED STATES AND CANADA. Published by W. T. Keener, Chicago.

This book is a revised and corrected edition of the Fifth Annual Report of the Illinois State Board of Health. The publisher has found it desirable to present it to the general public, as at this time much interest attaches to the subject. The edition at the disposal of the Board of Health was also inadequate to supply the demand.

The material of the book is distributed under the following headings: Schedule of Minimum Requirements Entitling a College to Recognition; Laws Regulating the Practice of Medicine in the United States and Canada; Medical Institutions in the United States and Canada—Extinct and Existing—Including Examining and Licensing Boards; Medical Colleges—Existing; their Organization; Course of Instruction; Requirements for Admission and Graduation; Fees; Number of Students; Percentage of Graduates to Matriculates, etc.; Auxiliary and Post-Graduate Schools; Colleges for Women only; for Both Sexes; for Colored Students; Colleges Conferring Degrees on Summer Sessions; List of Institutions, Extinct and Existing, not Recognized; Summary and Tabular Statements.

FRACTURES OF THE NECK OF THE FEMUR, WITH SPECIAL REFERENCE TO BONY UNION AFTER INTRA-CAPSULAR FRACTURES. By N. SENN, M.D., Milwaukee, Wis. Extracted from the Transactions of the American Surgical Association, Vol. I, 1883. Philadelphia: Collins, Printer, 705 Payne St. 1883.

This is a neatly printed monograph of 113 pages, on good paper, and illustrated by nineteen well executed cuts.

In addition to a full, if not exhaustive examination of what had been done and written concerning fractures of the neck of the femur, the author has added a valuable series of original experiments on animals, chiefly on cats and dogs. These experiments, to the number of thirty-two, were instituted for the purpose of obtaining answers to the following questions: 1. "What is the mode of repair after non-impacted intra-capsular fracture of the neck of the femur? 2. What becomes of a bone or metalic nail when driven into the neck of the femur and retained permanently? 3. What is the effect of such a nail upon the adjacent bone tissue? 4. Can we, in cases of intra-capsular fractures of the neck of the femur, by immediate or direct measures, as by nailing the fragments together, obtain such accurate co-aptation and retention as to secure union by bone?"

The results of these experiments are given in the first fifteen pages of the work, together with the case of a female patient in which complete bony union occurred after an intra-capsular fracture of the neck of the femur. In the first twenty-one experiments on animals, no nails, either of metal or bone, were driven into the fractured part of the neck for the purpose of keeping the fragments more perfectly in apposition, and in none of them did bony union follow. In the remaining experiments the fractures were produced subcutaneously, and the parts subsequently secured in apposition by nails of bone or metal driven into the fragments. And in two of these cases complete bony union resulted; and in several, the nails of bone disappeared entirely by absorption.

The anatomy of the neck of the femur occupies ten pages, following which the author gives a description of the different varieties of fracture liable to occur, both intra and extra-capsular, occupying seventeen pages. The next ten pages are occupied with a consideration of the causes of fractures of the neck of the femur, including senile osteoporosis. After giving a very plain and interesting account of the symptoms and diagnosis of fractures of this part of the bone, the author enters upon the consideration of the production of callus. This is perhaps the most interesting and exhaustive part of the monograph. Having assumed that bony union can take place and in many instances has done so, after true intra-capsular fractures, he enters upon a thorough study of all the more recent investigations on this part of the subject, both in this country and Europe. The last ten pages of the monograph are occupied with a concise statement of the author's views regarding the treatment of the variety of fracture under consider-

ation. The reader will find in the 113 pages of the pamphlet before us, clearly and concisely stated, the results of a most extensive and impartial study of the long controverted questions concerning the results of intra-capsular fractures, to which the author has added much valuable, original matter of his own development.

Dr. Senn is a patient, accurate, and thorough investigator, with the happy faculty of expressing his thoughts in language both concise and elegant. And the present monograph merits a place on the table of every practitioner, whether physician or surgeon.

DOMESTIC CORRESPONDENCE.

Richmond, Ind., May 22, 1884.

CHAIRMEN OF SECTIONS.

At the recent session of the Association there was not time for all the chairmen of the Sections to read, in the general morning meetings, the address the plan of organization requires them to prepare for the occasion, and more than one of the excluded manifested a sharp sense of disappointment. There are now seven Sections, and the programme assigned two of the addresses of chairmen for Wednesday morning, two for Thursday and three for Friday morning. By a misapprehension of the law these addresses are usually an hour long, instead of forty minutes, and as the morning meetings are practically limited to three hours, the days on which two addresses are delivered have two-thirds of the time of meeting consumed by them, and on the day that has three assigned they would occupy the entire time, except it be on Friday when, without Section meetings in the afternoon, the general session may occupy as much of the day as its business requires. But the situation then has this drawback: so many of the members have departed for home or to look after outside affairs that there is left a formidable array of empty seats, which have a depressing influence on the reader of a paper, wherein he has with his best ability incorporated his richest ideas of a year's earnest cultivation in a special line.

True, these unread addresses are to be published the same as if they had been read, but this does not satisfy the chairman who has the reasonable ambition to present his own thoughts in person to his assembled confreres and enjoy the pleasurable inspiration of the moment.

The first four of these addresses, the two on the second day of the session, and the two on the third are usually read, and to audiences respectable in numbers; but those set for delivery on the fourth day have to be referred for publication unread, or delivered to scant and too often inattentive audiences. The situation this year was, therefore, not unlike that of other years. This in nowise, however, lessens the chagrin of those who, this year, were denied the privilege of reading these addresses.

For this disagreeable state of affairs there should be a remedy. What shall it be? We cannot now alter the law regulating this matter, and must seek what relief can be found within its purview. Fortunately this is much; the controlling regulation is this: "The chairmen of the several Sections shall prepare and read in the general sessions of the Association, papers on the *advances* and *discoveries* of the past year in the branches of science included in their respective Sections, the reading of such papers not to occupy longer than *forty* minutes for each." Great relief will come from a strict observance of the forty minutes limitation. Many of these addresses have occupied an hour or more in delivery. Let the committee fix an hour for the reading of the first address, fix the time for a second forty minutes later, and for a third forty minutes after this; give this arrangement the force of a special order and see that it is adhered to. This allots two hours for three papers on Wednesday morning, the time usually consumed by two. The following morning three more of the addresses could be read under like provisions, and this would leave but one to be read on the morning of the last day, for which time could certainly be spared.

Doubtless some chairmen will object to a restriction to forty minutes, but as that is the law under which they took service they should voluntarily conform to it, and if they do not the presiding officer should cut them off, each when his time is out, though his address be not finished, and give his successor his right of a hearing. Proper regulations, judiciously carried out, is the only feasible way of conducting successfully the business of a large assembly of men who have multiple affairs to consider and decide. Moreover there is small doubt that any chairman of a Section who knew in advance that his reading would be limited to forty minutes would prepare his paper to conform to that necessity.

It will be observed that another obligation of the chairman is that his paper to be read before the general session of the association shall be on the advances and discoveries of the past year in the branches of science included in the section of which he is chairman. This obligation is both significant and important and it is deemed safe to say that no chairman can ignore it and give entire satisfaction to the association. It is obvious that in adopting this regulation it was the purpose of the association to secure to itself annually the improving and enjoyable opportunity of listening to an intelligent résumé of a year's progress of medical science in the departments severally confided to the Sections, the presumption being that each chairman would, immediately on his appointment, devote himself to a careful scrutiny of the current literature of his department to be continued through the year and then sum up so much of the most important matter contained in his notes as could be intelligently presented to the association in forty minutes. This presumption has not always been realized, and there were some notable failures at the late session. But it is a fair conclusion that if the doctors who have had the honor of chairmanships conferred on them this year, realize how unsatisfactory were the addresses that did not conform to the law, there will be no failures in this behalf at New Orleans.

J. F. H.

THE ACTIVE AGENT IN JEQUIRITY INFLAMMATION.

Erroneous impressions about the influence of microbes is greatly to be deprecated, and by no one is this more keenly felt than by those who sincerely wish to give the microbe its due influence either for the weal or woe of the human race. It is consequently with regret that we find in the address of the Chairman of the Section of Practical Medicine of the American Medical Association, that the influence of the jequirity is said to be of special importance because "in it we have pressed into our service the ubiquitious microbe, which is receiving at present so much attention." See address Vol. I, No. 19, p. 517. This position taken by Sattler, and supported by Cornil and Berlioz, has been so completely overthrown by Neisser, of Berlin, and Salomonsen and Dirckinck-Holmfeld, of Copenhagen, and the question itself is of such intrinsic interest, that whilst the matter is fresh before the minds of the profession, we venture to offer to the JOURNAL an abstract of these critiques on Sattler's work, which we published in *Weekly Medical Review* of April 5.

The examination of Sattler's work was undertaken both in Breslau and in Copenhagen. In both cases the results furnished conclusions absolutely different from those advanced by Sattler. Dr. Neisser, who conducted the experiments made in Breslau, claims that the statement that inflammation is due to bacteria is not yet proven, and that the claims of Sattler do not correspond to the facts. If, says he, the inflammation is due to bacteria, then must the following conditions hold: 1. There must be a distinct species of bacteria in the infusion. 2. Without bacteria the infusion will be inactive. 3. The bacteria of pure culture should at least have the same activity as the fluid containing the bacteria. 4. In the pathological product developed, conjunctival secretion and exudate, the infecting entity should be found and then when transferred to the conjunctiva of another animal the same affection should be developed.

As a matter of fact relative to the first condition, there does exist in the infusion, as usually employed, a well-marked form of bacteria, which flourishes so abundantly that other forms are altogether in abeyance; but that the specific action of the infusion is to be attributed to this bacillus, after repeated and varied experiments Dr. N. positively denies. He thus formulates the results of his observations: 1. An infusion which is free from bacteria exhibits the same activity as that which contains bacteria. The infusion was made so as to be free from bacteria, by the rigid observations well known to those acquainted with that kind of work. So long as the infusion was kept free from bacteria it remained active, but lost its activity after the development of the bacteria. 2. The use of the bacilli of pure culture, in order to produce the characteristic ophthalmia, was powerless. The bacilli were introduced into the conjunctiva in large quantities, and often without any characteristic results. 3. I have never found in the secretions from the eyes affected with the jequirity inflammation, nor in the diphtheritic membranes, any evidence of the bacillus. Micrococci I have found, but the characteristic bacillus, never. 4. The application of the ophthalmic secretion to an eye not affected, produces no inflammatory action. Dr. N. believes that the peculiar action is due to a substance existing in the bean, which the chemists who have hitherto investigated the question have not been able to isolate—an amorphous ferment.

The subject is also taken up at length, and published in the same number of the *Fortschritte der Medicin*, from which we have extracted the above, by Dr. C. J. Salamonsen and M. Dirckinck-Holmfeld, in Copenhagen. Here observers also found that an infusion made with all due precautions, remains perfectly clear and active practically indefinitely, as long as the bacteria are prevented from disturbing its influence.

On the question of the existence of bacilli in the secretions and exudations, they say: We could not find, either in the pus or in the diphtheritic layer from the conjunctiva, when examined under the microscope, any bacillus. Sometimes we found micrococci in the secretions. The membranes and pus, moreover, were taken from the eyes, and an effort made to cultivate any special bacillus which might be present; but though certain forms of bacteria developed, the special form which dominates in the infusion under favorable circumstances, never presented itself.

Pus was also taken by these observers from the afflicted eyes, and an effort made to excite a similar affection in a healthy eye, but without producing anything more than the faintest conjunctivitis.

The characteristic bacilli of pure culture were, without any effect, rubbed into the conjunctiva also by these observers, and their conclusion naturally was, that the effect was due to a special proximate principle existing in the jequirity bean; and their further efforts were directed to establish their belief, or convince them of their error.

Their observations showed them that the active principle was insoluble in alcohol, chloroform, benzine and ether; that it was comparatively slightly soluble in water, but very soluble in glycerine. They were unable to extract any alkaloid, and expected the presence of an amorphous ferment. To establish this point, the jequirity seeds having been ground up, the powder was treated with ten times its weight of pure glycerine, rubbed up well and allowed to stand for twenty-four hours, filtered, and then precipitated with five times its volume of alcohol. This precipitate was again treated with the necessary means for purification, and the result, dissolved in both water and glycerine, gave the characteristic jequirity inflammation.

The smallness of the amount of the active principle necessary to produce the inflammation is very striking. The glycerine solution which corresponded to the one hundred-thousandth part of a gramme, developed the characteristic inflammation, but one-half the quantity produced no effect.

These two investigators thus sum up the result of their observations:

1. The jequirity inflammation is not the result of bacteria.

2. It is the result of an active principle in the seed, soluble in both water and glycerine, but insoluble in alcohol, chloroform, ether and benzine; and destroyed by a temperature of from 65° to 70° C., if sustained for an hour.

3. The quantity of the active principle contained in the one hundred-thousandth gramme of jequirity seed develops a well marked conjunctivitis. The poison, when injected subcutaneously in mice or frogs, quickly kills.

We have given this much space to this question because of its intrinsic interest. It is not likely that a substance as active will, in these days of rigid investigation, be confined to observation on trachomatous eyes. The investigators above referred to have not yet given a name to the amorphous substance which they extracted, but as we are likely to hear from them again on this subject, we have no doubt they will suggest some appropriate appellation. The bacillus, in this case at any rate, has to take a back seat.

R. TILLEY, M.D.

Chicago.

FROM WASHINGTON.

MATTERS OF MEDICAL INTEREST BEFORE CONGRESS.

May 9.—The bill (S. 1,044) to establish a University of original research and of medicine, as a part of the Smithsonian Institute, for the advancement of science and the discovery of improved methods of treatment and cure of disease, was brought up before the Senate by Mr. Call, of Florida. The bill is about the same in text as already referred to here, but now it is proposed to connect it with the Smithsonian Institute. Mr. Call made his speech, which was a long one, and, as he says, expressed the thoughts of others upon pretty much the whole range of scientific research that medicine could possibly embrace. The bill was not discussed, nor has there as yet been any disposition made of it.

May 12.—The petition of the American Medical Association, praying that proper provision be made for the prevention of epidemic diseases in the United States, was presented in the Senate, and referred to the Committee on Epidemic Diseases. The petition was presented in the House on May 14, and similarly referred.

May 14.—To the resolution directing the public printer to publish extra copies of the *Medical and Surgical History of the War of the Rebellion*, etc., the text of which is given on p. 529, was added "or for the volumes already published, or to be published hereafter, of the Index Catalogue of the Library of the Surgeon General's Office." This was agreed to, and the further statement made by Mr. Hawley that the public printer will undoubtedly prepare a little circular, or brief statement, giving the price, so that those who wish to obtain these documents have only to write to the public printer, and, on ascertaining the price, which to them will be 10 per cent. above the cost of paper and press-work, send the money with the order, and wait until an edition is struck off. There is, I believe, no fixed price for the *Medical and Surgical History*, which is sold here by second-hand book-dealers at $5.00 per volume. The Index Catalogue is valued at $2.00 per volume.

NECROLOGY.

BEALE, JAMES SHEILDS, M.D., of Washington City, was born in this city November 14, 1841; died suddenly of apoplexy, in the parlor of Providence Hospital, February 12, 1884, where he had gone to perform an important operation.

He was the son of Robert Beale, and was born in the old Read mansion, corner of B. and Pa. Ave., S. E. The doctor left college without the knowledge of his parents, and joined the Confederate Army at the outbreak of the war between the States. On the restoration of peace, he studied medicine, and graduated M.D. from the Medical Department of the University of Georgetown in 1859. Afterward he visited Europe, and took special courses in Paris, London and Vienna. Returning to Washington, he opened an office in the house where he was born, and speedily acquired a good practice. His preference was for surgery, and at the time of his death he was ranked among the leading surgeons of the city. Besides a large private practice, he was on the surgical staff of Providence Hospital, and had been connected with that institution for over ten years. He filled the chair of Anatomy of the Medical Department of the University of Georgetown from 1876 to 1883, when he resigned. He was a trustee and a member of the teaching Faculty in the "Washington Training-School for Nurses." He was a member of the Medical Society of the District of Columbia, of the Medical Association of the D. C., and the Gynæcological Society of Washington. These bodies held meetings and passed appropriate resolutions of regret, as did the staff of Providence Hospital and the students of the medical department of Georgetown University. Dr. Beale occasionally read papers before the Medical Society of the D. C., and contributed papers to medical journals. He was a man of cultivated manners, of sympathetic disposition, and untiring in his efforts to benefit his patients, and they were devotedly attached to him.

The doctor leaves a widow and three children. His funeral took place from Ascension church, the Rev. Dr. Elliot officiating. His remains were placed to rest in "Oak Hill cemetery." The funeral was attended by a large number of physicians and a great concourse of friends.

J. M. T.

JEROME, JAMES H., M.D., of Saginaw City, Michigan, was born at Cochecton, Wayne county, Pa., Sept. 28, 1812, died at his residence in Saginaw Aug. 8, 1883. His parents removed to Michigan when he was a lad about 15 years of age, and his father died three years later. He attended a district school, and had one year's tuition at the Ovid Academy. The limited means of the family compelled the youth to largely rely upon his own resources. He

learned the trade of a hatter, serving an apprenticeship, and followed the business until 1834. A fondness for study led him to a desire for a still higher education. After giving some time to the study of Latin he began reading medicine with Dr. Moses Tompkins, near Hector, N. Y. He attended the Geneva Medical College in the winter of 1834–5, and while there was fortunate enough to attract the attention and secure the friendship of Willard Parker, Professor of Anatomy and Physiology. He then attended a course of lectures at Pittsfield, Mass. At the invitation of Dr. Parker he returned to Geneva, and acted as his assistant in preparing cases for illustration in the lecture-room. Dr. Jerome graduated from Geneva Medical College in 1837. Immediately after obtaining his degree he began practice at Trumansburg, N. Y., where he speedily acquired business and held positions responsible in medical societies.

In 1855 he received the Honorary Degree of M.D. from Hobart Medical College, and in the same year was elected Professor of Anatomy and Physiology to his *alma mater*. In 1858 he was appointed Physician-in-Chief of the Marine Hospital at the port of New York. He then retired from the chair in Geneva Medical College and entered upon his duties in the Marine Hospital in 1859, but shortly afterward resigned in consequence of difference of opinion with the Commissioners of Immigration, and returned to his former field of labor at Trumansburg. In 1839 he was married to Lizette Atwater, of Perry, N. Y. Eight children blessed this union. Mrs. Jerome died in July 30, 1863. In 1865 Dr. Jerome removed to Saginaw, Mich., and married Calista Allen. In his new home he engaged extensively in manufacturing lumber, but never lost his interest in the healing art. In 1866 Jerome assisted in organizing the Michigan State Medical Society, and was always earnest in his support of regular medicine. He was a member of the Board of Councillors of Detroit Medical College, and its President from its organization. The Board passed appreciative resolutions after his death. The physicians who attended his funeral also joined in a series of resolutions of respect for his memory, which have been published in the Association journal of August 1883, p. 223. (From notes furnished by W. F. Breakey, M.D., of Ann Arbor). J. M. T.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT UNITED STATES ARMY, FROM MAY 17, 1884, TO MAY 23, 1884.

Sternberg, Geo. M., Major and Surgeon, relieved from duty in the Department of the East and ordered to report to the Surgeon-General of the army for temporary duty. (Par. 2, S. O. 115, A. G. O., May 17, 1884.)

Magruder, David L., Lieut.-Colonel and Surgeon, ordered to be relieved from duty as medical director, Department of the Missouri, and to proceed to Philadelphia, Penn., and assume duties of attending surgeon and examiner of recruits in that city

Fryer, Blencowe E., Major and Surgeon. From Department of Missouri to Department of Dakota.

Ewen, Clarence, Captain and Assistant-Surgeon. From Department of Missouri to Department of Platte.

Strong, Norton, 1st Lieut. and Assistant-Surgeon. From Department of Platte to Department of Missouri. (Par. 7, S. O. 115, A. G. O., May 17, 1884.)

Wilson, George F., 1st Lieut. and Assistant-Surgeon, ordered to proceed to Fort Canby, W. T., for temporary duty at that post, relieving Assistant-Surgeon, W. O. Owen, Jr., U. S. A., who will report in person at these headquarters for further orders. (Par. 5, S. O. 62, Hdqrs. Dept. of Columbia, May 12, 1884.)

LIST OF CHANGES IN THE STATIONS OF MEDICAL OFFICERS, U. S. NAVY, FOR THE WEEK ENDING MAY 24, 1884.

Assistant-Surgeon W. Martin, ordered to U. S. Str. "Constellation."

Medical Inspector H. C. Nelson, granted leave of absence for one year.

P. A. Surgeon L. B. Baldwin, detached from U. S. Str. "Pensacola," and "waiting orders."

Surgeon H. M. Wells, ordered to Naval Hospital, Brooklyn.

P. A. Surgeon J. M. Murray, detached from U. S. Str. "Minnesota," and ordered to U. S. Str. "Passaic."

P. A. Surgeon J. R. Waggener, ordered to U. S. Str. "Hartford."

S. Mitchell, E. T. Shepard, E. Souchon, T. D. Layton, T. S. Dabney, S. R. Olliphant, Edward Harrison, A. B. Miles, Joseph Holt, P. B. McCutchon, F. H. Parham, G. B. Underhill, Stanhope Jones, E. Chassaignas, R. Dell'Orto.

ASSISTANT SECRETARY.

Dr. W. H. Watkins, New Orleans, Louisiana.

BOARD OF TRUSTEES FOR JOURNALIZING THE TRANSACTIONS.

Drs. J. M. Toner, Washington, D. C., President;
M. Moore, Rochester, N. Y.; Leartus Connor, Detroit, Mich.;
J. H. Packard, Philadelphia, Secretary;
H. F. Campbell, Augusta, Ga.; A. Garcelon, Lewiston, Me.;
P. O. Hooper, Little Rock, Ark.;
L. S. McMurtry, Danville, Ky.; J. H. Hollister, Chicago, Ill.

OFFICERS OF THE SECTIONS:

"Practice of Medicine."

Chairman—Dr. H. Didama, Syracuse, N. Y.; Secretary—Dr. G. M. Garland, Boston, Mass.

"Obstetrics and Diseases of Women."

Chairman—Dr. R. S. Sutton, Philadelphia, Pa.; Secretary—Dr. J. T. Jelks, Hot Springs, Ark.

"Surgery and Anatomy."

Chairman—Dr. Duncan Eve, Nashville, Tenn.; Secretary—Dr. E. B. King, Allegheny, Pa.

"Ophthalmology, Otology and Laryngology."

Chairman—Dr. J. A. White, Richmond, Va.; Secretary—Dr. Eugene Smith, Detroit, Mich.

"Diseases of Children."

Chairman—Dr. J. H. Pope, Marshall, Texas; Secretary—Dr. S. S. Adams, Washington, D. C.

"Oral and Dental Surgery."

Chairman—Dr. W. W. Allport, Chicago, Ill.; Secretary—Dr. E. C. Briggs, Boston, Mass.

"State Medicine."

Chairman—Dr. E. W. Schaufler, St. Louis, Mo.; Secretary—J. N. McCormick, Bowling Green, Ky.

Committee on "Necrology."

Chairman—Dr. J. M. Toner, Washington, D. C.

ORIGINAL ARTICLES.

REPORT ON THE ADVANCES AND DISCOVERIES MADE IN THE STUDY OF CONTAGIOUS AND INFECTIOUS DISEASES.

BY WILLIAM LEE, M.D., BALTIMORE.

Address of the Chairman of the Section on Diseases of Children, May, 1884.

Opposed to specialties as they are generally practiced, as many of the best and wisest in our profession are, it must be admitted, nevertheless, that the formation of a Section on Children's Diseases by this Association was eminently proper, for not only has our example been followed by the British Medical Association, as shown at its last meeting, when a similar Section was inaugurated, but in these days, when the question as to division of labor in the science of medicine, as well as in other fields of human labor, is engaging so much attention, Pediatrics must sooner or later be allowed to hold that independent position which it deserves. This fact we are made to appreciate very forcibly through the leaves of the *Archives of Pediatrics*, lately started in our country, to which I hope each member of this Association will give his support. It is now four years since the establishment of this Section, and we believe the good effects to be derived are indisputable. Certain affections are met with in children only, and there are others common it is true to every period of life, but which are modified in peculiar ways when they occur in childhood.

The laws of the Association require the chairman of a Section to prepare and read in general session a paper, the reading of which shall not occupy more than forty minutes on the advances and discoveries in the branches included in his Section.

The contributions to medical literature in the Section over which I preside during the past year have been so numerous and important, that were I to attempt the complete review I would require more time than has been allotted me, and, possibly, not do full justice to those special diseases which are now claiming so much attention. I have therefore thought best to confine my report entirely to the infectious and contagious diseases of children, and in order to give as complete a review as possible, have deemed it wise to go back of the present year, particularly as at the last year's meeting no written report was presented.

DIPHTHERIA.

Dr. Carpenter[1] on the etiology and treatment of diphtheria, endeavors to show how by analogy diphtheria and potato-disease may be allied to each other, and then after mentioning the influence of sudden rise and fall of temperature, effects of sewers, impure milk, etc., gives facts to prove how the germ upon which he believes diphtheria to depend for its development, may be suddenly brought into activity, particularly amongst the poor, who allow their families to remain on wash-days in the steamy atmosphere of the rooms in which they not only do their work but likewise sleep.

He sums up this part of his article by classifying the conditions necessary for an outbreak of diphtheria under five heads:

1. The presence of certain forms of excreta.
2. Of an elevated temperature not much below blood heat, but below that requisite for the coagulation of albumen.
3. Of an atmosphere saturated with moisture, and probably also with (4) an excess of carbonic acid, or some other acid in the air by which the growth of the germ is determined, and (5) some other meteorological or electric manifestation at present entirely unknown.

For the treatment of this disease ammonia is recommended very highly, on account of its stimulating effects, to reduce acidity of the blood, and because it has been found in a number of cases of diphtheria that there is a rheumatic or gouty diathesis. In combination with the ammonia, lithia or potass. is generally given, and when there is an elevated temperature, he at once prescribes the sulpho-carbolate of soda, with the greatest possible benefit.

I would urge, says he, practitioners to continue the sulpho-carbolate in small doses, first with ammonia, and after a time with quinia, avoiding altogether the mineral acids—as such appear to allow of a more rapid development of the resting spores and a further relapse. For local treatment he strongly advocates washed sulphur, blown into the throat or by means of a brush with glycerine or honey.

While not being able to testify to the good effects of the internal treatment mentioned by Dr. C., I can bear testimony to the good to be derived from the local application of sulphur, particularly if used in the combination as first suggested by Dr. James

[1] *London Lancet*, Sept. 15, 1883.

Reed, of Savannah—which some of you may remember my calling to your notice last year. It is as follows:

℞ Resorcin .....grs. xxiv.
Tannic acid.....℥i.
Salicylic acid.....℥iv.
Boracic acid.....℥ii.
Flor. sulphuris.....℥ss.

M. ft.—Chart one. The above suitable for a child 4 years old.

S.—A small quantity to be placed on base of the tongue every two or three hours.

At the same time the powder is used, Dr. Reed gives resorcin internally, and believes it acts better than quinine in the treatment of diphtheria.

Dr. Henoch[1] considers that the undue way specifics are claimed for diphtheria, arises from its being confused with other diseases which it simulates.

Noticeable among these are cases of croupous angina, which in the first stage of the disease it is often difficult to distinguish from diphtheria. Specific diphtheria and non-specific croupous pharyngitis have also certain elements of difference, but they are not detectable in every case. The latter disease usually begins with violent fever, while the former ensues slowly with a moderate amount of fever.

In the non-specific oftener than in the specific there is in the beginning an invasion upon one side only, twenty-four to thirty-six hours elapsing before both sides are involved. The fact of the disease extending to the velum, particularly if the posterior pharyngeal wall be also attacked, makes the probability very strong that we have to deal with true diphtheria. But, after all, the condition of the nasal mucous membrane furnishes the chief criterion, for in the non-specific croupous form it is never attacked, while in the specific form it is almost invariably attacked.

Albuminuria is too often absent in diphtheria to be considered of importance in making a differential diagnosis. The author concludes by saying that although the scarlatinous form of diphtheria may follow quickly specific diphtheria, or *vice versa*, he is firmly convinced they can be differentiated.

Dr. Reese[2] has advised for the treatment of
theria a solution of bi-chloride of mercury in the proportion of one grain to four ounces of rain-water.

He orders the patient, if old enough, to gargle and rinse the mouth every two hours, and take afterwards internally a teaspoonful; should the disease be very severe, it must be done every hour. Within fifteen or twenty-four hours the exudation will disappear, but will return unless the remedy is continued. This treatment must be kept up for a week or longer, the strength of the gargle and frequency of use being regulated by the effects produced, namely: nausea, vomiting or purging. As long as the system is suffering from the poison, these symptoms will be absent. It is probable that the benefit arising from the bi-chloride is due to its influence upon bacteria, as demonstrated by Sternberg, and also to the remedy being rich in chlorine.

[1] Resumé in Jahrbuch, f. R. u. p. E. B. xx. H. Q.
[2] *Jour. Am. Med. Ass.*, Nov. 1, 1883.

Dr. Selldon[1] uses the cyanuret of mercury, one centigramme to 100 grammes of water—dose, two teaspoonfuls internally every hour day and night. Also, when children are old enough, allows them to gargle with a similar solution. In 1881, five cases were treated in the above manner, and four recovered; 1882, thirty-two, with only two deaths. Among those who recovered there were few paralytic sequelæ.

He also treated 200 cases of angina of the tonsils and fauces with the same solution, and always with good results. They were all treated with mercury upon the supposition that diphtheria might develop. As adjuvants to this treatment, he employed ice internally and externally, and when it could be borne, free stimulation. The latter procedure he considers very necessary in view of the danger of heart failure.

SCARLET FEVER.

Mr. R. W. Mullican,[2] in a paper on the Ætiology of Acute Specific Disease, and also in an article by Dr. John Meredith, some evidence has been brought forward to show that scarlatina may be evolved from diphtheria. The latter states, that towards the end of June, 1882, cases of illness of undoubted diphtheritic character occurred in the district of Wellington, Somerset county, London, where there neither was nor had been a case of scarlet fever for many months. Some of the earliest cases of diphtheria were very mild, and to this variety belonged the case of a housemaid in a family attended by him. This girl went one afternoon toward the end of June to see her father, who, it was found afterwards, suffered at the time with sore throat, but its specific nature could not be discovered, because he was not treated by a medical practitioner. A few days after this visit the girl became ill, and refused food, but made little complaint, and did not give up work, recovering in a day or two. Before being entirely well, her fellow-servant, the cook, was taken sick with sore throat and general weakness—upon examining her throat, several diphtheritic patches were found on the tonsils, which soon disappeared, and recovery followed, under treatment of tinct. iron, nitric acid and chlor. potass. gargle. The two servants occupied the same bed. In the house were three children, aged 8, 7 and 6, who passed much time with the cook, but this was stopped, as soon as the character of her illness was discovered.

However, on July 1, the oldest, a girl, complained of headache, sore throat, heat of skin, and some gastric irritation. On examination of her throat, it had a peculiar florid appearance, but no diphtheritic exudation. At the end of another day, scarlet fever rash came well out all over the body, and the case progressed favorably, with exception of much irritation of the bladder. The urine was found alkaline, of low specific gravity, and free from albumen.

On July 2, the youngest, also a girl, complained of head and ear-ache; was quite feverish, throat red, but no diphtheritic patches could be found; her condition resembling that of her sister, only there was not so much urinary irritation, and the rash was

[1] Archives of Pediatrics, No. 2, 1884, Jahrb. f. Kindhldke, B. xx. H. 4.
[2] *Lancet*, May 26, 1883.

more general, with higher temperature. An ulcer formed in her ear and discharged for some time.

On the 6th, the third child, a boy, age 7, was taken sick much in the same way as his sister, (she had been isolated from them for some days) and in due course the scarlatina rash came out all over his body in quite a typical character. This case proved a very mild one. At the time he was taken ill his mother became sick, her sickness beginning with a rigor, aching all over her body, and high temperature, which continued for several days. She had violent headache and free perspiration at intervals which left her prostrated.

Her throat had a reddish blush; nothing else. There was no rash anywhere over her body. Her illness in this case appeared to be diphtheria without the tonsil exudations that are usually seen, (possibly because she used freely antiseptic gargles). She had had scarlet fever in early life.

In conclusion, he forms the opinion that these cases of scarlet fever are evolved ones, a correlative out-come, and not the immediate result of contact.

In a very interesting article Dr. Oxley attempts to show that scarlet fever is not a very infectious disease, during the first two or three days, and says that such is the case, may be easily explained, if we only accept the theory that the fever depends upon specific germs being introduced into the body and bred there, and only becomes infectious after they are reproduced in the host and thrown off, either from the skin, throat or other secreting surfaces. There are exceptions where the disease when present, even in a very mild form, may prove infectious very early in the illness; but this is probably due to the fact that owing to the initial symptoms being mild this disease is only discovered after making considerable progress. In alluding to the possibility of the medical man carrying the requisite quantity of the poison, says, I have often been told that "you doctors carry fever in visiting from case to case." A friend of mine who has always something *apropos* to say when a remark of this kind is made, replied, "If we did so, we should have a great deal more doctoring to do." And this is true; for if the infection was carried by medical men, think for a moment how great the spread of fever would be.

He next alludes to the complication of rheumatic fever, a complication which has a very great pathological interest owing to the fact that it is a grafting of another disease. Rheumatic fever he says may come on during the course of scarlet fever as early as the sixth or eighth day, or during convalescence, when we think our patient doing well.

In speaking of the treatment in this complication the doctor strongly interdicts the use of the salicylates, because the skin and kidneys are both desquamating and not in a fit condition to be called upon to do any extra work. He relies upon quinine and tinct. of perchloride of iron in small doses, with application of a blister over the heart, where it is affected; or if they are contra-indicated, carb. ammo. and chlorate of potash in small but repeated doses.

[1] The *Lancet*, Oct. 27, 1883.

Tonge Smith[1] from an experience in treating 2,000 cases of scarlet fever, observed within the last three and a half years, has become convinced that the incubation period does not last more than three days.

Liechtenstein,[2] on the treatment of scarlatina, says that while his remarks are based upon an extended observation he has no new theories to advance.

The chief means on which he relies are cold baths, administered from the time the exanthem is well developed. He usually immerses the child from ten to fifteen minutes.

The antipyretic action of the baths becomes manifest not only in the reduction of temperature, but in the lessening or the ending of delirium, steadying of the heart's action and decrease of frequency of the pulse, with relief of dyspnœa, etc. While recommending very highly the cold water treatment, he gives five conditions which contra-indicates its use. (1) Cardiac collapse, or a tendency thereto. (2) Laryngeal stenosis, with diphtheria complications. (3) Inflammatory swelling and infiltration of the cellular tissue of the neck with venous obstructions. (4) Possible hæmorrhage from diphtheritic inflammation extending to the pharynx and nasal cavity. (5) The severe form of polyarticular synovitis and scarlatinous tendonitis, in which the slightest movements are painful.

Quinine the author has found less reliable as an antipyretic, and not without danger in children, on account of the possibility of quinine collapse. If given, it should be in small and rather frequent doses.

The author considers salicylate of soda far more reliable as an antipyretic, and gives it in half-gramme doses at intervals of half an hour, until the fever is controlled. He thinks its supposed unfavorable effects upon the heart are imaginary. For nourishment, milk, eggs, gelatine and nutritious soups are prescribed. If stimulants are necessary, they should be given in the form of red wine, cognac or champagne. Counter-irritations and massage are also beneficial.

CEREBRO-SPINAL FEVER.

Dr. Smith[3] in an exhaustive paper on the Etiology, etc., of this disease, reports as follows, that, according to Lyden and E. Sandier, micrococci seem to be associated with the cause of this disease, but proof is wanting that this germ bears a causative relation to it.

As it occurs in localities where the diet is to a great extent dissimilar, particular kinds of food have no influence as a cause.

Medin thinks that the infectious material is absorbed by the lymph-spaces of the nasal mucous membrane; which, according to Key and Retzius, communicate on the one side with the atmosphere through openings between the epithelial cells, and on the other side with the sub-arachnoid spaces at the base of the brain.

In winter a greater number of epidemics occur than at any other season, on account of overcrowding and poor ventilation.

Causes which predispose to this disease are anti-hygienic unsanitary conditions, overwork, lack of sleep, prolonged abstinence from food; followed by over-eating indigestible and improper food.

In children who worry over their studies, and are easily chagrined at being reprimanded or punished, there seems to be an especial liability to attacks of this disease.

(I have met with three cases during the past winter, when this was positively demonstrated.)

Males are more frequently attacked than females.

Symptoms.—In the 36 cases tabulated, the disease showed itself between midday and midnight, beginning with violent headache, vomiting and aslight chill, but usually without any premonitory symptoms.

In children, clonic convulsions take the place of the chill. Stupor or coma follows, and when the patient can be aroused, complaint is made of pains in the trunk and extremities.

The pupils are dilated in the early stage of the disease, or less frequently contracted, and if the attack be severe, they respond to light feebly, or not at all.

Pain in the head is very sharp and lancinating during the first week.

In children the pulse is more or less accelerated.

The respiration is proportionately faster than the pulse, which fact, possibly, is owing to tonic contraction of the abdominal muscles.

Temperature.—Although the surface does not indicate it, the temperature is above normal. Wunderlich has recorded one or two severe and fatal cases when the temperature was as high as 110°.

Tonic contractions of the cervico-occipital muscles and back begin in all typical cases from the first to the third day, but to a less degree in those of the abdomen or lower extremities.

The hearing may be entirely lost, and not regained, as the result of otitis media.

Urine contains occasionally a small quantity of albumen.

Complications.—Croupous pneumonia and arthritic rheumatism are the most frequent and fatal. Strabismus is common.

Sometimes the sight of one eye is completely destroyed by inflammatory changes.

Nature.—Evidence is strongly in favor of its being a constitutional malady, with meningitis as a local manifestation.

Anatomical Characters.—The most common abnormal appearance of the blood observed at the autopsies is a dark color, with unusual fluidity and some dark clots; the meninges of the brain and cord are hyperæmic, with exudations of serous, fibrinous and purulent nature.

The brain is softened; ecchymoses are present.

Prognosis.—Patients who live beyond the first week without serious complications will probably recover.

Numerous and large petechial eruptions show a profoundly altered state of the blood, and are therefore a bad prognostic, and so is continuous albuminuria. Under the age of five and over that of thirty the prognosis is less favorable than between these ages.

Diagnosis.—Owing to the nature and severity of its symptoms, and the suddenness of its attack, cerebro-spinal fever may be mistaken for scarlet fever, and *vice versa*. From the common form of meningitis ordinarily there is no difficulty. Continued fever, typhoid or typhus, somewhat resembles cerebro-spinal fever, but it lacks the muscular contraction and rigidity which characterize the latter.

Treatment, Prophylactic.—All measures looking to a good hygienic and sanitary condition must be strictly enforced during an epidemic.

Curative.—Efforts must be made at once to relieve the intense inflammatory congestion of the cerebral and spinal meninges. For this purpose bags or bladders of ice answer well; they should be used over the head and nucha.

In convulsions, hot mustard foot-baths.

For internal treatment, large and frequent doses of the bromides and ergot stand at the head of the list.

When headache is severe, and there is much restlessness, opium and chloral.

In the latter stages of the disease, iodide of potass.

The doctor concluded by saying that no disease requires more urgently kind, intelligent and constant attendance night and day.

TYPHOID AND TYPHUS FEVER.

[1]Amongst the various forms of typhoid fever which occur in children, it is scarcely necessary to insist upon the importance of diagnosing the transient variety which so frequently escapes observation.

The premonitory symptoms are so vague, and the headache, restlessness at night, constipation and fever are so ill defined and so slight that it is no easy matter to discover them. When the affection is once declared, however, it remains for some time, the chief symptom being that the child does not sleep, whilst the tongue is somewhat red, and the abdomen is slightly swollen.

The spots are often difficult to see on account of the local applications which have been employed; but at a later stage the fever become well defined with morning remissions until the fifteenth day, when the patient begins to convalesce.

Ashby[2] says typhoid fever more often aborts in children than in adults, that is the disease runs a course of two weeks instead of three or four.

The onset in the majority of cases is very gradual.

Temperature.—Morning remissions are greater than in adults.

Tongue not specially characteristic.

Abdomen as a rule is gradually distended.

Spleen can be felt in some cases.

Rose Spots seen in 39 out of 50, or 78 per cent., and are observed either on abdomen, chest or back.

Diarrhœa is slight.

---

[1]*Practitioner*, June, 1882.
[2]*Practitioner*, June, 1881.

Complications are principally pneumonia, bronchial catarrh or bronchitis.

Hæmorrhages from the bowels are rare.

Relapses are by no means uncommon.

Mortality.—Barthez and Rilliet, Hillier, Gerhardt and others, place the death-rate of children from two to twelve years at 10 per cent.

During nine years in our hospital at Manchester, 265 cases have been treated, with twenty-one deaths, making a mortality of nearly 8 per cent.

Treatment.—Little medicine is required, excepting for the purpose of lowering the temperature, unless complications arise.

Tompkins,[1] in giving the clinical features of 164 cases of typhus fever seen by him in the last two years, says that 17 were in children under 10 years.

The initial symptoms in these were less pronounced, rigors being often entirely absent or unnoticed. Headache was usually the only thing complained of, which had accompanying it a rise of temperature seldom higher than 103°F. There was a marked difference in the mental symptoms from those of the adult. At the end of three or four days the patient became exceedingly torpid and lethargic, remained for hours in a dull, heavy sleep, as if under the influence of some narcotic, and could be roused with difficulty. This continued for from four to six days without much real or active delirium. During this time the temperature generally falls, gradually in some, in others more rapidly, becoming normal by the end of a week from its onset. They now would begin to brighten and go on to rapid convalescence.

Sometimes from the commencement of the disease there is a steady decline in the temperature.

The rash, which was not at all characteristic, varied in its occurrence, and in at least half the cases it was difficult to define any true rash.

A dirty mottling of the skin is frequently all, and is seen on the face as well as elsewhere; it is accompanied by a flushed look, and lasts only three or four days.

Prognosis is most favorable. All the seventeen cases recovered. Murchison gives the mortality under ten years as 35 per cent., and under five years 6 per cent. Lebert put it at 27 per cent.

Dr. Tompkins closes the article by calling attention to the great difficulty in making diagnosis when the epidemic commences among children.

MEASLES.

Dr. Meedigan[2] records three cases of insanity which occurred either during the course of, or in convalescence from measles. The youngest of those affected was 15, and the oldest 26 years.

Dr. Pellerean[3] calls attention to the influence of malaria during an epidemic of roseola and measles.

In many cases of roseola which appeared first, the fever would assume a remittent type, either preceding the rash for from two to eight days, or the rash would precede the fever. Then again, both fever and rash would declare themselves simultaneously. The severe symptoms noticed were headache, heat of skin, furred tongue and vomiting.

That the febrile disturbances were caused by malaria intervening, he thinks was demonstrated by the rapid reduction of the temperature under the influence of quinia. When fever subsided, sweating profusely set in, and, unlike what is the case both in roseola and measles, the temperature fell, and continued to do so when the rash appeared. The rash presented two distinct varieties. It was either uniformly red, not unlike scarlet fever, or consisted in small dots, slightly elevated above the skin, more or less disseminated at first, and then coalescing so as to form large patches, completely disappearing under pressure, and giving rise to itching.

Long after the fever had subsided, the eruption of roseola was often seen to persist, and to be followed by very little desquamation. Relapses were common, and an attack of it seemed to confer a predisposition to measles, especially among infants and children.

Like roseola, measles presented in its symptomatology most important modifications and variations. All classes and all ages were affected with it, except Chinamen. The incubation period varied from two to nine days.

There was entire absence of any prodromic stage, most cases being ushered in by fever, which soon assumed the intermittent or remittent type.

The rash, which appeared in a few days, had but little, if any, influence on the character of the fever.

Later in the disease, the spleen was often found more or less enlarged from effects of the malaria.

Besides the usual complications, there was congestion of the liver and hepatitis, both of which were ushered in suddenly with pain in the right shoulder, pain and tenderness in the right hypochondrium—vomiting, icteric tint, furred tongue and shivering. In some cases preceded by dysentery, and in others not.

With the exception of quinine, in most cases the treatment was upon a merely expectant plan.

Prof. Demme[1] in a report on an Epidemic of Measles and its peculiarities, mentions two cases, one a girl suffering from chorea, and the other a boy, 9 years old, suffering from prurigo—both of whom were freed of their respective diseases upon measles appearing; also that of a child three years old who had measles twice in ten weeks.

Dr. Keating[2] gives a very interesting report of a recent epidemic of measles, and in it calls especial attention to the following points, viz: the microscopic examination of the blood and the constant association of *micrococci* with the general manifestation of malignancy, (a condition already well known), and the gradual but positive amelioration of all bad symptoms by treatment, which was directed to the micrococci as the *fons et origo* of trouble.

The investigations were all carefully made with the assistance of Drs. Henry F. Formad and W. A. Edwards.

After giving the history of a number of fatal cases

with their post-mortem, the result of which showed death to be from the gradual forming of right side heart-clot, he asks the question, What causes it?

In January, 1882, No.—, *Amer. Journ. of Med. Sciences*, Dr. K. gave his experience in a number of cases of diphtheria, scarlet fever and measles, and at that time attributed the condition to an increase of fibrine, due to the rapid tissue-changes and the malignancy of the type of disease, and urged the importance of pushing an alkaline treatment from the start.

In these cases the microscope in Dr. Formad's skillful hand has shown that this condition is due to something more; for the moment the symptoms of malignancy appeared, examination of the blood demonstrated micrococci to be present in large quantities. These micrococci appearing coincident with symptoms of malignancy, all remedies should be addressed to check their development, and with this end in view he asked Dr. Formad what, in his experience, most readily arrested the growth of micrococci in his culture solutions, obtained from erysipelas, diphtheria, etc.; he answered, *alcohol.*

The other remedies were at once withdrawn and whisky substituted, which was given in frequent and small doses. This treatment soon began to show its beneficial effects, and with the assistance of arsenic the blood became normal, recovery following in a short time.

In order to test the microscope, Dr. K. with Drs. Campbell and Markoe, after carefully examining a number of cases, got Dr. Formad to examine the blood of each without reference to their condition of which he knew nothing, and in only one were micrococci present, that being a case with all the malignant symptoms.

Vegetable acids the doctor says also have the effect of checking the development of micrococci in culture solution, especially acetic acid; but the mineral acids, also carbolic acid, it is said, has no such action. Bi-chloride of mercury also possesses this quality to a very marked degree.

Rötheln.—Dr. Reed[1] reports the following facts observed during the progress of a number of cases at Atlantic City, of Rötheln or German measles:

The almost uniform enlargement of the chain of cervical lymph-glands. The apyrexial character of the disease: the temperature rarely rose higher than 100 or 101°, and always falling to the normal on the second day.

There was little if any constitutional disturbance; some of the children were allowed to run about the streets, covered with a formidable-looking eruption, without a suspicion of their suffering from anything but a tooth-rash.

In some of the cases there was desquamation, and in one instance slight albuminuria and dropsy following the attack. Three cases occurred in one family in a modified form. One a boy of five years presented a decided dermatitis, involving both cheeks, and in a less degree the sides and front of the neck; the skin was fiery red, very finely punctated and hot to the touch, and the lower eyelids were œdematous; temperature of rest of body and pulse normal. Another a girl of three years, had diffuse punctated rose-colored rash, covering the whole thorax and extending slightly to the abdomen, the rest of the surface being entirely free; at the same time there were two patches of genuine dermatitis, three inches in circumference, upon the breast.

The eruption did not disappear in either of these cases until the fourth or fifth day, a somewhat longer duration than usual. The third, a child, had slight erythema of the fauces and a fine punctated rash on the tonsils and velum palati, but no rash on the skin.

Dr. Maclean[1] says he treats measles very successfully with the following mixture, which should be given every three hours: Ipecacuanha wine, half drachm; syrup of squills, half an ounce; quinia, two grains; acetate of ammonia, liquor, two ounces. Dose for a child two or three years, a teaspoonful in water. The quinia to be increased according to age.

We have thus in this mixture a stimulating expectorant and diaphoretic to relieve the skin, and also in the quinia a specific to destroy or abate the violence of the primary ferment. When cough is very irritating, tinct. of hyoscyamus may be added.

As the quinia is essential for the destruction of the ferment, when the stomach is irritable it may be omitted from the mixture and given in powder mixed with saccharated carbonate of iron, which diminishes the irritating action of the drug when taken alone.

This form of treatment for measles is good in all types of the disease, whether the attack be mild or severe, but more especially valuable when we have that dangerous form in which the eruption is of a deep purplish color, a form which is generally recognized as being the most fatal.

VARIOLA AND VACCINIA.

Dr. Stewart[2] refers to a case reported by Dr. Richard S. Stewart, in which a child was born with pustules over its body, and died on the fourth or fifth day of smallpox, mother having been attacked two weeks before parturition with this disease.

Dr. Roger McNiel[3] says that so far statistics go to show that under ten years the initial rash is extremely rare, and that comparatively few vaccinated children under that age are affected with smallpox.

Dr. I. E. Atkinson[4] saw a woman, under care of another physician, who, immediately preceding her confinement, was living in a room with a case of confluent smallpox. She was successfully vaccinated, and six days and nineteen hours after gave birth to an apparently healthy child.

Three days after her labor her child was attacked with the disease, but of the discrete variety, and recovered without secondary fever or subsequent pitting.

He thought the results of this case indicated a protection.

In April, 1881, Dr. Leonhard Voigt,[5] the superin-

tendent of the Vaccine Institute at Hamburg, experimentally solved the vexed question of the origin and nature of cowpox, and in his most recently published report sums up the results of his observation under nine heads, which may be looked on as an epitome of the whole question:

1. It is possible to create vaccine by the inoculation of the calf with lymph from the pustules of human beings, the subjects of smallpox; but success must not be expected in every case.

2. The energy of variola-vaccine obtained in this way is such, that it is not fit for the purpose of vaccinating human beings until it has been several times transmitted from calf to calf, or from ox to ox, and its intensity has been thus diminished.

3. In the first year, this new lymph has a greater protective power than animal lymph of older stocks.

4. Vaccinia and variola are derived originally from the same contagion, and give to those affected by them an immunity one against the other.

5. The duration of this immunity depends on the intensity of the pathological process.

6. After the lapse of twelve years, persons who have been attacked with smallpox show the same susceptibility to vaccination as those who have been vaccinated at an equally remote period; consequently, children of 12 years of age, vaccinated in infancy, present a moderately favorable soil for the poison of smallpox.

7. Therefore, re-vaccination of all children at or even after the age of 12, is highly to be recommended.

8. Animal lymph, originally very active, diminishes in efficacy when transmitted from calf to calf, sooner than humanized lymph transmitted from arm to arm. On the whole, *i. e.*, after a long time humanized lymph gives better results both in man and beast; whence it follows that animal lymph from old stocks gives less success than retro-vaccine of the first generation.

9. Carefully generated, and in well ventilated and regulated stalls, variola-vaccine is the most energetic of all, not only when taken direct from the calf, but especially in its humanized form. Consequently, if we would obtain the most powerfully protective lymph, we should, when occasion offers, from time to time reproduce a stock of variola-vaccine.

Dr. Page on treatment says: I have been so much pleased with the apparently abortive action of actea racemosa on variola, in the case of a negro man who had "just moved to Baltimore," and on four of his children, all of whom had the disease coming out in rich profusion—that I made a note of the fact.

Under the use of this drug the cases progressed to the papular stage, and in the case of the father pustulation took place only on the face; but in the cases of the children, the secondary fever and pustulation did not take place. The actea racemosa was administered in the form of the tincture with simple elixir. I have had no opportunity to try the medicine except in that one family.

Rosenthal,[1] acting on an article by Boyer, has employed salicylic acid in many cases with good results.

His formula is the following:

℞. Acidi salicyli.....3i.
Spts. vini rectificati.....3ss.
Misc. et adde elix. simplices ad..3vi.

For the angina of variola, he uses in conjunction with this the following gargle:

℞. Xylol.....3i.
Gum acacia.....3ii.
Aquæ menth. pip.....3vi.
M.ft.—Emulsio.
Sig.—Use as a gargle and mouth-wash.

He confirms the statement that salicylic acid in smallpox reduces the temperature, is sedative, and modifies the eruption.

MUMPS.

MM. Cabitun & Charrin,[1] at a recent meeting of the Biological Society of Paris, gave an account of the investigations in which they have for some time been engaged, on the presence of minute organisms in the blood of persons suffering from mumps. These are multipliable by cultivation in Liebig's broth, and are found to consist of minute *batonnets*, but chiefly of micrococci all in a state of motion. These minute organisms, they consider, corroborate the clinical observations which tend to place mumps among the infectious diseases.

The absolute proof that this disease is due to these minute bodies by reproducing it by inoculation of the cultivated forms, has not been attained by the experiments made to that end.

William H. Walter, M.R.C.S., B.M.J., Dec. 22, 1883, reports the following case in a boy of 14 years:

He had been ailing for a week with "a bad cold and sore throat," it was stated. He was found unconscious with contracted pupils, tem. 105, 5° F., rapid feeble pulse. The history given pointed to mumps, though the parotid glands were not swollen.

A day or two before a sister had been seen with a pain and soreness about the jaws, and a little later, a case of undoubted mumps occurred in the same family.

These circumstances sufficiently establish the fact that the primary affection in the case was mumps. The high temperature lasted two or three days, but the cerebral symptoms of delirium, coma, etc., for nearly a week. He made a slow recovery. Attention is called to the fact of the great frequency of meningitis as a metastasis and to the combination of this with orchitis. This combination, the writer believes, has not been recorded.

INFANTILE DIARRHŒA.

Ballard[2] on the Etiology and Pathology of Summer Diarrhœa in Children, says that while the subject-matter of his paper is far from complete, some of the conclusions come to are as follows: The disease cannot be considered a simple diarrhœa, but rather an affection of the system at large, which can in less than twenty hours produce lesions of considerable greatness. Autopsies have unfortunately been

[2] *British Med. Journal*, Aug. 25, 1883.

too seldom performed; notwithstanding this, they show the pathology of summer diarrhœa to be somewhat analogous to that of cholera. This disease is not the result of a relative lack of attention, which happens to children in the great manufacturing centres: for example, while three centres, Leicester, Nottingham and Preston, head the list of infant mortality from summer diarrhœa, three other centres not less important, Oldham, Rochdale and Halifax, occupy the foot of the same list.

Another cause of diarrhœa which is very much dwelt upon by some men, is the use of feeding-bottles; but the author says he is satisfied they have nothing to do with it, at least not leading causes. Artificial alimentation is also a decided factor in the mortality of this disease, for, of 341 children dying from the cause in question, only 2 per cent. were fed with breast-milk. Cow's milk, which formed the nourishment of 60 per cent. of them, is far from being a faultless means of nourishment. The influence of elevated temperature is undeniably efficient in producing this disease, and that influence remains even after the months of autumn.

Speaking in general terms, it may be said that in great cities the maximum of heat in July will have a direct bearing upon the maximum of mortality from infantile diarrhœa. The fetid exhalations of sewers have been accused by certain hygienists as the cause of this trouble, and admitting that there may be some room for such a charge, it is to be observed that Nottingham, which possesses no sewers, has a high death-rate from infantile diarrhœa.

Excrementitious odors are also potent causes, but not the most influential, as proven, at least at Nottingham, for there the matters are removed twice a week, and these odors are unknown, and, nevertheless, it has a high death-rate. On the other hand, Helston, which, from this cause, is one of the most infectious localities in the United Kingdom, suffers very little from infantile diarrhœa.

We are, therefore, led to infer from all this, that further information is required in the light of well-reported cases, and post-mortem examinations carefully made, before the true etiology of this disease can be reached.

Morison[1] has published a paper on Infantile Diarrhœa and its Treatment, and in it refers especially to two forms, milk diarrhœa and teething diarrhœa. For the former he considered mild cholagogue remedies the best, and gives with the view of gently effecting biliary secretions, one or other of the following: euonymin, podophyllin, phosphate of soda, or ipecacuanha, these having been found, according to Rutherford's[2] experiment, the best. A small quantity of an alkali may be sometimes added to each dose.

The quantity used is just sufficient to secure the digestive, without the purgative action of bile.

For the latter form of infantile diarrhœa, besides the gum lancet, nervine tonics and sedatives are advised, arsenic, oxide of zinc, bromide of potassium, or ammonium and camphorated tincture of opium, especially the two latter, and usually with evident benefit.

Dr. Christopher Elliott[1] recommends the infusion of chamomile flowers as highly beneficial in infantile diarrhœa, especially when proceeding from dentition, and when the stools are greenish in color, or are slimy and streaked with blood, it will quickly calm a fretful child. The dose of the infusion is ʒss to ʒi for a child under one year; for a child over that age double, three times a day or oftener, according to the severity of the attack.

The *rationalé* of the treatment is the power which chamomile flowers possess of subduing reflex excitability, this power belonging to the volatile oil they contain.

Dr. Lewin[2] gives, with great success to very young infants, the soluble albuminate of tannin, made by adding white of egg to a solution of tannin; the white of egg must be previously beaten up with some water.

ERYSIPELAS.

Dr. Lawrence[3] draws our attention to the importance of bearing in mind the frequency of infantile erysipelas. It may originate from either puerperal fever or some epidemic influences prevailing at the time of birth. Again, erysipelas may occur as an idiopathic expression of a blood infection. More frequently, however, it has a traumatic origin, the starting-point being the umbilicus, but any abraded cutaneous surface renders the disease possible, as eczema, intertrigo, impetigo, cicatrizing vaccine pustules, etc.

As illustration, a case is cited of an infant, in whom vaccine scabs were separated some days after vaccination, who was handled by an aunt, just from the country, who was recovering from erysipelas. The next day the infant was restless and refused food, and on the following day erysipelas began at seat of cicatrices, spreading rapidly along the arm.

Dr. L., besides advising the usual treatment, lays great stress upon the importance of paying strict attention to bodily cleanliness, and to the hygiene of both the lying-in room and nursery.

W. A. Macleod[4] reports a case to substantiate the infectious nature of erysipelas. Whilst visiting a Mrs. F. during her puerperium he was asked to see her child who had been taken ill on the previous day. He diagnosed the case as erysipelas. Shortly after he saw a woman who had been visiting the child, and frequently played with it, and he found that she had taken the disease.

WHOOPINGCOUGH.

It has been rightly said that until lately the profession has bestowed but little, if any, serious scientific attention on some of the commonest maladies to which flesh is still heir, and whoopingcough seems to be most conspicuously of that number.

Prof. Rossbach,[5] after studying the conditions presented by the larynx and the air-tubes in all stages of

[1] *British Med. Journal*, August 25, 188 .

[5] *Berlin Klin Wochenschrift*, Nov. 18, 1880.

the disease in four children, respectively six months, four, seven and ten years, and in a woman, says that in regard to the essential nature of pertussis, bronchial catarrh must not be regarded as a mere complication, but as immediately connected with the very existence of whoopingcough. The disease has its seat especially in the large bronchi. The violent attacks of coughing, however, cannot be attributed exclusively to bronchial catarrh, nor to masses of mucus reaching an irritable region of the trachea, since bronchial catarrh under similar circumstances may occur without inducing coughing of equal intensity or duration.

He further says that the attacks of coughing are not alone produced by the mucus, but also by the irritation of the violent draughts of air accompanying forced respiration. One of the essential etiological conditions is the existence of a reflex neurosis, and he thinks it probable that in whoopingcough the coughing centre in the medulla oblongata is in a state of abnormal excitability owing to the presence of some specific virus, so that a slight peripheral stimulus conducted through the centripetal fibres of the superior laryngeal nerve is sufficient to excite coughing.

The results of treatment, he considers, support these views. After finding that change of air produced no effect, he endeavored to restore the nervous apparatus to the normal stability in the younger children by transmitting a strong, constant current through the spinal cord, and obtained favorable results; at the same time he administered to the older children quinine in large doses, the latter producing its effect by lowering the excitability of the medulla, and not, as Letzerich believes, by its local lethal action on a supposed fungus, since it was given in the form of capsules.

M. Gueneau de Mussy[1] has constantly found enlargement of the mediastinal glands and compression of the recurrent laryngeal nerves in children that have died of whoopingcough. He regards the compression of the nerves and consequent irritation as the cause of cough, and considers whoopingcough to be an eruptive fever in which the eruption is internal.

Its stages are local lesion of the pulmonary mucous membrane, enlargement of the peribronchial glands, compression of the recurrent nerves and cough.

Dr. Burger[2] not only believes in the germ theory, but thinks he has discovered in the sputa in cases of whoopingcough certain organisms which he holds to be specific and the cause of the disease. These organisms he describes as small, rod-shaped structures.

Toeplitz,[3] of Breslau, mentions whoopingcough as being treated successfully by means of various kinds of powder which were blown into the larynx by means of an insufflator or gum-elastic balloon. Salicylate of soda was principally used.

Robert Lee,[4] applying the general principles of antiseptic treatment for the cure of this affection, used carbolic acid, combined with turpentine, benzine, or one of the fragrant oils; he also tried sulphur in frequent and small doses, and has obtained from them sufficient good results to warrant a suggestion that trial should be made of other volatile agents, such as creosote, oil of amber, etc., he also adds that the common plan of stirring some tar with a hot poker in the room where cases of whoopingcough are is certainly attended with benefit, and is largely used in hospital practice by him.

Prof. O. Heubner[1] has tested the comparative action of five of the most common remedies in this disease, viz.: bromide potassium, quinine, hydrate chloral, salicylic acid, and belladonna. The bromide was given in doses 7 to 45 grs. per diem in aquæous solution, in twenty-three cases; salicylic acid in a 1/3 to 1/2 per cent. solution, as inhalations with Siegle's spray-producer, about an ounce being used at a time, in seventeen cases, and belladonna in doses of 1/4 to 1 grain per diem, in eight cases. In none of the twenty-three cases in which the bromide was given, was the duration of the disease lessened. Chloral was given in divided doses, in two, and an enema, in eight cases. In two, the duration of the disease was lessened, and the intensity and length of the paroxysms, in six cases. Salicylic acid was given by inhalation in sixteen, and as salicylate of soda internally, in one case.

In two, the duration of the disease, and in ten, the length and severity of the paroxysms were lessened. Belladonna was given in eight cases. In three, the duration of the disease, and in one case the intensity of the paroxysms were lessened.

Thus salicylic acid and chloral tend to relieve the paroxysm; belladonna and quinine to shorten the disease.

Dr. John Dewar[2] calls attention to ergot as being the safest and best remedy.

This conclusion he came to after extensive trial of a vast number of useful drugs, viz.: Bromide potass., belladonna, and zinc.

He says ergot seldom fails to cure whoopingcough in from one to three weeks, the cases longer in getting better being those complicated with bronchitis, or with troublesome bronchial catarrh.

The dose used was 4 to 15 minims of the fluid extract every three or four hours, to a child of 3 months and upward.

In reference to how ergot acts in whoopingcough, he says: "I regard the spasmodic cough as due to reflex action, and that in its turn brought about by the peculiar condition of the blood irritating the peripheral ends of the sensory nerves. Ergot dulls or paralyzes these nerves, and so lessens and eventually prevents the spasms."

Although he considers the true pathology of whoopingcough yet to be doubtful, regards it as a germ disease, as only on that ground can its infectious nature be explained.

I have used ergot both in the form of ergotin and the fluid extract for various cough troubles, notably

[1] *London Practitioner*, Vol. 18, page 292.

[2] John Dewar, L. R. C. P., on Physiological and Therapeutical Action of Ergot, *London Practitioner*, Vol. 28, 1882.

whoopingcough, since 1881, when my attention was first called to it as a cough sedative by Dr. James Allen.[1]

The doctor claims that when used hypodermically it is a remedy having notable power in allaying coughs of various lung conditions, and in diminishing sputum. I have found it acted as well, if not better, when given internally.

Ergot seems to have been first prominently brought forward in the treatment of whoopingcough by Dr. Griefenkel,[2] who reported the case of a boy 6 years old whom he cured in eight days by the use of this drug. While being able to endorse Dr. Dewar's statements in regard to ergot in the treatment of whoopingcough, it must be borne in mind that there often arise stages of the disease in which other remedies must be used at the same time, viz.: If there is much febrile disturbance, aconite should be used, and is probably the best; in cases where subacute catarrhal bronchitis ensues, alum, owing to its astringent, bracing and tonic action on the blood, mucous membranes of the stomach and air passages, will be found, if given in small doses, very serviceable.

W. Squire[3] finds that an aqueous solution of ethyl bromide, strength 100 to 200, gives good results in whoopingcough. Half to 2 ounces should be used at a time.

Dr. Cullimore[4] offers the following prescription for whoopingcough, which, while containing nothing new, is worthy of notice:

℞. Aluminis sulph.....grii.
Tinct. belladonna.....m iii. to v.
Tinct. cinchoniæ.....m xii.
Syrupiaurantii.....ʒss.
Aquæ.....ʒii.

M. ft.—Suitable dose for a child of the age of 4 years.

M. Campardon[5] has employed carbonic acid in this disease.

The gas was formed in a seltzer water apparatus, which is conducted by rubber tubing to the nostrils, where it was slowly delivered.

Cure in one was complete and rapid. In using the carbonic acid, it is necessary that the gas be charged with vapor of water.

MILK TREATMENT OF DISEASE.

BY JAMES TYSON, M.D., PHILADELPHIA, PA.

(Read before the Section on Practice of Medicine and Materia Medica of the American Medical Association, May, 1884.)

In the course of a somewhat extended experience with what is known as the "milk cure," it has occurred to me that the growing popularity of this form of treatment, demanded, at this time, some systematic consideration of the principles and practice on which its use is justified, as well as an outline of the class of cases in which it may be expected to be of advantage.

It is now a little more than eighteen years[1] since Dr. Philip Karell read his paper on the "Milk Cure" before the Medical Society of St. Petersburgh.

To this paper I must refer for a large number of interesting historical facts, of both ancient and modern date, bearing on this subject, beginning with Hippocrates and coming down to the date of the paper itself. Among the diseases for which it had been recommended during this period, were phthisis, gouty affections, particularly articular, sciatica, leucorrhœa, hectic fever, dropsy, typhoid fever, intestinal obstruction, Bright's disease, intermittent fever, obesity.

Karell himself numbers the cases of successful treatment with milk "by hundreds." Dr. Inozemtseff, the author of a work on the "Milk Cure," published in Moscow in 1857, treated, with the help of his assistants, 1,000 cases. The former further says, "With regard to my own practice I have, after fruitlessly trying all sorts of remedies in many chronic and obstinate diseases, at last succeeded in bringing the elementary canal, that seat of so many diseases, under my control. I did this by administering milk according to a new method." He says also, "After a great deal of experience, I have arrived at the conclusion, that in all dropsies, in asthma, when the result of emphysema and pulmonary catarrh; in obstinate neuralgia, when its cause lies in the intestinal canal; in diseases of the liver (simple hypertrophy and fatty degeneration), and generally in diseases when there is faulty nutrition, often a consequence of obscure sub-acute inflammation of the stomach or intestines, followed by affections of the nervous centers—in all these cases I consider milk as the best and surest of remedies. Even in those cases where the dropsy is the result of organic heart disease, or of old standing liver complaint, or of far advanced Bright's disease, I have seen very marked improvement take place, which also lasted a considerable time."

I have thus freely quoted Karell, because I believe the date of his paper marks an era in the history of the milk cure. He was instrumental in directing the attention of many to this method of treatment, and among them Prof. Niemeyer, who writes to him in 1861; "I thank you sincerely for having recommended the milk cure to me. I often resort to it and can praise it highly. If one were to acknowledge the existence of a number of diseases, the cause of which is not to be sought for in the remediable affections of certain organs, but rather in a perverse nutrition of which we are unable to define either the extent or nature, we must then admit the curative virtues of milk, and regard as a true advance in science, the discovery that this aliment is an innocent, and at the same time efficacious remedy, for producing a complete change of nutrition."

Referring to the extraordinary success claimed by some, Karell says he has no faith in so large a num-

[1] On the Milk Cure, by Philip Karell, M.D., Physician to His Majesty, the Emperor of Russia. Translated from the author's manuscript, by G. L. Carrick, M.D., Physician to the British Embassy at St. Petersburgh. *Edinburgh Medical Journal*, Vol. xii, Pt. I, p. 96, Aug., 1866.

ber of fortunate cases. He does not attempt to decide whether the beneficial influence of milk in certain illnesses is due merely to its nutritive qualities or some occult medicinal virtue. He simply calls attention to the fact that milk and chyle resemble each other very closely, insists that it must be taken at regular intervals under the direction of an experienced person, in doses from two to six ounces of *skimmed* milk, and that the best results are only obtained when the diet is an exclusive one. He further characterizes it as a regulator of nutrition.

My own experience with the milk treatment includes the following classes of cases: diabetes, calculous disease, Bright's disease, dyspepsia, obesity, and certain instances of the so-called nervous prostration in women, in which its use formed a part of the treatment by rest, seclusion, massage, and electricity, and which has produced such satisfactory and widely known results in the hands of Dr. S. Weir Mitchell, of Philadelphia.

First, as to *diabetes mellitus*, it is now generally conceded that no measures are so efficient in removing the sugar from the urine, and relieving other symptoms, as the dietetic, and of the dietetic treatment none has been so promptly efficient in my hands as an exclusive milk diet. As to the degree in which relief is afforded, it must be admitted that a cure cannot always be guaranteed. The possibility of this depends upon the lesion at the bottom of the disease. But I add my testimony to that of Donkin and others to the effect that a certain number of cases are completely relieved, and that the symptoms do not return, after a cautious addition to the milk diet, and gradual substitution by nitrogenous, and, still later, even by starchy and saccharine foods. Other cases, again, show no sugar in the urine as long as the milk diet is continued, although this and other symptoms recur immediately that it is omitted and other food is substituted. In a third class of cases, sugar is much diminished, but does not disappear, and in such instances I have invariably found, in the most carefully conducted comparative experiments, that no other treatment is as efficient in diminishing the glycosuria. In a last, and smallest number of cases, the milk diet is really badly born, and it is impossible to carry it out; but in the large majority it is the most efficient remedy of which I know.

My method of exhibiting milk in diabetes, and indeed in all the conditions, to which I will refer as adapted to it, is to begin with half a tumbler-full, or four ounces of skimmed milk every two hours, for the first day, from which it is evident only thirty-two ounces, or a quart, can be given from 7 A. M. to 9 P. M. This is, of course, insufficient for an adult person, and even the second day I increase to six ounces every two hours, and after a day or two more to eight ounces, in which way sixty-four ounces, or two quarts are reached in the period named. This amount is quite sufficient for many persons of both sexes with small frames and light weight, but is quite insufficient for others, for whom the quantity may be increased by taking more at one time, or beginning a little earlier in the day and continuing later; or a glass or two may be taken during the night. Or, the interval may be increased to three hours, when still larger quantities must be taken at a time, until an amount sufficient to appease hunger or to maintain a good weight is reached. I have known twelve and a half pints to be taken per day by a large man whose average weight was 195 lbs., but it is very seldom that so much is needed, and its ingestion becomes very inconvenient. When, however, such quantities are necessary, a part may be taken in the shape of curd, as suggested by Donkin. Thus, the man just referred to, took the curd from four and a half to six pints, and drank the remainder of twelve and a half pints per day, he having found this much necessary in order to retain his weight while exercising actively during the day. While using eight to ten pints a day, part in milk and part in curd, he lost a half to three-fourths of a pound daily, although his health and strength continued perfect.

It is impossible to lay down a rule as to the quantity required in the twenty-four hours, but it may be roughly put at from five to ten pints for persons of medium stature, the larger quantity being necessary for those who are exercising, and the smaller for persons at rest.

The milk should be taken slowly, and not gulped in large amounts at a time. Not less than five minutes should be occupied in the drinking of a single glass of eight ounces. Nor should it be taken very cold. In summer the temperature should be about 60°, or a little below that of the surrounding atmosphere, and in winter it may be raised to the same temperature, or even slightly warmed, but it should not be boiled, unless diarrhœa is present.

Such a diet is of course quite compatible with health and strength for an indefinite time. And while I hardly advise that no attention be paid to the complaints of those who say that milk does not agree with them, I always insist on being allowed to settle that question myself by actual trial; and it is well known that where unskimmed milk is not well born, producing, as it sometimes does, discomfort from flatulence or other cause, the skim-milk may be taken without causing any such sensations. Should the latter still disagree, which is very rarely the case, the liberal addition of lime water in the beginning, say but an amount equal to one-fourth, or even one-half the milk used, will often correct the difficulty; and later the milk can be gradually resumed in full strength. Occasionally, too, persons will complain of feeling weak upon a milk diet. This complaint, which is also often unfounded, may be met by increasing the amount prescribed.

A complaint of greater importance is the constipating tendency of a milk regimen, particularly at first. But this may be corrected by the daily use, if necessary, of one of the saline aperients, of which sulphate of magnesium is one of the best, or one of the aperient mineral waters, as Hunjadi Janos, or Friedrichshalle, or some one of the Saratoga aperient waters; or if these are insufficient, a pill of compound extract of colocynth, podophyllin and extract of hyoscyamus may be used; or a cup of black coffee in the morning may be sufficient. In many cases this symptom disappears after a time, and the

whitish, almost odorless evacuations continue daily.

In diabetes mellitus, more than in any other conditions to which the milk treatment is applicable, it should be exclusive, at least at first. My plan is to continue the milk until sugar has been absent for from four to six weeks, after which I gradually add other foods, beginning with unskimmed milk, meats, oysters, fish, tomatoes, the green vegetables, gluten, bread, fruits. The urine is tested after each addition of food, and if glycosuria is found, the article of food responsible for it is omitted for a time longer.

If I am asked the rationale of the action of skim-milk in the treatment of diabetes, I am compelled to admit that I have no reason to believe it is directly curative. The most that can be said of it is that by furnishing a food which is nonirritating and easily assimilable, even as to its saccharine constituent lactose, we give a rest to the starch and sugar assimilating apparatus, and allow the reparative tendency of nature to assert itself, and the hepatic or intestinal condition which causes the glycosuria, to disappear.

This is no time to discuss the pathology of diabetes, but there can be no doubt but that a certain number of cases consist in a simple organic or functional derangement of organs which only require to be let alone in order to restore themselves to a normal state, while the irritation caused by foods which can only be assimilated through their offices, must result in more or less permanent lesions. There are few who have not realized in some degree the suffering incident to the use of an inflamed muscle which prompts us to place it in a state of rest. The liver can make no appeal of this kind against its abuse; and whether the condition as the result of which it cannot make the normal disposition of the glucose be primary to it, or secondary to a primary lesion elsewhere, the continued use of such foods can only aggravate both primary and secondary lesions.

Now, the skim-milk furnishes a food of a kind which gives the liver a thorough rest—and a more complete rest than any other diet as yet suggested. This, I am forced to admit, is the only way in which I conceive it acts in the cure of diabetes. Hence it is that there are certain cases due to lesions remote from the liver, which are themselves incurable, either spontaneously or through direct treatment, which milk cannot reach; such, I believe, are some forms of pancreatic disease. In these cases, the lives of the patients are prolonged by any diet which furnishes the requisite reparative and force-producing elements in an available shape. In such case, a starchy and saccharine food is wasted, simply because the resulting grape sugar passes directly through the system. Milk and the albuminous foods, not being converted to any extent into grape sugar, are still available as force producers, and thus defer the unfavorable termination, or, in a word, keep the diabetic from starving.

It may also reasonably be asked, why is skim-milk superior to unskimmed? I believe any superiority consists in the fact that milk deprived of its cream is simply more easily assimilable than unskimmed milk, and therefore less likely to disturb digestion. There are probably none here who have not heard the complaint from certain patients that a milk diet makes them bilious, by which is merely meant that it causes indigestion. And there are doubtless many who have found the substitution of skimmed milk to remove these symptoms. I have, too, quite frequently observed that whatever food produces indigestion in a diabetic is apt to cause an increase in the glycosuria, independent of its composition, and I have sometimes thought that the use of the curd I have alluded to causes a slight return of glycosuria from this cause.

On the other hand, as already stated, I am quite in the habit of gradually adding unskimmed milk to the skimmed in cases of diabetes, and where there occur no symptoms of indigestion, I have continued it before adding other articles of food. In like manner, peptonised skimmed milk in which the casein is partly digested, is even more easily assimilated than the non-peptonised.

A second class of cases, in which the skim-milk has been of signal usefulness in my experience, and in which its results are capable of a more rational explanation than in diabetes, are cases of *uric acid gravel*. I have yet to see an instance of persistent uric acid sediment, in which the exclusive use of milk was not followed, sooner or later, by a total disappearance of the deposit, while I have known its persistent use to be followed by the easy discharge of uric acid calculi of considerable size, *per urethram*.

The rationale of these results has been made perfectly plain by the chemical study of the urine of persons on such a diet, by Dr. John Marshall, of the University of Pennsylvania, undertaken at the suggestion of Dr. Mitchell, a year ago, and repeated recently for me. It is rather singular that although skim-milk has been used for so many years in diseases involving a study of the urine, examinations of this kind were not previously made. The most important result of these analyses, is the fact that in the total twenty-four hours' urine of persons on the skim-milk, *no appreciable amount of uric acid could be found*.

Here, too, as might have been expected, the same results obtained, whether the patient used a diet of skimmed or unskimmed milk. Dr. Marshall examined for me for three days in succession, the urine of Mr. M., who had been for several weeks upon a diet of unskimmed milk. The quantity of milk ingested during these three days, was on the first day six pints, or 2,838 c.c.; on the second day the same, and on the third day five pints, or 2,365 c.c. The quantity of urine passed, was on the first day 1,356 c.c.; on the second day 1,580 c.c., and on the third day 1,070 c.c. The total urea in the first was 31.59 grams, in the second 27.96, and in the third 19.68. *Uric acid was not present in recognizable quantities—i. e.* 500 c.c. of each sample evaporated to dryness and properly extracted, gave no reaction with the murexid test. Dr. Marshall says further: "Uric acid probably might be found if five or six liters of the urine in question were evaporated to dryness and tested, most likely, however, only a trace."

Here, then, we have a simple rational treatment

for uric acid gravel, and as successful as it is simple. There seems, too, to be no reason why the milk should be skimmed for this use, rather than unskimmed, while the latter has the advantage that a smaller amount is needed to satisfy hunger and keep up the weight of the body.

As to the propriety of an exclusive milk diet in these cases of uric acid gravel, it may be determined by experience. While it may not be necessary in every case, in some it is absolutely so. In the case of Mr. M., who had several severe attacks of nephritic colic, and who, under ordinary mixed diet, as constantly passes a large daily amount of uric acid, as he is constantly in discomfort, the addition of bread only, to a meal, causes a return of uric acid, while a pure milk diet is unattended by such discharge.

While an exclusive milk diet is so efficient in cases of pure uric acid gravel, it is not to be especially recommended in *phosphatic calculus*. Indeed, it is rather contra-indicated. For the effect of a milk diet is to alkalise the urine, and therefore to tend to maintain a phosphatic sediment.

While nothing can be hoped for in respect to solvent action, or tendency to solvent action upon *oxalate of lime* sediments, by urine derived from a milk diet, yet, as it is commonly supposed that the same conditions of system which tend to produce uric acid are those which produce oxalate of lime, it may be expected that milk treatment will also be useful in the oxalate of lime tendency.

The third set of diseases in which I have found the milk treatment especially useful, are certain forms of *Bright's disease*. In these, more discrimination has to be exercised than in any of the foregoing. In general, it may be said that it is in the contracted kidney of interstitial nephritis that milk is most useful, the headache, nausea, vertigo, and "fulness" in the head, and the palpitations which are so often very annoying symptoms, are frequently relieved by it. Here, too, the skimmed milk is especially indicated, because anything which increases the labor of digestion aggravates the symptoms above mentioned as characteristic. It would seem, too, that those suffering with contracted kidney are better when the blood is not too good in quality or too rich in solids. On the other hand, it is not so necessary that the diet should be exclusively milk, and a sufficient quantity of bread and vegetables may be permitted to break up the monotony, while meat, eggs, and all foods rich in albumen should, as a rule, be prohibited. In this disease, especially, the constipation incident to a milk diet should be guarded against.

In parenchymatous nephritis and amyloid kidney I have found milk less useful, while it is still a very convenient and suitable diet, often producing diuresis and relieving dropsies. When a diuretic effect is desired, buttermilk is to be preferred, while it is as easily assimilated as skim-milk, and often more palatable.

That a milk diet should be useful in certain cases of *gastro-intestinal disease*, is generally recognized. There are two classes of cases for which it is adapted. The first is that represented by the ordinary dyspeptic, whose symptoms are sometimes dispelled as by magic by a pure skim-milk diet systematically carried out, and modified by the free addition of lime water. In a few instances of ordinary dyspepsia I have found the use of milk to produce flatulence, and to be altogether ill borne, but this tendency is corrected by peptonising the milk.

At the same time, I cannot too strongly recommend in all cases of simple dyspepsia where other measures have failed, a trial of the milk treatment in the systematic manner described, and modified as the peculiarities of the special case may demand, and especially in the event of failure with simple skim milk that the peptonised milk be tried.

But it is more particularly in the treatment of organic diseases of the gastro-intestinal tract that the bland and unirritating qualities of milk diet are indicated. In gastric ulcer the use of no other food than peptonised milk should be permitted. In chronic enteric disease of both small and large intestines, and particularly of the latter, it is very doubtful whether it is in our power, by therapeutic means, to directly affect the diseased parts. Our treatment must therefore consist in such measures as will favor nature's inherent tendencies to restore lost tissue. This can only be done by placing the patient on a diet which is nonirritating, leaves little waste, and at the same time makes the smallest demand upon the digestive function. To accomplish this, it is necessary to obtain his consent to the use of a diet of peptonised milk for an indefinite period. For no promises can be made as to the date at which other food dare be permitted. The uninterrupted presence of natural stools, and the continued absence of pain, are the only reliable criteria. To be able to carry out such a treatment satisfactorily, it is absolutely essential to secure the confidence of the patient. The process of obtaining this depends largely upon the personal qualities of the physician, and the ability to be able to speak authoritatively, but when the probability of almost certain recovery is held out, and it is shown that the good effect of weeks of treatment are undone by so simple a solid as a small piece of bread, the battle is half won. Particularly in those cases of irritation of the large bowel, attended by the discharge of mucus or mucus-casts, may we expect from the milk treatment the most satisfactory results, while success by local treatment is very rarely attained. The use of milk is rational, and consistent with what we know of the essential conditions of growth and repair.

I will allude to but one more use of the milk treatment, referring to Dr. Mitchell's little book on "Fat and Blood" for a better exposition than I can give of its use in the class of cases in the treatment of which he has earned so much reputation. The purpose to which I will refer is that for the removal of excessive *obesity*, and for this a skimmed milk is necessary. No treatment which has ever been suggested, is half so efficient. I have seen a lady disposed to obesity, who, in consequence of a more than usually quiet summer, and the liberal use of food, return to the city so much increased in flesh that she could not put on the clothing which a few months before was worn with ease, and suffering with a shortness of

breath which made walking any distance almost impossible, resume in the course of two weeks' use of skim-milk, to her usual weight and state of comfort. In these cases a pint of milk may be taken every four hours, or fifty-six ounces in the day, with directions to take more if hunger is not appeased. It is scarcely likely that even with this freedom too much can be taken to prevent the desired reduction in weight. It will be remembered that I referred to the case of a large man who was able to retain his weight upon twelve and a half pints a day, but when consuming ten pints daily, lost half a pound each day.

It may not be proper in all instances to reduce the weight so rapidly as can be done upon a skim-milk diet, especially when the subject is active or hard working, but it is to be remembered that obese persons are not usually of this kind, and that activity is facilitated by some loss of flesh. It is to be remembered, too, that the fat they carry is simply stored up in the subcutaneous tissue, because it is more than enough to supply the force-demands of the human machine, and has really had no use until the requisite daily amount of oxidizable material is not supplied in the daily food. Hence it is that when the weight is reduced approximately to a certain standard ratio to height, unskimmed milk or other articles of food should be judiciously added to furnish sufficient oxidizable material. But it is an interesting and important fact that when a certain stage of reduction is attained, further falling off, even with a moderate amount of milk, ceases, or takes place so slowly that it is easily made up by additions to the diet, to which of course there is no objection at this stage in the condition under discussion.

MEDICAL PROGRESS.

SURGERY.

THE TREATMENT OF GONORRHŒA BY OPEN WIRE BOUGIES.—D. C. M'Vail, M.B., in the *British Med. Journal*, gives a wood-cut showing three pieces of wire soldered together at one end with a flaring extremity at the other, of the size and shape of an urethral sound. The instrument is intended to keep separate the inflamed mucous membrane of the urethra during gonorrhœa, and also to allow the discharge to drain freely away, and not lie in the passage and give rise to renewed secretion. Another form has, instead of the flanged extremity, a short length of catheter-tube attached, and to that a short piece of rubber tube. The solution to be injected is introduced by a syringe, and when quite full, the India rubber tube is compressed by a spring clip, to prevent the escape of the fluid. Within from twenty to thirty minutes, the injection will be almost wholly absorbed by the urethral walls, and then the clip may be detached. These instruments are well borne in the urethra and the patient can pursue his ordinary avocations while wearing them.

PROF. LORETA'S NINTH OPERATION FOR FORCIBLE DILATATION OF THE ORIFICES OF THE STOMACH: RECOVERY.—On the 15th of March Professor Loreta forcibly dilated the cardiac orifice in the Surgical Clinique of Bologna. The patient, E. L., a young woman aged twenty, had for four years manifested all the symptoms, rational and direct, of ulcer of the stomach. For the last twelve months constriction had steadily increased; at first solids, and then liquids, entered the stomach with difficulty, so much so that only a few drops of broth could be swallowed at a time. Regurgitation of substances swallowed became the rule. The body wasted rapidly, and life could only be maintained with nutritive enemata. Having diagnosticated stenosis of the cardiac orifice, Professor Loreta proceeded to dilate it. He opened the abdomen in the linea alba, and found the stomach thick, small, and contracted. He incised it freely, and passed an elastic sound through the cardiac orifice to make way for his dilating instrument. This soon overcame the obstacle, in spite of efforts to vomit, and the œsophagus was found much dilated. The apertures in the stomach and in the abdominal wall were sutured separately. The operation was performed under chloroform in thirty minutes; and the patient, so soon as she had recovered from the narcosis, to the great surprise of the onlookers, swallowed three spoonfuls of water with perfect ease. Professor Loreta in a note to the *Lancet* states that the patient has entirely recovered.

RUPTURE OF THE URINARY BLADDER.—Dr. B. Beck, General and Corpsarzt of the 14th Army Corps of the German Army, has observed twenty-five cases of traumatic rupture of the bladder, and in the *Deutsche Zeit. f. Chirurgie*, he reports two cases at length, and adds the following conclusions (*Medical Press*):—

1. That simple rupture of the bladder may be caused by direct or indirect violence — falls on the feet or the lower end of the trunk — and that the momentary position and attitude of the body contributes in determining the situation, form, and extent of such rupture. The bladder will always give way at its weakest part, the anterior or posterior wall, the point being determined by the direction in which the contents of the bladder are pressed by the outside force.

2. The only characteristic symptons are those furnished by the wounded bladder itself, and these are: violent, frequently-returning attempts to urinate; inability to pass water spontaneously; flow of small quantity of bloody urine on passing the catheter; strong contraction of the bladder, whereby its capacity is diminished; free movability of the catheter, after which the small emptied space speedily fills up with some urine, which sets up renewed straining. If bloody urine escapes, the diagnosis may be made of extra peritoneal rupture, as it is only rupture of the anterior wall in the vicinity of blood-vessels that give rise to hæmorrhages. Oedema of the external genitals, caused by disturbance of circulation, supports the diagnosis of extra-peritoneal rupture.

3. The fatal termination in cases of simple rupture of the bladder is not a consequence of peritonitis, but of intoxication by resorption of decomposed urine.

4. Internal medicines are insufficient. The first requirement is the introduction of a permanent catheter, under strict antiseptic precautions.

As the urine that is poured out into the abdominal cavity is the greatest source of danger to the organism, the treatment in intra-peritoneal rupture should not be expectant. At the onset, or increase of local symptoms, if the general condition be gravely affected —and this will be seen in the course of a few hours— the following is the only mode of procedure calculated to save life: Laparations, removal of the urine poured into the abdominal cavity, thorough disinfection, and, finally, closure of the bladder-wound by suture. In extra-peritoneal rupture, when the urine has permeated the extra-peritoneal connective tissue, an expectant plan of the treatment is allowable so long as changes at the centre of infiltration do not point to the necessity for surgical interference. The main point in the treatment is the employment of a retaining catheter, with occasional cautious washing out of the bladder with some antiseptic fluid in order that no fluids capable of becoming disorganized may be allowed to remain, to the jeopardy of the patient.

MATERIA MEDICA AND THERAPEUTICS.

The Theory of the Mode of Action of Sulphur. —Unna (*Monatshefte für Praktische Dermatologie; Edin. Med. Jour.*) divides into two classes skin diseases benefited by sulphur. In the first — as acne, pityriasis capitis, and icthyosis, sulphur should be used in strong doses and persevered in. In the second — as eczema, sulphur should be used much weaker and only temporarily. If sulphur be applied to the sound skin, it soon produces an unnatural dryness, and finally, a weeping surface. In moist eczema, for a couple of days it dries and lessens inflammation. If injudiciously persevered in, it causes slight fresh outbursts of eczema. To account for this, Unna considers that sulphur in contact with the skin may originate various compounds, which may act differently on different tissues, and change in its action may be occasioned by its being brought in contact during its employment successively with deeper layers of tissue. The ordinary action of sulphur is comparable to that of very weak sulphuretted hydrogen. To study this, Unna prepared keratine by a complicated chemical process from fine horn shavings. This was soluble without difficulty in solution of sulphuretted hydrogen, and as the keratine dissolved the sulphurous odor disappeared. So that it is likely that a soluble keratinate of sulphur was produced. It is known that the process of cornification consists in great measure in a drying up, and it was found that the keratine of the young epidermic cells was more soluble in sulphuretted hydrogen than the older horny layer. The keratolytic property which sulphuretted hydrogen has been proved to possess is not so marked as that of dilute caustic alkalies, but is more noticeable, because sulphuretted hydrogen is more approximated to the acids, and keratine is in general (acetic acid being an exception) not soluble in acids. It is plain, however, that this keratolytic property of sulphur only explains the irritant action — that which causes eczema and artificial pityriasis. But it cannot account for the primary effect of sulphur when, employed in very minute doses, it "dries," cures eczema, and renders the epidermis smooth. This Unna explains by a keratoplastic action which sulphur exercises. It acts as a deoxidizing agent. In becoming horny the epidermis undergoes a reduction of its organic combinations, and a diminution of its vitality. Thus, in treating eczema with sulphur, its employment must be discontinued as soon as the desired effect, the drying up of the weeping surface, has been reached.

The Italian Medical Revival.—No one who watches with any degree of care the progress made in his profession can but admit that in the last few years Italian clinicians and medical writers have been coming to the front in a marked degree; and the *Lancet* calls attention to this in an article with the above heading, which reviews the medical men of Italy and their works in a brief but very satisfactory manner. Turin has now a thriving university under such leaders as Bizzozen and Novaro. Milan is now a great publishing centre. At Bologna Lireta has sustained, with some of the boldest achievements of modern surgery, the fame bequeathed by Rizzoli. Rome has become a center of greater intellectual activity than at any former period in the history of modern Italy, while Naples, with its 1,200 students and its staff of distinguished teachers, is, for numbers and activity, in the very front rank of contemporary medical schools. There are fifty-four Italian medical periodicals. If monographs and treatises are not relatively so numerous as the periodicals, it is nevertheless a fact, that in all departments of medicine and surgery, the Italians are every year giving proof of increased activity, to wit, the writings of d'Antonia, Bottini, and Mazzoni, of De Rossi, Massei, Maturi, and Bufalini.

Rectal Feeding and Medication. —Dr. Wm. Julius Mickle gives some very useful hints in a paper on this subject published in *The Journal of Mental Science*. In using nutrient enemata he advises that:

Alcohol should not be added to albuminous food.

If necessary, the bowels should previously be cleared out by a simple or aperient clyster, and a daily copious cleansing clyster is required in some instances. The bowels may have to be rested, but we must persevere if the first attempt fails. Where it is apt to return, the patient's best position to receive the enema is on the back or left side. The nozzle or tube should be comfortably warm, so should the food injected. The amount injected may sometimes with advantage be small at first, gradually increasing from 2 to 10 ozs. If the foods are ejected, we may try the plan (Dr. Hine's) of depositing them higher up in the viscus by means of elastic tubing and a funnel. But plugging the anus is often necessary, and has been done in many cases.

Conflicting as are the results of experiments on the subject, he concludes that the rectum and colon digest but little, and that, even when inverse peristole is set up, the action of the bowel upon enemata is chiefly absorptive. If so, the food should either be

introduced mixed with digestive substances, or else before administration should in some way or in some measure be digested, and ready for absorption into the venules and lymphatics of the intestinal walls.

The following methods are all considered good:

Leube. Three parts of meat to 1 part of pancreas, both finely minced and mixed with a sufficient quantity of warm water for clysis. Carefully remove all fat and connective tissue. The hog's pancreas is the favorite.

Rennie. To a basin of good beef-tea, add ½ lb. shredded lean raw beef; ʒj fresh peps. porci; ʒij dil. hydrochloric acid; warm for four hours, stir frequently. Beaten egg or alcohol (?) may be added.

Catillon. A saturated solution at 19° C. of peptone of meat, 40 grammes; water, 125 grammes; laudanum, 3 to 4 drops; bicarb. of soda, 3 centigrammes.

Dobell. Cooked, finely grated beef or mutton, 1 lb.; pancreatic emulsion (Lawry and Moore), 1 oz.; pancreatic powder, 20 grs.; pepsine (pig's), 20 grs. Mix quickly, add half an ounce of brandy, and warm water sufficient to bring it to the consistence of treacle.

Henninger. Very lean meat, finely minced, is placed in a glass receiver; water and H. Cl. are poured on, and pepsine, at the maximum of its activity, is added. The whole is left in a water-bath or stove to digest for 24 hours at 113° F.; it is then decanted into a porcelain capsule, brought to the boiling point, and whilst the liquid boils a sol. of sod. carb. is added to it, until it shows a very slight alkaline reaction. Then the boiling liquid is passed through a fine linen cloth. The liquid is reduced in bulk in a water-bath. White sugar is added before administration.

Mickle. A pint of milk, with one-fifth or one-fourth of a pint of water, is carefully heated to 140° F. Two drachms of liquor pancreaticus (Benger's), and 20 grains of bicarbonate in solution in one or two ounces of water, are added. The whole, in a covered vessel, is kept near the fire at 140° F. for an hour or an hour and a half, then thoroughly boiled for two or three minutes. Thus prepared the food keeps for half a day or a day.

In rectal medication Dr. Mickle has made extensive use of enemata of chloral hydrate in many cases of epilepsy and of epileptiform seizures. He gives thirty grains dissolved in two ounces of water, and has found it very useful.

OBSTETRICS AND GYNÆCOLOGY.

THE CASTRATION OF WOMEN.—Dr. Wilhelm Tauffer, of Buda-Pesth, gives in the *Zeitschrift für Geburtshülfe und Gynäkologie*, an account of twelve cases of this operation performed by himself, and then presents the following conclusions: (*Medical Times*).

1. Castration is an operation, which with proper care is not attended with any great risk; the unavoidable mortality being now less than 10 per cent. 2. The operation should be performed with antiseptic precautions and under carbolic spray; the abdominal cavity should be closed; drainage is only exceptionally required. 3. The limitation, that castration is not called for when the climacteric is near, can only be conditionally accepted, because the age at which the climacteric occurs is very different in different individuals, and cannot be foretold. 4. The condition laid down by Hezar, that the ovaries should be distinctly felt before their extirpation is attempted, is an impracticable one. 5. Both ovaries should be removed, even if the disease be limited to one; excepting in cases where special circumstances make it desirable to leave behind the apparently healthy ovary. The reason for removing both ovaries is, that the remaining gland has a tendency to become diseased in the same way as its fellow. . 6. It is generally desirable to remove the tubes as well as the ovaries; and it is unconditionally necessary if there be the slightest appearance of disease in them. 7. Hystero-epilepsy is curable by castration. 8. The symptoms grouped together under the name of hysteria, when rightly analyzed, can often be traced back to ovarian disease. 9. The question as to the influence upon uterine fibroids of the ligature of large nutrient-vessels going to them, without castration, is worth consideration. 10. With regard to prognosis, it is important to remember that the menopause only follows immediately upon the operation in those cases in which the neighboring organs are not diseased; but all inflammatory conditions of them delay the climacteric. 11. The final result of castration can only be determined after the lapse of months. 12. It must be regarded as an open question, how far diseases of the female sexual organs influence the development of certain psychoses. 13. So must the question whether such psychoses are curable by castration. 14. In the interest of unity and comparison of observations, it is desirable that the classification of cases (suitable for this operation) adopted by Hezar should be generally accepted.

NERVOUS DIARRHŒA.—Dr. Silverio Dominguez (*Anales del Circulo Medico Argentino Buenos-Ayres*) says on this subject: The violent emotions may be the cause of diarrhœa, and the female sex is peculiarly disposed to them. This nervous diarrhœa is probably produced by a paralytic dilatation of the intestinal canals from a reflex cause, in consequence the pains are but slight, and the dejections most frequently are aqueous, without being associated with any catarrhal or inflammatory process. The treatment should be directed to the nervous system; assafœtida in four gramme doses as an enema, may be given every two hours to advantage; while as an adjuvant an anti-spasmodic mixture of tilia and valerian may be used.

RESIGNATION.—Dr. C. C. Fite, Secretary of the State Board of Health of Tennessee, resigned that office on the 29th of May, 1884. Dr. Fite has been a faithful and efficient officer, and his retirement is much regretted, not only by members of the Board, but by all interested in the sanitary affairs of that State. His successor is not yet elected.

THE

Journal of American Medical Association.

PUBLISHED WEEKLY.

THE EDITOR of this JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information, should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE..... $5,00.
SINGLE COPIES..... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 65 RANDOLPH STREET,
CHICAGO, ILLINOIS

SATURDAY, JUNE 7, 1884.

COLLECTIVE INVESTIGATION OF DISEASE.—As stated in the minutes of the recent meeting of the American Medical Association, published in the JOURNAL of May 24, page 572, the invitation extended by the General Collective Investigation of Disease Committee of the British Medical Association, to coöperate by establishing similar work in this country, was accepted, and the President was requested to appoint a committee of seven members of the Association to take charge of the subject. The President did not announce the names of the committee at the time, and consequently they do not appear in the published minutes. He has since, however, authorized the appointment of the following members to constitute the general committee:

N. S. Davis, Chicago, Ill.; H. O. Marcy, Boston, Mass.; James Tyson, Philadelphia, Pa.; H. B. Baker, Lansing, Mich.; F. D. Cunningham, Richmond, Va.; S. E. Chaillé, New Orleans, La.; and Thos. F. Wood, Wilmington, N. C.

This committee was authorized by the Association to enter into correspondence and coöperation with the General Committee of the British Medical Association; to appoint, either directly or through the agency of the State Medical Societies, subordinate committees in the several States; and to adopt such measures as would best secure the efficient execution of a plan for the Collective Investigation of Disease in this country, so nearly parallel with that established in Great Britain, that the results in the two countries would be capable of mutual interchange and comparison. The State Medical Societies of Pennsylvania and Illinois, and perhaps some of the other States, have already appointed committees on the same subject for organizing the work in their respective States. It is desirable that all such committees appointed by State or local societies, put themselves in correspondence immediately with the above general committee, for the purpose of securing concert of action, economy in both labor and expenditure, and the greatest degree of efficiency in the practical execution of the work.

LEGAL DECISIONS AND THE ILLINOIS STATE BOARD OF HEALTH.—In another part of this number of the JOURNAL will be found a brief notice of two cases recently adjudicated in this State, one arising under a law creating a State Board of Examiners for licensing parties to practice dentistry, similar to the law regulating the practice of medicine, and the other under the last named law. In the first, the direct question brought before the court, was, whether the State Board had the right to go beyond the fact that a dental college was a legally chartered institution, and define what should be the extent of its curriculum or requirements for graduation, and exact compliance with its definition, before granting licenses to the graduates of such college? The decision of the court sustained the authority of the Board. On the same principles it would sustain fully the State Board of Health in enforcing its authority to define what should constitute a medical college on whose diploma a license to practice medicine should be given. In the second case the question presented to the court was, whether under the law regulating the practice of medicine in Illinois, the State Board of Health had the right to refuse a license to a party presenting a diploma from a medical College acknowledged to be in good standing, on the ground of unprofessional conduct on the part of the applicant himself? This was also decided in the affirmative by the court. These decisions are important, not only because they will add to the influence which such State Boards are capable of exerting over the medical colleges, but equally so in showing a disposition on the part of the courts to protect the people from the impositions of men guilty of unprofessional conduct and false pretenses before the public.

NEW JERSEY STATE MEDICAL SOCIETY.—This, the oldest State Medical Society in this country, will hold its one hundred and eighteenth annual meeting, in the Stockton House, Cape May, on Tuesday and Wednesday, June 10 and 11, 1884. President,

Stephen Wickes, A.M., M.D.; Secretary, Wm. Pierson, M.D., Orange, New Jersey.

DIPHTHERIA AND MICROCOCCI.—According to the remarks of Dr. H. C. Wood, in the recent meeting of the Pennsylvania State Medical Society, there is in the ordinary natural saliva of every person's mouth, a micrococcus or plant that cannot be distinguished from the micrococcus of the most malignant diphtheria; they were, as far as could be discovered, identical. The same micrococci were found in great abundance in cases of puerperal metritis, sloughing sores, and gangrenous wounds; from which he infers that diphtheria is not a specific disease, but simply a putrid or septic sore throat, of greater or less severity in different cases. This is returning very nearly to the opinions derived from clinical observation fifty years since.

DIFFICULT PROBLEM. — The Pennsylvania State Medical Society recently adopted the following resolution, offered by Dr. Jackson, of West Chester: "*Resolved*, That a committee of seven be appointed to consider the best method of making a diploma, which permits a man to practice medicine in Pennsylvania, an evidence of real worth." We fear that it may take seven very wise men a long time to discover a practicable method for accomplishing the object proposed.

TEXAS STATE MEDICAL ASSOCIATION. — At the annual meeting of this rapidly developing State organization held at Bolton, April 22 to 25 inclusive, a large number of interesting papers were presented in the Sections, among which was one on the Mineral Waters of that State, by Dr. J. M. Wells, containing much valuable information. The Association voted $100 to the Sims monument fund. The next meeting is to be held in Houston, commencing the fourth Tuesday in April, 1885. Dr. W. J. Burt, of Austin, Texas, is Secretary.

SOCIETY PROCEEDINGS.

GYNÆCOLOGICAL SOCIETY OF BOSTON.

Stated meeting second Thursday of October, 1883, President Wm. G. Wheeler, M.D., in the chair.

Dr. M. D. Church read a paper upon "Post-uterine Abscess," of which the following is a digest:

A brief history of the medical recognition of the disease was first given, it being but recently that this variety of abscess was distinguished from a less limited inflammation of surrounding parts.

Doherty, in 1843, in a paper entitled, "Chronic Inflammation of the Appendages of the Uterus," made the first comprehensive attempt to elucidate the pathology of pelvic inflammation. A brief review of the anatomical features of the lower pelvic region was given, attention being especially called to the large quantity of loose tissue surrounding the uterus, into which exudative products may pass, liable at any time to ripen into pus, such tissues as support the vagina and cervix uteri laterally, from the base of the broad ligaments, Virchow declaring to afford one of the most frequent seats of disease.

Pelvic cellulitis, it should be remembered, may occur both in the puerperal and in the non-puerperal subject. This is not necessarily synonymous with pelvic abscess, pus formation being only one of the results of cellulitis. We may still have the further conditions, viz.: (1) Congestion and effusion of serum, and (2) exudation of coagulable lymph. According to Priestley, in patients enfeebled and of impoverished blood, the inflammation generally results in serous effusion only, but this may be very extensive. Such *e. g.* was a case of Simpson's, who confidently diagnosticated abscess, but the exploring needle gave issue to lymph only. Such effusion may become so extensive and cause such distension as to simulate a solid growth. In a case attended by the reader, the exudation in Douglass' pouch assumed a rounded form, and it was difficult to decide between serum and pus. A study of the anatomy of the parts has been proposed as a means of determination of what course exudative material may follow, but without satisfactory results. If the phlegmonous inflammation is of moderate limits, however, the resulting tumor will pretty surely develop between the cervix uteri and the rectum in the direction of the broad ligament. Other possible locations were also declared.

There may be more than one focus of pus-formation with different issues correspondent. The evacuation may occur through the bladder, rectum, external surface of the abdomen, and rarely by the uterus. The most common place for an abscess to point is much disputed by authorities, but all agree that evacuation within the peritoneal cavity is very rare.

As respects treatment, more reliance is placed by modern therapeutists upon the dietetic management of the case than in the specific action of drugs. Keep patient well nourished, ensure sleep, relieve pain. As respects surgical interference, opinion is divided. Nature will generally secure final evacuation and in a manner favorable to the patient. Such casualty, *e. g.*, as an opening into the peritoneal sac, as already said, being very rare. If an artificial opening is to be made, the median line behind the cervix, unless the tumor point toward the rectum, is the point of election. The opening must be sufficiently large and a drainage-tube be inserted.

The following summarized statement closed the paper:

1st. Parametritis and perimetritis are rarely idiopathic or primary.

2nd cause. Either mechanical injury, uterine, tubal or ovarian disease of an inflammatory character, possibly tuberculous or malignant.

3rd. Cold, suppression of milk, etc., appear to have no etiological connection.

The question was proposed, At what time is a woman comparatively secure from attacks of parametritis and perimetritis? Also, How long after parturition, gonorrhœa, or local surgical operation, may she continue in danger?

Dr. A. P. Clarke followed with a series of reports of cases bearing upon the same subject, of which an abstract follows:

1ST CASE.—Mrs. —— had been married five years; had never had a living child. Upon summons, found her sitting up, complaining of pain in bladder and left groin; had had chills, which were referred to a coincident sore throat. Pain steadily increased in extent and severity. Repeated vaginal examinations failed to discover any marked and localized point of tenderness. Later the pain became more severe, with an occasional chill, which was invariably followed by profuse sweating. Diagnosis, pelvic cellulitis, with probable formation of abscess. No fluctuation nor marked swelling present, but at times there could be elicited greater tenderness behind the uterus than in any other part. Patient stated she had had a similar experience one and a half years before, but had recovered, and, in the opinion of her physician, had not had an abscess, but some kind of a nervous attack.

Later, on vaginal examination, a small quantity of pus was discovered, but its source could not be determined. She now became easier, and was able to be about the house. Again she was suddenly taken worse. There were several repetitions of this experience, and indeed, she had two subsequent attacks, in which a very little pus was seen, aside from what escaped with vaginal discharges. Still, the general character of the attacks, the chills, sweatings, etc., seemed to indicate suppuration, and such was the diagnosis.

The following year she was seized with all her old symptoms, but having in the meantime moved from the place of her former residence, she was obliged to call in another physician—an eminent surgeon connected with the City Hospital, Boston. In his hands the case remained for a short time until Dr. C. was called in to take charge. The surgeon, in the meantime, had wholly discredited the diagnosis, which had been made on occasion of former seizures, and did not believe she had ever had abscess. He had not used a speculum as an aid to diagnosis, nor, indeed, instituted any thorough local investigation. The next day, with the help of a Sims' larger speculum, and the assistance of a view in a good light, Dr. C. was so fortunate as to detect a point where there seemed to be fluctuation, and by means of a small trocar and bistoury, was enabled to let out a large amount of fœtid pus, to the speedy and great relief of the patient. She had since removed beyond observation, and is understood to have had since then, still another attack, of which, however, no definite knowledge has been obtained. The original cause was, doubtless, a hæmatocele or some accident to the perimetric cellular tissue upon occasion of abortion. (Dr. C. followed with several similar reports, of which, however, a digest cannot be given for lack of space).

The chair remarked, as introductory to the discussion, that Dr. Clarke had been unusually fortunate in his series of cases—certainly as judged by his own experience.

Dr. M. L. Brown referred to a class of cases not considered by Dr. Church, where we have what may be called a peri-uterine abscess. In such occasional cases, doubtless, where death had followed, the patient might have been spared had the diagnosis been made earlier and the pus evacuated. Such cases too often break into the peritoneal sac and cause death, whereas the abscess, which Dr. Church had described, is more apt to make for the surface, burrowing under the sheath of muscles.

Dr. A. P. Weeks recalled a case, previously reported in part, where a Boston physician had attempted to replace a retroverted uterus, allowing the patient immediately after to return to her home in Chelsea. A week afterwards, Dr. W. detected fluctuation, and with Dr. Warner's assistance, had aspirated. The woman had never fully recovered, was not well to-day; the uterus was low down in the pelvis and fixed, and the tissues about it hard, contracted and unyielding. Saw another case while in the country; it had run on since Christmas and continued till the following May. The accompanying swelling had been diagnosticated as pregnancy by successive physicians, and had been called a tumor. There was a mass rising up to the crest of the ilium and filling the cavity as high as the umbilicus on the right side; was very tender. A spiritualist was called in who made certain motions and required certain movements on the part of the patient, when the tumor suddenly burst, was discharged by the rectum and the patient got well.

In such cases it is important to make an early diagnosis and evacuate as soon as possible. Once that the pus gets loose, it burrows and runs everywhere. Recollect a case of Dr. Wheeler's where the pus, after such history, presented at many points and continued to discharge for two years. Dr. Mundé, in a recent paper, had distinguished perilymphangitis from cervicitis; in the former condition applications of iodine do harm. As to treatment, Dr. Weeks had used mercuric chloride, hot injections, iodine locally applied, and insisted upon rest.

Dr. Wheeler emphasized the difficulty of getting to the bottom of the sac; the distribution of the deep fascias causes the pus to appear at the most unlooked for points. We make an opening at a point so remote from the primary abscess that we have a long, fistulous passage, and cannot know what the most pending point is. In Dr. Weeks' case, he opened in five places, but could never detect a point of fluctuation or bagging internally. Patient suffered for three years from these fistulous openings before final closure and recovery. Now all this could have been avoided if diagnosis could have been made, and proper measures taken, early.

Dr. Stoddard applied the same criticism to the case first reported.

Dr. Clarke rejoined: One patient had been told by a prominent physician that there was no pus there, and it was very difficult to prove that there was. So with another patient—a prominent surgeon had declared that there was no abscess; and yet she had chills and other symptoms of suppuration; but he was fortunately able to demonstrate the fact of the presence of pus by means of a speculum in a good light.

Dr. Church responded that at least three authors unite in reporting cases in which there having been constitutional evidence, but no local signs of pus, it was believed there may have been an opening into the bowel so high up that pus mingled with the fæcal matters and thus escaped detection when discharged with the excrement.

Dr. W. S. Brown thought Mathews Duncan, in writing upon the present subject, sometimes made too nice distinctions. The relation of gonorrhœa to the disease under discussion was of interest. Had at present a case under observation, where both husband and wife acknowledged such origin; and he had his suspicions in another case. Inflammation, thence resulting, may present the tissues so agglutinated together that we can hardly tell one from another. Veins and lymphatics are also affected, and patient suffers from pains passing down the legs. As respects the question of gonorrhœal implication, the woman does not know and the man will not tell,—this is too often the case, at least,—and we are left to our own unaided investigations. As to treatment, one thing is essential,—early evacuation, washing out the cavity and drainage. Prompt diagnosis is of the utmost importance. Here is an argument in favor of making vaginal examinations. There is an unfortunate prejudice with many physicians in this direction, but such examination should be insisted upon whenever we have cause to suspect inflammation.

Dr. Church proposed the question: Called to a case of a week's standing, with history of pain, a soft spot is found, but even by bimanual examination, no evidence of fluctuation is afforded:—should an incision be made at a venture, or should the physician still wait?

Dr. Wheeler replied, If there are well-marked constitutional symptoms, with hardness indicating pressure of pus, it is no longer necessary to wait for fluctuation now that we have the aspirator. It is the surgical part in these cases that is apt to fail of due attention; there is too general a fear that by interference we shall do the patient harm; we rather do harm by waiting, as the pus will burrow, and, not having contact with the air, occasion but little trouble to the patient until it finds its opening; then the mischief is done, as in Dr. Clarke's case.

Dr. Weeks estimated that a week's time was short for pus to be formed in such a case; moreover, we should not expect pus until after the chills and sweating. Then we hardly get fluctuation in this location so much as the so-called bagging.

Dr. W. S. Brown had observed that some hesitate on account of hæmorrhage, which it is especially hard to avoid and control. A good method is to make a very small opening, and then dilate as with Hanks' dilators, and tear the parts. Thus we get a better, safer opening, and one not so liable to close.

Dr. Norris referred to a class of subjects who have what may be called *pyrotechnic* pelves—inflammatory subjects, who are always ready to take fire, and on small provocation. Such are pretty sure to have trouble, and make trouble, after any surgical operation. Had a case in mind to whom mischief came after every confinement, four in succession. She would have an inflammatory seizure even after the passage of a sound, when in a non-puerperal state. Should expect such subjects to cause especial trouble in the complication under question.

And they are not to be recognized, rejoined Dr. Field, by any sign or condition they carry about them. The fact that such subjects are very sure to afford a certain ratio out of all patients treated, should serve as a constant warning against gynæcological interference—even to the passage of Simpson's sound—at the office of the physician, the woman being expected to go home afterward. The uterine patient should always be treated upon her own bed, where she can be kept absolutely still from the moment that the examination is completed or the application made, for an hour or a day or two afterward, as the case may be.

Society adjourned.

HENRY M. FIELD, M.D., Secretary.

PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

SECTION FOR CLINICAL MEDICINE, PATHOLOGY, AND HYGIENE.

ALBERT N. BLODGETT, M.D., SECRETARY.

MARCH 12, 1884.

Meeting called to order at 8 o'clock. Dr. Edes being absent, on motion of Dr. J. W. Farlow, Dr. E. T. Eastman was elected chairman *pro tem.* A summary of the records of the last meeting was given by the Secretary, which was approved.

The first paper of the evening was by Dr. G. Liebmann, entitled

SPINAL IRRITATION AND NEURASTHENIA.

Dr. S. G. Webber in opening the discussion said that the difference between neurasthenia and spinal irritation is not so definite as the author states in the paper to which we have listened. The two diseases depend upon similar conditions. The distinctions made in the paper are purely arbitrary. The two affections run into each other. That state or condition which the author calls "false spinal irritation" depending on irritation of the pelvic organs cannot be too constantly kept in mind. We do not always realize how much disturbance may arise from this cause, not only in women but also in men. Dr. Webber is far from satisfied with the usual explanations of spinal irritation, and does not believe that

anæmia or hyperæmia of the cord is a necessary or universal condition. In many cases there may be at times excess and at other times deficiency of blood supply. In most patients it is doubtful if the symptoms depend on disturbance of the circulation. There is probably an exhaustion of the nerve-cells, often in the brain, sometimes in the cord or in the sympathetic system. Their reactions are irregular, and disturbances of function and secretion result. Heredity exerts a grave influence in neurasthenia and spinal irritation, and is an important etiological factor in these diseases. In such cases the parents, frequently one, often both, have not strong and vigorous constitutions. The scenes and influences of childhood are sometimes at fault, and the neurotic condition may be developed where there is no hereditary tendency. Late hours are not beneficial to children, but predispose to the various neuroses. We do not see children romping and playing nowadays as was the habit years ago, but they go to evening parties, sit up late, and eat stimulating food at unseasonable hours. Too warm and ill-ventilated rooms are also doubtless predisposing factors in the production of nervous diseases. Our school-rooms are often kept at a temperature of 72° F. to 75° F. Children are also sent to school at too early an age, and are thus exposed to unfavorable influences at a perilous period in their nervous development, and frequently become the subjects of neurotic derangements.

Dr. J. J. Putnam said that he did not believe that there was any clinical or pathological advantage in trying to draw a line between neurasthenia and "spinal irritation," so called.

The former term, although vague, is a convenient one, but does not, like the latter, prejudge the pathological diagnosis. Our knowledge of the functions of the spinal cord does not justify us in referring the majority of the symptoms of so-called "spinal irritation" to the disease of that organ. On the contrary, the complicated cerebral functions, including those which have to do with the animal and vegetative processes, probably are affected in all the cases of this class, and this affection furnishes their predominating characteristics. It is on these functions that the evil influences transmitted by heredity mainly fall.

At the same time it is not to be denied that the ganglia of the spinal cord and sympathetic may share in the disorder. Dr. Putnam agreed with the reader and with Dr. Webber that the tendency has been to pass slightingly over the nervous symptoms to which diseases of the male genital organs may give rise, although it is true that congenital instability of the central nervous system is usually needed to furnish the material for these symptoms.

Dr. Douglass Graham said he thought we were inclined to be myopic in limiting our observation to reflex neurasthenia arising from irritation of the sexual organs alone, even if this were one of the most frequent causes. Pain or disturbance in any organ, especially below the diaphragm, he said, gave rise to reflex neurasthenia. Indeed, neurasthenia forms the background to the picture of all diseases and injuries whether of an organic or functional nature. The simplest form of neurasthenia is the natural and not unpleasant fatigue which results from an active and satisfactory day's work, from which we recover by food and sleep. After this comes the fatigue from which we do not recuperate as usual, the fatigue of being overworked, or in common parlance "played out," when rest and change are of the first importance. Thirdly, there are the continually wearied, wakeful, nervous business or professional men with numerous and varying ailments who have learned by experience that "the labor they delight in physics pain," and who find more relief in work than in rest Many physicians, doubtless, find themselves in this class, especially at this time of year. Then there are the neurasthenics who are such because they have no object in life, who are spoiled children with plenty to live on, and usually more, who can do what they please and cannot do what they do not please, who take delight in telling of all the eminent medical authorities whose care they have been under without benefit, and who are never happier than when they can be regarded as interesting, by trying some method of treatment that is novel to them, so that they may finally have the satisfaction of saying that it did them no good. A classification of neurasthenia based on causation might be indefinite.

Dr. G. L. Walton considered the brain the chief if not the only sufferer in the cases under consideration. Certainly such symptoms as cramps and pain in the back and loins could arise from the brain as well as from the cord, while the mental symptoms could only arise from the brain. Whether the spinal centres were implicated or not, enough had been said to show the non-existence of a distinct class of cases to be gathered under the term spinal irritation. In this case further division into pseudo-spinal irritation was absurd. He thought that all we could say by way of pathology at present was that there is a large number of nervous patients whose symptoms fall neither under hysteria nor hypochondria, whom we may name neurasthenical, locating the functional disturbance in the central nerve-cells. It remained to inquire if the sub-classification proposed would prove of clinical value. The impression conveyed by the paper was that the practitioner had only to ask himself whether the patient before him suffered from neurasthenia, spinal irritation, or pseudo-spinal irritation, and to regulate his treatment accordingly. In point of fact all these cases had to be treated as individuals, one needing rest, another exercise, and so on, any attempt to treat in classes being destined to prove a failure.

Dr. Morton Prince spoke as follows: There is one point which has been raised here on which I wish to say a few words, and that is the question of the cerebral origin of the symptoms of spinal irritation. I cannot agree with Dr. Putnam as to the cerebral origin of these symptoms. This view has lately been advanced with considerable force in an article by Dr. Walton. That some of the symptoms met with in spinal irritation, or neurasthenia (as you may choose to term it), such as vertigo, melancholia, anorexia, pains about the scalp, mental weakness and irritability, and many symptoms distinctly hysterical, are cere-

bral in their nature every one admits. About such symptoms there is no question. But that there is another larger group of symptoms which are of spinal origin, I believe there is also no question. Such symptoms are numbness and pricking in different parts of the body, pains over the spine, neuralgic pains of all kinds. In some cases of nervous prostration the cerebral symptoms may be so prominent as to predominate. Such cases have been denominated *cerebrasthenia*, in distinction from others where the cord and nerves are principally implicated.

When a functional nervous disease is met with, the symptoms presented are individually such as are caused by organic disease of the same segment, the difference being due not to the essential character of the symptoms, but to the method of grouping, the absence of some symptoms and presence of others, the onset, course, severity, etc. The symptoms met with in functional disease of the cord are such as occur in organic disease of the same part, and the symptoms observed in functional disease of the brain are such as occur in organic disease of the brain. In other words, the symptoms caused by functional or organic changes in a part are conditioned by the physiological functions of the part. For example, we get atrophy with the electrical reaction of degeneration in the muscles of the limbs from organic disease of the anterior cornua of the spinal cord and not from disease of the brain, and conversely we get aphasia from disease of the brain and not from disease of the cord. Now, the group of symptoms met with in pure spinal irritation(?) are such as are met with in organic disease of the cord and not of the brain; and therefore there is every reason to believe that their origin is spinal and not cerebral, and especially is this the case when in severe cases the symptoms are so similar to, nay, almost identical with, those produced by inflammation of the cord and its membranes, that it may fairly be questioned whether we have not to do with an organic and not a functional disease. I cannot help thinking that some cases which have been described as spinal irritation are in reality mild forms of inflammation.

I do not mean to say that some of these symptoms may not occur isolatedly in organic brain disease. That may happen with some symptoms, as, for example, anæsthesia and paralysis, which are common to both cerebral and spinal disease. But they do not occur in similar groups, and some symptoms are not present at all. In functional brain disease nearly every kind of symptom may be met with, but here the grouping is different, and it is a question whether some of the symptoms of functional brain disease, as hysteria, may not be dependent upon implication of the cord. In fact, this is much more likely than that the fundamental symptoms called spinal irritation are due to cerebral disease.

As this is a practical and important question, it may not be out of place here to refer to the argument advanced in the paper I have just mentioned. Pains in the back and sensitiveness over the spine are referred to irritability of the *cerebral* centres, because the centres for *feeling* are in the brain and not in the cord. A similar process of reasoning would as well explain the pains and tenderness complained of in sciatica, spinal meningitis and myelitis by a disease of the brain.

In regard to the differentiation of spinal irritation from neurasthenia, Dr. Prince was glad to hear Drs. Webber and Putnam express doubts as to whether they could be regarded as distinct diseases. If we examine the descriptions of spinal hyperæmia, anæmia, irritation, and neurasthenia given in the text-books, it would be found impossible to form any clear and definite picture of each as distinct from the others. Erb, to be sure, had described neurasthenia as characterized by being more common in the male sex, while the symptoms exhibited were principally sexual and motor weakness, sensory disturbances being less prominent. Spinal irritation, on the other hand, he had practically limited to females, while the sensory disturbances were very prominent. Ross, in England, had followed Erb's description. In America, on the other hand, the speaker thought that it was the general experience of neurologists that neurasthenia was greatly more common in women, while the group of symptoms included under the name was identical with that described in Germany and England as spinal irritation. It did not seem, then, that there were sufficient grounds for differentiating two diseases.

It is impossible that the disease could be occasioned by molecular changes in the spinal cord without having resort to the theories of anæmia or hyperæmia. Sigmund Mayer has made some investigations on the changes which physiologically occurred in normal nerves. His observations were made on the nerves of a large variety of animals and also of men, and showed that the peripheral nerves of vertebrates are not fixed structures, but are continually going through a process of degeneration, followed later by regeneration and a return to the normal condition. The changes observed were similar to those which take place in a nerve which has been divided or otherwise injured. These changes he believes to be constantly taking place, so that in every nerve may be found a number of fibres in this condition.

The thought naturally suggests itself whether these changes may not play some important part in the production of functional nervous diseases. Mayer suggests that this may be the case, and that those neuroses represented by transitory impairment of the sensory and motor functions are due to an increase in the normal number of degenerated fibres, and thinks that these changes are destined to become prominent factors in future neuro-pathology. If these results shall be confirmed by other observers, we have here a means of understanding how disturbances of sensation and motion such as are met with in neurasthenia may be caused by molecular changes alone, and this thought is reënforced by the fact, that while the anatomical changes which are said to occur in normal nerves are similar in kind to those observed in an injured nerve, differing only in degree, so, many symptoms met with in spinal irritation (neurasthenia), such as formication, numbness, pain, muscular weakness, etc., are similar in *kind* to those caused by injury to a nerve, though they differ in

degree, grouping, mode of onset, and persistency. If similar changes shall also be shown to take place in the central nervous structures, we shall have a complete theoretical picture of anatomical changes which may be at the bottom of neurasthenia.

The idea at present is merely speculative, but is interesting as suggesting a direction for future investigation.

Dr. T. A. DeBlois read a paper upon

TONSILLITIS.

Dr. J. W. Farlow opened the discussion upon this subject as follows: I agree with Dr. DeBlois in thinking that it is not possible to draw so sharp a line as is generally done between follicular, parenchymatous, and phlegmonous tonsillitis. When the parenchyma is affected, the follicles are also liable to be, giving rise to the secretion, more or less of which we find in most cases. Of two cases which begin and continue alike for several days, one may remain an ordinary case of tonsillitis, while the other goes on to the formation of an abscess.

The difficulty of knowing whether diphtheria or some other disease is to follow what looks at first like simple tonsillitis, has been well described by the reader, as also the need of "hedging" in communicating the diagnosis to the friends of the patient.

In cases seen early where there is much fever, I am in the habit of ordering a Dover's powder or aconite, to be followed by a saline in the morning. I have never satisfied myself that I had benefited a case by the use of guaiac or chlorate of potash.

I have never found astringent gargles of more use than very hot water. I direct the patient to fill his mouth at frequent intervals with hot alkalized water and hold it for several minutes. He is then to let the water run out by holding his head over a basin. This serves to remove the thick, tenacious secretion of which patients always complain, and which they find great difficulty in expectorating. Gargling is always a painful process in such a case.

I find relief from scarification, especially when the uvula is œdematous. When the presence of pus is probable, a deep incision, whether pus is found or not, makes the patient much more comfortable.

Dr. Prince thought it was a very interesting paper, and agreed with the reader in what he had said regarding the efficacy of the different varieties of treatment that were in use. For himself, he took a different view of the pathology of the affection from the reader, and believed in the *constitutional nature of the disease*. This was a point of considerable importance from the stand-point of treatment. He did not mean to say that every case of follicular tonsillitis was the expression of a constitutional fever. On the contrary, as in inflammations in other parts of the body, there was a local as well as a constitutional form.

Specialists who principally have to do with cases in dispensary and office practice meet with the former variety, while general practitioners see the constitutional form. The latter class of patients are usually too ill to leave their beds, much less the house, and are not found in out-patient departments of hospitals, or at least not till the disease has run its course. In this way the difference of opinion regarding the pathology of the affection can be explained. He thought that specialists were more inclined to see in follicular tonsillitis only a local affection, while general practitioners more commonly thought it of constitutional origin.

His own views of the constitutional nature of the affection are based upon various facts; among others, the severity of the constitutional symptoms observed. Even when associated with insignificant local inflammation, it is not uncommon to see high fever, great prostration, severe backache, sweating headache, anorexia, and stupor, followed by protracted convalescence, though the local trouble was so slight as hardly to induce the patient to use the gargles, etc., prescribed.

As a result of his studies he has found:

(1.) With slight local inflammation high fever and severe constitutional disturbance, and *vice versa*.

(2.) Slight local inflammation and slight increase of temperature, combined with severe constitutional symptoms, showing that the latter were not dependent upon the fever.

As "hospital sore throat" the disease was very common amongst internes and nurses in hospitals. He had found as a result of his inquiries that 63 per cent. of the internes in the Boston City Hospital had the disease, and that 59 per cent. of the nurses in the hospital at the time the inquiry was made had already had it. Many more would probably have it before their term of service was finished. Under these conditions the disease was usually very severe, more so than could be accounted for on the theory of a simple local inflammation.

The disease also occurred in epidemics, of which several had been reported. He had recorded two in a paper on this subject read before the Society about two years ago. In the epidemic form it was certainly constitutional.

The reader had said that he himself was liable to the disease and was frequently affected, but Dr. Prince believed that while this might be true of simple catarrhal sore throat, such as is met with in dispensary practice, the form to which he referred he believed usually occurred but once in the same individual.

In regard to treatment of this form, he had found the best to be painting the throat frequently, every hour or two, with co. tinct. benzoin. The tonsils must be thoroughly covered each time so as to leave a deposit of the yellow gum upon the surface. This always relieved the pain, and enabled the patient to swallow with comparative comfort. He had not yet met with a case which was not benefited by this, though of course it could not be inferred that the remedy would never fail. An ice-bag around the neck gave great relief to the head symptoms, while sponging the body with alcohol and water did the same for the backache. He also gave Dover's powders at night, and sometimes during the day. The constitutional symptoms, in his experience, called for more active treatment than the local manifestations.

Dr. Cobb mentioned a case of tonsillitis occurring

in a Swedish girl, accompanied with the appearances of abscess. On puncture, a small amount of pus was liberated, but the entire quantity was not evacuated. Within a week the girl was admitted to the City Hospital with scarlet fever. The question was asked if such cases were frequent.

Dr. DeBlois stated that one such case had recently come to his notice. The case was one of follicular tonsillitis with much depression and exhaustion of strength. The prognosis was of a grave character from the threatening nature of the symptoms, which led to the apprehension of some other more serious disease, and a few days later the patient suddenly expired while being brought down stairs to be taken to the City Hospital.

The following particulars in this interesting case were communicated by Dr. George G. Hayward, the physician attached to the dispensary district in which the patient lived.

DIPHTHERIA WITH COMPLICATIONS.

Patient, male, nineteen years of age, laborer, single, born in Ireland, had only been in this country a few months, was a strongly built man, of temperate habits. He first came under my charge December 12, 1883, and was treated at that time for dyspepsia and a heavy cold, from which he soon recovered, and after a few days went about his work again. I next saw him February 2, 1884, and learned that the day previous he had been to the Boston Dispensary Throat Department, where he had been treated, and that diphtheria had been suspected. At this time I found him with a high fever. Temperature 105° F., rapid pulse, tongue heavily coated, and all the soft parts covered with a distinct membrane, some of which was with difficulty removed. On further examination the body was found covered more or less thickly with a fine rose-colored eruption, more especially marked upon the lower part of the abdomen and thighs (where he was actually the color of a boiled lobster).

Diagnosis, was made of diphtheria with scarlatina. I afterwards learned that there had been scarlet fever in the house a few weeks previous.

Treatment, was Dover's powder at night, hot gargles, or rather douches, steamed flannels externally, changed often, and replaced by dry ones, steam inhalations, and as much steam as possible kept in the room, carbolic sprinkled about the floor. The mouth was swabbed out three times daily with hot water applications.

Diet. Milk, beef-tea, ice. Stimulants in milk occasionally. Nourishment was taken fairly well until the last day, so much so that it was only given by the mouth.

February 3. Temperature 104° F. About the same condition, breathing well, however; treatment continued.

February 4. Temperature 103.5° F. Seemed somewhat improved and brighter; more membrane removed, and it was stated that some more had been coughed up during the night.

February 5. Was called early, on account of alarming symptoms. Temperature 104° F. Face flushed; skin dull color; pulse slow and feeble, but breathing was good; voice very feeble. There was no indication for tracheotomy, which I had supposed might be required from what was told me of the symptoms.

The trouble seemed to be rather failure of the heart's action than anything else.

Dr. Kingman saw the case with me in consultation, agreeing with me as to diagnosis, and we decided it was best to send the patient *at once* to the hospital.

The heart was examined at this time as it had been several times previously, and no organic trouble could be detected.

Digitalis was at this time given, followed later by carbonate of ammonia, and the patient was ordered to the hospital. On leaving him he seemed considerably improved, and roused himself enough to shake hands and ask me to come and see him.

Brandy in milk was ordered before starting.

Instead of taking him at once, he was left three hours, and while being carried down stairs, having just reached the lower landing, he fell and died soon after. This would seem to indicate failure of the heart, and had it not often been previously examined, should have been inclined to suspect organic disease.

The case seems to me doubly interesting,—

(1). As a rare combination of diseases.

(2). As to the cause of death.

Dr. Farlow asked if any member had been able to observe any beneficial result from the employment of chlorate of potassium in tonsillitis.

In answer to Dr. Farlow's question as to the curative effect of chlorate of potassium in tonsillitis, Dr. V. Y. Bowditch said that he had no faith in its curative effect, but believed that hot gargles containing it often gave great relief both from the grateful sense of warmth and from the fact that it seems to cleanse the mouth from the thick secretions and disagreeable taste which are present. He also testified to the efficiency of the guaiac lozenges in relieving soreness of the throat, and recommended those of the London Hospital Pharmacopœia as being pleasant to the taste.

Dr. Disbrow asked Dr. DeBlois if there was any means of aborting the disease in its early stage. Speaking from his own experience, having suffered for many years with attacks of tonsillitis, he found by painting the tonsils with tinct. iodine comp. two or three times a day in its early stage, he prevented the formation of pus and cut short the disease. He had also found a strong solution of nitrate of silver useful, and had used the comp. tinct. guaiacum, but had not found any benefit from it. He had used, to hasten the formation of pus, an old domestic gargle composed of vinegar, water, sugar, and capsicum in conjunction with hot poultices externally. In follicular tonsillitis he had found painting with tinc. iron very useful. In regard to the guaiacum troches, they have been very useful in a case of irritative cough after other means had failed.

Dr. DeBlois thought that patients often swallow with less difficulty after the use of chlorate of potash, and this is certainly of benefit as far as it goes. If we can remove the pain and discomfort, the inflam-

mation will in many cases take of itself. Scarification is often of service in the same way. Troches containing guaiacum are also often of service in tonsillitis.

Dr. Harlow stated that in the opinion of an eminent Boston physician, now dead, guaiacum never did anybody any good except the apothecary.

Adjourned at 10.5 o'clock.

STATE MEDICINE.

THE ILLINOIS MEDICAL PRACTICE ACT.

Recent decisions in two cases, one under the act to Regulate the Practice of Medicine in Illinois, the other under the Dental Surgery Act, sustain the right of the State Board of Health to determine the status both of a college and of a practitioner. Under the latter act the Supreme Court refused the petition of Isaac Sheppard for a writ of mandamus to compel the State Board of Dental Examiners to issue him a certificate or license, based upon a diploma of the Indiana Dental College. The Board refused the license on the ground that the college was not a "reputable institution." It was argued that the law constitutes the Board, judges of the standing of a college, and there is no power of review vested in any other body. "If the Board should arbitrarily or unreasonably abuse their discretion, and refuse a license without any reason therefor, there is a remedy for such abuse of said discretionary power." But there was no ground for claiming that this was the case in the present instance. The Board in its judgment had decided that the curriculum of study and requirements for graduation of the Indiana Dental College were not such as to entitle it to be classed as "a reputable dental college;" and there is no power in that law, given to any person or body to review and set aside, or confirm, the exercise of the discretion by the board. The petition for a mandamus was denied.

In the case of the State Board of Health against C. Buel Rice, of Cincinnati, a graduate of the Medical College of Ft. Wayne, tried in the Sangamon County Court, the defense set up the plea that, being a graduate of a "legally-chartered medical institution in good standing," the defendant was entitled to a certificate of the Board; and that it was not competent for the Board to inquire into the moral or professional character of such graduates. On the part of the prosecution it was shown that charges had been presented to the Board, alleging that Rice was in the employ of, and associated with, the "K. & K. Surgeons," a firm of advertising quacks, from Cincinnati and elsewhere, and that, in various ways connected therewith, his conduct was unprofessional and dishonorable within the meaning and intent of the Medical Practice Act. Upon these charges the Board had refused to issue Rice a certificate until he had disproved the same. Instead of making any attempt at such disproof, Rice continued to practice; whereupon he was arrested for practicing without the necessary certificate. The facts were admitted by the defense, but, as already stated, the court was asked to dismiss the suit on the ground that it was obligatory on the Board to issue its certificate to the possessor of a genuine diploma of any "legally-chartered medical institution in good standing," regardless of the moral or professional status of the individual. This the court declined to do, but found the defendant guilty, and assessed a penalty of $50 fine and costs.

BOOK NOTICES.

Annual Report of the Health Officer of the District of Columbia, 1883.—This report by Dr. Smith Townshend is filled with the usual valuable tables for reference, and is prefaced by a congratulation on the part of the health officer that the efforts of his department were successful in preventing the introduction of small-pox into the city during its prevalence in an epidemic form in Baltimore in the fall and winter of 1882–83, which certainly shows watchfulness and energy when we reflect that the two cities are not forty miles apart, and communication is constant and varied. Washington it seems with its population of 191,980, has 15,611 sick poor cared for by this office, of which 10,264 are colored, and it costs $3,156.85 to furnish them with medicines. There certainly seems to be no waste expressed in these last figures. Dr. Townshend handles the subject of trade nuisances in a very practical and satisfactory manner; he devotes some space and illustrations to showing how the odors, etc., in making ammonia, illuminating gas and asphaltum are got rid of. With ammonia the gasses are passed in an upwardly-ascending (?) current over moist retarding surfaces and upward through a descending spray of water, so as to cool and wash the gases, and then turning them in their washed and cooled condition at an intense heat by forcing them into intimate contact with incandescent or ignited combustible and inflammable substances. To explain this properly of course requires reference to the illustrations. The apparatus has been in use for over a year and seems to have accomplished all that is claimed for it. With asphaltum the high heat used (700° F.) in refining it, results in the formation of hydrogen sulphuret, bisulphite of carbon and other very disagreeable gases. To destroy these gases combustion is employed by exhausting them from the covered kettle containing the heated asphaltum, through a close conduit into a furnace, where they are consumed. The thoroughness with which this is done remains yet to be seen.

Under the head of vital statistics the tables show for the year ending June 30, 1883: *Deaths*, 4,286, of which 3 are set down to smallpox; 24 to croup, 85 to diphtheria, and 125 to scarlet fever. Consumption is credited with 730, but of these less than 17 per cent. were white natives of the District.

Births, 851 white males, 833 white females, 715 colored males, 715 colored females, in all 3,116.

Marriages, 607; whites; 235 colored; 1 mixed. The register shows 448 practicing physicians within the District, of whom 15 are women.

One of the most interesting features of this report is the fact that the diseases, to a certain extent, are located on maps showing the different squares of the city.

FOREIGN CORRESPONDENCE.

LONDON, May, 1884.

At the annual meeting of the City Orthopædic Hospital in Halton-Garden, it was stated the past year's working of the charity was the most satisfactory for many years, showing that as many as 2,500 patients had been admitted and twelve extra beds had been provided. It was stated that since the opening of that and other orthopædic institutions the number of deformed poor walking about had become appreciably less.

A gargle made of strong black tea and used cold, night and morning, is now the fashionable preventtive against falling a victim to sore throat during the cold winds of the spring.

The University Tercentenary celebration at Edinburgh has passed off without a hitch, largely owing to the authorities having wisely altered their original plans so as to allow the students to take a prominent part in the entertainments. The young gentlemen, appreciating the justice of this arrangement, were on their best behavior, and only created a very moderate disturbance when some of their guests abused their hospitality by inflicting on them long speeches in foreign languages. During the meeting attention was drawn to the unnecessarily high salaries which the Edinburgh professors enjoy. At Oxford or Cambridge the busiest "Don" is only able to make about £1,000 a year. In Edinburgh professors can usually manage to earn £2,500, a difference which is not to be accounted for by the superior fame of the northern teachers. At Oxford and Cambridge the income of all the teachers is fixed by law; at Edinburgh they are allowed to make what they can out of their pupils.

The inaugural lunch of the newly formed Society for the study and Cure of Inebriety has just passed off in a most successful manner at the premises of the Medical Society of London. The Society is to consist of medical men as members, and laymen as associates, for the study of the various physiological and psychological causes of inebriety. The president is Dr. Norman Kerr, who occupied the chair, and in his inaugural address after the luncheon said that although the Society had only been in existence six months it already numbered 67 members. He went on to say that so far from everything being known about intemperance, there was nothing indeed accurately known, that even of the action of alcohol on the healthy living body our knowledge is limited, and there is a vast field of inquiry to be covered by close and patient investigation ere the truth can be elucidated. Inebriety was a disease, but he had no sympathy with those who ignored its moral and spiritual aspects and recognized only the physical. To say that addiction to drinking was always and never anything else than a physical disease was not science but nonsense. He would not dogmatise on disputed points as to whether inebriety was a sin, a vice, a crime or a disease. In his judgment it was sometimes all four, but oftener a disease than anything else, and even when anything else generally a disease. The object of the society was to investigate, by strictly scientific methods, the various causes, and to educate the professional and public mind to a knowledge of those causes and to the recognition of the physical aspect of habitual intemperance. Among the associates of the undertaking are the Earl of Shaftesbury and McTool, the actor.

Dr. Ebstein's much talked-of treatise on the cause and cure of obesity has appeared in an English dress, and is attracting much attention, especially among the ranks of those who carry "too much weight." Professor Ebstein agrees with Mr. Banting in advocating regimen alone as the only safe cure for an inconvenience which most frequently results from too much food. But he adopts a dietary widely different from those prescribed by Mr. Banting, or rather Dr. Harvey, the practitioner whose maxims that gentleman enlarged and made his own. The crucial difference is on the question of eating fat. Fat is the sheet-anchor of Dr. Ebstein. No dyspeptic, we are assured, need fear fat so long as he does not take too much, and, indeed, so admirable is that substance, long dreaded by delicate stomachs, that, by checking nitrogenous waste, it appeases thirst as well as hunger, a fact, in part at least, known even by Hippocrates. Mr. Banting permitted any fish except salmon, but Dr. Ebstein encourages his patients to enjoy, "in moderation, of course," not only this dish but *paté de foie gras* and similar delicacies. Sugar is tabooed as well as sweets of all kinds, and potatoes in every form he prohibits unconditionally. Three to four ounces of bread per day are permitted, and of vegetables, asparagus, spinach, cabbage, and the various legumes rich in albumen are allowed. Of meats he excludes none. He allows three meals a day, but on no condition must there be an afternoon tea or snacks between meals. Alcohol drinks are allowed to the extent of two or three glasses of light wine at dinner, but beer is barred unless, indeed, the permitted carbo-hydrates be correspondingly restricted, though then the ale accepted as an equivalent must be extremely moderate in amount. The diet of a cured patient was something like the following: "For breakfast, a large cup of black tea, without milk or sugar, and two ounces of bread with plenty of butter, at half-past seven in winter, or at six or half past six in summer. For dinner, between two and three o'clock, soup often with marrow, four to six and a half ounces of roast or boiled meat, vegetables in moderation, but no potatoes, and almost no saccharine turnips. After dinner a little fresh fruit or a salad, or stewed fruit without sugar, with two or three glasses of light wine, followed by a large cup of black tea without milk or sugar. Supper of black tea, fat roast meat or eggs, or some ham, fish, a little

well-buttered bread, with cheese and fresh fruit formed the concluding meal, at the hour of seven or eight." Mr. Banting's rule was opposed to the best received physiological principles, and Dr. Ebstein's has yet to win the approval of the scientific world.

Dr. Koch, with the other members of the German Cholera Commission, have just returned after nearly nine months' absence in Egypt and India. Dr. Koch will shortly receive a professorship in the Berlin University.

The following extract is from the *Scots Magazine*, March, 1755: "There was presented to the Empress of Russia a laboring man who has had two wives, the first of whom brought him four times four children at a birth, seven times three, and ten times two. The second wife has lain-in seven times; the first time she brought forth three children, the other six times two. The whole number of children by the two wives amounts to seventy-two. G. O. M.

MISCELLANEOUS.

PIERRE, Hughes County, Dakota, May 21, 1884.

EDITOR OF THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION:

At a regular meeting of the Central Dakota Medical Society, held in Pierre, May 7, 8 and 9, the following preamble and resolutions in regard to the death of the eminent surgeon, Professor Samuel D. Gross, were adopted:

WHEREAS, During the session of the Central Dakota Medical Association, held in Pierre, May 7, 8 and 9, news reached us of the death of the eminent surgeon, Professor Samuel D. Gross, of Philadelphia, who has been at the head of the profession in America for the last half century, and whose numerous works on surgery are the leading text-books in Europe and America for both students and practitioners, and who has been one of our most faithful and earnest teachers for the last fifty years; therefore be it

Resolved, That we express most profound regret and sorrow for so great a loss to the profession, and the greatest sympathy for the bereaved family and the many personal friends who have been associated with him as teachers and students during his life-work.

Resolved, That a copy of these resolutions be furnished the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION for publication.

A. J. DICKINSON, M.D., President.
N. S. SMITH, M.D., Secretary.

OFFICIAL NOTICE.

ANNUAL DUES from members of the Association—*Five Dollars* per annum—are payable directly to the Treasurer. Such payment entitles them to receive the JOURNAL of the Association for one year.

SUBSCRIPTIONS TO THE JOURNAL from those who are not members should be forwarded to the office of publication, Chicago.

BACK VOLUMES of the TRANSACTIONS may be procured, at reduced rates, by addressing the Treasurer.

THE INDEX to the 33 Volumes of Transactions will be forwarded, postpaid, on receipt of *One Dollar* by the Treasurer.

According to a resolution passed May 9, 1884, at the Washington meeting, continuous payment of Annual Dues is required, to retain permanent membership.

RICHARD J. DUNGLISON, M.D.,
Treasurer.

Hutchinson, J. Illustrations of Clinical Surgery. Flasc. 16. London: Churchill. 6s. 6d.

James, J. B. Aids to Practical Physiology. 12mo, 60 pp. London: Bailliere. Sewed, 1s.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT UNITED STATES ARMY, FROM MAY 24, 1884, TO MAY 29, 1884.

Hall, Wm. A., Captain and Assistant Surgeon, assigned to duty at Fort Stockton, Texas. (Par. 1, S. O. 63, Headquarters Department of Texas, May 19, 1884.)

LIST OF CHANGES IN THE STATIONS OF MEDICAL OFFICERS, U. S. NAVY, FOR THE WEEK ENDING MAY 31, 1884.

Passed Assistant Surgeon F. Anderson, ordered to Navy Yard, New York.

Passed Assistant Surgeon H. G. Beyer, detached from Coast Survey Steamer "Blake," ordered to Smithsonian Institute for special duty.

Past Assistant Surgeon W. H. Rush, detached from U. S. S. "Despatch," and ordered to Coast Survey Steamer "Blake."

Past Assistant Surgeon L. G. Heneberger, detached from Navy Yard, New York, ordered to U. S. S. "Despatch."

Past Assistant Surgeon S. H. Griffiths, ordered to U. S. S. "Lancaster," on expiration of leave of absence.

Past Assistant Surgeon M. D. Jones, detached from Naval Hospital, New York, and resignation accepted—June 15, 1885.

Surgeon I. C. Wise, detached from Academy, and ordered to U. S. S. "Constellation."

OFFICERS OF

THE AMERICAN MEDICAL ASSOCIATION

AND OF ITS SEVERAL SECTIONS, 1884–5.

PRESIDENT.

Dr. H. F. CAMPBELL, of Augusta, Georgia.

FIRST VICE-PRESIDENT.

Dr. J. S. Lynch, of Maryland.

SECOND VICE-PRESIDENT.

Dr. S. D. Mercer, of Nebraska.

THIRD VICE-PRESIDENT.

Dr. J. H. Parsons, of New Hampshire.

FOURTH VICE-PRESIDENT.

Dr. H. C. Ghent, of Texas.

PERMANENT SECRETARY.

Dr. Wm. B. Atkinson, 1400 Pine St., Philadelphia.

TREASURER.

Dr. R. J. Dunglison, Lock Box 1271, P. O. Philadelphia.

LIBRARIAN.

Dr. C. H. A. Kleinschmidt, Washington, D. C.

Place of meeting, 1885, New Orleans, La.; Time of holding meeting, last Tuesday in April.

COMMITTEE OF ARRANGEMENTS.

Samuel D. Logan, Chairman; S. E. Chaillé, E. S. Lewis, Joseph T. Scott, W. G. Austin, W. H. Watkins, J. P. Davidson, J. A. G. Fisher, Geo. W. Lewis, B. A. Pope, W. C. Wilson, M. Schuppert, Geo. J. Friedrichs, F. Loeber, D. Jamison, G. K. Pratt, L. E. Solomon, J. H. Bemiss, Geo. Lawrason, G. U. Gaudet, Sam'l M. Bemiss, B. J. Bickham, Chas. Turpin, Jno. Carter, A. W. DeRoaldes, S. S. Herrick, W. S. Mitchell, E. T. Shepard, E. Souchon, T. D. Layton, T. S. Dabney, S. R. Olliphant, Edward Harrison, A. B. Miles, Joseph Holt, P. B. McCutchon, F. H. Parham, G. B. Underhill, Stanhope Jones, E. Chassaignas, R. Dell'Orto.

ASSISTANT SECRETARY.

Dr. W. H. Watkins, New Orleans, Louisiana.

BOARD OF TRUSTEES FOR JOURNALIZING THE TRANSACTIONS.

Drs. J. M. Toner, Washington, D. C., President;
M. Moore, Rochester, N. Y.; Leartus Connor, Detroit, Mich.;
J. H. Packard, Philadelphia;
H. F. Campbell, Augusta, Ga.; A. Garcelon, Lewiston, Me.;
P. O. Hooper, Little Rock, Ark.;
L. S. McMurtry, Danville, Ky.; J. H. Hollister, Chicago, Ill., Secretary.

OFFICERS OF THE SECTIONS:

"Practice of Medicine."

Chairman—Dr. H. Didama, Syracuse, N. Y.; Secretary—Dr. G. M. Garland, Boston, Mass.

"Obstetrics and Diseases of Women."

Chairman—Dr. R. S. Sutton, Pittsburgh, Pa.; Secretary—Dr. J. T. Jelks, Hot Springs, Ark.

"Surgery and Anatomy."

Chairman—Dr. Duncan Eve, Nashville, Tenn.; Secretary—Dr. E. B. King, Allegheny, Pa.

"Ophthalmology, Otology and Laryngology."

Chairman—Dr. J. A. White, Richmond, Va.; Secretary—Dr. Eugene Smith, Detroit, Mich.

"Diseases of Children."

Chairman—Dr. J. H. Pope, Marshall, Texas; Secretary—Dr. S. S. Adams, Washington, D. C.

"Oral and Dental Surgery."

Chairman—Dr. W. W. Allport, Chicago, Ill.; Secretary—Dr. E. C. Briggs, Boston, Mass.

"State Medicine."

Chairman—Dr. E. W. Schaufler, Kansas City, Mo.; Sec'y—J. N. McCormick, Bowling Green, Ky.

Committee on "Necrology."

Chairman—Dr. J. M. Toner, Washington, D. C.

ORIGINAL ARTICLES.

ADDRESS ON OPHTHALMOLOGY.

Presented to American Medical Association, May, 1884,

BY JULIAN J. CHISOLM, M.D., OF BALTIMORE, CHAIRMAN OF THE SECTION ON OPHTHALMOLOGY, OTOLOGY, AND LARYNGOLOGY.

GENTLEMEN:—Instead of formulating the advances made in ophthalmology, otology and laryngeal surgery for the Section over which I have the honor to preside, I have thought it best to take up as the subject of my address before the Association, the diagnosis and treatment of some of the most common diseases of the eye with which the profession at large cannot become too familiar. Within the last thirty years, the special study of the eye by physicians skilled in the general knowledge of medicine, made ophthalmology the pioneer in the work of specialties, and for many years it held exclusive sway in its isolated position. This conspicuous progress was made when good men in the profession, with a foundation of medical and surgical lore, concentrated all study and observation in working out obscure symptoms which time enabled them to classify, and by which a more comprehensive understanding of eye diseases was secured. It made the study and practice of eye surgery so very attractive, on account of its positiveness, that the good work which had been done stimulated pathological research in other directions, so that now the disturbances in the numerous organs which comprise the human body have become the absorbing subject of honorable investigation. The greatest excellence is naturally attained by the division of labor. As each part or organ of the human body is brought under the critical investigation of a corps of learned and experienced observers, who hasten to divulge to the professional world the wonderful discoveries which they make for the amelioration of suffering humanity, the entire subject of scientific and practical medicine makes conspicuous progress, which it could obtain in no other way. We must thank the specialist for the lofty position which general medicine has secured and for the progressive advances which each year's work in the aggregate develops.

It is very easy to appropriate what another has, by weary toil, discovered. The intelligent labor of many years of hard work can be condensed in a few printed pages, and the practical application can be summed up in a few, short, plain sentences. It is by the liberal distribution of these truths in medicine, worked out by the assiduous labor of specialists who restrict their observation, thought, reading and experience to the changes which disease produces in a single organ or in a very limited part of the living body, that the sufferings of the human race are to be alleviated, and that the length of life of a generation is to be prolonged. The general practitioner avails himself of the fruit matured through special work: and when he shows an aptitude to learn what must be useful in his every day practice, the family physician becomes truly the honored advocate of advanced medicine, and properly acquires the title to be considered the very head of the medical profession. It is from this standpoint that I bring before this large assembly of thinking men some of the truths with which a daily walk with those afflicted with eye and with ear diseases made me acquainted.

From an every day familiarity symptoms, not usually estimated in their true significance, become conspicuous for detecting diseases which otherwise would escape recognition. It is generally considered a very important factor in the successful treatment of a disease that its true nature should be detected in its very incipiency. For, although there are many diseases of the eye, which, like those of other and larger parts of the body, run their course uninfluenced by medication, there are on the contrary many which, when early seen, can be checked promptly, as the lighted match thrown on the floor can be put out by a stamp of the foot, if seen early enough and before the room is in a blaze. It is the early recognition, and the early application of judiciously selected remedies which gives the specialist the advantage over the general practitioner, who loses this opportunity, often to the serious and permanent detriment of his patient, because he was not alert in recognizing the disease for the control of which his services were required. The specialist knows often, but should only confess it to himself, that the lost eye for which he is consulted could have been saved if properly treated, and is often lost for the want of very little knowledge.

That one whose daily avocation brings him in contact with the varied disturbances of the whole organization should be as familiar with the practical details of changes which take place in a single organ of this intricate body of ours as the physician who devotes his time exclusively to one study, cannot be reasonably expected. The studious physician may read to satiety on all the branches of medicine, and be in

every respect what is properly called a well-read practitioner, but if he cannot apply his newly acquired knowledge for want of opportunity, the utility of his information will lose its acumen, and most probably will not be called up at will when needed.

The tendency of the day is to allow the specialist too much scope. The general practitioner abandons too readily most important fields for successful work which do not fall in, what he calls, his line of professional duty. Many of them confess at once that as to eye and ear diseases they know nothing. But should this be? Does this come up to the standard of conscientious duty to those who confide in their family physician for all things pertaining to the well-being of themselves and children? How often does it happen that a specialist is not at hand and it is impossible for the sufferer to seek one! Is the eye of so little value in the general utility that it should be lost because it unfortunately happens that the family physician has given no careful thought to the diseases of this very important organ? It was not so formerly: and with the flood of light which modern investigation has poured upon this special pathology, there is less excuse for it now.

There are certain duties which a general practitioner may delegate to those who by an everyday experience have acquired a skill in the manipulation of instruments which cannot be obtained from any amount of reading or thought. In eye surgery this is a recognized condition. Of two persons equally familiar with eye diseases and their treatment, the one who knows how to handle instruments the most skillfully will save the largest number of eyes. The casual use of eye instruments at long intervals does not give facility of manipulation, and therefore cannot secure for the patient the best promises of success. It is in this respect alone that the general practitioner should acknowledge the superiority of the specialist. In obscure cases he will also seek advice to aid him in defining the disease and in determining the proper course of treatment. But as to the ordinary diseases which affect the eye, ear or throat, and which are met with in the daily routine of practice, any physician ought to be thoroughly competent to treat them as skilfully as does the specialist, particularly as the requisite knowledge can be acquired with so little outlay of time and study.

I am sorry to say that there is a very dangerous self-confidence at times met with among medical men which would rather sacrifice the innocent patient than acknowledge any deficiency in medical preparation. There is also a class of physicians blindly ignorant, who are content to grope in darkness under the belief that special knowledge is beyond their attainment. Of both of these professional conditions the specialist in medicine sees a great deal too much. When an honest desire to acquire useful knowledge exists, the truths developed by the successful study of the specialties in medicine are within the grasp of any practitioner. Especially in relation to familiar eye and ear diseases there is now no excuse for ignorance. The literature of the profession is largely made up of the writings of specialists. Libraries can be filled with books on special medicine; and no medical journal published, however modest it may be, can avoid giving pages to the practical discoveries in eye, ear and throat surgery. Through these channels of cheap medical literature, within the reach of every one, the profession at large ought to be theoretically well instructed in the specialties. Many doctors can discuss learnedly the differential diagnosis of the everyday diseases of the eye, ear and throat, and yet my experience fully sustains me in saying that very few general practitioners are positive in their diagnosis of any of the diseases which affect these organs so essential to life and comfort.

Take the common diseases of the eye. Inflammation of the conjunctiva, iris and cornea, also the intra-ocular diseases affecting the lens, choroid, retina and optic nerve; troubles which the ophthalmoscope so positively reveals. To diagnose any of these diseases the general practitioner should be as apt as the specialist. *To know a cold in the eye when he sees it, and always to recognize it with certainty,* is easy work for the specialist, and should be knowledge ready for immediate use by any one who undertakes to treat the diseases of the eye at all; and yet I may venture the assertion, based upon a very large experience, that very few physicians have the necessary knowledge. I do not mean to say that their diagnosis would not be most frequently correct; but from the very confidence which all have that they certainly do know an injected conjunctiva when they see one, they call all such congestions of recent development cases of catarrhal ophthalmia, not remembering that iritis will often develop with conjunctival inflammation, sure to mislead those who are not always on the watch for this complication. What general practitioner is there who has not fallen into this error?

Whether the patient seeking relief has an incipient conjunctivitis or an iritis is often a very weighty matter. The consequences of an error in diagnosis may lead to the most direful results. It has reduced many a family from comfort to want, and where the head of the family is affected, may become even a question of bread for the wife and children. A cold in the eye, even if ignored, is often but a temporary inconvenience, which the powers of nature will throw off. An iritis, if not recognized, will lead to more or less permanent impairment of vision, and very often to the total loss of sight amidst much suffering. One of the most painful incidents of my past year's experience was when a physician in full practice brought to me for consultation his friend, also a physician, who was suffering from what was called a serious cold in the eye which would not yield to a solution of nitrate of silver applied assiduously three times a day. I recognized at a glance a case of plastic iritis. Every drop of the caustic application was exciting increased effusion, to say nothing of the intensity of the suffering which the treatment engendered. In this case the adhesions were allowed to become so free and firm that a strong atropia solution could not break them up, and therefore the eye was seriously and permanently injured by the error of diagnosis.

Every physician knows that inflammation of the iris has its peculiar symptoms, but, unfortunately, they are not as conspicuous as the congested vessels of the conjunctiva. The pink zone of ciliary vessels

directly around the border of the cornea is so much less red than the injected vessels of the conjunctiva, that it escapes general professional observation. The torpidity of the pupil, when exposed to various degrees of light, is not usually looked for by the family physician. Dullness of sight, which belongs to iritis and not to conjunctivitis, is ignored. The discoloration of the inflamed iris is looked upon as a freak of nature. Pain, which may or may not exist to a marked extent, is usually attributed to neuralgia. From the recognized symptoms the diagnosis of conjunctivitis is, therefore. most frequently made out, and astringents are prescribed, with the knowledge that a cold in the eye is properly treated with a solution of borax, zinc, or nitrate of silver. In the meantime inflammatory exudations are sticking together the border of the pupil and the capsule of the crystalline lens upon which the iris glides.

As such eye inflammations do not yield kindly or speedily to this kind of treatment, the idea may occur that something more than a cold in the eye exists. An experimental drop of an atropia solution is then applied, but it is now found that the pupil cannot dilate. This condition corrects the diagnosis, but too late to be of service to the patient's eye.

Every physician knows that a solution of the sulphate of atropia will dilate promptly a normal pupil. All equally know that inflammation of the iris interferes with dilatation, by causing adhesions between that portion of the iris and the capsule of the lens which are juxtaposed, also that such adhesions are among the early symptoms of iritis. When recent, these adhesions yield usually to the dilating influence of a 4 gr. solution of atropia. When long standing they cannot be broken up by any mydriatic eye-drop. It is also generally known to the profession that the future danger to the eye, after an attack of iritis, depends to a large extent on the number and firmness of these adhesions. The mistake of not recognizing sufficiently early iritic inflammations is made by physicians of undoubted skill, who deservedly occupy the very highest professional positions. Very few physicians escape this error in the course of their experience. A few will try to correct their diagnosis during the treatment, but will not succeed in removing the sequel of troubles which an earlier recognition would have prevented. The majority of physicians never see their error till pointed out by the specialist, to whom the case of impaired vision is finally brought for treatment. This mistake could never be made, were it not for the self-confidence with which the majority of the profession diagnose congestions of the eye-ball.

It would save much trouble and mortification if every physician who undertakes to treat the diseases of the eye would look upon a congested eye with suspicion, and make it a rule to instill a drop of a weak solution of atropia into every inflamed eye which he may meet with in practice. If the pupil dilates freely within a half hour, the iritic complication does not exist. In this way the diagnosis of cold in the eye can always be confirmed, and the safe treatment with weak astringent eye-drops can be instituted with surety. Should the pupil enlarge irregularly, or not at all, the diagnosis of iritic inflammation is equally clear, and stronger solutions of atropia must be frequently used or no successful results can be obtained.

While a few drops of an atropia solution may be put in all acutely congested eyes, to aid in establishing the diagnosis, which is so very important to the well-being of the patient, it is but very seldom that any harm will come from this application. Only in one disease alone can injury follow the use of the atropia drop, and that is in cases of inflammatory attacks of glaucoma with conjunctival complications. Such cases, however, are rare. They seldom occur in persons under 45 years of age, and most frequently in females. The condition is accompanied by severe pain in the face as well as in the eye, with rapid or sudden deterioration of vision. Most frequently, in such cases, the necessity for the atropia would not mislead, because the pupil is already larger than normal, and does not contract when exposed to strong light.

The next most common error in ocular diagnosis is when the disease called glaucoma, with its diffused severe head pains, is mistaken for trifacial neuralgia, and treated accordingly, to the final destruction of vision. Headache is such a common accompaniment of systemic disturbances that very few cases of acute disease exist without this symptom being present. Then comes the large list of purely neuralgic headaches, sometimes of the greatest severity and duration, occurring chiefly in females, and often defying the utmost efforts of the physician. It is under this guise of neuralgia of the temple, head and face that the terrible disease, acute glaucoma, attacks the eye. It is often accompanied with nausea, which stomach symptom again misleads. The agonizing pain in the forehead, temple and teeth constantly mask the pain in the eye, and the impairment of vision, with steady and often very rapid deterioration, does not attract at the time sufficient attention. The eye-ball is hard, and this so-called tension indicates at once that the serious trouble is, primarily, an eye disease with face symptoms; but the family physician is not accustomed to feel the eye-ball, and, therefore, does not recognize that the eye on the painful side of the face is more stone-like than the one not complained of.

Unfortunately glaucoma is a disease which medicine will not cure, and unless relieved by early operation its tendency is to permanent and complete blindness. Whenever a patient, usually a female over 45 years of age, complains of severe pain in the brow, temple, and teeth of one side of the face, most frequently also in the eye, especially when the vision on the painful side becomes suddenly defective, the attending physician should always suspect glaucoma, a destructive eye disease with conspicuous neuralgic complications. Patients with these symptoms are usually found in bed, and the entire armamentarium of anti-neuralgic remedies are tried in succession by the attentive family physician. Days, weeks, and months are often passed in fighting these pains. If the eye defect has been finally recognized, tonics are given to secure to the patient strength enough to visit a distant specialist. If instead of the repeated

use of the hypodermic syringe and the many doses of iron, quinine and morphia and all to no purpose, the physician has suspected the true source of all the trouble, by puncturing through the cornea near its temporal border with his lancet, he would have relieved the tension of the eye-ball promptly, the pains would have disappeared as if by magic and the patient would very soon have been convalescent. Nothing in the whole list of remedies relieves these frightful head pains so promptly and efficiently as free puncture. The moment the hardness of the eye-ball is relieved by removing some of the aqueous liquid the pain subsides.

Very seldom does a specialist see a case of glaucoma diagnosed as such by the family physician. Always the history given is that of facial neuralgia actively treated by anti-neuralgic remedies, and when a lull occurs in the symptom, which is one of the peculiarities of this eye disease, the impairment or loss of vision, as it may now be, attracts attention, often too late to secure any return of it. Terrible is it when one eye having been lost in this manner, the second eye becomes similarly attacked, when irrevocable blindness is the result of the faulty diagnosis. Glaucoma is possibly the most frightful disease which attacks the eye, and is the one the least amenable to therapeutical remedies; and yet its facial neuralgic complications which will not yield to quinine, morphine, leeching, etc., will disappear speedily when an iridectomy has been performed.

Another class of dangerous eye troubles, not fully appreciated by the family physician, are those produced by the accidental wounding of the eyes, and more especially by perforating wounds involving the ciliary regions, where the white and colored portions of the eye join. When sight has been lost by such an injury it is difficult for the unexperienced to appreciate the fact that it is dangerous to retain the lost eye on account of the risk of having sympathetic irritation excited in the remaining good eye. Sympathetic iritis is an incurable form of destructive disease excited by the presence of the injured eye. It cannot be too generally known and remembered that an eye lost from accident is too dangerous to be kept in the head. It can be of no possible use. Most frequently it looks badly, is often liable to attacks of suffering and is always dangerous in its tendency to extend destructive inflammation to the other. That persons have gone through a long life carrying with them a lost eye, which happened to give them no trouble, has deluded many into the belief that they may be equally successful.

If there was a fixed interval of time in which to look for the extension of sympathetic inflammation from the lost to the sound eye after which safety could be ensured, the patient could then be watched over this dangerous period. Unfortunately the time for sympathetic inflammation to be transmitted is at any period during the life of the individual who carries in his person the source of danger. In my personal experience I have seen the good eye destroyed from sympathetic iritis three weeks after the receipt of a perforating wound in the opposite eye. On the other hand I have had a patient who was not threatened with injury to the good eye until an eye lost in childhood by a scissor's puncture had remained quiescent for thirty-five years. At any time during this long interval an explosion of destructive inflammation might have occurred. Safety resides in the removal of the lost eye before the good eye takes on any trouble. This course alone can put the sight of the patient in a condition of absolute safety.

This fact, in the prognosis of eye injuries, is well-known to the profession, but like much that may be equally well-known, it is not recalled when most wanted for the protection of those who, confiding in their family physician, entrust their case into his professional hands.

The enucleation of the eye-ball is one of the simplest operations in eye surgery, which any physician could safely undertake. With scissors, forceps and blunt hooks, the conjunction can be divided around the corneal border, the recti-tendons can be found and severed, and by cutting the optic nerve and oblique tendons the eye-ball is isolated from the socket tissues. The only rule of procedure is to keep close to the eye-ball and remove it alone, leaving all other tissues in the socket. Should the unskillful operator allow the scissors to stray a little no very great injury will be inflicted.

To remove a destroyed eye is quite a simple operation when contrasted with the delicate manipulation necessary for restoring sight. These latter operations may require such a degree of skill in the handling of instruments and experience in guiding the knife so as to sever only the parts designed, as to restrict their successful performance to the hands of specialists. Even with these the largest percentage of cures usually follows in the wake of those who have had the largest experiences in operations. Every patient operated upon teaches the observing surgeon something, and adds to his facility in manipulation, and therefore to his success in the aggregate. For this nice surgery the aid of specialists must ever be sought, but for the treatment of the most common form of eye diseases, the physician should surely prepare himself, so that he will know how to detect without any question of failure in diagnosis, an iritis when he meets one, and a case of glaucoma, even if its trifacial neuralgic pains should tend to attract attention away from the primary eye disease. These cases are not as difficult to diagnose as chest or abdominal troubles, and are equally important for the well-being of the patient. As the general practitioner will without hesitation attempt to define the one, he should be prepared equally to determine the other.

The stethoscope is put into the hands of every physician, who is expected to use it correctly as an aid to diagnosis. The ophthalmoscope, an equally necessary instrument, should go along with it, so that the eye as well as the ear may be educated to aid in the detection of disease. The manipulation of the ophthalmoscope is so simple that, how to use it can be acquired in a very few easy lessons. A little practice will enable one to detect easily all the

grosser diseases of the interior of the eye-ball. After a very few days' instruction in the use of the ophthalmoscope, any physician will be able to say whether the lens is clear or cloudy, whether the choroid and retina are of normal appearance, or whether the optic nerve is in a healthy condition. A very little practice will enable one to explore the interior of the eye, so that by the aid of a few colored diagrams, found in most hand-books on eye diseases, he can determine in cases of imperfect vision whether he should investigate for local diseases or for general blood poisoning.

As one of the great aids to differential diagnosis, it would really appear as if this window of the pupil was especially opened, that we may be brought face to face with the innermost workings of the system in health and in disease. We can look into the open chambers of this living organ and see the blood circulating in the throbbing veins. Only here are the naked nerves exposed to view. By observation and analogy, we can determine how hidden parts of the body are influenced by diseased action. How the nerve tissue becomes suffused in neuritis. How inflammatory exudates look while going through their varied metamorphoses for increase, shrinkage or removal. How blood escapes from delicate blood-vessels, and the damage done by very limited extravasation in the substance of nerve-tissue. We can observe the changes which a thrombus produces in the territory supplied by any special vascular area. As these changes are seen to take place in the inner chambers of the eye, so may they be produced in the brain or in other organs not so favorably circumstanced for exploration.

In many a patient have I, by ophthalmoscopic examination, directed attention to the analysis of the urine, and the recognition of a well established case of Bright's disease, which up to that time had not been suspected. The changes which take place in the retina and choroid are often made available for establishing a correct diagnosis of brain diseases. Incipient changes in the spinal cord may exhibit the earliest symptoms of impending trouble in the appearance of the optic nerve, and the general poison, syphilis, will in the interior of the eye often show indubitably its destructive tendency.

To any observer desirous of investigating pathological changes, the eye is a mine of wealth and will repay one hundred fold for the little labor needful to prepare one to appreciate fully its wonderful revelations.

I have said enough to draw attention to the fact that through the special study of ophthalmology the classification of eye diseases and the value of symptoms have been clearly defined. There is now no excuse for errors in diagnosis of the common eye affections which every general practitioner must meet with from time to time in the routine of even a moderate practice. With a very little labor one can be thoroughly posted as to the disease and the most successful methods of treatment. If the case is one in which skilled manipulation is most likely to give the desired relief, then the physician should be in condition to appreciate fully the dangers to his patient and put the responsibility for a cure upon those of larger experience than himself; but all the ordinary cases of eye disease should be as safely treated by the family physician as by the specialist. Make it a rule to examine thoroughly every case of eye disease, especially those of an inflammatory nature. This is particularly needful in the purulent ophthalmia of newly born children. If a child less than a week old gets inflamed eyes, do not attribute it to a cold, to be indifferently cared for by the mother or nurse. Remember, that such inflammations a few days after birth are most frequently the result of inoculation from poisonous vaginal secretions, a purulent ophthalmia very destructive in its tendency, and to which is attributed very truthfully one-half of all blindness in children. A suppurative inflammation, which if neglected, will cause the cornea to slough and the eye to be destroyed, yet is an inflammation which when properly treated should leave no bad results whatever. When the eye of an infant is lost under the care of the family physician it can only be charged to professional neglect. Thorough cleanliness, the removal of all purulent secretions from the eye every half hour, day and night if needful, and the frequent use of a mild astringent of borax, grs.x to ʒ i, with the occasional use, once a day, of a solution of nitrate of silver, gr. v to ʒ i, should save the eyes of any little patient, when the disease is recognized before the cornea ulcerates and the eye becomes on that account permanently injured.

What the general practitioner most needs is not a detailed account of scientific researches, nor even the narration of the novelties in practice which the last year has developed. What is of the most value is a familiarity with well established facts of practical use for the recognition and cure of serious diseases. How to use remedies aright, is of the greatest importance. Take atropia, for instance, which is invaluable for the successful treatment of some of the most destructive inflammations of the eye, but it is far from being the universal panacea for every eye affection, as some professional gentlemen seem to think.

What I have said for the eye, I may equally duplicate for the diagnosis of ear diseases. Many of these to be sure are very obscure, and can with difficulty be reached even by the process of exclusion. Yet, hid away as this organ is in its labyrinthine portions, it can be as successfully studied as any of the other hidden organs of the body. We have, however, a portion of the ear under direct ocular exploration. The external ear, so-called, and the drum-head at the bottom of it, can certainly be as thoroughly studied as the skin in the palm of the hand. Everybody has heard of the drum, and every physician knows where the drum-head is to be looked for, but very few have ever seen it, to know its healthy from its diseased appearances. Many cannot recognize the drum-head at sight, or know whether they are looking at the skin lining the ear passage, or the drum-head at its extremity. They do not remember, when the knowledge is most needed, that the healthy drum membrane always exhibits a bright spot of reflected light at the lower end of the long process of the maleus, and that the sight of this, marks with certainty its exposure

upon inspection. Were this fact better known, cerumінous deposits concealing the membrane and causing deafness, would not be sent to specialists by good physicians, so that the former may secure great reputation in restoring hearing through means of a syringe and warm water. I have had patients travel from their homes and back again, from Texas to Baltimore, fully 3,000 miles, to go through this operation, because the family physician, a gentleman of very large experience and one well-read in his profession, was not sure of the appearances of a drum membrane, although thoroughly familiar with the book anatomy of the hearing organ. Make it a rule, without a single exception, to examine the external ear of every patient who complains of deafness, and not send them to a specialist until you are convinced that the disease lies beyond the drum-head. The general practitioner should be as skillful as the specialist to detect cerumінous deposits and to remove them.

I would urge upon the profession at large to appropriate to their own uses the simple truths which special medicine has made so easily understood. Make up your minds that as to the common diseases which attack the eye and the ear you will become as familiar with them as can be any specialist, and that hereafter no mistake shall be made in the differential diagnosis of conjunctivitis and iritis as long as a solution of atropia can be obtained. Be firm in the determination that if any credit or reputation is to be gained by the restoring of hearing through the removal of excretions in the external auditory passage, no specialist shall rob you, at least, of this award. In other words, make the peculiar knowledge of the specialist the common knowledge of the profession.

THE AMERICAN MEDICAL JOURNAL OF THE FUTURE AS INDICATED BY THE HISTORY OF AMERICAN MEDICAL JOURNALS IN THE PAST.

ADDRESS BEFORE THE AMERICAN ASSOCIATION OF MEDICAL EDITORS, WASHINGTON, MAY 5, 1884, BY LEARTUS CONNOR, A.M., M.D., PRESIDENT.

Published by Request of the Association.

The nineteenth century is full of achievements far surpassing the tales of the Arabian Nights. First among these is the printing press. In all directions it incites rapid thinking and vigorous action. All trades, all arts, all sciences, all professions, indeed all callings, have been driven onward and attracted forward by its powers. In fact this force so occupies all our time and all our energies, that we do not realize the spell under which we are moving. With annuals, quarterlies, monthlies, weeklies, tri-weeklies, bi-weeklies, dailies, morning, noon and evening, we find that even journalism taxes all our powers to keep pace with the ever onward rush of human events. Of the other work of the printing press we can gather but the most general notion. In medical journalism proper, there are but very few that can do more than keep track of the most notable events in certain lines of medical work. The medical journal is greatly influenced by the medical men among whom it circulates, and in turn largely influences both these and others. Unquestionably it is the greatest factor of modern medical progress.

It is in a very real sense a medical college, a post-graduate school, a preceptor, a host of text-books, new editions ever appearing, the old editions taking their honored place upon the library shelves. It is a medical society in that it permits constant conversation and discussion between all working, thinking practitioners of every age, language and degree of medical accomplishment. It encourages the most frequent meetings of all members of the great medical profession. In short, it is the great unifier of the past and present, the diffuser of all new facts, new thoughts, all new and better appliances for the study of the human body and for the relief of its derangements. It at once gives to all that which any one person has found helpful or useful in his fight with disease and death. It enables thus the profession to move onward as one man in the pursuit of its high calling. As medical journalists, it is worth our while to occasionally consider the history of this mighty power, if perchance it may help us in our endeavors to so shape activities as to gain the highest good possible under existing circumstances. Such is my object at the present time. I desire to present some facts relating to the history of medical journalism in America in the hope that they may suggest lines of more useful endeavor in the future.

For many of my facts I am indebted to the courtesy of Dr. J. S. Billings, the able chief of the library of the Surgeon General's office, U. S. A. Portions of this data appeared in the Boston *Medical Journal* Jan. 2, 1879, and the *American Journal of Medical Science* for 1876. The rest has been gathered from files of medical journals since accumulating in the Library of the Surgeon General, and such other sources as were accessible to me. I do not flatter myself that I have collected all the medical journals of the United States, but I have obtained all that I could, and think that but few have escaped my attention.

The first medical journal[1] published according to Dr. Billings was issued at Paris in 1679. It was edited by Nicholas de Blegny, who seems to have been "a good bit of a charlatan." This journal was translated into both Latin and German. In the United States the first medical journal printed was the translation and selection from the "*Journal de Medicine Militare*," issued in Paris from 1782 to 1788. It was published in New York about 1790.

The first American medical journal was "*The*

[1] "Les Nouvelles Découvertes sur toutes les parties de la Médecine. Recueillies en Annie 1679, par N. D. B., 12 mo. Paris 1679." Continued the following year as "Le Temple d'Esculape." In 1681 it appeared as "Journal des Nouvelles Découvertes, Concernant les Sciences et les Arts qui font partie de la Médecine" 12 mo, 631. Dr. J. S. Billings.

Medical Repository," a quarterly edited by S. L. Mitchell, Edward Miller and E. H. Smith, New York, 1797–1824. Of the twenty-three volumes of this journal, Dr. Billings says "they are well worthy of a place in the library of the physician of to-day." From that day to this New York has never lacked one or more medical journals.

The second American medical journal was the *Philadelphia Medical Museum*, edited by Dr. Coxe from 1804–1811. Baltimore gave us the third medical journal, the *Baltimore Medical and Physical Recorder*, edited by Dr. Tobias Watkins, 1808–9. The first medical journal of Boston was the *New England Journal of Medicine and Surgery*, 1812–27. It began as a quarterly, and in 1828 was consolidated with *The Boston Medical Intelligencer*, forming a weekly, *The Boston Medical and Surgical Journal*, which has continued to the present time.

The *American Journal of Medical Sciences* began as the *Philadelphia Journal of the Medical and Physical Sciences* in 1830. It is said to have been started by Dr. N. Chapman under the stimulus of the phrase of Sidney Smith, "Who reads an American Book?" A new series began in 1825, which continued till 1827, when Dr. Isaac Hays took charge and gave it its present name. Since then its editorship has continued in the hands of Dr. Hays and his son. Throughout its entire history it has exerted a wide and lasting influence for good upon the best medical thought and work. Its contributors and its readers have long included the very best minds of the English speaking medical profession. It would be hard to find a medical scholar who would confess that he did not read the *American Journal of Medical Sciences*. West of the Alleghanies the first medical journal was the *Western Quarterly Reporter of Medical and Surgical and Natural Science*, 1822–23, Cincinnati, O.

The *Transylvania Journal of Medicine* was the first Kentucky medical journal published in Lexington, 1828–39. West of the Mississippi the first journal was the *St. Louis Medical and Surgical Journal*, 1843 to the present.

In the south the first medical journal was published at New Orleans, 1831, the *Journal de la Societe Medicale de la Nouvelle Orleans*. The most important journal was the *New Orleans Medical and Surgical Journal*, which was continued from 1844 to the present. The oldest existing medical journal of California is the *Pacific Medical Journal*, 1858 to the present.

From these beginnings have come a multitude of medical journals of all sizes, shapes, and prices, animated with very diverse aims, and edited and published with as diverse ability and care. Altogether the entire number of titles of medical journals started previous to February, 1884, is 509. Of these 136 are now current. 373 have passed over to the silent land. The accompanying table† gives the beginnings and endings of these journals in periods of four years, except the last period, which includes six years. It will be observed by this table that periods of great commercial depression are marked by a diminution in the number of journals started. Thus, from 1812 to 1816 but one journal is started, while in the four previous years there had been six, and during the four following years there were seven. The same remark applies to other periods of similar commercial disaster. Since the recovery from the panic of 1873, the multiplication of medical journals has been unprecedented. Thus, from 1878 to February, 1884, we have 173 started. The mortality was also terrible, being 106. It seems from these facts evident that the number of new medical journals bears a definite relationship to the general prosperity of the country.

† [illegible]

1848–1852	21	7	4	5	3	2	4	8	36	18
1853–1857	27	27	5	10	1	2	5	4	31	48
1858–1862	32	35	6	5	1	3	5	6	42	45
1863–1867	18	15	13	4	1	1	6	3	36	22
1868–1872	31	22	6	7			11	6	43	35
1873–1877	30	24	8	9					49	40
1878–1884										
Total...	378	234	66	48	19	19	46	35	509	373

To the total number of medical journals ceased as given above, must be added thirty-seven. These could not be given in the table as the data did not permit me to separate the regular from the irregular. The summary will then stand thus:

			Feb.
378 Regular	begun	1797–	1884
56 Homœopathic	"	"	"
19 Botanic	"	"	"
46 Eclectic	"	"	"
509 Total.			
234 Regular	ceased	1797–	1884
48 Homœopathic	"	"	"
19 Botanic	"	"	"
35 Eclectic	"	"	"
37 Some of each	"	"	" 1879
373 Total	"	1797–	1884
135 Current			

It is also apparent that of all medical journals started but few are long lived. Most die young, some very young, as the following table* shows. Thus taking the period commencing Jan., 1879, and ending Feb., 1884, there were commenced titles of 129 regular medical journals. Of these, five issued

but one number, twenty-five did not complete the first volume, thirty-seven did not go beyond the first volume, forty-seven did not go beyond the second volume, while but eighty were current at the end of the period. The same remark holds true of the irregular medical journals. Or taking all medical journals, of all kinds, since the settling of the country and we have a total of 509 titles started. Of these twenty-six did not issue more than one number, seventy-three did not complete the first volume, 161 did not go beyond one volume, 105 did not go beyond two volumes:

*

Mortality Statistics of Medical Journals from 1879 to Feb., 1884, of those started during this period.

	No. Titles Commenced.	Only one No. Issued.	Vol. I. not Compl'ed.	No. that did not go Beyond one Vol.	No. that did not go Beyond two Vols.	Current, Feb., 1884.	Total Ceased.
Regular	129	5	25	37	47	80	49
Homœopathic	13	0	2	2	2	6	7
Eclectic	4	0	0	0	0	3	1
Chemistry and Pharmacy	13	0	1	2	2	5	8
Dental	12	1	1	1	1	9	3
Veterinary Medicine	2				1	0	2
Total	173	6	29	42	53	103	70

Perhaps the first thought of one interested in medical journalism on the learning of these facts, is, why are so many journals so short lived? The answer to this query is not so simple as it seems. It calls for an analysis of the motives that induce men to start and maintain medical journals. If the object be accomplished by one number, surely it were Utopian to expect the journal to continue longer. If the experience obtained during the issue of a journal for one year has sufficed to convince its projectors that their end could not be reached in this manner, it is plain why the journal should be discontinued. Or, if it should be proved by an experience of two years that the attainment of the end sought by the publication of a medical journal is more costly as to money, time, friends, etc., than the end would be worth, then surely the journal must stop. As will appear, many of the motives influencing the starting of medical journals are of this temporary sort, and hence the journals are correspondingly short lived.

The study of the medical journals of the United States, as arranged by States, is of considerable interest. In the accompanying table* they are so arranged, giving also the total number started in each State, the number now current, and the number that has ceased.

We find that thirty-one States and Territories are represented by medical journals. Of these, New York produces the largest number, viz., 125; Pennsylvania follows with 63, barely more than half; next is Ohio, with 49; then Illinois, with 29; Missouri, with 24; Massachusetts, with 22; Kentucky and Michigan, with 21 each; Maryland, with 18; Louisiana, with 17; Virginia, with 15; Tennessee and Georgia, with 14 each; Indiana, 13; California, 10; Texas, 6; South Carolina, Kansas, Iowa, and District of Columbia, 5 each; Arkansas, Maine, and Minnesota, 3 each; North Carolina and Oregon, 2 each; West Virginia, Vermont, and New Hampshire, but 1 each.

Even a casual glance at these facts shows that the greatest number of medical journals has sprung up in those States having the largest amount of trade. In order, these are New York, Pennsylvania, Ohio, Illinois, Missouri, and Massachusetts. Here we find the great cities of commerce—New York, Brooklyn, Albany, Buffalo, Philadelphia, Cincinnati, Chicago, St. Louis, and Boston. In a smaller way other commercial centres have produced their share of medical journals.

It is plain that where men are gathered for large and extensive commercial ends, there will be found the largest number and most important medical journals. The philosophy of this is not at all intricate. It is here that the largest financial, social, scientific and professional rewards are to be had for the highest practical knowledge and skill. As men go to these places for rare and choice merchandise, so they go there for the most expensive and celebrated medical and surgical aid. Hence men best able to meet these demands are attracted to these places. To still further exercise their powers, and to reach and attract a larger clientage, these write much for the benefit of their professional brethren. These writings call for medical journals by which they may be widely scattered. If needful, either they establish medical journals or cause their establishment. According to their wisdom in making their foundations temporary or permanent, so is the life of the journals long or short.

Competition between the profession of these commercial centres is so sharp, that only those of exceptional advantages as to capital of money, culture, brains or social position can hope to win. None ever reaches a great supremacy over all his competitors, so the struggle never ends, but continues till the powers are exhausted or death ends the scene. Large expense of living calls for large returns from work done. These returns are best secured from difficult or dangerous cases. To obtain many of these it is needful that the powers of individual doctors be made known to the profession. Hence the necessity of medical journals to carry a knowledge of these powers to the rank and file of the profession. 'Tis not uncommon for doctors to figure up the direct financial return from the publication or an article describing a new operation, etc. Where the financial pressure is greatest there will be the greatest inducement to relieve that pressure by such labor as has a money value. Where professional competition is sharpest for the securing of difficult cases there will be the greatest demand for medical journals which reach the greatest number of physicians scattered over the largest extent of country and readily accessible by lines of travel.

The same conditions are a stimulus to the physician who delights to overcome difficulties for the satisfaction of being conqueror. In a smaller degree every smaller centre for publishing medical journals feels the influence of the same principles of human activity. No doubt other agencies are at work in all places, and peculiar ones in particular towns, but these in no wise conflict with the ones mentioned. Nor do they at all controvert the fact that the permanent home of the best medical journals is in the political and commercial centres of the United States.

As to the character of the medical journals the accompanying table is of interest.[1] This shows that from Jan., 1879, to Feb., 1884, inclusive, medical journals were started in twenty-five states. In each one of the twenty-five, one or more regular journals were started. In six States Homœopathic journals were started, and in four Eclectic. The States starting Homœopathic journals are Illinois, Michigan, Missouri, New York, Pennsylvania and Texas. One Eclectic journal was begun in each of the following States, viz., Georgia, Indiana, Massachusetts and New York. Illinois began four Homœopathic journals, New York three, Michigan and Missouri each two, Pennsylvania and Texas each one. From this it would appear that the States in which Homœopathic and Eclectic journalism has been the most active during the past six years are Georgia, Illinois, Indiana, Massachusets, Michigan, Missouri, New York, Pennsylvania, and Texas. It will be noticed that these States are of great commercial importance and activity. Judging by this alone it would seem as if the influence of commercial centres tended to the development and propagation of "Isms." Is it true that the pressure brought to bear upon the profession in such centres turns the brains of many to the popular "Isms?" Certain it is that the facts point to this conclusion. Historically the great cities of the past have been the centres of the first development of those departures from truth and virtue which have ruined prosperous empires, carrying down scientific medicine and the liberal arts. Are we to expect that the influence of the medical journalism of the great commercial centres is to permeate the entire mass of the profession in other States? Certainly, if the same causes continue to operate. Will they continue to operate? It remains for the profession to determine this. If illegally educated doctors by the thousand are yearly turned loose in the ranks of the profession until competition becomes so sharp that few can make a fair living by honest logical methods of procedure, then such journals will rise all over the land, even more abundantly than in the States in which they now exist. At least they will do so until some new "Ism" enters the field to tickle popular fancy and open up another way of making a living. Bearing upon this question is the fact exhibited by the careers of the Botanic medical journals. Nineteen of these have started and nineteen have died. The period of their rise and fall is included between 1828 and 1862. All there was of good in them was absorbed by the medical profession and the rest so shrunk that there was no call for a distinctive representation among the medical journals.

In the earliest development of medical journals it appears that they bore a close relation to medical colleges. The publication by the colleges of the theses of their students, permitted the professors to make a statement before each thesis not to exceed sixteen pages. This gave professors a chance to publish some of their writings, as the subject-matter of their prefaces was not required to correspond with the subject of the thesis. But other doctors had no such means of reaching the profession, as usually the professors preferred to occupy all the space themselves. Hence the doctors were compelled to publish their own articles at their own expense. Later, as the medical journal became more definitely formed, it was mostly in the hands of college men. But in

Excluding the Journals on Chemistry and Pharmacy—on Dentistry and Veterinary Medicine, the total of Medical Journals started was 146.

the lapse of time the pressing duties and other engagements of the professors became such that medical journals little by little fell into the hands of outsiders. At the present time only the newer and less stable medical colleges possess an organ in the shape of a medical journal.

Medical societies have also exerted a large influence in developing medical journals. Just how large this influence has been is difficult to determine. Indirectly it has operated in this direction by awakening a desire on the part of individuals to learn the views of particular men as presented in medical society gatherings. This desire called for the publication of the records of the meetings in the form of transactions. Usually if the society be large and have but yearly meetings, a single volume is issued at periods of a year. The permanent additions to our medical literature by these volumes have been large. Still all that is of real value to the reading medical public is now given to the profession months before the appearance of the volumes of transactions. Hence these volumes have come to be the repositories of details and elaborate articles, as such can find no place in the general medical journals.

Meantime, some societies have adopted the methods of the medical journal in the publication of their transactions. Perhaps the most successful of these journals is that published by the British Medical Association. Edited with great ability it has gradually won for itself and the organization it represents, the admiration and respect of the thousands who weekly reads its pages. The process by which this brilliant result was reached was a slow one, but it has demonstrated that it is possible for a large medical society to successfully organize and conduct a medical journal.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION is now passing through the first stages of a similar development under less favorable circumstances. Like its English brother, it has already been subjected to sharp criticism, it has had to meet the envy, jealousy, and disappointed ambition of disappointed persons and localities, but we have no doubt that in the end it will surmount all these obstacles, and have a future even more brilliant than its English brother.

Brooklyn, N. Y., has for several years given us two excellent society medical journals, the "*Proceedings of the Kings County Medical Society*," and the "*Annals of the Anatomical Society*." Unfortunately, both have suspended publication for the present. But however it may be that some medical societies may successfully conduct medical journals, it still remains true that the problem of medical journalism of the future does not admit of its best solution in this manner. The organizations are too unstable for the maintenance of permanent medical journals.

In examining for the causes which have led to the rapid and widespread multiplication of medical journals, we find them as numerous as the several classes of journals started.

One class, and that a large one, owes its existence to the desire of some person or persons to start a medical college, or to advance its supposed interests. It would perhaps be easy for individuals in each State to name the journals started for this purpose. But generally the purpose of these journals is so evident that all must recognize it. There are two ways by which these journals operate. The first and most creditable way is for the managers of the journals to incite a scientific and literary activity among all the persons interested in the proposed or existing medical college. The publication of excellent material in a journal emanating from any particular city directs the attention of the readers of the journal to this city, to these men, to this journal and this college. So long as this work is honestly done and the conduct of the journal creditable in all other respects, it is regarded with good-will by even such as differ from it in its ultimate aims. Unquestionably a large amount of scientific and literary work has been done under this stimulus which otherwise would have remained undone. On the whole, we think that such journals have earned the substantial regard of the profession.

But, especially in the past, a portion of these journals have operated in quite a different manner. They have devoted time and energy to the making of representations respecting themselves more creditable than the truth would warrant, and in attacking the persons and reputation of their rivals, real or supposed. The work of these journals makes a sorry spectacle to the medical student of past journalism. In this sort of journalism, personalities of the most bitter nature were often exhibited. Fortunately, the progress of events has removed most of these excrescences of medical journalism, and we may indulge the hope that they may never reappear.

Another class of medical journals sprang from the desire of some person to attack his real or supposed enemies without restraint. Perhaps the most noted example of this class is that of the "*Rush Light*," published in New York in 1800 by William Corbett, under the pseudonym of Peter Porcupine, for the villification of Dr. Benjamin Rush. Only seven numbers were published and only two bore the imprint of the place of publication. The last two were printed in London.

Another class of medical journals came from the desire of some person or persons to extend their reputation in certain lines of practice. This desire has given us many very excellent journals which we could ill afford to lose. They have gleaned the best the world has to give in knowledge or skill in certain lines of work and presented it to the profession in a compact readable form. The special disadvantage of these publications is that they are unstable. Generally they are discontinued as soon as their projector has established sufficient reputation and practice so that he can accomplish his wishes without this additional labor and expense. In so far as we have known they are usually published at a pecuniary loss to the individuals publishing them. The reason for this lies in the fact that their circulation is small and their expense great.

Within the past few years, manufacturers of drugs and chemicals, etc., have become the owners of medical journals, with the view of bringing their

products more clearly to the notice of the profession. For years they have practically supported medical journals by the money they have paid for their advertisements. In this manner they have practically controlled, in so far as they desired, the utterances of a considerable portion of medical journals upon subjects in which they had a special interest. Hence it was but a step to run a journal wholly in their own interests. Some excellent medical journals are now conducted on this basis. It does not appear that they are more subservient to the manufacturers' desires than those journals who carry large advertisements for the same manufacturers. Besides, most of the manufacturers have been shrewd enough to see that if they reached the ear and pockets of the profession, they must do it by obtaining and keeping their confidence. To obtain this confidence has been a difficult task, but that it can be done "The Ephemeris" of Dr. Squibb is abundant proof. Of course the danger of this class of medical journals lies in the possibility that the powerful influence of the capitalist may end in bending the journals to their present interests irrespective of the real facts and future profit. But this will doubtless correct itself, in that it will soon appear that any course other than a strictly fair and honest one will at last be suicidal both to the journal and the manufacturer.

Another class of medical journals has grown up in connection with the publication of medical books. Firms having large numbers of medical books to sell have found it to their advantage to publish medical journals. In this manner they have better been able to place their books before the individual physician. As a rule, these have been the best of medical journals. It would not be profitable to attempt to sell a good book by the publication of a low grade medical journal. As the value of the best medical books becomes more apparent, so will this class of medical publications come to the front. This class draws its contributions from a wide source and contains very much of the best material published. Large capital sustains them and large financial interests depend upon the excellence of their management. Hence it is reasonable to look to these for the best medical journals of the future.

A distinct profession of medical editors has not as yet been developed. Few even gain their living by acting as both editors and publishers. Some possibly live entirely by their editorial work, but their number is extremely small. A number get some pay in money for their work, but most get nothing. Not a few pay considerable sums for the chance of acting as editors. Most get simply the books and journals received in exchange. Hence as a rule medical editors get their living by the practice of medicine, their editorial duties being performed in the intervals of their regular daily work. Unquestionably medical journals as a whole suffer from this condition of things, but the remedy for it is not yet apparent. When medical colleges shall be able to pay each teacher, so that he can devote his entire life to study and teaching, then perhaps medical journals will be able to pay their editors sufficient to enable them to devote their entire energies to the conduct of their respective medical journals. As the day for the former seems far distant, so that of the latter is not near at hand.

The influence and power of medical journals depend largely upon their subscription lists. It is a difficult subject upon which to collect reliable data; still, it is certain that the paying subscription lists of most medical journals is small. A few issue from 1,000 to several thousand copies of each number to paying individual subscribers. But more issue less than 1,000, and not an inconsiderable number less than 500. Of course larger editions are issued, but several hundreds are sent to book-publishers, advertisers, exchanges, and deadheads. The reason why it is so difficult to get accurate information in regard to exact circulation, is that upon this circulation, real or unreal, is based the estimated value of the advertising pages. To confess a small circulation, would at once discourage advertisers from paying so large a price as is asked for the advertising columns. Still, the advertising value of a medical journal cannot be accurately estimated from even the exact number of copies mailed to paying subscribers. Much depends upon the persons who read the journal, and the confidence they repose in its statements. Shrewd advertisers recognize this fact, and upon it base their estimate of the relative value of advertisements in different medical journals. The roar of a lion will arouse more attention in a given community than the bleating of a lamb.

The history of the past ninety years shows that the number of medical journals with large subscription lists is constantly increasing. While none are able to maintain a continued prosperity without advertisements, it is to be expected that advertisements will have a decreasing influence upon the utterances of the editorial pages. A large subscription list is the only condition of escape from all bondage in this respect. Being wholly free from any bondage to the advertising pages, these pages would still remain both a source of increased income to the journal and of instruction to all its readers, in matters pertaining to the preparations produced by the arts of chemistry and pharmacy. But it has always seemed to us that in the pages of the real medical journal of the highest class, no advertisements of preparations would find a place which the reader of the journal might not prescribe with the feeling that he was doing that which would encourage both medical and pharmaceutical art.

The prices of medical journals have presented a curious spectacle, one worthy of careful study. Just now medical journalism is passing through an epidemic of cheap medical journals. I do not use the word "cheap" simply in the money sense, but in every sense—cheap in price, from $1 to nothing, and even paying the purchaser for taking them; cheap in make-up, in paper, in press-work, cheap in editorial work, and cheap in contributed articles. These journals have had a large patronage, by appealing to that thrift which eagerly seeks to get things for less than their actual value, and by that self-complacency which makes its owner believe that through this slight expenditure of money, and effort to read and brains

to understand, he can keep fully posted as to the changes taking place in the medical world. Farther, this style of medical journalism has led to the propagation of much nonsense respecting the calls of the "busy practitioner" for brief articles. This call for brief articles has just this truth in it, which saves it from being an unmitigated falsehood, viz.: The shortest space in which thought and facts can be clearly and forcibly set forth, is just the space each article should occupy. Many excellent articles do occupy far more space. But, on the other hand, a large proportion of the so-called brief articles contain absolutely nothing worthy the attention of any studious medical man. Then, the busiest men in the profession are those who not only find time to read all the long articles in all the medical journals which have a bearing upon their studies and practice, but they also find time to write long articles for medical societies and medical journals, and even to write our very best medical books. The "cant" of those who "boom" the cheap medical literature is harmful to all concerned, unless it is discounted at its actual value. It is a settled principle that in trade men usually get only that for which they pay. They may be deceived and get less, but not more. Hence, it may be understood by every intelligent physician that when he subscribes for a 50-cent journal he will get 50 cents' worth, just as when he subscribes for a $5 journal he will get $5 worth. Occasionally, it is true, that far more than the subscription value is given by a medical journal, because the proprietor has quite other ends to attain than the simple publishing of a journal for the returns by subscriptions. An illustration of this is seen in the *Ephemeris*, by Dr. Squibb. It is sent to those who wish it, for nothing. His object is simply to advertise his goods, by educating physicians as to their exact nature and peculiar virtues. Other excellent journals are published in a similar manner. The publishers get their pay for their publications by the sale of their goods. These are, however, exceptions, and so serve to prove the rule as old as the world and based upon commercial principles. We regard this epidemic of cheap medical literature as short-lived, and as a needful preliminary to the further development of the best sort of medical journalism. It is making a demonstration of an unfruitful field of medical journal labor. A cheap medical journal may be a good thing for the waste-basket, but it is not a product to which its owner will in the future point with pride, as it stands upon his library shelves. Its existence will serve to induce the publishers of the best sort of medical journals to furnish their products at as low a price as is consistent with excellence of work. It also shows the folly of attempting to cover even a small field of medical science regularly for 50 cents a year, more or less by a few cents.

Such are some of the facts relating to the growth of American medical journals. In truth these journals will compare favorably with the medical journals of any country. We have some good as the best, we have many poor, but it does not appear that we have the poorest. Many have been stranded by the progress of events, their history remaining to teach us the mistakes of their founders and conductors. Considering the crudities by which all such enterprises are surrounded at their beginning in a new country, it is surprising that the United States has made so good a record. As a whole our medical journals have advocated the right and labored for what they regarded as professional advancement. If they are to be compared with their allies in making and moulding medical thought and progress, medical colleges and medical societies, we think that medical journals have no occasion to be downcast. But comparison is unprofitable. Each has done its part more or less imperfectly but still so as to gain the general commendation of all real workers for medical progress. But what of the future? Does the past ninety years of medical journalism give any hint as to the medical journalism of the future? In a general way, yes; as to details, no.

In a general way, judging from the facts presented and suggested, we venture to suggest some general principles along which the medical journals must move.

1. A great many different persons having diverse aims will endeavor to originate and conduct medical journals. Of these the fittest will survive, those who can teach best through medical journals, the largest number of practitioners and investigators. In this manner the best available talent for editorial work will find its fitting field. A medical editor like a poet is born and not made. Only by the fullest liberty can he find his fitting work.

2. The largest and most influential medical journals will develop in the great commercial centres. Those of less power in the lesser cities. All these will at last so be established that it will become a matter of such difficulty to start new journals at every new cross-road, that few will care to undertake the task.

3. With increase of wealth and power the great medical journals will be able to pay their editors such salaries that they can afford to devote all their time and energies to the conduct of their several journals. This will result in the formation of a profession of medical journalists. As reporters, as correspondents, as editorial writers, etc., a corps of many workers will be found under each editor. Those exhibiting greatest fitness for editorial work will in turn take their places at the head of medical journals. Thus will medical journalists attain their highest teaching power, and an influence unsurpassed by any class of instructors in the profession.

4. The medical journals of the future will more and more be separated from medical colleges, medical societies, and all other corporate bodies that in any way cripple their perfect independence to work, and think, and speak for the great masses of the medical profession. This separation will be an indication that the best days of medical journalism are approaching, and that the conductors of these journals have recognized the elements of best success in medical journalism. Being thus perfectly independent of any particular body of men or special interests, medical journals will be able to speak for all interests in so far as they tend to the common good

and to condemn all that are opposed to the common good.

5. The advertising columns of the medical journal of the future will have less and less influence over the utterances of the editorial pages. One of the sad things of past medical journalism is the prostitution of the reading pages to the supposed interests of the advertising columns. Secular journals have sinned in this respect, but medical journals cannot be called spotless. But the future medical journal of greatest power for good in the profession, will show itself without stain even in every advertising page, as well as reading matter proper.

6. The advertising columns of the best medical journal of the future will contain a notice of nothing which shall not be free to every pharmacist to manufacture, as free as the formulas of the pharmacopœia. This will exclude all proprietary and copyrighted medicines of every sort. It will serve to encourage skillful and learned pharmacists to work with and for the medical profession directly, and so stimulate the best growth of the science and art of chemistry, pharmacy and medicine. Each respecting the rights of all other workers, will contribute their utmost to the advancement of common interests. If reduced to their proper number and supported by the medical profession as a whole, the medical journals could afford to take this step in the direction of freedom in all that pertains to the materials of the medical art.

7. The medical journals of the future will be able to pay more and more for the contributions to their pages as well as to their editors. This will encourage every struggling practitioner to make the most of all the material at his disposal. It will also place the editor in such a position that he can refuse all articles that have not decidedly positive merit in them. In this manner a vast amount of worthless trash will be prevented from cumbering the libraries of the future. Money compensation for all work done on a medical journal will sift the good from the poor, and obtain the very best the profession can produce with a minimum of the worst.

8. How shall we reach this end? It strikes me that it will be best to let experience do most of the teaching. The past shows that it is impossible to persuade a man that he is unfit to run a medical journal, until he has convinced himself by trying. The more who try, the more will there be of the class who know themselves unfit for medical editorship. Colleges have largely learned already that a college "organ" does not pay. Hence they have largely dropped this method of advancing the interests of their schools. Others who start medical journals to build up special interests will ultimately find that these interests would have been better served by not starting a journal. Naturally they will drop it.

Then as the conviction grows in the profession, that eminence and power in the profession must be earned by honest hard work, so will there be less inducement for the starting of numerous medical periodicals.

Beyond a doubt, years of prosperity will in the future as in the past be attended by a large crop of new medical journals, and years of depression by a small crop. But out of it all shall surely rise the medical journals of the future—journals in all true senses independent of all influences not tending to the uplifting of the medical profession to the highest position attainable for it—journals that in pure English shall represent the finest scholarship of the century—the truest manhood, the honesty and courage to speak the truth as occasion shall call for it without favor or fear of any college, advertiser, or clique of men of any sort—journals that shall not only fully and fairly represent the past and present condition of medical science and art, but shall inspire enthusiasm in all their readers to struggle for the best attainments possible in the future.

103 Cass St., Detroit, Mich.

PHTHISIS—ITS SUCCESSFUL TREATMENT.

BY J. P. MILLER, M.D., BUCKHANNON, W. VA.

Read in the Section of Practice of Medicine and Materia Medica, May, 1884.

At this, the noon of micro-organific light, it would be a breach of order in medical authorship to touch the intra-thorax without a temerarious parade of one's knowledge of the *bacillus tuberculosis*. But in these halcyon days of elaborate reviews, retrospects, weekly couriers, records, bulletins, and budgets, almost universally distributed to members of the profession through the advertising and enterprising ingenuity of medical publishers, few, if any, of us could come here other than replete with knowledge and opinion of this much-discussed organism.

To dispel the incubus of your apprehensions I shall begin by promising not to subject you to the tedium of a bacteriologist. Though not assuming such proportions, I shall not avoid a casual notice of this "idea of the season."

When Koch, the great apostle of bacterian pathology, made known the results of his investigation in Berlin a few years ago, in less than forty-eight hours the contents of his paper were telegraphed to the world, the important part of which, and that which defined his position, said: "The active agent in the causation and propagation of tuberculosis is a distinct species of bacterium—a bacillus. Tuberculosis does not occur without the presence of these organisms, and conversely, no disease should be regarded tuberculosis * * * without the presence and vital activity of this bacillus."

Out of 150 tubercular specimens at various stages of development, Spina *did not find bacilli in one*.

Dr. H. B. Formad,[1] with the view of proving or disproving the position of Koch, utilized tubercular material from the autopsy table of over 400 cases, the result of which was the conclusion on his part that tuberculosis is not a contagious disease.

In the nature of things it involves so many ques-

[1] Journal American Medical Association, Feb. 9, 1884.

tions of actual scientific research that your opinions would probably be little aided, if at all, by any position which I might now assume. I avow my belief, however, that Koch's discovery will not assist us in either remedying the disease when it comes before us, or diminishing the frequency of its occurrence. His theory of contagiousness is already waning. Upon the threshold of the decadence of its lustre we stand much advanced, and in the full light of science which has doubtless attained to the ultima thule of the bacillus tuberculosis. But I must avoid posing here, taking counsel of the opportune suggestion of the Chairman of this Section in our last meeting, that one can now illy afford to shine with borrowed light. I shall offer facts of which I have the best verification—the evidence of my own senses.

In pulmonary consumption we recognize a malady at once the saddest and most important of all somatic diseases. It chooses its victims chiefly among those who are marked as "superior men and women," because of their bright intellects and often high culture, carrying away fully one-third of all who die in middle life. The prevailing belief with the populace is that a person affected with phthisis is surely doomed, whether speedily or slowly, to an uninterrupted progress to death. This shadowy belief is sustained by a very large majority of practicing physicians, some of whom denounce with vehemence any and all who claim to remedy this disease, as being charlatans.

Having for ten years done an extensive practice in a climate remarkable for its excessive humidity and its variable, very rapid and extreme thermal changes, respiratory diseases have been no small factor in the total sum of diseases I have been called upon to treat. During winter and spring thirty-five to fifty degrees Fahrenheit rise or fall in twenty-four hours is not uncommon, and I remember a rise from 10° below zero at morning's dawn to 54° above at 3 o'clock P. M., or sixty-four degrees in nine hours. Though 1,600 feet above tidewater, this extraordinary climate has been peculiarly favorable in affording large opportunities to the rural practitioner for clinically studying phthisis in its many phases, forms, peculiarities, and complications.

By reason of my success in its treatment during the last five years, I am prepared to place myself in opposition to the common belief that it is an irremediable disease. I shall not enter upon a disquisition of its history, pathology, etiology, or semeiology, but will confine myself chiefly to the treatment of its various stages and complications.

There lurks in the memory of all of us a nebulous notion that phthisis is refined into a certain number of distinct types. Furbish up our knowledge of these anatomo-pathological refinements as we may, we are liable to fail, clinically, to determine the presence or absence of tubercle.

In the so-called caseous phthisis or *phthisis florida*, pyrexia is the more conspicuous symptom, ranging from 104°-106°. The stomach will seldom bear our most potent antipyretics. Dr. Bartholow, to whom I sent a patient with this disease four years ago, advised me to give quinine grs. xx, in ten-grain doses night and morning with digitalis grains j-ij, three to four days each week, but the intestinal irritability and nausea which followed made me chary of its use—indeed, since the death of that patient I have not regained courage to try it again. I have tried every known antipyretic. Salicylate of sodium will more often than any other be found serviceable.

The type of fever should be carefully studied: Is it in its usual form, quotidian; if so, simple or double? Let salicylate of sodium grs. xvi-xxiv, and where there is gastric or intestinal irritability, or diarrhœa, morphia gr. ¼-½ combined with each dose, be given during remission and one hour before exacerbation. If this does not hold fever in check give two doses; three hours and one hour before thermal rise. The stomach may bear this from one to three weeks.

Anorexia, as a concomitant of phthisis, is the rule, its absence the exception; especially in fibroid and tubercular phthisis during incipiency is this a prominent symptom. Here I permit small doses, about a tablespoonful, of whiskey with a bitter, as wild-cherry bark or nux vomica, with each meal, but I never fail to impress my patient with the fact that whiskey is not antidotal to pulmonic degeneration.

The *Liver*, in phthisis as in pneumonia, is congested, and jaundice, more or less decided, may be present. This condition is conspicuous in those addicted to the use of alcoholics, and those tainted with malarial infection. An accompanying gastro-duodenal catarrh may so derange digestion as to necessitate the constant use of stomachics, and in the early stage laxatives. Dextro-quinine is antidotal to malaria and at the same time a laxative and antipyretic. Its adaptability here is patent. But before long it usually proves irritant to the stomach and bowels, when it may be given alternate days or weeks with hydrastis in such doses as the stomach will bear, and enough to produce one and two actions on the bowels daily.

Our more unfortunate patient—disciple of Bacchus—dare not now if he choose and can, break the habit of years however detrimental to the lungs, but a gradual diminution of quantity is to be enjoined. Stomachics, laxatives, and tonics may be combined with his "bitters," and if degeneration can be arrested and the lungs restored, the use of alcoholics of all kinds must be interdicted.

Nausea and vomiting are often coupled with lack of appetite, emaciating the patient to an alarming extent. This is doubly unfortunate, as food and remedial measures are alike rejected and ejected by such stomachs. These valetudinarian stomachs are a very "Safe" against therapeutics, of which I do not profess to carry the "combination." It is difficult to conceive of a condition more embarrassing to our skill, and burdensome to our powers. However, I do not banish my patient to despair. The doctor here may take latitude in caprice with the stomach and try almost everything. I usually begin with:

℞ Acid carbolici..... 3i.
Tincturæ iodi..... 3ij.
M. S., gtts. iij in water before food.

Or,

℞ Strychnia ..... gr.i.
Acidum nitrohydrochloricum dilutum ..... ℥ss.
M. S., gtts. v–viij in water before food.

Again, Fowler's solution may be given in small doses, not to exceed three drops, in water before eating. Three to six drops of deodorized tincture of opium added to each dose of Fowler's solution when there is diarrhœa is very efficient. Sinapisms over the pit of stomach before eating are necessary in very obstinate cases until digestion is established, which will be aided by giving pepsin after eating. The potency of pepsin is increased by giving nitrohydrochloric acid before meals.

Having subdued pyrexia, allayed nausea, and overcome anorexia, an enormous leverage has been obtained for direct methods of remedial treatment of the lungs. If caseous or tubercular formations have invaded the alveoli or parenchyma of the lungs, do we possess means to procure softening, absorption and extrusion? In attesting to the affirmative of this question I shall do so only so far as my own clinical observation warrants. The best knowledge for practice is what a man gets for himself. In medical or surgical practice, it is said, the results obtained from any means or methods of treatment are proper tests by which their value may be judged.

Qualified by the precision of this formula, the article of first value is Yerba Santa. I administer it in the form of fluid extract in half to teaspoonful doses three times a day, just before or after food.

As intelligent men, scientific and enlightened practitioners, you will demand the rationalé of its action. This I cannot give, for the resulting benefits are empiric facts which you must take on trust. I am unadvised of its chemical parts, nor have I learned of its physiological action. I have not even heard it extolled by any medical writer or teacher, but I have used it in no small number of cases during the last four years and its remarkable effects, even in typically bad cases, induced me to prepare a clinical record of some of these as a part of this paper, but its technical limit suggests the omission of the prosy narration of cases, than which nothing can be more dreary.

In puissance, as a solvent of tubercular and caseous deposits in the lungs, Yerba Santa has no equal in our materia medica. It is a laxative, and in the early stage of phthisis while there is gastro-hepatic torpor, duodenal cattarrh, with accompanying irregularity or inaction of bowels, Yerba Santa is all that is required, and yet its mildness of action does not prevent its use in more advanced cases when the bowels are moderately lax. Diarrhœa must, of course, first be checked.

I have repeatedly observed in cases of pyrexial phthisis, where every conceivable antipyretic means failed to make an impression, the free and continuous use of Yerba Santa bring a temperature of 105½° to 99½° in less than a week, and while under its influence not rise above 102°. The patient complained of sweating too freely all that time.

It is known that night sweats do lower temperature, and until the subsidence of pyrexia they should not be stopped by the usual means; as continuous diapedesis will surely and permanently bring down fever. Yerba Santa will produce such perspiration during waking hours that your patient will soon tell you that he no longer has those cold night sweats. When the temperature is normal, or sub-normal, and owing to loss of power of the vaso-motor system, the patient has night sweats, picrotoxine, or atropia and strychnia, will be efficient and proper.

As all our efforts of medication and alimentation are recuperative, we would naturally cast about for some counter-irritant that is not depleting—not a vesicant. This ensnaring plausibility is purely speculative, as heavy perplexity and embarrassed satisfaction have long ago taught me. I have for some years used cantharidal unguents to most thorough vesication over entire area of diseased lung or lungs, and I have never had to do other than congratulate myself upon the immediate advantage. There is no time here for following the vagaries of theory or of therapeutists. Blisters and every relay of blisters will cause you to exult over your pluck. The more abiding its issue the more marked is its good effect, and when we find phthisis the sequel of pneumonia, more especially of pleuro-pneumonia, or interstitial pneumonia where the inflammation of pleura and interlobular connective tissue is largely increased, the invading disorganization and degeneration are modified, if not arrested, by this potent means.

During incipiency, before the thermal rise is great, and again when it is waning, the absolescence of the exudate will be greatly facilitated by the use of iodide of iron and cod liver oil. The best way of administering this is with Trommer's extract of malt. Additionally, this is the most admirable constitutional support of which we know for those cases, and has a well known advantage in those tainted with scrofula. The stomach must be made tolerant of its use by beginning with very small doses, a half teaspoonful or less, gradually increased to a teaspoonful, never to exceed a dessertspoonful, just at the beginning of each meal.

When the alveoli are being invaded by an extension of catarrh of the bronchi, as the sequel of rubeola, scarlatina, pertussis, or a succession of deep colds, I like the effects of the iodide and carbonate of ammonia, and give it in pleasant form.

℞ Ammonii Iodidum..... ℥j.
Ammonii Carbonas..... ℥iss.
Syrupi Tolutanus.
Aquæ .....ãã ℥ij. M.

Signa: A teaspoonful every four hours.

This form is more usually accompanied with a harassing cough, granular pharyngitis, burning in throat and fauces often compared by the patient to a "coal of fire." Insufflation of sulphur is often good. I prefer boracic acid in fine powder and bicarbonate of soda equal parts. The best instrument for this purpose, so far as I know, is Trodd's Powder Blower, manufactured by Sharp & Smith, Chicago. I order the powder to be blown into the pharynx as often as pain is experienced, even if every half-hour. Iodoform ℥j., sulph. æther, ℥j M., in very obstinate cases may

be necessary; of this, two drops thrown in the pharynx twice a day in addition to the above will be found beneficial. Expectoration, when profuse, is usually acrid, producing erosion of upper larynx, and pharynx. Atropia, gr. j–℥j in one and two drop doses every six hours, will be highly serviceable here.

I shall now speak of one or two types of phthisis which offer almost nothing but discouragement, and do so without going into the intricacies of semiology. Miliary tubercles, when scattered even in very large quantities throughout the lung substance, give rise to no symptoms by which their presence might be recognized or even suspected so long as they remain isolated. The wily artifice of death here bespeaks a very entity of intelligence, moulding and fixing, cautiously isolated with covert hand, a calculated abundance of these nodes, as torpedoes, to fatally shatter its victim in the explosion of coalescence which must before long follow.

This class we will usually see at, or shortly after, pubescence. They are sallow, anæmic, of a decidedly phthisical dyscrasia, which the history of the case discovers to us as the stamp of patrimony, by Bartholow facetiously designated as "gelatinous children of albuminous parents." The bravest of us, graced with an array of successfully treated cases on our list, must lack courage when brought before one of these. The lung change, when once discovered, is active, temperature-course remarkably fitful, morning depression may be 96; evening exacerbation 104.

Lastly, I wish to call your attention to a form of phthisis on which our books are silent. It is a slow form of phthisis peculiar to women unbraced by chronic uterine ailment. The buoyancy so characteristic of consumption is wanting here, and we find our patient in the slough of despond. Though her whims are pampered, and her slightest caprices anticipated, she may be irritable or melancholy over imagined neglect or supposed tire of those in whose affection she is nearest. Subjective symptoms are vague and mostly phenomenal, the slightest of which is brooded upon and nursed into an unwholesome importance, requiring as great æsthetic skill to right her psychical wrong, as medical knowledge to treat her physical ill. We have no complication of phthisis, which we may reasonably hope to benefit, that will ever and under all circumstances so perplex us when we come to treatment.

Having no data except that of my own experience, which until quite recently had nothing to encourage, and is still not ripe in assurance, I mean at present to merely call attention to this condition, and if with farther observation of my present method of treatment, its success warrants, I may again address this Section.

Finally: Being called upon for help by a subject of phthisis, we should be fully alive to the fact that he is closely besieged by Death; and beyond the immediate redoubt of therapeutics we must reconnoiter and sentinel, with sleepless vigilance, the environment. Undue anxiety of friends, superstitions of neighbors, the allurements of the advertising charlatan, the wily and wise nihilists, in and out of the profession, bring influences to bear upon our patient that operate as a Gatling against us, and we may be vanquished.

Time, and other observers, may reverse the verdict, but I cannot help feeling that, these adverse influences successfully guarded against, conjoined with the remedies and methods herein recommended, boldly, skillfully, and persistently applied, will prove the means for the fine achievement of curing a high per cent. of that form of thoracic degeneration which has hitherto baffled our science, and is a standing opprobrium to our profession.

Buckhannon, W. Va., April 23, 1884.

MEDICAL PROGRESS.

ANATOMY AND PHYSIOLOGY.

MOVEMENTS OF THE BRAIN.—M. Béclard at a recent meeting of the Paris Academy of Medicine replied at length to the statements of M. Luys respecting the movements of the brain, to the effect that the question itself was an old one, and that certain very restricted movements were noticeable after trephining the skull, and that polygraphic tamtors have registered these movements in unison with those of respiration and circulation. What is thus seen after trephining in the dog is also seen by watching the fontanelles in the infant. In the adult these phenomena also exist. Slight movements are rendered possible by the presence of the subarachnoid fluid and the elastic tissues. The brain with its envelopes fill completely the cranial cavity, the dura mater acting as the periosteum. There is no empty space in these visceral cavities. To detach the brain from the superior wall of the cranium requires a force equivalent to a column of mercury 76 centimeters high and two decimeters square at its base, that is to say, more than 200 kilogrammes. He had examined with care the illustrations given by M. Luys, whose arguments were not based upon any experiments applicable to man. On the contrary, there were experiments made upon animals, which are absolutely demonstrative and contradict the conclusions of M. Luys. It is now over 30 years since they were first made. Among them he cited those of M. Salatĕ who showed the movements of the brain under the influence of the circulation and the respiration, and its immobility in whatever position the cranium was given.

SURGERY.

ON THE OPERATIVE TREATMENT OF HEPATITIS AND HEPATIC ABSCESS.—Dr. Patrick Manson in the *Medical Reports of the Chinese Imperial Maritime Customs*, uses in abscess of the liver a drainage-tube of stout rubber 8 or 10 inches long, with a bore of at least one-quarter of an inch, about 3 inches of one end of which is perforated with large holes like an ordinary drainage-tube, its outside circumference is considerably greater than that of the canula through

which it is to be introduced. After puncturing the abscess, withdrawing the trocar, and the matter ceases to flow in full stream, the rubber tube, mounted on a steel stylet provided with a silver cap loosely fitted to the end of the stylet, is passed through the canula until the cap is felt to impinge upon the posterior wall of the abscess. While one hand gently but firmly holds the stylet and tube in position, the other carefully and slowly withdraws the canula from the side of the patient, the fingers gaining the requisite purchase for the very considerable pull and half-rotating movement required, from the eyes of the canula. The tube has been kept on the stretch by a string tied to the eye of the stylet, this is now cut—the tube is held tightly grasped by the tissues, and its perforated end lies in the abscess sac—the elasticity of the rubber causes it to resile towards the fixed abscess end, and, expanding, firmly to block the wound in both liver and abdominal wall. The peritonæum is thus bridged across, and pus flows freely through the tube without any risk of escape by the side. The stylet is then withdrawn. The operation is performed with all antiseptic precautions and the dressings are made upon the same principles, the end of the drainage-tube is inserted into a silver tube two inches long, which has carbolized gauze and a stout macintosh attached to it, all of which is secured by two broad flannel rollers, one thoracic and one abdominal, the drain lying between. To the silver tube is attached six feet of rubber tubing five-eighths of an inch bore, already filled with carbolic acid solution kept from running out by clips, and with its free end placed in a wide-mouthed bottle of a capacity of about two ounces and firmly secured—this small bottle is placed in a large bottle containing carbolic solution. The syphon is now complete, and the abscess contents are discharged as soon as formed, by the tube and into the bottle. A fall of about 18 inches is usually sufficient to insure a steady drain. The object of the small bottle is to prevent the entrance of air into the tube when the larger bottle is emptied of discharge from time to time. As no discharge can pass by the side of the drainage-tube, there can be no soiling of the dressings, consequently the patient need not be disturbed to have these changed for a week at least, or as long as discharge readily escapes by the syphon. The advantages claimed for this operation are: 1. The ease with which it is performed. 2. Skilled assistance is not necessary. 3. It is absolutely bloodless—no small advantage where a patient by long illness is reduced almost to the last extremity. 4. It is applicable to both very deep and superficial abscesses. 5. By means of the syphon action of the drainage-tube, the most dependent part of the abscess is as thoroughly drained as the highest. This important point is not met in the operation by incision, where bagging of pus is as a rule inevitable. 6. Antiseptics are easily and efficiently used. 7. In the operation by incision or puncture, the dressings must be frequently changed, especially during the first few days after operating; in this operation a week may safely elapse without its being necessary to disturb the patient to dress him. This means an enormous saving in suffering and risk to the patient, and in trouble to the surgeon. 8. Liver pus is often so thick and viscid that it will hardly, unaided, flow through an ordinary drainage-tube, and when it does get through, being forced out by accumulation in the abscess cavity, it coagulates into a sort of jelly and is not absorbed like ordinary pus by gauze dressings. It tends to collect in a mass round the end of the drainage-tube, effectually plugging this and preventing free discharge. This peculiarity of some kinds of liver pus is very remarkable, and is a great obstacle to successful treatment. But by the methods of dressing recommended, this viscid coagulating pus is removed as soon as formed, and no blocking or obstruction occurs—the abscess is always empty. 9. In the operation by incision the patient lies in soiled dressings, and is in consequence uncomfortable and perhaps restless; by the syphon-drain this is entirely obviated. 10. In this operation there is no danger to be apprehended from escape of pus into the peritonæum, and it is therefore a matter of indifference whether adhesions have formed or not. The canula, and afterwards the tube, are so thoroughly grasped by the tissues that leakage is impossible; and before the tube has become slack, adhesions are likely to form between the peritoneal surfaces of the liver and abdominal wall. Besides, the abscess being always kept empty there is no pus to escape at the side of the tube; and, as a matter of experience, even when the tube has been weeks in position, not a drop of liver pus has ever soiled the dressings. 11. It is manifest that an elastic tube is superior to the rigid silver canula that is sometimes used. The latter must tear the liver tissue in the up and down movements of respiration; this is a very extensive motion, as one can easily see by watching the motion of the aspirator-needle when its point is buried in the liver.

Objections that may be raised to this operation are:—

1. The elasticity of the tissues may be so great as to compress the rubber tube and block it. This Dr. Manson has not found to occur. 2. As the ribs come together in empyema, or in liver abscess opened through an intercostal space, they will compress the tube. Once for a day or two in one case this seemed to happen, but the obstruction was never complete, and very soon the edges of the ribs, where the tube pressed in them, apparently became absorbed, just as bone is under the elastic pressure of an aneurism. 3. The difficulty of keeping the dressing in position. This undoubtedly is considerable, but can be met by care and contrivance. If insuperable, the ordinary dressing may be adopted and the syphon discarded. 4. The necessity for special apparatus. Manson has performed the operation with an ordinary large trocar and canula, an ordinary large sized drainage-tube, and the stylet of a No. 12 gum-elastic catheter.

Dr. Manson regards puncture with the aspirator as a valuable therapeutic agent in hepatitis, where abscess has not yet formed—he has never seen any bad results from its use in such cases, and is satisfied that it has averted the formation of abscess.

One of the cases cited by him is of peculiar inter-

est, as it presents the rare condition of a complete biliary fistula existing under observation for about two months. In this case after relief from hepatic abscess by this operation, the patient gained in strength and weight, his temperature was normal, the pulse 100 per minute. Two semi-solid stools, entirely devoid of bile, were passed every morning with the utmost regularity; sometimes the action of the bowels was preceded by colicky pains, but there was no diarrhœa. Food of the ordinary character, with a plentiful allowance of milk was freely consumed. Two hours after eating, 5 grains of inspissated ox-gall, made up into a pill, was taken three times a day. From the tables given the inference may be drawn—first, that the average secretion of bile in a man weighing about 100 pounds, eating heartily of ordinary food and taking no exercise, is over 28 ounces in the 24 hours; second, that the rate of secretion is very irregular, and has no apparent relation to the hours of eating; third, that in the case cited the escape of bile was in some measure vicarous of the urinary secretion.

MATERIA MEDICA AND THERAPEUTICS.

THE HYGIENIC TREATMENT OF ALBUMINURIA. — Senator (*Berl. Klin. Wochenschr.*); (*Jour. de Med.*), in considering the degree of albumen in the urine as the index to the character and severity of renal disease, regards its presence not objectionable from the amount of loss to the system which it represents so much as that it is *the* diagnostic symptom of importance. This being generally recognized the presence of albumen is important from another standpoint, if we admit that perhaps in many of such cases the albuminoid matters act as irritants to the parenchyma of the kidney itself. We know that egg albumen, when introduced into the blood, is eliminated through the kidneys, and, what is most interesting, that the amount of albumen discharged exceeds the amount injected; so that it is not only the egg albumen which passes out with the urine, but also the albumen of the blood-serum—thereby determining the excretion of a new quantity of albumen. It is not improbable that the peptones act like the egg albumen, and it is possible that the albumen excreted in Bright's Disease is so altered as to act like a poison upon the kidney.

The general uselessness of drugs in chronic nephritis, and the often spontaneous relief to acute nephritis, with the variations for better and for worse which occur in chronic nephritis independent of all medication, and the benefits of a rational hygienic treatment, give to the latter a considerable degree of importance. The first question here, then, is upon diet, in which two things are to be considered: the quantity and the quality of nourishment.

As to the *quantity*. The latest researches have shown that albumen in the urine increases during digestion, in those in whom it is constantly present, and that it reappears where it had apparently disappeared. Even in healthy persons we may note its presence after a copious repast. The patient, then, must avoid abundant repasts; he may eat often, but little at a time.

As to the *quality*. From what has been said Senator interdicts positively the use of eggs. Cheese and meat come under the same ban, and for the same reasons. Lichtheim adds another inconvenience which results from an alimentation rich in nitrogenous matters, viz.: the accumulation of urea in the blood with its consequences (uræmia). Recognizing their importance as food to many, Senator considers it necessary to *moderate* the use of meat and cheese, and to confine the diet to flesh which contains comparatively little nitrogen, as veal, young chicken, fish, etc. On the other hand, he recommends the free use of a vegetable alimentation, especially those vegetables which are poorest in albuminoid matters, such as the greens, salads, fruits, etc.; regulating the diet, of course, as far as possible, to the preferences of the patient and the condition of the digestive organs. The fats may be allowed in certain quantity if well tolerated.

As to *drinks*, it has been the custom to interdict empirically the use of alcoholic drinks. Senator is of the opinion, that we should not always interdict their use, particularly with those habituated to them. We may deny the use of brandy, etc., but allow the use of red wine (claret). He has seen beer increase the quantity of albumen, but has never observed a case where claret influenced the presence of albumen in the urinary secretion. Spiced and smoked meats are objectionable.

As to the *milk cure*, which has been so justly appreciated for a long time, it is not a question of an exclusive milk diet, for such a regime would not be tolerated for many days—it requires to be absorbed in too great quantity—two liters of milk would not contain enough of the albuminoid substances to nourish a man who passes his time in inaction. To assist this Senator gives with the milk a small quantity of white bread, or perhaps a little soup.

Of *mineral waters*, the saline and alkalino-saline waters as drinks are the best, and may be either hot or cold as the case may be. We do not know what the action is. One would suppose that these salts would irritate the kidney rather than benefit it, but experience proves the contrary—perhaps they act by assisting the digestive functions and modifying the decomposition of the blood. Employed as baths they have also an undeniable influence upon assimilation and disassimilation, thereby acting perhaps favorably in albuminuria; but their action on the skin is of the first importance—however it may be explained, it is an established fact that if a patient loses much water by the skin, the absolute quantity of albumen diminishes in the urine; its relative quantity, it is true, is greater, but that is accounted for by the diminution in the quantity of water. Therefore it is well to keep the skin in a constant state of more or less active transpiration—warm baths; flannel next to the skin; keeping to the bed for weeks or even months, and suppressing as much as possible, *muscular movements*. Observation has shown that muscular movements increase the quantity of albumen. The same may be

said of moral emotions. Menstruation regularly increases the quantity of albumen, so that we must be particularly careful to observe prescribed rules at such periods.

Finally, to produce the best results an appropriate climate must be selected by choosing the dry regions of the South, where the beneficial influence is exerted upon the skin, with muscular and intellectual repose, and with a vegetable diet.

Musk.—Dr. D. J. Macgowan (*Chinese Customs Medical Reports*) records two cases illustrating the beneficial use of the Chinese musk-plaster with four grains added. The first was a case of severe lumbago, in a rheumatic patient, and of ten days' standing, which had been treated in the usual way without relief. The application of the plaster was followed by sleep in two hours, the next morning the pain was barely perceptible, and in three days it wholly disappeared. The second was a sprained ankle with extensive tumefaction and intolerable pain; the application was made eleven hours after the injury. Ten hours later the patient fell asleep and in the morning the joint was painful only upon pressure. On the fifth day walking was partially renewed, and in a few days more the only trace of the injury was a stiffness of the joint, which continued much longer.

Dr. Macgowan gives an account of the Chinese mode of obtaining musk from the musk-deer and civet-cat; and tells us that this valuable substance no sooner leaves the hunter's hand than skilful manipulators adulterate the article for wholesale dealers, who adulterate it for the trade, when it is found to possess about 10 per cent. of genuine musk.

MEDICINE.

A Contribution to the History of Syphilis.—Dr. B. Schenhe, of Leipzig, refers (*Chinese Customs Medical Reports*) to a work of Japanese origin, and drawn up in the year 808, by two of the private physicians to the then reigning emperor, as an annotation and collection of all that was extant relating to the national art of medicine. It unfortunately remained unknown, and it was only at the beginning of this century that it was for the first time printed. In 1827 a certain Bude found a well-preserved manuscript in a temple, and published it. Since then it has been several times re-issued. It is composed in the ancient language of Japan, but it is transliterated into Chinese characters. Two chapters relate to syphilis. We see bubo, chancre, œdema preputii, phagedenic chancre, exanthemata, bone and joint affections, ulceration of the throat, and severe tertiary symptoms briefly indicated in their order, and finally otorrhœa added, though this, indeed, is here not so thoroughly in its place.

The inter-dependence of all these affections was known to the authors; they already, therefore, considered syphilis as a specific disease. It is not possible to say whether they hold that it is contagious, and especially whether they believe it to be communicable by sexual intercourse; for the doctrines of Chino-Japanese medicine attribute other diseases which are not contagious to the operation of special poisons.

A Case of Anuria Persisting for Fifteen Days Without Injurious Effects.—Dr. L. Chappot de la Chanomé, in *Le Concours Medical*, cites a case occurring in a man aged 66 years, who complained of pains in the lumbar region, general discomfort, and loss of appetite. There was no fever, and the tongue was natural. He prescribed a saline purgative, and friction over the painful region. The next day the patient declared that he had not passed urine for three days, but that it did not trouble him, as he felt no desire to do so. Palpation showed that the bladder was empty, or nearly so; but to make sure, he introduced a catheter, without producing a single drop of urine. He prescribed energetic diuretics, but without result. Six days later he called Dr. Bonin, of Monchamp, in consultation, and catheterism was again practiced, without effect. The prognosis naturally was very grave. The patient kept to his bed, had no fever, but a strong dislike to food and a decided relative weakness. He talked freely with those around him, and complained somewhat of lumbar pains. Diuretics and sudorifics were freely used, strychnia was given, the lumbar region was blistered, and warm baths were administered. Every day there was a moderate amount of perspiration, of an odor like that which is found in some cases of rheumatism, and each day there were two or three stools of the character of an ordinary diarrhœa. Finally, on the fifteenth day of the anuria the patient felt for the first time a pressing desire to urinate, and he hardly emptied his bladder before the desire returned, and the urinal was filled more than once. This continued for the first twenty-four hours. The second and third days found the amount diminished, but much more considerable than under ordinary circumstances. After that the secretion became normal, the health of the patient was rapidly re-established, and the patient has been perfectly well ever since (eighteen months).

Prizes.—The Illinois State Medical Society, at its recent annual meeting, offered a prize of $100, for the best Essay on Diphtheria; and another of $100, for the best Tabulated Statement of ten cases of any important disease occurring in the practice of the writer. The awards are to be made by a committee of three appointed by the President of the Society, and to be done in time to have the papers presented at the next annual meeting of the Society.

Baby-Farming and Mortality.—At a Sanitarium or semi-charitable establishment near Hammonton, New Jersey, for the reception and care of foundlings, twenty-five infants were received since January 15, 1884, of whom twenty-three are dead. So extraordinary a mortality has attracted attention, and the coroner is investigating the institution and its surroundings. The mortality in all establishments for the reception and care of foundlings, is and must be large, unless healthy wet-nurses can be provided for the unfortunate infants; and too much care cannot be given to the management of such institutions when they are permitted to exist.

THE

Journal of American Medical Association.

PUBLISHED WEEKLY.

THE EDITOR of this JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information, should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE..... $5,00.
SINGLE COPIES..... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 65 RANDOLPH STREET,
CHICAGO, ILLINOIS.

SATURDAY, JUNE 14, 1884.

NEW MEMBERS OF THE ASSOCIATION AND THE JOURNAL.—We have received a few letters from new members or those who first acquired membership by attending, as delegates, the recent meeting of the Association in Washington, manifesting some impatience because they had not immediately commenced receiving the JOURNAL. We wish to state for the benefit of all parties that the editor and publisher are entirely dependent upon the Permanent Secretary for the minutes or official record of proceeding of each annual meeting; and upon the Treasurer for the names and addresses of all members, new or old, who are entitled to the JOURNAL from having paid their annual dues or membership fees.

The number of new members at Washington was unusually large, and to separate the new names from the old, the whole registration list must be carefully compared with the previous roll of paying members, requiring no little time and patience on the part of the Treasurer. When he had completed his work, and forwarded the names and addresses of between four and five hundred new members to this office, a considerable number of them were found to have been taking the JOURNAL as subscribers, and consequently their names were already on the mailing list. To prevent duplicating these, necessitated a close comparison of the new list with the mailing books throughout. These necessary preliminaries were not completed until the first week in June, during which the JOURNAL was mailed to nearly all the new members, although their regular Journal year will not commence until the first number in July, which begins the third volume. For it must be remembered that the membership fees for 1883 paid for volumes one and two, commencing July 1, 1883, and ending June 30, 1884; and the dues for 1884 pay for volumes three and four commencing July 1, 1884, and ending June 30, 1885. Consequently all numbers sent to new members between the time of the annual meeting and the first of July will be gratuitous, or in excess of their regular Journal year, during which they will have the two volumes, for which they pay, complete with title-page and full index for each.

THE HOSPITAL COLLEGE OF MEDICINE OF LOUISVILLE, KY.—This institution, which constitutes the Medical Department of Central University, held its regular annual commencement exercises on the evening of May 29, 1884, and conferred the degree of M.D. upon thirty-one candidates. The valedictory address in behalf of the Faculty was delivered by Prof. Dudley S. Reynolds, who, with many other items, gave the class the following good advice: "You should join the medical societies to which you are eligible. Comparison of experience and interchange of opinions strengthen and enlarge your views of practice. Publish all your particularly interesting observations and experiences for the benefit of your brethren." And he should have added, "keep a faithful record of all acute cases of disease, especially in reference to date of beginning, apparent etiological conditions, and results of treatment." Such a record commenced in the beginning of professional life, begets a habit of closer observation, greater accuracy of knowledge, and furnishes a storehouse of facts capable of correcting many erroneous general impressions made by the popular sentiments and doctrines everywhere surrounding the practitioners of the healing art. It was also announced that hereafter a moderate standard of general education will be required of all new applicants for admission to the courses of medical instruction in the college.

THE TREASURER'S REPORT.—The detailed report of the Treasurer of the American Medical Association, which should have been included in the Secretary's minutes of the recent annual meeting, will be found in another part of this number of the JOURNAL. It was unintentionally omitted from the minutes as furnished at the proper time.

MEMBERSHIP DUES AND SUBSCRIPTIONS.—Under the head of Miscellaneous matter will be found a standing official notice on this subject by the Treasurer. As there stated, all membership dues should

be paid to the Treasurer of the Association; and if not paid at the annual meeting, they should be remitted by mail to him (Rich. J. Dunglison, M.D., Lock Box 1274, Philadelphia, Pa.). If members fail to pay their dues for three years in succession, after due notice from the Secretary, they lose their membership. And if a member fails to pay his dues for one or two years, he cannot retain his membership by simply paying the dues for the *third* year; but the arrearages for all the years must be paid. We call attention to this, because the Association took direct action on the subject at its recent meeting, and left no discretion with the Treasurer in relation to the construction of the rules relating to the subject. We wish to call special attention, also, to the fact that under the new constitutional provision for admitting members by *application*, the application should be made in writing, directed to "the Treasurer of the Association," and accompanied by the membership fee, five dollars, and by a certificate of good standing as a member of the State or local Medical Society where the applicant lives, signed by the President and Secretary of such Society. Only subscribers to the JOURNAL who are not members of the Association, and advertisers, should remit money to the publication office, 65 Randolph street, Chicago, Ill.

SCARLATINA IN UTERO.—In an interesting paper read before the New York County Medical Association, April 21, 1884, Dr. Charles A. Leale relates a well marked case of scarlet fever in a child at birth. The mother was attacked with the disease at the end of the ninth month of pregnancy. Labor was induced when she was in the early part of the eruptive stage of the fever. The child was readily delivered with the forceps, and "was unmistakably in the midst of the eruptive period simultaneously with its mother."[1]

The disease proved highly malignant in the mother, causing her death fifty-six hours after her delivery. The child recovered. Such cases are very seldom met with, although a few are on record.

EPIDEMICS OF CHOLERA AND YELLOW FEVER.—Reports show that up to April 12, 1884, the cholera had been on the increase in Calcutta, while yellow fever prevails only very moderately in Rio de Janeiro, Havana and some other places within its native limits.

Whether either of these dreaded scourges will extend beyond their ordinary limits during the present summer remains to be seen. The health authorities in the South and Southwestern States are taking active measures to prevent any invasion of those States.

[1] MEDICAL NEWS of May 31, 1884.

LONG ISLAND COLLEGE HOSPITAL.—At the annual commencement of this college, held May 21, 1884, the degree of M.D. was conferred upon 44 candidates.

SOCIETY PROCEEDINGS.

CHICAGO MEDICAL SOCIETY.

The semi-monthly meeting of this Society was held on the evening of May 5, 1884, when two important papers were read. The first being on "Puerperal Septicæmia and Prophylaxis of Puerperal Inflammations," which was ably presented by Dr. G. Frank Lydston, wherein he differed from many eminent writers on these subjects. The paper is some 70 odd pages in length, written on legal cap, and consumed the greater part of the evening's session. Below will be found a brief synopsis. After reviewing with some vigor the discussion of "Puerperal Fever," in a New York journal, and that of the New York County Medical Society, and the admirable essays upon the subject by Drs. Thomas and Garrigues, the writer asks, What is puerperal fever? To define this, he stated, is a most difficult problem. Referring to the descriptions of Leishmans, Hervieux and Lusk, how widely different are their definitions, made at intervals extending over a period of years. Barker states that puerperal fever is an entity. To assume that diseases which may occur from numerous and most diverse causes in the non-puerperal female should change and become suddenly "specific" is illogical.

The writer did not, however, wish to be understood as advancing any arguments in favor of ignoring the danger of septicæmia, but simply offering a protest against what he was pleased to term the "septophobia" prevalent in some quarters. In other words, defined his position as midway between the two extremes of practice. Through the medium of the placenta, there is a constant interchange of nutritive and waste materials between the vascular systems of the mother and child. The former is far in excess of the latter, and is a physiological necessity. In this process of osmosis, the fluids are chiefly towards the child. At birth, however, all this is changed, and the osmosis is in the direction towards the maternal circulation. The afferent current is checked, and the lymphatics and veins of the mother are more active than ever, as it is mainly through them that the retrograde metamorphosis of tissue occurs, and which is the essence of physiological uterine involution. Or, as is described later in the paper, the function of the lymphatics and veins of the puerperal woman, is to remove those nutritive materials which by the removal of the fœtus have been rendered unnecessary. That a large amount of waste

material is thus removed is evidenced by the peculiar character of the colostrum. This, rather than the patulous condition of the uterine sinuses, is the most important physiological circumstance favoring septic absorption, for with the products of retrograde metamorphosis of tissue, we are likely to have absorbed the products of putrefactive changes. The so-called "Milk Fever" may also be ascribed to this cause, that is not necessarily injurious, as experienced obstetricians have lately stated, and Lusk states, that round micrococci are the necessary causal element of true septic fever. This, if it be true, agrees very well with the view just advanced. Lydston's belief is that milk fever is simply due to hyper-activity of the nutritive functions, resulting from the sudden introduction of an excessive amount of nutritive material into the circulation. It will be observed that the fever lasts only until the excess of material has had time for elimination chiefly through the selective action of the mammary glands. Of course, it must be admitted, that if products of putrefaction be also introduced, the rise of temperature and danger of eventuation in septicæmia will be proportionately increased. * * * * * * * * * * * * * Pale, weak, anæmic women are most liable to develop septicæmia, while if more robust women are sick at all, are most likely to be attacked by some variety of *local inflammation*, yet, should the latter have the clinical characteristics of a typical case of the disease. The origo-mali in the first case cannot be the same as that of the second, and the two forms will depend upon widely different causes in spite of the theory of the common cause, "septic absorption." Hypothetical typical cases of "puerperal fever," "local inflammations," with moderate and quite intense fever, etc., etc., were clearly illustrated and graphically described in a few succeeding pages of the paper where one woman that has passed through labor is a victim to toxic infection, whilst the other, who is plethoric, is markedly predisposed to inflammation. The one, whose tissues do not want for an abundance of nutritive pabulum. The other, whose tissues fairly crave for supplies of new material, and who practically speaking is a huge sponge ready for the absorption of any materials of an organic nature.

The writer though being inclined to believe that septæmia may occur from the absorption of fluid from which bacteria are absent,—sepsin—in its results, differs not at all from snake virus, and its destructiveness depends in a great measure upon local and constitutional conditions in the affected individual. In "pyæmia," however, which is but one grade of "septicæmia," bacteria must necessarily be present. In certain cases of mild febrile attacks following child-birth, it may be simply a traumatic fever. This, while often due to septic absorption, may also be due to nervous influences, or traumatic fever, resulting from nutritive disturbances (as shock) which is due to excessive reaction following nervous depression. Shock also may be due to the use of instruments. Malarial fever may also come on in the puerpera. Certainly then septic infection may not be present in any of these instances, and yet the case is diagnosed as septicæmia. In certain cases of septic infection, following labor, we have diffuse suppurating abscesses, differing little, if any, from "pyæmia" that may follow surgical operations, but the characteristic temperature curve is exceptional in the former, which is present in "pyæmic" fever. This form of puerperal septicæmia is sometimes very chronic, resulting in gluteal abscesses, and even secondary suppurative processes have been found (by himself) at the autopsy in the liver and kidneys. The causal element of the phases of diseases usually termed respectively pyæmia and septicæmia is the same, but the former is a misnomer. In one we have the formation of thrombi which contain micrococci and which become detached, enter the circulation until they lodge and form new foci for suppuration, etc., etc., etc., while in the other no thrombi are formed, or if formed, became so rapidly and thoroughly disintegrated that secondary suppurations do not result. Comparative illustrations were then given why metastatic abscesses cannot result from dissecting a wound which is septicæmic. In a general way the formation or non-formation of thrombi depends upon the intensity of the infection and the local and constitutional conditions present. Metastatic abscesses are quite exceptionally seen in the puerpera. This may be due (in part at least) to the fact that the patients are so speedily destroyed by the intense infection characteristic of puerperal septicæmia. Thomas goes to the extreme of attributing all puerperal disorders to the absorption of septic poison, and in further quoting that author, according to the writer, it matters not whether the disease be a phlebitis, cellulitis, lymphangitis, or peritonitis; the essence of the disorder is the absorption of poison into the blood of the puerperal woman through some solution of continuity in the genital tract. How about exposure as a cause?

Phlebitis following labor may give rise to the disease known as phlegmasia dolens, and may result from trauma, especially if exposure be superadded; or it may arise from simple thrombosis occurring independently of bacteria or septic processes in the same manner as cellulitis may arise. * * .* * * A "locus minoris resistientiæ" may be afforded, and the women being especially susceptible to cold and depressing influences of all kinds, it remains but for an exposure to a draught of air to light up an inflammation of the uterus constituting a metritis, or a pelvi-peritonitis, or cellulitis. The simple passage of a sound into the non-pregnant uterus has been known to produce pelvic inflammation, severe cellulitis, etc., etc. A rapidly fatal general peritonitis has also been caused in the puerperal woman by simple extension of the pelvic peritonæum. In these cases if septicæmia occur at all, it is secondary to, or a complication of the inflammatory affection.

Before closing the review of this portion of the article the reporter wishes to *add* again that Dr. Lydston does not deny that puerperal peritonitis undoubtedly often is septic in origin, but he emphatically insists that it is not always so, and that there is not a characteristic "septic peritonitis." * * * * *

Regarding the conversion of the poison of the exanthemata into a specific "puerperal poison," the

writer states *it is absolutely untenable* for the reasons explained in his paper.

The "Unity" of the "materies morbi." The apparent inter-dependence of the poisons of different diseases were to some extent forcibly impressed in the paper by the writer's citation of numerous cases, and the variations dependent upon sanitary surroundings, etc., etc.

Considerable space was devoted to the diphtheria of puerperal wounds, and puerperal erysipelas. The former happily is not of very great frequency, and it has possibility or a strong probability of parasitic origin along the genital tract. The latter disease, however, may be located remote from the genitals the same as in non-parturient women, a number of instances of which were given.

Some cases of erysipelas were also given which could be traced to no other cause than cold and exposure to dampness, apparently independent of possible contagion.

Regarding prophylaxis of the puerperal diseases, said the writer: Bi-chloride of mercury, antiseptic pads, and injections, with bare walls, floors, and other surroundings characteristic of small-pox and typhus fever, are not a necessity in the lying-in chamber. In private practice almost non-interference can be carried out, but under the present system of hospital construction this plan can rarely be so absolute. Several pages were devoted to giving his experience, while Resident-Surgeon at Charity Hospital, New York, at Maternity Hospital, etc., and statistics which, on comparing with those given by Dr. Garrigues, do not well tally or correspond. From August, 1880, to December, 1880, there were confined in Maternity proper 50 selected cases. Of these, 5, or 10 per cent., died of puerperal metritis, septicæmia, or peritonitis. In the waiting wards, during the same months, there were confined 72 cases, also selected. Of these, 6 died, only 3 of which, or about 4 per cent., died of septic infection. During October and November the writer delivered, in the waiting wards alone, 25 women, of whom 1 died, and she of extensive heart lesions and pulmonary œdema. During these same months 30 out of the 50 cases cited from the Maternity records, 5 fatal cases occurred, making a mortality for the two months of 16⅔ per cent. from septicæmia at the Maternity proper. In 1875, the first year of the occupancy of the Maternity Hospital, there were 570 deliveries, with a mortality of 15, or 2.67 per cent. In 1881 the mortality fell to 2.36 per cent. In 1877 it rose to 6.67 per cent., the reasons of which were elaborately dwelt upon.

During the service of Dr. B. Wood at the Maternity, of 68 cases there were 3 deaths (from all causes). In the next two months, of 62 cases 3 deaths occurred, 1 of which was due to septicæmia. The grand total for the waiting wards and pavilions from August, 1880, to April, 1881, was 202 cases, with a mortality of 12, only 5 of which, or a little more than 2½ per cent., were due to septicæmia or puerperal fever. Of 130 cases, the writer stated, the let-alone plan of treatment was more rigid than his own, vaginal injections not being allowed. From April, 1881, to April, 1882, 423 cases were delivered, with but 2 deaths from puerperal fever. The treatment of this series was also non-interference. On the other hand, the writer stated, he has seen the temperature rise and pelvic inflammations follow the use of frequent vaginal injections, and cases which may eventuate in puerperal septicæmia and lead to a fatal issue would often do well and make a perfect recovery if let alone and kept quiet, and free from CURIOUS visitors. As for prophylactic intra-uterine injections, the man who uses them will sooner or later come to grief, in making too general use of this procedure. Regarding "placental compression," or Crede's method, to "press it out," is almost invariably absurd and pernicious. No more harm or serious result is likely to arise at the present time from a few minutes retention of the placenta than there was centuries before Crede was ever heard of. Without wishing to underrate the importance of freeing the womb from putrescible substances, the writer deplored the practice of inserting one's hand into the uterine cavity, seeking for an imaginary piece of placenta or for portions of secundines of microscopic size. Another, yet more clear illustration of the advantages of the non-interference plan of treatment in obstetrical practice, was cited while the writer acted in the capacity of Resident-Surgeon to the New York State Hospital for Emigrants, where the deaths occurring from septicæmia were in the minimum. A year since a so-called "reform" was instituted there in the emigrant service. The *prophylactic* injections and complicated manipulations were introduced, and with the direct and immediate effect of increasing the mortality rate, which became alarmingly high. Simultaneously upon Ward's Island there were present a large number of Russian-Jewish refugees, who were filthy and were mentally despondent. Upward of 90 of these women were delivered without a death. There were numerous forceps deliveries, but there was absolute non-interference in the after-treatment. Here was a good opportunity to compare fancy-midwifery results with the let-alone method.

Primary Operation for Perineal Lacerations.—In severe lacerations the primary operation is very essential, and often productive of the best results, but the tendency is toward too much routine practice in this respect, especially in hospitals. Those of less degree will heal of themselves. Chromated catgut is probably the best material for sutures to be used in deep and extensive lacerations, which it is desirable to repair at once and thus diminish the surface for septic absorption; but if a laceration extend completely into the rectum, the tendency is to the secondary in preference to the primary operation. Meanwhile, cleanliness and iodoform are the most important elements of treatment. In some cases the slight fever resulting from the sutures is likely to prevent the secretions, and convert them into a favorable nidus for the development of bacteria. In general the operation is very successful if properly performed. Instrumentation or passage of a catheter at frequent intervals is unnecessary. A bed-pan should be used, and a stream of iodized water from a fountain-douche allowed to flow over the vulva during

urination. Iodine is a more efficient deodorizer than carbolic acid, being destructive to bacteria in a strength of 1 to 5,000. Bichloride of mercury, if used, should be in very dilute solutions; and in view of its chemical action in forming albuminates, its superior usefulness may be questioned. A few other general suggestions for this accident closed the succeeding few pages upon the primary operation.

Injections during Labor.—This is recommended by some of our antiseptic extremists. Lydston's remarks condensed were: They are not only useless, but injurious, and all unnecessary manipulations, as introduction of the hands frequently within the rimæ vulvæ is prejudicial to the safety of the patient, and only that which is consistent with careful watching of the case should be attempted.

Tardy Delivery.—The use of the forceps at the second stage, care in changing the linen of the patient, (first by warming it), also the same should be done with a cold bed-pan before placing it under a patient, were the chief items requiring attention.

Administration of Ergot.—It is undoubtedly prophylactic of puerperal diseases, for it produces uterine contraction and hastens involution. In feeble subjects and after severe or instrumental deliveries, give small doses of the drug with quinine for a week or ten days. Hour-glass contraction should be carefully guarded against and borne in mind before the placenta has been expelled, although this condition is rare. After labor a pad of oakum placed over the vulva is much neater than a napkin. The potency of germs and the value of antiseptics are well appreciated, but the woman should now be interfered with as little as possible. We should regard labor as a physiological process rather than in the light of being pathological. Women are to-day entitled to the same natural advantages that they were long before syringes, antiseptics and microscopes were ever dreamed of, although when fœtor or suppression of the lochia indicate danger, intra-uterine injections, and other hygienic measures are demanded, and in these severe cases a glass tube after being introduced may be left in *situ* until danger is passed. Even constant irrigation may be advisable. Jones, of St. Paul, has recently reported several interesting cases in which they were useful. Sloan recommends suppositories of iodoform and eucalyptus. Curetting would not be proper excepting when portions of secundines were known to be left. The success also of the iodine treatment in typhoid fever ought to be a good basis for its use in septicæmia. Also antipyretics, as the salicylate of iron is almost specific in its action, this will often rapidly lower the temperature where quinine has failed. The hot vaginal injections to be effectual should be given through a cylindrical speculum. The faradic current was spoken of as one of the best remedies to induce resolution of pelvic exudations. * * * General peritonitis complicated by septicæmia is the most fatal disease to which the puerpera is liable, the vital powers being overwhelmed by a most powerful poison. The treatment suggested for septicæmia comprises the measures already stated, in combination with very free use of opium and stimulants. Hot applications over the abdomen, or, perhaps, cold, applied may be a useful measure in this fatal malady, and to support the system in its efforts to rid itself of the poison already absorbed. About six pages of goodly advice to our esteemed bacteriophobic friends in the East, and to those having direct charge of Maternity Hospitals eloquently closed what probably is one of the most comprehensive papers upon a single topic ever presented to this society. But many valuable formulæ and interesting points in this review have been unavoidably omitted.

Fracture of the Greater Tuberosity of the Humerus Extending into the Bicipital Groove, was the subject of a paper read by Dr. F. C. Schaefer, who also presented the case of a man, 55 years of age, having met with this rare form of fracture. As the paper is not at our command we must limit our remarks, which are from memory. Two years ago the patient received an injury to his shoulder by falling forward from a height of about three feet, resulting in fracture of this variety. The various fractures and dislocations of the joint were enumerated at the time of reading the paper, and the characteristics of this lesion were given as follows: A flattening of the shoulder and an increase in its antero-posterior diameter. At first this will suggest that there is a dislocation. This flattening is caused by the drawing backward of the fragment of bone by the attached muscles and consequent crowding forward of the head of the humerus. The displacement leaves a deep sulcus in place of the bicipital groove. Crepitation confirms the diagnosis. After the subsidence of the inflammation consequent to the injury, there was partial fibrinous anchylosis of the joint, which was with great difficulty broken up. At the present time upward and backward extension of the arm is but slightly limited, as was demonstrated by the mobility of the limb. The alteration in shape of the upper part of the bone is evident on palpation, though this was barely perceptible to the eye, the patient being somewhat *embonpoint*, and an almost perfect recovery had been the result of treatment. The speaker, in conclusion, cited several cases of this injury in which the diagnosis had been confirmed by autopsy. Perhaps not more than ten cases of this rare form of fracture are on record.

The case was examined by the members present, and its peculiarities informally discussed.

Owing to the late hour, and the fact that a number of our members, who are experienced surgeons and obstetricians, had gone to Washington to attend the National Medical Association, a motion prevailed that discussion of both the above papers be deferred until a future meeting. L. H. M.

ILLINOIS STATE MEDICAL SOCIETY.

TUESDAY, MAY 20, 1884—FIRST DAY.

The thirty-fourth annual meeting of the Illinois State Medical Society commenced its sessions on Tuesday morning, May 20, 1884, at 10:30 A. M., in the First Methodist Church of Chicago. There were about two hundred delegates and members present.

The President, Dr. Edmund Andrews, of Chicago, called the meeting to order, and an appropriate prayer was offered by Rev. A. E. Kittredge. Dr. E. Ingals in behalf of the Committee of Arrangements gave an address of welcome, which was responded to by Dr. S. K. Crawford, of Monmouth.

Dr. D. W. Graham, Chairman of the Committee of Arrangements, presented the following as the order of business: Reports of the Committees on Practical Medicine; Surgery; Obstetrics; Gynæcology; Ophthalmology and Otology; Drugs and Medicines; Necrology, and Special Committees appointed last year. Volunteer papers on various topics were in the hands of the Committee from Drs. F. C. Shaefer, F. C. Hotz, A. B. Strong, R. H. Babcock, C. Fenger, D. W. Graham, H. A. Johnson, C. E. Webster, J. S. Whitmire, C. W. Earle, David Prince, E. C. Dudley, C. T. Parkes, W. P. Verity and R. Tilley. The Committee recommended that the sessions be held from 9 A. M. to 12 M., and from 2 to 5 P. M.

The Society was invited to visit all of the public institutions, the County Hospital, parks, Academy of Sciences, and points of attraction at 4 o'clock this afternoon.

Dr. C. W. Earle moved the reference of several papers to the proper committees, and on motion a paper by Dr. Prince on "Palatoplasty" was set for reading at 2 P. M., and one by Dr. C. Fenger on "The Diagnostic Peculiarities of Malignant Growths" at 10 o'clock next morning.

The President, Dr. E. Andrews, then delivered his annual address, which was devoted chiefly to a discussion of the nature of ethics and etiquette in general, and their relations to the medical profession. The address was well received, and at its close on motion of Dr. E. Ingals, it was referred to the Committee of Publication, and a vote of thanks tendered to the author.

Reports of Standing Committees being ordered, Dr. J. C. Frye, of Peoria, Chairman of the Committee on Practical Medicine, presented his report. He stated that after receiving the appointment of chairman of the Committee he was taken ill, and therefore been unable to do full justice to his subject. He called upon Dr. McIlvaine, of Peoria, to read his report. He regarded the germ theory of disease as one of the most important branches of medical science. The paper as read, treated largely of the germ theory of disease, the advancement made in the diagnosis and treatment of many of the more prevalent diseases, and detailed the medicines and quantity of the same given in notable cases.

THE AFTERNOON SESSION.

At the opening of the afternoon session, Dr. Graham moved that the action taken in the morning regarding the report from the Committee on Arrangements be rescinded, and the Society concurred. On the motion of the same gentleman, the order of business was made as follows: 1. Reports of standing committees. 2. Reports of special committees. 3. The reading of voluntary papers.

Dr. Prince spoke on the subject of "Palatoplasty," showing how successful operations could be made on the palate to overcome impediments in speech. To illustrate his topic, a small boy who was treated was induced to read a few lines, which he rendered in a very creditable manner.

The list of members of the Society and delegates from other societies was then read by Dr. J. F. Todd, the Assistant Secretary.

Dr. Roswell Park, formerly of Chicago, now of Buffalo, N. Y., Chairman of the Standing Committee on Surgery, presented an interesting report, commenting on the recent advances in the different departments of surgery. He said one heard but little at present concerning the once favorite spray application of solutions to wounds for preventing septicæmia and promoting repair. The general principles of antisepsis were becoming better established, and the properties of particular antiseptics better appreciated. The poisonous properties of carbolic acid were limiting its use in the best institutions both in this country and Europe. Time, and additional clinical observations, had strengthened the favorable opinions he had formerly expressed in regard to the value of naphthaline as a soothing and antiseptic application in dressing wounds and injuries. He stated that surgical pathologists had discovered erysipelas to be a germ disease; the specific quality of the germs having been demonstrated by the successful inoculation of dogs. He alluded to several successful cases of skin grafting over large surfaces, and to pulmonary surgery. In the most important cases of the latter, he claimed that the most eminent operators had abandoned the use of thermol and boracic and carbolic acids, and had substituted solutions having salicylic properties. He alluded to the case of one patient, who had nearly the whole upper lobe of the left lung separated from the pleura and removed. The patient lived until the ninth day, when it was claimed that he died from carbolic acid poisoning. He also alluded to successful resections of the larynx, and to the recent case of resection of the trachea which had been performed in London, followed by entire recovery.

Dr. D. S. Booth, of Sparta, Ill., related a case of extensive gunshot wound, in which the breast, armpit and side of the patient, were perforated and extensively torn; but which recovered by rest, cleanliness, and judicious attention to position.

Dr. Henry Gradle, of Chicago, read a paper on Practical Medicine supplemental to that of Dr. Frye, in which he devoted attention chiefly to the germ theory of disease, giving many observations and diagnoses, and the course of treatment pursued to destroy the bacilli found in many diseases. Referring to cholera he said that the bacilli made their way into the intestines while the patient was suffering from indigestion; when the digestion was good they were carried off. The paper also reviewed the recent discoveries made by Koch and Pasteur in their investigations of the bacillus-tuberculosis and in tracing the bacteria that create various diseases.

Dr. J. A. Robison, of Chicago, read a paper on "Alkaloidal and Kindred Medication," in which he demonstrated that crude drugs vary much in the number of active medicinal properties; that the pro-

cesses of manufacture of these drugs into tinctures and fluid extracts are very faulty. He further demonstrated the vast progress which had been made in the chemistry of inorganic drugs, and urged the application of the principles of organic chemistry to medicinal plants; extracting their active principles and recombining them in preparations of uniform chemical composition, definite therapeutic powers, and ease of administration.

Dr. L. H. Corr, a lady physician of Carlinville, from the Committee on Gynæcology, read a paper on the diseases of women, which had special reference to some plastic operations, and possessed the merit of concise briefness.

On motion of Dr. Hollister it was decided to witness at 2 o'clock Wednesday, the practical demonstrations of subjects afflicted with paralysis of the vocal chords, to be introduced by Drs. Johnson and Graham.

On motion of Dr. Ingals the President's address was referred to a special committee consisting of Drs. Ingals, Hamill, and Graham, with instructions to report before final adjournment.

The Society then adjourned until 9 o'clock Wednesday morning.

SECOND DAY.

The second day's session was called to order in the First Methodist Church at 9:15 o'clock Wednesday morning by the President, Dr. Edmund Andrews. Dr. E. Ingals, Chairman of the Committee on Necrology, read a report, in which it was stated that he had during the year obtained a necrological report from the State Board of Health, in which were recorded the deaths of 108 physicians between 1882 and 1883. Among the number there were no names of members of the Illinois State Medical Society. Of seventy-nine doctors whose death had been reported, the average age was 52 years. He thought physicians ought to hold on to life longer than that, and said that the record indicated that they did not take good care of themselves. The members of the Society who died during the past year were Dr. Joseph Osmond Hamilton, of Jerseyville, and Dr. C. E. Parker, of Beardstown. The former was President of the Society in 1881, and was born at New Design, now Waterloo, Monroe county, April 2, 1824. His father, Thomas S. Hamilton, was a descendant of the Preston branch of the Scottish house of Hamilton.

Dr. Parker settled at Beardstown in 1855. He was a graduate of Yale College, and practiced in Massachusetts prior to coming West. He died of hemiplegia. The report was accepted and placed on file.

[TO BE CONCLUDED NEXT WEEK.]

MISCELLANEOUS.

TREASURER'S REPORT.

DR. RICHARD J. DUNGLISON, TREASURER, IN ACCOUNT WITH THE AMERICAN MEDICAL ASSOCIATION.

1883.		DR.

RICHARD J. DUNGLISON,
Treasurer.

WASHINGTON, May 8, 1884.

This certifies that we examined the foregoing accounts and accompanying orders and vouchers, and find them correct in all respects.

(Signed,) ALONZO GARCELON,
Auditing Com. of Amer. Med. Ass'n.

OFFICIAL NOTICE.

ANNUAL DUES from members of the Association—*Five Dollars* per annum—are payable directly to the Treasurer. Such payment entitles them to receive the JOURNAL of the Association for one year.

SUBSCRIPTIONS TO THE JOURNAL from those who are not members should be forwarded to the office of publication, Chicago.

BACK VOLUMES OF THE TRANSACTIONS may be procured, at reduced rates, by addressing the Treasurer.

THE INDEX to the 33 Volumes of Transactions will be forwarded, postpaid, on receipt of *One Dollar* by the Treasurer.

According to a resolution passed May 9, 1884, at the Washington meeting, continuous payment of Annual Dues is required, to retain permanent membership. RICHARD J. DUNGLISON, M.D.,
Treasurer.

Lock Box 1274, Philadelphia, Pa.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT UNITED STATES ARMY, FROM MAY 31, 1884, TO JUNE 6, 1884.

Heger, Anthony, Major and Surgeon, assigned to duty at Fort McHenry, Md., as Post Surgeon. (Par. 1, S. O. 108, Headquarters Department of East, June 2, 1884.)

Baily, Jos. C., Major and Surgeon, now on leave of absence, is relieved from duty in Department of Texas, and ordered to report to Commanding General, Department of the East, for assignment to duty at Fort Monroe, Va., to relieve Lieut. Col. Charles Page, Surgeon, United States Army, on July 1, 1884, from duty at that Station.

Lieut. Col. Page, on being relieved by Major Baily, will proceed to Fort Leavenworth, Kans., and report to Commanding General, Department of the Mo., for assignment to duty as Medical Director of that Department (Par. 12, S. O. 125, A. G. O., May 29, 1884.)

Wright, J. P., Major and Surgeon, directed to perform, temporarily, in addition to his other duties, those of Medical Director, Department of the Mo. (Par. 2, S. O. 107, Headquarters Department of Mo., May 28, 1884.)

Huntington, David L., Major and Surgeon, during the absence of the Surgeon General, directed to take charge of the office of the Surgeon General and perform his duties. (Par. 6, S. O. 129, A. G. O., June 4, 1884.)

Bentley, Edwin, Major and Surgeon, assigned to duty at Fort Clark, Texas, as Post Surgeon (Par. 1, S. O. 68, Headquarters Department of Texas, May 31, 1884.)

Koerper, Egon A., Captain and Assistant Surgeon, assigned to duty at Fort Keogh, M. T. (Par. 1, S. O. 58, Headquarters Department of Dakota, May 27, 1884.)

Barnett, Richards, Captain and Assistant Surgeon, now on sick leave of absence, is relieved from duty at Columbia Bks., Ohio, and ordered to report to Commanding General, Department of the East, for assignment to duty. (Par. 2, S. O. 129, A. G. O., June 4, 1884.)

Middleton, Passmore, Captain and Assistant Surgeon, granted leave of absence for one month on surgeon's certificate of disability (Par. 2, S. O. 107, Headquarters Department of Mo., May 28, 1884.)

Wilson, Geo. F., First Lieutenant and Assistant Surgeon, relieved from temporary duty at Fort Canby, Washington Territory, and ordered to return to his proper station, (Fort Walla Walla, Washington Terr.) (Par. 2, S. O. 70, Headquarters Department of Col., May 26, 1884.)

Owen, Wm. O. Jr., First Lieutenant and Assistant Surgeon, having reported at these headquarters in compliance with par. 5, Department Special Orders, No. 62, current series, will return to, and take station at Fort Stevens, Oregon.

In addition to his duties at Fort Stevens, Assistant Surgeon Owen will perform those of medical officer at Fort Canby, Washington Territory. (Par. 1, S. O. 70, Headquarters Department of Col., May 26, 1884.)

Moore, John, Lieutenent Colonel and Assistant Medical Purveyor, ordered to perform in addition to his present duties, those of medical storekeeper, San Francisco, Cal.

Johnson, Henry, Captain and Medical Storekeeper, relieved from duty at the medical purveying depot at San Francisco, Cal., and ordered to report for duty at the medical purveying depot, New York City, relieving Captain Andrew V. Cherbonnier, medical storekeeper.

Captain Cherbonnier, on being relieved by Captain Johnson, will proceed to St. Louis, Mo., and report in person to Captain Geo. T. Beall, medical storekeeper and acting assistant medical purveyor, for duty at the purveying depot at St. Louis, relieving Captain Beall of his duties as medical storekeeper. (Par 9, S. O. 125, A. G. O., June 3, 1884.)

Fryer, Blencowe E., Major and Surgeon, granted leave of absence for one year from July 1, 1884. (Par. 7, S. O 128, A. G. O., June 3, 1884.)

Hall, John D., Captain and Assistant Surgeon, granted leave of absence for three months, to take effect on his arrival at St. Paul, Minn. (Par. 8, S. O 128, A. G. O., June 3, 1884.)

LIST OF CHANGES IN THE STATIONS OF MEDICAL OFFICERS, U. S. NAVY, FOR THE WEEK ENDING JUNE 7, 1884.

Passed Assistant-Surgeon T. M. Murray, detached from U. S. S. "Passaic," ordered to U. S. S. "Constellation."

Assistant-Surgeon W. Martin, detached from U. S. S. "Constellation," ordered to U. S. S. "Passaic."

P. A. Surgeon T. C. Craig, detached from U. S. S. "Minnesota," ordered to U. S. S. "Vandalia."

P. A. Surgeon C. W. Deane, detached from U. S. S. "Vandalia," ordered to U. S. S. "Minnesota."

P. A. Surgeon J. H. Hall, detached from U. S. S. "Minnesota," ordered to Naval Hospital, Brooklyn.

Medical Director P. S. Wales, to continue present duty until August 1, 1884.

Surgeon H. M. Wells, to continue temporary duty at Naval Laboratory.

P. A. Surgeon E. H. Marsteller, detached from U. S. S. "Vermont," ordered to U. S. S. "Monongahela."

Assistant-Surgeon H. B. Scott, commission to date from July 11, 1883.

Assistant-Surgeon V. C. B. Means, commission to date from June 3, 1884.

Assistant-Surgeon F. A. Hesler, commission to date from June 3, 1884.

OFFICERS OF

THE AMERICAN MEDICAL ASSOCIATION

AND OF ITS SEVERAL SECTIONS, 1884–5.

PRESIDENT.

Dr. H. F. CAMPBELL, of Augusta, Georgia.

FIRST VICE-PRESIDENT.

Dr. J. S. Lynch, of Maryland.

SECOND VICE-PRESIDENT.

Dr. S. D. Mercer, of Nebraska.

THIRD VICE-PRESIDENT.

Dr. J. H. Parsons, of New Hampshire.

FOURTH VICE-PRESIDENT.

Dr. H. C. Ghent, of Texas.

PERMANENT SECRETARY.

Dr. Wm. B. Atkinson, 1400 Pine St., Philadelphia.

TREASURER.

Dr. R. J. Dunglison, Lock Box 1271, P. O. Philadelphia.

LIBRARIAN.

Dr. C. H. A. Kleinschmidt, Washington, D. C.

Place of meeting, 1885, New Orleans, La.; Time of holding meeting, last Tuesday in April.

COMMITTEE OF ARRANGEMENTS.

Samuel D. Logan, Chairman; S. E. Chaillé, E. S. Lewis, Joseph T. Scott, W. G. Austin, W. H. Watkins, J. P. Davidson, J. A. G. Fisher, Geo. W. Lewis, B. A. Pope, W. C. Wilson, M. Schuppert, Geo. J. Friedrichs, F. Loeber, D. Jamison, G. K. Pratt, L. E. Solomon, J. H. Bemiss, Geo. Lawrason, G. U. Gaudet, Sam'l M. Bemiss, B. J. Bickham, Chas. Turpin, Jno. Carter, A. W. DeRoaldes, S. S. Herrick, W. S. Mitchell, E. T. Shepard, E. Souchon, T. D. Layton, T. S. Dabney, S. R. Olliphant, Edward Harrison, A. B. Miles, Joseph Holt, P. B. McCutchon, F. H. Parham, G. B. Underhill, Stanhope Jones, E. Chassaignas, R. Dell'Orto.

ASSISTANT SECRETARY.

Dr. W. H. Watkins, New Orleans, Louisiana.

BOARD OF TRUSTEES FOR JOURNALIZING THE TRANSACTIONS.

Drs. J. M. Toner, Washington, D. C., President;
M. Moore, Rochester, N. Y.; Leartus Connor, Detroit, Mich.;
J. H. Packard, Philadelphia;
H. F. Campbell, Augusta, Ga.; A. Garcelon, Lewiston, Me.;
P. O. Hooper, Little Rock, Ark.;
L. S. McMurtry, Danville, Ky.; J. H. Hollister, Chicago, Ill., Secretary.

OFFICERS OF THE SECTIONS:

"Practice of Medicine."

Chairman—Dr. H. Didama, Syracuse, N. Y.; Secretary—Dr. G. M. Garland, Boston, Mass.

"Obstetrics and Diseases of Women."

Chairman—Dr. R. S. Sutton, Pittsburgh, Pa.; Secretary—Dr. J. T. Jelks, Hot Springs, Ark.

"Surgery and Anatomy."

Chairman—Dr. Duncan Eve, Nashville, Tenn.; Secretary—Dr. E. B. King, Allegheny, Pa.

"Ophthalmology, Otology and Laryngology."

Chairman—Dr. J. A. White, Richmond, Va.; Secretary—Dr. Eugene Smith, Detroit, Mich.

"Diseases of Children."

Chairman—Dr. J. H. Pope, Marshall, Texas; Secretary—Dr. S. S. Adams, Washington, D. C.

"Oral and Dental Surgery."

Chairman—Dr. W. W. Allport, Chicago, Ill.; Secretary—Dr. E. C. Briggs, Boston, Mass.

"State Medicine."

Chairman—Dr. E. W. Schaufler, Kansas City, Mo.; Sec'y—J. N. McCormick, Bowling Green, Ky.

Committee on "Necrology."

Chairman—Dr. J. M. Toner, Washington, D. C.

ORIGINAL ARTICLES.

THE TREATMENT OF COMPOUND FRACTURES, INCLUDING A REPORT OF ONE HUNDRED AND FORTY-FOUR CASES WITHOUT A DEATH FROM SEPTIC INFECTION, AND ONE HUNDRED CASES WITHOUT A DEATH FROM ANY CAUSE.

BY FREDERIC S. DENNIS, M.D., NEW YORK CITY.

MR. PRESIDENT AND GENTLEMEN:—The treatment of compound fractures is a subject of great practical importance. In advocating any special plan of treatment there are several salient points to consider.

First. The method should be a safe one and proved to be such by the crucial test of experience.

Second. The method of treatment should yield results, unattended by septic infection, by non-union, by shortening, and by deformity.

Third. The method should be a simple one, and uncomplicated by any inaccessible splint, or complicated dressing.

That plan of treatment of compound fractures, therefore, which has safety, complete restoration of the injured member, absolute simplicity, and at the same time as slight constitutional disturbance as possible, as its characteristic features, is a method which would naturally commend itself to the profession.

It will be the aim of this paper to demonstrate by the results of a large number of cases that the treatment of compound fractures is best accomplished by adherence to three well-recognized and established principles.

1st. Absolute cleanliness.

2nd. Immediate fixation.

3rd. Provision for free drainage when necessary.

The treatment which has been employed for the most part in the cases to be reported is in brief as follows:

The patient having been taken to the operating theatre, is placed upon the table, and if the exigencies of the case demand, an anæsthetic is at once administered. Anæsthesia relaxes the muscles, affords the surgeon an opportunity to explore thoroughly the extent of the injury without inflicting pain. The injured limb is washed with soap and warm water and scrubbed well with a brush. The dirt, debris, and blood are thus removed, and the hair on the extremity is cleanly shaved, and then the limb is irrigated for a few moments with a solution of carbolic acid (1-40) or with a solution of corrosive sublimate (1-2,000) or with any other well-known disinfectant. Gentle traction is made upon the extremity, while at the same time counter-extension is employed with a view to bringing the broken fragments into coaptation. If the bones protrude through the wound and cannot be reduced without the exercise of too much violence, the projecting end is removed by a chain-saw. It has been my custom when the protruding bones cannot be reduced without the exercise of undue violence, to divide subcutaneously all tendons and thus overcome all resisting forces. This operation secures physiological rest during the repair of the fracture.

Attention now must be directed to the wound itself. Any loose fragments or spiculæ of bone are removed, except where they are adherent to periosteum, in which case these detached pieces are preserved, and they seldom exfoliate owing to the blood-supply through the periosteum. The interior of the wound is thoroughly irrigated by a syringe, or by a tube from an Esmarch's wound-douche. Having cleansed the limb, including even the fingers and toes, and having adjusted the fragments and having washed out and disinfected the interior of the wound, the application of a splint is now made. The limb is elevated, and under it are placed towels saturated in some disinfectant solution, which keeps the limb from coming in contact with the covering upon the operating-table, or from the opposite limb, or from any part of the body. If the wound is small a piece of surgically clean adhesive plaster is placed over the seat of fracture, and then collodion is painted over the plaster. If the wound communicating with the seat of fracture is too large to hermetically seal in the manner already described, a part of the wound can be closed by catgut suture, and a drainage-tube is introduced into the bottom of the wound. Decalcified bone drainage-tubes are used, as they seem to answer the purpose in the most satisfactory manner. Into the wound, and over, and around the wound is sprinkled a layer of iodoform and then over this any of the many differently prepared dressings, such as corrosive sublimate gauze, or Iodoform gauze, or absorbent cotton. The limb is now ready for the splint. A roller of Gamgee's absorbent cotton is heated which causes it to swell, and this is now made

to envelope the entire limb. Heating the cotton seems to permit it to expand, and any dressing, such as a plaster of Paris bandage, can be snugly applied over it, and the cotton will not lose its wonderful elasticity. During the application of the bandage, extension and counter-extension should be employed, the patient being at the same time well under the influence of ether. The bandage is now permitted to dry, and great care must be exercised while the bandage is drying, lest the patient while returning to consciousness, disturb the setting of the plaster and consequently the wound. The patient is placed in a suitable bed after the plaster of Paris bandage is firm. If there is no irritation or unpleasant sensation at the seat of fracture, if the toes or fingers are free from any numbness or cyanosis, if the respiration, pulse and temperature are normal, the first dressing is left undisturbed. In many cases the plaster of Paris bandage is worn until the fracture is repaired and primary intention has been obtained.

If, on the other hand, there is a slight irritation or unpleasant sensation at the seat of fracture, if the toes or fingers are numb or cyanotic, if the respiration, pulse and temperature are not normal, or if there are any other indications of disturbance, a fenestrum is cut over the site of the fracture, and the wound examined. Should the wound be inflamed and the tissues tense, the opening down to the fracture should be enlarged and the bottom of the wound washed out with a solution of bi-chloride of mercury or carbolic acid. The wound is now left to freely suppurate exposed to the air. The key-note to success under these conditions when suppuration is in process, is to keep the parts absolutely clean and pure from all contamination. A healthy granulating surface, secreting pure, rich, yellow, creamy pus is in itself a barrier to the entrance of septic absorption into the general system. If the granulations are weak and flabby, a poultice of flax-seed and carbolic acid placed over the wound for a few hours will stimulate the granulations. When the poultice is removed, some stimulating application may be employed with advantage, among which may be mentioned balsam of Peru, iodoform, powdered red cinchona bark, bismuth and oxide of zinc. These remedies seem to stimulate with greater efficiency when employed in alternation, as one remedy by continual application soon loses its efficacy. Absorbent cotton should be nicely packed in and around the fenestrum and changed whenever soiled. When a fenestrum exists, the limb can be suspended to great advantage in a Fluhrer's swing, which not only affords the patient great comfort, but permits the limb to be turned so as to allow free drainage from the open wound. When the leg, for example, is thus suspended, the patient can move about in bed, or even lie upon his side. If the inflammatory swelling is considerable, and other things denote that the splint is too tight, the plaster of Paris bandage is immediately cut down and the leg put into a fracture-box. This point cannot be too strongly impressed. Plaster of Paris can do irreparable mischief in a few hours, and for this reason, the splint should be sacrificed at once when there is the least suspicion of anything wrong. It has been my misfortune to have seen in the hands of a colleague two patients die from neglect to cut down the splint before it was too late. In both of these cases, gangrene was the cause of death. Plaster of Paris bandage in the treatment of fractures, properly and carefully applied, is the greatest boon. On the other hand, improperly or carelessly applied, it becomes a most potent source of evil. After the leg has been removed from the plaster of Paris bandage it should be put into a fracture-box. It is seldom the surgeon is required to do this; but occasionally, from some unknown cause, it becomes necessary. The fracture-box should be filled with oakum, or what is better, ordinary bran thoroughly soaked with carbolic acid, and then allowed to dry in the sun. This hint was given to me by Prof. Hamilton, whose reputation in the treatment of fractures is world-wide. When the limb is in proper condition, it should be again replaced in the plaster of Paris dressing, to remain until union has taken place. Great care should be taken to prevent any infiltration of pus or the formation of an abscess. Counter-openings should be promptly made whenever necessary.

Before entering upon a discussion in detail of this subject, it is well to define exactly what is meant by a compound fracture; for frequently surgeons report cases of simple fracture associated with a lacerated wound under the heading of compound fractures. The entrance of air to the seat of fracture is an essential condition to the formation of a compound fracture, and hence it is evident that the wound in the soft parts is produced by violence which is exercised from within, and finally, in a pathological sense, it is the presence of air that causes the great difference in the repair of simple and compound fractures. We know by microscopical investigations that in simple fractures, from the granulation tissue cartilage is formed, and that bone is developed from the cartilage—whereas in compound fractures no cartilage is formed, unless all suppuration is completely prevented. It is suppuration which prevents the development of cartilage. Hence it is evident that the processes of repair are different, and that, owing to the presence of air in the seat of fracture, additional dangers are unavoidably encountered.

In submitting these cases of compound fractures to this distinguished Association, I shall endeavor to prove that the success, which I may say has far exceeded my most sanguine expectations, is equal to that obtained by any other method. I shall demonstrate by referring to a large number of cases, that exposure of a fracture to the air whenever necessary, with proper precautions, is attended with no danger of decomposition or septic infection. I shall also establish the clinical fact that this plan of treating compound fractures has been unattended in a single case with non-union or with deformity. Finally, after showing that the mortality is no greater than by any other method, and that as regards shortening, deformity and non-union, the results are equally satisfactory, it still remains to prove that during the process of repair, there is no more constitutional disturbance than is present during healing by any other method. The solution of this most difficult

problem can only be obtained by a careful analysis and thorough examination of the daily charts, which record every twelve hours the pulse, respiration and temperature in each case. These charts are all here on the table for inspection and study. It will suffice to say that in dividing the entire number into thirds, in the first third two patients reached a temperature of 104 F. and one patient 104½ F. on only one occasion; but these three temperatures fell in a very short time to 100 F. Of the remaining number in the first third, ten cases reached a temperature of 103 F. and 102 F. respectively; but these temperatures were not elevated any length of time, and the charts show a gradual decrease to the normal standard. In the second third, no temperatures rose above 101 F. during the entire process of repair.

In the last third, the temperature never rose higher than 100 F. at any time, and in these cases the respiration, pulse and temperature were absolutely normal.

The following cases of compound fractures have been under my charge in Bellevue, St. Vincent, and the Ninety-ninth Street Reception Hospitals, in New York City, and also in private practice. Several cases are also included which have been previously published by myself in connection with another subject. From the list is excluded one case which terminated fatally, and I mention this case with the following explanation: The patient was a boy, who fell from the top of a high building, and sustained, as a result of the fall, three compound fractures, one of each thigh and one of the lower jaw.

The boy was treated by Dr. T. H. Manley, Assistant Surgeon to the Ninety-ninth Street Hospital during my absence in Europe, but I saw the case with him upon my return. The boy died from exhaustion, consequent upon profuse hæmorrhage, and the autopsy, which was conducted by Prof. W. H. Welch, failed to show any evidences of septicæmia, or blood-poisoning of any kind. While the case was not mine, I prefer to mention it with the others, because the patient was admitted into a hospital of which I am the attending surgeon. But the case was admitted to the hospital and to my wards during my vacation, and was under the charge of Dr. Manley, who, it may be said, treated this case, as well as many other cases of compound fracture, with unusual skill.

In Dr. Manley's case there was no evidence of blood-poisoning, notwithstanding the fact that his patient suffered from a double compound fracture of the thigh, and also one of the lower jaw. My report covers 144 cases of compound fractures which have occurred in succession. While it is impossible to describe in detail each of these 144 consecutive cases, I have arranged them in tables for publication. The charts of the cases are here upon the table for examination; also in these bottles are some 200 pieces of fragments of bone which have been removed in the cases of compound fractures of the skull and long bones. I shall take up in order the different varieties of fractures, and then give a summary. They are tabulated in the following order: Skull, thigh, leg, arm, forearm, lower jaw, hand and foot, miscellaneous fractures.

COMPOUND FRACTURES OF THE SKULL.

NO.	NAME.	AGE.	DATE.	INJURY.	TREATMENT.	RESULT.
I.	H. R.	49	Oct., 1883	Compound comminuted fracture of skull. Patient struck with a brick over frontal bone. Patient conscious. No paralysis.	Patient was trephined; 28 pieces of bone removed; wound washed out with carbolic acid water; wound left open.	Recovery
II.	R. O.	31	Jan., 1883	Compound comminuted fracture of skull, produced by kick of a horse; 2½ inches by 1½ inches was the size of wound. Patient unconscious.	Patient was trephined; 64 pieces of bone removed; wound left open to granulate. Irrigated with carbolic acid.	Recovery
III.	D. F.	28	May, 1883	Compound comminuted and depressed fracture of skull. Paralysis of arm; severe hæmorrhage. Stone fell from a height of 25 feet.	Trephined; 16 pieces of bone removed. Paralysis disappeared. Wound treated openly.	Recovery
IV.	A. H.	18	April, 1883	Depressed fracture, followed by persistent headache for 6 years. One pupil dilated. End of 6 months, after operation, no headache.	Trephined over fracture. Dura mater thickened. Pachy-meningitis externa. Headache disappeared. Wound open.	Recovery
V.	P. R.	40	February, 1883	Compound fissured fracture of skull.	Treated openly with carbolic acid balsam of Peru.	Recovery
VI.	B. C.	45	Jan., 1883	Compound fissured fracture of skull. Fracture extending several inches.	Treated openly; carbolic acid, balsam of Peru.	Recovery
VII.	M. D.	8	May, 1883	Boy struck with a pitcher. Compound fracture of skull, extending over a large area.	Treated openly; carbolic acid, balsam of Peru.	Recovery
VIII.	E. D.	34	Feb., 1884	Compound fracture of skull. Patient was struck with an axe. Fracture was punctured. Wound in scalp extensive. No symptoms.	Trephined because a punctured fracture. Removed 10 pieces of bone splintered off from internal table.	Recovery
IX.	G. C.	8	Jan., 1884	Caries and abscess mastoid portion of temporal bone. Strumous origin.	Trephined opened abscess. Gouged out carious bone. Balsam of Peru.	Recovery
X.	J. D.	30	Feb., 1883	Compound fracture of orbital plate of frontal bone. Gunshot injury.	Wound kept clean; washed with carbolic acid.	Recovery

COMPOUND FRACTURES OF THE SKULL—*Continued.*

NO.	NAME.	AGE.	DATE.	INJURY.	TREATMENT.	RESULT.
XI.	J. D.	53	Feb., 1884	Compound fracture of skull. Patient unconscious, and in profound shock.	Stimulants. Patient never rallied.	Died within 24 hours
XII.	U. S.	20	Oct., 1883	Compound fracture right zygoma. Fracture extending downward toward base.	Stimulants. Patient never rallied.	Died within 24 hours
XIII.	A. C.	24	May, 1883	Compound depressed fracture of skull.	Stimulants. Patient never rallied. Pulse scarcely perceptible.	Died within 6 hours
XIV.	G. H.	35	April, 1883	Compound fracture mastoid portion of temporal bone, result of gunshot injury.	Bullet and loose bone removed. Patient bled profusely.	Died within 48 hours
XV.	J. C.	62	May, 1882	Compound fracture frontal and nasal bones.	Wound washed. Nasal bones adjusted. Patient did well.	Recovery
XVI.	G. P.	35	Nov., 1883	Compound fracture of skull. Result of 3 pistol-shots.	Loose fragments removed, also bullet; wound cleansed.	Died within 24 hours
XVII.	T. D.	30	Sept., 1883	Compound fracture of frontal bone.	Wound cleansed; dressed with oakum and balsam of Peru.	Recovery
XVIII.	G. H.	20	April, 1882	Compound fracture of skull. Result of gunshot injury.	Stimulants. Patient never rallied.	Died within 24 hours
XIX.	J. L.	46	March, 1884	Compound punctured fracture of skull. Patient was struck by locomotive. Paralysis, etc.	Trephined. Removed 25 pieces of bone. Wound treated openly.	Recovery
XX.	J. K.	14	April, 1884	Compound depressed fracture skull (frontal bone). Dura mater lacerated. Brain substance protruded.	Trephined. Removed 8 large pieces; sewed up dura mater with catgut suture.	Recovery
XXI.	A. H.	23	Sept., 1882	Compound depressed fracture of skull. Patient in profound shock.	Trephined; 28 pieces removed.	Recovery
XXII.	J. H.	7	Sept., 1883	Compound depressed fracture.	Bones removed.	Recovery
XXIII.	T. C.	32	May, 1884	Double compound fracture of skull, also nasal bones. Struck by glass bottle.	Drainage-tube inserted; wound sewed up; no depression.	Recovery

This table shows twenty-three cases of compound fractures of the skull with no deaths except six, which occurred within forty-eight hours after injury, and which were due to shock. These patients never rallied from collapse and died from causes which could not have been prevented by any plan of treatment. Excluding then the six cases there remain 17 cases of Compound Fractures of the Skull in succession with no death, and of these seventeen consecutive and successful cases, ten of them were trephined. In two of the ten cases a disc of bone was removed for the purpose of elevating fragments. In the third case there were eight pieces of bone removed, in the fourth case ten pieces of bone were removed, and also the dura mater was torn and sewed up with catgut sutures. In the fifth case there were sixteen fragments removed, in the sixth case twenty-three fragments, in the seventh case twenty-five comminuted fragments, in the eighth case twenty-eight pieces, and in the ninth case sixty-four pieces, involving nearly the entire frontal bone, in the tenth case the mastoid cells were opened. Notwithstanding this series of compound fractures of the skull with paralysis, hæmorrhage, depression and compression, and all the other unfavorable symptoms, every case in order recovered.

COMPOUND FRACTURE OF THIGH.

NO.	NAME.	AGE.	DATE.	INJURY.	TREATMENT.	RESULT.
I.	P. P.	20	May, 1883	Compound fracture of thigh. Patient was caught between wall and elevator for two hours.	Wound washed; sealed; plaster Paris bandage immediately applied.	Recovery
II.	L. D.	25	Sept., 1876	Compound fracture of thigh. Knee joint opened; great shock.	Primary amputation of thigh. (Upper ⅓.)	Recovery
III.	J. B.	12	Nov., 1883	Medullary canal freely opened by free incision on both sides to remove sequestrum.	Esmarch applied; large wound made; considerable hæmorrhage.	Recovery

This table shows three cases of compound fracture of the thigh with no deaths. One case was a boy who was caught between an elevator and the wall and who was thus held for two hours before he could be extricated.

The second was a man who was injured in such a way as to require primary amputation.

The third case was that of a boy who sustained a simple fracture, and at the seat of fracture an abscess was developed. The medullary canal was freely opened by two long incisions and some pus and carious bone were removed.

COMPOUND FRACTURES OF THE LEG.

NO.	NAME.	AGE.	DATE.	INJURY.	TREATMENT.	RESULT.
I.	C. W.	20	Dec., 1883	Compound fracture leg. Tibia protruded, alarming hæmorrhage.	Plaster of Paris bandage applied at once. Cut down splint in six weeks. Union perfect.	Recovery
II.	R. H.	41	Aug., 1883	Compound fracture fibula. Contusions opposite leg.	Plaster of Paris bandage applied with a bracket.	Recovery
III.	R. M.	32	May, 1883	Compound fracture of leg.	Plaster of Paris bandage with fenestrum.	Recovery
IV.	W. E. M.	40	March, 1876	Compound fracture both bones. Tibia sawn off with chain saw.	Plaster of Paris bandage applied at once—with fenestrum.	Recovery
V.	† D.	50	Apr., 1883	Compound fracture of leg.	Plaster of Paris bandage applied.	Recovery
VI.	B. C.	30	Oct., 1882	Compound fracture of leg.	Plaster of Paris bandage applied with fenestrum.	Recovery
VII.	T. C.	24	Apr., 1883	Compound fracture of leg.	Plaster of Paris bandage applied.	Recovery
VIII.	J. B.	35	Dec., 1882	Compound comminuted fracture leg. Laceration of soft parts.	Amputation six inches below knee-joint. (Primary.)	Recovery
IX.	M. F.	26	Oct., 1882	Compound fracture both bones. Ankle-joint opened, great comminution.	Plaster of Paris bandage. Patient left hospital in two months with good limb.	Recovery
X.	M. R.	20	Dec., 1875	Compound comminuted both bones of leg. Extensive burns and laceration of soft parts.	Amputation. (Primary.)	Recovery
XI.	A. D.	14	Nov., 1882	Compound fracture, ankle joint opened. Bones protruded.	Plaster of Paris bandage applied. Leg was satisfactory after removing splint; joint useful; very little impairment.	Recovery
XII.	O. D.	34	Jan., 1876	Compound fracture of leg. Great laceration of soft parts.	Amputation. (Primary.)	Recovery
XIII.	W. C.	24	Aug., 1883	Compound comminuted fracture of foot and ankle.	Amputation. (Secondary.)	Recovery
XIV.	F. McC.	24	Oct., 1882	Compound fracture of leg and simple fracture of thigh.	Plaster of Paris bandage applied to leg and thigh.	Recovery
XV.	T. M.	30	Aug., 1883	Compound fracture both bones of leg. Longitudinal fracture.	Plaster of Paris bandage applied.	Recovery
XVI.	T. S.	40	June, 1878	Compound fracture of leg. Result of a heavy stone falling upon the leg.	Plaster of Paris bandage applied immediately.	Recovery
XVII.	J. A.	30	Apr., 1883	Compound fracture of leg.	Plaster of Paris bandage applied.	Recovery
XVIII.	M. M.	22	Oct., 1882	Compound fracture of leg.	Plaster of Paris bandage applied. Fenestrum.	Recovery
XIX.	J. B.	34	Oct., 1883	Compound fracture of leg.	Plaster of Paris bandage applied.	Recovery
XX.	A. M.	34	Oct., 1875	Compound fracture of leg.	Amputation of leg. (Primary.)	Recovery
XXI.	R. W.	46	Dec., 1875	Compound fracture of leg. Ankle-joint involved.	Amputation at knee-joint. (Secondary.)	Recovery
XXII.	T. M.	12	Nov., 1875	Compound fracture of leg. Ankle-joint opened.	Amputation. (Primary.)	Recovery
XXIII.	J. B.	56	Apr., 1884	Compound fracture of head of tibia. Knee-joint filled with blood.	Plaster of Paris bandage applied. Good movement in joint; result satisfactory.	Recovery
XXIV.	T. T.	40	Oct., 1883	Compound comminuted fracture tibia. Ankle-joint involved.	Plaster of Paris bandage applied.	Recovery
XXV.	T. T.	40	March, 1876	Compound fracture of tibia and fibula.	Amputation. (Primary.)	Recovery
XXVI.	T. T.	40	Feb., 1884	Compound fracture of head of tibia, knee-jnint implicated.	Plaster of Paris bandage. The joint was anchylosed.	Recovery
XXVII.	D. B.	35	March, 1884	Compound fracture of leg.	Plaster of Paris bandage applied.	Recovery
XXVIII.	T. M.	38	March, 1876	Compound fracture of leg.	Amputation. (Primary.)	Recovery
XXIX.	D. C.	24	Sept., 1883	Compound fracture of foot.	Amputation, (Primary.)	Recovery
XXX.	R. S.	20	Apr., 1883	Compound fracture of leg.	Plaster of Paris bandage applied.	Recovery
XXXI.	J. B.	40	Feb., 1883	Compound fracture involving knee-joint.	Plaster of Paris bandage applied. Knee anchylosed.	Recovery
XXXII.	P. Mc. K.	50	Feb., 1883	Compound fracture of leg.	Plaster of Paris bandage applied.	Recovery
XXXIII.	F. C.	31	Aug., 1883	Compound fracture of leg; kicked by a horse.	Plaster of Paris bandage applied. (Bracket.)	Recovery
XXXIV.	T. E.	40	March, 1876	Compound fracture of both bones of leg.	Amputation. (Primary.)	Recovery

COMPOUND FRACTURES OF THE LEG—*Continued.*

NO.	NAME.	AGE.	DATE.	INJURY.	TREATMENT.	RESULT.
XXXV.	J. L.	45	Sept., 1883	Compound fracture of tibia and fibula.	Plaster of Paris bandage applied.	Recovery
XXXVI.	M. McC.	35	Aug., 1883	Compound fracture of leg.	Plaster of Paris bandage applied.	Recovery
XXXVII.	M. B.	35	Aug., 1880	Compound fracture of leg.	Plaster of Paris bandage applied.	Recovery
XXXVIII.	G. W.	18	Dec., 1883	Compound fracture of leg; alarming hæmorrhage.	Plaster of Paris bandage applied.	Recovery
XXXIX.	D. B.	30	Jan., 1876	Compound fracture of leg.	Placed in fracture-box with extension.	Recovery
XL.	W. W.	40	April, 1883	Compound fracture both tibia and fibula. Longitudinal fracture.	Plaster of Paris bandage applied with large fenestrum.	Recovery
XLI.	J. D.	50	Nov., 1883	Sequestrotomy. Medullary canal freely opened, with large wound.	Wound packed with strips of sheet lint.	Recovery
XLII.	T. M.	30	April, 1884	Sequestrotomy. Medullary canal of femur freely opened for 4 inches.	Wound packed with jute and Balsam of Peru poured into wound.	Recovery
XLIII.	G. R.	26	Feb., 1884	Compound dislocation ankle-joint; wound 5 inches long; foot right angles to leg.	Plaster of Paris bandage. Leg suspended in a swinging apparatus.	Recovery
XLIV.	J F.	45	June, 1881	Compound fracture of patella and lower end of femur.	Fragments removed. Plaster of Paris bandage applied.	Recovery
XLV.	P. D.	38	Oct., 1883	Compound comminuted fracture of tibia and fibula; also opposite ankle opened.	Stimulants administered.	Died within 14 hours
XLVI.	J. H.	30	May, 1884	Compound comminuted fracture of tibia and fibula, foot also crushed.	Stimulants administered.	Died within 12 hours
XLVII.	J. M.	30	May, 1884	Compound fracture of tibia and fibula.	Plaster of Paris bandage applied. No fenestrum.	Recovery
XLVIII.	B. McN.	35	May, 1884	Compound comminuted fracture of leg, both bones; 10 fragments.	Plaster of Paris bandage applied. Fenestrum cut.	Recovery
XLIX.	B. McN.	35	May, 1884	Compound comminuted fracture of tibia and fibula. This patient had both bones of both legs fractured.	Plaster of Paris bandage applied; fenestrum cut.	Recovery
L.	E. H.	30	Aug., 1883	Compound fracture opening into ankle-joint. All tendons exposed. Fracture astragalus.	Plaster of Paris bandage applied; fenestrum cut; slight movement in joint.	Recovery
LI.	E. W.	25	Nov., 1883	Compound fracture tibia and fibula.	Plaster of Paris bandage applied.	Recovery
LII.	H. C.	14	Oct., 1883	Compound fracture. Medullary cavity of bone opened to remove sequestrum.	Wound left open; simple dressing applied.	Recovery
LIII.	J. S.	53	Sept., 1883	Compound fracture of tibia and fibula.	Plaster of Paris bandage applied.	Recovery
LIV.	B. F.	15	May, 1884	Compound fracture tibia and fibula. Originally simple. Soft parts sloughed.	Plaster of Paris bandage applied immediately. Fenestrum cut.	Recovery
LV.	M. C.	52	May, 1884	Compound fracture of the tibia. End of bone protruded.	Plaster of Paris bandage applied. No fenestrum.	Recovery
LVI.	J. O. D.	42	May, 1884	Compound fracture of the tibia and fibula. Wound one and a half inch. Patient fell from a high tree.	Plaster of Paris bandage applied.	Recovery
LVII.	B. G.	30	May, 1884	Compound fracture of Leg. Fibula alone compound. Patient was struck by policeman's club while under arrest.	Plaster of Paris bandage immediately applied.	Recovery
LVIII.	J. Z.	40	May, 1884	Compound fracture of right leg; large wound. Comminuted fracture left leg; large wound extending up under patella; left arm broken; fell four stories.	Three plaster of Paris bandages at once applied. Patient had delirium tremens and was shackled. Is living while going to press, after 3 weeks.	Recovery

This table shows fifty-eight cases of compound fractures of the leg, all of which recovered, except two which died from shock within twelve hours after admittance into the hospital. In many of the cases the bones protruded through the wound and in three of these cases it was necessary to saw off with the hain-saw several inches of the projecting ends. Two of the cases were longitudinal fractures of the tibia splitting the long bone into halves. In these longitudinal fractures a horse-shoe tourniquet was applied, a device of my own as far as I know, to keep the long fragments in contact with each other. In a few cases a compound fracture was made, but no case is recorded where at least the end of the finger was

not introduced well into the medullary canal of the tibia or femur. Ten of the cases opened into the knee and ankle-joints. In a few the hæmorrhage was a very formidable symptom. One case was a double compound fracture of both bones of both legs. The wounds were large in both legs and in both legs several large pieces of bone were removed, amounting to four inches in one leg and three inches in the other leg. Considering the fact that the patient received a double compound fracture, that the wounds were large, that the loose pieces of bone were many, that the hæmorrhage was alarming, and that the patient not only recovered, but was out of bed sitting up in a chair upon the fourteenth day, without a bad symptom, it is one of the most remarkable cases ever published by any surgeon in this category. In another case there were two legs and one fore-arm fractured with a wound extending up under the patella. Patient jumped from the roof of a four-story building with intent to kill.

COMPOUND FRACTURES OF THE ARM.

NO.	NAME.	AGE.	DATE.	INJURY.	TREATMENT.	RESULT.
I.	U. P. R.	20	April, 1883	Compound fracture of humerus, result of a gunshot injury.	Plaster Paris bandage applied.	Recovery
II.	A. M.	12	April, 1883	Compound fracture of humerus.	Plaster of Paris bandage applied.	Recovery
III.	M. D.	22	May, 1883	Compound fracture of carpal bones opening into wrist-joint, laceration of muscles, fore-arm and radial artery.	Amputation few inches below shoulder-joint during gangrene. (Secondary.)	Recovery
IV.	J.W.	16	May, 1883	Compound fracture of humerus, near shoulder-joint.	Plaster of Paris bandage applied.	Recovery
V.	D. D.	20	May, 1883	Compound fracture of humerus, near shoulder-joint.	Plaster of Paris bandage. Fenestrum cut.	Recovery
VI.	H. C.	35	May, 1883	Compound fracture of humerus, near shoulder-joint, result of a flag-staff falling upon patient from a height of 60 feet.	Plaster of Paris bandage applied.	Recovery
VII.	T. McD.	13	Sept., 1883	Compound fracture of humerus.	Plaster of Paris bandage applied.	Recovery
VIII.	J. H.	11	Aug., 1883	Compound fracture of humerus. Elbow-joint opened, bones protruded, serious hæmorrhage.	Plaster of Paris bandage applied.	Recovery
IX.	J. N.	30	May, 1884	Wired an un-united fracture; bones exposed and fragments sawn off.	Plaster of Paris bandage applied with fenestrum union.	Recovery
X.	J. T.	28	April, 1884	Gunshot fracture of head of humerus. Ball extracted.	Splint applied. Drainage-tube used.	Recovery
XI.	J. G.	30	Dec., 1883	Wired an un-united fracture humerus, near shoulder-joint.	Plaster of Paris bandage applied.	Recovery
XII.	B. B.	4	May, 1884	Compound fracture of humerus. Child fell from a 4-story building, also depressed fracture of skull with convulsions. Fracture of skull not compound.	Plaster of Paris bandage applied. Wound admitted the finger.	Recovery

This table records twelve cases of compound fracture of humerus. All of which recovered. In those cases where the joints were involved, recovery took place with little impairment in movement of the joint. One of the twelve cases, involved also the wrist-joint; another the elbow-joint, and another the shoulder-joint. Two of the cases were the result of gunshot injuries. These cases then of the arm were all of a serious character. In one of the cases of compound fracture of the humerus, there was a depressed fracture of the skull in a child. The patient had convulsions, but these disappeared when the overlapping was replaced and the indentation was rectified.

COMPOUND FRACTURES OF THE FORE-ARM.

NO.	NAME.	AGE.	DATE.	INJURY.	TREATMENT.	RESULT.
I.	J. W.	12	Oct., 1882	Compound comminuted fracture of radius and ulna.	Plaster of Paris bandage applied.	Recovery
II.	L. S.	14	May, 1883	Compound fracture wrist-joint. Opened, tendons torn and divided.	Amputation of fore-arm. (Primary.)	Recovery
III.	J. G.	20	March, 1875	Compound fracture radius and ulna opening into elbow-joint.	Amputation of arm. (Primary.)	Recovery
IV.	D. H.	20	May, 1883	Compound fracture of radius and ulna.	Amputation circular flap. (Primary.)	Recovery
V.	G. H.	20	Aug., 1883	Compound comminuted fracture of radius.	Plaster of Paris bandage applied.	Recovery
VI.	T. McC.	20	April, 1883	Compound fracture of ulna.	Plaster of Paris bandage. Patient had an attack of erysipelas. Patient admitted into ward with facial erysipelas.	Recovery

COMPOUND FRACTURES OF THE FORE-ARM—*Continued.*

NO.	NAME.	AGE.	DATE.	INJURY.	TREATMENT.	RESULT.
VII.	A. S.	24	May, 1883	Compound fracture of fore-arm; gangrene; vessels divided.	Amputation. (Secondary.)	Recovery
VIII.	J. O. B.	42	June, 1883	Compound comminuted fracture of radius and ulna with extensive burns.	Stimulants.	Died within 24 hours
IX.	J. B.	10	April, 1883	Compound fracture. Radius and ulna, bones protruded.	Wound washed out; 1-40 solution carbolic acid; splint.	Recovery
X.	C. H.	40	April, 1883	Compound comminuted fracture of radius and ulna. Extensive laceration.	Wound irrigated; carbolic acid; several kinds of splints applied.	Recovery
XI.	G. T.	30	Sept., 1882	Compound comminuted fracture of fore-arm with laceration of tendons.	Amputation. (Primary.)	Recovery
XII.	H. T.	13	May, 1884	Compound comminuted fracture of radius and ulna.	Plaster of Paris; no fenestrum; patient about ward.	Recovery
XIII.	J. N.	19	May, 1884	Compound comminuted fracture into wrist joint. Radius fractured.	Dressed with wooden splint and irrigation.	Recovery
XIV.	M. McD.	28	May, 1884	Compound comminuted fracture meta-carpal bone, also styloid process of radius; joint opened wide and filled with persulphate of iron before admittance.	Plaster of Paris bandage.	Recovery

This table records fourteen cases of compound fractures of the fore-arm, all of which recovered except one case, which died from shock within twenty-four hours, and which had in addition to his fracture severe burns of the 1st, 2d and 3d degrees. Of the remaining thirteen cases, three of them opened into the wrist-joint and one into the elbow-joint.

COMPOUND FRACTURES OF THE LOWER JAW.

NO.	NAME.	AGE.	DATE.	INJURY.	TREATMENT.	RESULT.
I.	R. B.	21	June, 1883	Compound fracture lower jaw, produced by kick of a horse.	Wound enlarged and cleaned. The fragments were united by silver wire.	Recovery
II.	M. P.	28	June, 1883	Compound fracture lower jaw, result of a blow.	Wound cleansed and enlarged. Fragments sutured by silver wire.	Recovery
III.	F. F.	14	Sept., 1883	Compound fracture upper and lower jaw, also simple fracture of thigh. Fall of 80 feet.	Retentive apparatus. Plaster of Paris to thigh.	Recovery
IV.	A. H.	55	Aug., 1883	Compound fracture lower jaw at dental foramen. Two teeth wedged in between fragments.	Barton's splint. Mouth washed every few hours with carbolic acid and water.	Recovery
V.	H. W.	30	May, 1883	Double compound fracture of lower jaw.	Barton's bandage applied, also a cork between the two rows of teeth	Recovery
VI.	F. F.	12	Sept., 1883	Compound fracture of lower jaw, simple fracture of thigh, also tibia and fibula.	Retentive apparatus to jaw, also a cork. Plaster of Paris to thigh and leg.	Recovery
VII.	J. F.	20	June, 1883	Compound fracture of lower jaw.	Retentive apparatus, also cork. Mouth rinsed out at frequent intervals.	Recovery
VIII.	S. M.	25	Dec., 1875	Compound fracture of lower jaw. Great displacement. Kicked by a vicious horse.	Patient was placed under ether to reduce the fragments. A leather splint applied also.	Recovery
IX.	F. W.	14	May, 1884	Pistol shot injury upper jaw.	Wound scaled.	Recovery

This table shows nine cases of compound fractures of the lower and upper jaws, in all of which the injuries were of a severe character. In two of the nine cases the fragments were reduced and silver sutures were introduced to keep the fragments in coaptation. In two of the remaining seven, the thigh was fractured in addition to the compound fracture of the jaw, and the leg was also fractured in one of the two cases just mentioned. One case was a pistol-shot wound of superior maxilla with comminution of the fragments.

COMPOUND FRACTURES OF THE FINGERS AND TOES.

NO.	NAME.	AGE.	DATE.	INJURY.	TREATMENT.	RESULT.
I.	W. F. K.	44	May, 1883	Lacerated and contused wound of foot produced by a loaded truck passing over foot causing compound comminuted fracture.	Foot bandaged to wooden splint; treated openly; balsam of Peru.	Recovery
II.	M. K.	20	May, 1883	Compound comminuted fracture meta-carpal bones. Amputation part of hand.	Treated openly; hand on Palmar splint.	Recovery
III.	W. K.	24	May, 1883	Compound fracture of all toes, joints of meta-tarsus opened. Gangrene.	Splint; toes allowed to granulate; balsam and other stimulating applications employed.	Recovery
IV.	R. G.	20	Feb., 1883	Compound fracture of fingers. Contusions.	Primary amputation of injured part.	Recovery
V.	T. C.	16	Sept., 1883	Compound fracture of middle phalanx.	Wooden splint; treated openly to granulate.	Recovery
VI.	C. H. P.	42	Sept., 1882	Compound dislocation; joints all open; circular saw injury.	Amputation middle finger; conservative treatment in other fingers.	Recovery
VII.	J. H.	30	May, 1883	Compound comminuted fracture of phalanges.	Wooden splint; wound treated openly to granulate.	Recovery
VIII.	R. G.	16	Sept., 1883	Compound comminuted fracture 1st 2d and 3d fingers; tendons torn; lacerated wound.	Primary amputation; healed by granulation.	Recovery
IX.	A. R.	20	May, 1883	Compound comminuted fracture meta-tarsal bone. Railway car wheels passed over foot; wound 4 inches in length to tarsal bones.	Wooden splint; treated openly; allowed to granulate, useful foot.	Recovery
X.	J. H.	22	Dec., 1875	Compound fracture of meta-tarsal bone.	Wooden splint; wound treated openly; good result.	Recovery
XI.	J. M.	27	April, 1880	Compound fracture of toes.	Wooden splint, jute, balsam, treated openly.	Recovery
XII.	S. H.	60	Sept., 1882	Compound fracture of meta-tarsal bones.	Wooden splint, jute, balsam, treated openly.	Recovery
XIII.	J. M.	18	Sept., 1883	Compound comminuted fracture toes.	Wooden splint, jute. Balsam of Peru; treated openly.	Recovery
XIV.	J. C. H.	45	Sept., 1883	Compound comminuted fracture fingers.	Wooden splint. Balsam of Peru; treated openly.	Recovery
XV.	P. McV.	52	April, 1884	Compound comminuted fracture toes. Foot badly crushed. Patient had a bad bed-sore.	Wooden splint. Balsam and iodoform; treated openly.	Recovery
XVI.	J. R.	16	April, 1884	Compound fracture thumb and meta-carpal bone.	Primary amputation. Wound healed nicely.	Recovery
XVII.	J. O. B.	30	April, 1884	Compound fracture of great toe; foot contused.	Plantar wooden splint; jute, iodoform; treated openly.	Recovery
XVIII.	J. L.	65	May, 1882	Compound fracture meta-tarsal bone, and compound dislocation of great toe.	Wooden splint; iodoform, jute; treated openly.	Recovery
XIX.	M. C.	14	May, 1882	Resection and gouging os-calcis; large wound opening on both sides of foot.	Plaster of Paris bandage applied; fenestrum cut; treated openly.	Recovery
XX.	J. F.	21	May, 1884	Compound comminuted fracture of fingers; amputation of one finger, the remaining left to granulate.	Wooden splint; simple dressings.	Recovery
XXI.	J. C.	45	May, 1884	Compound fracture of three fingers; amputation of one finger.	Wooden splint; simple dressings.	Recovery

Here are 21 compound fractures of the hand and foot. All of these cases were complicated by great crushing and laceration of the soft parts, produced by railway injuries, circular saws, or by the falling of heavy weights. The joints were opened, and the bones were comminuted, the tendons exposed and the soft parts badly lacerated and contused. Although these compound fractures, on account of the peculiar nature of the accidents, were troublesome to treat, I shall in accordance with writers in general, exclude these twenty cases from the final list, remarking, however, that they all recovered.

There are twelve miscellaneous fractures which were compound, and some complicated with other injuries. Eight of the cases were of the lower and upper jaw, and were all serious injuries. Four were of the ribs and nasal bones. All of these compound fractures recovered. I have inserted these compound fractures because they have been more troublesome to treat, and have given me greater anxiety than the other fractures.

Finally, to recapitulate, there are in all 144 cases of compound fractures, of which number 23 are of the skull, 3 are of the thigh, 58 are of the leg, 12 are of the arm, 14 are of the fore-arm, 9 are of the upper and lower jaws, 21 are of the hand and foot, 4 are of the ribs and nasal bones. Total—144.

COMPOUND FRACTURES OF RIBS AND NASAL BONES.

NO.	NAME.	AGE.	DATE.	INJURY.	TREATMENT.	RESULT.
I.	T. B.	33	Sept., 1883	Compound fracture of two ribs, with considerable hæmorrhage.	Wound cleansed; adhesive plaster applied, and collodion, opium.	Recovery
II.	J. T.	30	Aug., 1882	Compound fracture nasal bones, with displacement and hæmorrhage.	Fragments reduced, and simple dressing applied.	Recovery
III.	M. T.	65	April, 1884	Compound fracture of nasal bones; two wounds leading down to fracture; severe hæmorrhage and shock.	Wound cleansed; fragments reduced; wounds sealed.	Recovery
IV.	J. A.	45	Dec., 1878	Compound fracture nasal bones; result of a blow from a heavy club.	Fragments reduced, which were comminuted; wound cleansed.	Recovery

Now following the example of surgical writers, who have carefully tabulated the results of treatment in compound fractures, I shall eliminate all those cases in which primary amputations were performed, because they do not concern the point at issue, but add the important fact that all the cases upon which any amputation was performed in compound fractures recovered without an exception; and, I shall also, according to the practice of all writers, reject all those cases which died of hæmorrhage, collapse, shock, etc., within forty-eight hours, although most of cases died within a few hours after injury. I shall also leave out all those cases of compound fractures of the hand and foot, remarking, however, that all these cases recovered and the results are as follows:

Deducting 21 cases of compound fractures of the hand and foot, and 14 cases of primary amputations, and 9 deaths which occurred within 48 hours or less from shock, there remain 100 consecutive, and of course unselected compound fractures, occurring in three large metropolitan hospitals without a death.

I have still other successful cases with which to begin my second series of one hundred cases of compound fractures, and I hope to report these cases at a future meeting of this Association.

In conclusion, gentlemen, let us compare the results of the treatment of compound fractures by the simple, open method already described, with that obtained by the true Listerian method.

In the *Boston Medical and Surgical Journal*, Hodges reports 19 cases of compound fractures treated strictly according to Lister's method with no deaths.

Lo Grasso reports 25 cases of compound fractures treated by Albanese under strict Listerian method with no deaths. Black, in the *Edinburgh Medical Journal*, reports eight cases of compound fractures treated *a la* Lister with no deaths.

Sir William McCormac reports 16 cases without a death, and refers to his 45 cases of compound fracture in St. Thomas' Hospital, which fractures were made by the surgeon. Vollkman reported at the International Congress, in London, 75 cases of compound fractures treated under the most rigid Listerian method without a death. These cases are reported by different surgeons throughout the world as the results obtained by a rigid adherence to the Listerian method. The results are brilliant beyond description. Sir Joseph Lister reports in his list 97 cases with two deaths.

Finally, in *Billroth und Luecke Deutsche Chirurgie*, published in 1882, in Lieferung 27, 1. Hälfte, is a most exhaustive treatise on fractures by Prof. Dr. P. Burns. He has made a table of compound fractures in which there is an analysis of 254 cases which were treated by Listerian method. Of these 254 cases, 224 cases were treated conservatively, (*i. e.*, without interference by operation or resection, etc.) and 30 were obliged to submit to amputation or resection. Of the 224 treated conservatively, 14 died, and of the 30 operated upon, 9 died, making a total of 23 or 9 per centum of all the cases from all causes. Excluding such cases of deaths which occurred from causes entirely disconnected with any plan of treatment; (e.g.) collapse, fat embolism, hæmorrhage from rupture of the liver, each 1, delirium tremens 7, tetanus 2; there remain 11 cases, which died of septo-pyæmia, a percentage of 4.3 (four and three-tenths). Owing to 2 of these 11 cases having manifested general septic infection before they came under treatment, they may for statistical purposes be eliminated, thus giving a mortality of 9 or 3.5 per centum, (three and five-tenths.)

To make a summary, there were 254 cases of compound fractures, and excluding the deaths not connected with the plan of treatment, there is a death-rate of 3.5 per centum from septo-pyæmia.

The results obtained by this simple and uncomplicated method which can be employed by any one without the ready facilities of a hospital, or by any one who has no opportunity to obtain special dressings, compare most favorably with any statistics yet published. In bringing these 144 cases before the meeting of the American Medical Association, and in offering them as a clinical contribution, I do not wish it to be understood that I under-value antiseptic surgery. On the contrary, I am a great advocate for, and believer in, those principles of antiseptic surgery, which have been so emphatically enunciated by the renowned Lister. I only contend that the same results can be obtained by other and simpler methods, which are within the reach of all. The aim of this paper is to maintain that cleanliness is the *sine qua non* for surgical success, and that wounds and compound fractures can repair kindly and quickly without danger though exposed to the air. The open treatment of wounds of a certain character is after all the highest type of antiseptic surgery. These serious wounds will heal kindly when the surgeon acts well his part. There are certain wounds and

certain injuries which repair best without primary intention, although I obtain primary intention in osteotomies, in the major amputations, in excision of large tumors and other capital operations. I believe thoroughly in the germ theory, but I contend that these germs are for the most part harmless unless a wound is foul and unhealthy, for which condition the surgeon should hold himself responsible. The presence of air *per se* in a wound will excite no dangerous complication unless the wound is in an unhealthy condition. If the surgeon affords nature her prerogative and acts his part, there is no reason why a wound, and especially a compound fracture, should not repair kindly, quickly and satisfactorily.

In conclusion I invite your attention to some of the temperature charts which I have selected at random from the entire number which lie before you upon the table. They are all here for your examination.

MEDICAL PROGRESS.

ANATOMY AND PHYSIOLOGY.

THE DISTRIBUTION OF UREA IN THE BLOOD.—Gréhant and Quinquaud have undertaken an investigation into the amount of urea in the blood, of which the first instalment has just been communicated to the Society of Biology, of Paris. The main object of the inquiry is to determine the source of the urea. In the first place, they have ascertained the relative quantity of urea in blood *going to* and *coming from* the periphery, and afterwards they have determined the relation between that of arterial blood and that in the abdominal veins. Their figures show (1) that there is about the same quantity of urea in the blood returning from as in that going to the periphery, from which we may conclude that any urea which may be formed there must be carried to the centre of the circulation by the lymphatics; and (2) that the blood coming from the spleen and the liver is always considerably richer in urea than the arterial blood, especially during digestion. The difference may be as much as 9 milligrammes in every 100 grammes of blood in this condition, and if we suppose that 100 grammes of blood come from the liver every minute, carrying an excess of 9 milligrammes of urea, it gives 540 milligrammes per hour, or 13 grammes in 24 hours. On the other hand, if the animal is fasting the difference may only be 3 milligrammes per 100 grammes, which, on the same supposition as to blood-flow, gives 180 milligrammes per hour, or 4.32 grammes per day.—*Comptes rendus, Edin. Med. Jour.*

MOTOR FIBRES IN THE CARDIAC PORTION OF THE VAGUS.—Wedenskü has made some telephonic researches into the heart-sounds, which seem to point to the existence of motor filaments in the cardiac branches of the pneumo-gastric nerve. The heart of a dog was connected by means of two needles with a telephone, and on listening, the normal heart-sounds were heard. The vagus was then stimulated with a weak current, which only showed the rate of the heart's action, and a series of short sounds could be heard, accompanying the normal sounds. When the electrical stimulus was augmented in strength, so that the heart was stopped, nothing could be heard. After the injection of atropia by the jugular vein, to paralyze the inhibitory fibres, these sounds could be produced by any strength of current; and on the other hand, after the administration of curara to paralyze the motor fibres, no sounds could be caused by stimulating the vagus. From these facts Wedenskü concludes that there must be in the pneumo-gastric nerve some sort of motor control over the heart.—*Centralbl. für die Med. Wissenschft.—Edin. Med. Jour.*

A NEW FUNCTION OF THE RED CORPUSCLES.—Fano has studied the manner in which peptone is altered after being injected into the blood of animals. It is a well-known fact that it cannot be detected half an hour after injection, and by very careful investigation he thinks he has proved that the red corpuscles have the power to transform the peptone into globulin. The corpuscles, after a certain time, give up the globulin to the tissues, and thus form a nutritive reserve. We may liken the process to the glycogenic function of the liver cells.—*Sperimentale, Edin. Med. Jour.*

MATERIA MEDICA AND THERAPEUTICS.

IODOFORM IN ERYSIPELAS.—Mr. C. Clark Brennan, in the *Practitioner*, relates his success with this agent in erysipelas, which was, as he puts it, an accidental discovery. He gives four cases treated with iodoform collodion, a mixture of one part of iodoform to ten of collodion. Its prompt relief of the burning pain, which is such a constant symptom of erysipelas, its apparent power of arresting the progress of the disease and the remarkable freedom from irritation during the period of desquamation following the subsidence of the disease, are all strong reasons in favor of its extended use.

OSMIC ACID TREATMENT OF PERIPHERAL NEURALGIA.—Dr. Eulenberg, of Berlin, has employed subcutaneous injections of osmic acid in 29 cases of peripheral neuralgia. The dose employed was 7 minims of a 1 per cent. aqueous solution. The treatment was persisted in for periods of from 1 to 6 weeks, and the number of injections made varied from 3 to 14. Of the 29 cases only 7 are reported as cured, viz., 4 of sciatic, 1 of lumbar, 1 of brachial, and 1 of intercostal neuralgia. The success has not been as great as previous trials would lead us to hope for; but supposing that the whole 29 cases had resisted all other methods of treatment, success in 25 per cent. of the cases must have been gratifying, at least to those who were benefited.—*Medical Press.*

THE BENZOATE OF SODIUM IN THE SUMMER DIARRHŒA OF CHILDREN.—Dr. R. Guaita (*Gaz. degli Ospitali Bull. Gen. de Therap.*) considers the summer diarrhœa of children as a zymotic disease, caused by the presence of a special microbe introduced from without, or developed in the alimentary canal during digestion. A deficient diet, bad hygiene, excessive heat being the predisposing causes. With this idea he employs the benzoate of sodium, which has already been used to advantage by Kapuscinsky and Zilewiez in the vomiting and diarrhœa of children, as being anti-fermentative and modifying the intestinal mucous membrane.

Dr. Guaita used the benzoate of sodium alone and without any other treatment in 53 cases of children, varying in age from 6 months to 2 years. In 35 of these cases the affection was 24 to 30 hours old; in the other 18 it dated from 6 to 14 days. With the first he produced perfect relief always in from 4 to 8 days; with the second, after about 21 days, without a single death in either.

After the use of a purgative (calomel, jalap), he gave from 4 to 6 grammes of the benzoate of sodium in 100 grammes of water during the 24 hours, and continued its use for 2 days. The third day he gave a slight purgative (magnesia, manna), followed by a repeated use of the benzoate. At the end of 2 days an improvement in the character of the stools was very noticeable, with but little fœtid character, and a checking of the vomiting. During treatment the child is strictly dieted, only taking a little lemonade and a few spoonfuls of good wine. Milk and soup are absolutely interdicted, as Dr. Guaita finds that milk, particularly that of the cow, ferments readily in the stomach, and increases the trouble. Children at the breast are allowed to nurse 4 times in 24 hours.

MEDICINE.

THE PATHOLOGY OF PNEUMOTHORAX.—Dr. Samuel West gives in the *Lancet* an analysis of the records of the City of London Hospital for Diseases of the Chest, extending over a period of twenty-eight years, as a contribution to the pathology of this disease. He finds: First, that 90 per cent. of all the cases are attributed to phthisis.

Second. About 5 per cent. of all deaths from phthisis are the result of pneumothorax.

Third. Of the cases of pneumothorax, about 75 per cent. die within the first fourteen days, and about 90 per cent. before the end of the first month, though the duration of life of the remaining 10 per cent. may be considerable.

Fourth. The period of greatest frequency coincides with the period of greatest mortality from phthisis, and lies between the ages of twenty-five and thirty-five.

Fifth. Pneumothorax is very rare before the age of fifteen or after forty.

Sixth. It is commoner in men than in women, but the mortality is greater in women.

Seventh. One side of the chest is not more prone to be attacked than the other, nor does the side attacked modify the prognosis.

Eighth. Effusion commonly occurs, though not necessarily. It is not necessarily purulent; in fact, serous, sero-purulent, and purulent effusions are of about equal frequency, though in cases of long duration, an effusion which was serous to begin with often becomes purulent.

Ninth. The chances of effusion being present, and of that effusion being copious and probably also purulent, increase with the duration of the case; but effusion may be absent throughout, or be scanty in old cases and copious in recent cases, or, whether large or small, remain serous throughout or be purulent from the commencement.

Tenth. The perforation is found in about two-thirds of the cases, and may be discovered even in cases of long standing. It is usually single, but may be multiple. It is generally circular in shape. Its size is commonly small, two or three lines; but occasionally it is large, even an inch or more in diameter. Its favorite position is in the upper lobe, where it occurs nearly twice as frequently as elsewhere, and in the mid-lateral region.

Eleventh. There is, lastly, no relation between the amount of lung disease and the occurrence of pneumothorax.

CYSTICERCUS OF THE BRAIN.—In the March number of the *Archives de Neurologie*, M. Bernard records a case of this somewhat rare affection. The patient was a man, aged 24 years, who had suffered from attacks of headache and vomiting for a year when he came under observation. These attacks were accompanied by vertigo and transient loss of vision. Latterly the headache had become constant; there was no loss of motor power, but the patient staggered in walking, and complained of numbness in the right side of his face and tongue. There had also rapidly ensued impairment of vision. On examination, there was marked retraction of the field of vision, especially on the right side; his color fields could not be taken; the visual acuity was much diminished on the right side. The pupils were dilated, and very sluggish both to light and during accommodation; there was a typical "choked disc" on each side. After his admission to the Salpétrière the vomiting was checked, but he suffered much from head-

ache and from vertigo, and he gradually became quite blind. He died from double pneumonia. At the necropsy, a small sac was found just in front of the optic commissure, but not having any direct relations to it; a second sac was seen depressing the second frontal convolution on the left side; and a third embedded in the wall of the fourth ventricle, on a level with the left eminentia teres. There was evidence of inflammation of the ependyma here, and a general increase of cerebro-spinal fluid. It is to this third cyst that the author would attribute all the symptoms observed. The cysticercus which was found in it, measured five millimeters in length, four in width, and three in depth.—(*Medical Times.*)

A Vibrio Observed During Measles.—M. J. A. LeBel (*Journ. de Méd. de Paris*) reports that he has observed in the urine, during measles alone, the appearance of a slightly-curved rod, very refracting, and endowed with very slow movements. The length varies considerably, so that the observer sees them of every appearance, from that of the typical vibrio to that of the bacteria.

In the case of ordinary measles this vibrio only appears in the urine during a few days, and disappears almost simultaneously with the appearance of the fever and swelling of the face. He has observed, in the case of an infant, on the second day of the eruption, the vibrio and spores; the protoplasm which enveloped them disappeared very rapidly.

The naturally acid urine is a favorable soil for this micro-organism; it may be found in abundance in the vessels in which the urine is placed, distributed in the mass of the liquid. It is well, if one wishes to judge of the intensity of any particular attack, to examine each specimen of urine as it is passed.

This vibrio makes its second appearance at the desquamative stage; at that time, also, it is easy to recognize it. The skin may be scraped, and the scales placed first in sterilized water and then in sterilized urine; within twenty-four hours large numbers of the micro-organism may be seen. In severe and persistent cases it re-appears in the urine and on the skin for weeks and even months.

LeBel states that he has been extremely careful in his observations, and has no reason to think that they are not correct.—*Midland* (*Med. Miscellany.*)

Scarlet Fever of the Fœtus in Utero, and of the Mother at the Ninth Month of Pregnancy.—Dr. Charles A. Leale, of New York, has recently read (*Medical News*) a paper on this subject before the New York County Medical Association, in which he gives a brief review of the literature of this disputed subject. He was further stimulated to do so after reading an article on the subject in this Journal, on page 432. He makes the distinction between septicæmia and scarlet fever to be as marked as between measles and small-pox, and after a thorough and interesting review of the subject comes to the following conclusions:

Scarlet fever may attack the fœtus in utero.

The large proportion of children born with scarlet fever recover.

Scarlet fever of the newly born child has like manifestation as when it occurs later in life.

Scarlet fever may attack the woman during pregnancy and also immediately after childbirth.

Scarlet fever is exceedingly fatal to the woman during pregnancy and during parturition.

Scarlet fever rarely, if ever, affects the parturient woman if she has had a previous attack.

Scarlet fever causes death in the parturient woman by coma, exhaustion, or by convulsions.

Scarlet fever, being a self-limited disease, is best treated by relieving dangerous symptoms, and in accordance with the rules of hygiene.

Scarlet fever only exceptionally occurs during the ages that women bear children; therefore, the proportion of those liable to contract the disease during pregnancy and childbirth, must necessarily be small.

Scarlet fever and septicæmia are distinct diseases, being unlike in many respects.

This paper, by Dr. Leale, excited a good deal of discussion in the Association, and the discussion was of a character to support his conclusions. Dr. Dwyer had seen one case of scarlatina in the parturient woman, in which the mother suffered from violent eclampsia and expired at the moment of the birth of the child. He had, however, met with three cases in which pregnant women nursed children having scarlet fever, who escaped the disease themselves and whose infants, when born, did not have it.

Dr. Detmold and Dr. Gouley dwelt upon the condition of the kidneys in pregnancy, making the liability to scarlatina of peculiar interest, as, if the disease were recovered from, there was imminent danger of their being affected with permanent nephritis.

Dr. Lusk considered the subject at some length. He thought it best not to run any risks, mentioning the case of a practitioner with a very large obstetric practice, who from the very unfavorable results, was forced to the conviction that he had been carrying infection directly from his scarlet fever patients to his parturient women. Scarlatina in the parturient woman, as a rule, he believed, was not associated with inflammation of the peritonæum or with pelvic celilultis. As to the possibility of the occurrence of a scarlatinous rash due to puerperal septicæmia, and entirely independent of the infection of true scarlatina, he had his doubts, as the exanthemata occurred sometimes without rash, and scarlet fever sometimes occurred without the throat symptoms. Braxton Hicks in his researches, maintained that there were cases of puerperal septicæmia without the ordinary signs of scarlatina which were in reality due to this disease; but of 68 cases of puerperal disease seen in consultation by Hicks, no less than 37 were distinctly traced to the scarlatinal poison. Of these, 20 had the characteristic rash of the disease; but the remaining 17, although the history clearly proved exposure to the contagion of scarlet fever, showed none of its usual signs, and were not to be distinguished from ordinary typical cases of the so-called puerperal fever.

SURGERY.

A NEW SPONGE.—Sampson Gamgee, in the *Lancet*, describes a sponge made of curled cocoanut fiber, which will take up sixteen to eighteen times its own weight of blood or water, which when squeezed out still leaves it elastic and absorbent, readily filling and swelling out again, when dipped in liquid and squeezed, a number of times in succession. To make this permanently antiseptic, he encloses within an absorbent cotton nucleus a very thin ball or capsule, containing the antiseptic of any kind, and, within certain limits, in any quantity desired; the antiseptic to be set free by cracking the capsule with a squeeze, just before using the sponge.

ON THE SURGICAL TREATMENT OF VARICOCELE.—M. Hache (*Annales des Maladies des Organes Génito-Urinaires*) gives two cases illustrating the treatment of this disease by Prof. Guyon, who combines the ligature of the veins with a resection of the scrotum. The patient being anæsthetized, the scrotum shaved and washed with a 20 per cent. phenic solution, the boundaries for an elliptical incision greatest in its transverse diameter, are traced out upon the skin; the dimensions varying according to the volume of the varicocele, and the degree of flaccidity of the skin, after prolonged rest has diminished the size of the tumor. In one of these cases, where the affected side was 9 centimeters in its transverse (from the exterior to the posterior raphes of the scrotum) and 4 centimetres in its long diameters in excess of the sound side, M. Guyon made an incision 25 millimetres in length in the vertical, and 7 centimetres in the transverse diameter. After removing the skin, the common fibrous tunic is exposed, with the tunica vaginalis just beneath it. Then the anterior venous plexus is to be ligated without opening the tunica vaginalis, by passing a curved needle or grooved sound behind the venous plexus, after isolating the vas deferens. Two ligatures are then applied, which are separated from each other as far as possible. This avoidance of opening the tunica vaginalis except for the passage of the ligatures, M. Guyon considers as of great value, and as simplifying greatly the operation. After proceeding thus far with the operation, it only remains to close carefully the lips of the cutaneous incision, with antiseptic washing, etc. It is preferable to leave a small drain at one of the angles of the wound for twenty-four to forty-eight hours.

This operation embraces four points:

First. An elliptical incision, with its greatest diameter transverse, of the skin of the anterior portion of the scrotum.

Second. Ablation of the portion circumscribed by this incision.

Third. Double ligature of the anterior venous plexus of the cord, through the non-incised tunica vaginalis and common fibrous tunic.

Fourth. Suture of the skin.

OBSTETRICS AND GYNÆCOLOGY.

MENOXENIA—A YOUNG GIRL 17 YEARS OF AGE MENSTRUATES BY THE LEFT BREAST.—Dr. Rouxeau gives, in the *Gazette Médicale de Nantes*, the account of a young girl, of medium size, apparently in excellent health, who consulted him from the fact that she had never lost any blood through the ordinary natural passages, but that for four or five months she had a discharge of blood at regular fixed periods from the left breast, which continued for three or four days. At other times than the menstrual period the two breasts were similar. When seen by Rouxeau at the menstrual period, her chest-linen was bloody, her left breast covered with blood and a third larger than the right—the nipple being prominent and turgescent. The blood oozed from the nipple.

THE RELATIONS OF EPILEPSY TO PREGNANCY AND LABOR.—Dr. Raoul Béraud (*Archives de Tocologie*) gives the results of his observations in forty-six cases, taken from various writers and from his own experience, with the view of ascertaining the asserted injurious effects of the alkaline bromides upon the fœtus when taken by the pregnant woman, and the asserted curative influence of marriage upon epilepsy. He arrives at the following conclusions:

1. Pregnancy is not a cause of epilepsy; the epilepsy of olden times so described is the eclampsia of modern times.

2. The influence of pregnancy upon preëxisting epilepsy is favorable, unfavorable or null. When favorable it either suspends the attacks, or diminishes their frequency. When unfavorable it increases their frequency. Generally the character of the attacks is not modified. The form and intensity remain the same.

3. Those cases in which the influence of pregnancy is favorable are the most numerous.

4. In the same woman, the influence of pregnancy upon epilepsy is stereotyped, uniform. The effect produced by the first pregnancy is repeated by the following pregnancies.

5. The modifying influence of pregnancy is generally limited to the duration of gestation. In other words, the ultimate progress of the epilepsy is not modified.

6. There does not seem to exist a group of precise conditions, clearly determined, which would enable one to prognosticate the modifications which pregnancy might exert upon epilepsy.

7. The influence of epileptic attacks upon pregnancy is null. They do not produce either abortions or premature deliveries. The children are born alive and at term.

8. Labor is not a cause of epilepsy.

9. The influence of delivery upon preëxisting epilepsy is null.

10. In those exceptional cases where delivery occurs during an epileptic attack, there seems to be no influence upon the uterine contractions.

11. Marriage does not cure epilepsy, it aggravates it.

12. Bromidism which is useful to the mother, is not injurious to the child.

13. Epilepsy does not appear to predispose to eclampsia.

SATURDAY, JUNE 21, 1884.

Heroic Doses Prompted by Germ Theories.—During the last twenty-five or thirty years the profession has been strongly influenced by a prevailing therapeutic skepticism. It had become a popular habit to decry active medication in the treatment of almost all forms of disease, and to extol the powers of nature aided by simple hygiene. The reaction from this state of skepticism and expectancy in the treatment of disease, began with the revival of the antipyretic treatment of fevers, and is being pushed on by the rapid development of the doctrines of germ etiology and consequent germicide therapeutics, until even now, it is becoming an important question whether the patients are not in more danger from the large doses of microbe remedies administered in some cases, than from the microbes themselves.

Our attention was directed to this subject by two paragraphs in the present number of this Journal, one under the head of Medical Progress, and the other in the Proceedings of the Illinois State Medical Society. In the first, Dr. Guaita is represented as attributing the "summer diarrhœa of children" to the presence of a special microbe, and as giving to children between 6 months and 2 years of age, affected with the disease, first a purgative of calomel or jalap, followed by from 4 to 6 grammes (℥i to ℥iss) of benzoate of sodium dissolved in 100 grammes of water every twenty-four hours for two days. On the third day he gives a milder purgative of magnesia or manna, and then resumes the administration of the benzoate of sodium, and continues it from two to four days longer. It will be seen that the quantity of the benzoate reported as given in the twenty-four hours, is equal to from $2\frac{1}{2}$ to $3\frac{4}{5}$ grains every hour. We have repeatedly seen decidedly sedative or depressing effects from such doses, given to children between three and five years of age, only once in from two to three hours. When they are given every hour for several days in succession, to infants under one year of age, aided by one or two cathartics and an almost entire prohibition of nourishment, we are quite certain the little sufferers are in more danger from the remedial measures employed than from all the microbes they may have in any part of their digestive organs.

The paragraph in the Proceedings of the Illinois State Medical Society relates to the, so-called, specific treatment of diphtheria, by large doses of the corrosive chloride of mercury.

In the paragraph alluded to, the doses given by Dr. Cook are not stated, but they ranged from two to three milligrammes (gr. $\frac{1}{30}$ to $\frac{1}{20}$) at short intervals, to children between three and ten years of age. These doses, though large enough certainly to be efficient, were yet within the limits of safety, so far as direct toxic effects upon the patients are concerned. But elsewhere we have seen several reports representing the giving of eight, ten, and even fifteen milligrammes (gr. $\frac{1}{8}$-$\frac{1}{6}$ and $\frac{1}{4}$) at a dose, of the same active drug, to children suffering from severe diphtheria. That this disease is accompanied by a very marked diminution of susceptibility to the influence of all drugs, is well known; and that some cases recover after taking very large doses of bichloride of mercury, whiskey, and many other things, is true. This, however, does not prove that such doses, repeated at short intervals, are not liable to accumulate, in one or two days, a sufficient quantity of the drug to produce dangerous or even fatal effects.

Dinner to Dr. Alfred Stille.—On the evening of the 5th inst. a dinner was tendered to Dr. Alfred Stillè, on behalf of the medical profession of Philadelphia, prompted by his recent retirement from the Chair of Theory and Practice of Medicine in the University of Pennsylvania, after a distinguished career as a teacher, author, and general practitioner. The entertainment was an elegant one, and the occasion highly enjoyed by the participants. Dr. J. M. DaCosta, President of the College of Physicians, presided; and the occasion was honored by the presence of Dr. Austin Flint, of New York; Dr. George C. Shattuck, of Boston, and Dr. J. S. Billings, of Washington, as guests.

The place vacated by Dr. Stillè has been most ap-

propriately and worthily filled by the appointment of Dr. Wm. Pepper, who is also Provost of the University.

NEW JERSEY STATE MEDICAL SOCIETY.—At the recent annual meeting of the Society, the following officers were elected for the current year: President, Dr. P. C. Baker, of Morristown; Vice Presidents, Drs. Joseph Parrish, of Burlington; Charles J. Kipp, of Newark, and J. W. Ward, of Trenton. Corresponding Secretary, Dr. Wm. Elmer, Jr., of Trenton. Recording Secretary, Dr. Wm. Pierson, Jr., of Orange. Treasurer, Dr. W. W. L. Phillips, of Trenton.

THE MISSISSIPPI VALLEY MEDICAL ASSOCIATION.—This organization, which was formerly called the Tri-State Medical Society, will hold its next regular meeting in Springfield, Illinois, in September next.

GOVERNMENT PRIZES FOR IMPORTANT DISCOVERIES IN MEDICINE.—Our Washington correspondent in the present number of the JOURNAL, gives a petition recently presented to Congress, asking the National Government to offer a prize of $100,000 for the discovery of the efficient cause of yellow fever, or of a reliable mode of preventing its epidemic prevalence. The evident object of the petitioners is to excite the most active and persistent investigation concerning the etiology and mode of propagation of yellow fever, by holding out the certainty of an ample reward to the investigator who shall actually succeed in identifying its efficient cause or in reliably controlling its propagation and diffusion. The object is a very important one, and we may concede it to be a proper function of government to appropriate money for its promotion. But is the offering of a large prize the most appropriate and efficient method for the Government of a great Nation to adopt, for the promotion of scientific investigations, and especially for the promotion of an investigation so extensive and complicated, and withal so intimately related to the sanitary and commercial interests of the whole people, as that for the identification of the cause or causes of yellow fever? The only valid excuse for asking government aid, is the fact, that the time and means required for prosecuting the investigation proposed to a thoroughly reliable and successful issue, are beyond the reach of the individuals most competent to execute the work. Yet the offer of a prize of $100,000 to be paid only after the investigation has been successfully completed, and then solely to the one fortunate competitor, furnishes no one with either food, clothes, or materials while prosecuting the important work, perhaps at the risk of his own life. It seems to us more consonant with the dignity and honor of the Government, as well as far more likely to accomplish the object desired, to appropriate a sufficient sum of money, whether it be $50,000 or $500,000, and charge the National Board of Health or some competent commission with the duty of employing a sufficient number of the most competent and reliable investigators to man every department of such an inquiry, and prosecute it at every available point, until the results obtained were clearly demonstrated facts. Such a course would permit the necessary combinations of labor and skill, and the prosecution of parallel lines of work in different places, and secure to each scientific workman a just compensation at the time he would most need it.

SOCIETY PROCEEDINGS.

THIRTY-FOURTH ANNUAL MEETING OF THE ILLINOIS STATE MEDICAL SOCIETY.

[CONTINUED FROM No. 24.]

WEDNESDAY, MAY 21, 1884—SECOND DAY.

Dr. Christian Fenger, of Chicago, read a paper on Excision of the Hip and Knee Joints, with special reference to the final results of successful operations, these results being illustrated by the exhibition of patients treated by Dr. Fenger.

Dr. M. F. Bassett, of Quincy, read a paper on Vaccination, taking the ground that humanized virus, as shown by a long experience, was preferable to bovine virus, and produced results more satisfactory. So far as he was concerned, he was determined that his patients who repudiated humanized virus should take the risk of death by small-pox rather than receive bovine vaccination at his hands. The paper led to a debate. Dr. Lyman said there was one thing not noted in the paper, and that was that the humanized virus produced results in five days, and the bovine in from seven to ten days. Dr. Ingals said it was more important to prevent disease than to cure it. He had used in the main humanized virus, but of late years had used bovine virus. One was just as good as the other if it was good virus and judiciously applied. He had never perceived any great difference of results in the use of both kinds. Dr. E. P. Cook indorsed Dr. Ingals' remarks, and took exceptions to Dr. Bassett's paper. Dr. A. B. Strong, of Chicago, said in a wide experience in vaccination he had found that bovine virus had taken more violently and produced more fever than human virus. Dr. Cochran, of Greenfield, was opposed to the vaccination of infants with humanized virus, on account of the danger of syphilitic poison. Dr. Johnson, of Chicago, said he had studied the effects of 40,000 vaccinations with humanized virus in this city after the great fire, and there was not a single case in which any syphilitic or constitutional disease had resulted. He had the statis-

tics of these cases, and also of the work done by the State Board of Health in vaccinating with bovine virus thousands of emigrants arriving here on their way west. Vaccination was a fine art, and if practiced with sufficient care was always beneficial. Dr. Gill, of Cleveland, Dr. S. J. Jones, and Dr. Andrews, of Chicago, took part in the close of the discussion, which resulted in the decision that the condition of the patient and the manner of applying the virus caused various results, but that either bovine or humanized virus was efficacious, and would continue to be used by physicians according to their preference.

A recess of ten minutes was taken, to give the delegates time to select a member from each county for the Nominating Committee, and after their report was received, an adjournment was taken until 2 o'clock.

THE AFTERNOON SESSION.

At the opening of the afternoon session Dr. H. A. Johnson, of Chicago, read an interesting and technical paper on the "Bilateral Paralysis of the Abductors of the Vocal Chords." He said the difficulty was one solely of inspiration. Patients have been known to die suddenly. One of the spmptoms of the disease was difficult breathing. In every case there was greater difficulty in inspiration than expiration. To illustrate his subject the doctor exhibited a patient, who had been subjected to the operation of tracheotomy by Dr. Edmund Andrews on May 8, 1881, and who now breathes freely through a tube with a ball slot inserted in his neck, which he will be compelled to wear all his lifetime.

Dr. Graham, of Chicago, produced a girl 13 years of age upon whom the operation of tracheotomy had been performed by himself and Dr. A. B. Strong, with advice from Dr. Skeer. The operation was made four weeks ago. In this case the patient was afflicted with goitre, which was being reduced by daily applications of iodine and galvanic treatment. An incision for a tube had been made above the thyroid, but a lower one had to be made before the patient was given relief. In this case the Durham and other ordinary fenestrated tubes could not be used, and a tube was invented for the purpose. The patient was now doing nicely, although at one time she was in a decidedly precarious condition.

The Committee of Arrangements announced the election by invitation of Dr. A. J. Stone, of St. Paul.

Dr. J. P. Matthews read a paper on the diseases of children. The higher mortality among children over adults might be accounted for, first, on the principle of the survival of the fittest, and, after this, by injudicious clothing, bad diet, and impure air. These gave rise to the diseases that wrought the greatest havoc among children. Scarlatina was in this category. It was generally imported, although the germs might have had their origin in certain undiscovered meteoric conditions. The doctor detailed a number of cases illustrating the insiduous character of the contagion and the ease with which it spread. He had found an efficacious treatment to be sponging with vinegar, the application of tincture of aconite and of carbolized vaseline to ulcers. Diphtheria arose from the same sources, practically, as scarlatina, as did also membraneous croup. For these cases he had used, with the greatest success, a steam bath, holding the patient where it would inhale the steam and fumes from the slacking of quick lime. In cases of diarrhœa and other infantile complaints the milk and food supply was to be considered; the mother's mode of life, and her ignorance and carelessness of the first principles of the proper care of her children, were not only the causes of much disease among infants, but it prevented successful treatment. Children were also given too much tea and coffee. It led to tobacco and whiskey and other stimulants in later life. A cup of strong tea or coffee at night often prevented a strong man from sleeping by acting directly on his brain, and what must be the effect of such powerful stimulants and astringents upon the delicate and sensitive nerve-tissues of a child? In the vast majority of the diseases of children, and especially in epidemics, the disease arose from the breeding of germs.

Dr. K. E. Rich, of Winona, and Dr. Whitmire, of Metamora, accepted the germ theory, and the latter had used the steam and a chloride of lime bath with beneficial results in several cases. Dr. Hamill, of Chicago, said he had used with great success a preparation of chlorate potash and guaiacum. He was in the habit of treating diphtheria by this method.

Dr. Whitmire explained, in response to a question, that he had applied the chloride of lime and steam treatment by the spray method.

Dr. Davis, of Chicago, said that inasmuch as the germ idea seemed to be a favorite one, he would like to ask what effect large doses of bi-chloride of mercury had had in cases of diphtheria. Since everything was running to germs, and this was the greatest germicide known, he would like to know the effect of its use by members of the Society.

Dr. E. P. Cook, of Mendota, a former President of the Association, acknowledged that he had had a limited experience in the use of bi-chloride of mercury. His experience of its use was that in follicular pharyngitis the patients all got well, but in malignant diphtheria they died. In the latter form of the disease, seven out of a group of eight of his patients had died after treatment with bi-chloride of mercury.

Dr. Wetmore, of Waterloo, read a paper on Physiology. The speaker illustrated his theme with a number of charts.

Dr. J. F. Todd, of Chicago, read a paper on "Original Investigation," pertaining in its subject-matter more particularly to the etiology of disease.

THIRD DAY.

The third day's session of the Illinois State Medical Society opened in the First Methodist Church at 9:45 o'clock Thursday morning. In the absence of the President, Dr. Andrews, Dr. David S. Booth occupied the chair. The Committee on Medical Legislation for the Insane, consisting of Drs. Walter Hay, E. P. Cook, and William Hill, reported progress, and was continued for the purpose of presenting certain suggestions to the legislature at the next meeting of that body.

Dr. A. B. Strong, of Chicago, called the attention

of the society to the deficiency in the wording in the law of this State providing anatomical subjects for dissection, and asked every physician to aid in the enactment of a law that would be *mandatory* and thus enable the profession to secure subjects for dissection without the usual circumlocution they had been compelled to resort to during the past year. There had been more difficulty experienced in getting cadavers for dissection since last winter than ever before. Dr. Cook said that although he was not locally interested in the pursuit of medical studies, yet he would heartily indorse any effort to secure needed legislation that would enable the Faculty of the medical colleges to secure the bodies of paupers after all due diligence had been used to find the friends of the unfortunates. He advised that attorneys be employed for that end, for the reason that it would be undignified for the members of the profession to enter ward politics for any such purpose. Dr. M. F. Bassett thought that cities of 100,000 inhabitants and over, should not be favored in the law governing the disposition of the pauper dead any more than cities of lesser population, which may contain medical schools. Dr. H. A. Johnson, of Chicago, said the present law was imperfect, but it was the best that could be secured at the time of its passage. It required amendments and additions to the end that medical science may progress and the graves of the dead be saved from desecration. Two arguments should be used in urging the passage of a new bill; first, the demands of humanity in the education of men in medical schools, and second, the pauper class only should be drawn from to secure subjects, and to achieve that result, public sentiment, through the press, should urge legislators to the proper action.

Dr. R. Boal, of Peoria, suggested that the members of the Legislature should attend to the bills on dissection and on the commitment of the insane early in the session. Dr. Walter Hay advised the delegates to have patience until the Legislature should meet again, when new bills might be presented, and in the meantime, the members of the Legislature could be seen by the physicians and copies of the laws proposed furnished and their adoption urged. Dr. A. H. Burr wanted to have the proposed amendments read, but on motion of Dr. Cook, the discussion was closed.

Dr. E. Ingals, Chairman of the Nominating Committee, reported the following list of officers and standing and special committees for the ensuing year, and the Society adopted the report: President, Daniel S. Booth, Sparta; First Vice-President, S. C. Plummer, Rock Island; Second Vice-President, W. T. Kirk, Atlanta; Treasurer, Walter Hay, Chicago; Secretary, S. J. Jones, Chicago; Assistant Secretary, H. B. Buck, Springfield. Members of Judicial Council, S. K. Crawford, Monmouth; George Wheeler Jones, Danville; John Wright, Clinton. Committee of Arrangements, Drs. Griffith, Matthews, Rauch, Whitney, and Buck, all of Springfield. The standing committees are as follows: Committee on Practice, Norman Bridge, Chicago; C. H. Norred, Lincoln; J. R. Livingood, Rossville. Surgery, W. A. Byrd, Quincy; D. A. K. Steele, Chicago; Cass Chenowith, Decatur. Obstetrics, Charles W. Earle, Chicago; T. D. Washburn, Hillsboro; Mrs. Anna S. Adams, Peoria. Gynæcology, David Prince, Jacksonville; Sarah Hackett Stevenson, Chicago; O. B. Mill, Peoria. Materia Medica and Therapeutics, Thomas M. McIlvaine, Peoria; J. F. Todd. Chicago; Miss Catharine Miller, Lincoln. Ophthalmology and Otology, W. T. Montgomery, Chicago; C. R. Park, Bloomington; Robert Tilley, Chicago. Necrology, E. Ingals, Chicago; William Hill, Bloomington; M. F. Bassett, Quincy. Special Committees: Laryngology, E. F. Ingalls, Chicago. Oral Surgery, J. S. Marshall, Chicago. Pediatrics, Mrs. Dr. A. F. Rooney, Quincy. Dermatology, Dr. W. J. Maynard, Chicago. Orthopædic Surgery, Dr. C. E. Webster, Chicago. Tetanus, C. Truesdale, Rock Island. Insanity, R. J. Patterson, Batavia. Alcohol as a Therapeutic Agent, M. F. Bassett, Quincy. Effects of Malaria in Puerperal Cases, H. Judd, Galesburg. Physiology, A. Wetmore, Waterloo. Treatment of Epilepsy, D. R. Brower, Chicago. Analysis of a Certain Class of Remedies of which Physicians are Not Positive as to Their Therapeutic Value, W. L. Ransom, Rockford. Biographical Committees: J. H. Hollister, Chairman; on the Influence of Appreciable Meteorological and Topographical Conditions on the Prevalence of Acute Diseases, N. S. Davis, J. H. Hollister, J. F. Todd, of Chicago. Medical Legislation, B. M. Griffith of Springfield, Walter Hay of Chicago, A. B. Strong of Chicago, J. L. White of Bloomington, T. B. Haller of Vandalia, W. A. Haskell of Alton, E. P. Cook of Mendota. The Committee on Original Investigation is to be continued. The Committee on Malignant Growths, Dr. C. Fenger, Chairman, was continued for another year.

FURTHER REPORTS.

Dr. Ransom, of Rockford, read a report on certain therapeutical remedies, with which he said physicians were not wholly acquainted. He called attention particularly to the "spurge," or euphorbia corollata, commonly called the blooming spurge, wandering milkweed, go quick, etc. The resinous principles of euphorbia were emetic, diuretic, and diaphoretic in their action. It was but little used except by the eclectics, and was given in one-tenth and one-thirtieth grain doses, and even in one and two-grain doses sometimes. It might be given in all cases of dropsy, and especially in hydrothorax, and it was said to excel ipecacuanha as an expectorant for the latter affection. Tincture of euphorbia was used as an antidote for rattlesnake-bites, and the stings of tarantulas and other poisonous insects. His conclusions were that it could be applied most efficaciously in infusions, in cases of dropsy, where there are functional cardiac disorders, also in the treatment of ovarian cysts. He advised the use of the remedy in the dropsy of Bright's Disease, to remove the anasarca.

Dr. C. Fenger, of Chicago, read a paper on The Treatment of Acute Gangrene of the Lung. Four cases are now on record as having been operated upon. Two of the patients died, and one recovered

after a long convalescence. The fourth and last case was operated upon by Dr. Fenger in this city four weeks ago, at the end of the second week of the disease, which was the result of croupous pneumonia. The patient is now almost well. The doctor held that an operation is always justifiable, and if done early and with care would effect a cure in most cases.

The Standing Committee on Obstetrics was next heard, through Dr. H. K. Crawford, of Monmouth, who presented a report on Postpartum Hæmorrhage, of which he gave merely a condensed statement. There were embodied in the report 2,110 cases for the past twenty-five years. A few of the anomalies and deformities were mentioned of children at birth which closed the report.

Dr. R. H. Babcock reported a case of dexeocardia, in a child 3 years of age, which is not congenital. The liver is normalty located, also the spleen; the heart had rotated to the right side. The doctor had seen a similar case in a man 32 years of age, six months ago.

THE AFTERNOON SESSION.

At the opening of the afternoon session the Secretary read a congratulatory telegram from the Missouri State Medical Society, in session at Sedalia, and was instructed to send a suitable reply. Dr. E. A. Ingersoll, of the Committee on Obstetrics, reported a case of caput succedaneum of a female child, weighing ten and one-half pounds at birth. The report was voted to be received and published. Dr. Vanhorn, of Jeffersonville, reported a paper prepared by Dr. Duhadway, of the same place, on Postpartum Hæmorrhage, which was received and ordered published. The reading of the remaining papers was limited to five minutes each. Dr. Caldwell, of Freeport, read a report on gynæcology, being a paper on Ulceration of the Cervix Uteri, which was referred to the Committee on Publication. Dr. A. F. Rooney, of Quincy, submitted a paper on Menorrhagia, giving interesting details of the effect of female troubles in producing melancholia and insanity. It was referred to the Committee on Publication. Dr. R. Tilley, of Chicago, of the Committee on Ophthalmology, read a paper on the "Jequirity Bean," a solution of which, applied to the conjunctiva of the eye, is efficacious in the treatment of pannus and dry conjunctivitis, but should not be used in the case of very young people. The paper by Dr. I. N. Danforth, of the Committee on Simple Renal Catarrh, not being ready, he was continued on the committee for another year. Dr. B. F. Crummer, of Warren, presented a paper on Drugs and Medicines, in which he led the idea that patients and physicians would be better if the latter would compound their own prescriptions. The Treasurer, Dr. Walter Hay, reported receipts for the year of $1,742, expenditures of $601, and a balance on hand of $1,141. The report was accepted.

It was decided to read abstracts of the voluntary papers, so that under the by-laws they might be incorporated in the proceedings. The first was by Dr. F. C. Hotz, on Myopia Usually Developed During School Life. The doctor thought that there had been a great improvement in the typographical construction of school-books of late, and that the greatest danger was to be apprehended from miscellaneous literature printed in small and imperfect type. Dr. J. S. Whitmire, of Metamora, read a paper on the Suppression of Catamenia. He did not favor hip baths and catharsis, but avoidance of drugs and plenty of outdoor exercise for young people. Dr. C. E. Webster, of Chicago, read a paper on Potts' Disease of the Spine, and being a sufferer from the disease himself, his paper had additional interest. Dr. C. W. Earle, of Chicago, read a paper on Pancreatic Anæmia, giving the particulars of four cases treated by him. Dr. Robert Tilley exhibited an improved ether inhaler. A paper on Mastoid Abscess was read by Dr. E. L. Holmes, of Chicago. Dr. H. Gradle presented a paper on Purulent Inflammation of the Middle Ear.

The election of delegates to the American Medical Association, which meets in April next in New Orleans, resulted in the selection of the following list: Drs. G. M. Chamberlin, Walter Hay, R. Tilley, Moses Gunn, J. H. Hollister, F. C. Shaefer, L. H. Montgomery, J. F. Todd, N. S. Davis, W. W. Jaggard, Arthur R. Reynolds, S. H. Stevenson, D. W. Graham, N. S. Davis, Jr., L. L. McArthur, E. W. Andrews, W. T. Belfield, A. H. Burr, Simon Strausser, C. E. Webster, E. F. Ingals, H. A. Johnson, all of Chicago; and G. W. Jones, of Danville; P. H. Oyler, Mount Pulaski; H. Judd, Galesburg; M. F. Bassett, Quincy; S. K. Crawford, Monmouth; S. H. Lambert, Assumption; A. K. Vanhorn, Jerseyville; T. D. Washburn, Hillsboro; W. R. Caruthers, Delevan; O. B. Mill, Peoria; J. B. Matthews, Carlinville; Dr. Haller, Vandalia; E. P. Cook, Mendota; M. Reece, Abingdon; O. W. Moon, Lockport; C. C. Hunt, Dixon; C. L. Armstrong, Carrollton; J. F. Keifer, Sterling; W. L. Ransom, Rockford; H. B. Buck, Springfield; T. F. Worrell, Bloomington; B. M. Griffith, Springfield. Delegates to adjacent State Societies: Dr. R. W. Gillette, Danville, to Indiana; Dr. W. Mendenhall and Dr. B. H. Harris, of Groveland, to Missouri; Dr. L. H. Montgomery, of Chicago, to Ohio; Dr. E. Andrews, of Chicago, to Michigan; Dr. S. J. Jones, of Chicago, to Wisconsin; Dr. W. Hay, of Chicago, to Iowa.

Dr. Walter Hay offered a resolution, which was adopted, authorizing a prize of $100 for the best treatise on the treatment of diphtheria, and $100 for the best tabulated statement of any ten cases of any disease coming under the treatment of the practitioner, the same to be decided by a committee of three.

Dr. M. F. Bassett, of Quincy, offered resolutions returning thanks to the Chicago delegates for their hospitality.

The Society then adjourned, to meet in Springfield next year.

The Illinois State Board of Health is now engaged in revising the Register of Physicians, preparatory to publication. Any changes or corrections should be promptly sent to the secretary. Lists of the officers of the medical societies in the State are also requested.

BOOK REVIEWS.

ELEMENTS OF HUMAN PHYSIOLOGY. By HENRY POWER, M.B., F.R.C.S., Examiner in the Board of Anatomy and Physiology, Royal College of Surgeons, etc., etc. Philadelphia: 1884. Henry C. Lea's Son & Co.

The study of physiology, with all its fascinating details of experimental research, cannot be regarded as secondary, either in importance or interest, to the student of medicine. So extensive is its scope, and so inseparably is it bound to the kindred subjects of anatomy, physics and chemistry, that any attempt to separate it from them must inevitably lead to incompleteness and a certain degree of confusion, while it robs the subject greatly of its interest. To strip it only of the details of experimentation, leaves it bare enough; but when most of the considerations of physics, anatomy and chemistry are banished, there is left little besides the naked mathematics of physiology.

The volume in hand is one of the manuals for students of medicine. A small manual of a vast subject must necessarily be unsatisfactory in many regards, and so we find it in this instance; for, as we are apprised in the preface, the simultaneous appearance of four complementary volumes has caused the omission of many subjects usually included in the text-books of physiology.

The character of the work done is excellent, but there is too much left undone to make this book a very great aid to the average American student, at least, who would scarcely find it a valuable adjuvant in preparing for his examinations, provided he had in his library a copy of Foster, Dalton or Carpenter.

T. C. H.

FOREIGN CORRESPONDENCE.

PARIS, May 21, 1884.

It was only about a month ago that Professor Wurtz delivered a most touching funeral oration over the tomb of his late master and friend Professor J. B. Dumas, the illustrious chemist and Perpetual Secretary to the Academy of Sciences, who died at Cannes on the 10th of April, but was interred in Paris.

Professor Wurtz has since been called away, and his death, which took place on the 12th instant, was as sudden as it was unexpected, and caused great consternation among all who knew him. He had been laboring under a diabetic affection, but nothing in his physical bearing or intellectual faculties betrayed any falling off, much less any thing that would portend so near a fatal end.

Dr. Adolphe Wurtz was a native of Strasburg, where he was born on the 26th of Nov., 1817. He went through his medical studies, and graduated at the Faculty of that city in 1843, when he sustained with great credit, his thesis on albumen and fibrine. Two years later he came to Paris, where his brilliant qualities soon became known, and he was appointed Chief of the Chemical Laboratory of the Faculty of this City and Assistant to M. Dumas, whom he eventually succeeded as Professor of Organic Chemistry at the School of Fine Arts. In 1847 he became Agrégé of the Faculty of Medicine, and was subsequently promoted to Professor of Chemistry. In 1866 he was unanimously chosen to the Deanship of the Faculty, which became vacant by the resignation of Professor Tardieu. During his Deanship he effected great reforms in the School of Medicine and was much beloved by both professors and students. In 1875 he resigned, owing to the multiplicity of his functions, but the Faculty conferred on him the title of Honorary Dean. In 1856 he succeeded the celebrated Magendie at the Academy of Medicine in the Section of Physics and Chemistry, and in 1867 was elected member of the Academy of Sciences. He was the author of several remarkable memoirs, bearing principally on Organic Chemistry, and he held a sort of transition position between the old and new schools. In 1850 he was created Chevalier of the Legion of Honour, and in 1869 was invested with the Grand Cross of the same Order for the valuable services he had rendered to science, and last year he was nominated Permanent Senator of the French Republic.

His funeral took place at the Père-Lachaise, in Paris, on Thursday last, with all the honours due to his rank as Senator and Academician. The Government, the School of Medicine, the Academies, and the various learned societies to which the deceased belonged, were represented by delegates, and several orations were pronounced over his grave.

At the death of Professor Lasègue, about a year ago, Professor Jaccoud was transferred to the chair of Clinical Medicine at La Pitié Hospital, and Professor Damaschino was appointed to succeed him in the chair of Medical Pathology at the Faculty of Medicine. In inaugurating his new chair and his summer course of lectures, he chose for his first lecture the History of the Circulation of the Blood, as a preliminary to his subsequent lectures on the Diseases of the Sanguineous and Lymphatic Vessels. In going back to the remotest periods of medical history, Professor Damaschino pointed out the vague notions entertained by the ancients in respect to the circulation of the blood, before the remarkable discovery of Harvey, which rendered his name immortal. In a few well-chosen phrases M. Damaschino gave an admirable exposition of the work done by the Alexandrian school for the advancement of medicine, the remarkable works of Galen, and rendered justice to the investigations so precise of Vesalius, the celebrated anatomist. He then referred in flattering terms to Sanctorius, the father of clinical thermometry; to Servetus, to Cesalpin, to Colombo, and finally to Harvey, the great discoverer of the circulation, whose theories and demonstrations were corroborated by the microscopic researches of Leuwenhœck. The latter made great advances toward the elucidation of cardiac pathology, which was gradually developed and perfected by Morgagni, Senac, Van Swieten, Avenbrugger, Corvisart, and Bouillaud. "A knowledge of pathology," added the Professor, "should

be obtained not only by clinical observation, but by the aid of every branch of all the sciences and instruments of precision applicable to medicine." It was thus that Marey rendered such signal service by his invention and practical application of the sphygmograph, which may be considered the crowning edifice of the discovery which has rendered the name of Laënnec immortal. Dr. Damaschino impressed upon his hearers the necessity of never flagging in their studies, and this advice applies as much to graduated practitioners as to medical students, as medicine is an ever-progressing science, and he who does not make himself acquainted with the new inventions or discoveries will find himself lamentably distanced by his more diligent confrères, as much to his own prejudice as that of his patients; and although a medical man should be eclectic, yet he should not sacrifice his personality to any particular doctrine or method simply because they are in fashion, but he must first put them to the crucial test of experimental and clinical observation before he adopt either.

Hitherto ophthalmia neonatorum has been a very common complaint among new-born infants in the lying-in institutions in Paris, but since the introduction of more sanitary measures this and other puerperal affections have been very much reduced. In addition to improved sanitation, the following course is adopted as a prophylactic measure against purulent ophthalmia: In changing the clothes of the infants morning and evening, a few drops of a 3 per cent. solution of boracic acid are instilled into the eye. This practice has been adopted at the "Clinique d'Accouchements," which has reduced the cases of ophthalmia from one in every six new-born infants to one in nineteen, according to a thesis lately submitted by Dr. Connen for the Doctorate of the Paris Faculty. ALEX. BOGGS.

DOMESTIC CORRESPONDENCE.

FROM WASHINGTON.

MEDICAL MATTERS BEFORE CONGRESS—YELLOW FEVER.

June 3, Mr. Brown presented the following petition, which was referred to the Committee on Epidemic Diseases:

To the Senate and House of Representatives of the United States:

The undersigned respectfully represent that the insecurity to the public health from the epidemic prevalence of yellow fever is chiefly due to a total ignorance of the real cause of the disease, together with the circumstances and laws governing its generation, reproduction, and spread; that the portability and reproductive nature of said cause suggest the idea of physical and perhaps physiological qualities that may lead to its ultimate identification by some means within the reach of science, or, if not to this, to a more intimate knowledge of its organic potencies by which its virulence as a poison may be reduced; therefore, with a view to stimulate inquiry in this direction, and thereby subserve the commercial interests of the country and the welfare of its citizens, your petitioners pray your honorable bodies to offer a premium of $100,000, open to the world, for the discovery of the true cause (or germ) of yellow fever, with (or in default thereof) any certain means of effecting its prevention, destruction, or material modification, the same to be subjected to such practical tests, under the direction of Congress, as will determine its real merits and efficiency.

In support of this petition we will present no array of statistics to show the frequency of the epidemic prevalence of the disease, the loss of life and suffering to the people, the disasters to commerce entailed by the suspension of intercourse with infected ports and even cities of the interior of our country, the bankruptcy of cities caused by its blighting presence, or even that it (yellow fever) is a perpetual menace to this country. All of this and much more is familiar to you and to the intelligent American public, who since the epidemics of 1876, 1878, and 1879, have favored controlling legislation on the subject. We do desire, however, to present and stress the fact, more potential than the most convincing statistics above alluded to, that the failure of sanitary bodies, as well as of all legislation (State and Federal), to give security to the public interests against this disease, which ranks floods and fire and all other sources of devastation in the certainty of its coming and in the powerlessness of the people before it, arises from a painful, helpless ignorance of its cause and the laws governing its origin and reproduction. Its fatality is but slightly affected or altered by medical treatment, the death-rate being determined rather by the degree of poisoning.

Science hitherto offers no practical defense against it, except in a quarantine, which to be reliable must be so perfect as to prevent evasion. This is so difficult of attainment that when a sporadic case occurs in one of our ports it is forthwith charged to an evasion of quarantine, and every effort made thus to explain its origin. When the disease extends to an interior city the difficulties in the way of a successful quarantine are greatly increased. We therefore pray a beneficent government to aid in dispelling this cloud of ignorance with the light of positive knowledge, if it be attainable, by stimulating observers, known and unknown the world over, with the hope of reward as well as of merited honor and distinction.

Positive knowledge upon all subjects pertaining to sanitary science, and on this one in particular, is the great desideratum. All measures of quarantine and internal hygiene, however judicious and forcible, are simply defensive in character and altogether indirect, and must of necessity remain so as long as directed against an unseen, intangible, and unknown entity protected by ignorance and clothed with mystery.

The discovery of only a single additional feature in the character or quality of this poison, or germ, or cause, of whatever nature or source, may reveal the secret of its prevention, destruction, or material modification, and thus place it in the power of sani-

tarians to disarm it as completely as vaccination does small-pox.

The aim of the present efficient quarantine, on which confidence mainly reposes, is to prevent its introduction; it may or may not confer practical immunity against the disease. Too much, however, should not be conceded to it, since the history of yellow fever shows that even when one far less efficient was in force, or virtually none at all, yellow fever has spared for years in succession the Gulf and Atlantic coasts. But, admitting all that its most sanguine advocates may claim for it, shall its enforcement be accepted as a perpetual duty and the limit of our resources; or, in imitation of the wise policy of other enlightened governments, shall we so legislate as to invite a knowledge of the *causa causans*, and thus possibly make precise for its destruction what is at present left solely to empirical observation? The problem is more pressing now than ever, because the railroad transportation of disease-germs has acquired equal dignity with their importation by ships, and thus the danger has been made co-equal with the railroad development of the Southern section.

The French and German cholera commissions now engaged in a philosophic and strictly scientific inquiry into the cause of Asiatic cholera, with a view to the arrest of this disease in its westward progress, may be referred to in this connection. One lesson is certainly taught by the example thus set to the world by France and Germany, namely, the folly of longer dependence upon empirical observation for protection against this subtile disease; the line of progress is the path of diligent research, fearlessly, faithfully made.

The British Parliament voted £30,000 to the immortal Jenner for the discovery of vaccination against the then greatest scourge to mankind. The prevention of small-pox by vaccination is indeed the greatest achievement of sanitary science known to the world; it was then seemingly as unattainable as the problem in hand may now appear. Who will dare say that a similar ultimate success may not attend the effort that you are solicited to further by a premium scarcely equal to the annual appropriation made for the maintenance of quarantine? The award is based upon the successful discovery of some certain means of preventing, destroying, or materially modifying the cause (known or unknown) of yellow fever. It is not offered for the successful treatment of yellow fever; that is a problem for the medical profession, who wish only to become the beneficiaries of whatever light, research promoted by your generous interest, may reveal. It is rather for the prevention of the disease, with all the beneficent results that are likely to follow to humanity and to commerce, that you are asked thus to legislate.

The amount specified is not large when the time, labor, and expense incident to such investigations are taken into consideration.

WM. H. DOUGHTY, M.D.

AUGUSTA, Ga., April 30, 1884.

GEORGIA MEDICAL SOCIETY, SAVANNAH, Ga., December 14, 1883.

Dear Sir: At a meeting of the Georgia Medical Society, held the evening of the 11th instant, the committee to whom was referred your papers and resolutions to memorialize Congress to appropriate a premium of $100,000 for the discovery of the cause of yellow fever, &c., reported for its indorsement, and the Society unanimously indorsed the same.

Very respectfully,

[SEAL.] JNO. M. JOHNSTON, M.D.,
Recording Secretary.

W. H. DOUGHTY, M.D., Augusta, Ga.

The above petition was read in meeting of the Board of Health of Augusta, Ga., and received its approval, and was ordered to be signed officially by the President and Secretary of said Board.

AUGUSTA, Ga., May 1, 1884.

[SEAL.] EUGENE FOSTER, M.D.,
President Board of Health, C. A.

Attest:

L. T. BLOME,
Secretary Board of Health, C. A.

This memorial was read before the Augusta Academy of Medicine, and received its unanimous indorsement. The President and Secretary were directed to append their official signatures.

AUGUSTA, Ga., May 9, 1884.

THEO. LAMB, M.D.,
President Augusta Academy Medicine.
WM. H. HARRISON, SR., M.D.,
Secretary Augusta Academy Medicine.

In consequence of the receipt of this petition, Mr. Brown introduced a bill, Senate 2281, which embodied its request.

ARMY MEDICAL DEPARTMENT BUILDING.

The Senate passed the following bill:

That the sum of $300,000 is hereby appropriated, out of any moneys in the Treasury not otherwise appropriated, for the purchase of a site and the erection in Washington of a brick and metal fire-proof building to be used for the safe-keeping of the records, library, and museum of the Surgeon-General's Office of the United States Army; and the building shall be constructed in accordance with plans and specifications provided by the Surgeon-General of the Army and approved by the Architect of the Capitol Extension; and the money hereby appropriated shall be expended under the direction and superintendence of the officer in charge of the State, War, and Navy Department building.

MEDICAL MATTERS BEFORE CONGRESS.

May 29, Mr. Riggs, of Illinois, reported from the Committee on Public Health a recommendation that the following resolution be referred to the Committee on Appropriations, which was so ordered:

Resolved, That the Committee on Appropriations of this House be, and they are hereby, instructed to include in the sundry civil appropriations for the year ending June 30, 1885, the following items:

"For the contingent epidemic fund to be at the disposal of the President and to be expended at his discretion, the sum of $200,000, including the unexpended balance of previous appropriations, amounting to $115,000.

"For the support of the National Board of Health the following sums:

"For pay and expenses of the members of the board, and for the investigation of questions affecting the public health, including the study of other diseases than small-pox, cholera, and yellow fever, $18,000.

"For rent, fuel, postage, telegraphing, printing, and all other miscellaneous expenses, $2,500.

"For disbursing agent, clerks, and messenger, $4,500; amounting in the aggregate to $25,000."

MISCELLANEOUS.

OFFICIAL NOTICE.

ANNUAL DUES from members of the Association—*Five Dollars* per annum—are payable directly to the Treasurer. Such payment entitles them to receive the JOURNAL of the Association for one year.

SUBSCRIPTIONS TO THE JOURNAL from those who are not members should be forwarded to the office of publication, Chicago.

BACK VOLUMES OF THE TRANSACTIONS may be procured, at reduced rates, by addressing the Treasurer.

THE INDEX to the 33 Volumes of Transactions will be forwarded, postpaid, on receipt of *One Dollar* by the Treasurer.

According to a resolution passed May 9, 1884, at the Washington meeting, continuous payment of Annual Dues is required, to retain permanent membership.

RICHARD J. DUNGLISON, M.D.,
Treasurer.

LIST OF CHANGES IN THE STATIONS OF MEDICAL OFFICERS, U. S. NAVY, FOR THE WEEK ENDING JUNE 14, 1884.

P. A Surgeon A. A. Austin, detached from U. S. S. "St. Louis," ordered to Naval Rendezvous, Philadelphia.

P. A. Surgeon T. M. Edgar, detached from U. S. S. "Wabash," ordered to U. S S. "Nantucket"

P A. Surgeon L. B. Baldwin, ordered to U. S. S. "Wabash."

Assistant-Surgeon H W. Whitaker, detached from Naval Rendezvous, Phila., ordered for examination preliminary to promotion.

Assistant-Surgeon F. A. Hesler, ordered to U. S. S. "Minnesota."

Assistant-Surgeon V. C. B. Means, ordered to U. S S "Vermont."

Medical Director T. M. Browne, to attend the International Health Exhibition at Liverpool, Eng., and Delegate to International Medical Congress at Copenhagen, per steamer of July 2.

Surgeon I. R Tryon, to same duty, with Medical Director Browne, and on completion of this duty, to report for duty on U. S. S. "Quinnebaug."

Surgeon J. Hugg, detached from "Quinnebaug" on reporting of relief, to return home and report arrival.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT UNITED STATES ARMY, FROM JUNE 7, 1884, TO JUNE 14, 1884.

Middleton, Passmore, Captain and Assistant-Surgeon, leave of absence extended three months on surgeon's certificate of disability. (Par. 3, S. O. 134, A. G. O., June 10, 1884.)

Bennett, Richards, Captain and Assistant-Surgeon, assigned to duty as post surgeon, Mount Vernon Barracks, Ala. (Par. 2, S. O. 113, Hdqrs. Department East, June 9, 1884.)

Gardner, Edwin F., Captain and Assistant-Surgeon, relieved from duty at Fort Walla Walla, Wash. Terr., and assigned to duty as post surgeon, Fort Canby, Wash. Terr. (Par. 1, S. O. 75 Hdqrs. Department of Columbia, June 3, 1884.)

Cunningham, T. A., Captain and Assistant-Surgeon, ordered to relieve Assistant-Surgeon C. B. Byrne, U. S. A., from duty at Fort Lewis, Col., Assistant-Surgeon Byrne, when so relieved, to proceed to Fort Gibson, I. T., and report to the post commander for duty. (Par. 2, S. O 112, Hdqrs. Department of Mo., June 4, 1884.)

Banister, J. M., Captain and Assistant Surgeon, granted leave of absence for one month and 7 days, to commence June 13. (S. O. 22, Hdqrs. Division of the Atlantic, June 5, 1884.)

McCreery, Geo First Lieut. and Assistant-Surgeon, granted leave of absence for two months, with permission to apply to the Adjutant-General of the Army for two months's extension. (Par. 3, S. O. 56, Hdqrs. Division of Missouri, June 5, 1884.)

The Army Medical Examining Board, New York City, is dissolved, to take effect June 14, 1884.

Brown, Jos. B., Lieut-Colonel and Surgeon, upon completion of the business of the A. M. B., directed to comply with S. O. 44, current series, A. G. O., and return to New York City.

Clements, Bennett A., Major and Surgeon, directed to await orders in New York City.

Kimball, James P., Captain and Assistant-Surgeon, granted leave of absence for two months and 14 days, to take effect June 14, 1884, and ordered to relieve, August 28, 1884, Captain Robt. H. White, Assistant-Surgeon, from duty at U. S. Military Academy, West Point, New York.

Captain White, on being relieved, to report in person to the commanding general Department of Cal. for assignment to duty

Sternberg, Geo. M., Major and Surgeon, relieved from temporary duty in S G. O., and ordered to assume the duties of attending Surgeon and examiner of recruits, at Baltimore, Md. (S. O. 121, A. G. O., June 6, 1884.)

Finley, J. A., Captain and Assistant-Surgeon, relieved from duty at Fort Stockton, Texas, and assigned to duty as post surgeon, Fort Concho, Texas. (Par. 4, S. O. 69. Hdqrs. Department of Texas, June 2, 1884.)

Chairman—Dr. J. M. Toner, Washington, D. C.

—THE—

Journal of the American Medical Association.

EDITED FOR THE ASSOCIATION BY N. S. DAVIS.

PUBLISHED WEEKLY.

VOL. II. CHICAGO, JUNE 28, 1884. No. 26.

AMERICAN MEDICAL ASSOCIATION.

PLAN OF ORGANIZATION FOR A NATIONAL MEDICAL ASSOCIATION.

Whereas, The Medical Convention, held in the city of New York, in May, 1846, have declared it expedient "for the medical profession of the United States to institute a National Medical Association;" and,

Inasmuch as an institution so conducted as to give frequent, united and emphatic expression to the views and aims of the medical profession in this country, must at all times have a beneficial influence, and supply more efficient means than have hitherto been available here for cultivating and advancing medical knowledge; for elevating the standard of medical education; for promoting the usefulness, honor and interests of the medical profession; for enlightening and directing public opinion in regard to the duties, responsibilities, and requirements of medical men; for exciting and encouraging emulation and concert of action in the profession, and for facilitating and fostering friendly intercourse between those who are engaged in it: therefore,

Be it resolved, In behalf of the medical profession of the United States, that the members of the Medical Convention held in Philadelphia in May 1847, and all others who, in pursuit of the objects above mentioned, are to unite with or succeed them, constitute a National Medical Association; and that for the organization and management of the same, they adopt the following *Regulations:*—

I.—TITLE OF THE ASSOCIATION.

This institution shall be known and distinguished by the name and title of "The American Medical Association."

II.—MEMBERS.

The members of this institution shall collectively represent and have cognizance of the common interests of the medical profession in every part of the United States; and shall hold their appointment to membership either as delegates from local institutions, as members by invitation, as permanent members, or members by application.

The *Delegates* shall receive their appointment from permanently organized State medical societies, and such county and district medical societies as are recognized by representation in their respective State societies, and from the medical department of the Army and Navy of the United States, and the Marine Hospital Service of the United States.

Each delegate shall hold his appointment for one year, and until another is appointed to succeed him, and shall participate in all the business and affairs of the Association.

Each State, county and district medical society, entitled to representation, shall have the privilege of sending to the Association one delegate for every ten of its regular resident members, and one for every additional fraction of more than half that number; *Provided*, however, that the number of delegates from any particular State, Territory, county, city, or town shall not exceed the ratio of one in ten of the resident physicians who may have signed the Code of Ethics of this Association. The Medical Staffs of the Army and Navy shall be entitled to four delegates each. The Marine Hospital Service of the United States shall be entitled to one delegate.

No individual who shall be under sentence of expulsion or suspension from any State or local medical society of which he may have been a member, or whose name shall have been, for non-payment of dues, dropped from the rolls of the same, shall be received as a delegate to this Association, or be allowed any of the privileges of a member, until he shall have been relieved from the said sentence or disability by such State or local society, or shall have paid up all arrears of membership; nor shall any person not a member and supporter of a local medical society, where such a one exists, be eligible to membership in the American Medical Association.

No one expelled from this Association shall at any time thereafter be received as a delegate or member, unless by a three-fourths vote of the members present at the meeting to which he is sent, or at which he is proposed.

Members by Invitation shall consist of practitioners of reputable standing from sections of the United States not otherwise represented at the meeting. They shall receive their appointment by invitation of the meeting, after an introduction from, and being vouched for by, at least three of the members present, or three of the absent permanent members. They shall hold their connection with the Association until the close of the annual session at which they are received; and shall be entitled to participate in all its affairs, as in the case of delegates, except the right to vote.

The *Permanent Members* shall consist of all those who have served in the capacity of delegates, and of such other members as may receive the appointment by unanimous vote, and shall continue such so long as they remain in good standing in the body

from which they were sent as delegates, and comply with the requirements of the By-laws of the Association. Permanent members shall at all times be entitled to attend the meetings, and participate in the affairs of the Association, so long as they shall continue to conform to its regulations, but without the right of voting; and, when not in attendance, they shall be authorized to grant letters of introduction to reputable practitioners of medicine residing in their vicinity, who may wish to participate in the business of the meeting, as provided for members by invitation.

Members by Application shall consist of such members of State or county societies, certified to be in good standing by the president and secretary of said societies, as shall make application for admission. They shall simply have the right to receive the JOURNAL on the same terms as other members.

Every member elect, prior to the permanent organization of the annual meeting, or before voting on any question after the meeting has been organized, must exhibit his credentials to the proper committee, and sign these regulations, inscribing his name and address in full, specifying in what capacity he attends, and, if a delegate, the title of the institution from which he has received his appointment.

III.—MEETINGS.

The regular meetings of the Association shall be held annually. The place of meeting shall be determined, with the time of meeting for each next successive year, by vote of the Association.

IV.—OFFICERS.

The officers of the Association shall be a President, four Vice-Presidents, one Permanent and one Assistant Secretary, a Treasurer, and Librarian. They shall be nominated by a special committee of one member from each State represented at the meeting, and shall be elected by vote on a general ticket.

Each officer, except the Permanent Secretary, shall hold his appointment for one year, and until another is elected to succeed him. The Permanent Secretary shall hold his appointment until removed by death, resignation, or a vote of two-thirds of the members present at a regular annual meeting.

The Presidents and Vice-Presidents shall assume the functions of their respective offices at the beginning of the annual meeting next succeeding their election; all other officers shall enter upon their duties immediately after their election.

The President shall preside at the meetings, preserve order and decorum in debate, give a casting vote when necessary, and perform all the other duties that custom and parliamentary usage may require.

The Vice-Presidents, when called upon, shall assist the President in the performance of his duties, and during the absence, or at the request of the President, one of them shall officiate in his place.

The Permanent Secretary shall record the minutes and authenticate the proceedings; give due notice of the time and place of each next ensuing annual meeting; notify all members of committees of their appointment, and of the duties assigned to them; hold correspondence with other permanently organized medical societies, both domestic and foreign; serve as a member of the Committee of Publication; and carefully preserve the archives and unpublished transactions of the Association.

The Assistant Secretary shall aid the Permanent Secretary in recording and authenticating the proceedings of the Association; serve as a member of the Committee of Arrangements, and perform all the duties of Permanent Secretary temporarily whenever that office shall be vacant, either by death, resignation, or removal.

The Treasurer shall have the immediate charge and management of the funds and property of the Association. He shall be a member of the Committee of Publication, to which committee he shall give bonds for the safe keeping and proper use and disposal of his trust. And through the same committee he shall present his accounts, duly authenticated, at every regular meeting.

The Librarian shall receive and preserve all the property in books, pamphlets, journals, and manuscripts presented to or acquired by the Association, record their titles in a book prepared for the purpose, acknowledge the receipt of the same, and he shall be a member of the Committee of Publication.

V.—STANDING COMMITTEES.

The following standing committees, each composed of seven members, shall be organized at every annual meeting, for preparing, arranging, and expediting business for each next ensuing year, and for carrying into effect the orders of the Association not otherwise assigned, namely, a Committee of Arrangements and a Committee of Publication.

The Committee of Arrangements shall, if no sufficient reasons prevent, be mainly composed of seven members, of whom the Assistant Secretary shall be one, residing in the place at which the Association is to hold its next annual meeting; and shall be required to provide suitable accommodations for the meeting, to verify and report upon the credentials of membership, to receive and announce all essays and memoirs voluntarily communicated, either by members of the Association, or by others through them, and to determine the order in which such papers are to be read and considered.

The Committee of Publication, of which the Secretaries, Treasurer, and Librarian must constitute a part, shall have charge of preparing for the press, and of publishing and distributing such of the proceedings, transactions, and memoirs of the Association as may be ordered to be published in such manner as the Association may direct. The six members of this Committee, who have not the immediate management of the funds, shall also, in their own names as agents for the Association, hold the bond of the Treasurer for the faithful execution of his office, and shall annually audit and authenticate his accounts, and present a statement of the same in the annual report of the Committee; which report shall specify the character and cost of the publications of the Association during the year, the number of copies still at the disposal of the meeting, the funds on hand

for further operations, and the probable amount of the assessment to be laid on each member of the Association for covering its annual expenditures.

VI.—FUNDS AND APPROPRIATIONS.

Funds shall be raised by the Association for meeting its current expenses and awards from year to year, but never with the view of creating a permanent income from investments. Funds may be obtained by an equal assessment of not more than ten dollars annually, on each of the delegates and permanent members; by voluntary contributions for specific objects; and by the sale and disposal of publications, or of works prepared for publication.

The funds may be appropriated for defraying the expenses of the annual meetings, including the necessary expenses of the Permanent Secretary in maintaining the necessary correspondence of the Association; for publication; for enabling the Standing Committees to fulfill their respective duties, conduct their correspondence, and procure the materials necessary for the completion of their stated annual reports; for the encouragement of scientific investigation by prizes and awards of merit; and for defraying the expenses incidental to specific investigations under the instruction of the Association, where such investigations have been accompanied with an order on the Treasurer to supply the funds necessary for carrying them into effect.

VII.—PROVISION FOR AMENDMENT.

No amendment or alteration shall be made in any of these articles, except at the annual meeting next subsequent to that at which such amendment or alteration may have been proposed; and then only by the voice of three-fourths of all the delegates in attendance.

Provided, however, that when an amendment is properly under consideration, and an amendment is offered thereto, germane to the subject, it shall be in order, and if adopted, shall have the same standing and force as if proposed at the preceding meeting of the Association.

And, in acknowledgment of having adopted the foregoing propositions, and of our willingness to abide by them, and use our endeavors to carry into effect the objects of this Association as above set forth, we have hereunto affixed our names.

NAMES OF MEMBERS.	RESIDENCE.	INSTITUTION REPRESENTED.

BY-LAWS.

I.—ORDER OF BUSINESS.

The order of business at the annual meetings of the American Medical Association shall at all times be subject to the vote of three-fourths of all the members in attendance; and, until permanently altered, except when for a time suspended, it shall be as follows, namely:

1st. The calling of the meeting to order by the President elected the preceding year, or, in his absence, by one of the Vice-Presidents.

2d. The report of the Committee of Arrangements on the credentials of members, after the latter have registered their names and addresses, and the titles of the institutions which they represent.

3d. The reception of members by invitation.

4th. The election of permanent members.

5th. The reading of notes from absentees.

6th. The hearing of the annual address of the President.

7th. The reception of the reports of all special committees and voluntary communications, and their reference to the appropriate Sections.

8th. The appointment of the committee of one from each State represented, to nominate officers of the Association, and to fill the standing committees.

9th. The reading and consideration of the reports of the Standing Committees, of Publication, on Prize Essays, and of Chairmen of Sections.

10th. Resolutions introducing new business, and instructions to the permanent committees.

11th. The selection of the next place of meeting.

12th. The report of the Nominating Committee, and the election of officers of the Association.

13th. Reports from the several Sections.

14th. Reading of the minutes by the Secretary.

15th. Unfinished and miscellaneous business.

16th. Adjournment.

II.—SECTIONS.

The general meetings of the Association shall be restricted to the morning sessions; and the afternoon sessions, commencing at three o'clock, shall be devoted to the hearing of reports and papers and their consideration, in the following *Sections*:—

1. Practical Medicine, Materia Medica, and Physiology.
2. Obstetrics and Diseases of Women.
3. Surgery and Anatomy.
4. State Medicine.
5. Ophthalmology, Otology, and Laryngology.
6. Diseases of Children.
7. Dental and Oral Surgery.

The chairman and secretary of the several Sections shall, like other officers of the Association, be nominated by the special committe of one member from each State represented at the meeting, and elected by a vote on a general ticket. They shall hold their office until the close of the proper business of the annual meeting next succeeding their election, and until their successors are appointed.

The Section on State Medicine shall be composed of one member from each State, one from the army and one from the navy of the United States, representing, as far as practicable, the State Boards of Health. The officers of this Section to be also designated by the Committee on Nominations.

The chairmen of the several Sections shall prepare and read in the general sessions of the Association, papers on the advances and discoveries of the past year in the branches of science included in their respective Sections; the reading of such papers not to occupy longer than forty minutes for each.

It shall be the duty of every member of the Association who proposes to present a paper or report to any one of the Sections, to forward either the paper, or a *title* indicative of its contents, and its *length*, to the Chairman of the Committee of Arrangements at least one month before the annual meeting at which the paper or report is to be read. It shall also be the duty of the Chairman and Secretary of each Section to communicate the same information to the Chairman of the Committee of Arrangements concerning such papers and reports as may come into their possession or knowledge, for their respective Sections, the same length of time before the annual meeting. And the Committee of Arrangements shall determine the order of reading or presentation of all such papers, and announce the same in the form of a programme for the use of all members attending the annual meeting. Such programme shall also contain the rules specified in the By-laws and Ordinances concerning the consideration and disposal of all papers in the Sections.

No paper shall be read before either of the Sections, the reading of which occupies more than twenty minutes. Such papers shall be referred by the Section to sub-committees especially appointed for their examination. The sub-committees shall be allowed thirty days for such examination; at the end of which time they shall forward the papers to the Committee of Publication, with such recommendation as they may deem proper. The author of such papers, however, may read abstracts before the Section within the allotted twenty minutes. No member shall address the Section more than once upon the same subject, nor speak longer than fifteen minutes without unanimous consent.

All papers presented directly to the Association, and other matters, may, at the discretion of the Association, be referred to the various Sections for their consideration and report.

Prize Essays.—There shall be four annual prizes of two hundred and fifty dollars each, which shall be awarded at the close of the second year after announcement, as hereinafter explained, for strictly original contributions to medical and surgical progress.

It shall be the duty of the chairman of each of the following four Sections: 1. Practical Medicine, Materia Medica, and Physiology; 2. Obstetrics and Diseases of Women; 3. Surgery and Anatomy; 4. State Medicine, to appoint annually before the adjournment of the meeting of the Association three members of ability and good judgment, who shall constitute a Committee of Selection, and who shall, within thirty days thereafter, select and publicly announce for competitive investigation and report, a subject belonging to one or other of the branches of medicine included in the title of the Section.

It shall also be the duty of the chairman of each of the Sections mentioned to appoint annually a Committee of Award, consisting of three experts, who shall carefully examine the essays offered for competition, and, if any one shall be found worthy of the prize as a substantial contribution to medical knowledge, to recommend the same to the Association.

All essays placed by their authors for competition shall be in the hands of the chairmen of the respective Committees of award on or before the first day of January preceding the meeting of the Association at which the reports of the committees are required to be made.

All Prize Essays shall be considered as the property of the Association.

The names of the authors of the competing essays shall be kept secret from the committees by such means as the latter may provide.

Membership in either of the two committees shall not debar from membership in the other; nor shall membership in the Committee of Selection exclude a member from the privilege of offering a competing essay.

III.—STANDING COMMITTEES.

The following are the Standing Committees of the Association, to be filled by the Committee on Nominations, and to report at the next annual meeting subsequent to their appointment, namely, Committee of Arrangements, Committee of Publication, and Committee on American Medical Necrology.

The *Committee of Publication* shall append to each volume of the *Transactions* hereafter published, a copy of the Constitution, By-laws and Code of Ethics of the Association. It shall print conspicuously, at the beginning of each volume of the *Transactions* the following disclaimer, namely, The American Medical Association, although formally accepting and publishing the reports of the various standing committees, holds itself wholly irresponsible for the opinions, theories or criticisms therein contained, except when otherwise decided by special resolution.

The *Committee on American Medical Necrology* shall consist of one member for each State and Territory represented in the Association, whose duty it shall be to procure memorials of the eminent and worthy dead among the distinguished physicians of their respective States and Territories, and transmit them to the chairman of this committee on or before the 1st of April of each and every year.

IV.—THE PUBLICATION OF PAPERS AND REPORTS.

No report or other paper shall be entitled to publication in the volume for the year in which it shall be presented to the Association, unless it be placed in the hands of the Committee of Publication on or before the first day of July. It must also be so prepared as to require no material alteration or addition at the hands of its author.

Authors of papers are required to return their proofs within two weeks after their reception; otherwise they will be passed over and omitted from the volume.

Every paper received by this Association and ordered to be published, and all plates or other means of illustration, shall be considered the exclusive property of the Association, and shall be published and sold for the exclusive benefit of the Association.

The Committee of Publication shall have full discretionary power to omit from the published *Transactions*, in part or in whole, any paper that may be referred to it by the Association, or either of the

Sections, unless specially instructed to the contrary by vote of the Association.

V.—ASSESSMENTS.

The sum of five dollars shall be assessed, annually, upon each delegate to the sessions of the Association, as well as upon each of its permanent members, whether attending or not, for the purpose of raising a fund to defray necessary expenses. The payment of this sum shall be required of the delegates and members in attendance upon the sessions of the Association previously to their taking their seats and participating in the business of the sessions. Permanent members, not in attendance, shall transmit their dues to the Treasurer.

Any permanent member who shall fail to pay his annual dues for three successive years, unless absent from the country, shall be dropped from the roll of permanent members, after having been notified by the Secretary of the forfeiture of his membership.

VI.—DELEGATES FROM THE MEDICAL STAFFS OF THE ARMY AND NAVY.

Delegates representing the medical staffs of the United States Army and Navy, shall be appointed by the Chiefs of the Army and Navy Medical Bureaus. The number of delegates so appointed shall be four from the army medical officers, and an equal number from the navy medical officers.

VII.—DELEGATES TO FOREIGN MEDICAL SOCIETIES.

The President shall be authorized annually to appoint delegates to represent this Association at the meetings of the British Medical Association, the American Medical Society at Paris, and such other scientific bodies in Europe or other foreign countries as may be affiliated with us.

VIII.—DUTIES OF MEMBERS.

No one shall be permitted to address the Association, except he shall have first given his name and residence, which shall be distinctly announced from the chair, and the member may be required to go forward and speak from the stand, but not more than ten minutes at one time.

No one appointed on a special committee, who fails to report at the meeting next succeeding the one at which he is appointed, shall be continued on such committee, or appointed on any other, unless a satisfactory excuse is offered.

IX.—CONDITION EXCLUDING REPRESENTATION.

No State or Local Medical Society, or other organized institution, shall be entitled to representation in this Association that has not adopted its Code of Ethics; or that has intentionally violated or disregarded any article or clause of the same.

X.—OF THE PREVIOUS QUESTION.

When the previous question is demanded, it shall take at least twenty members to second it; and when the main question is put under force of the previous question and negatived, the question shall remain under consideration the same as if the previous question had not been enforced.

XI.—JUDICIAL COUNCIL.

A council, consisting of twenty-one members, shall be appointed by the Nominating Committee, whose duty it shall be to take cognizance of, and decide, all questions of an ethical or judicial character that may arise in connection with the Association. Of the twenty-one members of the council first appointed the seven first named on the list shall hold office one year, and the second seven named shall hold office two years.

With these exceptions the term of office of members of the council shall be three years, seven being appointed by the Nominating Committee annually.

The said council shall organize by choosing a President and Secretary, and shall keep a permanent record of its proceedings. The decisions of said council on all matters referred to it by the Association shall be final, and shall be reported to the Association at the earliest practical moment.

All questions of a personal character, including complaints and protests, and all questions on credentials, shall be referred at once, after the report of the Committee of Arrangements or other presentation, to the *Judicial Council*, and without discussion.

XII.—NEW BUSINESS.

No new business, resolutions by members, etc., shall be introduced at the general session of the Association except on the first and fourth days of meetings.

XIII.—OFFICERS AND COMMITTEES.

In the election of officers and appointment of committees by this Association and its President, they shall be confined to members and delegates present at the meeting, except in the Committee of Arrangements.

ORDINANCES.

Resolved, That the several Sections of this Association be requested, in the future, to refer no papers or reports to the Committee of Publication, except such as can be fairly classed under one of the three following heads, namely: 1. Such as may contain and establish *positively* new facts, modes of practice, or principles of real value. 2. Such as may contain the results of well-devised original experimental researches. 3. Such as present so complete a review of the facts on any particular subject as to enable the writer to deduce therefrom legitimate conclusions of importance.

Resolved, That the several sections be requested, in the future, to refer all such papers as may be presented to them for examination by this Association, that contain matter of more or less value, and yet cannot be fairly ranked under either of the heads mentioned in the foregoing resolution, back to their authors with the recommendation that they be published in such regular medical periodicals as said authors may select, with the privilege of placing at the head of such papers, "Read to the Section of the American Medical Association on the day of 18 ." (Vide *Transactions*, vol. xvi. p. 40.)

Resolved, That, instead of yearly reprinting the

list of members of the American Medical Association, the Committee of Publication be instructed to prepare and print in the *Transactions* an alphabetical catalogue triennially, containing a complete list of the Permanent Members, with their names in full, designating their residences, the year of their admission, the offices they may have held in the Association, and, in case of death or rejection, the date thereof. (Vide *Transactions*, vol. xvii. p. 33.)

Resolved, That no report or other paper shall be presented to this Association unless it be so prepared that it can be put at once into the hands of the Permanent Secretary, to be transmitted to the Committee of Publication. (Vide *Transactions*, vol. xvii. p. 27.)

Resolved, That the Permanent Secretary hereafter and from this date be authorized to draw a warrant upon the Treasurer for the expenses incurred in his attendance upon each session of the Association, and that the Treasurer is hereby instructed to pay the same. (Vide *Transactions*, vol. xviii. p. 42.)

Resolved, That the faculties of the several medical colleges of the United States be recommended to announce explicitly in their annual announcements, circulars and advertisements that they will not receive certificates of time of study from irregular practitioners, and that they will not confer the degree upon any one who may acknowledge his intention to practice in accordance with any exclusive system. (Vide *Transactions*, vol. xix. p. 31.)

Resolved, That those gentlemen who desire to report on special subjects, and will pledge themselves to report at the next meeting, be requested to send their names, and the subjects on which they desire to report, to the Permanent Secretary. (Vide *Transactions*, vol. xix. p. 42.)

Resolved, That hereafter the necessary expenses for rent of hall for general meetings and rooms for sections to accommodate the annual meetings, and the necessary expenses for cards of membership, be paid out of the treasury of the Association. (Vide *Transactions*, vol. xix. p. 42.)

Resolved, That each State Medical Society be requested to prepare an annual register of all the regular practitioners of medicine in their respective States, giving the names of the college in which they may have graduated, and date of diploma or license. (Vide *Transactions*, vol. xx. p. 20.)

Resolved, That this Association recognizes specialties as proper and legitimate fields of labor.

Resolved, That specialists shall be governed by the same rules of professional etiquette as have been laid down for general practitioners.

Resolved, That it shall not be proper for specialists publicly to advertise themselves such, or to assume any title not specially granted by a regularly chartered college.

Resolved, That private handbills addressed to members of the medical profession, or by cards in medical journals, calling the attention of professional brethren to themselves as specialists, be declared in violation of the Code of Ethics of the American Medical Association. (Vide *Transactions*, vol. xx. p. 28.)

Resolved, That a Committee of one be appointed, residing at Washington, to render the Librarian of Congress such assistance as the interests of the Association may require. (Vide *Transactions*, vol. xx. p. 29.)

Whereas, The proper construction of Art. IV., Sec. 1, Code of Ethics, A. M. A., having been called for, relative to consultation with irregular practitioners who are graduates of regular schools.

Resolved, That said Art. IV., Sect. 1, Code of Ethics, excludes all such practitioners from recognition by the regular profession. (Vide *Transactions*, vol. xx. p. 30.)

Resolved, That if any member fail to reply for more than one year to the circular sent to him by the Committee of Publication he shall forfeit his right to the volume, and it shall revert to the Association, to be sold to any applicant at the current rates. (Vide *Transactions*, vol. xxi. p. 30.)

Resolved, That the Committee of Arrangements for the next ensuing meeting of this Association, and for all meetings thereafter, be directed to prepare a list of members present on a separate roll, for convenience and accuracy in calling the ayes and nays when the same shall be demanded. (Vide *Transactions*, vol. xxi. p. 60.)

Resolved, That each year, until otherwise ordered, the President-elect and the Permanent Secretary be directed to appeal in the name of the Association, to the authorities of each State where no State Board of Health exists, urging them to establish such boards. (Vide *Transactions*, vol. xxvi. p. 50.)

Resolved, That the Permanent Secretary is hereby directed annually to report the names of States where boards of health exist, and also of those which decline to establish them; said report to form a part of the annual proceedings of the Association. (Vide *Transactions*, vol. xxvi. p. 50.)

Resolved, That members of the medical profession who in any way aid or abet the graduation of medical students in irregular or exclusive systems of medicine, are deemed thereby to violate the spirit of the ethics of the American Medical Association. (Vide *Transactions*, vol. xxvii. p. 48.)

Resolved, 1. That the American Medical Association adopts the International Metric System, and will use it in its Transactions. (Vide *Transactions*, vol. xxx. p. 44.)

2. Requests that those who present papers at its future meetings employ this system in their communications, or reprints thereof. (Vide *Transactions*, vol. xxx. p. 44.)

3. Requests the medical boards of the hospitals and dispensaries to adopt the Metric System in prescribing and recording cases; and that the Faculties of the medical and pharmaceutic schools adopt it in their didactic, clinical, or dispensing departments. (Vide *Transactions*, vol. xxx. p. 44.)

Resolved, That the President and Secretary of this Association are directed to annually petition Congress to enact a law which shall permit every person engaged in a scientific pursuit to import for his own use, free of duty, any one book or instrument appertaining to his special pursuit. (Vide *Transactions*, vol. xxx. p. 45.)

Resolved, That the above-named officers are further directed to urge the State Medical Societies and their auxiliary branches to aid this Association in accomplishing this purpose, by petitions to Congress, and by otherwise influencing Congressmen. (Vide *Transactions*, vol. xxx. p. 45.

Decision by Judicial Council: A gentleman who is not in affiliation with a County, District, or State Medical Society, where such organizations exist, is *not* entitled to be registered as a permanent member upon the claim of having been a delegate from a body not now entitled to representation in this body. (Vide *Transactions*, vol. xxx. p. 57.)

Resolved: First. That a committee of five be appointed by the President of the Association, to be called the Standing Committee on "Atmospheric Conditions, and their relations to the Prevalence of Diseases."

Second. That that committee be authorized to select such places as will best indicate atmospheric conditions in the more important climatic and sanitary districts of the United States—not less than six, nor more than twelve—and establish therefor a means for continuous observation and record of all appreciable conditions of atmosphere, according to the most approved methods, and of the origin and prevalence of all acute diseases.

Third. That the Committee, through their chairman, be authorized to draw upon the Treasurer of this Association for such sums as may be found necessary for the proper execution of the work assigned to it, the aggregate amount not to exceed $500, during the ensuing year, and that a detailed report of all sums drawn and expenditures made must be presented at the next annual meeting of the Association. (Vide *Transactions*, vol. xxxii. p. 35.)

CODE OF MEDICAL ETHICS.

OF THE DUTIES OF PHYSICIANS TO THEIR PATIENTS, AND OF THE OBLIGATIONS OF PATIENTS TO THEIR PHYSICIANS.

ART. I.—*Duties of physicians to their patients.*

§ 1. A physician should not only be ever ready to obey the calls of the sick, but his mind ought also to be imbued with the greatness of his mission, and the responsibility he habitually incurs in its discharge. These obligations are the more deep and enduring, because there is no tribunal other than his own conscience to adjudge penalties for carelessness or neglect. Physicians should, therefore, minister to the sick with due impressions of the importance of their office; reflecting that the ease, the health, and the lives of those committed to their charge, depend on their skill, attention, and fidelity. They should study, also, in their deportment, so to unite *tenderness* with *firmness*, and *condescension* with *authority*, as to inspire the minds of their patients with gratitude, respect, and confidence.

§ 2. Every case committed to the charge of a physician should be treated with attention, steadiness, and humanity. Reasonable indulgence should be granted to the mental imbecility and caprices of the sick. Secrecy and delicacy, when required by peculiar circumstances, should be strictly observed; and the familiar and confidential intercourse to which physicians are admitted in their professional visits, should be used with discretion, and with the most scrupulous regard to fidelity and honor. The obligation of secrecy extends beyond the period of professional services; none of the privacies of personal and domestic life, no infirmity of disposition or flaw of character observed during professional attendance should ever be divulged by the physician except when he is imperatively required to do so. The force and necessity of this obligation are indeed so great, that professional men have, under certain circumstances, been protected in their observance of secrecy by courts of justice.

§ 3. Frequent visits to the sick are in general requisite, since they enable the physician to arrive at a more perfect knowledge of the disease—to meet promptly every change which may occur, and also tend to preserve the confidence of the patient. But unnecessary visits are to be avoided, as they give useless anxiety to the patient, tend to diminish the authority of the physician, and render him liable to be suspected of interested motives.

§ 4. A physician should not be forward to make gloomy prognostications, because they savor of empiricism, by magnifying the importance of his services in the treatment or cure of the disease. But he should not fail, on proper occasions, to give to the friends of the patient timely notice of danger when it really occurs; and even to the patient himself, if absolutely necessary. This office, however, is so peculiarly alarming when executed by him, that it ought to be declined whenever it can be assigned to any other person of sufficient judgment and delicacy. For the physician should be the minister of hope and comfort to the sick; that, by such cordials to the drooping spirit, he may smooth the bed of death, revive expiring life, and counteract the depressing influence of those maladies which often disturb the tranquillity of the most resigned in their last moments. The life of a sick person can be shortened not only by the acts, but also by the words or the manner of a physician. It is, therefore, a sacred duty to guard himself carefully in this respect, and to avoid all things which have a tendency to discourage the patient and to depress his spirits.

§ 5. A physician ought not to abandon a patient because the case is deemed incurable; for his attendance may continue to be highly useful to the patient, and comforting to the relatives around him, even in the last period of a fatal malady, by alleviating pain and other symptoms, and by soothing mental anguish. To decline attendance, under such circumstances, would be sacrificing to fanciful delicacy and mistaken liberality, that moral duty which is independent of, and far superior to, all pecuniary consideration.

§ 6. Consultations should be promoted in difficult

or protracted cases, as they give rise to confidence, energy, and more enlarged views in practice.

§ 7. The opportunity which a physician not unfrequently enjoys of promoting and strengthening the good resolutions of his patients, suffering under the consequences of vicious conduct, ought never to be neglected. His counsels, or even remonstrances, will give satisfaction, not offense, if they be proffered with politeness, and evince a genuine love of virtue, accompanied by a sincere interest in the welfare of the person to whom they are addressed.

ART. II.—*Obligations of patients to their physicians.*

§ 1. The members of the medical profession, upon whom is enjoined the performance of so many important and arduous duties toward the community, and who are required to make so many sacrifices of comfort, ease, and health, for the welfare of those who avail themselves of their services, certainly have a right to expect and require, that their patients should entertain a just sense of the duties which they owe to their medical attendants.

§ 2. The first duty of a patient is to select as his medical adviser one who has received a regular professional education. In no trade or occupation do mankind rely on the skill of an untaught artist; and in medicine, confessedly the most difficult and intricate of the sciences, the world ought not to suppose that knowledge is intuitive.

§ 3. Patients should prefer a physician whose habits of life are regular, and who is not devoted to company, pleasure, or to any pursuit incompatible with his professional obligations. A patient should, also, confide the care of himself and family, as much as possible, to one physician: for a medical man who has become acquainted with the peculiarities of constitution, habits, and predispositions of those he attends, is more likely to be successful in his treatment than one who does not possess that knowledge.

A patient who has thus selected his physician should always apply for advice in what may appear to him trivial cases, for the most fatal results often supervene on the slightest accidents. It is of still more importance that he should apply for assistance in the forming stage of violent diseases; it is to a neglect of this precept that medicine owes much of the uncertainty and imperfection with which it has been reproached.

§ 4. Patients should faithfully and unreservedly communicate to their physician the supposed cause of their disease. This is the more important, as many diseases of a mental origin simulate those depending on external causes, and yet are only to be cured by ministering to the mind diseased. A patient should never be afraid of thus making his physician his friend and adviser; he should always bear in mind that a medical man is under the strongest obligations of secrecy. Even the female sex should never allow feelings of shame or delicacy to prevent their disclosing the seat, symptoms, and causes of complaints peculiar to them. However commendable a modest reserve may be in the common occurrences of life, its strict observance in medicine is often attended with the most serious consequences, and a patient may sink under a painful and loathsome disease, which might have been readily prevented had timely intimation been given to the physician.

§ 5. A patient should never weary his physician with a tedious detail of events or matters not appertaining to his disease. Even as relates to his actual symptoms, he will convey much more real information by giving clear answers to interrogatories, than by the most minute account of his own framing. Neither should he obtrude upon his physician the details of his business nor the history of his family concerns.

§ 6. The obedience of a patient to the prescriptions of his physician should be prompt and implicit. He should never permit his own crude opinions as to their fitness to influence his attention to them. A failure in one particular may render an otherwise judicious treatment dangerous, and even fatal. This remark is equally applicable to diet, drink, and exercise. As patients become convalescent, they are very apt to suppose that the rules prescribed for them may be disregarded, and the consequence, but too often, is a relapse. Patients should never allow themselves to be persuaded to take any medicine whatever, that may be recommended to them by the self-constituted doctors and doctresses who are so frequently met with, and who pretend to possess infallible remedies for the cure of every disease. However simple some of their prescriptions may appear to be, it often happens that they are productive of much mischief, and in all cases they are injurious, by contravening the plan of treatment adopted by the physician.

§ 7. A patient should, if possible, avoid even the *friendly visits of a physician* who is not attending him—and when he does receive them, he should never converse on the subject of his disease, as an observation may be made, without any intention of interference, which may destroy his confidence in the course he is pursuing, and induce him to neglect the directions prescribed to him. A patient should never send for a consulting physician without the express consent of his own medical attendant. It is of great importance that physicians should act in concert; for, although their modes of treatment may be attended with equal success when applied singly, yet conjointly they are very likely to be productive of disastrous results.

§ 8. When a patient wishes to dismiss his physician, justice and common courtesy require that he should declare his reasons for so doing.

§ 9. Patients should always, when practicable, send for their physician in the morning, before his usual hour of going out; for, by being early aware of the visits he has to pay during the day, the physician is able to apportion his time in such a manner as to prevent an interference of engagements. Patients should also avoid calling on their medical adviser unnecessarily during the hours devoted to meals or sleep. They should always be in readiness to receive the visits of their physician, as the detention of a few minutes is often of serious inconvenience to him.

§ 10. A patient should, after his recovery, entertain a just and endearing sense of the value of the services rendered him by his physician; for these are

of such a character, that no mere pecuniary acknowledgment can repay or cancel them.

OF THE DUTIES OF PHYSICIANS TO EACH OTHER, AND TO THE PROFESSION AT LARGE.

ART. I.—*Duties for the support of professional character.*

§ 1. Every individual, on entering the profession, as he becomes thereby entitled to all its privileges and immunities, incurs an obligation to exert his best abilities to maintain its dignity and honor, to exalt its standing, and to extend the bounds of its usefulness. He should, therefore, observe strictly such laws as are instituted for the government of its members; should avoid all contumelious and sarcastic remarks relative to the faculty as a body; and while, by unwearied diligence, he resorts to every honorable means of enriching the science, he should entertain a due respect for his seniors, who have, by their labors, brought it to the elevated condition in which he finds it.

§ 2. It is not in accord with the interests of the public or the honor of the profession that any physician or medical teacher should examine or sign diplomas or certificates of proficiency for, or otherwise be specially concerned with, the graduation of persons whom they have good reason to believe intend to support and practice any exclusive and irregular system of medicine.

§ 3. There is no profession, from the members of which greater purity of character, and a higher standard of moral excellence are required, than the medical; and to attain such eminence is a duty every physician owes alike to his profession and to his patients. It is due to the latter, as without it he cannot command their respect and confidence, and to both, because no scientific attainments can compensate for the want of correct moral principles. It is also incumbent upon the faculty to be temperate in all things, for the practice of physic requires the unremitting exercise of a clear and vigorous understanding; and, on emergencies, for which no professional man should be unprepared, a steady hand, an acute eye, and an unclouded head may be essential to the well-being, and even to the life, of a fellow-creature.

§ 4. It is derogatory to the dignity of the profession to resort to public advertisements, or private cards, or handbills, inviting the attention of individuals affected with particular diseases — publicly offering advice and medicine to the poor gratis, or promising radical cures; or to publish cases and operations in the daily prints, or suffer such publications to be made; to invite laymen to be present at operations, to boast of cures and remedies, to adduce certificates of skill and success, or to perform any other similar acts. These are the ordinary practices of empirics, and are highly reprehensible in a regular physician.

§ 5. Equally derogatory to professional character is it for a physician to hold a patent for any surgical instrument or medicine; or to dispense a secret *nostrum*, whether it be the composition or exclusive property of himself or of others. For, if such nostrum be of real efficacy, any concealment regarding it is inconsistent with beneficence and professional liberality; and if mystery alone give it value and importance, such craft implies either disgraceful ignorance or fraudulent avarice. It is also reprehensible for physicians to give certificates attesting the efficacy of patent or secret medicines, or in any way to promote the use of them.

ART. II.—*Professional services of physicians to each other.*

§ 1. All practitioners of medicine, their wives, and their children while under the paternal care, are entitled to the gratuitous services of any one or more of the faculty residing near them, whose assistance may be desired. A physician afflicted with disease is usually an incompetent judge of his own case; and the natural anxiety and solicitude which he experiences at the sickness of a wife, a child, or any one who, by the ties of consanguinity, is rendered peculiarly dear to him, tend to obscure his judgment, and produce timidity and irresolution in his practice. Under such circumstances, medical men are peculiarly dependent upon each other, and kind offices and professional aid should always be cheerfully and gratuitously afforded. Visits ought not, however, to be obtruded officiously; as such unasked civility may give rise to embarrassment, or interfere with that choice on which confidence depends. But, if a distant member of the faculty, whose circumstances are affluent, request attendance, and an honorarium be offered, it should not be declined; for no pecuniary obligation ought to be imposed, which the party receiving it would wish not to incur.

ART. III.—*Of the duties of physicians as respects vicarious offices.*

§ 1. The affairs of life, the pursuit of health, and the various accidents and contingencies to which a medical man is peculiarly exposed, sometimes require him temporarily to withdraw from his duties to his patients, and to request some of his professional brethren to officiate for him. Compliance with this request is an act of courtesy, which should always be performed with the utmost consideration for the interest and character of the family physician, and when exercised for a short period, all the pecuniary obligations for such service should be awarded to him. But if a member of the profession neglect his business in quest of pleasure and amusement, he cannot be considered as entitled to the advantages of the frequent and long-continued exercise of this fraternal courtesy, without awarding to the physician who officiates, the fees arising from the discharge of his professional duties.

In obstetrical and important surgical cases, which give rise to unusual fatigue, anxiety and responsibility, it is just that the fees accruing therefrom should be awarded to the physician who officiates.

ART. IV.—*Of the duties of physicians in regard to consultations.*

§ 1. A regular medical education furnishes the only presumptive evidence of professional abilities and acquirements, and ought to be the only acknowledged right of an individual to the exercise and honors of his profession. Nevertheless, as in consultations the

good of the patient is the sole object in view, and this is often dependent on personal confidence, no intelligent regular practitioner, who has a license to practice from some medical board of known and acknowledged respectability, recognized by this Association, and who is in good moral and professional standing in the place in which he resides, should be fastidiously excluded from fellowship, or his aid refused in consultation, when it is requested by the patient. But no one can be considered as a regular practitioner or a fit associate in consultation, whose practice is based on an exclusive dogma, to the rejection of the accumulated experience of the profession, and of the aids actually furnished by anatomy, physiology, pathology and organic chemistry.

§ 2. In consultations, no rivalship or jealousy should be indulged; candor, probity and all due respect should be exercised toward the physician having charge of the case.

§ 3. In consultations, the attending physician should be the first to propose the necessary questions to the sick; after which the consulting physician should have the opportunity to make such further inquiries of the patient as may be necessary to satisfy him of the true character of the case. Both physicians should then retire to a private place for deliberation; and the one first in attendance should communicate the directions agreed upon to the patient or his friends, as well as any opinions which it may be thought proper to express. But no statement or discussion of it should take place before the patient or his friends, except in the presence of all the faculty attending, and by their common consent; and no *opinions* or *prognostications* should be delivered which are not the result of previous deliberation and concurrence.

§ 4. In consultations, the physician in attendance should deliver his opinion first; and when there are several consulting, they should deliver their opinions in the order in which they have been called in. No decision, however, should restrain the attending physician from making such variations in the mode of treatment as any subsequent unexpected change in the character of the case may demand. But such variation, and the reasons for it, ought to be carefully detailed at the next meeting in consultation. The same privilege belongs also to the consulting physician if he is sent for in an emergency, when the regular attendant is out of the way, and similar explanations must be made by him at the next consultation.

§ 5. The utmost punctuality should be observed in the visits of physicians when they are to hold consultations together, and this is generally practicable, for society has been considerate enough to allow the plea of a professional engagement to take precedence of all others, and to be an ample reason for the relinquishment of any present occupation. But as professional engagements may sometimes interfere, and delay one of the parties, the physician who first arrives should wait for his associate a reasonable period, after which the consultation should be considered as postponed to a new appointment. If it be the attending physician who is present, he will, of course, see the patient and prescribe; but if it be the consulting one, he should retire, except in case of emergency, or when he has been called from a considerable distance, in which latter case he may examine the patient, and give his opinion in *writing*, and *under seal*, to be delivered to his associate.

§ 6. In consultations, theoretical discussions should be avoided, as occasioning perplexity and loss of time. For there may be much diversity of opinion concerning speculative points, with perfect agreement in those modes of practice which are founded, not on hypothesis, but on experience and observation.

§ 7. All discussions in consultation should be held as secret and confidential. Neither by words nor manner should any of the parties to a consultation assert or insinuate that any part of the treatment pursued did not receive his assent. The responsibility must be equally divided between the medical attendants—they must equally share the credit of success as well as the blame of failure.

§ 8. Should an irreconcilable diversity of opinion occur when several physicians are called upon to consult together, the opinion of the majority should be considered as decisive; but if the numbers be equal on each side, then the decision should rest with the attending physician. It may, moreover, sometimes happen that two physicians cannot agree in their views of the nature of a case, and the treatment to be pursued. This is a circumstance much to be deplored, and should always be avoided, if possible, by mutual concessions, as far as they can be justified by a conscientious regard for the dictates of judgment. But in the event of its occurrence, a third physician should, if practicable, be called to act as umpire; and, if circumstances prevent the adoption of this course, it must be left to the patient to select the physician in which he is most willing to confide. But, as every physician relies upon the rectitude of his judgment, he should, when left in the minority, politely and consistently retire from any further deliberation in the consultation, or participation in the management of the case.

§ 9. As circumstances sometimes occur to render a *special consultation* desirable, when the continued attendance of two physicians might be objectionable to the patient, the member of the faculty whose assistance is required in such cases should sedulously guard against all future unsolicited attendance. As such consultations require an extraordinary portion of both time and attention, at least a double honorarium may be reasonably expected.

§ 10. A physician who is called upon to consult, should observe the most honorable and scrupulous regard for the character and standing of the practitioner in attendance; the practice of the latter, if necessary, should be justified as far as it can be, consistently with a conscientious regard for truth, and no hint or insinuation should be thrown out which could impair the confidence reposed in him, or affect his reputation. The consulting physician should also carefully refrain from any of those extraordinary attentions or assiduities which are too often practiced by the dishonest for the base purpose of gaining applause, or ingratiating themselves into the favor of families and individuals.

ART. V.—*Duties of physicians in cases of interference.*

§ 1. Medicine is a liberal profession, and those admitted into its ranks should found their expectations of practice upon the extent of their qualifications, not on intrigue or artifice.

§ 2. A physician, in his intercourse with a patient under the care of another practitioner, should observe the strictest caution and reserve. No meddling inquiries should be made — no disingenuous hints given relative to the nature and treatment of his disorder; nor any course of conduct pursued that may directly or indirectly tend to diminish the trust reposed in the physician employed.

§ 3. The same circumspection and reserve should be observed when, from motives of business or friendship, a physician is prompted to visit an individual who is under the direction of another practitioner. Indeed, such visits should be avoided, except under peculiar circumstances; and when they are made, no particular inquiries should be instituted relative to the nature of the disease, or the remedies employed, but the topics of conversation should be as foreign to the case as circumstances will admit.

§ 4. A physician ought not to take charge of or prescribe for a patient who has recently been under the care of another member of the faculty in the same illness, except in cases of sudden emergency, or in consultation with the physician previously in attendance, or when the latter has relinquished the case, or been regularly notified that his services are no longer desired. Under such circumstances, no unjust and illiberal insinuations should be thrown out in relation to the conduct or practice previously pursued, which should be justified as far as candor and regard for truth and probity will permit; for it often happens that patients become dissatisfied when they do not experience immediate relief, and, as many diseases are naturally protracted, the want of success, in the first stage of treatment, affords no evidence of a lack of professional knowledge and skill.

§ 5. When a physican is called to an urgent case, because the family attendant is not at hand, he ought, unless his assistance in consultation be desired, to resign the care of the patient to the latter immediately on his arrival.

§ 6. It often happens in cases of sudden illness, or of recent accidents and injuries, owing to the alarm and anxiety of friends, that a number of physicians are simultaneously sent for. Under these circumstances, courtesy should assign the patient to the first who arrives, who should select from those present any additional assistance that he may deem necessary. In all such cases, however, the practitioner who officiates should request the family physician, if there be one, to be called, and, unless his further attendance be requested, should resign the case to the latter on his arrival.

§ 7. When a physician is called to the patient of another practitioner, in consequence of the sickness or absence of the latter, he ought, on the return or recovery of the regular attendant and with the consent of the patient, to surrender the case.

[The expression, "patient of another practitioner," is understood to mean a patient who may have been under the charge of another practitioner at the time of the attack of sickness, or departure from home of the latter, or who may have called for his attendance during his absence or sickness, or in any other manner given it to be understood that he regarded the said physician as his regular medical attendant.]

§ 8. A physician, when visiting a sick person in the country, may be desired to see a neighboring patient who is under the regular direction of another physician, in consequence of some sudden change or aggravation of symptoms. The conduct to be pursued on such an occasion is to give advice adapted to present circumstances; to interfere no further than is absolutely necessary with the general plan of treatment; to assume no future direction unless it be expressly desired; and, in this last case, to request an immediate consultation with the practitioner previously employed.

§ 9. A wealthy physician should not give advice *gratis* to the affluent; because his doing so is an injury to his professional brethren. The office of a physician can never be supported as an exclusively beneficent one; and it is defrauding, in some degree, the common funds for its support, when fees are dispensed with which might justly be claimed.

§ 10. When a physician who has been engaged to attend a case of midwifery is absent, and another is sent for, if delivery is accomplished during the attendance of the latter, he is entitled to the fee, but should resign the patient to the practitioner first engaged.

ART. VI.—*Of differences between physicians.*

§ 1. Diversity of opinion and opposition of interest may, in the medical as in other professions, sometimes occasion controversy and even contention. Whenever such cases unfortunately occur, and cannot be immediately terminated, they should be referred to the arbitration of a sufficient number of physicians or a *court-medical.*

§ 2. As peculiar reserve must be maintained by physicians toward the public, in regard to professional matters, and as there exist numerous points in medical ethics and etiquette through which the feelings of medical men may be painfully assailed in their intercourse with each other, and which cannot be understood or appreciated by general society, neither the subject-matter of such differences nor the adjudication of the arbitrators should be made public, as publicity in a case of this nature may be personally injurious to the individuals concerned, and can hardly fail to bring discredit on the faculty.

ART. VII.—*Of pecuniary acknowledgments.*

Some general rules should be adopted by the faculty, in every town or district, relative to *pecuniary acknowledgments* from their patients; and it should be deemed a point of honor to adhere to these rules with as much uniformity as varying circumstances will admit.

OF THE DUTIES OF THE PROFESSION TO THE PUBLIC, AND OF THE OBLIGATIONS OF THE PUBLIC TO THE PROFESSION.

ART. I.—*Duties of the profession to the public.*

§ 1. As good citizens, it is the duty of physicians to be ever vigilant for the welfare of the community, and to bear their part in sustaining its institutions and burdens; they should also be ever ready to give counsel to the public in relation to matters especially appertaining to their profession, as on subjects of medical police, public hygiene, and legal medicine. It is their province to enlighten the public in regard to quarantine regulations; the location, arrangement, and dietaries of hospitals, asylums, schools, prisons, and similar institutions; in relation to the medical police of towns, as drainage, ventilation, etc.; and in regard to measures for the prevention of epidemic and contagious diseases; and when pestilence prevails, it is their duty to face the danger, and to continue their labors for the alleviation of the suffering, even at the jeopardy of their own lives.

§ 2. Medical men should also be always ready, when called on by the legally constituted authorities, to enlighten coroners' inquests and courts of justice on subjects strictly medical—such as involve questions relating to sanity, legitimacy, murder by poisons or other violent means, and in regard to the various other subjects embraced in the science of Medical Jurisprudence. But in these cases, and especially where they are required to make a *postmortem* examination, it is just, in consequence of the time, labor, and skill required, and the responsibility and risk they incur, that the public should award them a proper honorarium.

§ 3. There is no profession by the members of which eleemosynary services are more liberally dispensed than the medical, but justice requires that some limits should be placed to the performance of such good offices. Poverty, professional brotherhood, and certain of the public duties referred to in the first section of this article, should always be recognized as presenting valid claims for gratuitous services; but neither institutions endowed by the public or by rich individuals, societies for mutual benefit, for the insurance of lives or for analogous purposes, nor any profession or occupation, can be admitted to possess such privilege. Nor can it be justly expected of physicians to furnish certificates of inability to serve on juries, to perform militia duty, or to testify to the state of health of persons wishing to insure their lives, obtain pensions, or the like, without a pecuniary acknowledgment. But to individuals in indigent circumstances, such professional services should always be cheerfully and freely accorded.

§ 4. It is the duty of physicians, who are frequent witnesses of the enormities committed by quackery, and the injury to health and even destruction of life caused by the use of quack medicines, to enlighten the public on these subjects, to expose the injuries sustained by the unwary from the devices and pretensions of artful empirics and impostors. Physicians ought to use all the influence which they may possess, as professors in Colleges of Pharmacy, and by exercising their option in regard to the shops to which their prescriptions shall be sent, to discourage druggists and apothecaries from vending quack or secret medicines, or from being in any way engaged in their manufacture and sale.

ART. II.—*Obligations of the public to physicians.*

§ 1. The benefits accruing to the public, directly and indirectly, from the active and unwearied beneficence of the profession, are so numerous and important, that physicians are justly entitled to the utmost consideration and respect from the community. The public ought likewise to entertain a just appreciation of medical qualifications; to make a proper discrimination between true science and the assumptions of ignorance and empiricism; to afford every encouragement and facility for the acquisition of medical education,—and no longer to allow the statute-books to exhibit the anomaly of exacting knowledge from physicians, under a liability to heavy penalties, and of making them obnoxious to punishment for resorting to the only means of obtaining it.

LIST OF DELEGATES AND MEMBERS.

THE FOLLOWING IS THE OFFICIAL LIST OF DELEGATES AND MEMBERS IN ATTENDANCE UPON THE ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION IN WASHINGTON, MAY 6-7-8-9, 1884.

ALABAMA.

State Medical Society.—Jerome Cochran, Augustus Jordan Reese.

Bullock County Medical Society.—Charles H. Franklin.

Mobile County Medical Society.—George Augustus Ketchum.

Permanent Member.—James Marshall Collier.

ARKANSAS.

State Medical Society.—John R. Dale, James A. Dibrell, David C. Ewing, P. O. Hooper, James Thomas Jelks, R. G. Jennings, James M. Keller, Thos. E. Murrell, W. N. Yates.

CALIFORNIA.

State Medical Society.—F. W. Hatch.

Alameda County Medical Association.—Frank Howard Payne.

COLORADO.

State Medical Society.—Charles Denison, Jesse Hawes.

CONNECTICUT.

State Medical Society.—C. W. Chamberlain, Frederick L. Dibbel, Horace S. Fuller, Stephen G. Hubbard, S. W. Rockwell, James Welsh, Frank Hamilton Whittemore, Francis J. Young.

Fairfield County Medical Society.—Curtis H. Bill, S. T. De La Mater, Andrew W. Lyons, George L. Porter.

Hartford County Medical Society.—E. P. Swasey, Wm. A. M. Wainwright.

Middlesex County Medical Society.—Moses C. Hazel, Sylvester W. Turner.

New Haven County Medical Society.—Walter L. Barber, Lewis Barnes, Frank E. Caster, Michael A. Cremin, Gustavus Eliot, Walter Hamlin Holmes, Chas. A. Lindley, Matthew C. O'Connor, Charles S. Rodman.

New London County Medical Society.—Francis N. Braman.

Tolland County Medical Society.—Elbridge K. Leonard.

Windham County Medical Society.—Emory H. Davis, Edwin A. Hill, John Bryden Kent.

Permanent Members.—George R. Shepherd, W. W. Welch, W. C. Wile.

DAKOTA TERRITORY.

Cass County Medical Society.—Hector Galloway.

DELAWARE.

State Medical Society.—Hiram A. Burton, Lewis P. Bush, Robert G. Ellegood, R. S. W. Hirous, James A. Hopkins, William Marshall, Read J. McKay, Charles H. Richards, Albert Whiteley.

DISTRICT OF COLUMBIA.

Medical Association of District of Columbia.—Thos. Antisell, Walter C. Briscoe, J. R. Bromwell, Leon L. Friederich, Henry Davidson Fry, Walter W. Godding, Daniel R. Hagner, James F. Hartigan, Raymond T. Holden, W. W. Johnston, Louis Mackall, Hamilton E. Leach, Thomas Eugene McArdle, Edward Martin Schaeffer, Thomas C. Smith, William O. Taylor, Lachlan Tyler, John Hepburn Yarnall.

Permanent Members.—George N. Acker, Samuel S. Adams, Preston H. Bailhache, Howard H. Barker, Jedediah H. Baxter, John Shaw Billings, Charles V. Boarman, John Mills Browne, John W. Bulkley, Samuel C. Busey, James M. Flint, Chas. Wm. Franzoni, Alex. Y. P. Garnett, Albert Leary Gihon, Wm. H. Gobrecht, Charles Evelyn Hagner, John B. Hamilton, Flodoardo Howard, Franck Hyatt, Joseph Taber Johnson, C. H. A. Kleinschmidt, William Lee, Nathan Smith Lincoln, James W. H. Lovejoy, George Lloyd Magruder, W. V. Marmion, Ethelbert Carroll Morgan, James E. Morgan, DeWitt C. Patterson, Gideon S. Palmer, Armistead Peter, D. Webster Prentiss, S. J. Radcliffe, Robert Reyburn, J. O. Stanton, J. Ford Thompson, Joseph M. Toner, Ralph Walsh, Geo. Wm. West.

FLORIDA.

State Medical Society.—R. B. Burroughs.

GEORGIA.

State Medical Society.—J. W. Bailey, Robert Battey, Henry Frazier Campbell, Elijah Lewis Connally, Benjamin Robert Dostor, Eugene Foster, James A. Gray, J. B. Hankins, Wm. F. Holt, Daniel H. Howell, A. J. Logan, Henry McHatton, T. O. Powell, Columbus D. Smith, Wm. B. Wells, A. Grattan Whitehead.

Permanent Member.—Ely K. Bozeman.

ILLINOIS.

State Medical Society.—Edmund Andrews, G. M. Chamberlin, Frederick Cole, E. P. Cook, Lucinda H. Corr, N. S. Davis, Caleb DuHadway, B. M. Griffith, Benjamin H. Harris, John H. Hollister, C. C. Hunt, Ellen A. Ingersoll, Joseph L. Kitchen, Newton S. Read, George H. Tebo, Robert Tilley, Washington West.

Northern Central (Illinois) Medical Society.—John B. Felker, Isaac W. Fink.

Southern Illinois Medical Society.—Augustus De Foe, Thomas G. Hickman, W. R. Mackenzie, Henry J. Peavler.

Adams County Medical Society.—Moses F. Bassett, William A. Byrd, Charles Wesley Rook.

Æsculapian Society.—W. H. McNary.

Aurora Medical Society.—Daniel S. Jenks.

Brainard District Medical Society.—Robert N. Barger, S. T. Hurst.

Champaign County Medical Society.—Levi S. Wilcox.

Chicago Medical Society.—Philip Adolphus, W. W. Allport, Frank Billings, Truman W. Brophy, Albert H. Burr, Eggleston Burrows, Henry T. Byford, Wm. E. Clarke, John H. Chew, Alexander H. Cooke, S. Charles DeVeny, A. W. Harlan, Marcus P. Hatfield, E. Fletcher Ingals, A. Reeves Jackson, John S. Marshall, Truman W. Miller, Liston Homer Montgomery, Charles T. Parkes, Sarah Hackett Stevenson, Adelbert H. Tagert, J. F. Todd, Wm. Porter Verity, Jane E. Walton.

Cook County Medical Society.—Charles J. Simons.

Fox River Valley Medical Society.—Catharine B. Slater.

McLean County Medical Society.—N. B. Cole, Thos. F. Worrell.

Macoupin County Society for Medical Improvement.—Marinus W. Seaman.

Military Tract Medical Society.—Herbert Judd, Milton L. Knowles.

Morgan County Medical Society.—G. V. Black, Thomas J. Pitner, Arthur E. Prince.

Peoria City Medical Society.—Anna S. Adams.

Will County Medical Society.—William M. Richards.

Winnebago County Medical Association.—Silas A. Austin, Edward P. Catlin, L. A. Clark.

Permanent Members.—J. Y. Campbell, John W. Cowden, Moses Gunn, Walter Hay, S. J. Jones, John H. Rauch, William R. Shinn, Chas. Gilman Smith, Lemuel Tibbets, Edwin R. Willard.

INDIANA.

State Medical Society.—Ferdinand W. Beard, W. J. Boyden, Louis O. Carson, Joshua Chitwood, Timothy B. Cox, Joseph Eastman, Elijah S. Elder, Vincent H. Gregg, M. H. Harding, Thomas B. Harvey, James F. Hibberd, N. P. Howard, Jr., G. W. H. Kemper, Thomas M. Kyle, C. B. Miller, Gonzalva Cordova Smythe, George Sutton, J. E. Taylor, W. M. Terrill, L. D. Waterman, John C. Webster, John B. Weever, Jacob R. Weist, William N. Wishard.

Blackford County Medical Society.—Henry C. Davisson, Calvin Shull.

Boone County Medical Society.—Carter H. Smith.

Clinton County Medical Society.—James S. McMurray, S. O. Knapp.

Dearborn County Medical Society.—William C. Henry, Edward D. Freeman, Andrew J. Bower.

Delaware County Medical Society.—Samuel V. Jump, Robert Winton, Joseph Ross.

Gibson County Medical Society.—Wm. G. Kidd, S. E. Munford.

Grant County Medical Society.—Wm. Lomax.

Hancock County Medical Society.—Warren R. King.

Henry County Medical Society.—William F. Boor, George W. Burke.

Huntington County Medical Society.—Andrew J. Boswell, B. H. B. Grayston.

Jackson County Medical Society.—Samuel H. Charttan.

Kosciusko County Medical Society.—Irvin J. Becknell, J. H. Davisson, Irvin B. Webber.

Madison County Medical Society.—Jonas Stewart.

Marion County Medical Society.—J. A. Sutcliffe, Green V. Woolen, Jas. Livingston Thompson, John J. Garver, John Chambers.

Miami County Medical Society.—E. M. Bloomfield.

Montgomery County Medical Society.—Oliver H. Jones, S. W. Purviance.

Noble County Medical Society.—Norman Teal.

Owen County Medical Society.—Frank M. Niles.

Pulaski County Medical Society.—Geo. W. Thompson.

Randolph County Medical Society.—Lewis N. Davis.

Rush County Medical Society.—Charles H. Parsons, Marshall Sexton.

Steuben County Medical Society.—Theodore F. Wood, H. D. Wood.

Tippecanoe County Medical Society.—Moses Baker, George F. Beasley, Luther M. Irvin, Robert M. O'Ferrall, William S. Walker.

Vanderburgh County Medical Society.—Charles E. Lining, Edward Murphy.

Vigo County Medical Society.—Stephen J. Young.

Wabash County Medical Society.—Ebenezer F. Donaldson, Perry G. Moore, Oren O'Neal, Andrew J. Smith.

Permanent Members.—Geo. L. Andrews, Robert P. Davis, Wm. M. Holten, N. P. Howard, Sr., Joseph Intzi, John E. Link, Wm. Lomax, R. C. Rice, Landon C. Rose.

IOWA.

State Medical Society.—Homer O. Bates, J. A. Blanchard, A. B. Brackett, R. S. Brice, James Carson, Elmer F. Clapp, Elbert W. Clark, D. W. Crouse, Geo. D. Darnall, Joseph M. Emmert, O. T. Gillett, Sanford T. Goodman, Henry W. Hart, Thomas M. Hedges, Geo. P. Hanawalt, E. C. Heilman, A. J. Hobart, C. M. Hobby, Henry C. Huntsman, Eugene A. Kegley, John M. Knott, John W. Mitchell, Washington F. Peck, Horace Bascom Ransom, Allen A. Rawson, Ephraim M. Reynolds, R. C. Rice, John S. Roome, W. H. Ward, Ira L. Welch, John S. Whitley, D. H. Worthington, J. W. Young.

Central District Medical Society.—Robert R. Williams, Arthur L. Wright.

Eastern District Medical Society.—H. Cushman.

Northern Iowa Medical Society.—Norman L. Kean.

Southwestern Iowa Society of Physicians and Surgeons.—Hiram Irving Nance.

Cedar Rapids Medical Society.—W. M. Skinner, Joseph H. Weller.

Cedar Valley Medical Society.—Amos Babcock.

Clinton County Medical Society.—H. M. McKenzie, M. C. Osborn.

Council Bluffs Medical Society.—J. H. Cleaver.

Delaware County Medical Society.—S. N. Bixby.

Des Moines Valley Medical Society.—Charles G. Lewis, Henry B. Young.

Dubuque Medical Society.—John E. Bready, George Minges.

Fayette County Medical Society.—Charles C. Parker.

Guthrie District Medical Society.—Jacob R. Dosh.

Jackson County Medical Society.—Geo. O. Johnson, David N. Loose.

Johnson County Medical Society.—John Clinton Shrader.

Louisa County Medical Society.—B. G. Kimmel, H. S. Rogers.

Marion County Medical Society.—Jas. H. Auld, Wm. E. Wright.

Muscatine County Society of Physicians and Surgeons.—Elbridge H. King.

Polk County Medical Society.—A. G. Field, Spencer M. Rice, A. C. Simonton, D. W. Smouse.

VanBuren County Medical Society.—Thos. Gillmore McClure.

Permanent Members.—Edward L. Baker, Thomas H. Barnes, Lewis Blanchard, Asa B. Bowers, B. E. Brockhausen, Wm. C. Davis, Albert A. Deering, P. J. Farnsworth, Joseph C. Hughes, Jonathan H. Kersey, Chas. Henry Lothrop, Stephen C. Robinson, D. W. Smouse, C. H. Smith, Fred. M. Ward.

KANSAS.

State Medical Society.—R. D. Adams, B. Aikman, J. Bell, F. F. Dickman, H. O. Hanawalt, V. G. Miller, Chas. V. Mottram, W. L. Schenck, D. W. Stormont.

East Kansas District Medical Society.—J. B. Britton.

Permanent Member.—B. E. Fryer.

KENTUCKY.

State Medical Society.—T. B. Greenley, J. N. McCormack, Anselm D. Price, Dudley S. Reynolds, W. H. Wathen.

Central Kentucky Medical Association.—Hankins Brown, John Lewis Price.

Southwestern Kentucky Medical Association.—John G. Brooks, Joseph W. Thompson.

LOUISIANA.

State Medical Society.—Thomas S. Dabney.

New Orleans Medical Association.—M. Schuppert.

Orleans Parish Medical Society.—Geo. J. Friederichs.

Permanent Member.—Tobias G. Richardson.

MAINE.

State Medical Society.—Augustus P. Duelley, Theodore L. Estabrook, Thos. A. Foster, Alonzo Garcelon, Hampton E. Hill, Cyrus Kendrick, Daniel E. Marston, Andrew Mitchell Peables, Horatio N. Small, Frederick Charles Thayer, Charles E. Webster, Milton C. Wedgwood.

Permanent Members.—Andrew J. Fuller, Seth C. Gordon, Albion P. Snow.

MARYLAND.

Medical and Chirurgical Faculty.—B. Bernard Brown, T. Barton Brown, Frank Donaldson, W. Stump Forwood, James E. Gibbons, Jacob H. Hartman, Thomas M. Healey, Christopher Johnston, Thos. S. Latimer, Charles G. W. MacGill, Thomas Opie, G. Lane Taneyhill, W. Chas. Van Bibber.

Allegheny Medical Association.—William H. McCormick, D. P. Welfley.

Baltimore Medical and Surgical Society.—Daniel Webster Cathell, J. W. C. Cuddy, A. Friedenwald, Geo. W. Hamill, Wm. N. Hill, Chas. Hampson Jones, Benj. F. Leonard, John S. Lynch, Wm. H. Norris, E. M. Reid, Henry T. Rennolds.

Baltimore Medical Association.—Augustus F. Erich, Thos. A. Ashby, John Morris, John Neff, Walter Wyman.

Baltimore Academy of Medicine.—Chas. Carroll Bombaugh, Denis I. McKew, Richard McSherry, John R. Uhler.

Clinical Society of Maryland.—John W. Chambers, Eugene F. Cordell, George H. Rohé, Joseph T. Smith, James A. Stewart.

Cecil County Medical Society.—Samuel Thomas Roman.

Permanent Members.—John J. C. Caldwell, L. M. Eastman, Thomas B. Evans, William Lee, J. H. Scarff, Wm. A. B. Sellman, Jas. Carey Thomas, Claude Van Bibber, William Whitridge.

MASSACHUSETTS.

State Medical Society.—J. F. A. Adams, Z. Boylston Adams, Edward C. Briggs, James B. Brewster, Wm. Terence Carolin, Benj. S. Codman, Robert T. Davis, James A. Dow, Wm. A. Dunn, Jerome Dwelly, Reginald Heber Fitz, Lorenzo Smith Fox, George M. Garland, Michael F. Gavin, John Henry Gilman, John Alexander Gordon, Douglass Graham, John Lewis Hildreth, Wm. H. Hildreth, Howland Holmes, Franklin H. Hooper, John H. Jackson, Frederick I. Knight, Wm. D. Lamb, Marcus B. Leonard, John Howell Mackie, Henry O. Marcy, Wm. M. Mercer, Ernest P. Miller, J. L. Miller, A. Mitchell Orcutt, Moses Greeley Parker, George Howard Malcolm Rowe, Ira Russell, Charles A. Savory, Frederic Cheever Shattuck, Edmund H. Stevens, John B. Taylor, Frederick Henry Thompson, Levi Farr Warner, Charles Everett Warren, Emory L. White, Horace C. White, Jacob L. Williams, Arthur H. Wilson.

Essex North District.—Oliver S. Lovejoy, George Montgomery, John F. Young.

Middlesex North District.—Herbert Perry Jefferson.

Middlesex South District.—Albert L. Norris.

Norfolk District.—Chas. C. Toner.

Plymouth District.—Benjamin Hubbard.

Suffolk District.—Edward H. Bradford, Asa F. Pattee.

North Worcester District.—Edward A. Sawyer.

Permanent Members.—Robert Foster Andrews, Vincent Yardley Bowditch, Theodore W. Fisher, Edgar Dwight Hill, Alfred F. Holt, David W. Miner, Austin Wilbur Sidney.

MICHIGAN.

State Medical Society.—Henry Brooks Baker, Lyman W. Bliss, Wm. F. Breakey, William Brodie, Carl Brumme, William E. Burtless, Leartus Connor, C. C. Dellenbaugh, Simeon S. French, William R. Gifford, Joseph B. Griswold, George K. Johnson, Amos Knight, Donald Maclean, Theodore A. McGraw, Alva W. Nichols, Foster Pratt, Geo. E. Ranney, Robert Stephenson, Horace Tupper, Columbus V. Tyler.

Southern Michigan Medical Society.—Anson R. Smart, Louis H. Wertz.

West Michigan Medical Society.—Willard N. Smart.

Calhoun County Medical Society.—Harry D. Thomason.

Clinton County Medical Society.—Louis W. Fasquelle.

Detroit Medical and Library Association.—Ernest L. Shurley, Eugene Smith, Henry O. Walker.

Detroit Academy of Medicine.—Jas. F. Noyes, Frederick Austin Spaulding.

Medical Association of Eaton and Barry Counties.—Hiram Walter.

Flint Academy of Medicine.—Henry R. Case, Henry Carlton Fairbank.

Grand Rapids Medical Society.—Ezra E. Hebburd.

Wayne County Medical Society.—Henry F. Lyster, Edward S. Snow.

Permanent Members.—Gertrude S. Banks, William J. Herdman, John F. Jenkins, John H. Kellogg, Thomas Noble Reynolds, Hal. C. Wyman.

MINNESOTA.

State Medical Society.—Frank A. Blackman, John F. Fulton, A. W. Giddings, Charles N. Hewitt, Charles Hill, Daniel Leasure, John H. Murphy, C. A. Wheaton, W. K. Whittemore.

Minneapolis Physicians and Surgeons.—Charles N. Hunter,

Ramsey County Medical Society.—Talbot Jones, W. W Mayo.

Permanent Members.—A. A. Noyes, Alexander J. Stout.

MISSISSIPPI.

State Medical Society.—Burwell A. Duncan.

Permanent Member.—A. G. Smythe.

MISSOURI.

State Medical Society.—John H. Duncan, John W. Jackson.

Northwest Missouri Medical Society.—George C. Catlett, N. Fred. Essig, James W. Heddens.

Jackson County Medical Society.—T. B. Lester, Flavel B. Tiffany.

Kansas City Medical Society.—N. N. Horton, Edward W Schauffler, A. B. Sloan, Simeon S. Todd, John H. Van Eman.

Linton District Medical Society.—Wesley Humphrey.
Marion County Medical and Surgical Association.—Joseph C. Hearne.
Moberly District Medical Society.—B. G. Dysart, Thomas Irwin.
Pettis County Medical Society.—Willis P. King.
Saline County Medical Society.—C. Lester Hall.
St. Louis Medical Society.—LeGrand Atwood, Washington E. Fischel, Robert J. Flitt, R. M. Jordan, John S. Moore, James M. Scott.
St. Louis Medico-Chirurgical Society.—Geo. J. Engleman, Robert M. Funkhausen, Gratz A. Moses, T. F. Prewitt.
Permanent Members.—George Halley, W. B. Outten, S. Pollak.

NEBRASKA.

State Medical Society.—Frederick N. Dick, F. 'G. Fuller, Wellington S. Gibbs, S. D. Mercer, Richard C. Moore, John Windsor Rawlins, Adam H. Sowers.

NEW HAMPSHIRE.

State Medical Society.—David S. Clark, Granville P. Conn, Mary Shepherd Danforth, Eli Edwin Graves, L. W. Jones, George S. Love, John Edwin Mason, Nathaniel H. Merriam, Joseph W. Odell, John W. Parsons, Winslow B. Porter, Abel Parker Richardson, Thomas B. Sanborn, Irving A. Watson.
White Mountain Medical Society.—Joseph L. Patten.
Permanent Member.—P. A. Stackpole.

NEW JERSEY.

State Medical Society.—Geo. Bayles, Dowling Benjamin, Henry G. Cooke, D. A. Currie, H. W. Elmer, Denman B. Ingersoll, William R. Little, B. A. Watson, George T. Welch, James H. Wikoff.
Atlantic County Medical Society.—Boardman Reed.
Burlington County Medical Society.—Joseph Parrish, Alexander Marcy Sr., Samuel C. Thornton.
Camden County Medical Society.—William Albert Davis, John W. Douges, Onan B. Gross, Wm. H. Ireland.
Essex County Medical Society.—E. F. Smith, James T. Wrightson.
Gloucester County Medical Society.—Henry G. Buckingham.
Hudson County Medical Society.—Isaac N. Quimby.
Middlesex County Medical Society.—Wm. V. Wilson.
Passaic County Medical Society.—John Quin.
Sussex County Medical Society.—C. K. Davison, J. Miller.
Permanent Member.—Theodore R. Varick.

NEW YORK.

State Medical Association.—Judson B. Andrews, Edward N. Brush, Darwin Colvin, Clayton M. Daniels, Henry D. Didama, William Giltis, Joseph C. Greene, Desault Guernsey, B. L. Hovey, Nathaniel C. Husted, Jos. C. Hutchison, Frederick Hyde, Edward G. Janeway, John K. Leaning, U. Colvin Lynde, Edward M. Moore, Joseph W. Moore, Thos. D. Strong, William S. Tremaine, Wm. D. Woodend.
Chemung County Medical Society.—Chas. W. Brown, C. M. Spalding.
Columbus County Medical Society.—John C. Buchanan.
Erie County Medical Society.—Albert H. Briggs, Alphonse Dagenais, Thos. M. Johnson, C. C. Wyckoff.
New York Academy of Medicine.—John Glover Adams, James H. Anderson, William Nelson Blakeman, F. H. Bosworth, Nathan Bozeman, Chas. Stedman Bull, John Call Dalton, Frederick L. Dennis, Austin Flint, Jr., Joel Foster, J. W. S. Gouley, Caspar Griswold, F. H. Hamilton, John H. Hinton, Frederick E. Hyde, Edward A. Judson, W. T. Lusk, Richard C. M. Page, Samuel S. Purple, Lewis Albert Sayre, Gouverneur M. Smith, J. Lewis Smith, Isaac E. Taylor, William H. Welch, Francis V. White, William T. White, Chas. S. Wood.
New York County Medical Association.—R. L. Miranda, Samuel W. Smith.
Onondaga County Medical Society.—John W. Brown, Amos S. Edwards, George A. Edwards, Alfred Mercer, Hiram Wiggins.
Ontario County Medical Society.—Cassius O. Jackson.
Rensselaer County Medical Society.—Charles S. Allen, D. D. Bucklin, E. D. Ferguson, R. D. Traver.
Sullivan County Medical Society.—W. W. Appley.
Union Medical Association of Vermont and New York Counties.—Wm. Wotkyns Seymour.
Washington County Medical Society.—A. J. Long.
Wayne County Medical Society.—John Franklin Mains.
West Chester County Medical Society.—Edward F. Brush.
Permanent Members.—Edward Ames, A. N. Bell, George H. Bennett, Reed B. Bontecou, J. H. Hobart Burge, Ephraim Cutter, Albert G. Ellinwood, Thomas M. Flandran, Patrick H. Flood, Peter Y. Frye, J. O. Hannam, Morris H. Henry, Robert Newman, Henry N. Porter, W. W. Potter, Ira B. Read, W. H. Robb, John O. Roe, James M. Rose, John P. Sharer, Henry M. Silver, Joseph T. Smith, George T. Stevens, James R. Taylor, D. B. Whitney.

NORTH CAROLINA.

State Medical Society.—Eugene Grissom, Charles James O'Hagan, James Daniel Roberts, F. M. Rountree, Thomas F. Wood.

OHIO.

State Medical Society.—D. D. Bramble, George A. Collamore, Howard Culbertson, James A. Duncan, E. W. Howard, E. H. Hyatt, Ben S. Leonard, John A. Murphy, Wm. J. Scott, X. C. Scott, Edwin Sinnett, Joseph T. Woods.
Northeast Ohio Medical Association.—William Snowden Battle, Amos B. Fuller, R. Harvey Reed, A. W. Ridenour, James D. Robison, George L. Stair.
Northern Central Ohio Medical Association.—Benj. Franklin Harvey, Hiram R. Kelly, Frank C. Larimore, Isaac A. Myers, W. H. Sykes.
Northwestern Ohio Medical Association.—A. Hurd, W. W. Jones, Jonathan B. Vail.
Brown County Academy of Medicine.—Wm. W. Ellsberry, Thos. Winslow Gordon.
Butler County Medical Society.—Dan. Millikin.
Clark County Medical Society.—John M. Buckingham.
Columbiana and Adjoining Counties Medical Society.—Jacob Bossert.
Champaigne County Medical Society.—Samuel M. Mosgrove.
Cincinnati Academy of Medicine.—Julia W. Carpenter, John L. Cleveland, Phineas Sanborn Conner, James M. French, Archibald E. Heighway, William W. Seely, C. O. Wright, James T. Whittaker, Gustav Zinke.
Cincinnati Medical Society.—C. G. Comegys, Nathaniel P. Dandridge, B. P. Goode, O. D. Norton, Jr., Wm. H. Taylor.
Cuyahoga County Medical Society.—Henry Z. Gill, J. M. Lathrop, H. G. Sherman.
Defiance County Medical Society.—W. S. Powell.
Delamater Medical Society.—Albert N. Read.
Erie County Medical Society.—Charles Graefe.
Hempstead Academy of Medicine.—Edwin S. Ricketts.
Holmes County Medical Society.—Simon P. Wise.
Mahoning County Medical Society.—Robert D. Gibson.
Miami County Medical Society.—J. Frank Gabriel.
Miami Valley Medical Association.—Gustave L. Kriegh.
Montgomery County Medical Society.—Alfred H. Stephens.
Portage County Medical Society.—Alexander W. Alcorn, Aaron M. Sherman.
Preble County Medical Society.—Jacob D. Haynie.
Ross County Medical Society.—Gustavus Scott Franklin.
Toledo Medical Society.—Oshea S. Brighan, Harrison Hathaway.
Trumbull County Medical Society.—F. Caspar.
Tuscarawas County Medical Society.—S. L. McCurdy.
Wayne County Medical Society.—A. B. Ferris, Hugh H. Hart, Eli D. Pocock, Joseph H. Todd.
Zanesville Academy of Medicine.—Alfred Ball.
Permanent Members.—T. J. Barton, Albert Beach, Wm. Morrow Beach, Austin C. Brant, A. J. Brockett, Alfred H. Brundage, Wm. H. Bunce, Alexander Dunlap, N. S. Everhard, C. C. Hildreth, John G. F. LIBRARIAN'S REPORT.

WASHINGTON, D. C., MAY 8, 1884.

Mr. President:—I have the honor to present the accompanying catalogue of additions made to this library by donations, exchange and subscription during the past year. It will be seen from the catalogue that since my last report 249 distinct titles have been added, including forty volumes of Transactions, Reports of hospitals, boards of health and volumes of medical journals not previously received and catalogued as such. The library thus increased, now contains 2,066 distinct titles, comprehending about 6,000 volumes, including pamphlets.

This rapid growth during the past year, which is in striking contrast with that of former years, is due mainly, if indeed not altogether, to the publication of the JOURNAL of the Association, to which books are sent for review and thus reach the library. But, while the increase in the number as well as value of the publications reaching its shelves is very gratifying, it at the same time has led to overcrowding of the space now at its command, and hence is greatly in need of better accommodations than are now afforded in one of the towers of the Smithsonian Institution, if ever it is to become useful to the members of the Association and to the profession at large. I would therefore respectfully recommend that a committee be appointed for the purpose of devising means by which this collection, so rapidly growing in point of numbers as well as value, may be housed in quarters better adapted to the purposes of a library.

I also respectfully recommend that the home and foreign exchanges be continued and, wherever possible, increased; that $200 be placed at the disposal of the Librarian, to be expended for the purpose of binding and purchase of periodicals, proceedings and transactions to complete sets already in our possession; also, that the subscription of $50 to the Index Medicus be continued for the present calendar year, and under the same conditions as have obtained heretofore.

In conclusion, I desire to express my thanks to the Editor of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION for the active part taken in building up the library by the prompt and regular transmission to me of books, pamphlets, journals, etc., sent to him for review or as exchanges.

Respectfully submitted,

C. H. A. KLEINSCHMIDT, M.D., *Librarian.*

3113 N. St., Washington, D. C.

SOME CURIOUS MORTALITY STATISTICS.—Dr. William Pratt, of London, in his address to young men, gives these facts: According to statistics, the married life is not only the purer, producing the minimum of evil-doers and criminals, but it is also by far the most healthy. Take the male sex, and it is seen that from twenty-five to thirty years of age, 1,000 married men furnish 6 deaths; 1,000 bachelors furnish 10 deaths; 1,000 widowers furnish 22 deaths. The figures, however, become very unfavorable if the marriage be contracted before twenty. Out of 8,000 young men married before twenty, their mortality has been found to be, before marriage, only 7 per 1,000; after marriage, 50 per 1,000. With respect to the female sex we find a similar advantage of marriage over celibacy, but on the same condition. If young girls be turned into wives before twenty a like mortality befalls them which befalls the other sex. Everywhere young married people from eighteen to twenty years of age die as fast as old people from sixty to seventy years of age. The common sense and common law of Western Europe have with perfect justice marked twenty-one as the age of maturity. After that epoch, however, marriage should be contracted as soon as practicable. It is the healthiest and the happiest life; the best for the individual and for the community.

REMARKABLE INSTANCES OF APHASIA.—Brown-Sequard, in the *Société de Biologie*, referred to a case of aphasia where the individual only had three words at his command, yet he sang admirably, and while singing made use of the words of the song. A physician in Cincinnati, who is suffering from aphasia, talks in his sleep at night. A third case is able to speak when delirious.

THE

Journal of American Medical Association.

PUBLISHED WEEKLY.

THE EDITOR of this JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information, should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE..... $5,00.
SINGLE COPIES..... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 65 RANDOLPH STREET,
CHICAGO, ILLINOIS

SATURDAY, JUNE 28, 1884.

CLOSE OF THE VOLUME AND OF THE FIRST YEAR.—The present number of the JOURNAL completes the second volume, and closes the first year of its publication. In accordance with the By-laws and Regulations of the American Medical Association it contains, besides the title page and full index to the volume, the Constitution and By-laws or plan of organization, the Code of Ethics, and the roll of members who attended the recent meeting in Washington. These matters have left but little room for anything else in this number. The title page and index, though stitched in the middle of the number, are so folded that the binder can readily remove them to the proper place whenever the volume is placed in his hands for binding. Each member of the Association now finds himself in possession of two large volumes, containing in addition to all the papers and other matter, that formerly filled the annual volume of transactions, a large variety of important papers read to other medical organizations; a considerable number of valuable original contributions accompanied by many well executed illustrations; a rich summary of "Medical Progress" culled from the most complete collection of medical literature to be found in any country; and a great variety of editorial and miscellaneous items of more or less special interest to members of the Association. And he has received all this in weekly instalments, when fresh, and as fast as his time would allow him to read it, instead of about one-sixth as much matter in a single volume at the end of a year after it had been written. It is presumed that the number of members who would wish the Association to return to the former method of publication is very small. That there are many imperfections in the work of the past year is freely admitted. Yet we are willing that the numbers issued during the last three or four months should be compared, in reference to all that relates to style of publication, with the best weekly medical publications in this country. An occasional typographical error is common to all periodical publications.

It is not many months since the *New York Medical Journal*, certainly one of the most correct usually, had something less than half a column of corections of typographical errors that had occurred in the publication of a single lecture. And within the last three weeks the *Record*, whose editor is so fond of criticising others, represented Dr. Alfred Stillé as resigning the Chair of Theory and Practice of Medicine in the *Jefferson Medical College*, and Dr. William Pepper as having been appointed his successor, at least, so says our correspondent at Tecumseh. Had either of these blunders occurred in this JOURNAL or any other outside of "one of the great *eastern* cities," it would have been held up as a sample of incompetent provincial work for the next six months. We do not allude to this, however, in deprecation of any just criticism. On the contrary, every wise man profits by the criticisms bestowed upon his work whether friendly or unfriendly. Having passed the ordeal of the initial year, and ascertained more definitely both our defects and our resources, we shall enter upon the second year more perfectly prepared to remedy the first, and by so using the second as to command a much greater amount of editorial assistance, make the JOURNAL in the future fully equal to the reasonable expectations of its patrons.

ÆTIOLOGY OF PHTHISIS.—At the conclusion of a lecture delivered at the Royal College of Physicians, London, by Dr. J. Andrews, physician to St. Bartholomews, upon the contagiousness of phthisis, he presents a brief summary in the following words as found in the London *Lancet* for May 10, 1884:

"Finally, allow me to recapitulate the conclusions which I have endeavored to establish as to the ætiology of phthisis with special reference to its contagiousness. None can be more sensible than myself of the many imperfections in the matter and form of my argument.

1. The historico-geographical argument is insufficient to prove that the present distribution of phthisis has been brought about by the carriage along lines of human intercourse of a special morbific germ. Indeed, many of the facts under this head are distinctly antagonistic to any such theory.

2. Before the discovery of the bacillus, one and all of the reputed causes of phthisis were inadequate to account for its distribution, or for the anatomical and clinical characters of the disease.

3. That these causes, even those among them which appeared to act as exciting causes, were all predisposing causes only.

4. That from the nature of these predisposing causes, their relation to each other, and the conditions under which their influence seemed to make itself felt, it was a probable inference that phthisis belonged to the group of specific febrile diseases, and that this view was held by some writers in the face of many difficulties and perplexities.

5. That the facts on which this inference was based were insufficient to prove that phthisis was personally contagious, and were indeed rather opposed to any such notion.

6. That the discovery of the bacillus proved that phthisis was a specific febrile disease, and thus the question of contagion cannot now be usefully discussed without acknowledging this fact.

7. That as some specific febrile diseases are contagious, and others not so, this property existing in very different degrees and modes in different members of the group, the question as to the contagiousness of phthisis can only be satisfactorily answered by direct evidence of its contagiousness and by determining its affinities with other members of the group.

8. That although phthisis may be undoubtedly produced in many ways experimentally in animals and also probably in man, there is not sufficient evidence to prove that its prevalence is materially affected by direct contagion.

9. That in many most important respects it very closely resembles ague.

10. That it is at least highly probable that the exciting cause of phthisis, like that of ague, be it the bacillus or some other micro-organism, is in no way dependent upon man for its existence, and is widely diffused, irrespective of human agency.

From these I may be allowed to make one short practical deduction—namely, that the prevention of phthisis, like that of ague, is to be attained by sanitary works, especially by improved ventilation and drainage, and not by isolation. And that for its cure, as we should not send a case of ague to the Pontine Marshes, so, too, it would be wise not to send a case of tubercular disease to any place where the death-rate from phthisis is high among the native population."

The inference announced in the fourth paragraph above, that phthisis belongs to the group of "specific febrile diseases," coupled with the ninth declaration "that in many most important respects it very closely resembles ague," would strike the clinical observer, accustomed to seek for differences as well as analogies in practical work at the bed-side, with surprise if the day of surprises at the announcement of anything in medicine had not passed by.

We had supposed that the group of affections denominated "specific febrile diseases," were universally conceded to be acute affections, characterized by certain febrile phenomena, an approach to a self-limited duration, and certainly destitute of any semblance of propagation by hereditary influence. On the other hand, it is doubtful whether any other disease in the whole catalogue of human ailments is accompanied by more evidences of hereditary influence in its causation than tubercular phthisis, or that more frequently develops through its early stages without febrile phenomena, without the least approach to definiteness of duration, and not untrequently the tubercular developments in various tissues so latent as to create no suspicion of their existence until revealed by a postmortem examination. If the presence of a bacillus in phthisis constitutes it a specific febrile disease, and justifies its being put into the same group with ague, we might as well at once include in that one group, all the affections to which the human race are liable. For, so far as examinations have been made, we have found none in which the presence of some variety of organic germ or microbe was not present during some part of the progress of the disease.

Vaccination as a Preventive of Hydrophobia and Yellow Fever.—While M. Pasteur claims to have more than twenty dogs which he has rendered no longer susceptible to attacks of hydrophobia by inoculating them with the virus of that disease, after it had been attenuated or diluted by passing through several monkeys and rabbits; Dr. Domingo Freire, of Rio Janeiro, claims to have discovered the specific virus of yellow fever, and after inoculating some of the lower animals with it, he had used the diluted virus for vaccinating several hundred persons, and rendering them unsusceptible to the fever. Dr. Freire represents the specific virus or cause of yellow fever to be a vegetable parasite, which he has named cryptococcus xanthogenius. By what processes his discovery was made we are not yet informed; neither have we sufficient knowledge of the tests to which the 400 inoculated persons have been subjected, to establish our faith in the reliability of the claims, so confidently expressed.

A Diploma by Mandamus.—The Woman's Medical College in New York is represented to have granted a diploma to one of its recent candidates under a threat of mandamus from some court, after the candidate had first been rejected. It was claimed

on the part of the candidate and her legal advisers, that the examinations for degrees being in writing, and the written answers of the candidate being sufficiently correct, the authorities of the college had no right to reject the candidate on other grounds. The same legal threats were persistently made in reference to one of the colleges in this city, a few years since, but not with the same effect upon the Faculty and Trustees of the College.

EPIDEMIC CHOLERA.—A telegram from Paris on the 23d inst. announces the outbreak of this dreaded scourge in Toulon, France, where twenty deaths are reported to have occurred in one day.

The soldiers have been removed from the barracks, active sanitary measures adopted, and rigid quarantine established in every direction. As usual, the disease commenced in the old, filthy part of the city, in the midst of the most unsanitary local conditions.

SOCIETY PROCEEDINGS.

CHICAGO MEDICAL SOCIETY.

Regular meeting May 19, 1884.

Exhibition of specimens of a monolocular ovarian cyst, weight 24 pounds; and uterine myoma, weight 35 pounds; in each of which there was recovery after the operation. The first case was presented by Dr. Charles T. Parkes, and was a most perfect specimen of a large single ovarian cyst, removed from a girl aged 19, four days previously, at one of the hospitals of the city. His remarks, verbally, were that she had been troubled during the past three years with increasing abdominal distension, and had been treated by a number of physicians during the first two years and a half for dropsy, when six months ago the patient was directed to him, and a diagnosis of monolocular ovarian cyst was made. It continued to gradually increase in size until the circumference of the abdomen measured 44 inches. She enjoyed good health, and there were no symptoms of inconvenience especially worth relating. Upon palpation and percussing the tumor, a simple wave was quite perceptible, nor were there present any symptoms of its being polycystic in character, or that there would be found many adhesions. The operation was, therefore, extremely simple. An incision 3½ inches long, sufficient to admit three fingers in the opening, was made, the tumor tapped, and 23 pounds of fluid were drawn from it. There was a very broad pedicle, which is characteristic of this form of ovarian cyst. There were no adhesions, either to intestines or omentum. The speaker here exhibited the sac to the members. When emptied it weighed just one pound. Inflated with air, it showed no corrugations, and, as above stated, was of the most perfectly developed character. There was but slight hæmorrhage from its removal; this was controlled with double ligatures. Since the operation, at no time has the temperature of the patient risen above 99⅕° F., pulse 100, and at this time these conditions are normal, and the young lady bids fair for an auspicious convalescence.

Dr. E. C. Dudley then recited, also verbally, the history of a case that is both rare and interesting, of which the following report is appended: The patient was a Norwegian woman, aged 48, a domestic, and had never been married, nor had she ever become enciente; and two years ago last fall her menstrual periods ceased. On the afternoon of the 17th day of March of the present year, the operation for the removal of this enormous mass was performed by Dr. Dudley. When he first saw the patient, upon examination it was supposed to be a large fibroid with extensive adhesions. The tumor developed in the left side of the pelvis, and of course there was no tympanitis on that side. There was a line of resonance, however, over the transverse colon, extending eight or nine inches. The cervix uteri could scarcely be reached per vaginam, and no outline of the vaginal portion of the cervix could be perceived, and by manual examination and other means a hard tumor of unusual dimensions could be outlined. His prognosis was fatal without operation, and with hardly a hope of recovery if operated upon. The patient went away, and in a few days returned to inquire if the operation was surely a fatal one. Answered no, not positively fatal, but was the only possible chance of prolonging her life much longer. Again she took her departure, and the third time called to consult him. The same advice was repeated, but more cautiously, for she had become more anæmic, and almost cadaveric in appearance from emaciation, dyspnœa, gastric disturbance, etc. It was decided to perform the operation with the able assistance of Drs. R. N. Isham, C. Fenger, W. W. Jaggard, W. P. Verity, George Isham, and a medical student.

Before doing so, however, the patient was handled for two days with the greatest care preparatory to the great ordeal in which she was about to enter. Having during this time had two Turkish baths, the room divested of every particle of furniture; the carpets, curtains and all else were removed. The ceiling and walls were calcimined, wood-work cleaned, and the room was subjected to fumes of burning sulphur for twenty-four hours, and everything about the surroundings thoroughly disinfected, her abdomen had been freely abluted with dilute solutions of corrosive sublimate. The hair over the pubes and vulva was shaved, and every possible care to avoid infection by scrupulous cleanliness was thoroughly attended to. The ligatures to be used were boiled in 95 per cent. carbolic acid for ten minutes, and then in a 5 per cent. solution for half an hour. All instruments were subjected to the flame and then carbolized. The operators and all hands assisting were washed in carbolized water, and we began by anæsthetizing our patient (ether being used.) An incision from the

umbilicus upwards to within two inches of the ensiform cartilage was then made, this being eighteen inches in length. The reason the incision was thus made (upwards) was because it was supposed the bladder was attached to the tumor, which event was subsequently disclosed as the bladder was drawn up to the umbilicus, and had the incision been made downwards, this organ would surely have been incised, as it was found to be adherent over the anterior surface of the tumor. Even as it was, the urachus was cut and opened, and this was followed by a spirt of urine. A large bundle of vessels was also cut into, which very much resembled intestine; these, however, were with some difficulty safely ligated. As stated above, the tumor sprung from the left side of the uterus, and there it had developed to the enormous size here exhibited. The broad ligament was involved in it, and the surface cut away, as was shown by the specimen, is equal fully to a square foot in diameter in all directions. The enucleation was singularly easy. The posterior surface was adherent to the peritonæum which was very firmly attached. The bladder, however, was easily peeled off. Having advanced this far with the operation which required fully an hour and a half before the pedicle was secured, which was done by an elastic ligature, consisting of a solid rubber cord one-fourth of an inch in diameter and placed four times around it, thus the tumor was isolated or secured and severed, which upon all sides is not less than one foot in diameter. Then another tumor at least the size of a fœtal skull filled the pelvis minor. This lesser tumor originated from the posterior wall of the uterus, and it is singular that the functions of the rectum and bladder had not been more seriously interfered with. The smaller tumor also required a ligature, and the same kind exactly was utilized as was used for the larger tumor, but the tumor was only the size of the closed fist. The large tumor was exceedingly vascular. Esmarch's bandage was first applied to this, but it slipped off. This was found to be impracticable, and as a matter of course, much valuable time was lost in essaying to do this. The patient was to all appearances nearer dead than alive, but the operation was as yet not completed, as a considerable portion of the larger tumor remained. This portion of it was also of considerable size which (was then shown) the operator being pleased to call it a shaving. This mass was as large as the two hands placed beside each other and was correspondingly thick, being two to three inches in thickness over its entire extent. A clamp and two drainage-tubes were then introduced, while the parts were cleansed very carefully with antiseptic solutions of weak carbolized water, and the minor details, such as closure of the wound and the parts carefully adjusted, were thoroughly attended to. His patient was placed in bed with pulse scarcely perceptible, and the operation was declared complete. She rallied from the shock, and for the first eight days she was conscious. Her temperature during this time ranged from 98° to 101° F., and the pulse 100 to 120. There was considerable flatus which passed downwards. All of these symptoms were regarded as being favorable to the patient. On the ninth day her temperature rose to 102° morning and evening 103°., and the pulse became correspondingly accelerated. On the eleventh and twelfth days her temperature rose to 104½°, and her pulse and respiration kept an even pace, having become alarmingly increased.

In consultation with Dr. R. Tilley and Dr. C. Fenger, we carefully examined the lower portion of her abdomen, and discovered pus forming. The former gentlemen administered ether again, and this pus cavity was explored, and fully one-half pint of fœtid pus was evacuated by an opening through the uterus.

A drainage-tube was passed into Douglas' cul-de-sac through the opening thus made, and the cavity of this abscess below the pelvic organs was washed out with weak solutions of carbolic acid. Through the counter-opening thus made a large quantity of matter was discharged during the succeeding few days. During the next two days her temperature fell to 101°, with pulse of 100, and no chills. She continued to remain about in this condition, with a temperature of 100° to 101°, until the 27th day, when one of the drainage-tubes through this last opening was removed, and also the lesser ligature, or the smaller rubber cord. At this procedure her temperature advanced a little. There was but little absorption of the ligature (which was shown to the Society). On the 37th day after the operation, the large double ligature consisting of the rubber cord was removed, and a considerable sloughing mass came away with it. After four days more, the drainage-tube was withdrawn from the cul-de-sac, and this opening into the womb and vagina closed spontaneously. Through this, the operator stated, a very large amount of pus had discharged, and the patient continued to improve until the 17th of the present month, *i. e.*, 60 days after the operation. Her temperature then arose to 101°, or perhaps a little above this point. Being hastily summoned to see her, the cause assigned for this state of affairs was, that the patient injudiciously exposed herself to a draft of air the day previously by arising from her bed and sitting at the open window for some moments. The next day her temperature had risen to 102°, accompanied by considerable fever. However, under suitable measures, this evening, which is the 63rd day after the operation, all her symptoms have again improved, and there can be no doubt as to her final recovery. Throughout the entire treatment of the wound, it was dressed with iodoform insufflations, and the drainage-tubes were at all times carbolized. Of late she has taken a large amount of food three times a day. There is no pallor in her face and lips, she has greatly increased in flesh, and she sleeps well.

This case illustrates a few things: first, that any amount of operating in the pelvic cavity of a patient may be done and recovery ensue; also that this variety of tumor may be removed as safely as it was formerly supposed an ovarian cyst could be. That in operations in the abdominal cavity, hæmorrhage is the chief source of danger, although sepsis through the uterus is another danger that we must well look after. Again, regarding ligatures; a silver

or silk ligature shrinks. Rubber cords doubled twice, as explained above, were employed in this case, and their contractile force proved advantageous. Other complications may arise. The operator stated that in the foregoing case, the patient had diarrhœa and a very sore mouth at one time.

In the discussion regarding diagnosis of these tumors, and also to differentiate them from other varieties, Dr. Parkes stated this to be a difficult question for doctors to consider. No exact set of rules can be given for this, except to investigate what we have to deal with by cutting into it. The symptom of difference is wide between myoma and ovarian tumors, of either monocystic or polycystic variety; but much difficulty may arise in our attempting to decide which variety of the latter we may have. The uterine sound, percussion, palpation, history of case, etc., will enable us to differentiate these growths, unless two or more varieties are blended together. As to an ovarian cyst of moderate size, and a multiple fibroma, he thought we could pretty accurately decide which we have before us to deal with.

Multiple fibromæ are difficult to remove. He had operated three times for this variety, and all the cases had died. Yet a physician is justified in advising an operation for their removal, and the chances of recovery are as good as when ovariotomy was performed years ago. Regarding his cases, one of the tumors removed weighed forty-two pounds. This patient lived five days after its removal and then died of exhaustion. In the other cases he operated upon, there were many fibroids, all of which were removed, but the cases later proved fatal. Dr. Dudley's case was extremely interesting, from its vast size, and the many other points he mentioned. There is no doubt about the pedicle as being an item of great interest in these cases, and should be secured by the extra peritoneal method as Dr. Dudley had done. This fastening of the pedicle outside is the only safe way to secure it, and not by the intra-peritoneal method. The case to which we have all listened with so much interest, will go on record as one of the many great operations of abdominal surgery (followed by success) that have been performed in the United States.

Dr. J. R. Flood spoke of the great interest centered in this case of "Uterine Fibromæ," and that it was certainly a triumph considering the magnitude of the specimen lying on the table.

Dr. G. H. Randall inquired if it would have been practicable to remove the uterus in the case cited here.

Dr. R. Tilley could bear testimony to the extensive adhesions and extreme emaciation in the case of uterine myoma; also that at the time of the evacuation of pus, he thinks that at least a pint or a pint and a half was discharged within three to five minutes, and that Dr. Dudley had so much under-estimated the quantity that he felt justified in making the correction.

Dr. L. H. Montgomery inquired of the operator: How much of the incision of eighteen inches in length yet remained open? He also presumed that when this was made, that it did not contract, as in cases of ovarian cystic tumors, which could be tapped and the fluid withdrawn, and where the incision would be much less in length. This gentleman thought both these cases reported were of so great interest, that inasmuch as the annual meeting of the Illinois State Medical Society was to be held in the city during the week, that each of them be requested to present the specimens before that Society. He thought these cases should both go on record, and that Dr. Dudley, especially, should have had his written; but that the oral report which he has given embraced undoubtedly the main points of his case.

Dr. J. H. Etheridge inquired what the depth of the uterine cavity was before the operation?

Dr. Dudley closed the discussion by first replying to the interrogatories propounded. Regarding the the depth of the uterus. This was nearly normal. It being only about three inches. Regarding the opening at this date, it has united along its entire length, except a small space only sufficiently large to admit the tip of his little finger; and further, as one speaker has stated, the incision was 18 inches long at first, and did not contract as if the removal had been an ovarian cyst.

Extra-peritoneal treatment is sometimes quite impossible to carry out. In his case nature had assisted in changing the intra-peritoneal treatment of the pedicle to extra-peritoneal, which saved the woman. One thing he omitted to mention in the treatment of this case. It was that a portion of the time it was necessary to insert disinfectant sponges in the cavity, and at one time these were soaked in weak solutions of corrosive sublimate. Perhaps only 1 part to 20,000 of water, which is said to be sufficient to destroy germs.

Upon motion of Dr. J. F. Williams, duly seconded, the authors of the cases reported this evening, were requested to present their cases before the Illinois State Society.

On motion the Society adjourned until the second Monday of June. L. H. M.

SUFFOLK DISTRICT MEDICAL SOCIETY.

SECTION FOR CLINICAL MEDICINE, PATHOLOGY, AND HYGIENE.

ALBERT N. BLODGETT, M.D., SECRETARY.

April 9, 1884. Meeting called to order at eight o'clock, Dr. R. T. Edes, Chairman, presiding. A summary of the records of the last meeting was presented by the Secretary.

Dr. F. I. Knight read a paper on the Laryngeal Complications of Pulmonary Phthisis, dwelling especially on those which are considered almost pathognomonic, that is, those of infiltration or ulceration, or both these processes combined. He described at some length the laryngoscopic appearances of these lesions, and said that while they usually followed the pulmonary disease in order of development, they probably preceded it in exceptional cases. The diagnosis was usually not difficult, but in doubtful cases anti-syphilitic treatment should be tried.

The prognosis was undoubtedly bad, but in some cases the laryngeal manifestation entirely disappeared. These cases afford a strong argument against the universal theory of tubercular infiltration.

In regard to treatment Dr. Knight said that a mild climate, or even a warm, moist one, seems to suit these cases better than the cold, dry air of high elevations, which was so beneficial to cases of incipient disease of the lungs alone. Semi-solid food, taken cold, as a rule, suits best.

Judicious local treatment not only makes the patient infinitely more comfortable, but also in certain cases apparently brings about an arrest of the local disease.

The old plan of cauterizing these ulcerations was bad. The whole local treatment of tissues so feebly nourished should be very gentle. In the first place, the mucous membrane should be kept as clean as possible by the use of alkaline sprays. Weak astringents may be added or used afterward. Carbolic acid in weak solution and iodoform do good in some cases. When there is much congestion and swelling, the frequent use of finely-powdered ice was advised. Scarification does no good, but rather harm, unless there is a translucent œdema. Cutting into a small-celled infiltration only makes troublesome cicatrices. The careful passage of bougies into the œsophagus sometimes gives relief, by producing absorption or diminishing the great irritability of the mucous membrane. Morphia powders, combined with sugar or starch, blown into the throat an hour before the principal meal, often gives great ease in deglutition. Mild vapors of volatile substances like the oil of pine, may be very grateful.

Tracheotomy may be necessary to avert asphyxia, but experience has not sustained the theory that cure of the laryngeal disease is facilitated by the rest to the organ secured by an earlier performance of this operation. Brushes, sponges, and all rough methods of making applications to the larynx should be, as a rule, avoided in this disease.

Dr. Cushing stated that he had very little to add in the way of therapeutics to the admirable suggestions contained in Dr. Knight's paper. A consideration of the pathological condition of the tissues surrounding tubercular ulcers, crowded with imperfectly-developed small cells, was sufficient to make any attempt at healing them hopeless. In hospital out-patient practice, and where the smell of iodoform was not objected to, he had found the insufflation of that substance, powdered and mixed with one-half its bulk of gum arabic, to be of great relief. The friends of the patient could easily learn to blow it on to the larynx without any mirror, for if a curved powder-blower were steered beyond the epiglottis, it was easy to diffuse the powder with tolerable accuracy over the diseased surfaces, and even in time the patient could learn to receive it in inspiration, so that a part would come into the trachea, which was often inflamed and ulcerated.

A mixture of morphine in glycerine made pretty strong, so that 10 drops would be a dose, and this applied with a spoon to the back of the tongue, and allowed to trickle down over the larynx, frequently gives great relief.

Dr. Cushing had little respect for the operation of tracheotomy as a means merely of prolonging life in these cases, believing that when bad enough to cause death, it was a kindness not to interfere in such hopeless cases; something might at times be said for the operation when required for relief of pain.

Dr. Cushing, by request, exhibited some of his microscopical preparations of tubercular larynges, showing how the small cells are first deposited along the tracks and at the forks of the smallest vessels; then the swollen mucous membrane of the infiltrated larynx was shown crowded with small cells, which in the neighborhood of the ulcers were so thick that no other tissue was discernible. At the edges of the ulcers it could be easily seen that the agglomeration of small cells had rendered the part incapable of self-support, and that increasing numbers when newly formed must swim off as pus, or keep together as best they could in granulations or badly-nourished vegetations, the origin of some of which was demonstrated. Some sections of the trachea showed a precisely similar process there; the nutritive support of parts of the cartilage of the rings being cut off, the part dies, and is finally thrown off, leaving a deep "punched" ulcer, more or less covered with weak granulations.

Dr. Cushing during his remarks spoke of the fact that cases of tubercular disease of the larynx frequently occur when the most careful examination can find no disease of the lungs until long afterward, and although theoretically it has been maintained that such trouble in the larynx must be secondary to disease in the lungs or cheesy deposits elsewhere, yet practically the throat symptoms are often sufficiently pathognomonic when no disease of the lungs can be detected, and thus constitutional treatment can be commenced or change of climate advised at an early date of the disease, although with poor chance of success. He suggested that, according to modern theories, such cases of apparently primary laryngeal tuberculosis might easily be such in reality, being caused by direct infection from particles or bacilli in the air inspired.

Dr. Hooper remarked that he had been much interested in the paper, and agreed with the reader in the importance of always obtaining confirmatory evidence of disease in the lungs, and a careful history of the patient, before making a diagnosis of laryngeal phthisis. We meet with the diseases in the larynx in more than one variety, and the appearances are so different in the different stages of each variety, that a positive diagnosis cannot be made without undoubted signs of chest lesion. In fact, in all the ulcerative processes of the larynx, whether due to syphilis, carcinoma, lupus, or disease of the lungs, a detailed history of the case, and evidence of disease in some other part of the body, is necessary before we can decide upon the exact nature of the destructive process. Even if we followed the plan of Fränkel and others, and, in doubtful cases, wiped off some of the discharges from the interior of the larynx, and found therein the bacilli peculiar to tubercular disease, we would then only be justified in eliminating with cer-

tainty syphilis and carcinoma; but whether we had to do with lupus, tuberculosis, or even leprosy, would still be an open question, unless, as already stated. we discover other manifestations of one of these tubercular diseases in a different region of the body.

With regard to the question as to tuberculosis occurring primarily in the larynx, Dr. Hooper thought that any one who accepted Koch's discoveries must believe that such could be the case. If the disease in the larynx arises from the presence of the tubercle-bacillus in the sputum coming from the lung, why should not the same specific parasite, when inhaled, produce tuberculization of the tissues, provided always, of course, that the laryngeal mucous membrane is in a proper condition to receive it, and there is an hereditary predisposition on the part of the individual.

In respect to treatment, Dr. Hooper had nothing to add to what had already been said, but was of the opinion that tracheotomy, in certain exquisitely painful cases, might afford relief by keeping the larynx at rest. The operation offers no hope of cure or of prolonging life, but only affords temporary relief from distress.

Dr. T. A. DeBlois said that often a great amount of comfort may be derived from scarifying the ary-epiglottic folds in those cases which are accompanied by much swelling, so that the epiglottis cannot properly close, and the patient is constantly choking from particles of food or drink which enter the air-passages with each act of deglutition. He has never seen any undesirable result follow this procedure. He never has observed ulceration of the cicatrix in these cases. In two cases he has seen laryngeal ulcerations heal under the use of iodoform, but in each case they broke down again after a few weeks. In one case in which the patient had been able to take no solid food for months, by the use of iodoform he was able to resume solid food for another full month. No other known form of treatment has ever accomplished more favorable results.

Dr. DeBlois showed an improved form of powder-blower for laryngological purposes.

Dr. W. J. Otis showed a powder-blower of a pattern originally brought from Vienna, but upon which he had adapted improvements which facilitated its manipulation and added to its usefulness.

In connection with the use of iodoform in tuberculosis of the larynx, Dr. E. W. Warren stated that he was working in Schrötter's wards in Vienna at the time when this became the regular treatment. Before this about one-fourth of a grain of morphia was blown in. The improvement was very marked, and though not recalling that he saw any ulcers entirely heal, there was great diminution of infiltration, and the pain was less than under the morphia.

Dr. J. W. Farlow remarked that he had seen laryngeal ulcers heal, at least temporarily, in dispensary practice under the use of iodoform. A gain of six or eight weeks is a great thing to these poor patients. Often the larynx is diseased for a considerable time before any disease of the lungs can be detected.

Dr. Bowditch agreed with the general tenor of the remarks of Dr. Knight upon the very great value of topical applications in diseases of the larynx, whether connected or not with pulmonary complications. But Dr Bowditch could not wholly condemn the use of the nitrate of silver as injurious in these cases. It is well known that the late Dr. Horace Green, of New York, published nearly forty years ago a volume[1] the object of which was to convince the medical profession that nitrate of silver applied at times in a strength of thirty to forty, or even eighty grains to the ounce of water, might be applied not only without danger to the larynx, but at times with great relief and final cure in some of the most obstinate and long-continued cases of "laryngeal disease." Dr. Green also applied the solid caustic to specially enlarged follicles in the throat. Dr. Bowditch, however, had gradually given up the nitrate of silver for the liquor iodinii compositus, as the latter seems more agreeable to the patient and is equally efficient. Dr. Bowditch, moreover, without employing the laryngoscope, for his powers of sight prevented it, had always used a fine camel's hair brush. With this he was sure that he could touch the vocal cords, often without the least choking. He knew so because the voice improved *immediately* in certain acute cases, and patients were cured after a certain number of such applications, made usually three times a week, and gargling with alkaline or other fluids three times daily. Dr. Bowditch found all spraying and powder-blowing objectionable, because of the choking that is often produced by them. Moreover, an expensive apparatus is needed, whereas the brush is a simple apparatus, which every general practitioner can and ought to have.

There is, however, some art needed in making the application. One case that happened soon after commencing the course of topical applications, had taught Dr. Bowditch that the operator must always be sure that the patient has *drawn a full breath, and is about to expire.* Let the cords be touched *at that moment* and no spasm will occur. Let, on the contrary, the touch be made at the instant of inspiration, and violent results may occur. In the case above alluded to, and in which this blunder was committed, the patient threw himself upon the floor, and for a time *seemed* choking. No evil resulted, but a very great discomfort, which latter should be avoided if possible. In addition to the above rules, Dr. Bowditch is accustomed, before treating the larynx, to make an application to each tonsil and to the back of the throat, allowing the patient to breathe in the intervals. In this way the patient will be gradually led to believe that the final operation will be equally slight. It usually causes *no trouble*, except heat in the parts, although the patient feels that the operator has "touched the spot." Often a clearer voice and ease in speaking will be apparent in a few minutes.

Dr. Bowditch would dwell upon the various points in this simple operation, because each one is important for the *comfortable* performance of it.

Any discussion of the subject of laryngeal phthisis, brings up a great number of important questions:

[1] A Treatise on Diseases of the Air Passages. . . . Chronic Laryngitis, Clergyman's Sore Throat, etc. New York and London: Wiley & Putnam. 1846.

What do we know about tubercle at present? How may we recognize tubercular from other forms of ulceration? Each of these single topics would form an inexhaustible subject of investigation and discussion.

Dr. Knight thought that Dr. Bowditch's method of applying medicines was a very good one, and would undoubtedly be a safe one to follow. There can be little doubt that tuberculous ulcers may sometimes heal, and the enormous swelling and other symptoms may quite disappear. Unquestionably this conduces greatly to the patient's comfort for a part, and frequently for the whole remaining period of life. In regard to the possible arrest of the laryngeal disease, three remarkable cases came to his mind at the minute. In all three the swelling of the cartilages was very great, the ulceration well marked, and the dysphagia distressing. There were positive signs of pulmonary disease in the first two, but not in the third. The swelling and ulceration almost entirely disappeared, and deglutition was relieved in the first two, but the patients died, one with symptoms of meningeal tuberculosis. In the third, the signs and symptoms disappeared, with the exception of slight swelling of the epiglottis, and slight loss of substance in one vocal cord, and the patient has remained well, without any tubercular symptoms in larynx or lungs, for a year.

Dr. J. V. Mott, of New York, asked the reader if he had observed the effect of iodide of potassium internally in laryngeal phthisis? To which Dr. Knight replied that he had seen no beneficial result from its employment, except in mixed cases, or those which were undoubtedly syphilitic.

Dr. Mott remarked that this medicine was much used in the Metropolitan Hospital, in New York, but the character of the cases is often very difficult to determine, as syphilis is frequently present.

In reply to a question as to the utility of general treatment, and the results to the patients, Dr. Knight replied that hygienic and other appropriate methods of treatment should be diligently pursued in all these cases. The value of topical applications is much enhanced by a generally invigorating treatment for the whole system.

DOMESTIC CORRESPONDENCE.

DR. N. S. DAVIS:

Dear Sir:—The second section of the Report of the Judicial Council of the American Medical Association, at its late meeting, announced that some facts had come to its knowledge rendering it probable that the Cuyahoga County Medical Society had been derelict, in not requiring its members to observe the Code of Ethics.

At the next meeting of the Society after the report was made public in the Association JOURNAL, the committee now addressing you was chosen to present to the Council, through the pages of the JOURNAL, an epitome of the Society's course in connection with the instances of the violation of the Code which have of late been acted upon by it, and which it is supposed have supplied the facts referred to in the Council's report.

The Society numbers some eighty members, and it is not surprising that it should at times have to act upon violations of the Code of more or less gravity.

These cases often involve delicate, embarrassing, and responsible features; and it is not always easy to determine what is just to all concerned, or to satisfy all concerned.

The Society took patient and mature action upon these cases, and while summary excision was not adopted, such a course was taken as seemed probable in brief time to lead those who had infringed on the Code, into full accord with its ethical requirements, expressed and implied. If this had not speedily proved true, decided action would have followed. The Society is and has been loyal to the Code, and naturally feels the Council's animadversion, so publicly dealt. We are confident this would not have occurred if the full history of the questioned cases, with the Society's action thereon, had been appreciated. We do not know what we ought to do. If specific charges had been made, we could reply. We can perhaps do no better than to ask that this outline of our position be published in the JOURNAL, pending the next meeting of the Judicial Council, when the full facts will be respectfully placed before it.

Very respectfully submitted,

H. K. CUSHING, M.D.,
E. D. BURTON, M.D.,
H. H. POWELL, M.D.,
A. S. HART, M.D.,
A. B. CARPENTER, M.D.,
L. B. TUCKERMAN, M.D.,
} Committee.

Per L. B. TUCKERMAN, Cor. Sec.

Cleveland, O., June 11, 1884.

NECROLOGY.

DUNGAN, DAVID H., M.D., of Little Rock, Ark., was born in Maury County, Tennessee, on the 11th day of March, A. D. 1839, died in said city on April 16, 1883.

In the year 1856 he went to Chester, South Carolina, and studied medicine under A. P. Wylie, who was a physician of considerable distinction. He attended his first course of lectures in the Medical Department of the Nashville University in the years 1858 and 1859. From Nashville he went to the University of Pennsylvania, where he graduated M.D. in the year 1861. He located at Thompson's Station, Tenn., in April of the same year. In the month of July ensuing, he entered the confederate army as a private. Soon afterwards, however, he was appointed assistant-surgeon in the second battalion of Tennessee Cavalry, and in October of the same year he went into the Anderson Hospital at Nashville. When the army retreated from Nashville, he was ordered to Chattanooga, Tenn., establishing a hospital there,

and maintaining it about two months. In March of the following year, he sent his patients to Atlanta, Ga., and reported to Gen. Albert Sidney Johnson for duty. After the battle of Corinth, Miss., he was assigned to duty as surgeon of the First Tennessee Regiment of Cavalry, in which capacity he remained till the close of the war. The regiment to which he belonged participated in the battles of Corinth, Chicamauga, Holly Springs, and many others. After the war closed he returned to Thompson's Station, Tenn. He remained there about five years, and in the year 1870 he removed to Little Rock, Ark., and remained there until the time of his death.

As a surgeon, he was possessed of skill, courage and talent, and performed many important operations with success. But a short time prior to his death, he performed tracheotomy on a child, removing a foreign body with success. He was honored with the Presidency of the Little Rock and Pulaski Society, was a member of the State Society of Arkansas, and of the American Medical Association, also of the American Public Health Association, and of the Sanitary Council of the Mississippi Valley. For a number of years he was a member of the Little Rock Board of Health, and was ever active and efficient as such member.

The subject of this sketch was married twice. Miss Alice Thompson, of Thompson's Station, Tenn., was his first consort. His second wife was Mrs. M. M. Lefevre, of Little Rock. He was a man of strong will-power, and when he espoused a course, his strong and earnest advocacy of its claims sometimes subjected him to the charge of stubbornness. His amiable qualities in other respects, however, went far to neutralize any defects in his useful life and valuable character.

H. H. TURNER, M.D., of Arkansas.

MEAD, EDWARD, M.D., was born in England, in 1819; died June 28, 1883, being shipwrecked on the coast of Pico while making a voyage in the Portuguese barque Pimpao to the Azores for recreation and health. Dr. Mead studied medicine early in life, graduating from the Medical College of Ohio, in 1841. He made mental diseases a specialty, was a devoted believer in his profession, and successfully conducted a private asylum in Chicago, Illinois, from 1842 to 1852, removing in the latter year to Cincinnati, Ohio, where he resided till 1869. He held for a time a professorship in the Illinois Medical College, and later a similar one in the Cincinnati College of Medicine and Surgery. At Cincinnati he filled several public positions, and during the civil war he was an active member of the Sanitary Commission. He came to Boston, Mass., in 1870, and established a private institution two years later. Dr. Mead was a member of the American Medical Association; of the Massachusetts Medical Society, and at the time of his death was one of the Councilors of the Norfolk District Medical Society.

RANNEY, MARK, M.D. Prominent among the medical men of Iowa, will stand the name of Dr. Ranney, the able Superintendent of the Hospital for the Insane at Mt. Pleasant. Of medium height, keen intellect, and a somewhat emphatic bearing, his life was active and efficient; more thoroughly appreciated by those who knew him best. Though not in robust health, to all appearances he had many years before him when suddenly claimed by death.

Dr. Ranney was born in Westminster, Windham Co., Vt., July 7, 1827. Having received an academic education, he entered Vermont Medical College, Woodstock, graduating therefrom in June, 1849. Immediately upon his graduation he was appointed Assistant Physician to the Butler Hospital for the Insane, Providence, R. I., where he remained five years under the direction of the distinguished Dr. Isaac Roy. In 1854 he was appointed to the same position in the McLean Asylum, Somerville, Mass., then in charge of the scarcely less distinguished Dr. Luther V. Bell. Here he remained until 1865, when he was elected Superintendent of the Iowa Hospital for the Insane, Mt. Pleasant, Iowa, a position he held continually until his death, save in 1873–75 when he was in charge of the Insane Asylum at Madison, Wis.

Dr. Ranney was an honored member of many medical societies, and for several years was Lecturer on Insanity in the medical department of the Iowa State University. The reports of the Boards of Trustees of the institutions where the doctor spent so many years of valuable life abound in expressions of intelligent appreciation of the character of the services rendered; and the pages of the University records bear unqualified testimony to his ability and worth as a man and teacher. His published works have been papers read before medical societies, and before the Association of Superintendents of Hospitals for the Insane, published in their several transactions.

He married, Oct. 1865, Martha Wright, daughter of Thomas Sawyer, Esq., of Sterling, Mass. He died after an illness of a week, of acute pneumonia, Jan. 31, 1882. S. B. CHASE.

Osage, Iowa.

SAWYER, EDWARD J., M.D., was born August 3, 1829, at West Haven, Vermont; died at his residence in Gardner, Mass., May 10, 1883, of pneumonia. He was the son of Rev. R. Sawyer, of Chester, Vt. His early education was received in New London, N. H., and at the Academy in Chester, Vt. He studied medicine with Dr. Lowell, of Chester, Vt., and attended lectures at the Medical School in Castleton, Vt., from which institution he received the degree of M.D., in June, 1853. In August, 1853, he commenced the practice of his profession at Acworth, N. H., but in 1858 he removed to Gardner, Mass., where he spent the remaining years of his life in active practice. Dr. Sawyer, as a physician, was very successful, and was highly esteemed as an intelligent, honorable, and conscientious practitioner. As a citizen he enjoyed the confidence and respect of his fellow-townsmen. As a Christian he was exemplary in his conduct and an honored member of the church. He was appointed examining physician by Gov. Andrew during the civil war;

was for two years president of the Worcester North District Medical Society; member of the State Medical Society, and of the American Medical Association. Dr. Sawyer was a prominent Mason, having received all the degrees in Masonry that can be conferred in this country. J. H. G.

LOWELL, Mass., June 5, 1884.

KEMP, DR. JOHN D., was born in Montgomery County, O., Oct. 19, 1830.

His parents were Isaac Kemp and Margaret (by birth Herring), he being the youngest of five children born to them. Only two, Lewis and Jacob, are now living. He studied medicine with Drs. Oliver and James Crook, graduated at Baltimore Medical College in the year 1856, commenced the practice of medicine in Vandalia, O., in the same year, and continued at the same place for sixteen years—having an extensive practice. He was married in June, 1871, to Miss Harriet A. Holderman, of Emporia, Kansas.

He then in May, 1872, removed to Dayton and resumed his practice. In October of the same year, he was seriously injured by being thrown from his buggy by a fractious horse, from the effects of which he never entirely recovered. In February, 1873, he was unfortunate in the loss of his wife by death, she leaving a babe but three months old who now survives the deceased. His health has been delicate for two years past, and he died April 17, 1884, aged 53 years.

Dr. Kemp represented Montgomery County in the Legislature for two terms, and he was elected for one term to the Senate by the counties of Montgomery and Preble. For several years previous to his death he was a member of the Board of Trustees of the Southern Ohio Association for the Insane, located at Dayton, O. He was an upright, honest man, respected and esteemed by all who knew him.

MISCELLANEOUS.

AMERICAN PUBLIC HEALTH ASSOCIATION.

SECRETARY'S OFFICE,
CONCORD, N. H., JUNE 2, 1884.

At a meeting of the executive Committee, held at the Museum of Hygiene in the city of Washington, May 7, it was decided to hold the Twelfth Annual Session of the Association on Tuesday, Wednesday, Thursday, and Friday, October 14–17, 1884, at St. Louis, Missouri, and to present the following topics for consideration:

1. Hygiene of the Habitations of the Poor.
2. Hygiene of Occupations.
3. School Hygiene.
4. Adulteration of Food.
5. Water Pollution.
6. Disposal of Sewage by Irrigation or Chemical Action.
7. The Observable Effect upon the Public Health of Official Sanitary Supervision.
8. The Work of Municipal and State Boards of Health.

IRVING A. WATSON, *Sec'y.*

OFFICIAL NOTICE.

ANNUAL DUES from members of the Association—*Five Dollars* per annum—are payable directly to the Treasurer. Such payment entitles them to receive the JOURNAL of the Association for one year.

SUBSCRIPTIONS TO THE JOURNAL from those who are not members should be forwarded to the office of publication, Chicago.

BACK VOLUMES OF THE TRANSACTIONS may be procured, at reduced rates, by addressing the Treasurer.

THE INDEX to the 33 Volumes of Transactions will be forwarded, postpaid, on receipt of *One Dollar* by the Treasurer.

According to a resolution passed May 9, 1884, at the Washington meeting, continuous payment of Annual Dues is required, to retain permanent membership.

RICHARD J. DUNGLISON, M.D.,
Treasurer.

Lock Box 1274, Philadelphia, Pa.
