A METHOD OF DETERMINING AMETROPIA BY PRISMATIC REFRACTION.*

BY H. CULBERTSON, M.D., ASSISTANT SURGEON U. S. ARMY, RETIRED.

About four years ago this subject first occurred to me, and I have at intervals been engaged with it up to the present time. I venture to believe I can present the instrument to the profession as an accurate one to decide quickly what glasses are required in hypermetropia, myopia, and in astigmatism. It does not concern presbyopia.

The problem is to utilize the refraction of a single prism in determining the glasses required. To illustrate, Fig. 1 is necessary. Let *a* represent a normal eye, placed behind an aperture in the diaphragm *b*; and *d* the base of a glass prism, its apex toward *c*, the truncated apex covering one-half of the said aperture. Let *f* be a circle placed in the axial line *f g*, and *g* the projection of said circle upon the retina. Through the aid of parallel rays of light the true image, *f*, is impressed upon the retina at *g*, and thus *f* is seen without the aid of the prism. But a portion of the rays from *f* are oblique, and reach the prism in the dotted line *f i*; these are refracted towards the base *d* of the prism at *l*, and passing onward through the aperture reach the retina at *m*, and returning from *m* to *l* in the same course they entered the eye and prism. They will appear to be refracted, by a well-known law, from *i* to *n*, or in the angle of deviation of the prism. The circle *n* is, therefore, the counterpart of *m*, and it is the false image of *f*. The refracting power of the prism is so arranged, that at a given distance of the prism from the true circle *f* the inner margins of the true (*f*) and false (*n*) circles shall be tangent in the normal eye. It follows that if the eye be hyperopic these images will be seen apart, and if myopic they will be lapped. If now, in hyperopia, we place the proper convex glass at *o*, and covering the aperture, the images will be rendered tangent; and in the case of myopia, a suitable concave glass at the same point, the lapped images will be rendered tangent. Thus, the glass applied is the measure of the ametropia. The distance from *l* to *f* is fixed. The patient has only to say are the images apart or lapped, and when they become tangent.

The prism is fixed to the diaphragm permanently, and the latter revolves in its plane, so that the prism becomes the measure of the ametropia of any meridian, and hence astigmatism is determined by revolving the diaphragm. If all the meridians are lapped or apart, and the corrective glass be applied, as at *o*,

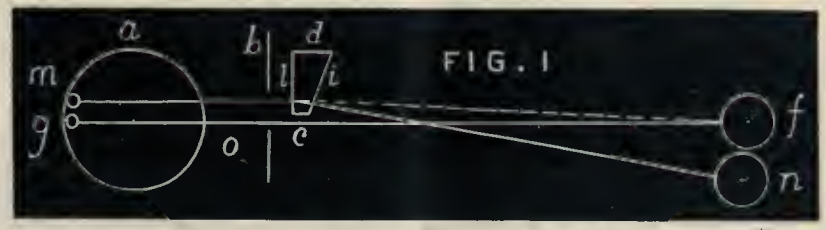

Fig. 1.

Fig. 1, the circles will touch at each meridian as the prism is being revolved, and hence in such a case there is no astigmatism, but simple general myopia or hyperopia.

By such a plan the proper glasses can be selected in a few moments, and the result verified by applying the same in the reading of Snellen's test-types.

The construction of the instrument is as follows. (See Fig. 2.)

Figure 2 represents the back surface of the eye-piece. The disc A revolves on its axis. To this disc is secured by clips a prism, the thin edge of which cuts the central opening F obliquely at an angle of 45°, in its diameter. The portion of brass wire, represented at E, is an index which denotes the degrees of the scale, shown on the back surface of the eye-piece, fig. 2. This index also denotes the *particular meridian* under observation; for with this instrument only one meridian of the eye is examined, and each meridian is tested as the index is turned from 90° to 0°, on the right or on the left side of the vertical meridian, fig. 2. The object of the oblique edge of the prism is to prevent the lateral

*This article was originally published in the Cincinnati *Lancet and Clinic*, January 20, 1883. It appears here as several modifications and improvements have been made in the instrument.

FIG. 2.

BACK SURFACE OF EYE-PIECE.

motion of the head of the observer, causing a variation in the position of the false image and thus falsifying the test.

The central opening, *f*, is in front of the flat surface of the prism, and is exactly in the center of the revolving disc, A, Figure 2. Through this the observer, seated, looks at the object circle placed at a proper distance in front of, and from, the eye-piece; K L is a spring clip for holding the trial glasses. This eye-piece is about four mm. thick; *g* is an upright of about one-fourth inch brass gas tubing, securely attached to the eye-piece, and of convenient length.

luster. The four sides, as at *d* of this shallow box, are each 1 inch in width, and the area of the galvanized iron front surface is 12x12 inches; C C represents two hooks to hang this frame securely against a wall, at some point in an office where the object-circle A can be plainly seen by diffused light. The disc with the prism attached to the eye-piece, is shown at B, and the eye of the observer is drawn at C looking through the central opening O at the object-circle A. The rays of light, E F, emanating from the object-circle, pass through the prism and enter the eye of the observer; and by prismatic deflection a false image, A′, of A, the true circle, will be seen on the front surface of the eye-plate *d*; and if the arrangement is perfect and the eye normal, their inner circumferences will touch, as well as the images at the retina of the eye, as shown at C. The eye-piece B, through the upright K, is secured at *f* by a screw to the solid rod *g*, which plays up and down in the gas tube *h*, and is secured at any point by the thumb-screw *i*. The upright, *h*, is screwed into the head of the tripod *l*, and the lower end of each leg of the latter is adapted to a slot in the plates *p p p*, which plates are screwed permanently to the floor. The foot of each leg can be sprung out of the several plates, and thus the tripod can be readily removed or placed in the clips, and set out of the way, or placed in position for use. The height from the floor to A, and from *p* to O, should correspond—about 44 or 45 inches. From the center of A to the center of O should be an imaginary axial line, and the planes of the eye-disc B and of the anterior surface of *d* should be directly opposed and at right angles to this axial-right-line in every meridian. Thus, as the eye-disc M revolves on its axis in an undeviating plane, the inner margin of the false image A′, will touch the inner edge of the true image A, at each meridian,

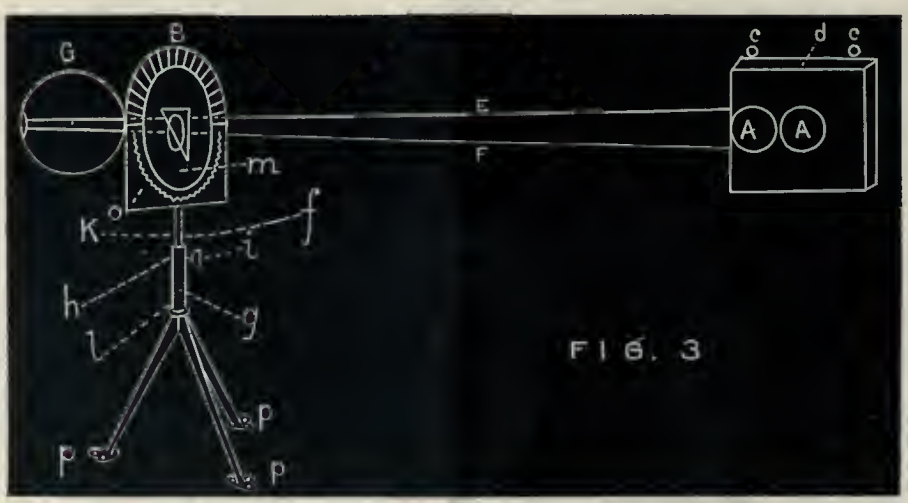

FIG. 3.

Fig. 3 represent the object-circle A, cut out of galvanized iron, behind which rests securely, by clips, a portion of *white opaque glass*, as pure white as possible. The surface of galvanized iron around this *single white circle* is made a deep black color, without

which would not be the case if the eye-disc did not revolve in a true plane.

The measurements are as follows: Diameter of the object-circle, A, 220.5 mm.; diameter of the eye-piece, B 6 inches; diameter of the revolving

disc, A, figure 2, 22 mm.; diameter of the central opening in the revolving disc (see figures 2 and 3), F, 3 mm.; the distance from the object-circle (from A to O,) to the anterior surface of the prism, 3075 mm.

A larger object-circle is not desirable, and if a greater distance between it and the prism is wished, say twenty feet, the deflecting power of the prism must be diminished. A longer space between these will secure a greater separation or lapping of the object-circles, which will enable the patient to see this effect more readily than when nearer to the object.

It is now desired to know the total refracting power of a given prism. To determine this the prism is mounted in the eye-piece, and the central opening exposed to a beam of sunlight, and the two round images of the opening received upon a white, flat surface, the latter placed at right angles to the beam of light, and say 1000 mm. from the anterior surface of the prism. The circumference of these two images is marked off on the white surface, and the distance between the inner edge of one circle and the outer edge of the other measured. This will give the deflecting power of the prism at 1000, which is 71.75 mm. in our prism. What will be the deflecting power of this prism at 3075 mm. from its front surface to the object-circle? This is found by simple proportion. Thus: 1000 : 71.75 : : 3075 : 220.-63125 mm. We construct an object-circle accurately round of 220.5 mm. diameter, in the front surface of the object-plate; and after carefully correcting our own eye, we find that the true and false circles touch at their inner edges. Since now we find the two methods verify each other, the instrument may be assumed to be correct, especially if, on revolving the prism, the inner edges of the object-circles touch at every point of the lower semi-circumference.

What is the deflection of this prism in degrees? This may be determined by the well-known proposition, that, in a right-angled triangle the square of the hypothenuse is equal to the sum of the other sides. It must be remembered that the distance from the prism to object-circle is cosine, and from this, in part, we obtain the radius.

Figure 4 is necessary to illustrate. Let A C be the cosine, 1000 mm. in this case, or one side of the triangle, A B C, and C B, be the other side, 71.75 mm., deflection of the prism at 1000 mm. Describe the arc, E B F G. What is the radius of this arc, or A B the hypothenuse? By the proposition we have the formula $\overline{AC}^2 + \overline{BC}^2 = \overline{AB}^2$. Substituting $\overline{1000}^2 + \overline{71.75}^2 = \overline{AB}^2 = 1000000 + 514{,}0625 = \overline{AB}^2 = 1005148.0625 = \overline{AB}^2$. Extracting square root last quantity AB = 1002.57072 mm. The latter quantity being the radius, the natural sine = the deflection of prism divided by the radius, or $\frac{71.75}{1002.57+} = .071655$. This denotes a prism having a total deflecting power 4° = 6′ 31.2″.

To render the rays of light still more parallel, I have lately increased the distance of the object-circle from the prism to about twenty feet, or 6045 mm., and diminished the refracting power of the prism, which gives a smaller object-circle.

This prism refracts at 1000 mm. 25.5 mm., and at 6045 the refraction is 154.1+ mm., which is the diameter of the object-circle, and agrees with the size of the same circle found by experiment with the corrected eye. The total refraction of this prism is = 0° 8′ 43.8″.

A few examples in the practical use of the instrument may be given:

A young man aged 17 years, on looking through the prism, states that the images are lapped when the index is horizontal. I know he is myopic, because these are lapped in that meridian, and now placing different concave glasses in the clip behind the eye-piece, it is found that a —37-inch glass causes the images to touch in the left eye. On revolving the prism the images separate, and this separation is greatest when the index is at 50° left, corresponding to 40° right axis of the prism. On placing a + 30-inch cylindrical glass, its axis is at 40° right side, the images just touch at that point. I now revolve the prism, leaving both glasses in the clip, and find that the images touch in all the semi-circumference. I place these glasses in a trial frame, the cylindric at an axis of 40° right, and he reads No. 15 Snellen at 15 feet.

In the right eye index horizontal (the defective meridian) the images are lapped; a —37-inch spherical glass brings them together. Turning the index to (left) 60°, the images are apart most at that meridian, and on placing a + 15-inch cylindric its axis at 30° right, the images touch, and now, on revolv-

FIG. 4.

ing the prism, they touch at every point of the semi-circumference. I place these glasses in a trial frame, as above, the axis of the cylindric at 30° right, and he reads No. 15 Snellen at 15 feet. $V_2 = {}^{15}/_{15}$.

CASE 2. A boy æt. 16; index horizontal; sees images lapped; on trial, a concave 21-inch glass brings them together. On revolving the prism, index at 5° right, images are apart most; on placing + 49-inch cylindric, its axis at right angles to the index, or 85° left, the images touch, and on revolving the prism they touch in all the semi-circumference in the right eye, V R$= {}^{15}/_{15}$. In the left eye index horizontal, images lapped; a—21″ spherical glass brings them together. On revolving the prism, index at 5° left, they separate most at that point, and on placing a + 49-inch cylindric, its axis at 85° right, they touch at that degree, and in all the semi-circumference on revolving the prism. I place the above glasses in a trial-frame, and he reads No. 15 Snellen at 15 feet. His astigmatism and myopia are, therefore, corrected.

CASE 3. A gentleman, 54 years old, on looking with his right eye, finds the images apart, index horizontal. By trial, a + 37-inch spherical glass causes the images to touch. On revolving the prism, they touch in all the semi-circumference. I place + 37″ spherics in the trial-frame, and he reads with each eye Snellen ${}^{15}/_{15}$, and with both eyes the same. His hyperopia has been corrected.

CASE 4. A lady, æt. 20, reads unaided with left eye Snellen 200 at 15 feet, and in right, O, Snellen at 15 feet. On looking, she cannot with the right eye distinguish the outlines of the circles, but only a light, blurred appearance. I do not know if she is myopic or hyperopic, but suspect myopia, from the form of the eye. I apply a 30″ concave; she sees better, and finally with a spheric 2½-inch glass the images are distinctly seen to touch, and on revolving the prism they do so in all the semi-circumference. In the trial-frame, with this glass she reads Snellen ${}^{15}/_{50}$.

In the other eye, index horizontal, images blurred —weaker concaves improve the vision, finally—8¼-inch spheric causes the lapped images to touch. On revolving the prism, index to 15° left, the images are lapped (to the greatest extent) again, and on placing by trial a —9¼-inch cylindric, its axis at 75° right, they are brought together, and now they touch in all the semi-circumference. On placing this combination in the trial-frame she reads Snellen ${}^{15}/_{70}$′ & $V_2 = {}^{15}/_{50}$′.

CASE 5. A lady, æt. 25 years, on looking through the instrument with her left eye, finds the images most lapped the index at 5° right, but they touch at the other meridians. A — cylindric of 21 inches, its axis placed at right angles to the index, or at 85° left, causes the object circles to touch. On revolving the prism, the images touch in all the semi-circumference.

The other eye, detected in the same manner, requires a—15-inch cylindric, its axis at 85° right, and now the images touch in all the semi-circumference. She can now read with either eye, and with both ${}^{15}/_{15}$ Snellen, and the simple astigmatism has been corrected.

CASE 6. A young man æt. 22 years, sees with his left eye the images most apart index at 30° right. A + eighteen and one-half inch cylindric, its axis at 60° left (at right angles to the index), causes the images to touch. On revolving the prism index to 30° right the images are most lapped, and a — thirty-seven inch cylindric, its axis at 60° left, causes them to touch. The images now touch in all the semi-circumference on revolving the prism. The other eye requires a + twenty-one inch cylindric, axis 75° right, and a — thirty-seven inch cylindric, axis 15° left. With either eye and both he reads S ${}^{15}/_{15}$, thus his crossed astigmatism has been corrected for each eye.

This instrument, excepting the prism, was made in this place. It need not be expensive, and any one familiar with the subject can set it up. Its description may seem intricate, but, when seen, its construction is quite simple.

All that the observer has to answer, in being tested, is, do the images touch, or are they apart, or do they lap? If apart this denotes hyperopia; if lapped, the patient is myopic. Even children can answer these questions satisfactorily. It is commendable, then, as the observer can at once comprehend his part in the examination.

It is also a great time-saver, a few moments enabling one to determine the glasses required, in the most exact manner.

The name selected for it is PRISOPTOMETER, from *prisma*, prism; *optikos*, optic; and *metron*, measure; denoting a method of estimating ametropia by means of a prism.

Finally, we could have demonstrated fully all the optical problems belonging to this subject, but do not consider it necessary, as these are found in standard works. We only have desired to present the instrument for consideration in a practical manner.

We have modified this instrument in various ways, but have decided this to be the most practical method of using a prism for measuring ametropia. Thus, we tried to use a + six inch glass in combination with the prism, to overcome the action of the ciliary muscle and enable the use of a short tube, to render the instrument more convenient, but this was not effectual in controlling that muscle. Again, we endeavored to use a telescope with the prism, but this would not answer, for the patient simply looked at the near image in the telescope, when the case demands that the object should be placed at quite a distance from the eye of the observer. Numerous other plans were adopted in the use of the prism, but all failed but this upon which we now rely.

It is the duty of the manufacturer to give the distance from the object circle A to the front surface of the prism at O, Fig. 3, for each instrument. The purchaser, in setting up this instrument, should hang up the object-plate *d*, Fig. 3, upon a wall securely, by the hooks *c c*, and place the eye-piece, attached to the tripod, at the distance A O given by the manufacturer. Looking through the aperture O at the object-circle A, Fig. 3, and the index being at 90°, on the *left* side, as at E, Fig. 2, the two images will touch, as at A A′, Fig. 3. Turning the index up to

0°, Fig. 2, the images will touch, and still revolving the index to 90°, on the *right* side, the images will be tangent, and if the images touch at *these three points* the position of the tripod is correct, and the foot-plates, *p p p*, Fig. 3, should be screwed to the floor securely and permanently. Thus the tripod can be removed from the plates, or placed in them when the instrument is in use, and the distance between the eye-piece and the object-plate is always the same when the instrument is in use, WHICH IS ABSOLUTELY ESSENTIAL. *The eye of the party setting up this instrument should be corrected, by test-types and glasses, else he will inflict his errors of refraction upon his patients.*

Messrs. Geo. Tiemann & Co., 67 Chatham street, New York City, are the manufacturers of the instrument.

Zanesville, O., Oct. 26, 1883.

SOME GENERAL FACTS CONCERNING INEBRIETY.

BY T. O. CROTHERS, M.D., SUPERINTENDENT WALNUT LODGE, HARTFORD, CONN.

A careful study of cases of inebriety from any point of exact science will always lead to the same conclusion, that inebriety is always a positive physical affection, with a distinct ætiology and symptomatology.

The theory of half vice and half disease, to be remedied by moral means at first, then, when these fail, resort to physical and medical appliances, has no support from scientific study and the natural history of the cases.

When the history of many cases are studied and compared, the evidence is unmistakable that inebriety is a form of insanity, distinct and prominent, requiring special study, and special means and methods of treatment. Also, that, ætiologically, they divide into two groups or classes in which are included all cases.

The first group are those cases in which inebriety is an expression of a neurotic defect of the brain centers, frequently inherited and developed through certain exciting causes, of which alcohol is the most prominent.

Inebriety is always associated and marked in this group with physical signs and hints that suggest an imperfect development; great weakness or convulsions during childhood; retarded mental growth, approaching idiocy, or extraordinary precocity, with brain growth and development far in advance of their age.

The crisis of puberty develops perversions and changes that determine all the after life in such cases.

From this time emotional exacerbations, nutrient disturbances and perverted ambitions, which merge quickly into inebriety from the slightest causes.

Obscure states of nerve exhaustion, called properly, "a decline," are most quickly relieved by some form of alcohol, which sooner or later ends in inebriety.

Often alcoholic excess or intoxication follows the first use of spirits, then a long period will follow in which no spirits are used, or, if any, in great moderation.

But an inebriate soil has been prepared, and only awaits a favoring germ cause to spring into activity. During this period of incubation, in which no alcohol is used, a high degree of mental activity is frequently prominent. He will exhibit great strength, coupled with eccentricity, and a changeable, erratic line of conduct.

If he is a public man his conduct will excite great admiration and condemnation. If in business circles, he will be an extremist in work and judgment.

Farther on, he may be very passionate and irritable, and will not bear opposition. Often these men are the wild advocates of new schemes of every description.

A large number of the foremost temperance reformers have been of this class; always on the verge of inebriety, with every symptom and indication present, except the use of spirits.

The religious ranks have numerous types of this class, in which some slight variation or change, and the pronounced inebriate appears.

They are neurotics from infancy, and varied conditions of brain and nerve instability appear along the course of life.

The organism is not fitted to harmonize with the varied surroundings, or to bear the strains incident to constant change.

Neurasthenic states, psychical neuralgias, marked by depressions, and complex symptoms of every kind, that are as intense as they are transient, all crave some relief from outside sources, and find in alcohol a narcotic of the most seductive character.

Thus, under the mask of relief, alcohol kindles and develops a disease that has a most favorable soil for its growth.

Hence it appears that inebriety is an expression of nerve degeneration and exhaustion, which has begun long before alcohol was used, and this drug builds up diseased tendencies and pathological changes that ever after crave its narcotic effect.

In the second group, inebriety is an expression of certain states of ill health, and failure of brain and nervous system, growing out of special physical conditions and surroundings.

This is seen in cases of inebriety that have sprung up in bad sanitary surroundings, where bad food, overwork and underwork, and want of proper rest, have brought on conditions of the body for which alcohol was demanded, and produced relief.

The two extremes of society furnish the most numerous examples.

The very poor, who from their sufferings and necessities develop a low state of health and impaired brain force; and the very wealthy, who from want of healthy activity and hyper-nutrition, are also equally impaired in vigor and health; are grounds from which a large number of inebriates are constantly recruited.

Where inebriety does not appear in the very wealthy class, it follows in their children with more or less certainty, and can be traced to a line of distinct physical causes.

Inebriety frequently appears in a middle class of hard-working, temperate men, and has in some cases an obscure origin and progress.

In many cases, active, temperate men will suffer from some protracted sickness, and after recovery begin to use spirits, either to excess at once or after a short period of moderate drinking. Thoughtless people will find that alcohol has been used as a medicine, and conclude that this was the only cause, and thus condemn the physician, when, in fact, inebriety came from some injury to the brain centers following the illness.

The changes of vigor and health following any protracted disease, and the entailments that develop other troubles, are the common observation of the profession.

The same will be found true in many cases of inebriety which are literally the results of pathological changes that have begun long before.

Traumatism is another starting point of inebriety in this class. A direct injury to the brain from a fall or blow, or a severe wound, or exhausting hæmorrhage, is in many cases the beginning of inebriety, which may begin with a period of moderate drinking, or with impulsive and excessive use of spirits at once.

Psychical traumatism, or injury from mental shock of any kind, is another common cause in persons who were previously temperate and healthy.

Here inebriety is a hint of some injury to the nerve centers, and unmistakable sign of pathological change.

These are the cases whose obscurity suggests a spiritual origin, to all who are anxious for an explanation of all the phenomena of nature.

Such cases are invariably interpreted as springing from the sudden growth of a sinful nature.

A great moral lapse of character and giving way to evil of the heart.

In the first group vice and sin was rampant from the start, in the latter it simply triumphed at last after a long struggle.

In the first group are those whose general history, both physiologically and psychologically, borders more or less closely on that shadowy land of disease, insanity and crime.

In the second group inebriety is acquired, and the outgrowth of physical states and injuries.

The theory that in all cases alcohol is the only cause, is unsupported by facts from a study of cases.

The methods of treatment where alcohol alone is removed, furnish strong evidence that this is only one of many causes, in the many failures that follow.

When the history and symptoms of a number of cases are accurately observed and compared, they will be found to follow a certain uniform line of progress.

Beginning at a certain point, the same stages, marked by the same symptoms, follow each other with a regularity that points to the reign of law, and causes that are uniform in their action.

In most cases two periods appear to be prominent; one beginning somewhere in the past, sometimes traceable, but generally obscure, marked by certain signs of mental and physical debility, which increase along a regular line, that can be often defined and predicted.

The second period dates from the first toxic action of alcohol, intoxication, or excessive use, and ending in death. This is also marked by distinct stages, that are uniform and clear. The progress of the case from this time is within the observation and range of every general observer.

It may not always be uniform; halts and variations in the order of events may appear, but the same general line is preserved.

All study of these cases indicates the possibility of predicting the approach of inebriety, and anticipating its march and progress at every step, with the same certainty that the movements of the heavenly bodies are known.

What we want, is a knowledge of the forces and causes, and the influences on certain physical organizations; then the problem will be clear.

Another conclusion still more startling comes from a general study of these cases. It is that inebriates are the results of physical causes and conditions; that they are grown and manufactured, as much so as cotton and wool, and the machines to work them into fabrics, the difference being only in the process of manufacturing, whose complexity is beyond our present knowledge to follow out.

In outline we can trace an intimate relation between inebriety and great social revolutions, wars, and disasters which affect the interests of large sections of country.

We can see inebriety coming from the neglect of great physical laws; we can mark its footsteps as a tide of disease, ebbing and flowing, following some unknown germ cause, and we know that the same eternal order of cause and effect reigns here as elsewhere.

As medical men, it is our duty to find out these causes and the laws which govern them.

The impulse to use alcohol is not an accident or evil impulse to do wrong, which might be checked with ordinary prudence and self-control. It is the outburst of some diseased tendency, which seeks relief, and grows into great proportions by the very means which it demands.

Let the conscientious observer start from any point of inquiry and seek facts alone, and he will arrive as the same conclusion, that inebriety is a physical disease, and as he goes on further in his investigations, the causes and their prevention will come out distinctly and with startling significance.

He has touched the shores of an almost unknown continent, about which to-day there are written those sands of volumes, and hundreds of papers, whose descriptions of this country are worthless, and whose theories are but fags and superstitions of the infancy of the subject.

Inebriety can not be reasoned out, it must be seen and studied as a new country, above all theory and speculation.

The problem is a serious one, and its solution determines the interests of vast numbers of persons. Personal, social and political interests are involved, the influence of which are becoming more and more important every day.

Inebriety is increasing far more rapidly than the increase of population.

Penal methods of punishment for restraint are everywhere recognized to be failures; and worse than all, increasing and making the victims more incurable. Short terms of imprisonment and fines for the purpose of checking inebriety, are literally building up and educating a chronic class, that always entails heavy burdens on the community, and is a source of peril to law and order.

The methods by appeals to the emotional faculties, to sign the pledge and become converted, must of necessity fail, as they do not recognize the physical condition of the inebriate.

The time has come for medical men to teach the public what inebriety is, and is not, and not the victims of this malady and the teaching of moralists whose shifting dogmatism is unworthy of notice.

The problem is a medical one, and can only be solved by an appeal to the facts gathered from many sources by accurate observers.

Every physician in the country can study inebriety in his own circle; he can group the facts he may discover, and deduce some laws which govern them. In this way he can become a pioneer, and thus help to solve a problem against which all theory and speculation will beat in vain.

The time has come to put on one side the theories of the hour, and demand the facts and their meaning above all theological and popular notions of the day.

If inebriety is a physical disease, then we have it in our power to reach and prevent it by the use of physical means along the line of causes.

If inebriety is the outcome of physical conditions and surroundings, then a knowledge of these will enable us to apply preventive medicines and means that will reach out and prevent the disorder, and restore the victim.

Here is a field where the best trained medical men of the country will find vast regions of unknown facts, and where each may be a discoverer untroubled by rivalry or competition with others.

SOME MEMORIAL REMARKS ON THE LATE DR. J. W. PRITCHETT.

Gentlemen of "The McDowell Medical Society:"

Fortunately for the present incumbent of that chair, the custom requiring an address from the President has been abolished. Yet it occurred to me that a few remarks upon the life work of our lamented Fellow and former President, Dr. Jno. W. Pritchett, would not be inappropriate on the occasion of its first meeting after his death.

Consequently I have jotted down during a few moments snatched from the cares of domestic affliction, and the worry of business, some notes of his life and death.

Dr. Pritchett was born in Hopkins county, Ky., near Madisonville, its capital, on the 6th of June, 1839, and died at his residence in Madisonville, July the 21st, 1883, being at the time of his death 44 years of age. Though thus early called from his labors, he had accomplished much that deserves commendation and honor, especially when we recognize the circumstances that surrounded his youth and embarrassed his early efforts. He had no opportunity of an early education, but was compelled to labor on his father's farm until he was eighteen years of age; when, inspired as it were by an irresistible desire for knowledge, and a larger field of usefulness, he determined to obtain an education, and prepare himself for a professional life, and chose medicine as affording greater opportunities for doing good. He accordingly went to Harrodsburg, Ky., one of the early fields of the professional labors of our distinguished Henry Miller, who was his model as a man and physician. There he attended a literary course. From Harrodsburg he went to Ann Arbor, Michigan, and attended its medical college for one term, doing some practice as an undergraduate between terms, and finally graduated at "Jefferson Medical College," Philadelphia, in March, 1864.

Immediately on his return from Philadelphia he resumed his practice in his native town, where, without intermission or rest, he continued to labor in the profession of his choice, up to the day on which his diseases, by their slow but sure inroads upon a constitution not naturally robust, but elastic and enduring, compelled him to give up work and an active life for a lingering confinement to a sick room—the greatest trial to such a spirit. He was confined to his bed nearly seven months by hepatic trouble and bronchitis, which latter, perhaps, terminated in phthisis pulmonalis. He suffered but little pain, but was the subject of constant cough, accompanied by fever. Though annoyed so long, one who nursed him much during his long illness, writes: "His patience and resignation have never been excelled, for in these he was perfect." Without a murmur he waited for the end. He was always conscientious in his attentions to all who placed themselves under his care, or to those who were committed to his professional guidance, whether rich or poor. He rarely ever permitted pleasure to interfere with his duties and obligations to his patients.

He continued to work long after he was physically unfit for exertion of any kind, and often would deprive himself of much needed rest to visit a patient whom he found much less disabled by disease than himself. From the beginning of his professional life he was very successful, both as a general practitioner and surgeon, and secured from the first a very extensive practice—but, as I am informed, not a very lucrative one, from the fact that he never paused to consider the financial condition of his patrons, but went when and where he was called, scarcely thinking of compensation or reward, except the consciousness of having done his duty by his efforts to relieve human suffering.

Dr. Pritchett could have consistantly adopted as the embodiment of his professional life the sentence attributed to the celebrated Borhaave, "The poor are my best patients for God is their paymaster," as he truly won the title of the "poor man's doctor," which to the eye of God and the true philanthropist, is a proud and noble title. As to his deserving it, no better proof is necessary, than the numbers who attended him daily during his long illness, and the

long procession that followed his remains to their narrow abode; and really there *can* be no better evidence of a useful and unselfish life; nor could a more eloquent eulogy be pronounced, than this demonstration of the high and grateful esteem in which he was held by those whom he had so faithfully served, and so often relieved by his skill and watchful care, those to whom he had never failed to minister in their hour of sore affliction and need. To them he was truly "the beloved plysician."

It was my good fortune to become intimately acquainted with Dr. Pritchett for several years before his death, and to some extent possess his confidence, often meeting him in attendance on the "American Medical Association".—The Kentucky Medical Society, and on this Society—of all three he was a member, and also of the Tri-State Society of Indiana, Illinois and Kentucky. Of this Society he was an ex-president, and consequently to you gentlemen who knew him so well, no eulogy of his life and character, or tribute to his memory is necessary, for I am convinced that no feeble words of mine could add to the already high position he occupies in your hearts, as an earnest and sincere physician, a modest and unassuming member of not only this Society, but of your good and truly great profession. He had profound confidence in medicine to prevent and cure disease. His courtesy and love for the members of his profession was constantly exemplified by his actions. He was always ready to uphold and encourage every worthy member of the profession by word and deed.

Though an enthusiastic advocate of medical organzations—unlike some, it was not with the hope of place or position in them—but for the aid, as he expressed it, which such organized bodies of medical men rendered medical progress, and the ethical spirit that such organizations promulgated, enforced, and kept fresh in the minds of their members, was the life of medicine.

Would to God this was always the case, and that every one who bears the title of M.D. would become not only members, but attending and active members of well organized societies. Dr. Pritchett's high sense of honor towards his professional brethren, and his strict adherence to every provision of the Code of Ethics—as far as your memorialist's observation extended—was especially commendable. His domestic relations, from the same standpoint, were characterized by pure affection. He was genial and affectionate in the domestic circle, where his loss is most deeply and keenly felt. Ever to the writer, his social qualities were of the most cordial character, his hospitality profuse, his friendship true, and characterized by sincerity and durability. One quotation made by his faithful nurse and devoted wife, in a letter to me, speaks a volume of the loss, grief and sorrow his death occasioned in the heart of her who deserves our sympathy, as the life-companion of our professional associate and friend.

In the letter giving date of his birth and death, etc., she says: "I can only add, how I grieve 'for the touch of a vanished hand, and the sound of a voice that is still.'"

Dr. Pritchett gave promise of much more than a local distinction as a surgeon, which he had already deservedly earned in his community, as the result of several successful operations of a formidable character; but, like so many of our promising workers in the field of medicine and surgery, he was prematurely cut down by that inexorable man with the scythe, yet in the prime of his usefulness, and just as he had fully entered the inner hall of the practical temple of medicine, with its walls adorned, as they must be to insure success, by the mind-pictures of long years of experience, and accurate observation of disease in all its protean forms; or, in other words, a memory well stored with pictures of his past experience, the only sure guide for the future, for theories are deceptive. He was evidently a "self-made man," which is always the more useful and better class of men, when they make themselves right.

He idolized his profession as the noblest, and reverenced the great among its members as the greatest among men; but if he had a special idol on earth, and one which he considered as the legitimate offspring of professional love and scientific zeal, that idol was "The McDowell Medical Society."

Consequently, in closing this brief, imperfect and unworthy tribute to the memory of one of its most faithful members and earnest workers to maintain its usefulness, and promote its reputation for scientific and practical work, which it has so deservedly earned by the character of its papers and the usual ability with which they are discussed at each semi-annual meeting, permit me to suggest the appointment of a committee to draft suitable resolutions of respect for *its* devoted son and *our* brother, and sympathy for his bereaved wife and five fatherless children.

MEDICAL PROGRESS.

MEDICINE.

ON PYLORIC INCONTINENCE.—Under this title Ebstein, in the *Press Medicale Belge* (Archives Medicales Belges), considers the difficulties in making a proper diagnosis of affections of the stomach, especially in locating the seat of the disease at either the pyloric or cardiac orifice of the stomach. Among the appreciable affections of the pylorus is the stenosis or contraction of the orifice, the symptoms of which, according to Abercromie, consist of periodical vomiting after meals, and a persistent, painful sensibility in the gastric region. There are also cases where the closure of the pylorus is incomplete, forming a true insufficiency or pyloric incontinence.

In the normal condition the pylorus closes completely, separating the stomach from the duodenum. The anatomical arrangement of the tranverse and longitudinal fibers is a proof of this. Glisson, however, considers that the cardiac orifice alone contracts. Henle believes that it (the cardiac orifice) closes as energetically as the pylorus. According to Ebstein, during digestion the pylorus, which has been closed, becomes fatigued, and relaxing, allows the alimentary fluids to pass out by degrees, to be followed by the solids. In other words, it loses gradual-

ly its contractility, under the influence of the repeated stimulus of the contents of the stomach.

Ebstein attempts to prove the occlusion of the pylorous by distending the stomach with carbonic acid, introduced as tartaric acid and bicarbonate of soda. He introduces 5 or 6 grammes of a mixture composed of 10 parts of bicarbonate of soda to 9 parts of tartaric acid, which results in the formation of 1,500 to 1,800 cubic centimeters of carbonic acid. If the pylorus is normal, the resulting distension, as shown with dogs, does not extend to the intestine; and he considers that this mode of procedure should prove of marked value in the diagnosis of pyloric incontinence. It also projects the walls of the stomach against the abdominal parietes, and permits of a mapping out, through percussion, of the contours of the organ itself. If the pylorus is sufficient and closed in the normal manner, percussion produces no modification of sound in other parts of the intestinal canal. On the contrary, if the pylorus is insufficient, we have a tumefaction of parts of the intestine in connection with the gastric distension, like acute tympanitis. Ebstein cites two cases where pyloric incontinence was diagnosticated in this manner during life, and the diagnosis confirmed by post-mortem evidences.

The established fact of pyloric incontinence does not, however, give any assistance in determining the nature of the disease which is present. Purely nervous causes may produce it, but for the greater part it is due to ulcerative destruction or to infiltrations, which interfere with the proper functions of the sphincter.

Local Temperature in Diseases of the Abdominal Viscera.—According to Prof. Peter, in *Le Praticien*, (Archiv. Med. Belges) the temperature in these affections is elevated in direct proportion to the intensity of the inflammation. In the absence of all disease, in the normal condition, the temperature of the abdominal parietes is much below that of the axilla, ranging from 95°.6 to 95°.9; but under the influence of a phlegmasia or of an irritation it may equal or exceed the axillary temperature. This fact may serve, for example, as a means of distinguishing between simple gastralgia and pains in the stomach which are due to some form of gastritis.

In a young girl suffering from ulcer of the stomach, while the axillary temperature varied between 98°.3 and 98°.6, the epigastric temperature was, in the intervals of pain and vomiting, between 98°.6 and 99°.5, and when the hæmorrhages occurred it reached 101°.3.

In a man affected with chronic alcoholic gastritis, the temperature of the epigastric region rose from its normal 95°.9 to 98°.3, while the axillary temperature was 98°.6.

In a patient affected with chronic gastritis, caused by insufficient alimentation, the epigastric temperature reached 98°.3, the axillary temperature being 98°.6. This elevation of the temperature led to a diagnosis of gastritis with fluxion or congestion, and eliminated the purely nervous gastralgia.

In a patient attacked with hepatic colic, at each crisis the temperature in the right hypochondriac region exceeded that in the left to the extent of 1°.8, 2°.7, and even 30.4.

In tubercular peritonitis, the temperature rises ordinarily 1°.8 to 2°.7. A case of tuberculosis, which suffered from abdominal distension, pains, etc., not having an abdominal temperature above 95° 9, enabled M. Peter to eliminate tuberculous peritonitis, and to diagnosticate a pseudo-hysteria, a grouping of nervous symptoms which are not rare in phthisical cases.

Severe Hiccough.—Dr. Ruhdorfer, in the *Allgemeine Wiener Medizin Zeitung*, reports a severe case of the above, lasting for three months, and which morphia, given hypodermically, could only check for a few hours or days. It resisted all the usual remedies, such as quinine, alone and with extract of belladonna, tincture of castoreum, or tincture of valerian, in water or with aromatics, mustard poultices over the stomach, dry cupping down the spinal column, chloroform, ether, zinc, bismuth, numerous emetics, and purgatives. The patient dragged on for three months under various remedies, morphia being administered whenever a single attack lasted beyond eight hours. At last the attack became overpowering, and the hiccough was so loud that the patient could be heard outside the house, through two doors. She sat up in bed, supported by her parents; there were dyspnœa and cyanosis; the head was jerked in all directions, the pulse was small and frequent; the neck was distended. Remembering a case in the *Revue Medico-Chirurgicale*, Dr. Ruhdorfer injected a solution of pilocarpine hydrochlorate (3 centigrammes in a gramme of water). The hiccough was at once cured, as if by magic, and has never returned since. —*British Medical Journal.*

Downward Displacement of the Transverse Colon. — Dr. Charles Hermon Thomas, in *Illustrated Medicine and Surgery*, records three cases of this curious affection. In the first, a man 80 years of age, the most dependent part of the gut was found midway between the umbilicus and the pubic symphysis; in the second, a woman 54 years of age, it was deeply impacted in the pelvis; and in the third, a man 30 years of age it reached the level of the umbilicus. In the first case there was tumor and profuse diarrhœa. In the second case there was pain, referred chiefly to the region of the liver, existing for five years, obstinate constipation with indications of obstruction, and two solid tumors occurring at intervals, which proved to be the descending and ascending limbs of the displaced transverse colon. In the third case there was pain, and tympanitic resonance on percussion. No adhesions of the displaced parts were found in any of the cases cited.

Nephritis Produced by the Compression of the Ureters in the Course of Cancer of the Uterus, with Consecutive Hypertrophy of the Heart.—M. G. Artland (*Revue de Médecine*) gives the details of six cases observed by himself and M. Straus, to illustrate the discussion of this subject. The con-

clusions reached by him are, in effect: That in the course of cancer of the uterus, there may develop, as the result of compression of the ureter, certain lesions of the kidney, differing in their character according to the degree and duration of the compression. When the compression has been slight, the kidney remains normal in size or is slightly increased in volume, the histological lesions consisting of a nuclear infiltration about the uriniferous tubules and vessels, a hypertrophy of the glomeruli, and a dilatation of the convoluted tubes, the epithelium of which has undergone a fatty-granular degeneration. The collecting tubes have remained very nearly normal, and their epithelium does not seem to be altered.

When the compression has been so prolonged that the ureter and pelvis have become markedly distended, the kidney atrophies, and the degree of atrophy is in direct relation to this dilatation of the ureter and pelvis. The histological lesion consists in the change to a fibrous condition of the previous nuclear infiltration, in the obliteration of the collecting tubes, the epithelium of which has undergone the embryonic retrogression. The glomeruli are either fibrous or cystic. The convoluted tubes present the same change in their epithelium as before mentioned.

These lesions of the kidney are similar to those which are produced in ligature of the ureter in animals. They differ from the latter in the fact that they constitute a diffuse nephritis, rapid in its course, in the development of which the inflammatory element takes the greater part; whilst the mechanical element is predominant in the evolution of the kidney lesions resulting from the aseptic ligature of the ureter.

These renal lesions caused by the compression of the ureter in the course of cancer of the uterus, frequently produce an hypertrophy of the heart, which affects exclusively the left ventricle, and which is rarely, if ever, accompanied by interstitial myocarditis

TOXICOLOGY AND MEDICAL JURISPRUDENCE.

ON PTOMAINES, OR CADAVERIC ALKALOIDS.—There has recently arisen in patholgical chemistry a class of substances known as ptomaines, the properties of which are becoming more clearly defined, but which are very little known to those who are not directly workers in that branch of medical science. A writer on this subject in the *Lancet*, R. N. Wolfenden, M.B., who is the lecturer on physiology in the Charing Cross Hospital Medical School, calls our attention to this, and to the fact that the lawyers have already found them out, and made use of some of their peculiarities in arguments for the defense in a recent trial for murder.

The term ptomaine is a misnomer. It was first applied by Selmi to these bodies, to indicate that they were of cadaveric origin; but investigations are rendering it more and more probable that alkaloids of a poisonous nature occur in certain pathological conditions, and possibly also normally as a product of change of living tissue. Selmi supposed them to be products of putrefaction of organized nitrogenous material. They are variable in their nature according to the length of time after death, and though not present within a few hours after death in any appreciable quantity, they slowly develop with advancing decomposition. They are often amorphous in form and alkaline in reaction, for the most part volatile and easily alterable, forming crystalline salts with acids as a rule. The addition of acids to them usually changes them, with the production of pleasant odors like orange flower, musk, etc. Allowed to oxidize by contact with atmospheric air, they emit disagreeable cadaveric or urinous odors.

Some of these ptomaines are not poisonous, but most possess strongly toxic characters, and cause profound symptoms when injected under the skin, such as paralysis, more or less complete, of hinder extremities, dilatation of pupils, convulsions, muscular flaccidity, slowing or acceleration of the heart, loss of cutaneous sensibility and of muscular contractility, possessing many of the characteristic physiological actions of muscarin or atropin. They answer to nearly the same reactions as the vegetal alkaloids, and all have a strongly reducing action on potash ferridcyanide. They yield color reactions with sulphuric acid (red), iodic acid and sulphuric acid (violet), nitric acid (yellow), etc. These ptomaines are met with under the following conditions:

1. As a constituent of normal tissues or juices. In this case they are products of tissue metamorphosis. *Saliva* evaporated to dryness, extracted with boiling water and filtered, gives a toxic substance which converts ferridcyanide of potash, along with one or two drops of ferrichloride, into Prussian blue. Injected into the thigh of a frog, it kills the animal, and differs from snake poison only in the greater intensity of the latter. Normal *urine* gave Gautier a fixed oxidizable alkaloid, which forms a crystalline chloride, and also a crystalline double salt with platinic and gold chloride. This alkaloid is very poisonous, killing quickly with systolic standstill of the heart, stupor, and paralysis.

2. In certain pathological conditions. In the urine of patients suffering from progressive paralysis there are two volatile bases, the one like nicotin, the other like coniin. In the urine voided during a case of interstitial pneumonia were two alkaloidal bases, one having the odor of stinking fish, the other of ammonia. Two similar bases were found in the urine of patients with abdominal typhus. In tetanus a base like coniin was discovered in the urine. In the urine of "miliary fever" an alkaloidal base having the odor of stinking fish has been observed.

3. As cadaveric or artificial. There can be no further doubt that these bodies are largely produced in the process of decomposition of nitrogenous or proteid tissues. There are many varieties of them and they vary much in their nature, according as the length of time after death is long or short. Stinking fish, bad meat, etc., all contain poisonous principles which can be extracted after the manner of ptomaines. The gastro-intestinal irritation and profound toxic symptoms produced by the ingestion of bad food are probably at the bottom processes of alkaloidal poisoning. By decomposition of neurin and albumen toxic bodies may be obtained much resembling mus-

carin. Both from freshly prepared peptone made by the action of gastric juice on pure fibrin, and from stinking peptone by boiling with caustic soda, evaporating, extracting and purifying, toxic alkaloids can be obtained which kill frogs and rabbits in a few minutes. Putrefying casein, brain substance, liver and muscle also yield these products. Some of these ptomaines are poisonous, some non-poisonous; and it is common to find a poisonous and a non-poisonous variety linked together. No chemical test has as yet been devised that is at all crucial, and the general reactions, taken along with their physiological peculiarities alone, can be taken as evidence of the presence of a ptomaine.

The ptomaines, so far described, are:—1. Ptomaines like atropin and hyoscyanium crystalline, and which dilate the pupil and accelerate the heart. They are obtained from putrescent albuminous fluids. 2. An alkaloid from decomposing yeast, called sepsin, which resembles strychnia. 3. An alkaloid resembling morphia in its tests, but not in its physiological properties. 4. One agreeing with delphinin. 5. One resembling strychnia, but not causing tetanus. 6. Alkaloids like muscarin. 7. Alkaloids like coniin. 8. Alkaloids resembling parvolin and hydrocollidin. To sum up the manner of production of these bodies:

1. There are developed in the body, post-mortem, poisons of an alkaloidal character, and which can be obtained also by decomposition of albumen, peptone, casein, muscle, brain, etc. Moreover, they seem to be present in some normal secretions (saliva and urine.)

2. These cadaveric alkaloids may be mistaken, post-mortem, for vegetable poisons administered with evil intent, but if the body be examined within from twenty-four to forty-eight hours after death, any alkaloid there found would be strong presumptive evidence of poison, and not ptomaine. After a couple of days it may be a matter of doubt.

3. There is no satisfactory test surely indicating the presence of a ptomaine. Physiological characters must be taken in conjunction with chemical tests.

4. Probably the production of ptomaines within the living body may be the pathological cause of many obscure conditions, especially those following on poisoning by bad food, such as stale fish, etc.

Tears of Blood.—M. Damalix has published in the *Archives d' Ophthalmologie* an interesting article on this rare phenomenon. A young girl, in the service of M. Panas, affected with non-convulsive hysteria, gave an account of being often affected with a discharge of blood, which soiled the handkerchief used in wiping her eyes. This discharge returned nightly during a specified time. Examination of the eyes showed that they were intact, the only noticeable affection being a marked blepharospasm, with photophobia and facial neuralgia.

There are a number of similar remarkable cases, the record of which leaves no question as to the possibility of such a hæmorrhage; in one case of Hasner's, and in another of M. Brun's, the observers saw the eye fill with liquid blood as it fills with tears, without the possibility of fraud. In the latter case, the microscope showed that the blood was very nearly normal.

As to diagnosis, it must be remarked that one would not describe as tears of blood the various hæmorrhages which are dependent upon a lesion of the orbit or of the mucous membrane. It might be that the little polypoid vegetations that develop in the conjunctival cul-de-sacs would escape attention, and cause a discharge of blood simulating this condition. But the tears of blood are absolutely independent of any ocular alteration, and their evolution is neither fixed nor regular. There seems to be no cause for their effusion. Without effort or pain these patients weep blood. The eyes become moist, the tears fall upon the cheeks, and it is when the patient wipes the face that the blood is first noticed. At other times there are certain premonitory symptoms, such as frontal pain, brow pain, or pain at the root of the nose; or perhaps a tickling or pricking sensation, with a feeling of warmth to the eye-lids; then, as the discharge occurs, the disagreeable sensations pass off. The discharge varies in quantity from a few drops to a liqueur-glass full, only lasting a few minutes. These phenomena are essentially intermittent, sometimes regular, but nearly always transitory and coincident with the different hæmorrhages of the skin and mucous membrane.

Considered ætiologically, the only fact which can be determined from analyzing these observations is that these tears of blood constitute a passing anomaly in individuals that are anæmic and inclined to hæmophilia. and that they can act as supplemental to the menstrual flow, but that they occur especially in the hysterical women.—*Revue Medicale.*

On the Possibility of Making a Cadaver Disappear Entirely by the Use of Ordinary Sulphuric Acid.—A. P. Reynard, Comptes Rendus de la Societe de Biologie) tells us that in consequence of the attempts made by Prof. Girard to totally destroy the bodies of sheep affected by charbon by placing them in their weight of commercial sulphuric acid, and thus destroy the virus that Pasteur declares cannot be destroyed by burial; he concluded that here was a means which might be employed to destroy the evidence of crimes committed, and made certain experiments to see how far a human body could be so disposed of.

This method could not very well be used in the case of adults, as it would require too much acid and vessels of too large size—but in the case of abortion or infanticide, unfortunately, nothing is easier than to destroy all traces of the crime by means of sulphuric acid. He placed the body of a new born child weighing 3 kilos, in a suitable vessel containing 4 liters of sulphuric acid. Thirty hours later, without the giving off of heat or odor, the cadaver had disappeared. The best means of disposing of the remaining acid is that which would most readily occur to the mind of the criminal, that is, to throw it into the drainage of the house—the pipes being made of pottery are not affected, the acid encounters the carbonate of ammonia from the urines, etc., sulphate of ammonia and carbonic acid is the result, and all trace, not only of the crime itself, but also of the means used to conceal it, is obliterated.

THE

Journal of American Medical Association.

PUBLISHED WEEKLY.

THE EDITOR of this JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information, should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE..... $5,00.
SINGLE COPIES..... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 65 RANDOLPH STREET,
CHICAGO, ILLINOIS

SATURDAY, JANUARY 5, 1884.

ANNUS MEDICUS, 1883.—It is withal a goodly custom which impels us at the beginning of each successive year to inquire into the year's endeavors, seek to discern its lessons, and thereby more advisedly enter upon the untried tasks and cumulative duties which are just ahead. Time and progress solve the most difficult problems. While some great genius may suddenly illuminate the scientific world, as instanced by Galileo and Newton, in the physical sciences, and our own Sims in surgical science, yet after all it is the steady accumulation of knowledge year by year which accomplishes the great achievements of scientific investigation.

In all departments of medical science the past year has been one of intense activity. Never before in the history of our profession have there been so many able investigators engaged in advancing the physical sciences, among which medicine stands preëminent. Human anatomy is regarded an exhausted science, and in so far as it is descriptive, justly so. Yet our esteemed contemporary, the *Annals of Anatomy and Surgery*, has given the profession some valuable papers in anatomy, and enters the new year with improved facilities for cultivating the sciences to which it is devoted. The past month witnessed the appearance of the last fasciculus of Prof. Harrison Allen's splendid treatise upon the human anatomy, of which a distinguished teacher of that department of science says: "I know of no similar work in any language which, either in text or illustration, is so well adapted to the wants of the medical student and practitioner." Thus it will be seen that anatomy continues to receive that attention from persistent and advanced investigators which it so eminently deserves, and which in time will materially improve existing knowledge. In physiology the greatest advances are evident in connection with researches upon the nervous system. We doubt not the forthcoming work of Professor John C. Dalton on the Topographical Anatomy of the Brain, will embody the results of mature and painstaking investigation in a field long cultivated by this distinguished author.

In general and special pathology, many valuable additions have been made to our knowledge. More than a year ago a strong impetus was given to the investigation of germinal pathology, by Koch's discovery and demonstration of the bacillus of tubercle. As usual with the advent of innovations, more was claimed by enthusiasts as the result of these investigations than is warranted. The professional mind has now realized that in this discovery more is indicated in the way of possibilities, than as absolutely determined in regard to the nature, progress, and communication of phthisis. In diagnosis, prognosis, and prophylaxis, Koch's investigations are destined in time to render most important service. Not the least agreeable to contemplate of benefits, is the encouragement given to that industrious and ingenious class of workers, headed by Virchow, who have done so much of late years to place practical medicine among the exact sciences. Among the notable events of the year, in this connection, is the work of the cholera commissions in Egypt, headed by Koch and others, the results of whose labors are not yet fully known. In practical therapeutics, the past year has witnessed a popularization of the physiological, in contradistinction to the empirical method, together with a wholesome appreciation of facts and a judicious examination of results. To our national pride it cannot but be gratifying, to realize that the two greatest works on therapeutics extant are from the hands of American authors, the preëminent value of which is attested by rapidly succeeding editions, and almost universal adoption as text-books, both at home and abroad.

The past year has witnessed the steady progress of surgical opinion towards a realization of the fact that the value of antiseptic methods consists for the most part in cleanliness and drainage, and little, if anything, beyond. In abdominal surgery, the most brilliant results have been achieved, and conditions formerly regarded incurable are now relieved by the bold use of the knife. In the various departments of general surgery, many and permanent additions to

knowledge have been made which time will not permit us to enumerate.

In obstetric practice, the greatest advance of recent times springs from the growing opinion that puerperal fever is not, as heretofore regarded, the result of a specific germ, but that it is identical in its nature with surgical pyæmia and septicæmia. The discussion of this subject by leading investigators in this department of medical science during the coming year cannot but be of great benefit to obstetric practice.

The advance of medical thought in America during the past twelve months has been more marked in no department than in the prolific field of sanitary science. In all matters appertaining to State medicine there is a degree of activity which has already accomplished much, and which is growing in efficiency and practical importance. That in all branches of preventive medicine we are making steady and substantial progress is evident to the most casual observer. One of the most welcome features of progress is the growing interest in sanitary matters on the part of the intelligent laity, and the increasing aid in the States to Boards of Health. There are still many needed reforms and improvements which we may confidently expect the near future to supply.

A consideration of the great activity in all the branches of medical science and practice brings to the mind of the appreciative reader at least one important suggestion. Never before was there a time when the duty was so imperatively enjoined upon the practitioner to study the development of recent investigations. To discharge the duties of the hour, the physician must be informed upon those advances which increase the extent and exactness of his knowledge, and extend the scope of his armamentarium. His greatest aid in all that appertains to progress and improvement is the medical journal which visits him from week to week.

In conclusion, we wish for all our readers a Happy New Year. In this trite form the compliments of the season are exchanged, but from one physician to another it means a great deal. No calling in life is so sublimely epic as that of the physician. His ministrations bring him daily in contact with scenes of anxiety and sorrow. His triumphs bring joy to men, women and children, and often he shares the common orrow. His happiness is so interwoven with that of his patients that in wishing him a Happy New Year, we bespeak the health and happiness of those who come under his care. Fully appreciating the import of these words, the editor of the JOURNAL wishes for all its readers a happy and prosperous New Year 1884.

WHAT CONSTITUTES A "PROFSSSIONAL CARD?"—In the *Medical Record* for December 15, the editor, in alluding to our article on Ethical Advertising, in the number of this journal for November 10, says: "We cannot but think that our Chicago contemporary is doing a serious injury to the profession by advocating for specialists and doctors generally a license which it never has been and is not now considered decent to assume." And *the license* thus spoken of, he quotes from our editorial as follows: "No one is prohibited from publishing or using a professional card as freely as he likes, simply announcing himself as doctor of medicine, and giving his residence and office hours. * * * If he desires to limit his practice to the treatment of any particular diseases, he can say on his card that 'his practice is limited' to this or that class of diseases." Then, with characteristic ethical perversity, our friend of *The Record* exclaims: "To say that any physician 'can publish his professional card as freely as he likes,' is to take down all the barriers at once against promiscuous medical advertisement. With such a liberty one could take up *half a column* in a daily paper, and still keep within the pale of the Code."

How easy it is by simply changing the *article* "a" to the pronoun "his" in one half of a sentence, and leaving the other half out, to misapply and misrepresent the whole. And how adroitly the editor of *The Record* does it. When we said, "a professional card" could be used as freely as the possessor might wish, we were careful to add that the card should "simply announce himself as a doctor of medicine, and give his residence and office hours." To talk about filling "half a column in a daily paper" with a card containing simply a physician's name, residence and office hours is too absurd to need comment. Does our New York contemporary really desire his readers to think that he does not know the difference between a professional card proper, and a handbill or a newspaper essay?

After the earnest protest against the dangerous "license" we are represented as advocating, our friend proceeds as follows: "In the larger cities of the East, and in most, if not all, of those in the West, reputable physicians do not put their card and office hours in the daily papers, as do the quacks and abortionists. * * * In small towns it is, perhaps, well enough to allow the local physicians to insert their cards along with the dentists, carpenters and tinware men."

Ah, yes! how graciously liberal, and withal how consistent our friend shows himself. "A *license* which it

never has been and is not now considered *decent* to assume," and which "reputable physicians" in the great cities of the East and West do not practice, may, after all, be "*well enough* to allow the *local physicians*" in the "small towns" throughout the country. Well might these "local physicians" in the small towns, who constitute two-thirds of the whole profession, ask this metropolitan editor, "on what has my lord been feeding," that he and his city friends should have developed a dignity so exalted as to require one code of ethics, while another and lower one will do "well enough" for their less exalted country brethren?

Does he suppose there is an intelligent physician in all the country who does not know, that the reason why physicians in the large cities do not put their cards into the daily papers, is because it is rendered wholly unnecessary and useless by the publication annually of city Directories in which all their names and residences, and business are announced, and that too, along with the "dentists, carpenters and tinware men," and even sometimes sandwiched between the "quacks and abortionists." These Directories, revised every year, and found in every public house and permanent business place, afford a far more effectual as well as cheaper mode of advertising the members of the profession in all the large cities, than would be a proper professional card in the advertising columns of a daily paper.

Again, we are told that, "the permission to announce the 'practice limited to,' will strike sensible people as being silly, if not actually dangerous. * * * * While the attempt to make a distinction between 'practice limited,' and 'practice special' appears to us a foolish quibble."

Is it possible that our New York contemporary can see no difference between the addition to an ordinary professional card of the words "practice limited to diseases of women," by which the public are notified that no other diseases will be attended to, and the favorite phrase, "Special attention given to diseases of women," by which the public fully understand that the party claims *special* or *superior* qualifications for the treatment of those diseases, and yet may do as well as ordinary physicians in the management of any other affections? Is there no difference between notifying the public and the profession that you will attend to but one class of patients, without any allusion to special qualifications, and a notice that you will give "*special*" (which means unusual or superior), attention to that class, and yet leave yourself free to attend to whatever else may offer? The difference is so plain, that although the "permission" and "license," which *The Record* affects to regard as so dangerous to the welfare of the profession, was sanctioned by a unanimous vote of the American Medical Association nearly ten years since, yet we have not seen a single specialist's card containing the dangerous declaration. Neither do we expect to see any, simply because the ambitious young specialist who would be very glad to have the ethical privilege of offering to give *special* and extraordinary attention to a particular class of diseases, will also be very careful not to notify the public that he will attend to nothing else.

It is a little singular that an editor who boasts of such ethical *liberality* as to permit the taking of every votary of the pathys, isms, and quackery of the day, who can get a State registration license, into consultation at the bed-side of the sick, as provided by the New York Code, should have such a horror of seeing a simple professional card in print.

We have nowhere advocated professional advertising, but, as our readers very well know, have simply pointed out, in answer to direct questions from correspondents, the only way that it can be done without positive violation of the rules governing the profession at large.

SOCIETY PROCEEDINGS.

THE CHICAGO MEDICAL SOCIETY.—REGULAR SEMI-MONTHLY MEETING ON THE EVENING OF DECEMBER 17, 1883.

Dr. D. W. Graham presided. The scientific business transacted consisted in the disposal of two papers. The first, being a paper on "Alveolar Abscess Opening into the Antrum and Nasal Cavity, Simulating Chronic Nasal Catarrh," was read by Dr. John S. Marshall. It contained the following salient points regarding the origin and causes of ozæna, namely, syphilis, struma, lupus, ulceration, caries of the bones or cartilages, inflammation of the mucous membrane of the frontal and maxillary sinuses, and alveolar abscess opening into the antrum of Highmore or the nasal cavity direct. The origin of certain forms of chronic nasal catarrh with fetid mucopurulent discharges is not always easy to locate, and especially is this true if the latter enumerated cause is the primary seat of trouble, and opens into the maxillary sinus. Abscesses forming at the apex of the roots of the superior incisor teeth, bicuspids or molars, may discharge into the cavities of the antrum or nasal fossa, and range from a slight nasal discharge to a most offensive ozæna, and it is not at all uncommon to find the roots of the superior molars penetrating the maxillary sinus. Less frequently, however, the bony plate over the apex of the incisors may likewise give way, especially over the apex of the central incisor this may occur, and an offensive discharge

per se into the nasal passages or posterior nares so closely simulate chronic nasal catarrh as to entirely mislead the most careful diagnostician, whereas the real source of trouble may be a diseased tooth. During the past three years the writer has seen two patients who were suffering from this form of disease, who had been treated for months as cases of chronic nasal catarrh. The sphenoidal and frontal sinuses and the maxillary antrum may each be the seat of this morbid condition, and fetid discharges from the nasal passages be the result, *i. e.*, of the accumulation of the morbid product in the accessory cavity, which becomes distended, and the overflow escapes from the little orifice into the nasal cavity. Text books allude to this disease in a mere paragraph sometimes and undoubtedly the subject deserves more attention than has hitherto been given to it.

Antral abscess is a much more serious difficulty than the affection just described, the former causing at its inception rigors and fever, and involves much more of the adjacent structures, periosteum, etc. In antral abscess the pus may be retained between this membrane and the bone, causing absorption of the walls of the antrum; and it may open into the mouth, orbit, or through the external surface, and cause hideous deformity. Extensive necrosis of the maxilla often follows, and it may extend to the ethmoid, lachrymal, palatine, and inferior turbinated bones, with cerebral abscess, unless early recognized and interfered with by surgical means.

When a dental abscess opens into the maxillary sinus, there may be danger of septic poisoning, if the secretions become foul and no other outlet is present. If this should occur, it will be attended, of course, by serious constitutional symptoms. When it escapes into the nose the discharge will be unilateral, in its always being from the same nostril, and most abundant when a patient is lying upon the opposite side.

After the cases, with the symptoms, history, etc., etc., had been cited, the paper concluded with the treatment, which consists in syringing the cavity of a tooth and abscess through the pulp canal with warm carbolized water, 2 grs. to the ounce, once daily, and packing the tooth with carbolized cotton, and sealing it in with gutta-percha stopping to exclude external moisture. Sometimes the buccal roots can be explored with a fine probe, by passing it upwards for an inch and three-quarters. Water can be thrown into the antrum of Highmore through the roots of the teeth, and the fluid will escape into the nose. A tooth always needs to be extracted, if not already missing, and we then discover, most likely, that the pus will escape into the mouth through the alveoli, and that the ends of the buccal roots are somewhat rough, and portions already have been removed by absorption. A few weeks' time of treatment in this manner usually results in a most satisfactory improvement or entire recovery of the patient.

The paper elicited considerable discussion. Dr. T. W. Brophy said that he had seen and treated a great many cases similar to those cited by the writer of the paper, that had previously been treated by physicians for nasal catarrh. He also illustrated his remarks by giving a method by which he was treating a case at present, and draining the antrum through an opening into the mouth by a metal tube or canula. The patient has been under his observation for ten months, and was for four months previously treated for the nasal difficulty alone, by a physician having a large practice. The case is now almost entirely well. I think the discharge of pus into the nasal cavity occurs more frequently from the incisor teeth than from the molars, and necrosis frequently results from the alveolar abscess that at first has formed at the roots of the teeth, and sometimes involes the entire upper maxilla. He was much pleased with the paper, and had been much interested thereby. Dr. Edmund Andrews inquired of the author what form of syringe he used in treating this class of cases? and what form of point the syringe had?

Dr. W. W. Allport stated that the paper presented by Dr. Marshall was well prepared and timely. That similar cases to those mentioned by him do sometimes occur there is no doubt, but not so frequently that any one individual sees and treats a great many of them, as Dr. Brophy states he has done. I think that I am an ordinarily careful observer, but during my thirty-five years of practice, I have seen but very few of such cases—not to exceed five or six—and I can hardly see how it is that any one man has treated so many cases similar to those mentioned in the paper as the gentleman preceding would have us infer that he has. Dentists frequently have fistulous openings and occasionally a diseased antrum to treat caused by alveolar abscess. But alveolar abscess simulating nasal catarrh is met with seldom, and I think Dr. Brophy has misunderstood the idea conveyed in the paper.

Dr. Robt. Tilley stated that he has treated catarrhal troubles of the ear that had been primarily connected with the teeth, but a case had never occurred in his practice of catarrh of the nose originating from the teeth where perforation had occurred, as was described in the paper, and he took pains to examine the teeth and mouth carefully in making his diagnosis. He would like to inquire, without naming any one, if dentists had ever tried using the remedy peroxide of hydrogen in "syringing out" this kind of pus cavity? He knew it to be an efficacious remedy for dentists to use, aud suggested it as a valuable agent in the treatment of alveolar abscess. Twelve volumes of oxygen in solution is used in full strength by oculists in Paris in treating eye affections, and he presumed it could be used in the same strength in treating these abscesses.

Dr. Brophy arose to add to his former remarks that he did not wish to be understood as saying he had seen more cases of alveolar abscess than other dentist, as might be inferred from the remarks of one of the gentlemen who had the floor a few moments ago. He, however, would verify the statement he made at the beginning of the discussion—that he had met with a good number of cases of this variety, and would at an early period present a paper on this subject before this Society, which he would be pleased to do as soon as he can have the drawings made to illustrate the facts

Dr. Allport said, regarding the use of peroxide of

hydrogen, it is coming into general use by dentists. He knows it to be an exceedingly useful remedy, as he has practiced using it a good deal, and concluded by saying the author of the paper, he thought, had ably called attention to an important subject this evening; one that is generally overlooked in diagnosing nasal catarrh.

Dr. Marshall closed the discussion by describing the kind of syringe used, as one speaker had inquired about it, by saying it was the ordinary dental syringe fitted with a flexible metal point. He stated that the peroxide of hydrogen was in general use, although he had not used the remedy in the treatment of this class of cases; but certainly should regard it as valuable in the treatment of blind alveolar abscesses. Regarding the cases he had reported, he said they had previously been under the observation of intelligent and well educated physicians. The object of the paper was to call the attention especially of the medical profession to one of the most obscure causes of fetid nasal catarrh—a cause which in a majority of cases, he thought, was overlooked by them.

The following is the substance of a paper presented by Dr. Wm. L. Axford, on "Packing-House Wounds," from observations made during the past three years. The bad consequences ensuing from very slight wounds on the hand and forearm (oftentimes amounting to a mere scratch), when inflicted by knives used in packing-houses, are familiar to many of you. When the skin has been cut through and the cellular tissue opened, an intense cellulitis, terminating in the formation of large quantities of pus, requiring free incisions, has been almost invariably the result. From a small cut in the back of the hand, a cellulitis extending half way up the forearm is not an uncommon result, and cases under observation have occurred where the inflammation extended to the elbow. If the sheath of a tendon be opened, or the tendon cut, sloughing is the usual termination. If the wound extend deeper and the periosteum is cut, nearly every case will be followed by periostitis with necrosis. The cause must, of course, be the septic material conveyed into the wound from knives used daily in cutting meat, which probably are rarely cleaned with care, and never disinfected, although they may be ground and washed daily. Wounds are of daily occurrence at some of these large houses, and from past experience I am led to think we may expect the worst consequences to follow where the knives used by "shavers"—*i. e.*, those employed in removing the finer hair from the bodies of the animals after they have passed through the "scraping machines." (The "American hog," of course, being the animal alluded to, that undergoes this sudden and complete metamorphosis).

The wounds seem to pursue the same destructive course and resist antiseptic measures, as if no treatment were adopted. The treatment of wounds of this nature is, when necessary, to approximate the edges with sutures, then by using freely either carbolic acid, solutions of eucalyptol, or iodoform, all of which have been tried, and still, union by the first intention has never yet occurred in the practice of the writer.

A better plan might be to put aside the idea of securing union by the first intention, (which is but problematical) and direct our measures towards preventing the inflammatory consequences by arresting the spread of the supposed poison through the tissues, or, in other words, treat these cuts from the first as poisoned wounds, and try to prevent the further invasion of the septic material. To do so, if called immediately, apply thoroughly to the cut the actual cautery as the best means of destroying the poison. This heroic method the writer is convinced will diminish the suffering of the patient, and lessen the actual inconvenience so far as time of recovery goes.

Perhaps, if we inject antiseptics, such as carbolic acid, tr. iodine, or other solutions, into the tissues about the wound, that they might take the place of the actual cautery, but their efficacy as adjuvants to the treatment by the cautery in fresh wounds can be better tested by using them after the more heroic method of searing the surface first, has been done.

If, however, some time has elapsed since the injury before we are called, it would be more advisable to dispense with the cautery and trust entirely to the injections, and environ the wound by a layer of some reliable antiseptic dressing.

Among those who discussed the paper was Dr. E. Andrews, who stated that he was frequently called to attend severe cases, the result of so-called "packing-house wounds." Some patients are more violently poisoned than others. He recalled a case of a man whose foot had been injured by a machine that is used in an "offal factory" to grind the bones of the animals slaughtered, and the foot was completely destroyed. The leg was at once amputated, but in 12 hours the flaps mortified, and the lower half of the thigh was distended with gas. In another 12 hours the entire thigh was tympanitic, and a few hours more the man died, not so much from shock as from being poisoned to death. Another case he saw, was where a man had been cut by a cleaver (used in a packing-house) in the lower portion of the "shin." It pursued the same course to a fatal termination. The juices that oozed from the stump after he amputated the leg contained large numbers of bacteria, and the case presented what he termed septicæmia with a vengeance. He also gave the history of a third case with the same final result, death. Some authors termed this traumatic gangrene; others, gangrenæ septicæ. It is a virus, but does not think many of the hogs have this virus.

Dr. Robert Tilley thought that no advantage could be gained by using a cautery in these cases, if amputation proves to be of no avail, and he thought a simple hot poultice would be the better method to destroy septicism, because bacteria do not thrive at a temperature a little above that of the body, or to keep a hot appliance continually to the wound. He had treated a number of cases of wounds received in soap factories, none of which had septicæmia.

Dr. Graham had seen a number of chronic cases of the kind of which the paper treated, and thought part of the virulence is due to the way this class of people live, as they live in a vitiated atmosphere at

their homes, also the peculiar modes of the individual in their hygienic care of themselves.

Dr. Axford thought the cause of these poisonings was due to the knife being dipped in blood nearly constantly by butchers, and is the carrier of the virulence instead of the hog, at least in most of the cases, and that we should be on the alert for the after consequences, which are most sure to arise. He was convinced that every man wounded at these places by the knives used there is actually poisoned.

L. H. M.

PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

[Section for Clinical Medicine, Pathology and Hygiene.]

ALBERT N. BLODGETT, M. D., SECRETARY.

SUDDEN DEATH DUE TO HÆMORRHAGE FROM THE HEPATIC VEIN.

Read before the Section for Clinical Medicine, Pathology and Hygiene, of the Suffolk District Medical Society, Nov. 14, 1883.

Dr. A. F. Holt, Medical Examiner for Middlesex, presented a paper upon a remarkable condition found at the judicial autopsy of a pátient dying under peculiar circumstances. The cause of death here reported, namely, hæmorrhage from the hepatic vein, has not, so far as known, been previously observed. The case occurred in the practice of Dr. Dow, of Cambridge, from whose notes the clinical history as here given has been copied.

J. C., an Englishman, fifty-six years of age, large, and strongly built, though slightly hunch-backed, died May 15, 1883. For the last six or seven years of his life he had been engaged in a small kindling wood trade, doing some of the manual labor required by such a business himself. For the ten years before this time he had been a police officer.

Ten or twelve years before his death he began to have severe attacks of colic. These continued to occur at irregular intervals during his life, and for the last six or seven years he was never quite well, although able most of the time to attend to his business. During these years he had consulted a large number of physicians. Most of these pronounced his trouble gall-stones, but some of them dyspepsia, and still others some obscure disease of the liver.

Seven days before his death, while in Boston attending to some business, he was suddenly prostrated with a very severe attack of pain in the region of the stomach, nausea, and faintness. He was taken to his home in Cambridge in a carriage, and his physician, Dr. Dow, was immediately summoned, who found him suffering from severe pain, vomiting at at short intervals, pale, and faint. The pain and faintness continued until evening, he having been taken sick about noon, when the doctor was hastily called again. He found him vomiting blood in the form of very large dark clots. This continued at short intervals about one hour, when it ceased. A little over three pints of blood was vomited at this time. The pain and faintness continued for three days. Although these symptoms were somewhat relieved by stimulants and opiates, at the end of this time he was again attacked with the vomiting of blood, as before, in the form of very large black clots. This continued at short intervals until nearly two quarts had been ejected, when it suddenly ceased; and after this he was very weak, faint, and nearly pulseless. The pain continued a few hours after this vomiting, when it ceased. Although his mind was clear, he did not rally, but gradually sank, and died forty-eight hours later, or a little less than seven days from the commencement of the sickness. No blood was at any time passed by the rectum.

Autopsy 23 hours after death. There was no sign of decomposition; rigor mortis well marked; body that of a large, muscular man, and quite fat. There was a thick layer of fat over the abdomen. All of the abdominal organs were imbedded in this tissue. The walls of the chest were expanded in front and at the sides to such an extent as to make quite a deformity; and all the organs of the chest were above the fifth ribs. There was a slight adhesion of the left lung to the chest wall at the top, otherwise the pleuræ were everywhere clear, pale and glistening. Pericardium normal, but on opening this sac the heart was seen to present a noticeably peculiar appearance, the right ventricle being distended so as to make a rounded prominence on its upper part near the auriculo-ventricular junction. The right auricle was also distended. Both of these distensions felt elastic to the touch. On opening this side of the heart there was an escape of a puff of gas, and the walls of the organ immediately collapsed. There was no blood in either of the cavities. The right ventricle was a little dilated, and its walls were slightly thinner than normal. Left side of heart empty. The whole organ was rather large. Its tissues were pale, but of a uniform color. The valves were in every way healthy, and but little blood flowed from the cut ends of the large vessels.

The lungs were very broad and thick, making up in these dimensions what they lacked in length. They were everywhere of a uniform pale color, with darker marbling, except the dependent portions, which were a little reddened. They were also everywhere crepitant, the cut surface showing nothing abnormal, except that the blood-vessels of these organs contained but little blood. The mucous membrane of the bronchi and trachea was pale, and in places smeared over with a little frothy mucus. The spleen was more than twice the usual size. It was fairly firm. Sections showed it of a dark-red or blackish color, and the pulp largely increased. But little blood flowed or could be squeezed from the vessels. Both kidneys were imbedded in large masses of fat. They were a little larger and firmer than usual, the capsules slightly adherent. The cut surface showed the cortical part of a uniform pale red color, and of proportionate thickness. The tubular part was of a bluish tinge, and the blood-vessels could be seen as red lines. These organs contained but little blood. Ureters and bladder healthy. The latter contained a little urine. The stomach was large and flabby, and contained about a pint of liquid food. It, as well as parts of the transverse colon, was firmly adherent to the

lower border of the liver. All its tissues were normal in appearance, except that part where it was attached to the liver, which was a little reddened. The pylorus readily admitted the thumb. The duodenum was empty. Opposite the head of the pancreas could be seen the papilla marking the entrance of the common bile duct, as large as the end of the finger, and projecting into the gut. The opening of this duct would readily admit a pencil. Just inside the duct, lying loosely in the canal, was a gall-stone of such a size as to render it a little difficult to force it through the opening into the intestine. The common duct increased in caliber as it approached the liver, until it and the hepatic duct were dilated into a sac or pouch of about two ounces capacity. The walls of this pouch were very thick and hard, and there was a deposit of a dense tissue around them. At the lower end of this sac, near where the gall bladder entered it, was a cup-shaped depression the size of half a chestnut. When a little water was poured into this a shreddy mass floated up, being attached to the sides and bottom (recent ulceration). On the upper side of this dilated duct, and immediately opposite where the blood-vessels entered the left lobe of the liver, was a similar spot of ulceration, somewhat larger and irregular in outline. On handling a little blood was seen to flow from the bottom of this depression, and an opening was readily found leading directly into one of the vessels entering the left lobe of the liver.

I believed this to be a branch of the hepatic veiu, but all of the tissues in this vicinity were bound together in such a confused mass I was not quite certain. The gall-bladder was much thickened, and contracted in such a way as to make its cavity very irregular, and of a capacity of not more than two or three drachms. Its mucous surface had wholly lost its honeycombed appearance. The opening between it and the sac was wide enough to readily admit the finger. Both the gall-bladder and sac, when opened, contained a little bloody fluid.

The right lobe of the liver was smooth and glistening; rather large, and a little darker colored than usual. The cut surface showed its cellular structure slightly fatty, and its blood-vessels nearly empty. The left lobe of this organ presented a remarkable appearance. It was of a uniform greenish-brown slate color, smooth, but not glistening; and the contrast between it and the right lobe was very striking. It felt firm. The cut surface was of the same uniform greenish-brown color. All appearance of structure had disappeared. A piece of this lobe could readily be broken with the hands: and the fractured surfaces had much the appearance of a nearly dried piece of mud treated in the same way. The larger blood-vessels could be made out in the mass. They were filled with a dryish brown-red material that remained formed when turned out of the vessel: but readily crumbled in the hand into a coarsely granular mass. The main vessels entering this lobe of the liver near the ulceration above described were filled with the same material.

The large intestine contained a little solid and semi-solid yellowish fæcal matter. The small intestine was nearly empty, but contained a little of the product of digestion, of a yellowish color. Nowhere in this tube was there anything that looked like blood.

Unquestionably the source of the hæmorrhage was this open blood-vessel supplying the left lobe of the liver, the blood readily finding its way into the duodenum by means of the largely dilated duct and its opening into the intestine, and through the rather open pylorus into the stomach. Why all of the blood should take this course and none of it go down the intestinal canal, as it apparently did not, is one of the points in this case seemingly worthy of discussion.

Of course the gas accumulating in the intestinal canal after death found its way by means of the same open vessel to the right side of the heart.

Hæmatemesis, with the blood coming from such a source, must be exceedingly rare, and so far as I am able to learn, this case is unique.

The peculiar condition of the left lobe of the liver I have never seen before. I believe it to have been caused by a complete cutting off of the blood supply, producing a necrosis of the part.

Dr. F. A. Harris, Medical Examiner for Suffolk, said that the strange and heretofore unknown occurrence recorded by Dr. Holt is valuable in making us acquainted with a new causation for sudden death. The medical examiner is required to investigate all cases of death of a sudden or suspicious character, and it no doubt may happen that cases are returned as due to disease of the heart, no other ascertainable lesion existing, which may be due to some cause not hitherto reported and entirely unknown. In many cases some obscure disease might easily be quite overlooked. Among such causes is aneurism, which, even when of small size, may at times obstruct the nutrition, or disturb, and at length entirely suspend, the function of important organs. In one case an unsuspected small aneurism of the internal carotid caused obscure cerebral symptoms, and finally death from pressure upon one of the pneumogastric nerves. Aneurism of the arch of the aorta may be suspected from the occurrence of disorders of the vocal apparatus in the larynx not due to any organic local disease, when the existence of aneurism is not evident from any other symptoms. In such cases the existing disease may be so slight that it may escape observation at the autopsy, and the death of the patient be charged to some other cause. The medical examiner is required to give a cause of death in all suspected cases, the law requiring him to ascertain the manner by which the patient met his death. For this reason, if for no other, all cases of death from rare diseases should be reported, for the benefit of State and local Boards of Health, as well as for statistical and other purposes.

Dr. Fitz considered the paper extremely interesting, and was glad to have heard the report of so rare a case. He said he had never met anything of a similar nature in his personal experience. Gall-stones may occasionally become a cause of ulceration of the gall-bladder and secondarily lead to much further mischief. The reported condition of the liver is very remarkable. Such a change is occasionally observed

in the lung, as a wedge-shaped necrosis of a part of the pulmonary structure due to embolism of some vessel. The necrosed portion then quickly becomes the seat of gangrene, and generally goes on to a fatal termination. The presence of gas in the heart is interesting. The opinion of Dr. Holt that the gas was formed from decomposition after death might be criticised, as it might quite as easily enter the venous channels during life.

Dr. Webber asked if gas, entering the circulation before death, would not be evidenced by a frothy condition of the blood on opening the heart.

Dr. Fitz replied that while this is often the case, it is not necessarily so. It may escape as a free gas. Atmospheric or gas embolism is sometimes observed in other parts, especially in the lungs.

Dr. Prince observed that pancreatic apoplexy[1] may be accompanied by many of the symptoms mentioned in this paper, and quite generally vomiting occurs.

Dr. Church, of Cambridge, presented the following

NOTES OF A PECULIAR CASE IN WHICH THE AUTOPSY SHOWED CONGENITAL ABSENCE OF THE LEFT KIDNEY.

On Tuesday A. M., November 6, I was called to attend Mrs. L., a Swede, in confinement. On arriving at her house I was shown into a room containing a bed, and upon it lay a well-dressed woman, apparently forty years of age; presuming her to be Mrs. L. I approached the bed, and made the inquiry if she was the person to whom I was called, to which she responded in the negative, saying that she was a friend of Mrs. L.'s, and had arrived from Vermont the evening previous, and had not felt well since her arrival. Complained of pain in the stomach and back, with slight headache, but thought she had taken cold, and rest would suffice to restore her to usual health. I then passed on to attend Mrs. L. in an adjoining room, and did not see Miss A. until three or four o'clock in the afternoon, when I obtained the following history: She was born in Sweden; was forty-five years old; came to this country two years ago; had always been well excepting "slight touches" of dyspepsia and occasional sharp pains in the epigastrium. Menopause fully established before she left Sweden. Had worked as a domestic in a farmer's family in Vermont for nearly two years. Said that the bowels were regular, and appetite usually good. Never used stimulants or narcotics. When asked if she had not better have some medicine she said no, as she thought rest and diet would be all that was necessary. Saw her on the following morning while visiting Mrs. L. Said she had not slept during the night previous. Bowels and bladder had been evacuated during the night, but the pain in the back and stomach had not subsided, and she had vomited twice during the morning, and had an attack of epistaxis and severe headache. The tongue was very dry, and in the center covered with a thick, brown incrustation; some sore throat. Examination of the chest gave negative results; the only peculiar feature was the feebleness of the heart sounds. Pulse 88; temperature 96.5° F.; respiration normal; slight tenderness on pressure in the right hypochondrium. Warm applications and stimulants were ordered, and at noon she got up, went into the kitchen, and drank some milk and tea. I did not see the patient again until Thursday morning at 9 o'clock, when I found her comatose. I was told by the people in the house that she had slept all night. At the time of my visit the respirations were heavy, tongue and mouth as dry as parchment, and mouth and throat full of a mixture of dried blood and saliva; pulse 88°; temperature 95° F.; pupils dilated; marked pallor, and a peculiar pinched expression of the face. Feeling that the case would prove fatal, and knowing that the patient had no relatives or friends in this country, I asked City Physician Bryant to see her. Pulse, at the time of visit—12:30 P. M.—90; respiration normal; temperature 95° F.; patient profoundly comatose. At 5 P. M. she became pulseless, and expired at 9 P. M.

Examination of the urine gave the following results: color pale; reaction neutral; specific gravity 1010; large trace of albumen; urea slightly diminished; phosphates and chlorides diminished. Microscopic examination showed triple pho phates, no pus or blood, a few degenerated renal epithelium cells, but *no casts* or *fat*.

Feeling that either from imperfect memory or inability to understand or express herself in our language the history given me by the patient was incorrect, I wrote her employers at Williamstown, Vt., and obtained the following additional history:

First. That she had suffered much from what had been diagnosticated by a resident physician as dyspepsia.

Second. That one year ago she had an illness of five weeks. Diagnosis, "ulceration of the lung and slow fever." That previous to coming into their employ she had visited the Massachusetts General Hospital for nausea and suppression of menses, and was thought to be pregnant.

Third. During the last year, though her appetite was good, she complained of feeling weak, of having headaches and frequent attacks of severe epigastric pains, and cramps in the lower limbs, also of some dizziness.

Fourth. That large quantities of urine had been voided, especially during the night, for a long time.

Fifth. That when she arrived at Mr. L.'s on Monday night she complained of feeling very dizzy, and trembled violently.

Sixth. That for the past eight or nine months the patient had complained of sleepiness during the day, and imperfect vision.

The autopsy was made by Medical Examiner A. F. Holt, Saturday morning, November 10, to whom I am indebted for the following report:

The body was that of a Swedish woman, 45 years of age. The heart was enlarged, particularly the left side. The left lung was adherent throughout. Spleen normal in size and appearance. Left suprarenal capsule in its usual position, but a little larger than normal. No left kidney, renal artery, or ureter could be found, or anything to indicate that they had

[1] A report of two cases, with references to fourteen other cases, was read before the Section May 6, 1882.

ever existed. The right kidney is the one here shown. It is very small, not larger than a large hen's-egg, and shaped much like one. The whole organ feels firm and rather hard. The capsule is much thickened and adherent. The cut surface, when removed, was of a uniform grayish color, with darker mottlings. The line between the cortical and tubular parts could not be made out at that time; now, as it has been in dilute alcohol for a day or two, it can be distinguished. The greater part of the organ seems to be made up of the cortical portion. The whole organ, without doubt, has undergone some marked change, probably interstitial nephritis, but of this I am not certain, as no microscopic examination has been made. The liver was a little larger than normal. Stomach and intestines apparently healthy.

In my experience in making autopsies only in one other case have I found but a single kidney; this was in a man, sixty-five years of age, who died of cancer of the stomach. In that case the single kidney was very large and healthy, and, as in the present case, it was the left kidney which was wanting.

I believe that both of these cases were congenital.

Dr. Church also exhibited the vermiform appendix of a patient who died from perityphlitis and peritonitis, and in which the cause of the disease was found to be an ordinary brass pin, which had been swallowed, had passed through the stomach, duodenum and the entire length of the small intestine, and had entered the vermiform appendix, head downward where it had awakened a violent inflammation with the subsequent fatal result.

BOOK REVIEWS.

PHYSICIANS VISITING LIST, 1884. P. Blakiston, Son & Co., Publishers, Philadelphia.

This convenient pocket memorandum and case book has appeared regularly for the last thirty-three years. It is too well known by the general profession to need any special description.

PHYSICIANS POCKET DAY BOOK, designed by C. HENRI LEONARD, M.A., M.D., Detroit.

This is meant to cover much the same ground as the last. It, however, lacks the dose tables and such information as is in the other. Both of these books are well bound and of convenient size.

THE RADICAL CURE OF HERNIA. A PLEA FOR THE CURE OF RUPTURE, OR THE PATHOLOGY OF THE SUBCUTANEOUS OPERATION BY INJECTION FOR THE CURE OF HERNIA. By JOSEPH H. WARREN, A.M., M.D. Boston: James R. Osgood & Co.

This is a small paper-covered volume of 125 pages, written apparently to uphold the injection method of treating rupture for radical cure, and perhaps also to identify the author as the legitimate successor of Dowell and Heaton, who formerly had a sort of proprietary hold upon the operation.

At the time of the publication of the supposed valuable secret of this method, it was very extensively tested by surgeons and by itinerants all over this country, as similar methods have been in Germany.

The operation, although a safe one, and the best so far tried, has met with a discouraging number of failures.

That the operation cures some ruptures of course is well understood, but it is also becoming evident that its successful cases, are those in which the simple wearing of a truss often makes a radical cure, *i. e.*, young persons.

Long after the operation has been performed a truss must be worn—a year at least the best writers think—after which time a surprising number of cases relapse and eventually are not improved. Such patients of course deceive themselves and their surgeon into the belief that a brilliant cure has been effected. Months usually elapse before a recurrence of the hernia, and the surgeon may never hear of the final result.

The constant appearance of ruptured patients at clinics and truss establishments, who have tried the injection method with only temporary benefit, is an argument not easy to answer by those who have put forth glowing promises and reports of cases. No case ought to be reported among "cures" until several years have passed by without a return. A prominent Philadelphia surgeon—who was once quoted by the originator of the injection method as having seen brilliant successes from it—afterward declared it as his opinion that no undeniable and permanent cure had ever been made by it.

A MANUAL OF PATHOLOGY. By JOSEPH COATS, M.D. Illustrated. Published by H. C. Lea's Son & Co., Philadelphia.

This manual consists of a single volume of about 800 pages. Its subject-matter is treated of under the headings of General Diseases and Diseases of Special Organs. Under the head of General Diseases are described affections of the circulation and of the blood, inflammation, retrograde metamorphosis, hypertrophy, repair, regeneration, infective tumors, tumors or morbid growths, and parasites. The largest part of the work is devoted to the diseases of special organs and systems. The book is well written and very well illustrated with wood-cuts. It presents clearly the most generally accepted views of modern pathologists. In the chapter on parasites, the author considers quite freely and very fairly the theories and facts pertaining to bacteria. First, the natural history of bacteria is briefly considered, and the methods of detecting them are described. Their influence on living tissue is then considered. Septicæmia, whose bacterial origin is pretty well proven, is described in detail. In regard to the pathogenetic powers of bacteria in acute specific diseases, the author places himself on conservative ground, although he gives full descriptions of the bacteria that have been found in them. He says in regard to the matter: "Bacteria have been found in the tissues in a large number of acute diseases in man, and most of these diseases belong to the class of zymotics. Among the diseases in which, up to the present, such organisms have been seen, may be mentioned small-

pox, scarlet fever, measles, diphtheria, acute rheumatism, erysipelas, typhoid fever, typhus fever, splenic fever, relapsing fever, pneumonia, leprosy, tuberculosis. All that is asserted, in the meantime, is that bacteria have been observed in these diseases; it is not meant that each of these diseases depends necessarily on a specific form of micro-organism."

The work, as a whole, is creditable to the author, and will prove a useful manual to English readers.

DOMESTIC CORRESPONDENCE.

PHILADELPHIA LETTER.

There has probably not been for many years a winter characterized by such indefatigable exertion on the part of the medical profession of Philadelphia as the present. The reason for this unusual activity lies in the fact that a new element has been introduced into the methods of teaching, that of post-graduate instruction. A number of gentlemen from the rank and file have been called upon to assume the responsible position of teachers, and as they are theoretically well qualified for the duties, there is a commendable spirit of rivalry existing which promises well for the future. The rivalry to which we have referred is nowhere more noticeable than at the meetings of the County Medical Society, which are held weekly and largely attended.

For the purpose of giving the readers of the JOURNAL an idea of the character and amount of work done at these meetings, it may be worth while to present some notes picked up from the last two.

On the 12th inst. a conversational meeting was held, the principal paper being that of Dr. Arthur V. Meigs, who selected as his subject, "Proof that Human Milk Contains Only about One per cent. of Casein, with Remarks upon Infant Feeding," a somewhat condensed summary of which would run about as follows: A paper relating to this subject read before the society nearly a year ago had been adversely criticised by reason of the peculiar views then held, but during the interval he had been engaged in further experiments, and so far they had only confirmed the statements then put forward. He said the methods of analyses by different chemists were not free from error, and besides, many of them had started with incorrect premises. As a rule, it was believed that the amount of sugar in milk was small and the casein large, and two reasons were given for this apparent condition, viz.: that there were variations in the milk itself or that the chemistry was faulty. He believed that if the proper precautions were observed, the amount of sugar in cow's milk would be found to be uniform and large, while on the other hand, the amount of casein would be small. By means of the necessary chemical reagents he had been able to obtain the sugar in a crystalline form, and so far as he was concerned, the matter was fully set at rest. Although cow's milk had been objected to on account of the casein it was supposed to contain, his experiments had proven conclusively that this was erroneous, and in this respect opinions were diametrically opposed. An analysis of forty-three samples of human milk, the tables showing the results being presented for inspection, has convinced him that cow's milk when diluted does not supply the place of human milk. The reaction of the former is acid, while that of the latter is alkaline, an important fact which has thus far been overlooked, as the character of the coagulum formed by milk depends largely upon its acidity. Another point to be observed is, that cow's milk contains much more casein, a substance which though but little known, has been found when subjected to the process of drying to become insoluble. The reasons for failure are now apparent, and the want of success can be accounted for, and although much time has already been given to the study of the matter, it is still evident that further investigations are necessary.

A formula was presented for the preparation of an artificial food which shall meet the requirements of the case, but as the paper will be published in full, its reproduction here will not be attempted. It may be added, however, that it will be found most satisfactory in the preparation of the artificial food to use good, fresh cow's milk.

The paper of Dr. Meigs is the result of long and careful investigation, and the principles laid down will undoubtedly have the effect of establishing a new era in the methods of infant feeding.

A clinico-pathological meeting, held on the 19th inst., from the character of the papers presented, may appropriately be termed a medical symposium, the entire evening having been devoted to the reading of papers on, and the discussion of the diseases of, the kidneys, more especially, however, with reference to albuminuria. The only paper referring to therapeutics in renal diseases, was that of Prof. Bartholow, the subject being, "The use of Nitro-Glycerine and Chloride of Gold and Sodium in Albuminuria."

Starting with the proposition that albuminuria was essentially a neural affection, he pointed out two conditions found to exist: first, that in which the vascular supply was deranged by reason of the contraction of the vessels, a circumstance due to the heightened activity of the sympathetic nervous system. In such cases, nitro-glycerine, by removing the tension of the peripheral vessels, lessened the work to be done by the heart, and had the effect of equalizing the general circulation, thus theoretically favoring recovery, and clinical evidence, he said, had confirmed this opinion. Second, a condition obtains in which there is an increased tissue formation, a hyperplasia, and these cases, when seen at an early stage, might be greatly relieved, if not entirely cured, by the appropriate administration of the chloride of gold and sodium, a remedy which in some respects resembles the action of corrosive sublimate. It is a remedy which appears to have a selective action on the sexual functions, but neither this nor its supposed value is a modern discovery, as the use of gold has been referred to by some of the most ancient writers; and in opposition to a generally received opinion that it was first used by Hahnemann, we find quite an interesting account of its history in that curious but antiquated work, "Burton's Anatomy of Melancholy," published, you know, long before the days of Hahnemann. Like all the productions of Prof.

Bartholow, this one partook of the usual features; it was clear, concise, exact, and the logic of his arguments unassailable.

The paper, however, which developed the greatest amount of discussion, was that of Dr. James Tyson, the subject being, "Some Recently Suggested Delicate Tests for Albumen." Dr. Tyson covered the ground pretty thoroughly, so far as known, concerning the substances to be used in testing, and amongst the number reference was made to picric acid, an old method which has recently been brought forward anew, and the drift of discussion seemed to rest particularly on this latter preparation. Along with others who gave an account of their experience with its use, none seemed to cover the ground more thoroughly than Dr. John Aulde, who is reported as follows: Having given this subject some study and investigation recently, I may be able to add something to what has already been said by the gentlemen who have preceded me. That a saturated solution of picric acid is a delicate test for albumen in the urine, none will question; but there is an objection to it, and the same may be said in regard to nitric acid, namely, that it stains the hands and clothing of the operator. The points in its favor are, that a solution can easily be prepared, and it is safe to handle; but there are chances of error, and unless these are first eliminated the physician may be misled by this method of examination at once.

If a quantity of albuminous urine is placed in a test-tube, and a single drop of the solution allowed to fall upon it, a distinct coagulum will be formed, but when there is an excess of albumen, agitation of the mixture will cause it to be readily dissolved. If there are peptones in the urine, the addition of picric acid will be followed by a precipitate, and contrary to the opinion of Dr. Tyson, Gerhardt has frequently observed peptones in urine free of albumen, either as a forerunner or consequence of ordinary albuminuria, while Senator states that peptones exist in every albuminous urine in slight quantities. Another source of error arises from the use of quinine, a substance excreted largely by the kidney, and it has already been stated that a weak solution of the alkaloid, when brought in contact with picric acid, will show the characteristic reaction, but there are other alkaloids which will act in a similar manner, although I am not able at present to name them. The presence of urates will likewise throw down a coagulum with this solution, but not until after some minutes, but it should be stated that there is a material difference between this and the coagulum formed by albumen. In the case of urates it is crystalline, while that of albumen is granular.

It will not be out of place here to call attention to the possibility of laying to much stress on the single fact that there is albumen in the urine, as it has been shown that it does exist in normal urine. The recent work of Dr. Millard, entitled "Bright's Disease," is authority for the statement that in a series of examinations conducted by French surgeons, the urine of soldiers supposed to be in good health and free from hereditary taint, discovered the presence of albumen in no less than eighteen cases out of one hundred.

Permission having been granted to ask a question, Dr. Aulde said, Dr. Tyson has related the case of a patient who was under treatment for some time, but the urine, although examined repeatedly, failed to discover the presence of albumen by the usual tests, but he says that when picric acid was added a coagulum was formed at once. He has further stated that the treatment embraced the use of the salts of potassium, a remedy which is now well known to cause this peculiar reaction when excreted by this channel, and the question is this: was it really albumen, or does the use of these salts furnish still another source of error.

The unusual marked success which has attended the use of the oleates, has prompted the writer to continue his investigations at the Philadelphia Hospital for Skin Diseases, which has resulted recently in the formation of oleate of nickel, and the development of a therapeutic value to the oleate of tin. This new chemical oleate is similar to the oleate of tin, quinine and others, which *I first described* as *salts*, in 1879, before the Pennsylvania State Medical Society, and again in 1881. It was manufactured by Dr. L. Wolff, of this city. It is prepared by the double decomposition of the nickel sulphate and sodium oleate, the chemist using the oleic acid of the U. S. P. in making the latter ingredient.

I might add in this connection that oleates made from the impure oleic acid, the so-called red oil of the candle-makers, while cheaper, are neither certain or decided in their action, and will often set up an irritation upon the skin when the opposite effect is desired. After some years of patient and careful investigation of the oleates, and a comparison of the therapeutic results of the salts made from the pure oleic and U. S. P., and the impure or red oil, has resulted in positive and excellent results with the former, and with disagreeable and very often irritating effects with the latter. I refer especially to this subject on this occasion, as many of the oleates now offered by manufacturers, and from which bad results have followed, are due entirely to the irritating action of this impure oleic acid or red oil.

The Oleate of Nickel, just mentioned, is a greasy amorphous, waxy, tasteless substance having most decided astringent action, almost bordering upon the effect of a caustic. I have tested it upon some chronic cases of the eczema of the extremities in which the skin was hard and of a leathery state, with some good results. The salt was used in from five to twenty grains to the ounce of lard. It is now also being tried upon some old ulcers and cancerous affections of the skin in the out-door department of the hospital.

The oleate of tin already alluded to is prepared by the double decomposition of the tin chloride and sodium oleate. It is of a greyish-yellow appearance, unguent consistence and possesses a metallic odor. It has been found to be of great utility in giving luster to diseased nails that have been abnormal or deficient in their growth. It assists by its local action in overcoming a brittle, split or soft condition of the nails that often follows certain skin affections and external injuries. It forms, especially when combined with a little carmine, an elegant article of toilet for the nails

and surrounding cuticle, giving the parts a beautiful polish. It assists in relieving by its astringent action the ragged and attenuated skin at the base of the nails, or what are known as agnails, that are so often observed from neglecting these important appendages.

FROM WASHINGTON.

The following bills of interest to medical men had been introduced in Congress previous to its recess for the holidays:

Senate Bill 403. Provides for the erection of a brick and metal fire-proof building to be used for the safe keeping of the records, library and museum of the Surgeon-General's office of the United States Army, to be constructed upon the government reservation in the City of Washington, in the vicinity of the National Museum and the Smithsonian Institution, on a site to be selected by a commission composed of the architect of the Capitol, the Secretary of the Smithsonian Institution, and the officer in charge of the State, War and Navy Department building, and in accordance with plans and specifications submitted by the Surgeon-General of the Army and approved by said commission, the cost of the building, when completed, not to exceed the sum of $200,000, the building to be erected and the money expended under the direction and superintendence of the officer in charge of the State, War and Navy Department building.

H. R. 159. Whereas alcohol enters largely into the medicines which are prime necessaries to the sick and afflicted, and is now taxed to a burdensome extent. Therefore, that the tax on alcohol used for medicinal purposes be, and the same is hereby abolished.

H. R. 307. Provides compensation for the services of all volunteer female nurses who rendered service during the war, in the field or in hospital, under the direction and control of the medical authorities of the army, at the rate of twenty-five dollars for each month of service. That the nurses who have received twelve dollars per month shall have an additional thirteen dollars.

Ex. Doc. No. 24. Is a message from the President transmitting a communication from the Secretary of the Navy, inclosing a letter from Surgeon-General Wales, U. S. N., which recommends that a measure be adopted authorizing the representation of the United States at an international convention for the establishment of definite and uniform standards of examination for color-blindness and tests of visual acuteness. To this commission delegates should be sent to represent the several governments interested in the subject.

S. 31. Provides for the establishment of a Bureau of Animal Industry, to prevent the exportation of diseased cattle, and the spread of infectious or contagious diseases among domestic animals. In its sections it 1st, prohibits the transportation of diseased cattle; 2d, fixes the fine at from $100 to $5,000; 3d, provides for the organization of a Bureau of Industry with a chief, to be a competent veterinary surgeon, whose duty it shall be to investigate and report upon the number, value and condition of the domestic animals of the United States, their protection and use, and also inquire into and report the causes of contagious and communicable diseases among them, and the means for the preservation and cure of the same, and to collect such information on these subjects as shall be valuable to the agricultural and commercial interests of the country. The National Board of Health is required to render all necessary aid for this purpose, and, further, two commissioners are to be employed—one a practical stock-raiser, and one an experienced business man. They are to be paid at the rate of $10 per diem., with all necessary traveling expenses while engaged in the performance of their duty. The salary of the chief of Bureau to be $3,000 per annum; and a clerk is to receive $1,800 per annum. 4th. Special investigations of pleuro-pneumonia, or any contagious or communicable disease, to be made to control specially its influence upon the exportations of live stock. 5th. Is a further definition of laws for this purpose. 6th. Requires the Commissioner of Agriculture and the National Board of Health to prepare rules and regulations for the speedy and effectual suppression and extirpation of such diseases, and to invite State and Territory authorities to coöperate in their execution and enforcement. 7th. Makes $50,000 immediately available. 8th. Gives explicit directions to the Commissioners of the District of Columbia for the control of such diseases occurring within the District; and Section 9th makes it the duty of the U. S. District Attorney to prosecute all violations of the act.

S. 338. Appoints Dr. A. Sidney Tibbs, of Leesburg, Virginia, now an acting assistant surgeon, to the position of assistant surgeon in the U. S. Marine Hospital Service, without regard and in addition to the number now authorized by law for such service.

S. 81. Revokes the honorable discharge, June 17, 1870, of Assistant Surgeon Benj. F. Pope, U. S. A., and considers him as having been continuously in the service, and confirms his relative rank and title.

S. R. 6. Provides for the payment of fees to examining surgeons of pensions for 1883 and 1884.

CRAWFORDSVILLE, IND., DEC. 14, 1883.

EDITOR OF THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION:

The article entitled "Retention of Placenta After Delivery in Uterine Pocket," on page 649, issue of Dec. 8, 1883, of your journal, raises an interesting question as to the causes of uterine pockets. I have seen cases where the entire placenta was retained after the delivery of a child by the breech, the uterus contracting down and around until it presented a regular gourd shape, and it was with difficulty I could pass my hand through the portion corresponding to the handle of the gourd to remove the placenta, which I would not find unduly adherent, but seemingly grasped in the contracted walls of the uterus. My theory was, that the head of the child pressing upon the placenta furnished the necessary resistance to prevent that portion of the uterine wall covering

the placenta from contracting and throwing the placenta off. Without the support furnished by the pressure of the child's head, the placenta would furnish much less resistance. Also, in normal presentations, the buttocks or feet of the child might furnish pressure enough to keep a part of the placenta from being thrown off, and cause what Prof. Herrgote so clearly sets forth when he says, "but that it rather results from the non-contraction of that portion of the uterus upon which the placenta was attached, and which was afflicted with inertia, while the remaining portion of the uterus contracted, thus being passively distended over its contents and thinned in its walls, becoming a true hernial pouch on the uterine surface, the constriction to which became more and more pronounced as the body of the uterus diminished in size."

Thanks to Indiana not having a law regulating the practice of medicine, I was called a short time ago to see a lady who had had a quack attend her in her confinement, some 24 hours before my visit. She had been delivered of a healthy child at full term, and I was told it was a head presentation. The placenta being retained, the doctor (?) (who by his advertising sociability and liberality amongst our fun loving part of the community, does a big practice) pulled his coat off. He then placed his patient in the knee-chest position, and introduced a cylindrical glass speculum, and with a pair of uterine dressing forceps removed shreds of the membranes, keeping her in this position one hour and a half. She was then allowed to rest six hours, when he emptied the vagina of blood clots and repeated the picking process—making three hours the woman was kept in that position. When I arrived, the doctor (?) showed me a chamberfull of clotted blood, shreds of membrane, and the cord, and told me that was the entire afterbirth, and advised that the patient be not disturbed. I introduced my hand into the uterus, and detached all the placenta except about as much as a man could grasp in one hand, on the edge, which was firmly grasped by a uterine pouch. By passing first one and then two fingers up into the pouch, I succeeded in removing the entire placenta, much to the surprise of the friends of the patient and the chagrin of the doctor (?) May God speed the day when our women will not be exposed to such dangers —I mean exposed to such doctors (?)

Yours truly,

T. F. LEECH, M.D.

EDITOR JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION:

In your issue of Dec. 15, brief reference is made to a suggestion of Dr. S. C. Gordon, of Maine, that stenographic reports of the discussions held in the various Sections at the annual meetings be provided for.

Such a provision, I feel sure, would well repay the cost. It might be advisable to have the reports edited, either by the editor of the JOURNAL or a proper committee; though even this, probably, should not work a too rigid trimming of matter.

Society reports, to many physicians, constitute the most interesting portion of a medical periodical. Therein are found the prevalent views upon present and living topics—a kind of clinical discussion, we might almost term it.

Often must one regret, when a subject of interest is being handled by some of the weightiest men of the profession, that most of the valuable thoughts are uncollected, running to waste, we may say, for want of competent record.

Many of our best physicians fail, in the rush of work, to write out the observations they are constantly making upon the subjects of the day; but the discussion once sprung, they do not hesitate to engage in it. A stenographer, from this cause, could catch for us some of the very best thoughts developed by our annual gatherings.

Respectfully,

JNO. THAD. JOHNSON.

Atlanta, Ga., Dec. 29, 1883.

NECROLOGY.

SAULSBURY, GOVE, M.D., was born in Mispillionneck, Kent Co., Delaware, May 29, 1815; died at his residence in Dover, July 31, 1881. He was the son of William Saulsbury, a man much respected and honored by his fellow citizens. His mother, Margaret Saulsbury (nee Smith), was the daughter of Capt. Thomas Smith, a lady of sound mind and Christian character.

There were born to them five children, James, William, Willard, Gove and Eli, of whom two yet survive,—Willard, formerly U. S. Senator from Delaware (now Chancellor), and Eli, at present U. S. Senator.

After an academic education, Gove studied medicine, and was graduated in the University of Pennsylvania in 1842. Subject of his thesis: Rheumatism. He commenced the practice of his profession in Dover, Delaware, and acquired an extensive professional business, which he retained to a considerable extent; even when his health was much shattered, he attended to it with great fatigue.

Dr. Saulsbury was an active member of the State Medical Society, and was honored with its highest offices. He was one of the original members who organized in 1846 the American Medical Association. Of these worthies but few now survive.

For 20 years he adhered closely to his profession, when he was elected to the State Senate, of which he afterwards became speaker, and *ex-officio*, Governor of the State on the death of Governor Cannon. In 1866, at the expiration of that *pro tempore* term, he was elected Governor, and in that office he exhibited the ability, decision, and controlling power of mind and presence, which contributed in a great degree to the influence which he continued to exercise in the State during his life.

His efforts in the cause of education were chiefly through the agency of the Wilmington Conference Academy of Dover, of whose Board of Trustees he was President from the time of its organization until his death.

As a member of the Methodist Episcopal Church he exercised so marked an influence, and his interest in its welfare was so appreciated, that he was selected to represent one branch of that church in the General Council of Methodism recently held in London, but which his death anticipated.

Dr. S. was much respected in the community in which he lived. A social and agreeable neighbor, a kind friend to the poor, warm in his attachments, and a devoted and affectionate parent; he has left behind him in his own city and State very many who will hold his memory dear while life lasts.

His wife was the daughter of Thomas Smith; their family consisted of five children, Margaret, Olivia Smith, Gove, jun., Rosa and William. The first three died young; Rosa, a lovely girl of 23 years of age, was taken away suddenly by death; William alone survives. The shock of the death of Rosa was too great for Mrs. Saulsbury's feeble health, and she soon followed her to the grave. Dr. Saulsbury was thus left alone with his son; to him the flavor of life had departed, and trials and disease soon did their work, and laid him beside so many of those dear to him in "the narrow house appointed for all the living."

L. P. Bush, M.D., of Delaware.

Williams, Lewis, M.D., was born in Pomfret, Connecticut, A. D. 1815. He died in his native town June 22, 1881, aged 65, of cerebral meningitis, with hæmorrhage upon the surface of the brain.

He entered Amherst College at the age of 19, but was obliged to discontinue his studies during his second college year, on account of ocular disease.

Upon recovering his health he commenced the study of medicine, and received the degree of M.D. from Harvard Medical College A. D. 1842.

He began the practice of his profession the following year in his native town, where he lived and labored forty years, winning the esteem and respect of all who knew him.

The same year that he settled in Pomfret he married Clara C. Baldwin, of Woburn, Mass., who survives him. This union was a very happy one. Mrs. Williams is spoken of by one who knows her well as "a woman of culture and Christian character. She was an inspiration to him in all his best endeavors, and made his home everything that the word can express, even in its highest and purest sense. Their hospitality was unbounded, yet in spite of the cares incident thereto, this ever active and tireless woman found time to assist her husband in much of his professional work, and he was proud to accord to her a large share in all his honors."

Dr. Williams was an active member of the Windham County Medical Society, the Connecticut State Society, and a permanent member of the American Medical Association since 1855. He was one of the Examining Committee of the Medical Department of Yale College, one of the quarterly visitors appointed by the State to the Retreat for the Insane at Hartford, and one of the Trustees of the State Normal School. He never sought public office, but devoted himself exclusively to the duties of his profession.

He was, however, much interested in the cause of education, and ever ready to do all in his power to assist all the educational interests in his town, county or State.

He was a man of pure character, strictly conscientious in all he did, and deeply impressed with the dignity and responsibility of his profession.

He was also a high-minded, whole-souled, generous citizen of broad culture, as well as a skillful, bold and careful physician. He loved the truth, and therefore detested quackery in all its forms. He was a diligent student to the end of his life, and fully up with the advance of the times.

He possessed in a large degree the confidence of his professional brethren, and his counsels were ever in demand by them near and far.

These calls from his associates, combined with the labors of a very extensive private practice, made his duties numerous and his life one of constant care. Still, although often oppressed with physical fatigue, his spirit was ever ready and willing to work for the benefit of his fellows, and his interest in his chosen profession never diminished.

The news of his death came unexpectedly to his large circle of friends and patrons, and was everywhere received with expressions of the sincerest regret.

The funeral services were held at the Congregational church at Pomfret, of which the doctor was long a consistent and prominent member. The occasion was one of universal sorrow, when all classes in the community, where he was born, lived and died, bore testimony of their love and respect for the good, pure, generous, wise friend and counselor who had been called from them forever.

Chas. H. Pinney, M.D.

Derby, Connecticut.

Whereas, The messenger "Death" has claimed as one of its victims our worthy and esteemed fellow member and ex-president, Dr. James Kerr.

Resolved, That we, the members of the Pittsburgh L. S. Medical Society, attest our sincere sorrow at the death of Dr. Kerr, and our high appreciation of his eminent attainments as a physician and surgeon.

Resolved, That as a society and individual members we shall keenly miss his genial features, his earnest sympathizing friendship, as well as his wise, efficient counsel.

Resolved, That in his death the community has lost a good citizen and a zealous, skillful and painstaking physician.

Resolved, That we extend to the family of deceased our heartfelt sympathy.

Resolved, That a copy of these resolutions be spread upon the minutes of this society, and one be sent to the family of deceased.

John M. Duff,
A. G. Case,
J. D. Thomas,
A. D. Brewster,
Committee.

Pittsburgh, Pa., Dec. 26, 1883.

THOMAS, J. R., M.D., of Bay City, Michigan, was born at Potter, Gates Co., N. Y., Oct. 17, 1827; died at his residence in Bay City, April 29, 1883 In youth, as is common with farmers' sons, he engaged in all the labors and duties of farm life. After acquiring a fair preliminary education, he entered the office of Dr. Charles H. Hoyt, of Potter, as a student of medicine and surgery. He graduated with honors at the Geneva Medical College, at that time one of the foremost medical schools in the State of New York. Soon after receiving his diploma he settled at Ellery Center, Chatauqua county, N. Y., for the practice of his profession. While there he was united in marriage with Emma Hilburt, of that locality, his present widowed wife.

In 1861 he entered the service of the United States as Assistant Surgeon to the 112th New York infantry, and went to the seat of war in North Carolina. After about one year he resigned his position, came to and settled n Bay City, where he has since practiced his profession very acceptably to the general public.

His affiliations with the profession of the State have been very cordial. In addition to his membership with the local societies of his own and adjacent counties, he was a member of the State Medical Society, having been one of its Vice-Presidents, member of the Judicial Council, a delegate to the American Medical Association, (of which he was a permanent member) and also President of the State Medical Society; he had also served two years as a member of the Board of Counselors with the Detroit Medical College. In all of these varied positions he had discharged the incumbent duties with credit and fidelity. He leaves a family consisting of an amiable and accomplished wife and two sons, the eldest of whom is now the editor of the *Jefferson* at Cairo, in this State, and the younger is now a sergeant in the regular service, and stationed at Fort Mead, in Dakota. The many and varied professional stations which the doctor was called to occupy during his life time sufficiently indicate his thorough accomplishments as a doctor of medicine, and his loss will nowhere be more keenly felt than by his numerous patrons.

The general public will attest fully the genial character of his social qualities, and his professional brethren, wherever known, will duly estimate their own bereavement.

His remains were taken to his old home in New York State.

At the meeting of the Board of Counselors of Detroit Medical College, and also of the State Medical Society, following the death of Dr. Thomas, members of both bodies gave expression to their estimate of the high character and sterling worth of Dr. Thomas, of his honorable professional bearing, and integrity and purity of life. Resolutions were adopted expressive of his services to medical science, of the loss to the profession and to those organizations to which he gave strength, and of sympathy to his family. H. TUPPER, M.D.

Forwarded by Dr. W. F. Brisky, of Mighigan.

SWEENEY, W. H., M. D., died at Red Wing, Minn., August 12, 1882, in the 64th year of his age.

Dr. Sweeney was born in Wilson, Pa., Dec 18, 1818, and began his education in the public schools. His father being a practical printer, and editor of a country paper, he early acquired a taste for literary pursuits, and became a ready writer. In 1836 he removed to Illinois, and for the next ten years worked hard on a farm and in a country printing office. In 1847 he began the study of medicine, and soon after came to St. Paul, Minn. Graduating at Rush Medical College, Chicago, in 1857, he returned to St. Paul, but the following year moved to Red Wing, Minn., where he finally located, and became the trusted physician of that beautiful young city. He was true and good in every walk of life, and when he died the expression of sorrow universal showed how he was honored.

He was a careful observer, and prepared many valuable papers for the medical journals and for the Minnesota State Medical Society, of which he was at one time President.

His views on the subject of epidemics, their origin, their relation to each other, etc., were original and striking.

D. V. HAND, M. D., of Minnesota.

VAN DYKE, RUSH, M.D., descended from an old and highly honorable family, whose records go back to the settlement of New York by the Dutch. He was born in Philadelphia on the 9th day of September, 1813, and was the son of Dr. Frederick A. Van Dyke, a noted practitioner, the private pupil of the celebrated Professors Rush and Physick. He died at his residence in New Brunswick, N. J., Sept. 25, 1882.

At an early age Rush Van Dyke entered the family of his uncle, the late Col. James Van Dyke, of New Brunswick, N. J., where he commenced his education, which was thorough and complete. He entered Queen's (now Rutgers') College Grammar School, May 9, 1823. In 1826 he became a member of the sophomore class of Rutgers' College. On account of his youth he retired among the freshmen in October of the same year, and graduated as A.B. in July, 1830, and as Master of Arts in 1833, being a prominent member of his class.

He chose the profession of his family for his vocation, and commenced the study of medicine, under the direction of his father, in October, 1830. He graduated from the medical department of the University of Pennsylvania in the spring of 1835, a far longer period than the great majority of students of the present day allow to elapse between their study of "the first bone" and the reception of their "blue-ribboned parchment."

Very soon after graduation he was appointed to and accepted the post of Hospital Surgeon—an arduous office—on the very extensive plantations in Cuba of the well-known firm of Messrs. Wright, Shelton & Co., in which situation, and in general practice in the vicinity, he remained between three and four years. During his residence in Cuba he perfected his knowledge of the French and Spanish languages and literature, and had enjoyed ample opportunities of observing disease in its most dangerous and rare phases, and of gratifying his desire of studying medicine as a science.

In 1838 he returned to Philadelphia and entered into general practice, where his skill and acquirements soon secured for him the position of medical adviser of many of the leading families. He was, soon after his return, elected to fill the Chair of Professor in the old Medical College on Fifth street, where he delivered annually for several years a series of instructive and exhaustive lectures upon Physiology and Medical Jurisprudence. In September, 1848, he was elected to the Chair of Materia Medica and General Therapeutics in the Philadelphia College of Medicine. An exceedingly able and practical valedictory address to the graduating class was delivered by him in March, 1848, and published by the class. The introductory address of the course of lectures in 1852 was delivered by him and published by the class. On the resignation of Prof. Mitchell in July, 1852, he was called to the Chair of Theory and Practice of Medicine in the same institution.

When the Rebellion broke out Dr. Van Dyke hastened to the aid of his country, and with the assistance of Col. Small was largely instrumental in raising the 26th regiment, Pennsylvania Volunteers, of which he was the Lieutenant-Colonel. The regiment served three years. He afterwards was in charge of the U. S. Medical Hospital at Beverly, N. J., where he was noted for the thorough manner in which he cared for the numerons victims of the war that were gathered there. After the close of the war and a brief residence again in Philadelphia, Dr. Van Dyke removed to New Brunswick, where he continued to reside till his death.

Dr. Van Dyke married Rebecca Beauvard Williamson (one of the daughters of the late M. Williamson, iron merchant of Philadelphia), in 1851, who survives him. They had no children. Throughout life Dr. Van Dyke pursued a characteristically independent course, which became the more marked in its closing years and which, in connection with feeble health prevented him from securing the active practice which his decided ability merited. He frequently wrote on medical subjects and on the passing events of the day. His writings, as well as his addresses, were clear, logical and dogmatic. Though generally exhaustive and sometimes lengthy, he never indulged in circumlocution, but used the plain Anglo-Saxon words that were sure to convey his meaning. One of the New Brunswick daily papers in commenting on his death says: "He was not at home in the practical and busy life of the age. He had but little care for the accumulation of money. Indulged in severe and caustic criticism upon the follies of the day, and freely expressed his opinion upon all charlatanry, whether in his own profession or out of it. For the last three years of his life Dr. Van Dyke has been in feeble health, due to chronic disease (intestinal) contracted during the exposure of the war. He was without doubt a man of great natural ability, and but for the absence of all ambition would have made a distinguished mark upon his times."

He was a member of the Middlesex County (N. J.) Medical Society after 1869, served as its President one year, and two years as its Secretary, and was frequently elected one of the delegates to the State Society. He was also a member and for some years an officer of the New Brunswick Historical Club. He was warmly interested in the affairs of Rutgers' College. He was in 1833 Secretary, and in 1871-72 the Vice-President of the Alumni Association. In the year 1868 he delivered the annual oration before the Association of the Alumni, on "the Philosophy and Educational Requirements of the Age," which was afterwards published by request of the Association and greatly admired as a masterly literary effort. In 1873 he was elected Permanent Chairman of the Standing Committee of the Alumni Association, and filled the position with satisfaction till his death. In a minute adopted at the meeting of the Committee held September 27, 1882, he is thus spoken of: "He was a friend of Rutgers' College, having a laudable pride in her history and growth. He was one of the most active members of this committee, and a faithful representative of the Alumni. He was a gentleman of culture and literary taste, frank and decided in his opinions, and in this minute we desire to record our sense of his loss to us. We have found him prompt and efficient in the discharge of duty, zealous in the cause of education, and ready to co-öperate with whatever might promote the prosperity of his Alma Mater."

D. C. English, M.D.

Forwarded by Dr. R. A. Watson.

Tunstall, Robert B., M.D., born August, 1818, died suddenly at his home in Norfolk, Va., April 1, 1883. He was educated at Norfolk, and at Hampshire-Sidney College, Virginia. He graduated in medicine in March, 1842, at the University of Pennsylvania. His thesis was on Delirium Tremens. He then returned home and entered upon his professional career, in which he soon gained an eminent position, and maintained it for more than forty-one years. Dr. R. B. Tunstall was a man of splendid physique, and was actively engaged in the performance of his duties up to within a few days of his death. Resolutions of respect were passed by the Norfolk Medical Society April 3, 1883. This, and other notices of his life and professional labors, may be seen in the *Virginia Medical Monthly*.

F. D. Cunningham, M.D., of Virginia.

Surgeon-General of the U. S. Army.—The appointment of Robert Murray Surgeon-General, to fill the vacancy occasioned by the death of the late Surgeon-General Crane, has proved highly acceptable to all parties. His rank of Senior Surgeon on the list for promotion, his long, faithful and valuable services, both in times of peace and war, no less than the high order of his attainments, all conspire to render his appointment one eminently proper and satisfactory.

Collective Investigation of Disease.—We have received a supply of the memoranda and cards from the Committee of the British Medical Association, for the investigation of pneumonia, diphtheria, acute rheumatism, and chorea. Those whose names have been sent to this office have been furnished with the necessary memoranda and cards, but there are enough left to supply, at least, one hundred more.

MISCELLANEOUS.

TREATMENT OF GLAUCOMA BY STRETCHING THE EXTERNAL NASAL NERVE.—Dr. Badal has an article on this subject in the *Annales D' Oculistique*, in which he gives the results of 24 cases that have been operated on by him. After discussing the mode of operation, he calls attention to the formulated conclusions of M. A. Trousseau, a student of M. Abadie, and based upon 10 cases, which he accepts. They are in effect:

1. The elongation of the external nasal nerve is a very simple operation, and is not a serious one in its effects. It may, in many cases, be substituted for iridectomy, and particularly for sclerotomy, in the treatment of glaucoma.
2. It succeeds sometimes where these operations have failed.
3. It may often delay the necessity for a more serious operation, such as extirpation or enucleation, and perhaps dispense altogether with the employ of these extreme measures.
4. It can be readily submitted to by patients, as it can be tried without inconvenience, and in case of failure leaves a free field for operations that are practicable directly upon the globe itself.
5. It can be essayed during the prodroma of glaucoma.
6. It relieves quickly the paroxysms of pain in glaucoma, and often prevents their return.
7. It sometimes increases the acuteness of vision.
8. It diminished markedly ocular tension.
9. In case of a negative result with the nasal nerve, it is well to try one of the other sensitive nerves of the orbit.

PERIMACULAR SYPHILITIC RETINITIS.—Syphilis may set its mark on every coat of the eye. The retina may be the seat of a recurrent form of central retinitis as mentioned by Von Graefe. M. Dehenne now believes that there exists another variety of central retinitis, to which he has given the name of "perimacular." The characteristic lesion of this newly discovered kind of syphilitic retinitis appears in the likeness of a hæmorrhage into the yellow spot; but this appearance is the effect solely of contrast. The apparent redness is surrounded by an ill defined area of greyish aspect, and is due to œdema of the retina. The malady sets in rapidly, or after a few abortive attempts. It is a rare affection, and seems to attack only one eye. The treatment should be actively antisyphilitic, but the prognosis is grave; atrophy of the optic papilla may be originated by the disease. Cases seemed to do well under the influence of subcutaneous injection of nitrate of pilocarpin (two centigrammes) used, when possible, in the morning, the patient fasting.—*Lancet.*

Professor Burt G. Wilder, of Cornell University, will deliver the Cartwright Lectures for 1884 in New York City February 2, 4 and 6. The subject will be "Methods of Studying the Brain."

A reception to Dr. M. Josiah Roberts, of New York, was given on Thursday evening by Dr. William H. Daly, of Pittsburgh, in that city. Several of Dr. Roberts' professional brethren in New York, Philadelphia, Chicago, and elsewhere, together with a large number of Pittsburgh physicians, were invited to be present.

LIST OF CHANGES IN THE MEDICAL CORPS OF THE NAVY DURING WEEK ENDING DECEMBER 29, 1883.

Medical Director A. L. Gihon, to the Naval Hospital, Washington, D. C.

P. A. Surgeon, Chas. W. Rush, U. S. S. Colorado, granted sick leave for three months.

NEW BOOKS.

Gross, S. W. A Practical Treatise on Impotence, Sterility and Allied Disorders of the Male Sexual Organs. Second edition. Revised. Philadelphia: H. C. Lea's Son & Co. 8vo. $1.50.

Hermann, L. Experimental Pharmacology; A Handbook of Methods for Studying the Physiological Actions of Drugs. Translated by Roht. Meade Smith. Philadelphia: H C. Lea's Son & Co. 12mo. Cloth. $1.50.

ORIGINAL ARTICLES.

MEDICAL EDUCATION THE FUNDAMENTAL FACT IN MEDICAL ETHICS.

BY ALBERT L. GIHON, A.M., M.D., MEDICAL DIRECTOR U. S. NAVY, PRESIDENT OF THE NAVAL MEDICAL SOCIETY.

[Read before the Section in State Medicine of the American Medical Association, at Cleveland, Ohio, June 5, 1883.]

[NOTE.—It is almost an insult to the intelligence of the readers of the Journal of the Association, to explain that this paper is not intended as a sectarian attack upon the organic law of the American Medical Association; but as this interpretation has actually been given to it by over-sensitive partisans, I deem it proper to reaffirm my loyalty to the code to which I have subscribed, without, however, surrendering the right, which in common with every intelligent man I claim, to criticise what I may think objectionable, and to call attention to the inconsistencies of its avowed adherents, who, attempting to observe its letter, ignore its spirit. I fail to see why honest advocates of its principles should be placed in an attitude of "rebellion" for merely defining these principles by the more liberal light of this day. The code properly interdicts any admission of the orthodoxy of the professors of exclusive dogmas, whether of homœopathy, allopathy, hydropathy, or the like; but it nowhere prohibits the intelligent physician giving *his* advice to whomever may seek it, especially when emergencies and the dictates of humanity demand. No one can more energetically discountenance than myself the impossible co-treatment of any case of disease by an educated physician and a charlatan, empiric, quack, or ignoramus, however regular; but it is quite another matter when one's own opinion is solicited in the interest of suffering humanity. I have yet to hear of any one of our profession soliciting an opinion from any of these, and without such an interchange of views there can scarcely be considered any *consultation*, in the sense of the clinical coöperation properly denounced by the code. Any narrower assumption will, as I have endeavored to show in this paper, necessitate the ostracism of those of our famous colleagues who have associated as fellow medical members with homœopaths and eclectics in the professional work of the National Board of Health, State Boards of Health, Boards of Medical Examiners, etc.; and I feel assured that the overwhelming sentiment of the American Medical Association will be in favor of the liberal interpretation I have here given the code, with the previous knowledge and approval of the Surgeon General of the Navy.]

Superficial observers see in the question which has arisen in the State Medical Society of New York, only an attempt to break down the guards which hedge in the kingship of our profession. They have, indeed, proclaimed afar that the time-honored traditions of the guild are to be ignored, and the right hand of fellowship given to the accursed unbeliever. A year has passed since this question arose, and the dignified body of which we are a part evaded meeting the issue face to face. A few voices were raised in explanation, but they were drowned in the cry, "Crucify him! crucify him! He breaks bread with a homœopath." The august fathers of the Association frowned their displeasure, and the venerable idols of antiquity were taken down from their dusty niches, and displayed to exorcise this new demon of the nineteenth century. Outside the halls animated ex-parte statements were circulated, and a thousand delegates went away believing that a few individuals in the city of New York, mainly specialists, for purposes of personal profit, were advocating the license to consult, confer and coöperate with avowed homœopaths—this and nothing more. Since then the matter has acquired a newspaper notoriety, and it is blazoned to the world as a fact that the delegates of the State and County Medical Societies of New York have disqualified themselves for association with us, because they have sanctioned the formal recognition of homœopaths in clinical conference, and the popular sympathy of the profession has been aroused against these mercenary innovators.

It is, of course, the business of the Judicial Council "to take cognizance of and decide all questions of an ethical or judicial character that may arise in connection with the Association," but every member of the Association has an equal interest with these twenty-one in the inquiry into the causes which have induced some of the most exemplary members of the profession to their course. Is it, as alleged, that the Code of Ethics is an antiquated piece of verbosity? Does it really accomplish what it proposed? Undoubtedly, its purport was the exclusion from professional fellowship of all but those who are entitled to it by their intelligence, their education, their professional skill and acquirements, and that fearless probity that doth become a man. Has it done this? Does it do it to-day? Are there intelligent, educated, skillful and upright men in the profession because of the Code, or in spite of it? It is unquestionably true that there are no homeopaths in the American Medical Association, but are there any *allopaths* there? Does it say "Brother" only to those who are fit to wear the mantle of the wise physician? These are questions for the Association to ask itself, and primarily it is for the State Medicine Section, in its purview over medical education, to discuss calmly, fearlessly and thoroughly, and to go with its conclu-

sions, and announce them to the Association, however unpalatable or unpopular.

I do not propose at this time any formal criticism or arraignment of the Code of Ethics. Practically three lines only are the shibboleth which the elect are required to utter: "No one can be considered as a regular practitioner or a fit associate in consultation whose practice is based on an exclusive dogma." Prior to this it is stated that "a regular medical education is presumptive evidence of professional abilities and acquirements," but you may search the fifteen pages of the Code in vain for the definition of what constitutes a *regular medical education*, and it is to this I now propose especially to limit my inquiry —whether, while straining at the gnat in the twelfth, thirteenth and fourteenth lines of Sec. 1, Art. IV, we have not swallowed a camel in the other eleven. I leave to others the question of the purpose or propriety of the sonorous chapters "On the Obligations of Patients to Their Physicians" and "On the Obligations of the Public to Physicians." The short time at my disposal will only enable me to endeavor to demonstrate the failure of the Code to define as rigidly what constitutes that regular medical education, which makes the physician, as it determines who are to be his fit associates. During a few minutes, at the close of the last annual meeting at St. Paul, I had occasion to refer to this matter, in connection with my proposition that it was our duty not to let down any of the bars which guard our entrance, but to put others up; not to admit into the flock any irregular black sheep, but to exclude the horned and bearded goats already there, clothed in ill-fitting suits of regular white lambskin; and I hastily read some extracts from a paper on Medical Education I had prepared for the Association about ten years ago. I had then just been relieved from duty as a member of the Naval Medical Board of Examiners of candidates for admission into the Medical Corps of the Navy, and the daily evidences of utter incapacity I had read, heard and witnessed from men, "who having had that regular medical education which," in the language of the Code, "furnishes the only presumptive evidence of professional ability and acquirements, and is the only acknowledged right of an individual to the exercise and honors of his profession," determined me not to rest until I had brought these facts before the Association. Orders to sea prevented me carrying that intention into effect, and on my return I learned that the paper had been lost, and it was only recovered by me a few days before our last meeting. In this paper I have collated some of the evidences of professional inability of men, who bear diplomas from honored institutions, and who, at the date of their examination, had been some one, some two, some three, and some six years exercising our profession, with all its honors, invested with all its responsibilities, admitted to fellowship in this Association, and duly guaranteed as fit to consult with or be consulted by any of you, without fear of soiling your professional ermine. The incredulous may verify my statements by consulting the records, whence I have obtained them. I have not specifically named the schools on which these wiseacres were grafted and blossomed, since my object has not been to make invidious comparisons, but to demonstrate how shallow the crust on which the foundations of medical education have been erected, and the absurdity of addressing fifteen octavo pages of a code of ethics to such as these, the majority of whom never read it, are not even aware of its existence, and could not understand it if they were. Is it at all credible that the man, however regular he may be certified, who informed the *Navel medicle bord* that "*the blud should be clened of its impurrities every spring*" can comprehend these well-turned sentences and lofty sentiments? Doubtless, he would, with orthodox fervor, execrate the *homeepaths*, even though, in the next breath, he proclaimed himself a *reglar alleepath!*

Before all, however, it is proper that I should satisfy you of my own right to sit in judgment, and to do this I must first explain that the conditions for admission into the medical corps of the navy are not of any exceptional or exclusive character beyond the limitation of age between a minimum of twenty-one and a maximum of twenty-six, but are merely such as should be fulfilled by any young man, who is certified in classic diction by seven or more distinguished professional elders, to be *doctus in arte medica*, learned in medicine. The prerequisites of respectability of character and correctness of deportment, established by testimonials from citizens of known probity, ought not to be considered superfluous, even for the matriculant, while the modest scholastic acquirements insisted upon, rarely extending beyond a rudimentary familiarity with orthography, grammar, geography and arithmetic, are not a tittle of what ought to be necessary preliminaries to the study of the first bone. The possession of a degree is not required, as it undoubtedly ought to be, and would be, did it carry with it any assurance of professional qualification, the Code of Ethics to the contrary notwithstanding. Why a degree, however regular in origin, is not considered satisfactory evidence of professional qualification, I expect to abundantly illustrate in this paper. Furthermore, the catholic liberty to compete for any position under the government, has not allowed the Board to decline to accept the candidacy of any individual claiming the ability to practice our art, and accordingly we have examined graduates of eclectic colleges and homœopathic colleges, as well as those who did not graduate at any college, who were thus permitted to stand on the same footing with the possessors of sheets of parchment containing their names in a form they would not recognize and in a language they could not interpret. Though all such *irregulars* have failed to pass our examination, it is but just to state that the files of the Department will show that they had no lack of peers in ignorance among the alumni of institutions of the most renowned name and unassailable regularity; and I fail to see how the Board in any way countenanced these practitioners of an exclusive dogma, or lowered the prestige of our own exclusive possession of the only true faith by consenting to demonstrate to these pretenders that they were really ignorant and incompetent. Had the door been slammed in their faces, would they have carried away with

them as lively a sense of their shortcomings, as when the opportunity had been given them to write themselves down asses?

A few words now as to the nature and routine of these examinations by the Naval Medical Board. After the physical inspection of the nude body and the written certificate of the candidate that he is free from inherited or undiscoverable disease, he prepares a biographical sketch, describing his academic and medical education, enumerating the authors read, and detailing his opportunities for acquiring practical acquaintance with any branch of his profession, especially his hospital and other clinical experience. After this, which is usually the work of one day, the formal professional examination begins, and comprehends—

First: An ESSAY, written without notes or references, within an allotted time, the subject ordinarily selected being one with which the candidate, in his preliminary letter, has shown evidence of most familiarity.

Second: The preparation of WRITTEN ANSWERS to fifteen questions propounded in writing, three in each of the following branches: (1) anatomy and physiology; (2) chemistry, hygiene and jurisprudence; (3) materia medica and therapeutics; (4) the principles and practice of surgery; (5) the principles and practice of medicine. These questions are purposely selected to cover as wide a scope as possible, and so serve as introductory texts for the oral examinations. All the written work is carefully scrutinized as to orthography and composition, the errors being indicated by red ink marks, and is filed at the Department as evidence against the candidate, in the event of the dissatisfaction of himself or friends.

Third: ORAL EXAMINATIONS, each about an hour in length, by the several members of the Board in rotation, on all the subjects within the domain of the properly educated physician, including the principles and practice of obstetrics, and forensic medicine, and cursorily on such subjects as may be judged necessary to determine the general proficiency of the candidate.

Fourth: PRACTICAL EXAMINATIONS in the recognition of drugs and pharmacal preparations; in the arts of prescribing and of compounding prescriptions; in the chemical examination of water, urine, etc.; in the uses of surgical instruments, the application of apparatus and the performance of operations and demonstrations upon the cadaver; and in clinical exercises in the wards of a hospital, the use of the laryngoscope, thermometer and other diagnostic apparatus, and the preparation of a written commentary on some one of the cases there examined.

The candidate has the privilege of introducing a friend at any stage of the oral examination. It is a courtesy seldom refused for him to be allowed to withdraw at any time, as it is the privilege of the Board to dismiss him whenever they may be satisfied of his failure. The examination concluded, his qualifications and standing are determined by a majority vote.

Further prolix detail is probably not necessary to satisfy you of the process by which these replies were elicited which I am about to read, a process to which I insist every person should be subjected before he is allowed to practice medicine.

I have selected from my notes samples of the replies of twenty-five candidates, *doctores* all of them, men certified to be learned in that noblest of all the sciences which engage the human intellect. I have endeavored to range them over as wide a field of inquiry as possible, to show that it was not abstruse or theoretical points on which the deficiencies were manifested. I have taken them from the graduates of schools in every section of the country, and those of established reputation, in order to prove that no one school, however exalted its rank, can claim exemption from the charge of having graduated grossly illiterate and incompetent men, and that diplomas have been sold, not cheaply and openly, as by Paine and his fellows, but still for a price, meaning two full sets of tickets, a matriculation and a graduation fee. I cannot, of course, say how many of these candidates actually fulfilled their implied contract to attend lectures by sitting wearily on benches listening to discourses that must have been totally unintelligible to most of them, because I am not unjust enough to intimate that these professors did not honestly and faithfully fulfill their part by lecturing, but I do declare that their words fell like idle wind upon hearers such as these, and that the dolt who sat there throughout the course, or part of it, or who did not even sit there, but bought the ticket, issued forth a full-fledged doctor, the peer of the brightest, most industrious, and most zealous student in the class. I do know of one instance which came to me in the shape of an indignant protest from a very accomplished physician at Yokohama, that an Englishman, who had been my apothecary for two years at Nagasaki, had taken the March steamer for San Francisco, and returned by that of July with the diploma of a regular medical school, which he displayed among his countrymen, to the great scandal of American institutions. I know that this man, a fair compounder of prescriptions and with a midwife's experience in obstetrics, had less right to practice our art than the Mrs. Gamp whose functions he had occasionally usurped; yet he was admitted to examination(?) after paying for one course of lectures, and pledging himself to produce a certificate from the London hospital in which he said he had studied and served. I do not know, nor have I sought to inquire into, the antecedents of any of the candidates whose replies I am about to quote. With these the Board had little or nothing to do. Our business was simply to ascertain whether A. B. was properly educated in his profession to be fit to be intrusted with the care of the officers and men of the naval service. Some of the revelations of these examinations would be amusing, were it not the lamentable fact that many of their authors have been for years intrusted with the lives of their fellow-beings, and this by the authority of the most respectable regular medical colleges in the United States.

To begin with the original seat of medical learning in this country, a graduate of one of its great schools, whose diploma was five years old, who had been recently prepared for examination, and whose demeanor evidenced the high opinion he entertained of his own

abilities, stated that "the corpus callosum is that part of the dura mater which separates the cerebrum from the cerebellum;" that "the vertebral artery communicates with the cavernous sinus;" that "the membranous part of the urethra is below the triangular ligament, which is an extension of Gimbernat's ligament;" and that "pneumo-thorax is a collection of pus in the chest."

A second from the same institution, four years graduated, informed us that "the principal muscles of the larynx are the vocal cords;" that "the one-seventieth of a drop of hydrocyanic acid is the dose for an adult, and the tenth of that the proper quantity for a child;" that "the boiling point of Fahrenheit is about 300°, that of the centigrade scale not so high, and that of Reaumur higher;" that he "could not tell what the zero of Fahrenheit was without having the other scales before him;" and that "the normal temperature of the human body is from 112° to 140°."

Still keeping among the "doctors in medicine," the learned ones of our profession from this same school, a regular of regulars, we find a graduate who had left the benches only two years, declaring that "cholera communis is communicable cholera," and "it is a disease of the sea coast of warm climates, occurring generally in the Gulf of Mexico, with a geographical limit of from 20° S. to 10° N.

From a sister school in the same city came a gentleman well provided with testimonials of his social, literary and professional qualifications for the Naval Medical Corps, who stated "that he did not remember the country nor the language of Hippocrates," that "Galen lived before him," and "Virgil died in the fifteenth century of the Christian era."

A brother alumnus, whose diploma was only a year old, declared that *the hole in a sample of Russian rhubarb* shown him *was natural and grew there;* that "accupressure is made with the finger or any other instrument," that "the laryngoscope is a short tube, which you put in the throat and look through;" that "the tuberosity of the tibia is the part broken in Pott's fracture;" that "ranula is a disease of the eye," *he could not tell which eye;* that "internal hemorrhoids are to be chiefly diagnosed from fissure of the anus;" and that he did not know the difference between chordee and priapism, nor could he tell what either was, other than that it was similiar to stricture.

It was a graduate of this same school, who, indeed, brought letters to me from an esteemed friend and deservedly distinguished physician in Philadelphia, who, having absented himself several days during the examination, on his return announced to the President that he had been ill with *cholera infantum*, and gravely reiterated the statement, when with some astonishment, I repeated the inquiry.

New England sent us a candidate who had been practicing medicine almost six years, who informed us that "nitrate of potassa is *insoluable* in water;" that "chondrus is isinglass and is used to make blanc mange;" that "liq. sod. chlorinat. is the chloride of lime;" and that insanity is a strictly mental disease, he did "not know that it was ever regarded as a physical disease."

Also from this section came an aspirant for the corps who was born and educated in Vermont, *wher I studed Latin grammer*, and, who, after certifying that his *helth* was good, stated that "orchites or Inflammation of the Testicls is produced by external ingurya manely although occasiunly it is produced by internal difficultys the Symptoms are pain through the lumbar regunn through the Kidneys and down the spermatic Cord. The Diagnosis is that it is so and also swelled. The Treatment is to Suspend the Scrotum by means of a Scrotal bag supporter. bathing the part freely with cooling lotions and Cold water to allay the Heat—and Inflammation as rapidly as possible, A low diert, avoiding excitment as far as possible if the Pains is to seveer an occasiunal anœsthetick should be givn to relax the muscle as well as giv rest to the Patient if the Inflammation does not subside but incesans the operatiun of extirpation of one or both of the testes must be submitted too. being the last and only resurse to be had that can possibly save the Patient."

Bear in mind, gentlemen, that this worthy possesses a diploma of no insignificant medical school certifying that he had had that regular medical education which is the only presumptive evidence of his professional abilities and acquirements, and is thereby entitled to the exercise and honors of our profession.

Hear further: "Scarlatina is an eruption on the Fæceis. or Face and Head It is divided into three symptoms Simple mideum and Malignant, The simple form is known by eruptions on the Face, Fever, the eruptions of a scarlet coler and small and Genelle lasts not more than a week. The mideum is like the simple save that the fever is higher and the spots larger. occasiunly attended with soar throat. The Malignant variety is the hardest form the fever running high and the Blotches genelle extending over the whole body with a Gray Sloughy soar Throat. this variety generly terminates in Death in a few days unless checked. by Mental, depression."

And again: "The temperature of the system is variable in helth the cuticle stands at 70°. the Dijestive organs at 100 before they act on the Ailment, Any great deviation frum this state denotes that the Patient is a Pathological condition. and that the Saliva being a powerful Alkaline, with phosphate Sode it base it causes a fermentation of the Ailment The Saliva is much stronger after than before a meal. It also renders assistance in the action of passing the Ailment through the glottis Œsophigus Thorax to the Stomach."

If you feel inclined to laugh at this tissue of absurdities, recollect that it is your professional brother and peer to whom I have introduced you. Rather shed tears for the poor wretch he may have castrated to save his life. A thousand times better for humanity had he drawn his inspiration at the Hahnemannian fountain, and prescribed trillionths and decillionths of carbo, spongia and sambucus.

A representative from another New England school announced that "phosphorus burns and makes nitrogen gas;" that "the crepitant rhoncus occurs whenever a membrane becomes dry;" and as a part of his academic education, that "Plymouth was settled

by Columbus, who gave the town its name;" and that "each State and Territory has one senator, who is a man of great influence," one of this great influential body having in fact indorsed this learned doctor's competency to assume the care and responsibility of the sick of the navy.

A very elegant young gentleman from New York, graced with all the accomplishments characterizing fashionable society pets, who had an office in one of our great cities, where, though the navy failed to appreciate his worth, he subsequently rose to a lucrative practice through the patronage of wealthy friends, said that "orchitis is a disease of the testicle affecting one of its coats, called the vas deference, which he believed was the external and was a serous tissue;" that "erysipelas is known by its shiny look, that it is confined to the head, and terminates by suppuration or by getting well;" that "the hot bath should have a temperature of 75°;" that "the hyaline appearance of tube-casts refers to their hair-like structure;" that "a microscope of one thousand powers is required to see a blood corpuscle;" that "the symptoms of delirium tremens, of which I have seen numerous cases, are dilated pupils, hot dry skin, slow pulse, and glassy eye;" and "that puerperal convulsions require diuretics at first and then diaphoretics, such as pulvis ipecacuanha compositi ℥j divided into six powders and taken every two hours until profuse sweating is produced, and if this does not succeed in sweating her, let her drink hot tea and give her a Russian bath!"

Another, also a practitioner by authority of the same renowned institution, stated that "a poison is any substance that acts as a local irritant upon the mucous surface and thus produces congestion of the brain;" that "acupressure may be pressure by a tourniquet, by a V-shaped bandage, a pad, or by the hand;" that he had always used stimulants, and liked the way his patients built up under them, although he *wholly condemned them as a beverage*, and added that "they ought never to be used in lung disease, for they increase the action of the heart."

A candidate likewise from this school, and whose right to the doctorate was doubly guaranteed by a previous diploma from a western university, in a theme of twenty-five lines on the assigned subject of "The botanical history, physical characters, chemical constituents, physiological action, therapeutic applications, and official preparations of jalap," stated that: "It is a small plant which grows from one to two feet high. There is nothing peculiar about its chemical properties, with the exception of a slight astringency and pungent bitter taste. The root, as found in the market, is about the size of a crow-quill. It acts by increasing the secretions of the *mucus membran* of the intestine. It may be used in any case where the action of a slow cathartic is required. It is also thought to increase the amount of secretion of the *mucus membran* of the lungs."

He said of hydrogen that "the danger attending its manufacture is from the danger of inhailing the gas whic is very injurious to the lungs and it is also exposive thereby causing more or less danger."

He also stated that "the antidote in poison from strychnia is physiologically belladonna, but a dose of the belladonna that would counteract the effect of the strychnia would *kill the patient*;" and that "the coats of the eye are the conjuntava sclerotic and choroid. The conjunctava is a mucus membran, It contains blood-vessels and nerves, The sclerotic membran is a dense white membran containing no blood-vessels, The choroid membran is not as dense as the sclerotic. The aqueous humor is not as thick as the vitrious, It occupies the anterior chamber. The vitrious humor occupies the posterior chamber."

A graduate of another deservedly celebrated New York school announced that "Galen introduced vaccination or inoculation in the seventeenth century, and that Aristotle was some ancient philosopher who wrote a book," probably intending that "masterpiece" which naughty youths delight to read, while still another New York M.D. explained that "The conditions which would render Bronchotomy necessary. would be wher a foreign body has lodged in one of the bronchial tubes. I know of but one method of performing it and it is to cut down carefully being giuded by the physical signs and your anatomy, and after severing the bronchial tube in a longitudinal direction I would remove the foreign body, and carefully close up the wound;" that "an astringent is a medicine which corrogates or contracts the tissues;" and that "to determine acurately whether a person be dead or not, a knowledge of anatomy and physiology is essential. One of the surest signs of death is conplete cessation ot the heart's action accompanyed with a cold surface of the skin. a blueness of the lips and fingers. and a *coldness of the teeth.*"

A doctor from a third New York college wrote as follows: "Scrotal hernia is where the intestine passes into the scrotum when it sometimes becomes of enormous size. The prominent symptom is a non inflamitory swelling of the groin and can be diagnosed from other swellings by the impulse conveyed to the fingure when placed over the tumor by coughing." "The pathology of surgical fever is a poisnous condition of the blood caused by the absorption of some poison from a wound or injury. This poison is carried by the sirculation to the nervous system and different organs of the body causing a general febrile action;" "Gonorrhoa is caused by a spesific poison generated by filth and excess of secual intercourse and by actual contact;" "Malaria is an invisable poison invading the air." This gentleman introduced many orthographical novelties in his written work, such as *spunging, annemia, coraccer bracheal-ius, fassia, abdoman, thygh, plexas, alumn, superation, accute, arrises frome betwene, shure, wair, beleaving*, etc.

Next after Philadelphia and New York, Maryland has supplied the largest number of applicants for admission into the medical staff of the navy. One of these, a graduate of seven years, informed us that "The phenic nerve is one of the cranial nerves, I don't recollect which pair;" that "The mind has more action on the cerebrum than on the rest of the brain;" that "The surface of the heart is a mucous membrane;" that "The temperature of the body in African fever is 96°, much above the normal temper-

ature of the body, which is 92° F;" and he wrote a prescription for an emulsion of copaiba containing more than twenty errors, the Board requiring prescriptions to be written without symbols or abbreviations:

"Ricipi

Copaiba Drachmæ quarto
Pulvis acacia
Sachrum Alba aña Drachmæ duo
Aqua Distilata Ouncæ quarto
Oleum sasafrass gutta viginte

Mice

Signa One Tablespoon 3 times daily."

The same alma mater sent us one of her sons whose fluent pen has largely contributed to our medical literature. The same pen in the written examination, beyond which we did not think it necessary to go, was made to state that "The larynx extends from the base of the skull to opposite the fifth cervical vertebra, where it divides;" that "The most simple form of the galvanic battery is that discovered by Buvens, of Leyden, and called by him the Leyden jar;" that "one of the common sources of Ammonia is Phenic Acid, a natural secretion from the beaver;" that "The gastric juice is one of chemical solution, and the vital attributes of the stomach are only employed in the preparation of the solvent; that "The gastric juice exists in most animals as hydrochloric acid, necessary for their digestion;" that "Food enters the stomach in successive curves by a peculiar peristaltic motion of the stomach acting through the fibers of its muscular coat;" and that "In the treatment of Measles you regulate the secretions by small doses of mercury and epispastics, astringents and farinaceous diet, and if the type should be malignant, we would relieve the congested organs as speedily as possible by venesection or by local depletion, together with good diet."

Another informed us that "Senna is indigenous, growing in the West Indies."

Still another, that "The Greek language is spoken by the people of the Isle of Greece, which island is southeast of Italy; that "Ovid flourished several centuries before Christ;" and that Longfellow is a great English poet."

A fifth defined coxalgia to be *inflammation of the coccyx.*"

A graduate from another school in the same State said that "There are two varieties of senna—Alexandria and Teneriffe;" that "The Technical name of Rhubarb is Colombo;" that "Jalap comes from Spain," and that "The Apothecaries' Weight there are sixteen ounces to the pound."

Another, who was graduated from the same institution four years before, and who was at the time of examination a leading practitioner and the city physician of a western municipality of considerable pretensions, stated that "Opium comes from Egypt and Asia Minor and Hindostun, but not from India;" that "Aloes is the gum of a tree growing in South America. There are two varieties of Aloes in use. The best is Soccotrine Aloes from South America—this variety costs much more but on account of its effects is more extensively used. The other variety the Cape Aloes of commerce is the inferior of the two and is brought from parts farther north than the Soccotrine variety;" that "Chlorine is a very poisonous gas of a blue color;" that "The difference between Galvanism and Electricity is that one is the substance itself and *the other its use;*" that "The galvano farriadaic company, of New York, are furnishing excellent machines;" that "I do not know the difference between primary and secondary, interrupted and continued currents;" that "In gonorrhœa we use strong injections to destroy the poisonous matter before it gets beyond the glans;" and that "To determine personal identity in a case of questionable personification, we should collect all the reliable evidence possible, and if not satisfied by thorough examination of the facts of the case, I would Chloroform or etherize the questionable party and judge from his expression when unconscious.

A representative from a school in a district farther south wrote that "The ureter is the duck of the kidney;" that "sporadic disease is locally a kind of epidemic;" that "Brandy is a vital stimulant and so is beaf essence;" that "The ordinary dose of Chloroform as an anæsthetic is ℥j of ether ℥ij;" that "The average respirations are 70 per minute;" and that "I believe there is a slight difference between the inspired and expired air."

From still farther south came a physician who declared that "Carron oil is so called on account of its bad smell;" that I dont know what is meant by colica pictonum; that "The period of utero-gestation is nine lunar months;" but that he "could not tell how long a lunar month was, nor why it was so called."

Finally, from the west we had a graduate of unimpeachable regularity, who said that "Campher is an aromatick gum from the ilands of the see;" that "The carotic arterie makes its exit between the 1 and 2 ribs and enters the cranial cavity through the petrous portion of the temporal bone;" and that "The best way of facilitating the expulsion of the placenta is to let the woman walk about the room, allowing five minutes to elapse after delivery before requiring her to get up and walk."

These examples were not especially collected for my present purpose. I have merely used such as I had casually jotted down among my memoranda. The notes of my colleagues and the archives of the Bureau of Medicine and Surgery can supply thousands of instances of professional incapacity where I have noted a hundred, and my successors of to-day upon the Board are having the same experience. Within a week one wrote me that "The comic opera and minstrel performances are nothing compared to the Board entertainments." Think of a candidate—a graduate, and a regular graduate—gravely informing us that "*Phimosis is the result of old age.*" Ridiculous errors in orthography, inexcusable in a day-laborer in this land of boasted educational facilities, are so common that one might believe correct spelling to be a refinement of culture. "What the hell has spelling to do with the practice of medicine?" demanded an irate Member of Congress of the Chief of the Bureau, Dr. Whelan, on being shown his protegé's written work, and doubtless so thought the

trustees of a charitable institution widely known, who admitted into its resident medical staff a gentleman, the medical graduate from a university, who two years subsequently gave the Board the following written evidence of his literary acquirements, viz.: *immergencies*, *attact*, *thare*, *redy*, *vigitable*, *xertion*, *urin*, *pluracy*, *deadly knight-shade*, and *expultion of its contence*. Without questioning that there are intellectual giants who achieve greatness in certain careers, though unable to spell at all, it may be doubted whether the average mind accustomed to write *scassity*, and *orful*, and *inturlec* and *aurora epileptica*, in total ignorance of their etymological significance, can ever succeed in comprehending the language which has come to be technical in every department of our science; and only errors such as these, and not mere phonetic mistakes have, of course, been taken into account. Indeed, we did not decline to examine the candidate who addressed his letters to the *Navel medicle bord*, and subscribed himself *yours respectively*, and I do not believe he was one whit the inferior of the regular graduate who this very year addressed the following epistle to Dr. John H. Rauch, Secretary of the State Board of Health and Medical Examiners of Illinois:

"To the *Secratary State boar* of health *Deear* Sir I sent you my *dipluma* early last March and have not heard from it *sinc* did you receive it or do you know anything about it I am become quite anxious concerning its *safty* My *dipluma* is from ——— Med College ——— ——— dated ——— —— 1882 I also sent you a letter containing a one dollar bill to pay for the *certifficate* If you will give me the information I *requist* I shall be greatly obliged to you Yours respectfully ——— ——— M. D."

Show me in your Plan of Organization, or in your By-Laws, or in your venerable and venerated Code, which it has been declared to be "rebellion" even to criticise, one line denying that regular graduate admission here on terms of equality with you all, if indeed he may not be here already.

But errors in orthography, faulty grammar, and the absurdities and senseless incoherencies of the oral examination, pale beside the display of ignorance during the practical examination. I have seen the spermatic cord demonstrated in a female subject; the structure of an entire limb torn up in the search for a superficial vessel in open view of the operator; the anterior tibial sought on the inner side of the bone, and again through the sural muscles; the posterior tibial ligated at the external malleolus; and the palm boldly laid open by a long, deep incision to secure the radial. I have witnessed the application to fractured limbs of apparatus that would have deformed the sufferer for life; prescriptions written that no apothecary could decipher or compound; and others compounded either with fatal doses deliberately prescribed, or ignorantly and carelessly weighed, which it would have been eminently proper, in the interests of humanity, to have required the exhibitor to have swallowed. Yet these were all the acts of men who had received that accepted "regular medical education" which makes of them the elect, who have the "acknowledged right to the exercise and honors of our profession." I appeal to these very Professors, who signed the diplomas of these men, whether any practitioner whose practice is based on an exclusive dogma, could rival in ignorance that regular doctor, who, having amputated through the thigh, regarded the stump sharpened like a lead pencil, and coolly remarked, "Why, I must have made my cuts the wrong way!" Can any Code of Ethics exalt him into a position fitting him to be consultor or consulted with, even by a homœopath; or him, who having a superabundance of flap in an amputation through the arm, neatly tucked in the superfluous ends and deliberately stitched the folded cuticular surfaces in apposition; or him, who having attempted a disarticulation through the tarsus, delared that he would allow the protruding cuniform bones to remain *until they skinned over*; or him, who having advised the operation of trephining, minutely described the method of introducing a silver plate in the cranium, the bone being carefully grooved to receive the plate in the fashion of a watch-glass; or him, who on the morning of his graduation, when requested by an old physician to bleed in a case of emergency, plunged his lancet on the cardiac side of the bandage; or him who proposed to treat orchitis by removing one or both testes, if the inflammation does not subside after rest, cold applications, and occasional anæsthetics; or him, who defined pneumonia to be a particular disease of one lung, and pleurisy the name given to it when it affected the other side; or him, who advised cauterization of the soles of the feet in congestion of the brain, using the actual cautery for poor people, and the potential cautery, by which he meant nitrate of silver, for rich patients, that they might not be discommoded *by the smell of the burning flesh!*

I do not want to be misunderstood as arrogating for the medical corps of the Navy, even by implication, any superiority to the average general practitioner. We do not pretend that any of our number has any claim to but the humblest seat in the medical forum, but we have striven, and I believe not in vain, to exclude from our rolls every one of these arrant fools and worthless graduates, who, not having succeeded in entering the Navy, where it is popularly supposed neither skill nor acquirements are essential, must remain in civil practice, slaughtering the unfortunates who fall in their power, and adding their share to the mantle of shame, in whose folds the whole profession is involved. Though we have no statistics of the future careers of those who have voluntarily left our ranks, nevertheless we can point with pride to the large number of ex-naval medical officers, who are now occupying distinguished positions as editors, teachers and practitioners.

Of 1,141 candidates for the medical corps in the twenty years since 1853, only 370, or about 32 per centum, have been accepted. Admitting that 10 per centum of those rejected might have been accepted by less rigid examiners, or were causelessly and improperly rejected, there still remain 700 graduates of regular medical colleges who can give the sign and pass-word that admit them to the benches on which sit Bowditch, and Agnew, and Gross, and the Flints, and Fordyce Barker, and all our other

great men. Many of these seven hundred have, doubtless, through native ability, industrious observation, and after study, learned something of the art they began to practice in the dark, but most of them have only learned to see as the blind see, and at what a fearful cost of human life!

Mr. Chairman:—The time has come when this Association must be up and doing. A few medical schools have undertaken the reform, but the movement that has been inaugurated notably by Harvard will avail little so long as the Association unconcernedly witnesses and indirectly countenances the wholesale manufacture of doctors elsewhere, by accepting their membership without question of their competence. The time has come when something more than paper bulwarks shall be considered defense for our orthodox stronghold, and paper partitions sufficient to separate the sheep from the goats. The time has come for us to act, and it is eminently proper that the Section in State Medicine shall be the scene of action. The dissension in New York has made it impossible for us to remain indifferent spectators. I trust no member of this Section has been misled into believing that any of the distinguished men who have taken part in this agitation have asked for anything that involves in the least degree any concession to the claims of homœopathy, allopathy, or any other exclusive dogma; that none of them have suggested, advocated or desired any arrangement that can provide for or permit the joint clinical treatment of any case by themselves and homœopaths, or any other paths. They have, however, claimed the right to give *their* opinion to any one who asks for it, and is willing to pay for it, to tell any sick person what *they* think of his case, and what *they* advise to be done. In this they give no sanction to the "irregular," whoever he may be, who has sought their advice, even though this irregular may be wiser than that regular who castrates in orchitis, and gives his puerperal woman a Russian bath. The very fact of their advice having been sought is an admission on the part of the irregular that he has done wrong or knows not what to do, and if, as alleged, these irregulars have not sought these so-called consultations, then none will be, and the storm is but a tempest in a tea-pot, since it is very certain that none of us will ever ask or accept, or care to know what they believe. It is for you, however, to determine decisively whether you will place under the ban the man whose only offense has been to say to one of these irregulars, "You are doing wrong," or will exclude from the ranks of the profession that one of your distinguished colleagues in New York, who, when called in consultation in a case of difficult labor requiring instrumental interference, did not stop to examine the diploma of the attending physician, but went to work, finding him an exceedingly expert assistant, and learned, when the patient had been rescued from danger, that he had been coöperating with a homœopath; or will threaten the young road surgeon, who, at the close of the meeting at St. Paul, asked me whether he should operate in a case of caries of the tibia in a poor woman at a station where the only physician was a homœopath:—"Do it if you dare! You shall never cross our threshold if you do. Let her die first."*

If it be unpardonable sin to give advice to one such, where is the sinning less for my honored friends Professor Cabell, and Professor Stephen Smith, and Professor Bowditch and Professor Hosmer A. Johnson, to sit in the National Board of Health in daily consultation with a homœopath as their medical peer, in consultation not over the life destiny of one individual, but over the life destinies of hundreds of thousands? Surely mere considerations of pecuniary recompense or public distinction did not tempt these men to voluntarily accept an association based on what the Code of Ethics has been interpreted to denounce as inconsistent with the honor and duty of a regular physician. When men of their unassailable integrity, against whom no other man in this Association can lift a finger, have done this thing, it ill becomes us lesser lights to thunder *anathema maranatha* against him who, once in his career perhaps, may have occasion to say to one of these irregulars, "Throw away your pellets—take a dose of castor oil." Or, if the litany of curses be hurled against all who violate even one aspect of one command of the ethical decalogue, be consistent and begin with these sinning elders in Israel. Excommunicate the members of the State Boards of Health and Medical Examiners, who sit cheek by jowl with both homœopaths and eclectics, even though they have done more, as in Illinois, to lift the wheel of progress in the true ethics of medicine out of the rut in the beaten road over which it has jolted, than any formal code however rigidly construed. Drive out from this Association whole societies, which, as none know better than your Permanent Secretary, have admitted graduates of eclectic and other spurious colleges as members and can send them here as delegates. Go further—add this new section to Article IV: No practitioner of medicine who counsels or allows his wife to employ any physician whose practice is based on an exclusive dogma for herself or his children, (and I know more than one such) shall be recognized as worthy of fellowship in this Association. And furthermore, look not only at the mote in the twelfth, thirteenth and fourteenth lines of Article IV, but make your combination general against all those who ignore or violate any line of any other section of the fifteen pages of the Code. Execrate the advertisers, the trumpeters of their own exploits, the slanderers and back-biters, the cutters-in and the cutters-out, and the man who prescribes "my diaphoretic mixture," or "my tonic cordial" to be had only at Mr. Jones' store and pockets a share of the sale. I fear you will have to decimate and re-decimate the 85,671

* Since this paper was read, my friend Dr. Bush, of Wilmington, President of the State Board of Health, of Delaware, and the member for Delaware of your section in State Medicine, narrated to me a case in point of a worthy old gentleman of his acquaintance, whom being seriously ill he went to visit and found under treatment by a homœopath for "disease of the kidney," but suffering intolerable agony from an enormously distended bladder. He did not hesitate to *seek* the homœopath and inform him, notwithstanding the latter's assurance that urine was dribbling away all the time; that the bladder must be evacuated or his patient would die, and he offered himself to catheterize him. Dr B. was chagrined when the homœopath asked leave to accompany him in his carriage, but he consented, discharged three pints of detained urine and then having saved his friend's life and relieved his sufferings, left the case, although the homœopath begged him to continue in charge.

practitioners of medicine in the United States until instead of 1 to every 585.44 inhabitants, there will remain but 1 to every 58,544, who can be adjudged by such a rule of ethics and found guiltless.

But a truce to these contentions. The Association must attend to weightier matters, and speak in no uncertain tone. Temporizing and procrastination have been practiced without success. If medical societies and medical schools and medical teachers will not act, this Association must do so for its own dignity and self-preservation. We have tilted against the wind-mill of homœopathy until every Don Quixote is assured he has attacked a castle. But for the prominence we have given it by the intolerance of our attitude, it would have shrunk into insignificance with Thomsonianism and the surgery of Regina dal Cin. The most blatant denouncers of association with homœopaths do not hesitate to proclaim themselves allopaths, "An allopath? Why an allopath is a regular physician," is the stereotyped reply to the questioner in fundamental methods of cure. "Certainly, sir, I am an allopath," is the unhesitating admission of men who have subscribed to a Code of Ethics, which denounces those whose practice is based on an exclusive dogma.

Such being the results, let it be your part to prescribe an efficient remedy. The expectant treatment will not answer. *Similia similibus non curantur.* The knife must be applied and the unsightly cacoplasm removed. To the schools we should be able first to look, and if *all* the schools would only matriculate those who can read and write the English language correctly and use the simple arithmetical processes involving a knowledge of weights and measures, the first important step would have been taken, but so long as M.D.'s are granted to men who are not A.B., or its equivalent, what can be expected? I was once asked by the Secretary of the Navy to obtain for him the requirements for matriculation at one of our great schools, and when I told him with much chagrin that I was sure there was none, he urged that I must be mistaken, since every literary college in the land insists upon some measure of preparation in those who enter its halls. What would he have thought of the requirements for matriculation at an institution whose graduates discoursed of the *blud*, and of *helth* and of *medasin*, who prescribed *granes of calomel*, *drams of lodnum* and *watter dressings*, and treated *spraned fingures*, *broken thyghs* and *fishers of the anise?* What of that school, one of whose quiz-masters, laughing with me at the failure of a candidate to define my question, "What constitutes potable water?" remarked, "Why, any fool should have known that. The very name denotes that it is water that can be carried, and I suppose you had special reference to taking it on board ship."

The standard of our profession is trailing in the dirt, and this not because the rank and file are unworthy, but because the standard bearers fail to hold it aloft, and the leaders are laggard. Of the seven hundred and seventy-one men we turned away, many, perhaps a majority might have been made competent physicians. One very sad case elicited the sympathy of the board. A candidate from the Eclectic Medical College of Philadelphia, who had shown considerable aptitude, lamented his own incompetence, and when asked how he came to study at such a place, said that he went there by the advice of his preceptor, a graduate of the University of Pennsylvania, and that he had spent in fees, tickets, etc., more than five hundred dollars, the savings of many years by his father, whose ambition had been to educate him thoroughly as a physician.

If preceptors fail to appiy the lash and spur, if mushroom schools can spring into existence wherever half a dozen men ambitious of the title of professor, get together, if colleges, in their rival contention for students accept any who apply and graduate all who pay their fees, this Association, at least, ought to bar the door against the pretenders who issue from them. Some years ago, in conversation with an intelligent mechanic, who was painting my house, and who had been a master workman until he lost health and everything he possessed by services as a subordinate officer in a volunteer regiment during the war, he told me that he had just met a former comrade in the army, a mechanic like himself, who was so well dressed that he congratulated him on the prosperity of which there were so many outward signs, and was amazed to learn that he was practicing medicine, having secured a petty position under the government, which only required his services during the day and left him free to attend the lectures at night, and in less than two years he emerged a doctor. I myself knew a messenger in one of the Bureaus of the Navy Department who accomplished this feat, and a young auctioneer's clerk, learning from me that twenty-one is the legal age for graduation, said: "Well, I am going to be a doctor, but I am not yet nineteen, and I will not begin before, since it only takes two years to get through."

But I am only repeating a trite, thrice-told tale. The necessity for reform in medical education is undeniable. Let us begin the work of reformation. If the American Medical Association is something more than a convivial assembly—if it is sitting here as a senate in serious deliberation as to the interests of the professson, it can no longer ignore this question. Years ago, your excellent committee, Drs. Davis, Toner and Weatherby, and the committee of the Medical Society of the State of New York, Drs. Squibb, Eliot and Bradford, provided for raising the standard of preliminary education required of medical students, by compelling preceptors to exclude from their offices all who fail to receive the certificate of a properly constituted Board of Censors, but the colleges must be coerced into doing their share. Harvard and the University of Pennsylvania will fight a hopeless battle if they are without allies.

It is for you to say to every one of these great schools and famous teachers, as well as to the petty schools and their tyros in teaching, you must, and at once, set the example of reform; require a preliminary scholastic training of your matriculants; appoint examining boards, who shall have no pecuniary interest in the size of your graduating classes; make your examinations in part written, to remain on record as evidence of the candidate's ability or lack of it; and

insist upon a practical familiarity by the novice with the tools of his art—its drugs, and apparatus, and instruments. For awhile, there will be a falling off in revenue, but the Code of Ethics denounces the prostitution of our calling for sordid purposes, and what more mercenary spectacle can there be than that witnessed at the close of a college session, when, with blessings and music and big bouquets, a new battalion of doctors marches forth, commissioned to assume the most solemn responsibilities humanity offers!

Should the colleges neglect to institute these reforms, then let the Association appeal to the State Medical Societies to urge the several State Legislatures to appoint State Boards of Medical Examiners, who alone shall conduct the final examinations and issue certificates of qualification. It will not be long before the public will recognize, appreciate and reward the work. Nowhere in the world are there more able teachers than in this country. Why should not their pupils be equally signal? While the former sow such good seed, why should it be cast on rocky, untilled soil? Let it be our part to see that only good grain, free from tares, shall be garnered into the storehouses as food for the suffering multitudes who cry to us for help.

In furtherance of these objects, I beg to offer the following resolutions, to be referred to the Association, should the Section in State Medicine give them its approval:

Resolved, That the Section in State Medicine urges upon the Association the necessity for at once taking steps to exclude unqualified members from the profession by refusing fellowship to illiterate, ignorant and incompetent graduates.

Resolved, That the Association be recommended to authorize the Section in State Medicine to act as a standing committee on Medical Education, the several elected members being required to communicate without delay, (1) with the several State Medical Societies and the Legislatures of the States they especially represent, with the object of creating *State Boards of Medical Examiners*, where such are not already in existence, whose certificate shall be necessary to the issue of a license to practice medicine in that State; and, (2) with the authorities of every regularly organized medical college in the State, which has not already taken such action, urging upon them, *First*, the *requirement of a proper preliminary education of matriculants*, to embrace at least a knowledge of English orthography, and grammar, the etymology of the more common Greek and Latin derivatives, and the fundamental rules of arithmetic, to be ascertained by a written examination, preserved for reference; and, *Second, greater care in ascertaining the fitness of candidates for a degree*, by making their final examination in part a written one, to be kept on record and accessible for inspection by State Boards of Medical Examiners, Boards of Censors of medical societies, and other authorized persons requiring information as to the professional qualifications of graduates.

Resolved, That it is the opinion of the American Medical Association, that medical colleges should confer upon graduates the degree of *Bachelor in Medicine*, such graduates to be eligible to the degree of *Doctor in Medicine* at the end of three years, after having given satisfactory evidence of their qualifications to the Board of Censors of the State Medical Society.

Resolved, That Article II. of the Plan of Organization of the American Medical Association be amended by this additional proviso: *Provided*, that every permanently organized State, County, or District Medical Society entitled to representation in this Association shall be required to appoint a *Board of Censors*, which shall rigidly scrutinize the literary and professional qualifications of every candidate for membership therein; and hereafter no delegate shall be admitted to a seat in this Association, who shall not have received the certificate of such a Board of Censors, or of a State or National Board of Medical Examiners.

A VERY LARGE SALIVARY CALCULUS REMOVED FROM A PATIENT.

BY JULIAN J. CHISOLM, M.D., BALTIMORE, MD.

Salivary calculi are not of very rare occurrence. A tumor under the tongue, on one side of the frenum, a dilated duct from the sub-maxillary gland full of fluid, and called ranula, might contain calcareous deposits. But very rarely have we the opportunity of reporting a calculus of such magnitude as the one which I extracted from the mouth of a patient two months since. I herewith append a report of the case:

Mr. W., aged 73, consulted me for a glaucomatous trouble. During the consultation, he desired to know whether his defect of vision could be aggravated by a disease of long standing in the mouth. In inspecting this cavity, I found a large swelling under the tongue, on the right side of the frenum. It was a very prominent elevation on the floor of the buccal cavity, extending from the inner face of the chin toward the root of the tongue. Its nature was apparent at the first glance, for at the anterior and upper part of this large, round, fleshy mass was an opening one-fourth of an inch in diameter, through which could be seen the exposed surface of a salivary calculus. A probe passed in through this opening entered into a large cyst, the thickened and distended duct of Wharton, which was filled with a solid calcareous mass. With a scissors I slit up the cyst wall, and removed from its bed a very large calculus of brownish-white color, which weighed, when thoroughly dried, 159 grains. It was pear-shaped, the stem or contracted part having been moulded in the less dilated posterior part of the salivary duct. The calculus was 1⅜ inches long, ¾ of an inch broad at its largest end, and ⅜ of an inch near its most contracted end.

A thread passed around the stone in its longest diameter measured 3⅜ inches. The circumference at the thickest part was 2¼ inches, and 1¼ inches

around its most contracted portion or stem. The surface of the stone was rough. It could be easily cut with a knife, the section showing a laminated structure. A drop of acid upon the surface caused carbonic acid to bubble up, showing that carbonate of lime entered into its composition. Chemical analysis showed that phosphate of lime was the chief constituent. The tumor had annoyed the patient for a long time. Its peculiar nature was not suspected till revealed by ulceration of the sac.

PERITYPHLITIS TERMINATING IN RESOLUTION.

J. B. STAIR, M.D.

John Frost; American farmer; aged 30 years; previously healthy, while eating supper on Monday evening, Nov. 26, 1883, felt a sensation of soreness in the right iliac region. It was not severe, and gave so little trouble that on the next morning he went to his usual work, and continued working until noon, when, the pain becoming much worse, he took to his bed. The pain from that time until Thursday morning, when I first saw him, was of an intermittent character, and very severe, and was general over the whole abdomen. On my first visit to the patient, the surface of the abdomen was excessively tender, the weight of the bedclothes even causing increased distress. Pulse was 108; temperature high. There had been some vomiting, and the bowels were constipated, though they had been moved freely by injection. I regarded the case as one of peritoneal inflammation, and sufficient morphia was given to procure rest, combined with small doses of calomel, and fomentations over the abdomen. I saw the patient again the next day, it being the 30th. General condition about the same; pain, however, had become located in the right iliac region; great tenderness there, and a not well-defined feeling of induration. Diagnosed forming abscess of, or in the region of, the vermiform appendix. Continued anodynes and the application of fomentations over the affected locality.

Dec. 1.—Tumor well-defined, hard and very tender. There has been no vomiting. Patient slept well under the use of morphia. Bowels moved by enema.

Dec. 2.—I saw the patient to-day with Dr. T. F. Stair, of Mazomanie. He confirmed the diagnosis already made. Pulse 90; temperature 101; takes nourishment well. The tumor is large, hard, and no evidence of fluctuation.

From this time on to the 6th, the pulse and temperature rose steadily until the latter reached 103½. There were no chills, but the patient sweat profusely whenever sleeping. No fluctuation could be discovered positively, but deep pitting could be produced by pressure around the circumference of the swelling. It was a question whether it was best to operate, or wait another day. It was finally deferred, and on my visit the next day I was somewhat surprised to find the temperature down to 98½; pulse 68, and the patient in every way comfortable. The tumor was no smaller, but much less tender. From that time the patient rapidly improved, and is now able to work. When seen last, a week ago, there was still a hard, indurated feeling over a space two inches in diameter at the site of the difficulty, but not tender, and occasioning no inconvenience.

Spring Green, Wis., Dec. 27, 1883.

NON-UNION OF FRACTURE OF THE SHAFT OF THE FEMUR TREATED BY EXERCISE.

BY G. W. NESBITT, M.D., SYCAMORE, ILL.

(Read before the Surgical Section of the American Medical Association June, 1882.)

Non-union of broken bones is so uncommon an event in surgery, that it has been estimated that it does not occur in a larger proportion that one in five hundred fractures. And as fractures of the shaft of the femur constitute but a small per cent. of all fractures, it must follow, that not one physician in ten, in general practice, will meet with one case in a lifetime, unless his treatment of fractures should be exceptionally bad.

But should the *one* case fall to either of you, you will, after having exhausted the resources of written surgical authorities, and taxed your own patience and ingenuity to the utmost, most gladly avail yourselves of any practical hints upon the subject, however humble the source, before subjecting your patient to the peril and uncertainty of a resection, or the dangers and professional disgrace of amputation.

And although the plan of treatment adopted by me in the case which I am about to report may not be wholly original, yet the fact that it has proved successful in this and several other cases that I have been able to collect; and that it is not described in any of our modern text-books of surgery, is the only apology I shall offer for presenting it in detail for your consideration.

September 30, 1877, Mr. E. E. Woodard, a strong, healthy man, age 29 years, fell from a tree, a distance of 61 feet, striking on the ground, producing a double Colles' fracture, and an oblique fracture of the left femur at the middle third. The patient was then living in an adjoining county, and was attended by a physician of that vicinity till Dec. 9, 1877, when he was brought to Sycamore and placed under my care.

At my first visit I found him looking well, after a wagon ride of sixteen miles. The thigh was incased in a loose pasteboard splint, over which was applied a starch bandage, and a long splint loosely tied to the outside of the limb as a temporary protection against accident while on his journey to Sycamore. I removed the dressings, and found the leg shortened to the extent of nearly four inches, with the inferior extremity of the superior fragment tilted forward and upward by the unrestrained action of the psoas muscle, while the inferior fragment was drawn downward and backward by the gastrocnemii muscles, thus separating the extremities of the two fragments

at least two inches. No attempt at union seemed to have been made. The pasteboard splint was so loosely applied that the hand could be easily passed between it and the thigh, thus allowing great freedom of motion of the fragments, while, as has been remarked, the muscular contractions tended to separate more and more their extremities.

The general health of the patient was apparently good, and the fact that the forearms had both united, added to the array of circumstantial evidence surrounding the case, led me to conclude that the causes of the non-union were local rather than general; viz., separation of the fragments and too much motion.

I decided to commence the work anew, so first endeavored to put the parts as nearly as possible into the condition of a recent fracture, by making extension till the ends of the fragments were very nearly in apposition; then by bending, twisting, and moving the fragments freely upon each other, to break up any adhesions of the soft parts, and finally by rubbing the opposing surfaces of the bones together until crepitus could be distinctly felt and heard. So well was I pleased with the result of my efforts to produce a recent fracture (?) that I put on firm, well-fitting splints around the thigh, and applied the long splint, with extension and counter-extension, with as much confidence in the final result as if the fracture had been an injury of to-day.

The degree of inflammation and excitement in the adjacent tissues was considerable, and gave the patient, as well as myself, confidence that it would result in union of the fragments. At the end of six weeks the union had become so firm (in the mind of the patient) that I removed the splints, to find that although the limb was in good shape, and nearly its full length, with the fragments in apposition, yet the false joint was as complete—non-union as perfect, as the day I first saw it. On moving the fragments upon each other now, I could only get a sliding sensation instead of crepitus; as if the bones had become entirely covered over with soft tissue.

On the 6th day of February, 1878, I cut down to the bone at the seat of the fracture, introduced a Brainard drill, and broke up all the intervening tissues, and perforated the ends of the fragments with four holes each, hoping thereby to produce sufficient inflammation to induce the formation of callus, and secure a bony union.

The patient was very much prostrated for several days subsequent to the operation, from the effects of the anæsthetic used; and before he had fully recovered his natural tone and appetite, a severe attack of nephritic colic supervened, which not only complicated an already troublesome and tedious case, but so undermined the general health of the patient, by bringing on complete loss of appetite, nausea and vomiting, with œdema of the feet and legs, etc., that I considered it necessary to get him out of bed, in hopes that fresh air and exercise might do for him what I had little hope of accomplishing with him in bed. Therefore, on the 18th day of February, twelve days after the operation, having applied a firm, well-padded, close-fitting sole-leather splint to the thigh, after the plan of Prof. H. H. Smith, *i. e.*, with a shoe and irons with joints at the knee and hip, upon the same principle as the ordinary club-foot shoe, or a brace for paralyzed limbs, I supplied him with crutches, and for the first time in nearly five months, he assumed his perpendicular and stood upright like a man. For the first few days, as might be expected, locomotion was slow, but the improvement in the general health was rapid. He passed a large number of renal calculi, soon after getting up, which gave relief to the pain, nausea, vomiting, etc. His appetite again returned, the œdema of the feet and legs disappeared, and, as he expressed it, he "felt first-rate."

The leather splint was fastened around the thigh with straps and buckles, and was loosened every day, and the limb exposed to the sunlight, and rubbed with the hand to induce a more healthy condition of the soft parts, and encourage the natural circulation. But very little inflammation followed the drilling, so, on the 6th day of March, there being no appearance of union taking place, the patient being put to bed, I again repeated the operation with the drill after the plan of Brainard, which being followed by only very slight inflammation, I again resorted to the drill on the 16th, and was again disappointed in not getting the inflammation and consolidation which the books lead us to expect.

Thinking, perhaps, the ends of the fragments might be diseased or wanting in vitality, I determined to try the drill once more, and, if possible, excite an inflammation in the healthy bone tissue. Therefore, on the 31st day of March, I entered a larger drill at a point nearly three inches above the inferior extremity of the superior fragment, and passing it obliquely downward and backward, drilled through both fragments, the point of the drill coming out on the posterior surface of the inferior fragment fully two inches from its superior extremity. Having made two other holes with the drill in a similar manner, and in a similar direction, I withdrew the drill and entered it again at the point of the overlapping superior fragment, passed it upward and backward between the fragments, moving the drill freely, breaking up all adhesions and tearing up the soft tissues between the fragments, and, *finally*, drilling obliquely into other fragments from the center, or the space between the overlapping bones. I removed the drill with much satisfaction, believing that if there was any benefit to be derived from drilling we must now get it. I was at least confident that inflammation would follow the operation, and in this I was not disappointed. The leg was again dressed as if it had been a recent fracture, this time using a weight and pulley to make extension, and, after a few days, putting on the long splint to prevent the toes turning out or in, and twisting the thigh at the point of fracture. Inflammation followed the operation to such a degree that I began to fear that my perseverance would be rewarded with suppuration. But this threatening appearance soon passed off, and at the end of three weeks I never saw a more promising case of recent fracture. Callus could be distinctly felt about the ends of the fragments, and a consolidation of the bones seemed inevitable, when another attack of

nephritic colic, with the passage of large quantities of calculi, came on, and in ten days the callus had disappeared, the inflammation had subsided, and the parts were in much the same condition they were two months before. I was discouraged somewhat, and undecided as to what step I should take next. I again put him on crutches with the limb supported by the leather splint, and while he walked about recuperating his strength, I pondered much on what the next procedure should be in his case.

About this time I attended the meeting of the American Medical Association at Buffalo, and while there I consulted several eminent surgeons in regard to the case, who agreed in the opinion that it would be necessary to make a resection in order to secure union, as they had fears that some portion of the muscular tissue was drawn in between the fragments, in which case it would be impossible for union to take place. Owing to the renal difficulty, they, however, advised a delay of the operation till the general health was restored.

On my return the patient was in the country, and I did not see him for two or three weeks. When he returned his health was much improved, and I commenced preparations for making a resection, but I so feared and dreaded the consequences of the necessary confinement that I at last decided to test the plan which I am about to describe, and which consists in applying a plaster splint and compelling the patient to walk without crutches, similar to the plan first recommended by White, of Manchester, and afterwards adopted by Hunter, Champion and several other surgeons, but which from some cause, or without cause, has so fallen into disuse that it is not even mentioned by a number of our standard authorities on surgery. And not one of those that do refer to it—so far as I have been able to learn—has given any description of the dressing and treatment, or any directions for applying it. This, as I have before remarked, together with the belief that the plan pursued by me was original in some respects, has induced me to present the particulars of the treatment.

But before proceeding with the dressing, I would remark that some soreness still continued in the bones from the last drilling, and the circulation in the limb was better than at any time previous to the operation of March 31, which encouraged me in a measure to wait and try this plan, which had been recently recommended to me by Dr. Horace Tupper, of Bay City, Mich., before resorting to resection.

July 25, having first applied a close-fitting elastic stocking to the limb, as far up as six inches above the knee, I then made extension, till the fragments were brought as nearly as possible into apposition, and applied broad strips of a firm woolen blanket lengthwise of the thigh, and extending below the knee, and above the trochanter major and the tuberosity of the ischium. These strips completely surrounded the thigh, and were held in place by a roller bandage of the same material, applied firmly from the condyles of the femur, to the perinæum and the tuberosity of the ischium. I next applied a roller of mosquito net, then a coat of plaster of Paris; and while it was yet soft, I applied strips of wire gauze, extending the whole length of the thigh, and outside of this another covering of the mosquito net, which was again coated with plaster, wire gauze, and more netting, till a splint was formed at least half an inch in thickness, and extending the entire length of the thigh. I now reflected the ends of she longitudinal strips of blanket stuff, which was first applied to the thigh, back over the outside of the splint, and secured it by a roller bandage of the mosquito net, extending from within half an inch of the lower border of the splint to within half an inch of its upper margin, and over this applied a thin coat of plaster, which in turn was covered by a muslin roller bandage, which gave it a finished appearance and completed the dressing.

The cushion-like margins of the splint above and below, formed by the reflection of the lining of the splint, as it were, were not only neat, but comfortable and firm, while the whole splint fitted so closely from the perinæum and tuberosity of the ischium above to the condyles of the femur below as to render shortening almost impossible after the plaster became hardened.

Extension was kept up till the splint became firmly set, when the patient was allowed to get up and go about, bearing his weight upon the broken leg without the aid of canes or crutches, except when taking a long walk—as coming down town—a distance of nearly a mile, when he used one crutch, and sometimes a cane and crutch. But he worked about home, sawing wood and doing chores about the house, without any artificial support most of the time.

The first few days he complained of some soreness at the point of fracture, but not sufficient to discourage him in his efforts at independent locomotion.

He was now really self-sustaining, and I left him to take care of himself till October 6, when I removed the plaster dressing, and found that a firm bony union had taken place, with the limb in good shape, and with less than three-fourths of an inch shortening. This man has since that time been employed as a house carpenter, also in putting up wind-mills. He walks without limping, does all kinds of heavy work, and climbs a ladder with as much agility as if nothing had ever happened him.

In addition to the general plan of treatment, I would call attention to the use of the wire gauze, for the purpose of strengthening and at the same time reducing the weight of the splint, as I do not remember to have seen any account of its employment for that purpose previous to its application by me in this case, while the same is also true of the use of the elastic stocking; and I am sure if any of my brethren should once test it in a similar case, where a bandage must be worn for several weeks, they will be convinced that there is more than the difference in the cost of the two, not only in the comfort to the patient, but in the annoyance to the surgeon.

The following letter, recently received from Dr. Horace Tupper, of Bay City, Mich., in which he reports four successful cases treated by this method, will be found of particular interest in this connection:

BAY CITY, MICH., May 8, 1882.

DR. G. W. NESBITT:

Dear Sir—Your letter of March 21 asking me for a report of the cases of non-union which I have treated with plaster of Paris bandages, and thereby obtained union, was received, and in reply would say, that the first case was that of Mr. B. T., aged 83 years, who broke his thigh by falling from his horse in 1868. I was called to operate on him in 1870. He then had non-union. On account of his age and enfeebled health I decided not to operate. But in order to get him out and strengthen his system, I applied adhesive straps to his foot and run a cord over a pulley, and put on about a ten pound weight with orders to let me know when it was getting so painful that he could not endure it any longer. I was sent for the next day. I then wrapped the thigh in a piece of old army blanket, in which I had a leather strap folded in the upper margin to serve as a perineal band to sustain counter-extension, the foot and leg having been bandaged the day before when I put the straps on the foot. Then, while making strong extension and counter-extension, I proceeded to apply the plaster of Paris bandage from the condyles of the knee up to the perineal band, and including the belt. I kept him recumbent until the next morning, when I got him upon his feet. He complained of pain at the point of fracture whenever he bore his weight on it for two weeks or more; but never complained of pain after the second bandage was put on. The first bandage was on about four weeks. The second one some two months, and the limb was perfectly solid when it was removed. I never had an opportunity of knowing whether the union that took place was ligamentous or bony.

Case No. 2 was a Mr. B., aged 43, a Canadian. He had his thigh broken in 1868. I saw him in 1870, with non-union. Put on heavy extension for about two days, then applied plaster of Paris bandage with complete success.

Case No. 3 was that of Mr. E., who broke his thigh in 1873, followed with non-union. He fell into my hands in 1875. I applied strong extension, then the plaster of Paris bandage as in the preceding cases, and obtained the result desired, viz., complete union.

Case No. 4 is one that came to my knowledge as having been treated by another physician after having seen the result of my treatment of case No. 3. The doctor put on the plaster bandage without making extension, so that although he got good strong union the limb was crooked, owing to the bandage being put on when the limb was out of position.

I mention this case because it shows that the application of the plaster bandage will unite the bones in some way, whether it be in apposition or not.

I have other cases, but deem the above sufficient for your purpose. Yours truly. H. TUPPER."

In addition to the above cases, I have learned of another case of ununited fracture of the femur, treated successfully by this method, by the late Dr. E. G. Castle, of Quincy, Illinois, but owing to the death of the doctor, I have been unable to get a report of the case, although it is vouched for by many responsible physicians of that city.

As is indicated in Dr. Tupper's first case, I would mention that generally, it will be best to remove the dressing at the end of three or four weeks, and apply it anew, as the muscles of the thigh are pretty sure to shrink under the pressure of the bandages, thus allowing too much motion at the point of fracture. But in my case, the leather splint had been worn so long that there was little danger of further shrinkage; hence there was no necessity for applying a second bandage.

The presence of *active inflammation* is always a contra-indication for this treatment, while the case of Mr. Woodard, and Dr. Tupper's first case, will indicate the class of cases to which I consider it most applicable, although I believe it should always be given a trial before resorting to the more severe and dangerous operations of resection or amputation.

As to the risks or dangers of this plan of treatment, I would state, that in one of White's cases, a large abscess formed on the thigh; this, however, did not prevent a favorable result, and is the only instance in which positive harm has resulted from the treatment. And in view of the great good that has resulted from this plan of treatment of non-union, or ununited fracture of the femur, and the very slight danger attending it, I ask only in justice that it be reinstated as a standard method of treatment by the surgical authorities of our profession.

EULOGY DELIVERED AT THE FUNERAL OF THE COUNT, KNIGHT-COMMANDER, PROFESSOR GIAMBATTISTA ERCOLANI.

BY PROFESSOR GIROLAMO COCCONI.

The profound sorrow felt by Bologna at the sad announcement of the irreparable loss of Giambattista Count Ercolani, calls us to-day, reverent and desolate, around this bier for the last farewell to the illustrious and excellent citizen.

But it is not the mourning of Bologna only; all Italy with emotion lifts the funeral shroud, and salutes the corpse of one of her most famous and favorite sons.

Wherever darted the swift, electric fluid, conveying the sad intelligence, a cry of grief burst from all who knew the man or his reputation.

Scientific academies, universities, bodies of learned men, politicians, civil and military authorities, civic, municipal and provincial associations vie with each other in rendering this tribute of respect, affection, and sorrow to the man who had such claims on the public regard.

The press of the city, every class of liberals in politics, are unanimously showing the general grief.

An eminent scientist, an upright citizen, a fearless patriot. Felsnia boasts of having given birth to this patrician who sought fame in the results of study rather than in the federal parchments of his ancestors.

Educated in the school of the great Antonio

Alessandrini, whose learned diligence he early imitated, in the most lamentable poverty of means, he contributed to the foundation of those monuments of surprising activity, the museums of comparative anatomy, and veterinary pathological anatomy.

But this youth of so brilliant promise Bologna lost in 1849, for he belonged to that pleiad of distinguished patriots who were guilty of having loved Italy, when, with the evil rulers who kept it enslaved and divided, the love of country was counted a crime.

The events of 1848, the historic incidents of August eighth, and the memorable defense of Rome in which he took part found him warm with this holy sentiment.

When the last bulwark of Italian liberty fell by the arms of the French Republic, and the Sacerdotal power was rëestablished, Ercolani, as a member of the Roman constituant assembly was driven into exile.

He repaired with other Bolognese to Tuscany where the regime of the Restoration seemed milder; but the persecution of the government that was constituted in the name of the Pontiff was not confined to the limits of the State; it could not tolerate in a neighboring territory, an asylum for the banished, and by constant pressure exercised upon the mind of the Grand Duke obtained from him the dismissal of all the patriots who had taken refuge in his dominions.

Ercolani, obliged to leave the Tuscan territory at 24 hours notice, went to Piedmont which alone held aloft and honored the Italian flag. There, with scanty means, he dwelt in a poverty sweetened by the sympathy of his wife and a beloved child, and by the friendship of the most eminent patriots throughout Italy.

But his mental endowments were quickly recognized, so that being by royal decree made a Piedmontese citizen, the government conferred on him the office of Assistant Professor in the Veterinary School of Turin, with trifling salary indeed, more not being allowed in the financial condition of Piedmont after the disaster of Novara.

Our Ercolani was, however, by no means discouraged. On the contrary, with the feverish activity which always distinguished him he was able, even from this humble position, quickly to emerge, and to make himself known to the scientific world.

Among the principal works of this period are especially his "Researches Historic and Analytical on the Writers of the Veterinary Art," a critical and biographical work entirely new, by the publication of which ancient manuscripts existing in various libraries were brought forward and interpreted.

With difficulty Professor Carlo Lessona, of Turin, founded in 1852 the first Italian journal of Veterinary Medicine for which, even then, the illustrious Professor Herring found words of praise and encouragement.

But the destinies of the country which, in 1849, appeared so adverse, brought forth, ten years later, that grand epic poem in action, from which Italy shone out one and independent.

In the first days of this unity, the minister Mamiani, rearranging the two veterinary schools of Turin and Milan, nominated Professor Ercolani to that of Turin. So that, from the lowest of the professorships, the lowest in seniority and compensation, he sprang to the highest position, which his deep learning had procured for him.

But a grievous family misfortune was quickly to bring days of renewed wretchedness, and to plunge again into sorrow the life of the poor Ercolani. His only daughter, the flower of his house, the comfort of her parents in long years of misfortune, who, although married, lived with her husband in her father's family, suddenly died when but little over twenty.

The parents, stunned and unable to endure such a loss, repaired to Bologna, bearing with them the anguish which can never find relief. Thus the school of Turin lost its illustrious Director, and science also seemed menaced with the loss of one its most ardent votaries, Ercolani, in the trouble of his mind, having firmly decided to withdraw from teaching. But the minister of that day, to whom it was highly important that Ercolani should not be lost as an instructor, releasing him from the duties of Director and Professor of the school of Turin, appointed him regular Professor of the Veterinary Institute in this illustrious University of Bologna.

Here he attained the higest offices, being several times President of the Medical Faculty, and twice Rector of the University.

His indefatigable industry and his love for zoötomical science did not permit him to drag out life in the mere germ of a veterinary school, carrying on alone the teaching of the various branches, and hardly aided by a single assistant. Hence he conceived the idea, and gradually attained it, of endowing Bologna with a complete superior school of veterinary medicine.

Aided by the liberality of the Province, and by government grants, he was enabled to enlarge the ill-adapted buildings, to erect new ones, and to procure the better accommodations that were demanded in order that the school might be adequately equipped for its purposes.

The shortness of the time that separates us from his death, the grief which oppresses our minds, deprive us of the ability even to enumerate his works, most of which are inserted in the memoirs of the Academy of Bologna.

It suffices to say that, endowed with an exquisite acuteness of intellect and with an iron will, he spent almost his whole life in subtle investigations, aimed at raising the edges of that veil under which nature conceals herself in her choicest workings. That he was a decided microscopist, when the microscope was in the hands of few, and an impassioned follower of both medicine and surgery, as well as of natural history, is shown by his numerous discoveries in the field of normal and pathological histology, of comparative teratology, of elmintology, of pathological anatomy, of embryology.

In a very learned work of historical and bibliographical curiosities, he restores to Carlo Buini, a Bolognese senator, the glory of the discovery of the circulation of the blood, this, too, carried off by for-

eigners, who assign it to Harvey, a physician in the time of Charles First of England.

Noteworthy among his many works are his patient "Researches on the Genetic History of Trematodic Worms, and the Adaptation of Their Species to the Surrounding Fluid," in which is shown his great skill as an observer and naturalist.

"The Formative Process of the Osseous Callus in the Different Fractures of the Bones of Men and Animals;" "The Interior Structure of Tendinous Tissue, and that of the Fibrous Tissue;" "The Transformation of the Histological Elements in the Animal Organism," and other works of minute anatomy, attest his skill as a histologist.

But the work that gained most attention from the learned of both continents was a series of papers regarding "The Intimate Structure of the Placenta in Woman Compared with that of Other Animals;" observations which led him to admit the unity of anatomical type and of nutritive function of the fœtus in all the vertebrates.

These works, of which we are at a loss to say whether they most exhibit his acuteness of observation, his intellectual strength, the exactness of his deductions or the vast extent of his knowledge, were reviewed in many foreign languages, and honored with a literal translation into English by Dr. Henry O. Marcy, of Boston, in order that the book might be in the hands of the physicians of England and the United States.

In opposition to the universal applause with which the scientific press received the discoveries of Ercolani upon the structure of the placenta, one of the most famous anatomists and histologists of Germany, Kölliker, maintained the old doctrines, and did not accept the new observations and inferences of Ercolani. The latter could not leave unanswered the objections of such a man as Kölliker, and published three long letters, rich with new facts and observations drawn from the fields of comparative and pathological anatomy, which, with much courtesy of manner, he addressed to his distinguished opponent.

And in this last work, which fell from his pen when the cruel disease which was to slay him had already developed its deadly germ, in this his profound learning especially shone, like a torch which flashes brightest before it is extinguished.

But among the most important scientific treasures which he left as results of his intellectual labors should be reckoned a valuable collection of works on the veterinary science, rich in manuscripts and rare editions, patiently collected by him in the course of many years, and sometimes at heavy cost, a collection which would have been unfortunately scattered if he had not, with munificent forethought, secured it for one of the libraries of this learned city.

His wide reputation had made him a member of the principal national academies, such as the Royal Academy of Turin, the Lombard Institute of Science and Letters, the Academy of Science, Literature and Art of Padua and of Palermo, the Medical and Surgical Academy of Genoa, the Physical, Medical and Statistical Academy of Milan, the Academy of the "Quirite" and that of Agriculture of Florence, the Scientific and Literary Academy of the "Concordi" and that of Physical and Mathematical Science at Naples, the Medical and Surgical Society of Bologna, of which he was also President; the Royal Society and National Academy of Veterinary Medicine of Turin, of which he was honorary President; and many others which escape recollection.

But strangers also wished to adorn his name. Three foreign veterinary schools, that of Stuttgart, of Dorpat, and of Kasan, named him honorary Professor. He was a member of the French Academy of Medicine, and of the Central Society of Veterinary Medicine of Paris, of the Royal Academy of Belgium, the Imperial Academy of Berlin, the Veterinary Society of St. Petersburg, the Royal College of Veterinary Surgeons of London, the Numismatic and Antiquarian Society of Philadelphia, the Veterinary Union of Wurtenberg, and he had a friendly correspondence with the most eminent European scientists, among whom may be cited the great names of Virchow, Owen, Turner, and Milne Edwards. Such, in short, was the patriot, the man of science. What was the citizen?

The object of public esteem, he was a member of the municipality of Bologna, and provincial Councillor, President of the Agrarian Society and of the local committee, member of the Provincial Sanitary Council, offices which he filled with love and honor.

Though a student, and apart from the strife of politics, he three times accepted a deputation to Parliament, not to satisfy a devouring ambition, but from loyalty to the party to which from conviction he belonged. He sat always "on the Right" from deference to his honorable political friends, and because his tendencies drew him to that party which had united the great Italian family. He took no active part in parliamentary labors, the scientific life, to which he was now devoted, not tolerating occupations foreign to study, and recoiling from the barren party strifes that are carried on in the parliamentary arena.

Deeply convinced of the goodness of our institutions, sincerely liberal, abhorring doubtful measures, jealous of meddling with internal arrangements, he appeared to oppose the important reforms, which were introduced by the ministers "of the Left." But this was not in him a blamable venting of systematic opposition, rather was it a natural result of excusable preferences and firm convictions.

The Italian government held him in high esteem, and availed itself of his wise assistance in many important contingencies.

The high renown which he had acquired in the sciences, and his services procured him many honors. He was "Knight of Civil Merit of Savoy, Knight Commander of the Order of Maurice, and of that of the Crown of Italy. He was a member of the Royal Commission for the publication of the classics in the Province of Emilia, and the colleges of all the universities of the Kingdom, without distinction between medical and veterinary, twice appointed him to the Superior Council of Public Instruction.

Of such honorable tributes Ercolani was truly worthy, because he did not seek them, nature having

constituted him modest and disinterested. Affable in manner with all, and especially so with the young, not rigidly bound to routine, but scrupulous in the duties of instruction, he was beloved by the youth whom he had as pupils for a period of more than thirty years. Cordial with friends and inferiors, he strove as much as possible for the advantage of all without injustice to any.

Men so excellent, intellects so supreme, must not disappear, though they quit this mortal life.

But those inmost secrets of the organism which Ercolani so many times sought to unveil by his minute researches seemed at last to rebel against him, fierce to destroy such robustness of intellect and potency of investigation.

Heart cannot endure to recall the sufferings that preceded his end—sufferings borne by him with touching resignation. There cannot be imagined a more cruel torture, against which strove in vain all the resources of that ungrateful science which he had so much loved.

With him gradually passes away a generation of deserving professors who, having for their mission the progress of science, as well as its teaching, leave the indelible impress of their steps upon the earth as they move across it.

Adieu, Giambattista Ercolani; science salutes thee for thy learned industry with which thou hast made the Italian name honored far and wide.

Adieu, Giambattista Ercolani; Italy in thee salutes one of those excellent patriots who, with self-denial, exile and martyrdom, prepared the triumph of her Holy cause.

Adieu, Giambattista Ercolani, oh, worthy citizen; thy Bologna, from whose walls thou has departed forever, salutes thee, her ornament and pride.

Adieu, Giambattista Ercolani, illustrious professor, attended by the sorrow of the colleges of this ancient seat of learning—Bologna—famous for so many ages for the renowned men who resembled thee.

Accept these, our unadorned but sincere words, as a poor tribute of the love we bear thee.

In this woful affliction, fain would we find for thy desolate companion, who in thee loses the last of those dear to her, some accent which might soothe her grief, but the word dies upon our lips, for we also have need of comfort.

Bologna, Nov. 19, 1883.

MEDICAL PROGRESS.

MATERIA MEDICA AND THERAPEUTICS.

Caffeine Considered Physiologically and as a Therapeutic Agent.—Dr. Leblond concludes, in *La Tribune Medicale* for November 18, a series of articles on this subject. His general conclusions are:

Of the physiological dose:

1st. Caffeine is an excitant of the nervous and muscular system.

2d. It diminishes the frequency of the pulse, increasing the force of the heart-beat and blood pressure by the vaso motor constrictors.

3rd. It lowers the peripheral temperature.

4th. It has no influence on the formation or excretion of urea.

Of the poisonous dose:

1st. Caffeine exaggerates the excito-motor force of the spinal cord, paralyzes the peripheral sensitive nerves, and diminishes the sensibility of the pneumogastric.

2nd. It causes a rapid lowering of the blood pressure through paralysis of the vaso-motors.

3rd. The heart, in cold-blooded animals, beats slower and slower, to be finally stopped in systolé; in warm-blooded animals, it becomes quicker at the close and stops in diastole.

4th. It produces tetanic contraction of the muscles.

5th. It rapidly lowers the temperature.

6th. It increases malassimilation.

As a therapeutic agent:

1st. It is, as a rule, tolerated much better by the system than is digitalis, and by beginning with small doses, there is no fear of the bad effects often produced by the latter.

2nd. It steadies the heart, increasing its force and slowing its beats.

3rd. It produces more or less of a diuresis.

4th. Not only is it a substitute for digitalis, but it should *always* be administered in serious cases which may result in immediate death, because its action is surer and more prompt than that of digitalis.

5th. It is best to administer the caffeine in small broken doses, in potions or subcutaneous injections, and to never begin with a stronger dose than 20 centigrammes, to determine the susceptibility of the patient, then to increase the dose rapidly, if necessary, to from 50 to 75 centigrammes. It is useless to give more than 1. gramme 50.

6th. In affections of the heart it should always be administered when, from any cause, the patient's condition requires that the use of digitalis should be stopped or when it is not well tolerated.

7th. Caffeine seems to lower the temperature in pyrexia, being useful also in these cases as a heart tonic.

8th. It is frequently very beneficial in albuminuria of cardiac or other origin.

9th. And finally, in cases of strangulated hernia it seems to act upon the muscular contraction of the intestine.

PHYSIOLOGY.

The Influence of Alcohol on the Physiological Action of Chloroform.—Dr. R. Dubois (*Comptes Rendus de la Societé de Biologie*) has been conducting a series of laboratory experiments upon this subject, by bringing dogs under the influence of alcohol and then administering chloroform as an anæsthetic. He has arrived at the following conclusions:

1. In the condition of acute alcoholism, anæsthesia is produced more rapidly.

2. The vital resistance of the animal is shorter.

3. The proportion of chloroform in an anæsthetic mixture can therefore be diminished.

4. The quantity, in volume, of the mixture required to penetrate the bronchi to produce anæsthesia and death is less than the amount necessary in the normal state.

5. As in the non-alcoholized animal, the lowering of the temperature is in direct relation with the duration of resistance on the part of the subject.

A REMARKABLE CASE OF TRANCE—A WOMAN "ASLEEP" FOR FIVE MONTHS.—A very peculiar case has occurred at the Western Infirmary, Glasgow—as reported in *The Medical Press*. It appears that a respectable married woman named Mrs. McInnes, the wife of a post-runner, after giving birth to a child became unconscious, and for seven weeks lay in bed in a comatose state. It was then resolved to convey her to the hospital, which she entered on August 1. From the day of her entrance she remained in the same unconscious state until Nov. 20. She lay on her back and never moved a muscle. Her pulse has averaged 80; her breathing was fair; and to keep up her strength she was fed three times every day by means of the stomach-pump apparatus. No hopes were entertained that she would recover, but on the 20th she opened her eyes, sat up in bed, and emitted an exclamation of astonishment on finding where she was. Mrs. McInnes is, of course, very weak, though conscious, and hopes are entertained of her ultimate recovery. Prof. Gairdner and Dr. Cameron have had charge of this singular case, and Dr. Gairdner promises to give a full account of the case in the medical journals.

UTERINE MILK.—A recent number of the *Zeitschrift für Geburtshülfe und Gynäkologie* contains an article by Dr. G. Von Hoffmann, of Wiesbaden, in support of the doctrine advocated by Ercolani, and to a certain extent by Dr. Braxton Hicks, viz., that the fœtal villi in the placenta do not float naked in the maternal blood, but are surrounded by cells whose function it is to secrete a special fluid serving for the nutrition of the fœtus and called uterine milk. Dr. Von Hoffmann believes that he has been able to extract this fluid from the human placenta. His method is simply this: He takes a quite fresh placenta, which has not been allowed to come into contact with water, and lays it with its maternal side uppermost. A cotyledon, the integrity of which has not been damaged, is then selected, and carefully dried with a sponge or towel, so that no blood adheres to it, and into it a capillary tube is then pressed, so that it may penetrate about one-third or half an inch. The tube thus used pushes the villi aside, and lies in the inter-villal spaces. It is important in inserting the instrument to see that no blood-vessels are injured by it, lest blood be effused between the villi. When a capillary tube is employed in this manner it sucks up the fluid from the inter-villal space (*i. e.*, the uterine milk) which can then be collected and examined. Dr. Von Hoffmann has examined the fluid from about forty placentae, some at term, others from cases of abortion at different months. Microscopically, he finds in it the following constituents:

1. Red blood corpuscles of different sizes and depth of color, often, especially in placentæ of the earlier months, with little or no tendency to aggregate into rouleaux.

2. White corpuscles.

3. The chief structures contained are what the author calls "uterine milk globules," peculiar, clear, round globules, having a very thin, feebly refracting wall, on the average about as large as white corpuscles, but varying from a tenth of to twice their size. These bodies precisely resemble those seen in "uterine milk" obtained from the placenta of the cow.

4. Clear, watery intercellular fluid. The above-described "uterine milk globules" are present in such numbers that Dr. Von Hoffmann calculates that each cubic millimeter of the fluid contains 180,000 to 200,000 of them.

5. There are also found free decidual cells and pigmentary molecules, granules and flakes of different shapes and sizes, which our author regards as products of the disintegration of red blood corpuscles.

Fluid such as this, Dr. Von Hoffmann states, can be extracted from every healthy placenta; if it is wanting, the placenta is not healthy. He believes, moreover, that he has traced the mode of formation of these "uterine milk globules" from decidual cells, and the production of the large decidual cells from the many nucleated "giant cells" of the decidua.

Dr. Von Hoffmann's views as to the physiology of fœtal nutrition are summed up in the following propositions:

First.—The general office of the decidua, both in animals and in man, is to supply the fœtus during its intra-uterine life with a part of the nutritive material necessary for its growth. To fulfill this function the decidua serotina becomes a special milk-secreting organ, which after the birth of the child is expelled, with and as an integral part of the placenta.

Second.—The secretion of this organ, the so-called uterine milk, is separated into gradually formed spaces, in which lie the placental tufts. Here the uterine milk is mixed with maternal blood, which is at the same time extravasated, and together with it forms the material for nutrition of the fœtus, this material being only suited for absorption by the placental villi when these changes have taken place.

Third.—From the point of view of the comparative anatomist, it can no longer be maintained that there is any essential difference in this respect between the placenta of man and the higher animals.

Dr. Von Hoffman promises a further communication in which he will elucidate the mode in which this uterine milk is absorbed by the placental tufts.—*Medical Times and Gazette.*

OBSTETRICS AND GYNÆCOLOGY.

THE COUVEUSE FOR CHILDREN.—On page 339 of this journal there appears a reference to the use of what is called the "couvreuse," a typographical error having reference to this apparatus, which has been detailed in full by M. A. Auvard in the *Archives de Toeologie*, and the description of its practical application is of sufficient interest to give it a place here. The great use to which the couveuse has so far been put, is to support life in cases of children prematurely,

born, and with congenital weakness. The records of the Maternité give the following striking instances. The numbers refer to the hospital register:

No. 7, age 6 months, 6 days, weight 1,720 grammes, remained 46 days in the couveuse with benefit; No. 8, age 6½ months, weight 1,820 grammes, remained 5 days; No. 14, weight 1,630 grammes, remained 11 days; No. 21, weight 1,530 grammes, remained 9 days; No. 71, age 7 months, weight 1,530 grammes, remained 12 days; No. 73, age 7 months, weight 1,400 grammes, remained 12 days; No. 109, weight 1,550 grammes, remained 10 days.

In cases of cyanosis and œdema, there were five so treated in whom the circulation was rapidly re-established. Generally a five days' sojourn was sufficient, in one case 11 days was found to be necessary. Benefit was also observed in cases of slight pulmonary congestion, and in apparent death where, after resuscitation, the children were placed in the couveuse. Dr. Auvard claims by statistics that the death-rate of children in the Maternité was reduced from 66 per cent. to 38 per cent. in consequence of its use.

Prof. Winckel published in 1882, in the *Centralblatt f. Gynäkolgie*, a description of an apparatus for placing children prematurely born, or suffering from affections of the respiratory organs, in a bath where they could remain indefinitely, and somewhat upon the plan of the couveuse. The bath tub was of metal, with a projection upon the bottom, so placed as to furnish a support for the back of the child. It had a moveable cover, pierced at the four corners by small openings, and having a little window in the center, covered by a moveable piece of glass. The head of the child was placed in a depression made for the purpose at one end of the tub, and was kept in place by the cover, which was protected by a piece of leather that fitted under the chin, and so prevented the head from slipping down. The capacity of the tub was about five gallons, and the water was discharged by two stop cocks, which also let out the fæcal matters. The water could be kept at a temperature of 96.8 to 98.6, by putting in a quart of boiling water every hour or half hour, the bath being wholly renewed every six or eight hours. Winckel has only recorded six observations. These were in cases of premature births affected with asphyxia, and were all favorable. The prolonged bath, according to this method, is undoubtedly a more energetic means than the couveuse of counteracting the low temperature in new-born children, but it must always be difficult to administer and require constant attention. It has not been used for longer than twenty-four hours at a time. A part of the chest must frequently be above the surface of the water, and thus exposed to a lower temperature, and the head being external, the child must inhale cold air.

M. Auvard, acting under the advice of M. Tarnier, has constructed a couveuse for private use, which he considers as an improvement on the bulky and expensive form used in the hospital. It is made of a box 25½ inches long, 14 inches broad, and 19½ inches high, the sides being about an inch thick. The interior of the box is divided into two parts by an incomplete horizontal partition, about six inches from the floor. At the lower part are two openings, one at the side extending the length of the box, with a sliding door for receiving the hot water vessels, the other and smaller is at the other end of the box, for the admission of a regulated quantity of air. The top has a glass cover, fastened by buttons which hold it close, and to one side is an opening to allow of the passage of air. In the opening of communication between the two compartments is placed a moist sponge and also a thermometer. The box can be lined at will with wadding and white felt. The heating is done by the introduction of vessels holding about a pint of boiling water, of which the box is capable of receiving five, four being generally all that is necessary to keep up a temperature of 87.8° to 89.6°. The box is heated by three of these vessels for a half hour, then, having reached the proper temperature, the child is put in, and in about two hours a fourth vessel is inserted, and from that time on about every hour and a half or two hours these vessels are changed, and to give sufficient heat they must contain *boiling* water.

SURGERY.

Belladonna Injection as a Cure for Gonorrhœa.—Dr. John Roche recommends this in the *Medical Press*, detailing a case of bad gonorrhœa with intolerable chordee at night; in which he ordered an injection of seven ounces of water, an ounce of mucilage of acacia, twenty grains of extract of belladonna, and twenty grains of sulphate of zinc, a tea spoonful to be injected immediately before and after micturating, and a similar amount the last thing at night, great care to be used in passing the injection fully down as far as the pain was most intense. An ointment of spermaceti and mercurial ointment, ʒiv. each, and ten grains each of extract of belladonna and powdered opium, as a paste to be smeared along the perinæum and around the crura penis at night. There was no chordee that night, and within a week there was a complete cure. This case occured thirteen years ago, since which time in numerous cases of gonorrhœa this injection has been used with unfailing success. Patients have always stated that it is the injection and not the ointment which stopped the chordee carminatively, and it has been used in the acute and in the chronic and gleety stages; in first attacks and in those making one of a series, and in cases complicated with inflamed testicle and chordee, and nothing seemed to contra-indicate its use nor mitigate its success.

Application for Warts.—Dr. Cordes, of Geneva, states (*Journal de Thérapeutique*) that he has always found the following application successful: Iodine six, crystallized carbolic acid twenty-one, and alcohol two parts and a half by weight. After scraping the wart or cutting it down to a level with the skin (without causing it to bleed), he touches the wart with a few drops of the above solution. In a minute it becomes soft, and allows of another scraping and a new application; and sometimes even a third scraping and application can be made without causing bleeding.—*Medical Times and Gazette.*

THE

Journal of American Medical Association.

PUBLISHED WEEKLY.

THE EDITOR of this JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information, should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE..... $5,00.
SINGLE COPIES..... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 65 RANDOLPH STREET,
CHICAGO, ILLINOIS

SATURDAY, JANUARY 12, 1884.

HOW TO BECOME A MEMBER OF THE AMERICAN MEDICAL ASSOCIATION.—We have been asked so many times during the past year how a physician can become a member of the American Medical Association, and we have so many subscribers who are not members, that we deem it proper to give the desired information through the columns of the JOURNAL. The Association, by its plan of organization, is a representative body, intended to "collectively represent and have cognizance of the common interests of the medical profession in every part of the United States." The membership consists of delegates appointed by "permanently organized State Medical Societies, and such county and district medical societies as are recognized by representation in their respective State societies," and from the Medical Departments of the Army, Navy, and Marine Hospital Service of the United States; and of Permanent Members, consisting "of all those who have served in the capacity of delegates, and of such other members as may receive the appointment, by unanimous vote" of the Association in annual session. During the last ten years, so few have been proposed and elected by unanimous vote, that this mode of gaining membership is too uncertain to be available, except in extraordinary instances. Consequently, the only reliable mode of becoming a member of the National Association is, first, to obtain membership in some regular State, county, or district medical society, and then obtain from such society an appointment as one of the delegates to represent it in the American Medical Association. Having obtained the appointment as delegate, it is necessary to actually *serve* by attending the annual meeting of the Association for which the appointment is made. Having thus attended and been registered as a delegate, in doing which he is supposed to have personally signed the constitution and by-laws, he becomes a permanent member so long as he pays the annual membership fee, and continues to obey the rules and regulations of the Association.

The object of thus limiting the mode of gaining membership is twofold, namely, to make the annual meetings of the Association substantially *representative* of the regular professsion of the whole country, and to encourage the formation and maintenance of State, county and local societies in all the States and Territories of the United States. Each State, county and district medical society, entitled to representation, has the privilege of sending to the Association *one* delegate for every *ten* of its regular resident members, and one for an additional fraction of more than half of that number. The medical staffs of the Army and Navy are each entitled to four delegates, and the Marine Hospital Service of the United States to one delegate. The liberal number of delegates allotted to medical societies renders it easy for any member of such societies, who desires to attend an annual meeting of the Association, to obtain an appointment as delegate, for the reason that there are not as many members ready and willing to attend any given annual meeting, as the societies are authorized to send, except in such as may be in the immediate vicinity of the place where the Association holds its meeting. Those who, by having once served as delegates, have become *permanent* members, can attend any annual meeting of the Association they may choose, without further appointment as delegates.

VISITOR.—Dr. J. B. Hamilton, Surgeon-General of the United States Marine Hospital Service, has been spending a few days in this city recently, during which he was pleasantly entertained at a dinner in the Tremont House, given by Surgeon Miller and a number of friends.

THE "SANITARIAN" FOR JANUARY.—The first number of the twelfth volume re-appears in the form of a *monthly*, but enlarged to 96 octavo pages of reading matter. It is filled with matter of interest and importance to physicians, municipal officers, boards of public works, school officers and teachers, heads of families, and all who are interested in promoting personal or public health. Price, $4.00 per year.

For convenience of reference and to facilitate correspondence, we have placed the names and address of the Officers of the Association and of the several Sections on the last page of the *Journal.*

SOCIETY PROCEEDINGS.

A PLEA FOR GREATER SIMPLICITY IN PRACTICAL MEDICINE.

BY JAS. F. HIBBED, M.D., RICHMOND, IND.

The following is the concluding part of a lengthy and most interesting paper on the subject named, which is published in the *Louisville Medical News*, advance sheets of which were kindly furnished us.—Editor.

There is a lesson in the history of the fashions that have had sway in the treatment of typhoid fever for the last fifty years, and I will briefly recite their salient angles for our improvement. The score of authors whose views I epitomize have been leading men in their day (except perhaps, the last, whose book is the child of the present year, and is an index of current opinions), and each is to be regarded, as he is, in fact, an exponent of the views of a large class of predecessors, contemporaries, and followers, and makes his declarations after the most ample opportunities for observation and the fullest experience.

Bartlett's classical work on the Fevers of the United States was first published in 1847, and a second edition, edited by Alonzo Clark, M.D., was issued in 1856. Before Bartlett wrote, the distinction between typhus and typhoid fever had already been fully accepted, and in introducing the treatment of a number of representative men, he does it in this language: "Various, and to some extent opposite, modes of management have been adopted by different practitioners; they have been conducted on a large scale, for the most part in a fair and impartial spirit, and under circumstances favorable to the discovery of the truth; but they have not yet resulted in the establishment of any uniform and satisfactory method of treatment. There is no unanimity in the opinions and conduct of different practitioners."

Dr. Jackson, of Boston, urges free evacuations, with tartarized antimony and calomel, then venesection, and this to be followed with more antimony every two hours, in increasing doses for two weeks.

Dr. Nathan Smith condemns the antimony, calomel, and bleeding treatment, and all perturbating remedies, trusting to nature, diluent drinks, and farinaceous food.

Chomel's treatment is tentative or symptomatic, relying on nature and refreshing drinks. For some years he regarded sodium chloride as a specific, but ultimately made a manly retraction, acknowledging his error.

Louis relied, for the most part, on venesection, less or more, according to the vigor of the patient, continued for two weeks, and then trusting to drinks.

Bouilland bled *coup sur coup*, and applied leeches and cups between the venesections. He claimed extraordinary success.

De Larrouque came upon the stage in the fading days of the doctrine of Broussais, which had forbidden the use of emetics and cathartics for all purposes in the Paris hospitals for fifteen or twenty years. He revised the evacuant method, administered antimonial wine as an emetic, and seidlitz water, castor oil, and calomel as purgatives.

Huss, of Stockholm, opposed bleeding and evacuants, gave phosphoric acid as a febrifuge, and camphor, musk, etc., as stimulants.

Bartlett further recites the alum treatment by Barthez and others, Dr. Gerhard's blue pill and castor oil, Dr. Dundas' large and frequently repeated doses of quinia, which Dr. Peacock, found ample experience in St. Thomas' Hospital, did no good, and often harm, and then announces, as his own conclusion, that the management of typhoid "must be eclectic and rational, not exclusive and specific," quoting approvingly the words of Burserius, to wit: "For the less the operations of nature are disturbed by art, the milder and safer the remedies we employ are, the more successfully do we restore the patient's health." Dr. Bartlett was a wise physician, and Dr. Alonzo Clark was another.

About the time of the second edition of Bartlett, Dr. Geo. B. Wood's practice came on the carpet, and was popular. He recommended bleeding, calomel to salivation, and, above all, turpentine. Turpentine had been applied externally by others, but Dr. Wood discovered it as an internal remedy, and pushed it *ad nauseam.*

Dr. Bennett, of Edinburgh, gave two hundred and five grains of quinia in two days, and thought it produced alarming prostration.

Dr. Flint makes no distinction in the treatment of typhus and typhoid fevers, regards large doses of quinia injurious, except for reducing temperature, but thinks wet sheets should have a fair trial, and may prove useful

Niemeyer has found that cold baths and wet sheets reduce the temperature, but at the same time increase the production of heat and cause dangerous prostration. He, however, approves of Ziemssen's method of baths, or wet sheets applied ten degrees cooler than the patient, and while applied reducing the temperature, say twenty-six degrees. He also objects, on his experience, to large doses of quinia, but approves of doses of one or two grains.

Roberts favors mineral acids and small doses of quinia, and objects to the routine hydropathic treatment, alleging that "there are grave objections to its adoption.".

Bartholow prefers ten grains of calomel in one dose every day, or every alternate day, according to the temperature, for the first week, and three to five minims of Lugol's iodine three times a day for two weeks, or up to convalescence. This he speaks of as the German specific method, and, relying on Liebermeister's statistics, deems it good. Under certain symptoms cold baths may be applied, but there are several contra-indications. Twenty grains of quinia every four hours is recommended, and the cautious use of digitalis favored.

Carpenter has a long catalogue of remedies, one or more for each threatening symptom. He thinks cold permissible, but it must be applied with care and dis-

crimination; he objects to the calomel treatment, and mentions iodine as a drug to which some practitioners have resorted.

These twenty-two authorities have been quoted in an approach to chronological order, but there is no pretence that this statement covers the whole therapeutic scheme of any one of the authors mentioned. The service aimed at is to present the leading features of each as an exemplor of and a commentary on the variety of methods which have been and now are in vogue in the treatment of typhoid fever, each, as a rule, claimed by its introducer or chief disciple to be superior to all others, and appealing to statistics to prove the superiority. And in the face of this exhibit is it not obvious to every discriminating mind that the heroic treatment of typhoid fever of to-day has no more justification than similar perturbating management had in the time of Bartlett; and shall we not now, in the interest of science and humanity, join him in the sentiment so tersely stated by Burserius, viz.: "For the less the operations of nature are disturbed by art, the milder and safer the remedies we employ are, the more successfully do we restore the patient's health."

And do not the facts of this review constitute a superlative plea for greater simplicity in practical medicine? And with the lesson of this history pervading my mind, was it any marvel that I was surprised when the several members of the Tri-State Society so promptly indorsed from their personal experience the enthusiastic extravagance of the eloquent essayist? Not that Tri-State members were presumed not to follow fashions in therapeutics; members of all societies and no society must do that, but because the treatment of typhoid fever since its recognition has progressed in alternating cycles of heroic and mild management, it was my understanding that with the best practitioners a mild cycle was now dominant, and I had supposed the auditors of that meeting to be fully in accord with the better state of affairs. This was, however, apparently a delusion.

As a recapitulation of the chief points set forth in this essay, I present the following aphorisms as my professional creed. I believe:

That every physician should have an abiding faith in the power,and the value,and the necessity of medicine.

That all medicine that has force enough to do good if rightly given, may do evil if wrongly given.

That medicine should not be prescribed unless a clear necessity is recognized for its employment.

That this necessity may arise from the patient's physical condition, from the patient's mental condition, or from the mental condition of others.

That in all cases the least disturbing remedies that will meet the indications should be prescribed.

That in all illnesses nature is the grand factor in restoring health; the role of art is that of auxiliary and assistant.

That much thought and talk about disorders may be a cause of ill-health in the parties so thinking and talking, and is at least a mark of ill-breeding, and a lack of good manners.

That details of personal distempers should only be made to the physician for his guidance, or to attendants, as an aid to nursing.

That routine in practice is never scientific, and is liable to be mischievous.

That fashions in therapeutics should be followed only when the new mode has the sanction of one's scientific knowledge, or is sustained by unimpeachable testimony.

That the guiding motto of every medical practitioner should be, "All diseases should be trusted to nature when art can not declare an assured benefit by intervening."

That evolution in the direction pleaded for in this paper must come through the experience of the graybeards in the profession; the young physician must practice what he has been taught, and he neither sees in a text-book or hears from a professor's chair a remembered plea for simplicity in medical practice.

Richmond, Ind.

DOMESTIC CORRESPONDENCE.

PHILADELPHIA LETTER.

JANUARY 2, 1884.

Since I wrote to you last a vexed question interfering much between the cordial feeling of physicians and pharmacists seems to be rapidly approaching its solution. I refer by this to the patent medicine nuisance. Pharmacists have long been made the dupes and catspaws of the vile impostors who palm off on the public worthless compounds, and by judicious advertisements they manage to spread the idea that their articles are possessed of great medicinal value, which they endeavor to prove by testimonials of persons who have made their diagnosis to suit their own fancy, or by using the well bought opinions of some Reverend clergyman, and even some physicians who have sold their standing with their colleagues for the sake of paltry gain or cheap notoriety.

The pharmacists have been cleverly deluded into acting as retail agents for such enterprising adventurous speculators in public health, they have allowed their goods to be displayed in their shops, large posters and gilded show-cards to adorn their premises, while they supplied their patrons with a class of literature that was calculated to deceive the ignorant masses in regard to the quality of the ware they praised. The pharmacists are by rights an auxiliary branch of medicine, and if they were to conduct their business in conformity with their medical ethics, they ought to belong to us as much as other specialists. Remonstrance on the part of the medical profession, however, proved of little avail with them, and they insisted that they had to make a living, and would do it as best they could, without regard to physicians who only gave them indifferent support anyhow.

Under such circumstances their establishments degenerated rapidly to fancy-goods stores, patent-medicine depots, cigar stores, and in many instances clandestine rum shops; no wonder that physicians' support became less and their patronage was more

centralized to better conducted places. As all social evils and abuses correct themselves in the long run, so has this, as I have said above, also brought about its partial downfall.

The snake that the pharmacist held nurtured in his bosom has awakened and stung its lifegiving benefactor.

The patent-medicine trade, not content with selling goods through the retail drug-trade alone, has endeavored to enlarge its sphere and to also introduce their goods in other quarters. To do this prices had to be cut and slaughtered, until to-day there are lots of stores retailing patent medicines all over the country for less than the average druggist, who was instrumental in making a market for them, can buy them.

An organization of druggists in our city at first attempted to maintain regular prices in spite of the opposition, but this plan was soon abandoned as impracticable, and resolutions instead adopted to the effect that cutting of prices of patent medicines should not longer be discouraged, nor the word cutter, as relates to the prices of these goods, should be any longer considered as an offensive opprobrium. This means that patent medicines should hereafter be retailed without profit, a most wholesome measure for stopping their sale by druggists entirely, unless they can afford to trade at a loss or do business without profit.

There will be some, no doubt, who will still hang on to the issue of traders at tradesmen profits, but the majority of pharmacists, who have both the ambition and the ability to raise themselves from a subordinate position, will discard such a trade as no longer profitable, and will coöperate with the medical profession in preparing and supplying for public consumption such medical articles and compounds as their joint skill will devise. The medical profession will recognize this by patronizing those who alone deserve the names of pharmacists, while the traders and dealers in patent medicines should no longer be intrusted with compounding or dispensing of medicines or preparing medical compounds. A happy illustration of possible coöperation and friendly spirit amongst physicians and pharmacists was given a few days ago by Dr. Lawrence Wolff, one of our foremost pharmacists and chemists here, who occupies the position of President of the Druggists Association, to the members of which he gave a reception at his fine residence, and to which he had invited quite a large number of prominent physicians. It was about the first time they had met as a class, and I am convinced that either class was glad to know the other and agreeably disappointed in the intellect they represented. The most prominent person there besides our city officials and leading citizens was the venerable Emeritus Professor S. D. Gross, America's greatest surgeon, who is still active and gives his hearty support to all measures tending to elevate our profession. Prof. S. W. Gross; Dr. J. V. Shoemaker; Dr. J. G. Lee; Dr. Woodbury; Dr. J. M. Barton; Dr. L. Turnbull; Dr. T. Hay, and many others of Philadelphia's leading physicians were also amongst the guests.

It occurred to your correspondent that such meetings were more practical in bringing about good results and improving the relation of medicine and pharmacy than all the papers, resolutions, etc., that can be adopted, raising pharmacists to our own standard and making them by ethics bound to oppose nostrums, quackery and quacks, and protecting the rights of suffering humanity.

I have no doubt the day will come when we will accept otherwise qualified pharmacists in our medical associations, have special sections for their branch, and have them participate in our debates. At any rate the prospects are favorable towards that end, and if we could not persuade druggists to abandon their nefarious traffic in nostrums, the failure of profit from such a source will prove a more weighty argument, to the persuasion of which they will not fail to yield. They certainly ought to, for, as I am informed, the money value of two-thirds of all medicines sold in this country is derived from patent medicines, the largest part of the profit of which goes towards the unscrupulous manufacturer and proprietor. If druggists will give up this pernicious trade, the profit thereof will surely find its way into their pockets from physicians' prescriptions and the sale of legitimate medicinal compounds.

PALESTINE, Dec. 5, 1883.

PROF. N. S. DAVIS, M.D., CHICAGO, ILL.:

I beg that you will excuse this trespass upon your time and patience, but knowing that anything connected with our profession and out of the beaten track possesses interest for you, I presume to make the following statement:

There have occurred in this city several deaths, some in one day, some in two and some in three days' duration of illness, and it is claimed by some physicians here that the cause of death, or the disease, was "malarial coma."

I have practiced medicine now some thirty-two years, and have read some and had some experience, and until now I have never heard of such a disease as "malarial coma." I can imagine a case where the malarial poison or influence may become so overwhelming and so obtunding to the sensorium or intellectual faculties as to at once produce a comatose condition, but for it to induce such a condition of things as occurred in my case confounds me, and obliges me to beg for light on this (to me) most inexplicable condition of things.

Monday evening, November 5, I was summoned to see Mr. T. R., aged 36 or 37 years, a saloon-keeper I found him suffering from a fever, it having been preceded by a slight chill. His temperature was about 106°; respiration hurried, about 32; tongue furred; pulse very rapid and bounding; bowels constipated; kidneys acting well. His previous history was that during the day he had eaten his dinner as usual and had gone to his saloon; in a couple of hours returned, feeling ill; got in his bed and sent for me. I found him as described.

I at once ordered cold applications to his head, and that his lower extremities be wrapped in a blanket wrung out of very hot water into which two handfuls of mustard and one handful of salt were mixed.

This was at once done, and the effect was to pro-

duce, in less than an hour, the most profuse sweating —so much that his clothing had to be changed and the mattress turned over.

I prescribed for him hydy. submur. and sodæ bicarb. aa grs. v, to be mixed, placed in a capsule and to be given him that night, to be followed in the morning by solution of crab orchard salts.

November 6. He had slept all night, perspiring well; the medicine had operated but once; he had not eaten anything, nor did he want anything; had no pain, complained of nothing, but thought the medicine had not acted enough; turned over in bed and went to sleep. I called at noon. Condition the same, and had slept all the time except when aroused. Temperature, morning, $98^{5}/_{10}$; pulse 74; respiration 44. Noon, pulse 76; respiration same; skin moist and pleasantly warm. In the evening, temperature $99^{3}/_{10}$; pulse 76; respiration 25; skin moist, and had slept all day except when spoken to; his answers to questions were prompt and rational. That night I prescribed two capsules containing hydrg. submur. grs. vii, podophylin, grs, ss, ext. hyosc., ext. taraxicum aa grs. iv, ext. jallapæ pulv. grs. vii.

Nov. 7. The medicine provoked five or six copious bilious evacuations. He had slept the whole of the previous night and during the morning until I visited him. He was perfectly conscious and conversed as usual, and upon some subjects not connected with himself or his illness. His temperature was the same as the day before, and so was his pulse and respiration. His skin was moist and pleasant; wanted nothing to eat; had no pain or unpleasant sensations. At noon I again called, and found him asleep. Skin moist and tongue clean. That afternoon he drank a good deal of lemonade, whisky toddy, milk punch and water, and drank in large quantities, so much so that it produced nausea and vomiting of what he had drank. There was no perceptible change in his pulse or respiration. His temperature $99^{3}/_{10}$; skin moist, and he slept between drinks, and as soon as he ceased talking. That night he would drink claret and ice.

Nov. 8. This morning his pulse is 76; respiration 28; temperature $99^{4}/_{10}$, and his stomach is nauseated; the claret had soured upon his stomach, and during my visit he vomited about a cupful of bile, and said, "If I could only get clear of that I would be all right." Thinking he had enough of cathartic medicine, I concluded I would order an emetic to cleanse the stomach of anything that might be offending there. I prescribed ant. et. pot. tart., grs 3, ipecac pulv., grs. 24, to be mixed and divided into charts two each, one to be mixed into two tablespoonfuls of cold water, and to be taken 15 minutes after the other.

He only took one of the powders, and instead of its emetic effect we got its cathartic. It provoked some seven or eight operntions, some large and some small, very yellow and bilious. They came without apparently any warning or control.

That evening his temperature was 96; pulse 74 and weak; respiration 29. His hands and arms, feet and legs up to his knees, were bathed in a cold, clammy sweat. I directed the extremities to be dried and rubbed, and a milk punch to be given him, and they soon regained their natural warmth and moisture.

Nov. 9. The night before he slept all night, and in the morning his bowels had moved twice, and so had the kidneys. The operations from the bowels were natural; fæcal, consistent, and of good color. He will not eat anything; temperature 99; pulse 75, full and strong; respiration 22; skin moist; tongue clean; eyes bright and clear; answers questions as previously, rationally and to the point; has no pain any where, and complains of nothing, and he seems more cheerful to-day; but as soon as he stops talking turns over and is asleep; will take no quinine, and in consequence of his great inclination to sleep I will not press it.

Nov. 10. At my morning's visit he was awake, and at once upon seeing me turned upon his side and seemed to be sound asleep; would not answer any questions, and would not be aroused. That same morning he conversed cheerfully and animatedly with some of his friends, and said he was getting on all right. In the evening he said to one of his friends, "I do not know what ails me, and while I have no pain any where, still I feel pretty bad." This night when I left him, at 10 o'clock, his temperature was 99, his pulse 72, and his respiration 28; skin moist and warm; neither his bowels nor his kidneys had acted during the day. I introduced the catheter and drew off a pint of healthy-looking urine.

At 10:30 I was hastily summoned to return to Mr. R.'s, and found he had a well-marked convulsion and that he was insensible. I injected brandy and ammonia hypodermically; he came out of it, and his temp. ran up to $101\ ^{3}/_{10}$, pulse 120 and weak; resp. 33. Drs. Hunter and Wood were with me. Dr. H. suggested the injection of quinine and brandy. Forty-five grs. of quinine and about 2 drachms of brandy were injected between 11 o'clock P. M. and 5 A. M. of the 11th. He winced when the hypodermic was given him, until 4:30; after that, no sensibility. The pupils of the eyes were enormously distended, and not sensible to the light. At 5:30 he had another terrible convulsion, and at 5:45 he died.

Now, of what did he die? He had had syphilis some time before. He drank very heavily, but never getting drunk, and he ate but little and very irregularly. He had not suffered with headache that I could learn. Was active and apparently in good health up to the day of his seizure.

We have now, and have been having, somewhat of an epidemic of jaundice; but he has not had it. I send you the thermometrical and barometrical ranges of the month here in this city.

We have had, and are still having, a great deal of typho-malarial fever. Now, dear doctor, please, if you can, diagnose this case, and give me your opinion of it and the treatment.

R.'s tongue was always moist, clean, nor showed any departure from normality, and his eyes were clear, with good expression, his position in bed was easy and natural, and his sleep apparently as pleasant and healthful as that of the tired laborer.

Now, doctor, coma is said to be a profound state of sleep from which it is very difficult to arouse the pa-

tient, and is the sequence of exhausting disease, and the consequence of some overpowering influence upon the brain, either from without or within, and, as I have thought, the expression of some disease the extent of which could be clearly defined.

But, my dear friend, I have failed utterly to find any cause for anything of the kind. Here is a man apparently in full vigor, in the prime of life, attacked apparently with a simple fever, and it yielding in a surprisingly short time to domestic remedies only, and not again reappearing; no evidence externally or by sensations experienced and described by the patient himself, when apparently he chose to give any expression of them, and then his real or apparent inability in the shortest possible time to give any expression of his feelings or anything about him, and then again, when those he desires to communicate with appear, he is able to laugh and talk with them as he would be in health. Is this an expression of disease, and if so, what disease? Sleep so deep, peaceful and continuous, and yet at times so easily ended, and at other times so profound. What does it mean?

He was not well, but where was the evidence of illness, except it be this strange and unnatural behavior, and what caused that?

Again, what caused the convulsion? and why should a simple fever usher in such a condition of things?

In 1853, I was practicing in New York city, and one day was suddenly called to see a woman having a convulsion. Upon arriving at her house, found her just recovering, and she seemed much astonished to find so many of her friends and neighbors assembled. Upon my telling her what had occurred, she was much surprised, and expressed herself as quite recovered, thanked me, and I left. In about an hour I was again summoned, and she continued to have recurrences of them the whole night, notwithstanding I leeched, cupped and bled, blistered and used revulsives, and did everything I could. The next morning I called upon my old preceptor, Dr. Mott, and he met me in consultation. As soon as he saw her, he said to me, "My son, she will die." Turning to the husband, said Dr. Mott, "Your wife is addicted to drinking to excess, is she not?" "Yes," said the man, "she never gets drunk, but drinks heavily, and then has intervals when she suffers terribly from remorse. Then she has much pain in her head." "Yes," said Dr. Mott, "she has softening, and effusion has taken place. She will die, and very shortly." And she did die in less than an hour, and before we left the room.

Now, could this have been a parallel case? Was the fever as manifested on the Monday, Nov. 5, the first giving way or effusion? And was the tendency to sleep or somnolent manifestations afterward present, the effect of that effusion? And were the intervals of lucidity and complete consciousness the result of a supreme effort of nature to rally, owing to the youth and great natural vigor of the man; and was the subsequent convulsion but the final giving way, and last falling back of the last great and successful charge of the grim monster over life?

And even so, it does seem to me, there should have been some external evidence denoting the terrible battle raging within.

Doctor, is there any evidence in the whole history of the case justifying it to be diagnosed "malarial coma?" Is there any such disease as malarial coma? Give me, I beg of you, your opinion, and of its treatment. I am, my dear doctor,

Very truly yours,

G. S. WEST, M.D.

AKESIS UNIVERSALIS.*

Thousands of dollars are being annually expended in the erection of stately medical colleges for the express purpose of producing more and better educated medical men and women. In fact, a higher preliminary and final education is demanded by the masses of the profession; and this is what the colleges are endeavoring to supply, for the express purpose of making our lives longer, happier, and less subject to disease.

Do they accomplish this? When we look at the certificates signed by "M.D's" we think not. As evidence of this, and the worthlessness of a higher education, let us examine two pamphlets: First, "A supplement to the *Journal of Materia Medica*," wherein thirty-six people with "M.D." appended to their names laud the "Elixir Iodo," for the following diseases: "Scrofula, scrofulous enlargement of the cervical glands, scrofulous affections of the bones, scrofulous eczema, cancerous affections, lupus, necrosis, osteo-periostitis, exostosis, caries, synovitis, (there spelled synoyities), hip joint diseases, anchylosis, psoriasis, prurigo, tuberculous affections of the bones, skin diseases *of all kinds*, cerebro-spinal meningitis, syphilis, gonorrhœa, enlargement of the liver, spleen, and kidneys, bronchocele, goitre, (two distinct diseases, sic.!) exophthalmic goitre, epilepsy, otorrhœa, deafness, diphtheria, erysipelas tonsillitis, gangrene of the lungs, dry gangrene and pleuro-pneumonia."

Whew! Here is a chance for a specialist. All he needs is a fountain which will furnish a constant supply of the Elixir, confine himself to the above diseases, which the Code will permit him to put on his card, and if the Elixir will do what the 36 M.D's say it will do, then for sure he has the remedy which has in vain been sought after since Æsculapius, Abernethy, Hunter, Drake, Mott. Sims, and that whole host of medical worthies, reaching from the present back into the past so far, that even time—that newly redivided substance—counts not the when.

Second. We have just received Part III. of Fellow's book (For the Medical Profession) on his Syrup of Hypophosphites. Therein the medical profession are thanked for their "generous patronage of his Syrup" which we suppose they do, for there are indexed recommendations in this number of 231 physicians and 26 medical journals, lauding the Syrup for: "Amblyopia, anæmia, angina pectoris, aphonia, asthma, apoplexy, imperfect assimilation, blepharospasm, bronchial affections—both chronic and capillary, broken heart (sic.), children's diseases, chorea,

*The universal cure of disease.

chronic chills, chronic congestion of the larynx, consumption, cough, convalescence, debility, diptheria, dyspnoea, dyspepsia, distrophia, glandular disorders, hæmorrhage, indigestion, insomnia, melancholia, menorrhagia, nervous affections, nervous system, neuralgia, night sweats, ocular paralysis, panphobia, ozena, paralysis, incipient phthisis, pneumonia, rapid growth, rickets, scrofulous diseases, skin diseases, strumous diseases and strumous keratitis, whooping cough, epilepsy, diarrhœa, incontinence of urine, paralysis agitans (Parkinson's disease, I suppose is intended, as there is in this disease no paralysis) leucorrhœa, marasmus, sleeplessness, loss of memory, loss of voice, timidity, despondency, hysteria, hypochrondria, wheezing, difficult or painful parturition, and change of life.

The medical press is loaded with tirades against admitting the non-educated into the profession, and yet the recommendations of this "Syrup" are signed by the best-educated physicians who have ever been produced in the whole civilized world.

This wholesale cure-all reminds me of a little story illustrative of some people's estimate of the action of remedies.

While a student of medicine under the late Dr. F. R. Payne, of Illinois, his friend, Dr. Johnson, came into my preceptor's office, and each related the greatest medical events of their long, large and successful practice. Dr. Johnson was a graduate of the old Jefferson Medical College of Philadelphia; was surgeon in the war of 1812; had treated nearly every medical and surgical trouble to which human flesh is heir, and in a large practice of over half a century, the events wherein his fees and *eclat* exceeded all the other achievements of his active medical life, were, rubbing a little sweet oil upon a child, which, while returning to his office, he saw playing in some smartweed near one of those large suburban residences near Philadelphia, to which he was subsequently called. The other, and possibly the greater, measured by the scale of dollars and honors, was wherein he was called a long distance to consult with a number of talented physicians in regard to a lady's health. As he and the other physicians were going from the bedside to a room where they might not be overheard in their sapient deductions, they passed through the dining-room, and as he passed, he picked up a piece of biscuit, which during the consultation he rolled into pills. At the end of a long and very learned history, diagnosis, prognosis and treatment of the case, he said, reaching out his hand containing the bread pills, "Gentlemen, I would give her one of these pills every third hour," which they did, without questioning as to their contents. It is needless to say the lady recovered (and a few years subsequently, was delivered of triplets.) This treatment is in keeping with the diversity and multiplicity of diseases for which these two—possibly most excellent syrup and elixir—are given, but the absurdity of any two remedies filling the requirements set forth by their respective proprietors—although thoroughly sustained by many physicians—is, to say the least, immense.

Our patrons, finding our prescriptions headed by never so reliable a drug firm's name, soon come to the conclusion that other people furnish us not only medicines, but also the brains to use them, and they say, why not get Mrs. Winslow's Soothing-Syrup; Dr. Hayhirst's Wild-Cat Liniment—as well do so as that their doctor should prescribe Fellow's, Tilden's, or anybody else's remedies.

There is a too successful effort being made by the leading drug houses to control, forestall, abridge, and render subservient to drug circles the whole medical profession. This is being effected by producing ready prepared compounds, not strictly patent medicines, yet answering the same purpose, for the dose and the diseases for which physicians must prescribe them is fully delineated on wrapper and pamphlet. As a sample of this, I have cited from two sample drug firms, who have lately supremely honored your scribe by sending him full instructions what to prescribe, without the trouble of consulting Stillé, Wood, Bartholow, Headland, and a host of other writers whom we once thought knew the action of medicines. The effect, both moral and medical, produced by this purchase of surnamed remedies, is injurious to the pocket and status of the practitioner, particularly if he be a neophite, for be it known the druggist who sells these proprietary preparations is much more liable to depreciate the merits of the prescriber, than if the dispenser's own pharmaceutical drugs were ordered. Besides this, no known remedy or combination of remedies will cure the list of diseases for which these drug firms have physicians' certificates as to the efficacy of their compounds. The trouble lies within the profession. They are owned by the druggists, and do not dare refuse certificates for fear of loss of influence.

In conclusion, I will ask the profession what is the necessity for students attending medical colleges, purchasing microscopes, and studying Koch's bacilli tuberculi, baccillivariolii, *et hoc genus omni*—when all they have to do in any disease is to get an almanac or one of these gratuitous pamphlets, printed solely for their professional benefit, wherein they will find more remedial expedients than were known to Hippocrates, Æsculapius, Sydenham, and their followers all.

GEORGE R. CENTER, M.D., M.A.
Evansville, Ind.

THE MICHIGAN MEDICAL REGISTRATION LAW.

This law is now in full force. Since the days of Solon down to the present time, it would be difficult to discover another piece of legislation equal to it in stupidity and uselessness. It would not be unreasonable to suppose, that the framer of this law had just emerged from the midnight of the Dark Ages in the form of a medical Rip Van Winkle, and through the thin mist of his recently acquired vision, saw the apparent dangerous condition of his professional brethren, as well as his constituents; then, after due deliberation, resolved to redeem the State from quackery, and thereby become a public benefactor in his day. But the reverse is the case.

The miserable charlatan, ignorant of anatomy and physiology; ignorant of every scientific fact in relation to the human system; destitute of every professional qualification, is a legal practitioner of medicine.

Men who cannot read three lines correctly in any scientific work; who have never dissected; who have never made a post-mortem examination of a body, with the exception of the pig; and then only to slice up the animal and devour him like a cormorant, are paraded before the public as legal physicians. These parasites of a noble art find their names published side by side with men of acknowledged skill and ability; men who have spent half a century in the profession, and who now for the first time witness their names in the same category with the most unscrupulous mountebank, "the steam doctor," and a list of ignoramuses whom this State has legalized as practitioners of medicine and surgery.

A law regulating the practice of medicine so broad that men without the slightest claim to medical knowledge; men whose only claim to medical education is that they have "practiced common sense for thirty years," or that they have put up a few cough mixtures, or a clap mixture for some gullible young man, but without sufficient ability to compound prescriptions properly, are now registered as physicians in the State of Michigan.

Such a specimen of medical legislation would doubtless do honor to the King of Dahomey; but to the State of Michigan it must ever remain an insult on her intelligence until repealed. The people are not benefited by it; scientific medicine certainly is not. The legislative body that passed this law, and the Governor who did not veto the bill, must ever look upon it as one of the most pusillanimous products of their puerile legislation.

THE COMPARATIVE VALUE OF THE NEWER TESTS FOR ALBUMIN IN URINE.

BY CHARLES W. PURDY, M.D.

Although the mere presence of albumin in urine can no longer be regarded as anything further than presumptive evidence of damaged kidneys; yet, it has so long formed the basis upon which the diagnosis of renal pathology has been constructed, and, moreover, as an element considered with other symptoms it still holds, and is likely to hold, an important place at least in preliminary investigations of renal disease. Therefore, all matters concerning the most reliable and ready methods of detecting the presence of albumin in urine must remain of practical interest and importance to the general practitioner. Much attention has been given of late to several newly proposed agents for detecting albumin in urine, both in this country and in Europe. Some of these, it has been claimed, are so exceedingly delicate in reaction as to detect the presence of albumin when the older methods, as by heat and nitric acid, failed to do so completely. Furthermore, most of these agents have been indorsed by some of the best authors on renal diseases, both here and abroad.

The general practitioner may, in consequence, encounter some confusion in deciding whether it be wise to accept the newer and readier methods or adhere to the older and long tried agents already in use. It is proper that we should carefully inquire into the relative value and reliability of the newer, as compared with the older tests, with the view of assigning to each their proper spheres in the routine of daily work.

First, then, we shall note the *acidulated brine test*, brought forward by Dr. Roberts in *The Lancet*, Oct. 14, 1882. It is prepared by mixing together a fluid ounce of diluted hydrochloric acid with a pint of water, saturating with chloride of sodium and filtering. It is claimed to be more delicate than Heller's test. It does not discolor the fingers or destroy the clothing in case it be spilled, and after a specimen of urine has been tested by brine for albumin, the *same* specimen may be tested for sugar by Fehling's test.

Picric acid was first brought forward by M. Gallipe in French current literature in 1872. Dr. G. Johnson more fully discussed its merits in *The Lancet* in Nov., 1882; as does also Dr. Pavy. Several articles appeared in that journal on the subject about the close of 1882 and the early part of 1883. The test solution is made by saturating boiling water with picric acid, and it may be applied by the contact method, viz.: by allowing the picric acid solution to flow down a glass rod, or pipette, over the surface of the urine, which latter must be previously treated with saturated solution of citric acid. If albumin be present, a white cloud is perceptible at the junction of the two fluids.

Tauret's test, or the potassio mercuric iodide solution, may be prepared as follows: potas. iodide 3.22 grammes, and hydrargyri bichloridi 1.35 gramme, are added to 100 cc. of distilled water and filtered. This salt was first proposed as a test for albumin by Tauret, of Troyes, in 1872. Mr. Guy Neville Stephen first called attention to its comparative value in *The London Lancet*. Its method of application is essentially the same as that of picric acid, previously having acidulated the urine with citric or acetic acid. It is claimed to be more sensitive in reaction with albumin than heat and nitric acid, that it is cleanly to handle, very permanent, and almost perfectly clear in solution.

Sodium tungstate was first proposed as a test for albumin by Dr. G. Oliver, of Harrowgate, in *The London Lancet*, Feb. 3, 1883. His method of preparing the test solution is as follows: a mixture of equal parts is made of saturated solutions of sodium tungstate (one in four) and of citric acid (ten in six) in water. It is claimed to be "an albumin precipitant of great delicacy, devoid of objectionable qualities."

Dr. Oliver also proposes in the same number of *The Lancet* as a test for albumin, the potassio mercuric iodo cyanide, but as this is practically the same test as the one last described, it is needless to consider it further.

Potassium ferrocyanide test is simply a saturated solution of the above salt in water. Its application is made by previously acidifying the urine with acetic acid, and adding the ferrocyanide solution, when, if albumin be present, a white cloud is at once formed. This was proposed by Bödeker as a volumetric test for albumin. Dr. Pavy proposed subsequently to make the test with citric, instead of acetic acid, and he also introduced the pellets (compressed) of sodic ferrocyanide and citric acid, which are simply crushed and placed in a test tube containing the suspected urine, agitating without heat.

Dr. Oliver first prepared all of these tests, save

brine, in portable form, so that they could be carried in the pocket-book, and applied at the bedside of the patient. His method consisted in saturating chemically inert filtering paper with the test solutions, and cutting the papers into small strips. An acid paper was also prepared by saturating filtering paper with strong solution of citric acid. The application of these tests are as follows: A small test tube is used, with a capacity of say 60 minims. This is filled about half full of the suspected urine, and a citric paper is rolled up and thrown into the tube. After agitating for a minute or so, one of the other papers is added, say the potassio mercuric iodide, or ferrocyanic, and if albumin be present, a white cloud at once forms about the last paper introduced.

Dr. Oliver has also prepared what he terms the compound papers, made by joining together a citric paper with one of the others. This simplifies the application of the test, inasmuch as but one paper need be used in testing. A full account of these test papers, and their application, is best told in Dr. Oliver's own words, which is done in *The London Lancet*, Jan. 27 and Feb. 3, 1883, or in a small book issued by himself on "Bedside Urinary Tests."

The carbolic acid test, in any of its forms, I have not used, for reasons which will become obvious to any one who tries it in detecting the smaller traces of albumin.

The above, then, in the main, are the newer tests proposed for detecting albumin in urine. It is proper that we next inquire into their advantages and disadvantages, in order to properly estimate their relative values. What I shall say upon this point is the result of a series of experiments with all of these agents, extending over the past eight months, or perhaps a little longer.

As to the test papers, Messrs. E. H. Sargent & Co., 125 State street, Chicago, kindly prepared, at my suggestion, about ten months ago, all these papers, according to Dr. Oliver's method; and as they have been in stock since, they may be procured by any one desiring to try them for themselves. I also procured, about eight months since, through Mr. Hawksley, 357 Oxford street, London, two complete series of Dr. Oliver's own papers, for the purpose of trial; and with all these, I have made careful and repeated experiments. I prefer the potassio mercuric iodide and tungstate papers to all others.

The most serious objection, perhaps, to all these newer tests, is the fact that they give a reaction with other matters, occasionally present in the urine, such as peptone, mucin, parapeptone, and urates, and, moreover, if the patient be taking certain of the vegetable alkaloids, (notably quinine,) or oleo-resins, or some of the alkalies, or even alcohol in considerable quantities, before the urine is voided, a similar reaction occurs, *none of which are distinguishable from albumin precipitate, without the additional employment of heat to the test;* and the latter in some cases decomposes the test solution, (notably the ferrocyanic.)

I think it may be laid down as a rule, to which I at least know of no exception, that *no test for albumin in urine is absolutely reliable unless combined with or followed by heat.* At a temperature of 72° to 75° C. serum albumin coagulates and becomes insoluble in *acid solutions;* and if of any quantity, the insolubility is perceptible in clear solutions in the formation of a more or less opaque cloud. I know of no other bodies met with in the urine, if that fluid be clear, and acid in reaction, which will give a similar reaction.

Of course, in dealing with urine where the amount of albumin is large, most of the ordinary tests are sufficiently accurate to determine its presence beyond reasonable doubt; because phosphates, urates, peptones, mucin, bacteria, or other bodies, which may give a precipitate simulating closely albumin, are almost never present in sufficiently large quantities to throw down a coagulum of the density, appearance and extent of albumin, when present even in moderately large quantities. And hence in those precipitates, filling, say a third, or half of the test tube, we are reasonably safe in assuming at least that albumin is present, whatever else may be also, though the reaction be brought about by most any of the tests in ordinary use.

As to the brine test of Dr. Roberts: it is cleanly, does not soil the hands, or clothing, keeps well, is easily applied, and is a very delicate reagent. In testing for very small traces of albumin, however, it is inferior to two or three others, and one reason for this may be, that it requires so large a quantity of the solution to cause a reaction, that it very much dilutes the urine, rendering detection of albumin in small quantity more difficult.

The sodium tungstate test does not stain, is very clear (the most so of all); its reaction is a little slower than some of the others, but extremely delicate, and properly applied is one of the best of all. It will not answer to apply this test as some of the others are done, namely, to acidify the urine first, and then add the tungstate solution, because an excess of the tungstate may get into the urine and render it inoperative, for it must not be forgotten that tungstate of sodium solution *in excess* in the presence of an acid *dissolves both egg and serum albumin.* We must thus use the test solution, as advised by Dr. Oliver, already described, to make it reliable.*

The picric acid test seems to have excited more discussion than any of the others. It will quickly react with albumin in small quantities, but it has some serious drawbacks for general use. If allowed to mix with the urine (and it is not always possible to prevent this) it colors that fluid yellow, which is unfavorable for detecting faint traces of albumin. Again, if picric acid comes in contact with the fingers (and it often does in manipulating) it leaves ugly stains behind for many days.

In a paper on the "*Clinical Diagnosis of Bright's Disease*," which I presented to the Chicago Medical Society a year ago, I mentioned that I had been in the habit for years of estimating the approximate quantity of albumin in urine by the potassio ferrocyanide solution and acetic acid. Subsequent use in my hands shows that it much less frequently produces

* I have observed that by previously heating the albumin solution to 212° the tungstate in excess will not dissolve it afterwards.

a precipitate with other bodies than albumin, in comparison to the other newer tests.

My reasons for using this test so much in daily work are as follows: In addition to being a fairly sensitive test, as to presence of albumin, it is a fair working volumetric test. I do not mean by this that it is to be absolutely relied upon as an accurate volumetric test, but rather that it will indicate sufficiently accurately the *relative amount* of albumin from day to day to make it valuable as a ready method of comparison in following cases of albuminuria. In using the test, I use a graduated tube, and as the albumin subsides to the bottom after a few hours (twelve) its quantity by bulk may be read off from the scale on the side of the tube and noted at each examination. I now do not use this solution for detecting the *presence* of albumin, because, in doubtful cases, the test can not be corrected by heat; the latter at once decomposes the ferrocyanide salt with an acid, liberating hydrocyanic acid, and producing a white turbidity in the solution, which might be taken for albumin.

The potassio mercuric iodide solution is an extremely delicate test (about equal to tungstate), very quick in reaction, almost clear (slightly bluish), keeps well, and is readily applied.

I have noted one objection which the tungstate does not possess, namely after the test is applied, it cannot be set aside and examined again satisfactorily. The potassio mercuric salt, in the presence of an acid, soon begins to decompose, liberating free iodine which discolors the solution and renders faint traces of albumin difficult to distinguish. This does not so materially detract from the value of the test, as the reaction is not immediate, and it is slow.

Now as to the relative sensitiveness of these tests. Dr. Oliver says, "as a result of many observations and experiments, that in his opinion, one part of albumin may be discovered in 20,000 by the iodo mercuric, picric and tungstate tests; in 10,000 to 12,000 by the ferrocyanide and brine tests, and in 6,000 to 7,000 by the heat and nitric acid tests."

The following are the details of some of my experiments, made with the view of satisfying myself on this point:

The urine of one of my patients was subjected to experiment, who was convalescing from acute Bright's disease. The urine, when experimented upon, contained a trace of albumin, was acid in reaction, sp. gr. at 60° F. was 1022, and contained a few epithelial casts.

1. On the undiluted urine all tests showed the presence of albumen.

2. 50 cc of the urine was diluted with 50 cc of distilled water, and the following noted. Reaction still apparent with all tests.

3. 50 cc of the above was diluted with 50 cc of distilled water, and the following noted. Reaction perceptible with mercuric, tungstate, and picric tests. The others were negative.

4. 50 cc of the above was diluted with 50 cc of distilled water, and the following noted. Mercuric and tungstate test showed faint change; all the others were negative.

The urine of a patient under my charge was next subjected to experiment, who was suffering from slight chronic nephritis (parenchymatous). The urine, when experimented upon, was normal in appearance, and reaction at 60° F., sp. gr. was 1025. A slight trace of albumin was present. The microscope showed a few granular casts and renal epithelium.

1. On the undiluted urine all the tests gave reaction, showing presence of albumen.

2. On diluting 50 cc of the urine, with 50 cc of distilled water, the following was noted. Mercuric, picric and tungstate tests gave reaction. The other tests were negative.

3. 50 cc of the above was diluted with 50 cc of distilled water, and the following noted. The mercuric and tungstate tests still gave faint turbidity. The other tests were negative.

4. 50 cc of above was diluted with 50 cc of distilled water, when all the tests failed to show any change whatever.

The urine of a patient, who was suffering from chronic interstitial nephritis (granular atrophy) was subjected to experiment. Having been under my charge for a year and a half, I knew his urine to average a small amount of albumin (6 to 8 per cent. by bulk) and to contain a few hyaline casts, sp. gr. (at 60° F.) ranged from 1008 to 1018, and reaction usually neutral or alkaline.* It was the latter when experimented upon.

1. Observations on the undiluted urine showed presence of albumin by all tests.

2. 50 cc of the urine was diluted with 50 cc of distilled water, when all tests still showed presence of albumin.

3. 50 cc of above was diluted with 100 cc of distilled water, and the following was noted. Mercuric, tungstate and picric tests showed faint reaction. All others negative.

4. 50 cc of above was diluted with 50 cc of distilled water, and all tests failed to show any perceptible change.

These experiments, and in fact all my experiments, were conducted with the same quantity of urine or solution operated upon in each case, and similar size and make of test tubes were used in all cases. Now with reference to the reaction of certain of these newer tests in dilutions beyond the point where heat and nitric acid fails to give any change. *Is this reaction albuminous?* If it be albumin in minute traces, which these so-called more delicate tests show, where heat and nitric acid fail; it would go far towards proving what Gubler first suggested, in 1865, and afterwards Ultzman, in 1870; and J. Vogel, in 1873; and Johnson, of London, in 1883: namely that traces of albumin may be a constituent of normal urine. While I know of no reason why traces of albumin (probably untransformed) should not be present in normal urine (as sugar is now known to be), if, as M. Leube† claims repeatedly, to have found it present in cutaneous sweat. But before accepting the above as fact, it must first be shown con-

*Autopsy since showed both kidneys contracted and granular; the left weighed 2¾, and the right one less than 3 ounces.

†Virchow's Archiv, Band 48, p. 181.

clusively that certain substances known to exist in urine, closely allied to albumin, are not the ones which these newer tests give reaction with instead of albumin. Bence Jones refers to a peculiar case of this kind.* Baylon describes an albuminoid substance under the name of albuminose, which is said to occur also in normal urine. Peptone-like bodies were found by O. Schultzen and L. Reiss in urine after phosphorus poisoning.† The identity of this peptone-like substance with true albumin peptones is still doubtful. Finally, according to Bechamp, a protean substance can be precipitated from *every normal urine* by three times its weight of 88 to 90 per cent. alcohol, which, after washing, is soluble in water. Bechamp has given it the name of nephrozymose.‡ It has furthermore been stated on high authority, that no test yet known will detect albumin in traces more minute than will the old heat and nitric acid test.

I have conducted a number of experiments with the view of throwing, if possible, more light upon this question, from which I select the following as examples:

First, I prepared a sample of pure blood serum from a healthy man, secured during traumatic hæmorrhage (epistaxis).

1. 50 cc of the above blood serum was diluted with 100 cc of distilled water and double filtered, and on testing the following was noted. The mercuric, brine, tungstate, ferrocyanic and heat and acid (nitric) gave very distinct reaction, showing albumin.

2. 50 cc of the above was diluted with 100 cc of distilled water, and still all tests gave reaction (positive.)

3. 50 cc of the last dilution was mixed with 100 cc of distilled water, and the following was noted. The mercuric, tungstate and brine tests gave the most distinct change. Heat and nitric acid, and ferrocyanic tests were still positive, but considerably fainter.

4. 50 cc of last dilution was added to 50 cc of distilled water, and the following noted. Mercuric and tungstate tests gave the most distinct change. Heat and nitric acid and brine were the faintest.

5. 50 cc of last dilution was added to 50 cc of distilled water, and the following noted. Heat and nitric acid practically failed to show any change, as did also brine. The mercuric and tungstate tests showed distinct change (positive.)

6. 50 cc of last dilution was still further diluted with 50 cc of distilled water, and the following noted. Heat and nitric acid and brine failed (negative.) The mercuric and tungstate gave distinct change (positive.) The temperature of the mercuric and tungstate tests was raised to 212° F. over a spirit lamp. The opacity was *not in the least cleared* thereby.

7. 50 cc of last dilution was further diluted with 50 cc of distilled water, and the following noted. The mercuric and tungstate tests gave perceptible reaction (positive.) The others failed (negative.)

8. 50 cc of last dilution was still further diluted with 50 cc of distilled water, and tests applied as before. The mercuric and tungstate tests both showed very faint but perceptible change (positive.) The others all failed as before.

9. 50 cc of the last dilution was further diluted with 50 cc of distilled water. The mercuric and tungstate tests now failed to show any change whatever. A tube of the diluted serum was compared with the tungstate and mercuric tests, and examined in various lights, but no difference could be distinguished.

The next experiment in this connection was as follows in general terms: The serum was obtained from a vesicated surface on a healthy man (save neuralgia.) The agent employed to produce the blister was cantharidal collodion. The experiment with this serum was conducted precisely similar to the last described, and gave substantially the same results.

I next experimented upon the fresh blood serum (18 hours after death) of a healthy pig; the blood being withdrawn from the carotid artery in killing the animal for use. The experiments with this serum were conducted similarly to those on the human blood serum, and the results were almost the same. A slight difference in favor of the heat and nitric acid test seemed to exist, that is to say, the heat and nitric acid test seemed to give positive reaction a little longer than in the case of human serum, but the mercuric and tungstate tests *unquestionably* detected the albumen diluted beyond the point where heat and nitric acid failed.

I next took 10 cc of human blood serum (from epistaxis case), and after diluting it with 90 cc of distilled water, I precipitated the paraglobulin therefrom, and double filtered. The solution was submitted to the same tests with substantially the same results. The mercuric and tungstate tests unquestionably showing distinct reactions considerably beyond the point of dilution, where heat and nitric acid failed to show any change.

In the case of egg albumen, however, the results will be found altogether different, as I have observed repeatedly; for instance, I took a weak solution of egg albumen in distilled water, and selecting as the most delicate tests, the potassio mercuric iodide and tungstate of sodium, I compared them carefully with the results of the heat and nitric acid test, which were as follows:

1. On the solution, as prepared, all three tests reacted distinctly (positive), showing albumen precipitate.

2. 50 cc of the solution was diluted with 50 cc of distilled water, when all three tests still showed reaction positive.

3. 50 cc of last solution was next diluted with 100 cc of distilled water, when all three gave reaction, though faint. The heat and acid, if anything, most distinct.

4. 50 cc of last solution was next diluted with 50 cc of distilled water, and the following noted. The heat and acid and mercuric tests gave a faint but perceptible change, distinguishable only on comparing them with a similar sized tube of distilled water, in

*Annalen A. Chem. u. Pharm., Band 67, pp. 97 to 105.
†Annalen des Charité Krankenhauses zu Berlin, Band 15, p. 9.
‡Neubauer and Vogel's Analysis of Urine, p. 100, (1879.)

front of a dark background. No change could be perceived with the tungstic test.

5. 50 cc of last solution was next diluted with 50 cc of distilled water, and the three tests applied. On holding them side by side, in various lights, no appreciable difference could be distinguished between any of the tests and a similar tube of distilled water, though examined by several individuals.

Thus it would seem there is a greater difference between the two native albumens (egg and scrum) than has been generally supposed. I believe that heat and nitric acid is a peculiarly delicate and appropriate test for the former, as I have noted in testing, in the presence of minute traces of egg albumen in distilled water, that the reaction produced by heat and nitric acid is considerably more pronounced than by any other test. The coagulum seems more dense and opaque, but it is about equal to the mercuric test as to minuteness of quantity it will detect.

Now as to physiological albuminuria, so-called. It is surprising how many people in apparently perfect health have small traces of albumin in their urine; even by the heat and nitric acid test, if properly and carefully applied, it will probably show traces of albumin in 8 or 10 per cent. of such individuals. I believe, as a result of my own observations, that the majority of people of all ages have traces of albumin in their urine, either occasionally or constantly, as determined by the mercuric and tungstic tests.

A number of observers, Senator, Leube, and lastly Chateaubourg, have recorded results from examinations on a large scale, which are quite startling to believers in the pathological significence of albumin in small quantities in urine. Chateaubourg, of Paris,* within the past year, has made a large number of examinations on healthy individuals, of which the following are a few of the results: 98 soldiers, from twenty-one to twenty-five years of age, were first selected and their urine obtained on *Monday* (hence there was no fatigue duty the day previous), 3 hours after the midday meal. Of the 98 samples, 44 showed the presence of albumin.

In July, 1883, he tested the urine of 94 soldiers, five hours after a meal, and 76 contained albumin, 82 per cent. He examined, at the *Hôpital des Enfants Assistés*, the urine of 142 healthy children, from 6 to 15 years of age, 111 of which contained albumin. Of 231 soldiers, on fatigue duty, whose urine was examined, he found albumin in 201 cases. I believe the test used by Chateaubourg was the potassio mercuric iodide. It cannot be claimed, that in all these cases the albumin was the result of pathological change, however slight; for Chateaubourg distinctly says, the urine of many of these cases was submitted to the microscope without finding any evidence of kidney lesion.

I have personally obtained very similar results from observations on a considerable (though smaller) number of cases. I have examined the urine of many healthy persons, where the urine was otherwise normal, save that it showed the presence of albumin on the application of the mercuric and tungstate tests, but no reaction could be found with the heat and nitric acid, however applied. When I say, the urine of these persons was normal, I mean in appearance, sp. gr., in quantity and reaction, and I carefully examined it with the microscope, going over several slides, but failed to find casts, renal epithelium, or bacteria.

It may be thought, perhaps, by strong believers in the delicacy of the heat and nitric acid test, that where it failed, and other tests showed albuminous reaction, the failure may have been due to want of the precautions necessary to insure success. So far as my own manipulations at least are concerned, this could not very well be the case. I am aware of the fact, that of all tests the heat and nitric acid requires the most care and precaution to insure accuracy.

One of the most serious objections to the heat and nitric acid test, especially in cases where albumin is present only in small quantity, is the fact that if the acid be not added in sufficient quantity, we sometimes fail to get any change; and, on the other hand, if too much acid be added, it will dissolve small traces of albumin: thus in either case the test may be negative.

My friend Prof. Walter S. Haines, of Rush College, has suggested to me a method of procedure, which I think obviates this difficulty. In applying the nitric acid to the urine, he inclines the test tube quite obliquely, and thus allows the acid to flow slowly down the side of the tube and through the urine (which latter it does owing to its greater gravity) to the bottom, leaving behind, the urine acidified in increasing intensity, each layer from the surface to the bottom. Some of these strata will be found of exactly the proper acidity to give the albuminous reaction.

In all cases where heat and nitric acid failed, and other tests showed any change, the former was given the benefit of most careful application, *and repetition* in several forms, among others the double method of Dr. Brown-Sequard,* was *always tried;* also the method of complete cooling and re-application of heat, as advised by Tyson.† In fact, the heat and nitric acid test was given by far the most care and attention of all, because, after the results obtained with it on egg albumen, I was working under the conviction that the heat and acid test would, *if properly applied*, reveal the presence of albumin, where any other known test would do so; for I had made my observations on egg albumen before I had experimented upon blood serum.

From the sum of my observations I draw the following deductions:

First:—That certain of these newer tests, as the potassio mercuric iodide, sodium tungstate, picric acid, and perhaps the brine and ferrocyanic, will detect *serum albumin* in more minute quantities than will the heat and nitric acid test.

Second:—That the most delicate and reliable of these, and possessing the fewest objections, are the potassio mercuric iodide and sodium tungstate tests.

Third:—That the test papers of Dr. Oliver, especially the sodium tungstate and potassio mercuric

*Chateaubourg Recherches sur l'Albuminurie Physiologique, Paris, 1883.

*Archives of Scientific and Practical Medicine, 1873.
†Practical Examination of Urine, 1883.

iodide, are handy measures for preliminary examinations of urine at the bedside of the patient for determining the presence of albumin in the urine.

Fourth:—That to be entirely reliable, the correcting influence of heat must be employed in applying all these newer tests.

Fifth:—That the potassio mercuric iodide, and sodium tungstate tests, and also the test papers of Dr. Oliver, are undoubtedly valuable acquisitions to our resources; inasmuch that through their greater delicacy and more ready applicability, they are likely to lead more frequently to resort to the microscope, and thus detect the early stages of certain forms of nephritis, which might otherwise escape observation, till too late to save or prolong life.

Sixth:—That the question of the near future, as to albumin in urine is likely to be, not only is it present, but *what quantity of albumin in the urine constitutes a pathological condition?* and this question must be largely determined by the microscope.

EXPECTANT TREATMENT IN SOME CASES OF ABORTION.

BY ADDISON H. FOSTER, M.D.

Mrs. A., American, aged 30, multipara, was taken, Christmas day, 1877, with severe labor pains, and expelled a four months' fœtus with very little hæmorrhage.

She being very fleshy, the firmly contracted os could barely be reached, and no active interference for the delivery of the placenta was advised. After a rest in bed for a week the patient was allowed to resume her usual household duties. Every few days a little hæmorrhage occurred, with some pain, and about once a month a portion of the placenta was expelled, until the 30th of April, or after four months, the last piece, the size of the thumb, came away as fresh and healthy as any before it. There never occurred any serious hæmorrhage or severe pains during the four months, and very little medicine was taken. The patient often went to town on the street-cars, a ride of over two and one-half miles; was in bed but a few days in all, and never had any symptoms of inflammation, and repeated digital examinations always disclosed a firmly-contracted os, with no tenderness. She helped to move May 1, and made an excellent recovery without any untoward result.

August 15, 1880, she again aborted at the fourth month, the placenta remaining under circumstances similar to the first. Upon getting up, after a week, considerable hæmorrhage and local tenderness occurred. A tampon of carbolized cotton arrested the hæmorrhage and allayed all the tenderness, so that the patient was up and about immediately, until October 18, when the secundines came away entire with very little hæmorrhage, and no local tenderness or troubles followed.

In March, 1881, she again aborted at about three months, and the placenta was discharged entire in two weeks, with no serious hæmorrhage. She was doing well until one cold evening two days after, contrary to orders, she got up and went to the theater, bringing on considerable metro-cellulitis, which was aggravated almost constantly by the obstinacy of the patient in refusing to remain quiet. I believe she would have had no complications if she had rested in bed for two weeks.

This case illustrates others in my experience, where, with a firmly contracted os and *no* material hæmorrhage, especially in a fleshy patient, with the uterus beyond easy reach without introducing the hand into the vagina, the organ is left to the efforts of nature, with satisfactory results.

Repeatedly I have seen the placenta expelled a few days after the use of the carbolized tampon, with very little hæmorrhage, pain, or subsequent trouble, when the pain and tenderness had been considerable before the tampon was used.

Hence I am advocating the "vis conservatrix naturæ" in occasional cases of abortion, rather than *constant* violent manual interference in every case, of whatever nature.

SUGGESTIONS ON THE EXAMINATION OF THE EYES OF APPLICANTS FOR PENSION.

BY J. L. THOMPSON, M.D., PROFESSOR OF EYE AND EAR DISEASES IN THE MEDICAL COLLEGE OF INDIANA.

(Read before the Mitchell District Medical Society, Dec. 28, 1883.)

In the examination of the eyes of applicants for pension, a more thorough knowledge of the anatomy, physiology and pathology of the organ is needed than in one's ordinary private practice, for the following reasons, to-wit:

1st. Many of them are impostors, who really have nothing abnormal about their eyes, they, in many instances having been induced by pension agents to add eye disease to their many other real or supposed infirmities.

2d. Others have slight disease, or abnormal condition, which they greatly magnify.

3d. In others, disease may have at one time existed and now have disappeared; but once having been on the pension rolls, they dislike to have their names stricken therefrom.

4th. Many present themselves whose troubles originated prior to their enlistment, or subsequent to their discharge from the service.

5th. Others fancy themselves entitled to a pension on account of failing sight incident to age, and other factors which we know have nothing to do with exposure incident to army service.

6th. On the other hand, many have been stricken from the rolls, or rated too low, or never pensioned at all, because the medical examiner has either failed to detect existing disease, or underestimated its gravity.

Examiners should always be provided with test-types of Snellen or others, remembering, though, that the applicant in many instances will not admit that he can read as well as he is able to, but tact and good judgment on the part of the examiner, aided by convex and concave glasses, will rarely ever fail in aiding him to reach a just conclusion in any case.

One should always have at least the following number of lenses: Convex, $^1/_{42}$, $^1/_{15}$, $^1/_{10}$, $^1/_5$. Concave, $^1/_{30}$, $^1/_{20}$, $^1/_{10}$, $^1/_5$, $^1/_3$, for the purpose of determining whether there is an anomaly of refraction. I have skipped over many numbers, as we simply wish to determine whether an anomaly exists, and not its exact degree. Then, one needs a convex lens of two or two and a half inches focal range for the examination by oblique illumination—a means of incalculable importance when we wish to detect disease in the cornea, anterior chamber, iris, crystalline lens, anterior and posterior capsule. To use this aid, one simply needs to have a lamp placed on a level with the patient's eye and obliquely in front and to the side of the same. By this means a pencil of rays may be so thrown upon the eye as to reveal that which cannot possibly be determined by one's unaided senses. It must be practiced on healthy structure first, and practice will soon teach us at just what angle to place the light, which, if too far in front or too much to the side, will not answer the purpose.

Then, one should be provided with one or two prisms set in a large frame, say two of 5° each; one with its base placed directly upward, and the other base downward. These are preferable to colored glasses combined with prisms, in cases where the applicant complains of blindness or defective vision in one eye. Prisms placed as above necessarily cause diplopia, (double vision), and with tact one can very quickly detect which is the defective eye, by simply having the person examined to close his eyes until a given signal, when, after placing these upon him, we hold a large white sheet of paper before him with a round, black spot, cross or other mark in its center, about one foot from his face. We tell him to open his eyes and quickly tell us just where they (the spots) stand, whether the lower spot is to the right or to the left of the upper, and which one is the plainer, etc., etc. If one meets with an old practiced hand at deception, he will commence winking and blinking and shutting first one eye and then the other, but we must then quickly raise the glasses and withdraw the paper from him or he will quickly detect the scheme. All that is necessary is to practice this on oneself to thoroughly understand the action of prisms, when many other methods of using them will be suggested.

Always have a mydriatic as well as a myotic at hand, so as to be able to dilate or contract the pupil, if needed. And if you wish to know all about any given case, provide yourselves with an ophthalmoscope also, as every disease behind the lens is a sealed book, objectively, without its aid. But, fortunately, a great majority of the cases which come up for pension are those where the anterior portions of the eye are diseased.

Were these examinations usually made by the younger members of the profession, no excuse should be offered as to one's inability to use this instrument. But it is a fact that nearly all of the medical examiners are gentlemen of at least twenty years' standing in the profession, whose hours are so occupied as to prevent the long continued practice with the instrument necessary to its proper use, for it is a well known fact to experts that it requires as much daily practice with it as is necessary to the acquisition of a foreign living language. I have met with cases where physicians have brought patients to me, just simply for a confirmation of diagnosis and prognosis, where they have used the ophthalmoscope and found no disease of the fundus of the eye; and yet I have silently, in their presence, made drawings of the gravest possible lesions. Not that I claim any superior skill in its use, but simply mention it to show that one must practice long with it before he dare pronounce positively in cases where it has been brought to one's aid.

We will now suppose that an applicant presents himself for examination. Look at his eyes thoroughly before touching them, as the slightest eversion of the lower lid will often cause such a congestion of the conjunctiva as to throw one off his guard in diagnosis. This one thorough glance takes in the surroundings of the eye, lachrymal derivative apparatus, eyelids, their movements, tarsal margins, etc., etc. We notice whether any of the ciliæ are inverted, or whether there is slight eversion of the lower punctum lachrymalis, remembering that if it does not hug the eye-ball closely, stillicidium, with its accompanying thickened lids and reddened conjunctiva, is always present. We notice the movements of the eye-ball, and if inverted or everted; we determine whether this is from strabismus or paralysis. Then the white of the eye, the cornea, the iris, and the lens, beyond which we cannot go without the ophthalmoscope.

We will now notice some of the affections which are very liable to be overlooked or underrated. One of them is

Cicatrization of the Superior Palpebral Conjunctiva.—Persons troubled in this way tell us that though their eyes feel very well when they present themselves before us, yet when they are called upon in harvest or threshing time, or to work in the hay-mow, or in burning brush, or in high winds, or any similar irritating employment, their eyes become very sore, and they are often disabled for weeks. In such cases the eye looks perfectly normal until we evert the upper lids, when, instead of the beautiful, smooth conjunctiva with the pearl-like meibomian glands seen beneath it, we find said conjunctiva cicatrized and hard, bound closely to the tarsal cartilage, which it very much resembles. In such cases we may rest assured that long ago the applicant had a long continued granular conjunctivitis, and that as these neoplastic growths were absorbed they destroyed the conjunctiva from which they sprang. All such persons should be pensioned, and no person so affected should ever be admitted to the army, no matter how well he sees, nor how well his eyes look, nor how much he protests that his eyes are just as perfect as any one's.

Nebulous Opacity of the Cornea.—This is an affection frequently overlooked, and many a poor fellow has had his claim rejected or his pension cut off, while

stoutly protesting that his vision was very poor. The reason of this is, that the unaided eye cannot readily detect these cases; but no sooner does one resort to oblique illumination than the case is immediately apparent, and it is astonishing how very much the thinest, faintest possible opacity of this kind will reduce the acuity of vision.

Large, Dense Opacity of the Cornea.—Where the cornea is white throughout its whole extent, or where it has entirely sloughed away in one or both eyes, be sure to thoroughly investigate the case as to the origin being in a gonorrhœa. 'Tis true, the case may come on from other causes, but do not forget this one fact deduced from extensive experience. The following case is interesting: X. Y. called on me several years ago, with a copious discharge streaming from his eyes. He told me that he was recently under a doctor's care, and that said doctor had used a foul brush in his eyes, and in that way had poisoned them. I asked him if he had the clap, which he vigorously denied. He went to another physician, but came back to me in just one week with both corneæ sloughed off. He threatened suit against the doctor alleged to have used the foul brush (an irregular, advertising doctor). So, to fully convince myself, I compelled him to allow me to examine his genitals. I then found a copious stream of pus from the urethra, on stroking the organ. His attorneys called upon me after they had commenced suit, and, after hearing what I had to say, dismissed the case. Three or four years afterwards this man applied for pension, for total loss of his eyes, the result of disease contracted in the army. Fortunately, the Board of Examiners sent him to me for an examination, when I gave them my former experience with the case. How this matter is to be settled, so that due justice may be done to all parties, I would very much like to know. That he contracted some form of disease while in the army he can prove, and that he was under treatment for the same when he contracted the gonorrhœa which destroyed his eyes, is also well known. But the solution of this knotty point I will leave for this society and the medical referees at Washington to determine.

Diseases of the Iris.—If one is not especially on the lookout for it, no trouble is more liable to escape one's notice than synechia posterior (adhesion of the iris to the capsule of the lens); it may be partial or total, with or without a false membrane in the pupil. Where a false membrane exists, it is liable to be mistaken for cataract. Whenever adhesions exist the eye is in great danger from occasional recurring iritis, which goes on until either the pupil is closed with or without said false membrane, or a total synechia posterior prevents the interchange between the anterior and posterior aqueous chamber, when the eye is ultimately lost from the glaucomatous process being set up, or from an irido-choroiditis. Sometimes these cases follow ulcerative keratitis, from malarious and other causes, sometimes from rheumatism; but remember that all iritic diseases should be thoroughly investigated, owing to the fact that great numbers are of syphilitic origin, especially where one notices no corneal complication nor evidence of rheumatism.

Choroidal and Retinal Diseases.—These can only be determined positively by the aid of the ophthalmoscope. Many have been rejected when no disease could be seen, and yet had the ophthalmoscope been used atrophied patches or pigmentary deposits might have been seen just as plainly as one sees the fruit in a freshly cut plum-pudding. Here, with this instrument can one detect between retinitis pigmentosa of congenital origin and that which is acquired later in life, as is seen in these two typical cases (shown to the society). The one was taken from a lady, æt. 30 years, and you see the deposits are like miniature blackbird's feet, and are very peripherally situated, only a few approaching near to the macula-lutea. The other was taken from a gentleman, about 48 years of age, where it followed an exhausting diarrhœa, in one of our Southern prisons during the late war. Here you see the patches are larger, more irregular and more centrally situated; both of them were sight-blind, as are all cases of this disease.

DISEASES AND ANOMALIES WHICH ANTEDATE ENLISTMENT.

Progressive Myopia.—Applicants often tell us that they had very good vision when they entered the service, but that during their army life their eyes became diseased, and that since leaving the service their vision has gradually or rapidly become worse. We find that they can not see test types at all, but if the man is honest he may admit that he sees some of the letters on the wall when a powerful concave lens is placed in front of the eye. Or he may want a pension more than a thorough examination, and may not admit that he sees better with any glass. In such cases one can not examine without the ophthalmoscope; but with it one may measure the degree of the myopia to within a half an inch, and can find a crescent on one side of the optic disc extending from the same, corresponding to a posterior staphyloma (bulging backwards of the back part of the eye) and often besides this large white patches where the choroid is atrophied and the sclerotic is to be seen behind.

Nystagmus (Oscillation of the Eye Balls).—Whenever this disease or symptom of disease is met with you may depend upon it that it occurred before the second year of infancy, except in the rarest cases possible, such as in paralysis agitaus, in confirmed drunkards, and in some brain or spinal affections. A typical case is as follows: A medical examining board sent a case to me where one eye was very much turned outward from divergent strabismus, he had nystagmus, and a very high degree of progressive myopia with its accompanying staphyloma porticum and white patches in the fundus, from sclerotico-choroiditis posterior. His vision was very poor. The board reported the facts to Washington, stating that the disease was not contracted in the army, but the case was returned to the board with instructions for a further examination, owing to the fact that the man had furnished evidence that he had shot at a mark and done many things which called for a tolerably fair degree of vision, and it was asked of said board if it were not

possible, in the light of this evidence, that they had done the man an injustice? It was not possible, it was a very well-marked case of an everyday occurrence in a large ophthalmic practice: triple evidence of its early origin was plainly manifest, nystagmus, divergent strabismus and progressive myopia. What more conclusive evidence could one wish for?

Suppose he could shoot at a mark. I have known men to shoot remarkably well, even though vision only equalled $^{20}/_{100}$ with both eyes. His may have been even better than this in one eye while in the army, but I question very much its equalling $^{5}/_{100}$ in the one that had such a high degree of divergence. This brings us to

Strabismus and Paralysis.—Strabismus is usually the result of an anomaly of refraction. In the convergent form the eye is hypermetropic (rays of light are brought to a focus behind the retina), while in the divergent the eye is generally myopic (the opposite to the above). Strabismus usually comes on before the fifth year of childhood, and wherever it settles on one eye the person has binocular vision (as a prism will show) and he becomes amblyopic from exclusion (weak from disuse). 'Tis true an opacity of the cornea or other blemish sometimes causes it, but that can easily be detected as can the date of its occurrence. Paralysis, on the other hand, is caused by wounds, brain disease, rheumatism and above all syphilis. Always investigate paralysis of the ocular muscles thoroughly, and never confound it with strabismus.

DISEASES AND ANOMALIES INCIDENT TO AGE.

Senile Cataract.—This, as its name indicates, occurs in those who have passed the meridian of life. It comes on slowly; dimmer and dimmer becomes the sight, until blindness is the result. No inflammation; no pain; nothing but a failure of the nutrition of the lens, with gradual and steadily increasing opacity of the same. It is usually entirely independent of any disease contracted while in the service. Cataract may be caused by blow, or punctured wound, or from a choroidal inflammation, but it usually follows very quickly upon them; while the senile variety we meet with is in those now past fifty, who left the army with very good vision, or they may have had some conjunctival trouble for which they were treated while in the service, and as their eyes may have troubled them occasionally since their discharge, they attribute the gradually failing sight to their former trouble, for which probably they may have been drawing a pension. It is in just such cases where the line of demarkation should be strictly drawn. The government is justly indebted to such for the disability caused by the superficial trouble, but in no way for the blindness caused from cataract, as it is in no way incident to army life. Cataract is very easily detected with the plain mirror of the ophthalmoscope, or by oblique illumination. If the anterior or peripheral parts of the lens are first affected, the latter is sufficient; if only the posterior pole, the ophthalmoscope must be used.

Presbyopia in Hypermetropes.—Presbyopia is also an anomaly which creeps upon us just as certainly as does age, but if we are emmetropic (in optical measure) it only annoys us for close objects; distant ones are seen almost as distinctly as ever, but let one be hypermetropic (a condition where rays are formed behind the retina) and he is very much troubled for distant objects as well as close ones. Now, suppose one so affected (and they are numerous), had some slight eye trouble while in the service, he immediately supposes that his present failing sight is due to the former trouble, and that he should be pensioned for the same. To detect these cases, convex glasses are required, and the strongest glass, with which one sees the best across a room, or at infinite distance, indicates the degree of the manifest hypermetropia. It has no connection with army service.

Many other affections might be mentioned, but these are the main ones upon which you will be called to pass judgment.

Resume:

Cicatrization of the superior palpebral conjunctiva, even though the eye looks perfectly normal, is a just cause for pension.

A slight nebulous opacity of the cornea is easily overlooked, except by oblique illumination.

Iritic adhesions are easily overlooked, except by the use of a very delicate and oblique illumination. They are seeds of ultimate destruction unless loosened. Look for syphilis when no other cause is apparent.

Progressive myopia has its origin in childhood, but may not seriously affect vision until much later in life. It is usually accompanied by staphyloma posticum and sclerotico-choroiditis-post.

Nystagmus (oscillation of the eyeballs) is usually accompanied by defective vision, and usually has its origin in early childhood.

Strabismus is generally an affection of early childhood, and when confined to one eye, it soon very much impairs the visual acuity, and the subject has not binocular vision.

In total destruction of the cornea and in leucoma (large white opacity) investigate thoroughly for gonorrhœa.

Where the eye is turned from paralysis, and no evidence of wound of head, or eye, or of brain or spinal cord is seen, look for syphilis.

Senile cataract usually comes on long after the applicant has left the service, and though he may have evidence of granular lids or chronic conjunctivitis, and may be already on the pension rolls, still, in ninety-nine cases out of a hundred, the cataract is entirely independent of army life.

Presbyopia, wheh occurring in hypermetropes, affects vision for distant as well as close objects, and often leads the applicant to believe it to be incident to army life.

All lesions behind the lens are a sealed book, objectively, unless one resorts to the ophthalmoscope.

Allow me to say, in conclusion, that in eye diseases, a mistake in diagnosis is almost impossible, when one knows what to look for, and yet it is a fact beyond contradiction, that greater ones are made than in any other part of the human economy.

MEDICAL PROGRESS.

HYGIENE.

THE PAVILION OF DR. KOCH FOR THE EXPOSITION OF HYGIENE AT BERLIN.—A writer in the *Revue Medicale of Louvain*, gives us a very interesting description of the workshop and museum of exhibit of Dr. Koch. It appears that in 1876, the Imperial German Government established a central committee to supervise the sanitary condition of the Empire, and to contribute directly, by especial researches, to the progress of hygiene. This committee, called the Reichsgesundheitsamt, was composed of five persons who were to collect, arrange and exhibit all material pertaining to the study and practice of hygiene, and to give its aid to the Minister of the Interior in the study of questions relating to hygiene, and in the preparation of laws and administrative measures relative to the same subject. In 1878 the committee was enlarged, and the Government appropriated generously the funds necessary for thoroughly equipped laboratories for original researches intended to solve certain important hygienic problems.

The building itself is located in the center of the medical quarter of Berlin. It consists of a very large house with a cellar, ground floor and two stories, with laboratories for chemistry, hygiene and experimental pathology, numerous work-rooms, a statistical bureau, library, lecture-room, consultation room, dwelling-rooms for the Director, and chambers for the assistants, with, finally, motor apparatus, rooms for disinfection, for combustion, for incubation, dark chambers, photographer's room, etc.

The *personnel* is made up of a Director, Dr. Struck, and four ordinary members, viz.: Dr. Koch, Prof. Roloff, of the Royal Prussian School of Veterinary Medicine, Profs. Sell and Wolfftingel, of the University of Berlin; of nine assistant physicians, and a sufficient number of employés to perfect the service. Besides these there are 25 extraordinary members chosen from among the most eminent hygienists in the principal cities of Germany. The Reichsgesundheitsamt erected a pavilion in the park of the Exposition of Hygiene, which contained two laboratories. 1. A laboratory for the analysis of alimentary substances. 2. A laboratory for researches into infectious diseases and the modes of disinfection. Entrance into this pavilion is interdicted to the non-medical public, which the writer from whom we quote criticises, having, as he says, seen a lively interest displayed by those not initiated in the mysteries of medicine, at seeing displayed before their eyes the chemical analyses of alimentary substances, and noting the tabular statements of the comparative nutrient value of different substances. The ocular demonstration of the purity of water and air through the bacterioscopic culture; the adulteration of milk, etc., must have a certain useful influence upon the mass.

Dr. Koch commenced his work on the microbia when he was a country physician, a *Kreisphyricus*, in a very small village of Silesia. It was in the midst of his duties as a practicing physician that he commenced and carried on those admirable labors which mark an epoch in our knowledge of the infinitely minute world. Gifted with sagacity and an exceptionally clearsightedness, joined with dexterity and the spirit of order and method, and with an indomitable perseverance, he made his first essays like those of a master. With a sober manner, and a style that is clear and curt, the most of his works are spread over but few pages, but every question submitted to his researches comes back perfectly answered from his hands.

To affirm that a given disease is the product of a special germ, Dr. Koch exacts the three following conditions:

1st. The germ should be be found in the diseased organism, in its secretions or excretions; it must be found in such forms and groups as show its special and characteristic dispositions.

2d. The germ must be capable of cultivation out of the body, and isolated from all living material and other germs.

3d. The germ so cultivated must be capable of being reproduced in the living organism of the original disease.

If these three conditions are satisfactory, the proof is complete.

1st. To ascertain the presence of the germ, Dr. Koch uses the simple and direct means, but more generally calls to his aid the aniline staining fluids, which possess a special affinity for the germs or microbia; and in the pavilion are to be seen the Abbe condensor, the different models of microscopes used in laboratories, and all made by Zeiss, of Jena.

2d. The microbia are sown in a suitable medium and kept at a proper temperature, where they multiply with a differing degree of rapidity, according to their species. As the use of a liquid medium presents certain objections, which render it difficult, laborious, long and uncertain, Dr. Koch, in searching for a more solid medium, has utilized the potato, which he sterilizes by first soaking it in a solution of corrosive sublimate for an hour, and then places it on a sieve in an iron box holding water to the depth of several centimeters, over which this is placed. The box is closed by a cork pierced by a thermometer; the temperature is raised to 212°, and kept so for from one-half to one hour. The potato is cut with a heated knife-blade quickly, and in as pure air as possible, a drop of the liquid to be examined placed upon it, and the whole covered by an hermetically sealed bell glass. Each species develops its own peculiar form of culture islet, which can be recognized by the naked eye. Thus, one sees a group of the micrococcus prodigiosus, the bacteria which gives the green color to pus, the *bacterium anthracis*, or, and here bread is preferred as the medium of culture, the *oidium lactis*, the *aspergillus glaucus*, etc.

By the aid of gelatine Koch is enabled to study cultivation in alimentary substances, such as the bouillon of different meats, saline solutions, Pasteur's liquid, etc.; it has the advantage of jellifying at the temperature suitable for the cultivation of these germs, but the disadvantage for others, as for milk, of liquifying at a higher temperature. In this way

he obtains the germs of chicken cholera, of typhoid fever, erysipelas, anthrax, septicæmias, the *bacterium termo*, etc. In the study of the germs which produce lactic fermentation, butyric fermentation, blue milk, etc., these germs have been so far isolated and cultivated, that it would seem as if before long the mystery attendant upon the numerous alterations of milk would be unveiled in its minutest details. As has just been said, gelatine not proving suitable, Dr. Koch takes the blood serum, pure, or gelatinized to facilitate its coagulation. He selects, by preference, the blood of an animal subjected to the disease of which he desires to study the germ. It (the blood) is taken from the carotid and collected carefully in a vessel, where it is allowed to remain until the contraction of the clot expresses the serum, which serum is then taken up by pipettes previously heated, and distributed into a series of test tubes, that have also been sterilized by a prolonged heat of 302° to 320°. The serum in these test tubes is then sterilized by being placed in a suitable vessel, and submitted daily to an hour's temperature of 136.4° F. for about six days. This results in a feeble coagulation of the serum, which remains transparent and quasi-gelatinous. To prevent the water of the serum from resting on the top, the tubes are laid obliquely. To carry on these investigations properly a delicate regulation of temperature is necessary, and for this purpose the thermostat of Arsonval is used, which allows of a constant heat to $^1/_{10}$ of a degree centigrade. The culture of the bacillus of tuberculosis has been so made, and in the same way the bacillus of glanders, of osteomyelitis, the microbia of the septecæmia of the rabbit, of the turkey, etc., etc.

Much laboratory work has been done in the bacteriscopic examination of the air, the water and the soil. To examine the air of an apartment it is simply necessary to expose sterilized slices of potato, upon which the germs fall and colonize themselves. For water, a weak solution of gelatine with the necessary nutrient salts, is mixed with a small proportion of the water, left to the surrounding temperature, and in a little time the solidified gelatine shows whitish or grayish granules, which the microscope resolves into colonies of special germs. To estimate the proportional quantity of these germs, the contaminated gelatine is spread out on a large plate of glass over paper that has been ruled and counter-ruled so that a rapid and satisfactory count of the islets of microbian vegetation can be made. Thus are to be seen the fractions of a drop of the water from the canals of Berlin, of pump water of the public fountains, of sewer water, and of the water of the river Sprée, above and below Berlin, these last demonstrating in a striking manner how water becomes contaminated and how it purifies itself by nature's processes. Nothing is more curious than to examine these plates covered with little clods of turf, islets of dust, white, green and brown spots, little collections of pearls and a crowd of special forms, so diverse as to appear like a public park or garden in miniature. As in all the other analyses, each variety of vegetation, after being carefully examined by the microscope to ascertain its purity from all foreign mixture, receives an isolated culture with the most diverse substances, in turn submitted to its influence.

3d. Finally comes the reproduction of the original disease by the aid of the artificially developed germs. This has definitely proven for the microbia of charbon by Pasteur, of tubercle by Koch, and for the bacteria of glanders, the coccus of erysipelas, etc. The pavilion displays numerous anatomical specimens from rabbits, dogs, and other animals that have been inoculated with the bacteria of tuberculosis, cultivated to the tenth, twentieth, and higher generations, and which demonstrate positively the presence of tubercles in the different organs. Other specimens show the inoculation of the cultivated bacteria of glanders on the rabbit and on the horse. The nasal mucous membrane and the ulcerated ears so exhibited give the most positive evidence of this infection. A group of photographs on glass completes the series of objects exhibited. These direct reproductions of the different varieties of the known pathogenetic inferior organisms, as well as the disposition they affect in the diseased organs, are for the most part, in spite of the often enormous enlargement which they have undergone, of an absolute sharpness and admirable precision of detail.

MEDICINE.

THE USE AND ABUSE OF THE MACKINTOSH.—A late number of the *Lancet* has a very practical article under this heading, and for our purposes the word mackintosh can be rendered gossamer or rubber coat. It says: "The season has set in for wearing mackintoshes. A caution may be therefore not unnecessary, and let us hope, not unheeded, as to the use and abuse of this serviceable, but, when improperly employed, dangerous article of clothing. When once a mackintosh is put on to defend the body from wet, it should on no account be taken off until the wearer has not only taken shelter, but is in a position to change his clothes. What a covering of oiled silk does for a wet rag in surgery—namely, convert it into a poultice—the mackintosh does for the clothes of its wearer. The insensible perspiration, which finds a way of escape through ordinary clothing, is kept in by the waterproof, and the clothes are saturated with moisture. A very few minutes will suffice to render the under-clothing "damp" under a mackintosh, particularly if either the wearer perspires freely, or the weather be what is called "muggy," as well as wet. When, therefore, the wearer of a mackintosh takes off that article of clothing, because it has ceased to rain, he is in the position of a person who has damp clothes on, and if he sits in the saddle, or walks home, or rides in an open trap, he is more likely to take cold than if he had not used the mackintosh at all. If, therefore, we say, a mackintosh is once put on, it should on no account be removed until the clothes can be changed or dried by a fire without reduction of bodily temperature. The use of a mackintosh is to protect a man from a severe storm of rain. His clothes must be damp if he wears one of these protectors. The sole gain from using it is to render the moisture warm instead of cold, and

to prevent loss of heat by evaporation. If the mackintosh be removed, evaporation commences immediately, with all the consequent risks of that process."

A NEW TREATMENT FOR NEURALGIA.—The latest agent introduced for the relief of neuralgia is a 1 per cent. solution of hyperosmic acid, administered by subcutaneous injection. It has been employed in Billroth's clinic in a few cases. One of the patients had been a martyr to sciatica for years, and had tried innumerable remedies, including the application of electricity no fewer than 200 times, whilst for a whole year he had adopted vegetarianism. Billroth injected the above remedy between the tuber ischii and trochanter, and within a day or two the pain was greatly relieved, and eventually quite disappeared. It would be rash to conclude too much from these results, in the face of the intractability of neuralgia to medication, but if it really proves to be as efficacious as considered, hyperosmic acid will be a therapeutic agent of no mean value.—*Lancet.*

TUBERCLE INFECTION THROUGH FOOD.—We translate the following notice, by Wernich, from the *Centralblatt f. die Med. Wissenschaften* for Nov. 10: In the *Bayerisches ärztt. Inteltigenz-Blatt*, 1883, No. 26, Herzevich reports the history of two girls, sisters, aged respectively fifteen and three months, who, after being nursed by an undoubtedly phthisical mother, the first for five months, the second for three, were reared and fed on soup, milk and pap. The mother adopted the following disgusting method of feeding: She first chewed the food herself, then spat it out into a spoon, and gave it to the children. So long as she had little expectoration, the children bore this feeding well; but so soon as her expectoration became abundant, although the children continued to take their food with appetite, they both rapidly emaciated; ulcers formed in the throat and insides of the cheeks, some large and of irregular shape, others small and round, both with infiltrated edges; and extensive swelling of the lymphatic glands occurred. Severe fever, putrid diarrhœa, and progressive atrophy caused the death of both children within a month of one another. The post-mortem appearances were the same in both. All the mediastinal lymphatic glands were swollen and caseated; caseous nodules occurred under the pleuræ and scattered throughout the lungs, also in the liver, spleen, and of smaller size in the kidneys—in other words, there was present tuberculosis pulmonum, hepatis, renumet lienis, lymphadenitis caseosa. The mother survived the children for some months, and died after extensive destruction of the lungs had occurred. It is worthy of remark that her children by a former marriage showed no signs of phthisis; also that the two children in question, so long as they were suckled by a comparatively healthy mother, remained themselves healthy. As the author says: "This important case has all the value of a pathological experiment, and must be considered as a pure case of tuberculosis derived from infected food." —*Dublin Journal of Medical Science.*

FOWL'S GIZZARD PEPSINE.—Dr. D. J. Macgowan reports that among the drugs exported from Wenchow, there is one which merits notice from the attention that the article has lately received from Western pharmacologists,—fowl's gizzard. It became an article of the Chinese materia medica in the early half of the eighth century A. D., having been employed probably in domestic practice long antecedently. The properties of the drug known as ingluvin, which is prepared from the gizzard of the fowl, are wholly due to the internal membrane of that viscus. It is supplied to the shops by cooks of eating establishments, who in dissecting out the membrane are careful not to wet or waste the secretion, and thus portions of the bird's food are sometimes found adherent. When dried, the article, from its plicated form, resembles a scallop shell; its color is a pale olive yellow, and it is very brittle. It is often found wasted or charred nearly black, and for the most part is employed in that form. It is generally boiled with other drugs; in a few cases it is administered unburnt, mixed with wasted rice, both being triturated together. Fowl's gizzard is employed by the Chinese largely in bowel complaints of children, but particularly in urinary disorders, curing them of a malady that is indicated by "milky urine." It removes abdominal tumefactions, corrects incontinence of urine; it is valuable in spermatorrhœa, leucorrhœa, and in flooding following delivery; it corrects nausea, and is used to allay morning sickness in pregnancy, but of course its main use is in indigestion. In domestic practice the lining of three gizzards is thought sufficient for an ordinary case, the whole being taken in the course of 10 days. It is enjoined that hens are to be used for men, but in practice no sexual distinction is made.

A writer of the seventh century A. D. advocated its use in a form of ophthalmia of children, due to deranged liver, for which it is still employed.

Externally it is employed in the treatment of indolent ulcers, carious teeth, ulceration of the throat (blown in through a bamboo tube), and in hæmorrhoids.

Cows' stomachs are employed for most of the complaints named above. The viscus is to be minced and boiled in 10 bowls of water, with ginger and vinegar, down to one bowl. In taking pepsine in this form, the patient must abstain from the flesh and blood of dogs. Pigs' stomachs are used chiefly for dyspepsia and analagous complaints, and also as an anthelmintic. The stomach of the sheep is used as a tonic and stomachic.

REMOVAL OF A RING FROM THE PENIS.—Dr. E. A. Aldridge, in his report from Hoihow, refers to a notion, prevalent probably throughout China, of the existence of a disease the most prominent symptom of which is shrinking of the penis; hence the common name, *so-yang-cheng*—the disease of the contracted penis. It is said most frequently to come on after sexual intercourse, but a man may be attacked by it at any other time. After the penis has once begun to shrink, if proper measures are not promptly taken, the sufferer becomes insensible, and the penis recedes into the belly, and remains there even after death, which soon takes place. The treatment first

to be adopted is to lay hold of the penis and draw it out; this is most frequently done by means of the ordinary Chinese scale-box, the two halves of which are made to act as a pair of tongs or pincers, while the sliding ring round the handle tightens the grip as necessary. The end of the spine is cauterized with artemisia moxa, acupuncture is performed with silver needles, and the penis bathed with hot, strong samshu. There have also been supposed cases of contraction of the female breasts, the disease being known as so-nai-cheng. In the case of a petty native official who, three days previously, felt chilled, and had some pain in the bladder, he thought his penis began to shrink, and as he greatly feared that it might recede into the belly, to prevent its doing so, he put a jade-stone thumb-ring round it, but the next morning was unable to draw off the ring. On examination, Dr. Aldridge found the thumb-ring near the root of the penis; the organ in front of the ring was greatly swollen, being 4¾ inches in circumference, and quite cold; the glans was of a dark color, and the skin tense and shining, and mottled with extravasated blood, showing all the signs of commencing mortification, the constriction having lasted for about 65 hours. After winding tape round the penis, and passing one end under the ring by means of an eyed probe, and then untwisting the tape, he moved the ring forward about 1½ inch, but by so doing considerably increased the swelling in front of the ring. However, after making numerous punctures and letting out some blood and serum, by making steady pressure, in an hour or so the ring was removed; lint spread with zinc ointment was wrapped round the penis, and in a few days it regained its proper form.

Cremation.—The Medical Reports of the Imperial Maritime Customs of China, as published by order of the Inspector-General of Customs, contain much that is curious, interesting and valuable. In No. 25, Dr. A. Henry reports in regard to cremation in Ichang, that sometimes children are cremated. This is only done from superstitious reasons. Where several young children of a family have died in succession, the body of one of them is burned, the supposition being that the ceremony will ensure the survival of the next child that is born to the family. "I witnessed last summer one performance of the kind. The body was simply brought to the open fields in a box, some firewood was piled around it, and set fire to. The absence of odor was remarkable. In the neighborhood, out of the many Buddhist temples around, there is only one the inmates of which are burned after death. The manner in which the process is carried out is both efficient and æsthetic, and, moreover, it is not expensive—at least, the cost does not bear comparison with the large sums that the admirers of the practice in Europe are reported to incur. In the grounds of the temple there is a small dome-like edifice, the interior of which communicates with the open air by a small door. On a stone seat inside the dome the dead friend is placed in a sitting posture, and around him is piled a quantity of charcoal and firewood. This is set on fire; the door is then shut until combustion is complete. The calcined bones are collected and placed in a jar, which is preserved in one of the niches in an adjoining mortuary chapel. The latter building is also a small dome, and contains great numbers of these mortuary urns."

OBSTETRICS AND GYNÆCOLOGY.

The Diaphoretic Treatment of Puerperal Eclampsia by Hot Baths.—Dr. C. Brens, of Vienna, has returned to this treatment. Last year he reported six cases—the satisfactory treatment of which induced him to give it a further trial and he has since (*Annals de la Societè Medico-Chirurgicalé de Liege*) reported eleven new cases with one death. The patient is put into a bath of 100.4°F, the temperature of which is gradually increased. After remaining in the bath for ½ to ¾ of an hour, the patient is wrapped in warm bedclothing, so as to produce an energetic diaphoresis, at the same time that injections of chloral hydrate are used to produce profound narcosis. The patients are put into the bath while under the influence of the narcotic, and if they awaken they are again brought under its influence. Attempts are made by the ordinary means and without force to shorten labor in the pregnant woman, and massage of the uterus is performed in the bath in the woman who has been delivered.

Four of these cases developed with the commencement of labor; in two the convulsions appeared during the first stage of labor, which was prolonged; one case developed during the stage of expulsion, and four cases the day after delivery. The case of death was in a patient who was syphilitic, and who had already suffered from several attacks before she came under treatment,—she died four days after the cessation of all convulsions, and the autopsy showed the presence of a phlegmon of the pelvis and peritonitis. Of the children, two were dead and were extracted by craniotomy, five were delivered by the forceps and survived—the remaining four were living, and belonged to the cases in which convulsions appeared after delivery.

In a number of cases of pregnancy where œdema was present with albuminuria, the prophylactic treatment of hot baths was used and in none was there premature delivery or any other disagreeable effects observed; particularly was it noted that in none of these cases did eclampsia occur. Among other cases one is given of a primipara aged 26 years, in the eighth lunar month of her pregnancy, who was markedly œdematous and whose urine was loaded with blood and albumen. She took forty-five baths, with marked relief to her condition and delivery at term of a healthy child; no bad after effects. In those cases where the convulsions set in after delivery there was no hæmorrhage—the uterus being subjected to massage as was noted.—*Journal des Sages Femmes.*

It has been announced that a baronetcy is to be conferred upon Professor Lister. This is a well-deserved honor, for no one has done more to advance our knowledge in the department of antiseptic surgery. His own original research, and important scientific work, make him deserving of the honor.

THE

Journal of American Medical Association.

PUBLISHED WEEKLY.

THE EDITOR of this JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information, should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE..... $5,00.
SINGLE COPIES..... 10 CENTS.

Subscriptions may hegin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 65 RANDOLPH STREET,
CHICAGO, ILLINOIS.

SATURDAY, JANUARY 19, 1884.

SIGNING THE CONSTITUTION, BY-LAWS, AND CODE OF ETHICS OF THE AMERICAN MEDICAL ASSOCIATION.—Perhaps no one act connected with the doings of the American Medical Association has heen more misrepresented, and consequently misunderstood, both by individuals and a large part of the medical press, than that which consisted in the insertion in the blank forms provided by the Permanent Secretary or the Registration Committee at the recent meeting in Cleveland, of a line by which the signer of the blank thereby endorsed the constitution and Code of Ethics of the Association. By some it was regarded as a mere trick, by which to gain fresh endorsement of the National Code of Ethics. By those who had any leaning toward the so-called New York Code, it was indignantly denounced as having been inserted without authority; while the newspaper reporters, and a large majority of the members of the profession present, readily assumed that the new line in the blank to be filled and signed had been placed there for the express purpose of shutting out all the much talked-of New York new code men. And for months afterward editors of many of the medical journals awarded to some one great credit for having devised a scheme so ingenious and effectual for accomplishing the last named object. It seems almost cruel sometimes to spoil oft-told tales, or to correct misrepresentations by which those making them fondly hoped to further their own ends. But a due regard for truth and the facts of history require us to do it in this case.

It is within our personal knowledge that the origin of the plan to make the signing of the blank provided for delegates and members to fill up and sign, as a prerequisite to being registered at each annual meeting, equivalent to signing the constitution, by-laws and Code of Ethics, had no reference whatever to the followers of the New York code, or to the exclusion of any person or party from membership in the Association. On the contrary, during the meeting at St. Paul, in 1882, while the Judicial Council was engaged in the investigation of charges of unprofessional conduct preferred against a member from a town in the northern part of Wisconsin, it appeared from the direct testimony of the defendant himself, that he had never signed the Constitution or plan of organization of the Association or endorsed the Code of Ethics, concerning the provisions of which he appeared to be quite ignorant. This caused a discussion in the Council in regard to the propriety or practicability of admitting parties to membership in the Association without their signing, or in some way pledging themselves to obey its fundamental laws. More especially so, when the last clause of the second section of the constitution, relating to members, provides as follows:

"Every member elect, prior to the permanent organization of the annual meeting, or before voting on any question after the meeting has been organized, must exhibit his credentials to the proper committee, *and sign these regulations*, inscribing his name and address in full, specifying in what capacity he attends, and, if a delegate, the title of the institution from which he has received his appointment." That the words, "these regulations," here include the Code of Ethics, as well as the constitution and by-laws, is evident from the *proviso* in the fourth paragraph of the same section of the constitution, and the ninth by-law. As a result of the discussion, the Permanent Secretary was invited before the council to explain why so plain and important a provision of the constitution had been, to say the least, but imperfectly complied with? The Secretary informed the Council that in the literal execution of the provision of the constitution in question, during all the earlier years of the Association, a large book was provided in which each member was required to sign directly the regulations constituting the plan of organization of the Association. But as the membership increased, the names were often duplicated, the size of the book became very cumbersome, and the time required for each to sign retarded the progress of registration. For these reasons the book for signatures had been omitted for several years past, and blank forms provided convenient for each applicant for registration, to fill up and sign, containing all the

items specified in the paragraph of the constitution quoted above, except that relating to the constitution, etc. This he claimed had been inadvertently omitted. Some members of the Council were disposed to insist that a book should again be provided, and the provisions of the constitution be literally complied with according to the original method. But after a further explanation by the Secretary to the effect that the *forms* filled up and signed by the present method were all filed, and from them the list of names of members compiled for publication, and that a line could be readily inserted which would cause the signer to directly endorse the constitution, by-laws and ethics of the Association as effectually as if he had entered his name in a book, it was agreed that at the next and all subsequent annual meetings the blank forms provided for members to fill and sign, preliminary to registration, should contain such provision as just stated. It was in compliance with this understanding between the Judicial Council and the Permanent Secretary at the meeting in 1882, that the new clause in the blank forms provided for members to sign before being registered, made its appearance at the meeting in Cleveland in 1883. It was a simple device for complying with an important provision of the constitution without delaying the progress of the registration of members at the commencement of each annual meeting, and having no more reference to the shutting of the door of the Association in the face of any one who was entitled to enter, than it had to the exclusion of the followers of Mahomet. And we trust the Secretary, in conjunction with the Committee of Arrangements, will see that the same object is fully and fairly accomplished at the coming meeting in Washington. The Association has never questioned the right of any member to propose and advocate such changes in the constitution, by-laws and Code of Ethics as he might deem proper, in the manner provided for by the plan of organization.

On the contrary, changes have been proposed by members almost every year, especially in the by-laws. And several important changes have been made at different times both in the constitution and by-laws. Ten years since, a committee was charged with the duty of examining and reporting on a revision of the Code of Ethics, and only three years since an important amendment or addition was made to the Code after full discussion in general session of the Association.

Consequently, all the allegations and inuendoes of open enemies or pretended friends about the gagging of members, the "evasion of issues," or the suppression of discussions, are without the least shadow of foundation in fact. Under the rules of the Association, any member can propose an amendment to any part of the fundamental regulations of the organization. It must be received, published in the minutes of the meeting, and lie over one year for consideration and information of members generally. At the next annual meeting it comes up in regular order for consideration, discussion, and final action.

We say again, therefore, that the Association has never placed the slightest restriction upon the right of any member to advocate any change in either constitution, by-laws or Code of Ethics in the manner provided for in the plan of organization. But it is quite a different thing, when a person seeking to gain or retain membership, openly unites with outside organizations in repudiating a part of the fundamental laws of the Association, and pledges obedience to others in conflict with them. Such an one assumes a position not regarded as enviable, to say the least, by intelligent and honorable men.

A Chicago Medical Library.—The Chicago Medical Society has recently completed arrangements with the authorities of the Chicago Public Library to have a regular department for medical books, to be cared for, and rendered accessible for use, under the same regulations and officers as the rest of the public library. The Medical Society appropriated $500 of the surplus in its treasury for the purpose of purchasing the first installment of books for this library. We say first installment, although soon after the great fire of this city in 1871, the Chicago Medical College, Medical Department of the Northwestern University, having accumulated a library of seven or eight hundred volumes, without a convenient library room in which to keep it safely, had the books transferred to the Public Library of the city, where they have since remained, and will constitute a part of this new collection of medical books. The present arrangement with the authorities of the Public Library, opens at once to the medical profession a valuable medical library and convenient reading-room, at the least possible cost. We trust it will be a well sustained and patronized department of one of the most important public institutions of this city.

Editorial Change.—The *Weekly Medical Review*, published simultaneously in Chicago and St. Louis, and having a corps of editors in each city, has recently changed its leading editor in the first named city. Dr. Robert Tilly, 125 State street, Chicago,

takes the place previously occupied by Dr. Roswell Park, who has removed to Buffalo, New York, and become a member of the Faculty of the Buffalo Medical College. Dr. Tilly is one of our most gifted and enterprising young members of the profession, and will discharge whatever duties he undertakes with fidelity and ability.

OFFICERS OF THE AMERICAN MEDICAL ASSOCIATION.—In the JOURNAL of last week, the list of officers given on the last page of reading matter, was copied from the record of proceedings ot the meeting at which the officers were elected.

The office of Secretary being permanent, the name of Dr. Atkinson does not appear on the record, and its absence was not discovered until too late to supply the defect in that number. It will be found in its proper place in the list in this and future issues.

CORRECTION.—In the list of names of members of the American Medical Association, who were in attendance on the meeting in Cleveland in June last, as published in the last number of the first volume of this journal, appears the name of O. W. Meeks, of Marion, Ohio, which should have been O. W. Weeks, M.D.

SOCIETY PROCEEDINGS.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting Thursday, January 3, 1884. The President, R. A. Cleemaun, M.D., in the chair.

BATTEY'S OPERATION.

Dr. E. E. Montgomery corrected a statement made in the report of the case of ovariotomy narrated by him at the meeting of December 6, 1883. Silk ligatures, not catgut, were used to tie the pedicles.

The convalescence of the patient had been very satisfactory. The temperature did not rise above 99° F. In performing this operation no antiseptic was used; all instruments, sponges, etc., were washed in boiling water, and boiled water was used in washing the wound and abdominal cavity. The mental condition of the patient was such that she was kept constantly under mechanical restraint, and on one occasion, when she had been left alone for a few minutes, she tore all the dressings off of the wound, and at the next visit it was found bare, but no bad result followed. The sutures were removed on the eighth day. Some pain in the lower part of the abdomen and slight fever commenced on the twenty-fifth day, but she has since again improved. Her mental condition is at the present better than it had been for a year before the operation, and she can now converse rationally.

SEPTICÆMIA AFTER ABORTION.

Dr. W. H. Parrish reported the following case: A young woman, 20 years of age, came into the Philadelphia Hospital in the finishing stages of an abortion, which had been coming on for some days. The cause was unknown, but was probably instrumental. At the time I first saw her, three days after her admission, her temperature was 103° to 104° F., and pulse 150. She had had a chill before admission; her abdomen was distended and tender, and the uterus was very sensitive. The right parotid gland was swelled and painful; it continued to enlarge, and fearing septicæmia, he gave fifty grains of quinine daily by rectum, as the stomach was too irritable to retain it. One ounce of whisky was given by the mouth every hour, day and night. A small quantity of morphia was given, to relieve the abdominal tenderness. The pulse and temperature fell rapidly, but the gland continued to be swelled and painful; it was quite hard, but was discolored. There were no chills now, but fearing the presence of pus, he made an opening by Hilton's method, incising the skin and using a director to tear an opening through the gland tissue. This opening was enlarged by passing a pair of forceps, closed, along the groove of the director, and withdrawing them opened. This opening gave exit to two or three fluid-drams of pus. The gland now improved in appearance, but another abscess opened behind the gland and discharged freely. The two abscesses did not communicate. The patient is now convalescent.

OFFICERS OF THE SOCIETY FOR 1884.

President—Richard A. Cleemaun, M.D. Vice Presidents—B. F. Baer, M.D.; W. T. Taylor, M.D. Secretary—W. H. H. Githens, M.D. Treasurer—Alfred Whelen, M.D. Librarian and Curator—T. Hewson Bradford, M.D. Councillors—R. P. Harris, M.D.; Lewis D. Harlow, M.D.; Wm. Goodell, M.D.; T. M. Drysdale, M.D. Publication Committee—John H. Packard, M.D.; James V. Ingham, M.D.; Elliott Richardson, M.D.; B. F. Baer, M.D.

PHILADELPHIA HOSPITAL FOR SKIN DISEASES, 923 LOCUST ST., PHILADELPHIA.—The bathing facilities of this establishment having been greatly enlarged and perfected, are now open and ready for patients sent there by the medical profession. They are under the supervision of an experienced balneologist, and are for such persons only as are sent by their medical attendants with instructions of what form of bath they are to receive. They are intended to fill the place of the many unscientific bathing institutions where patients are often promiscuously steamed, overheated, or unduly chilled, and more harm done by them than good accomplished.

A bathing establishment thus conducted is a great convenience in any city.

BOOK REVIEWS.

TRANSACTIONS OF THE MEDICAL SOCIETY OF NEW JERSEY. 1883. 8vo.

This is an admirably printed volume of 398 pages, containing the minutes of the meeting, addresses, essays, and reports of the district societies. In the minutes we find that:

"Dr. E. M. Hunt introduced the following:

"WHEREAS, The American Medical Association has, at its late meeting, made new requisitions of delegates before their names were allowed to be enrolled;

"*Resolved*, That in nominating delegates to that body, the nominating committee be requested to confer with our Committee on Ethics, and, if they think necessary, with this Society, as to the propriety of this course, and what action needs to be taken in reference thereto.

"After considerable discussion, the vote on the motion on the adoption of the resolution was taken by the raising of hands, with the following result: Ten in favor and thirty-two against. The motion was declared lost."

The Committee on the Curriculum of Medical Study made an important report, but there is no record on the minutes as to how it was received. It was recommended that a board of examiners be appointed, to pass upon the credentials of all persons contemplating the study of medicine in the State, and to examine such persons as fail to present a diploma from some respectable college or university, or a certificate of a completed course in a reputable academy or high school where certain (specified) branches are taught. That this be done by the State Medical Society, and that it require the district medical societies to make it a condition of membership that every physician belonging to or coming into them obligate himself to receive no person under his care as a student of medicine without the certificate of the board of examiners. That the medical societies of the several States be requested to actively coöperate, and that the National Medical Association be requested to signify its approval, and to use its influence to secure the general adoption of such measures.

The address by the President, Dr. John W. Snowden, takes for its theme: "The Advances Made in Medicine by Physical Diagnosis." Dr. Joseph Parrish has an essay on "Insanity and Its Problems," and Dr. George Bayles one on "Causes of Melancholia." Dr. Charles J. Kipp writes on "The Management of Cases of Iritis," and Dr. David Warman on "Professional Fees and Professional Honor;" while Dr. Stephen Wickes, in 124 pages, has an exhaustive article on "Sepulture; Its Methods and Requisites." This article forms a book in itself, and is provided with an admirable index. The report of the Standing Committee gives reports from all but two of the district societies, and these reports give the details of much valuable clinical material, to which is added the obituaries of thirteen deceased members.

TRANSACTIONS OF THE MINNESOTA STATE MEDICAL SOCIETY, 1883.—These Transactions come to us with a very satisfactory muslin-backed pasteboard cover—inexpensive, substantial, and quite sufficient for the purpose. If other societies could only be induced to follow this example, some of their volumes of proceedings would more easily find a place on library shelves. Among the valuable and interesting reports, the one on Practical Medicine discusses diphtheria from various standpoints, giving the special features of individual epidemics as elicited by correspondence from different parts of the State, and includes an account of an advanced case of cerebral softening where the patient had become almost a perfect automaton. The report of the Committee on Surgery gives, among other interesting cases, an admirable lithograph, with details of a case of pistol-shot through the stomach and kidney, with recovery. This report also includes two successful cases of ovariotomy. In the report on Medical Education is given the curriculum of the College of Medicine of the University of Minnesota, and we note that one chair teaches astronomy and physiology, which illustrates probably the printer's idea of the teacher's duties, rather than that of the incumbent. Some of us know how it is ourselves, with respect to printers' ideas. The Necrology embraces four obituaries, and the whole report is so full of interesting clinical details that it would be difficult, without consuming too much space, to give a more extended reference to it.

MEDICO-CHIRURGICAL TRANSACTIONS. Published by the Royal Medical and Chirurgical Society of London. Volumes LXV, LXVI.

Few of our Society Transactions can equal these volumes in their printing, binding, illustrations and general execution. They are filled with valuable material from the most prominent medical men of Great Britain, and the coloring of the illustrations is ahead of anything we have yet attempted. To be sure, the membership comprises over 600 names. The articles are comparatively short, but embrace a wide range of subjects. The cases detailed in Vol. LXV have for the most part already appeared in the current medical literature, but are here given more *in extenso*, with pertinent discussion. We find here Jonathan Hutchinson's two cases, with an illustration, of vaccinia gangrenosa and vancilla gangrenosa; John H. Morgan's two cases of congenital macrostoma, with an illustration; H. Langley Browne's successful case of simultaneous ligature of the carotid and subclavian arteries for innominate aneurism; Spencer Wells' complete excision of the gravid uterus at the sixth month, with epithelioma of the cervix; Reginald Harrison's enucleation of a tumor of the prostate; Berkeley Hill's removal of a fibrous polypus of the bladder, and three cases of tumor arising from skin-glands in the dog, by Dr. Charles Creighton. T. M. Girdlestone recommends highly the long, even tendon from the tail of the kangaroo as having all the valuable properties of the catgut ligature, without any of the defects. Francis Henry Champneys has a third communication on artificial respiration in

still-born children. Dr. Angel Money discusses the great frequency of cardiac murmurs in the puerperal state. Henry Morris has two cases of unreduced and two cases of reduced dislocation of the hip. Dr. Samuel Fenwick discusses the variations in the amount of sulpho-cyanide of potassium in the saliva of persons affected with different diseases. Thomas Bryant reports a successful case of lumbar colectomy. Sir Henry Thompson gives a case of successful removal of tumor of the bladder. Timothy Holmes discusses wounds of the theca vertebralis. Dr. Felix Lemon has two cases of laryngeal growths successfully removed by galvano-caustic operations. Timothy Holmes discusses thyrotomy, and Dr. Sidney Ringer and Dr. Harrington Lainsbury have a lengthy article, with graphic tracings, illustrating the action of the salts of potash, soda and ammonia, on the frog's heart. Sir James Paget gives 7 additional cases of osteitis deformans, and J. N. C. Davies-Colley gives the notes of two cases of malignant pustule, with an admirable illustration of the character of the pustule *in situ*, and its microscopical appearances. This closes the volume.

Volume LXVI contains, in order, the address of John Marshall, as the President, who limits himself to a full and interesting reference to the lives and work of deceased members, which includes, among others, such names as Sir Thomas Watson, our own J. W. Draper, and Charles Darwin. Mr. Richard Barwell has an article on "Dislocation of the Foot with Version and Torsion of the Astragalus;" Mr. Frederick Treves on "Resection of Portions of the Intestine;" Mr. Christopher Heath gives "A Case of Aneurism of the External Carotid Artery," and Mr. Howard Marsh one of "Aneurism of the Arch of the Aorta," with admirable illustrations. Dr. Francis Warner details a case of ophthalmoplegia externa complicating Graves' Disease. Dr. Vasy Lyle describes the endemic hæmaturia of the south-east coast of Africa, agreeing with the other authorities that it is due to the presence of the bilharzia hæmatotrium, but can throw no light upon the manner in which it is introduced into the system—impure water seems to be the most probable source. Dr. Percy Kidd contributes to the "Pathology of Diphtheritic Paralysis." Mr. Alfred Willett and Mr. W. J. Walsham give "A Second Case of Malformation of the Left Shoulder Girdle"—this malformation consisting of a triangular bridge of bone stretching between the spinal column and the scapula, and an abnormal development of the supra-scapular epiphysis, being homologous to the supra-scapular bone of some of the lower vertebrata. The movements of the scapula were restricted, but not prevented, by a hinge at the junction of the scapula and the bridge of bone. It was removed by an operation which resulted in a greatly increased freedom of motion on the part of the scapula. Dr. Thomas Barlow discusses cases described as "Acute Rickets" as probably a combination of scurvy and rickets, the scurvy being an essential, and the rickets a variable element. Mr. Herbert W. Page gives a case of subperiosteal hæmorrhage (probably scorbutic) of three long bones in a rickety infant, and Mr. Arthur E. J. Barker a case of cavernous nævus of the rectum proving fatal in an adult from hæmorrhage. A lengthy and valuable paper by Dr. Samuel West gives a case of purulent pericarditis treated by paracentesis and by free incision, with recovery, which is followed by the statistics of paracentesis pericardii. Dr. Angel Money places on record two cases of gliomatous enlargement of the pons varolii in children. Sir Spencer Wells details a case of excision of an enlarged cancerous kidney; Mr. John Marshall a case of suppurating traumatic hæmatoma connected with the left kidney, and treated by puncture and antiseptic drainage. Mr. Thomas Colcott Fox discusses urticaria pigmentosa, or xanthelasmoidea, and Sir Henry Thompson gives twelve cases of tumor of the bladder. Dr. George Thin, on the bacillus of leprosy, tells us of his investigations in specimens of leprous tissue in three cases from China, and one from the West Indies. The specimens were removed from the living patients, and immediately placed in alcohol. The bacilli were stained as in tubercle bacilli, and were found in the leprous infiltrated skin—none in the sound skin. In one section bacilli were found in the epidermis, in cells which Dr. Thin believes to be white blood corpuscles. In another the bacilli were found in two lymph corpuscles lying in the lumen of a lymphatic vessel. These facts give rise to a theory on his part, that the lymph corpuscles are one of the media by which the bacilli are carried from one part of the body to another. Mr. Seymour J. Sharkey gives a very interesting case of asymmetry of the brain, where the left hemisphere was generally smaller than the right, this inequality being due to the reduced size of the individual convolutions, with the exception that the angular and superior temporo-sphenoidal convolutions were absent. Accompanying this was a marked diminution in size of the right arm and leg, the right arm being rigid. The patient, who died at 25 years of age, from her birth had been left-handed and a little lame, but there was no peculiarity in her eyes or speech. The corpora quadrigemina were well developed, and equal on both sides. The left optic tract was very much smaller than the right, but the right optic nerve was but slightly smaller than the left.

ELEMENTS OF SURGICAL PATHOLOGY. By AUGUSTUS J. PEPPER, M.S., M.B., London; F.R.C.S. Eng.; Fellow Univ. Coll., London; Surgeon to St. Mary's Hospital, Teacher Practical and Operative Surgery at the Medical School. H. C. Lea's Son & Co, Philadelphia, Pa. Pp. 503. Eighty-one Engravings. (From Jansen, McClurg & Co., Chicago, Ill.).

This is one of the series of small volumes for elementary study issued under the title of Manuals for Students of Medicine. It is similar in form to the volume on Applied Anatomy mentioned recently (p. 734) in these columns. These little books fill a gap in medical literature between the bulky systematic treatises on the one hand, and the worthless and trashy *vade mecums* and compends on the other.

Cui bono? asks a critic in a recent number of the *Physician and Surgeon*, since these books contain

nothing which cannot be found in the standard authorities. The answer is simple. Medical college training, like all other instruction, must be made more systematic and special, and around it must grow up a specialized literature adapted to graded teaching. The present volume, beside being a most excellent introduction to any amount of pathological research, is in itself sufficiently complete to prepare a candidate for his final examinations. Its classifications are full and clear, as well as brief. The use of flat-face type in the headings to paragraphs relieves the eye and aids quick reference. These little handbooks are bound in "limp" red covers, are in size about four by six inches, and are altogether tasteful and attractive in appearance. E. W. A.

TRANSACTIONS OF THE AMERICAN GYNÆCOLOGICAL SOCIETY. Vol. 7. For the Year 1882. Philadelphia: Henry C. Lea's Sons & Co. 1883.

Volume 7 of the society's Transactions contains a valuable list of essays and discussions by specialists in the diseases of women, in addition to which is furnished a complete Index to the gynæcological literature of all countries for the year 1881, prepared with the coöperation of Dr. J. S. Billings, U. S. A., in charge of the National Medical Library in Washington.

A list of the contributors to this volume will furnish the best criterion to its value. These are: Thomas Addis Emmett, M.D.; Joseph Tabor Johnson, M.D.; Thomas M. Drysdale, A.M., M.D.; R. Stansbury Sutton, M.D.; Fordyce Barker, M.D., LL.D.; Theophilus Parvin, M.D.; J. Knowsley Thornton, M B.C.N.; Henry J. Garrigues, A.M., M.D.; T. Gaillard Thomas, M.D.; Samuel C. Bussey, M.D.; Ely Van De Warker, M.D.; J. Collins Warren, M D.; William L. Richardson, M.D.; Matthew D. Mann, M.D.; W. H. Baker, M.D. Dr. Thomas' name appears a second time as the writer of a memoir of the late Prof. James Platt White, of Buffalo. E. W. A.

DOMESTIC CORRESPONDENCE.

DAVENPORT, IOWA, December 1, 1883.

EDITOR OF THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

Your editorial on medical advertising, in which you take kindly pains in expressing your views on the pressing question of private institutions for the treatment of diseases, and the "necessity and propriety of such proper advertising as will make known their existence to the profession and the public," meets with my hearty second, and I believe, as you say, that the time has come when the subject should receive the earnest attention of both State and National medical organizations.

There is no doubt that all classes of ailments can be better handled and better results attained under the direct supervision of the doctor in hospitals, than when they are surrounded by so many influences that do not belong to the disease itself or the concomitants of the same.

Where patients are taken to health resorts, home, retreat, infirmary, sanitarium, or even prison, let the disease be constipation, fever, insanity, opium habit, ophthalmia, dyspepsia, or kleptomania, and put under direct charge of the surgeon or disciplinarian, the failure of proper results can be attributed more definitely to the correct cause. The basis of statistics is better defined, and therefore, in skillful and honest hands, the attainment and the standard of the profession will be raised.

Now, to make any distinction of any class as requiring special provisions, and open the gate to the specialist of any particular class, is not "the maintenance of the professional character as applicable to all," and will "invest him with a special advantage inconsistent with the equality of rights and duties pertaining to the profession." Then why be a judge as to whether one class should have special latitude or provision? That should be left to the man who has most studied the requirements of his specialty, and not dictated by the practitioner of other branches. This latitude belongs to him as much as the way he prefers to administer his medicines.

Provision, with its limitations, should be made for all by underlying principles.

The keynote to undignified advertisement is *brag*. The advertisement of special qualifications, present or former position, special attainments, peculiar advantages, extensive travels, unprecedented relationships, etc., etc., are all undignified, out of taste, and justly reprehensible.

The simple announcement of his business and the place for its transaction, when truthfully told, however, does not seem to me to be beneath the dignity of any calling in the world.

The ethics of proper advertising can on this basis be definitely prescribed; a declaration of its limits can be as definitely determined, as the present Code specifies its boundaries.

If "both public and private institutions for the accommodation" of invalids can be instituted, and they can be advertised to "the profession and the public without in the slightest degree violating any principle of ethics" the profession generally don't know how, and we would like very much to be informed, for many suffer from this misunderstanding.

Were the profession allowed to found private institutions and given the latitude in advertising of a first-class college, there would be many institutions of creditable pretensions in the hands of the regular, instead of the blatant quack. Their advantages in this respect over us in the sanitary conditions of their practice, and the extension of the field of operation, renders them close competitors in the number of cures made.

The restrictions in the manner of making oneself known, and the methods adopted under it, are such that the only way to become "eminent" in the profession is to start a college or free clinic, and thus propound to another community the enigma of free service. Does not such a proposition generally nauseate rather than appetize, and is it ever accepted as "explained away" by the projector?

As to the announcement of limitation of office

hours or special practice, I cannot see that this act either announces to the public that he is more physically able for practice the whole day, or that he is a more proficient practitioner of medicine; if anything, it would acknowledge a bodily weakness and a necessity of restricting his work, or an inability to maintain more than a part of general practice.

I agree that his announcing that he is an oculist, gynæcologist, dentist, etc., smacks of a short cut to his specialty, and it is by far the strongest presentation, to indicate that he is a member of general medicine and still belongs to it, but as to his announcing a superiority by thus designating his business, it can only be by inference at best.

I offer these thoughts as one interested in the determination of the true relation of the profession to the public, and one who labors within the pales to sustain the dignity of our calling to the best of his ability.

With respect, I am yours, E. H. H.

FOREIGN CORRESPONDENCE.

LONDON, December, 1883.

At the last meeting of the Cambridge Medical Society, a recent specimen was shown of union by bone in fracture of the ——— capsular neck of the femur. Professor Humphry pointed out that in all cases of fracture of the neck the portion adhering to the head became absorbed, and the head became united immediately to the shaft behind the trochanters He showed several examples taken from the pathological museum. He maintained that many such examples were looked upon as cases of impacted fracture, an accident he thought impossible.

An unique structure has been erected by the Metropolitan Asylum's Board for the reception and isolation of patients suffering from infectious fevers on plans which mark a distinct departure from old ideas. The diseases admitted include not alone cases of typhus, typhoid or scarlet fever, but measles, diphtheria and small-pox. Personal inquiry having been made by the architect to the local Government Board, and visits made to the hospitals in Berlin, Heidelberg, Dresden, Paris and other cities, a pavilion containing small wards and isolation rooms has been erected adjacent to the London Fever Hospital. As yet, owing to want of funds, only three rooms have been completed, but when finished the structure will consist of twelve ward-rooms, and two nurses' or administrative rooms. Externally, the pavilion presents a bright and cheery aspect—a sort of Swiss cottage. Within, everything is spotlessly clean, glazed, highly polished and without corners. Germs will be unable to find lodgment, and the accumulation of dirt an impossibility. Where the walls join the flooring or the ceiling, or form a junction with each other, instead of the angle common in all houses, a curve is made of special concave bricks. Moreover, the walls being of glazed brickwork of different and pleasantly harmonized colors, they can be easily washed and disinfected.

Again, the whole of the doors and window frames present no ledge or crevice, all the woodwork being rounded and curved, and capable of being cleaned without the least difficulty. The flooring is constructed of concrete in a framework of iron joists, and covered with oak blocks—the combination, when thoroughly bees-waxed and polished, creates a floor which has the advantage of extreme solidity and imperviousness. By a very simple but ingenious contrivance, merely that of having deeper framework than ordinarily at the sill, each window can be kept open at the central meeting bars for the admission of fresh air. The fanlights at the upper part of the windows are skilfully contrived to fall inwards when required, and to preserve uniformity of temperature; the glazing throughout the building is of stout sheet glass, in two thicknesses, with an interspace of three-quarters of an inch. Altogether the patients will have from 150 to 180 square feet of floor space and about 2,000 cubic feet each; their wards will be heated by ventilating grates having inlet flues which will allow of a constant passage of warmed fresh air. Of the many novel features, the pavilion stands clear of the ground, and on a series of strong brick arches that rest on a square basement of concrete, the earth around which is sloped away. Dampness is thus obviated; the admission by the floor ventilators of bad air is avoided; there is a constant circulation of good air beneath and around the entire structure, and there is none of the mischief arising from the comparatively stagnant angle formed by the junction of the surface soil with the main walls. In short, the committee have obtained a building in which dank sweats are impossible, where fresh air finds ready welcome, and from which foul air is promptly and effectively expelled.

Lately there have been several cases of false and unfounded charges of malpractice brought against members of the profession in the United Kingdom. A testimonial has been started in order to recoup Messrs. Bower and Keates, who had an action for damages brought against them by the father of a child who died after having tracheotomy performed for diphtheria. The father was told the only chance to save the child's life was to suck the tube, which had become blocked. He did so; the patient lived two days after the operation. The parent alleged he also suffered from diphtheria, and the nature of the disease his child suffered from was not explained to him. The evidence did not prove the man really suffered from anything more than an ordinary sore throat, and the verdict was given for the defendants. It is now proposed that a fund should be raised by the profession for the defense of members against whom charges may be brought.

The recent discussion about the weight of Turgienieff's brain has led to the publication of an article on the subject of the weight of brains by a Russian scientist, M. Nikiloroff, in the *Novosti*. According to him the weight of the brain has no influence whatever on the mental faculties. The average weight of a man's brain is, according to Luschka, 1.434 grammes, of a woman's, 1.272 grammes. The maximum weight is said to be 1.600 grammes, and the minimum 800 grammes. The brain of the celebrated mineralogist, Haussmann, weighed 1.206 grammes. It ought to be remembered that the sig-

nificance of the weight of the brain should depend upon the proportion it bears to the dimensions of the whole body and to the age of the individual. Byron died at the age of thirty-six, and the great geometrician Gauss, at seventy-eight years of age; the brains of the two should, therefore, not be compared. It is equally important to know what was the cause of death, for long disease and old age exhaust the brain. To define the real degree of development of the brain, it is, therefore, necessary to have a knowledge of the condition of the whole body, and as this is usually lacking, the mere record of weight possesses little significance.

STATE MEDICINE.

SANITARY REPORT FROM CONNECTICUT.

BY DR. C. W. CHAMBERLAIN, SECRETARY OF STATE BOARD OF HEALTH.

MORTALITY IN SEPTEMBER.

	HARTFORD.	NEW HAVEN.	MERIDEN.	WATERBURY.	NEW BRITAIN.	BRIDGEPORT.	NORWICH.	NEW LONDON.	MIDDLETOWN.	KILLINGLY.
Total deaths	86	86	26	37	23	46	27	19	19	6

The sanitary history of the month is, on the whole, more favorable than that of the same month in previous years. The death and sickness rate is not large except in a few places where the prevalence of some one form of disease to an unusual degree swells it, and even then there are no generally diffused types nor any that can be strictly called epidemic, except it be malarial diseases in some instances; nor does the rate in any of the cities reach a degree to cause alarm. The decrease in diarrhœal diseases partially accounts for this, as the table shows a decrease of nearly half from 1882, or 60 in place of 33 this year. This indicates also a corresponding decrease in the number sick—on an average eight cases for each death. In the table two or three classes of diseases only are considered, so that the columns if added do not equal the total number of deaths given. Thus the deaths from the causes given in the first column equal 55, the deaths in the month 86, the difference, 31, indidates the deaths from other causes not enumerated, as cancer, Bright's disease and the whole list not included in our discussion. The month is treated as if it were a year, so that the rate of September in 1883 is compared with that of September of previous years. The only trouble is in the February of leap-year, which is one day longer than other Februarys.

The prevalence of diphtheria in Hartford shows increase during the month, since then it waned, and now is prevalent as ever, *i. e.*, at the date of this writing. The mortality was 10 in June, 20 in July, 28 in August, and 32 in September—90 in all. So far, defective local plumbing, and especially unventilated drainage pipes in the house, and the use of cesspools and privy vaults in unclean by-streets and localities, still seem to be the principal contributing agencies. That it is a filth disease is shown by repeated instances. In one case where several members of one family died from this cause, the sink pipe had discharged into the cellar for a long time, creating a putrescent mass and saturating the soil where no sun nor air could reach it. Unfortunately, the cause was not discovered until the mother and all her children had perished. Similar instances are reported often, and greater care is the result among the thoughtful and wise. In looking up the surroundings where several members of a family have died from diphtheria, and scarlet fever as well, I have again and again found similar conditions. Oftener, however, the sink drainage percolates through the cellar wall or runs down half outside it and half inside. One would not suppose that privy vaults used by a whole family would be tolerated in a corner of the cellar, yet I have several times found such a state of affairs where there had been repeated deaths from filth diseases in families that have successively occupied a house. The outbreak of diphtheria or scarlet fever where local conditions have been suspected, is a strong proof of their unsanitary condition.

The increase in the prevalence of typhoid fever is seen forcibly when the mortality is compared with that from malarial fevers. Thus, in the present year the deaths in the cities reported are, from typhoid fever 23, all varieties of malarial, 8; in 1882, typhoid fever 21, malarial 23; in 1881, typhoid 7, malarial 18 (this is for September). The decrease in the mortality from malarial fever is quite regular. It is true that the total from typhoid is increased by its prevalence in Waterbury; but in quite a large area the reports show a similar increase of typhoid and decrease of malarial fevers. In Waterbury malarial diseases never have been the governing type, as far as I can learn. The amount of typhoid fever in Waterbury has, as is usually the case, been exaggerated. The dry weather, low water, and soil upheaval for sewers are all the factors yet charged. Perhaps there is some general influence whose laws we do not yet know that should be added to these.

The outbreak of scarlet fever in South Manchester and the unusual prevalence of diarrhœal diseases in children and adults in comparison with the rest of the State, are corroborative of the statements last month relative to the areas of sewage deposit and decaying organic matters exposed by the unusually dry season,

The scarlet fever in Hartford is adjacent to the cases of diphtheria, as far as I can learn.

Diphtheria is reported from New Hartford—several cases in one family—with a tendency to invade the larynx. Typho-malarial fever is reported from several towns near Manchester, and several cases also from Manchester by Dr. Griswold, who relates a case of suicide by the use of some salt of cobalt, not a usual agent for this purpose. A few cases of diphtheria are reported from Pleasant Valley, also Riverton, Avon and Suffield—one fatal in the latter place. In Winsted it is stated to be somewhat common. Scarlet fever is reported as prevalent to some extent in New Canaan, and to have appeared in Avon, in addition to the places already mentioned, Measles are not so common; from Hampton and New Canaan mention is made of the presence of the disease. Westport has, in addition tosome malarial cases, a few of whooping-cough and tonsillitis.

From Cheshire several deaths are reported from typho-malarial fever; malarial and typhoid fevers are reported from Plainfield, but less of the latter than usual. This is one of the towns recently invaded (comparatively) by malaria. Also from Avon; Suffield, where the number is the same, but one case of typhoid was fatal; New Canaan the same, but no typho-malarial, of which there was one case in Suffield; a sudden death on the road from heart disease occurred in Hampton and a machinery accident in Saugatuck.

An unusually healthy month is reported from Haddam, Greenwich and Oxford, with little disease except malarial, and also from Plainville and Willington. Several cases of lung fever are reported in one or two places—more than is common for this season.

HEALTH IN MICHIGAN.

Reports to the State Board of Health, Lansing, by observers of diseases in different parts of the State, show the principal diseases which caused most sickness in Michigan, during the week ending December 8, 1883, as follows:

NUMBER OF OBSERVERS HEARD FROM, 41.		For preceding week.
DISEASES ARRANGED IN ORDER OF GREATEST AREA OF PREVALENCE.	Per cent. of observers who reported the disease present.	Per cent. of observers who reported the disease present.
Rheumatism	71	61
Intermittent fever	66	55
Neuralgia	63	66
Influenza	49	41
Tonsilitis	46	50
Bronchitis	46	61
Consumption, of lungs	46	52
Remittent fever	34	36
Pneumonia	32	30
Diarrhœa	27	30
Inflammation of kidneys	24	25
Whooping-cough	22	18
Erysipelas	28	30
Scarlet fever	20	23
Measles	15	16
Typhu-malarial fever	15	18
Typhoid fever (enteric)	15	11
Diphtheria	15	23
Inflammation of bowels	15	18
Dysentery	11	7
Puerperal fever	7	9
Inflammation of brain	5	5

For the week ending December 8, 1883, the reports indicate that intermittent fever, rheumatism and influenza increased, and that bronchitis, erysipelas and diphtheria decreased in area of prevalence.

At the State Capitol, the prevailing winds, during the week ending December 8, were southwest; and, compared with the preceding week, the temperature was slightly lower, the absolute and relative humidity and the night ozone slightly more, and the day ozone the same.

Including reports by regular observers and by others, diphtheria was reported present during the week ending December 8, and since, at fifteen places, namely: Antwerp, Big Rapids, Detroit, Leslie, Mattawan, Manistee, Monroe, Niles, Novi, Pierson, Pontiac, Port Huron, Riley Center, Six Lakes, Ypsilanti. Scarlet fever, at twenty-three places: Adrian, Battle Creek, Clifford, Detroit, Ensley, Ironton, Kalamazoo, Manistee, Monroe, Maple Valley, Medina, Memphis, North Shade, Newport, Owosso, Oxford, Pontiac, Port Huron, Plymouth, Reynolds, Roxand, Salem, Winfield. Measles at nine places: Alpena, Brooklyn, Clinton, Cedar Springs, Charlevoix, Eagle, Gaines, Monroe, Richmond.

HENRY B. BAKER, Secretary.

Lansing, Dec. 12, 1883.

NECROLOGY.

THAYER, SAMUEL WHITE, A.M. M.D. L.L.D., was born at Namtree, Vt., May 21, 1817; died at Burlington, Vt., Nov. 14, 1882. He was the oldest son of Dr. Samuel White Thayer and Ruth Packard Thayer, formerly of Thetford, Vt. His early life was passed in his native town until 1832, when his parents removed to Thetford for the better advantages of Thetford Academy. Here he fitted for college, intending to take a college course at Dartmouth, but circumstances proving unfavorable, he commenced the study of medicine in his father's office in 1835. His first course of lectures he took at Dartmouth. In 1837 he was elected demonstrator of anatomy at Woodstock, (Vermont Medical College), which position he occupied until 1841. He graduated at the latter institution in 1838, and in 1840 settled for medical practice at Northfield, Vt. He remained here until 1854 in an extensive practice of medicine and surgery, when he removed to Burlington, Vt., partly for the purpose of assisting to sustain the Medical Department of the University Vermont. A medical school had existed here from 1823 to 1836, during which period about 114 students had graduated from it, but finally it closed for want of support. Ever since 1850 Dr. Thayer had been persevering and untiring in efforts to enlist sufficient influence to reorganize the school.

In 1853, with the assistance of President W. Smith, ex-President Wheeler, Prof. Benedict, and others, a corporation was formed, and the following Board of teachers were elected, viz.: Professor of Surgery, S. W. Thayer; Professor of Theory and Practice, Orrin Smith; Professor of Anatomy, Levi Bliss; Professor of Chemistry, Ezra Carr.

Some of these failed to appear, and Dr. Thayer, calling to his aid Dr. Nelson, sustained the college during its first term, delivering the first course of lectures. He was almost alone during its second course of lectures, himself delivering two lectures a day for four months, upon nearly all the branches of medicine, besides attending to a large private practice. As the college grew in favor and made advancement, he made a present to it of a large collection of specimens which he had collected for its museum. He served with energy and ability as Lecturer, Dean, Secretary, etc., in the college until 1872, when he was made Emeritus Professor of Anatomy.

When the war of the Rebellion broke out, he was appointed by Gov. Fairbanks Chairman of the State Board of Medical Examiners; his associates being Dr. E. E. Phelps, of Windsor, and Dr. S. Newell, of St. Johnsbury. He examined every medical officer of Vermont regiments, and many enlisted men. In 1864 he was appointed by Gov. Smith Surgeon General of the State of Vermont. In this new office, which had been created by the Legislature the same year, without material or precedent, he proved himself very efficient, with every arrangement necessary for providing for the sick and wounded, whether in the field or in hospitals at home. He assisted in establishing three military hospitals, at Montpelier, Brattleboro and Burlington, furnished with capable and efficient medical officers. Dr. Thayer also held a commission as Assistant Surgeon, U. S. A., and at the close of the war was breveted Medical Director.

In May, 1870, Dr. Thayer went West to Minnesota and along the line of the Northern Pacific R. R., and organized a medical service for the care of the employes constructing the road, such as has since been adopted by many other roads.

In 1872 he went to the Pacific coast in company with the officials of the N. P. R. R., along its proposed route to its terminus in Oregon. While on this route, he, with his accustomed energy, made a large collection of the woods, grains and grasses native to the region, which he afterwards exhibited at the Vienna exposition, and allowed to remain there by request of the Commissioners. He returned to Burlington in 1873, to his home, and resumed his practice of medicine and surgery.

In 1866 he received an honorary degree of A.M. from Dartmouth College.

In 1877 the University of Vermont conferred upon him the honorary degree of LL.D.

In 1867, or about that time, an accident happened to Dr. Thayer, which threatened his life, and seriously affected his health ever afterwards. In amputating a gangrenous leg he cut or scratched his hand, through which wound, slight as it was, he received poison into his system, septicæmia, from which he never fully recovered, and which had much to do in breaking down his constitution, and thereby inducing the disease that caused his death. Previous to this accident he had shown a fondness for travel, and had in 1855 visited Nova Scotia and other British provinces. In 1867 he made a trip to Europe, spending some months traveling in England, Scotland, Ireland, France, Germany, Switzerland, and Italy.

In 1869 he went, in company with ex-Governor Smith, Rev. Dr. Lord, C. C. Coffin and others, through the wilds of Minnesota, Dakota, and along the route of the Northern Pacific Railroad.

In 1874 he made a second trip to Europe. In 1876 he went to Bermuda, returning via West Indies. He also made a tour through Florida and other Southern States.

In 1878, in company with his long time friend, Col. John L. Merriam, he made a tour around the world, going via San Francisco, Yokohama, and India, and returning through Europe.

In 1882 he made his last long journey, to St. Paul, as delegate to the American Medical Association; from there with his friend, Col. J. L. Merriam, to Montana and to the Yellowstone Park, returning to his home in Burlington in July.

Soon after his return he was attacked with the painful disease which caused his death, gangrene of the foot, senile gangrene. He suffered with great fortitude the most intense agony, attended by skillful medical men, who combined the office of friend with medical adviser.

Dr. S. W. Thayer was a very skillful surgeon, the leading surgeon of the State. His operations include nearly or all of the most difficult which have ever been performed in Vermont. He was, as a general practitioner, a man of good judgment, of rare good sense. He was remarkably unselfish, and generous to a fault. He died universally lamented. The poor, the rich, all classes mourned him as a dear personal friend.

At his burial the entire city did him reverence—flags at half-mast, all places of business closed, all the bells of the city tolled. His bier was covered and his grave was filled with the choicest flowers, all moistened with tears. So departed our dear friend, our beloved physician.

Dr. Thayer was married Jan. 6, 1841, to Sarah Louisa, daughter of the late John A. Pratt, of Windsor, and she, with one son, Dr. Charles P. Thayer, survives him.

O. F. FASSETT, M.D., of Vermont.

ELIOT, JOHNSON, A.M., M.D., P.H.D., one of our best known physicians, was born in the city of Washington, August 24, 1815; died at his residence, 510 E Street, of pneumonia, Dec. 30, 1883.

He was descended from early and distinguished colonial settlers of Massachusetts and Maryland. His father, Samuel Eliot, Jr., of Puritan stock, through the "Apostle to the Indian," and nephew of Andrew Eliot, President of Harvard College, came to Washington shortly after it was selected and laid out as the permanent seat of the United States Government, about the time, or shortly before, Mr. James Greenleaf, Dr. Frederick May, Judge William Cranch, and others from Massachusetts settled here. Samuel Eliot engaged in business, and a few years later married Mary, daughter of Gov. Thomas Johnson, one of the three commissioners for laying out the city of Washington, and ex-Governor of Maryland, the personal friend of General Washington,

and throughout the Revolution one of the most active and influential patriots, who was appointed by President Washington Associate Justice of the Supreme Court of the U. S. in 1791. A first cousin of Mrs. Eliot, Louisa, second daughter of Joshua Johnson, married John Quincy Adams in 1797.

The subject of this notice was educated in the District of Columbia at the McLeod Seminary. Losing his father at 13 years of age, he entered the drug store of Dr. McCormack, and there studied pharmacy. In 1839 he began the study of medicine with Dr. Thomas Sewall, and about the same time received an appointment of steward in the Washington Naval Hospital; but the duties of that position did not interfere with his medical studies. He attended lectures in the Medical Department of Columbia University, where he graduated M.D. in 1842, and immediately after was appointed Demonstrator of Anatomy in that institution.

He opened an office on Seventh street, between G and H, where, by strict attention to his duties, he speedily acquired business.

He became a member of the Medical Society of the District of Columbia in 1843, and the same year joined the Medical Association of the District of Columbia.

He, with Dr. Noble Young, were the originators of the Medical Department of the University of Georgetown. Dr. Eliot was assigned the chair of anatomy, which he filled acceptably until he was, at the request of the Faculty, transferred to the chair of surgery. The latter position he held until he retired from the active duties of teaching, in 1876, accepting the position of emeritus professor of surgery and professor of clinical surgery. While not a fluent speaker, his exact knowledge of anatomy, and the subjects he taught, enabled him always to interest his hearers.

For the last sixteen years of his active connection with the college, he served as Dean of the Faculty.

For many years his practice was extensive and exacting, and early in his professional career he became recognized as one of the leading surgeons of the District. He has performed with success many capital, and some of the most difficult operations in surgery, including that of ovariotomy four times. Dr. Eliot has been for years connected with the management or on the surgical staff of Providence Hospital, Columbia Hospital for Women, and the Children's Hospital, which position he held at the time of his death. He was well read and widely informed on all matters connected with his profession, was careful in diagnosis, dextrous and skillful in operations, attentive and conscientious in the discharge of all his duties as a physician.

Besides his addresses at college openings and commencements, which were published, he contributed some valuable articles to the *American Journal of Medical Science*, and to other medical periodicals, including the "Transactions" of this Society. The following list of his publications, though known to be incomplete, is nevertheless presented:

Valedictory to the graduating class of the Medical Department of Georgetown University. 14 pp. 8vo. 1856.

Address delivered at the eighteenth annual Commencement of the Medical Department of Georgetown University. 12 pp. 8vo.

Address delivered at the twenty-third annual Commencement of the Medical Department of Georgetown University, 11. pp. 8vo. 1872.

Excision of Inferior Maxillary Bone, Left Side. Transactions Medical Society of the District of Columbia, Vol. V, p. 53-54. 1878.

Palato-Pharyngeal Tumor. *Amer. Jour. Med. Science*, Vol. 78, pp. 70-78. Phila. 1879.

Reprint of same. 3 pp. 8vo. 1879.

Successful Ovariotomy. *National Med. Review*, Vol. I, p. 4. 1879.

Dr. Eliot was always an active supporter of medical organizations, and a frequent participant in discussions, and presented various pathological specimens to this society, and read written reports of cases.

Beside the societies named, he was a member of the Pathological Society of Washington, organized in 1843; a member of the Section on Medicine of the "National Institute," which met at the Smithsonian Institution, and at one time sent delegates to the American Medical Association.

As an instance of his fidelity to professional duty and courage under trying circumstances, we will mention a single fact: After one of the severe battles of the late war (I think Chancellorsville), a call was made for volunteer surgeons. Dr. Eliot immediately provided himself with all the appliances necessary for immediate surgical dressings and for surgical operations, repaired to the front, and reported to the officer in command his readiness to serve as surgeon. He was at once assigned to duty. The whole night and next day were spent in most laborious professional work, with no rest and meager refreshments. The operating-room was a deserted house. The doctor worked on, regardless of self, absorbed in his desire to relieve as many of the wounded as possible. He neither knew or thought of the position of the contending armies. Suddenly he was informed that the Rebel cavalry was surrounding the hospital. He still continued his labors, and among those who had received his attention during the night and forenoon were several wounded Confederate soldiers. No parley, however, would be listened to, and Dr. Eliot was marched off a prisoner. He represented the humanity of his science so ably that his case was promptly reported as a non-combatant volunteer surgeon, and he was in a few hours paroled by Stonewall Jackson.

Dr. Eliot joined the American Medical Association in 1858, and attended its meetings in 1865, '67, '68, '70, '73, '74, '75, '76, and 1880.

He has at different times filled most of the offices in the Medical Society of the District of Columbia, including the presidency in 1874. He has also held most of the offices in the Medical Association of the District, and has been a most constant supporter of medical ethics. He was a member and Vice-President at the time of his death of the Alumni Association of Georgetown University. He was professionally connected with the Central Dispensary as consulting surgeon from its organization in 1871.

Dr. Eliot was a uniform and earnest friend of young practitioners, supporting, advising and directing them in their management of difficult cases. He loved his profession, and desired that every member should win and enjoy in it an honorable position.

He was himself the soul of honor, and never intentionally gave offense or took any undue advantage of a brother practitioner. In 1861, '62, '63 and '64 he served as physician to the city small-pox hospital, and in the year 1869 was appointed one of the surgeons to the "Metropolitan Police" of the city, and held the position to the time of his death. For many years he has been consulting surgeon to "St. Ann's Infant Asylum." In 1850 Dr. Eliot was united in marriage to Mary John, daughter of John Llewellyn, Esq., of St. Mary's county, Maryland, who with six children, three sons and three daughters, survive him. His oldest son, John Llewellyn Eliot, studied medicine, and for some years has been in practice with his father. His oldest daughter is married to Dr. Valentine McNally, chief clerk of the Ordnance Department.

A special meeting largely attended was held by the Medical Society of the District of Columbia on the announcement of Dr. Eliot's death, at which many members spoke of the long acquaintance with the deceased, and the great regard for his character. The judgment of the meeting was voiced in a series of resolutions, which were published in the daily papers. The Faculty of the Medical Department of the University of Georgetown held a meeting and passed resolutions of regard for the memory of the old and valued collegian. The "Alumni Association of Georgetown University," also held a meeting and passed resolutions of respect for his memory. The Medical Board of Providence Hospital, the Board of Directors of the "Childrens' Hospital," and the Directors of "Columbia Hospital for Women," each held special meetings and passed appropriate resolutions appreciative of Dr. Eliot's life and labors. His funeral took place Wednesday morning, January 23, 1884, at 10 o'clock, from St. Aloysius church, where a funeral mass was celebrated and a brief sermon preached by the Rev. Father Murphy. The church was well filled by the profession and friends of the doctor, many of whom joined in the long cortege as it marched to Mount Olivet Cemetery, where the remains of the good physician were placed to rest.

J. M. T.

St. Louis Medical Society.—At a recent regular weekly meeting of this society, the following is reported as a part of its proceedings:

Dr. Atwood, from the Committee on Ethics, reported the resolution of Dr. Pollak, offered at previous meeting, protesting against the custom of physicians holding chairs in medical colleges advertising themselves in the circulars and catalogues of the colleges. The report states that such advertising is not only a violation of the Code of Ethics, but highly reprehensible, tending to lower the standard of the profession and to bring into disrepute medical colleges; also, that the reference in such circulars to clinical practice and free dispensaries was also a violation of the Code. The report was adopted.

MISCELLANEOUS.

THE TUBERCLE BACILLUS.

[To the Editor of the *Canada Lancet*.]

Sir:—I send you the following lines, which you may thing worth inserting: "A saturated watery solution of carbolic acid, even though it acts as long as fifteen minutes, is not sufficient to arrest the development of the tubercle babilli."—*Braithwaite*, July, 1883; p. 73.

What say you, Koch, can this be true?
(The very statement seems to chill us);
Is there, then, nothing we can do
Against this terrible bacillus?

A molecule, brandishing fell darts,
Arm'd, in the air, to meet and kill us;
Or burrowing in our vital parts,
Oh, dread, invincible bacillus!

Monster! in microscopic space,
Who doth with seeds of death instil us;
Hast thou no vulnerable place,
No heel like that of old Achilles?

Has science nought for such a foe,
(Just as new hope began to thrill us)?
Come! who will strike a mortal blow
And vanquish the renowned bacillus?

Yours, &c.,
Thomas W. Poole, M.D.

Lindsay, Nov., 1883.

Surgical Diseases of the Kidney.—At the annual meeting of the British Medical Association, Mr. Clement Lucas opened a discussion on "The Surgical Diseases of the Kidney, and the Operations for their Relief," of which the following is an abstract: He commenced by stating that the greatest advances in the treatment which had taken place of late years, were those made in the indefinite border-land which separates medicine from surgery. In was in this barren and desolate tract we must look for fresh discoveries. Ovariotomy and the various operations upon the intestines and stomach he put forward as instances of work recently advanced in this territory, but he claimed as the most remarkable incident of this decade, the sudden light which fell upon the profession in its relation to renal disease and the rapid growth and recognition of renal surgery. The credit of having awakened a new interest in renal diseases, and of having, by experiment on the lower animals, made sure of his ground, was due to the late Professor Simon, of Heidelberg, who in 1869 successfully performed nephrectomy for the cure of a fistula of the ureter following ovariotomy. Since then, extirpation of the kidney has been performed upwards of a hundred times. The operation of nephrotomy has been much more frequently undertaken, and the removal of a stone from the kidney, which used only to be attempted when a sinus or tumor existed, has been several times successfully performed before the kidney had suffered any severe damage.

In casting a glance over diseases of the kidney to

determine which might admit of surgical treatment, it was necessary to exclude at once all such diseases as attack equally the two organs; hence, the various degenerations, included under the name of Bright's Disease and lardaceous disease, must ever remain outside the province of renal surgery. On the other hand, conditions which disturb the functions of one organ only, for the most part admit of relief by operation.

Painful moving or floating kidney being only a mechanical disturbance, admits of relief only by mechanical means. Simple exploration and replacement through an incision in the loin would probably be found sufficient, in the majority of cases, for the cure of this condition, the adhesion resulting, serving to retain the organ in position. Stitching of the capsule to the parietes, or, as it is termed, nephroraphy, is a somewhat serious, but still simple, undertaking. In eight cases in which it has been performed the patients all recovered and were relieved. There might still be cases where intense suffering was experienced and where the other means had failed, which would suggest nephrectomy. Martin, of Berlin, had in six cases removed floating kidneys through the peritonæum, and four of these recovered.

Hydronephrosis, a dilatation of the pelvis and calices of the kidney with watery fluid as a result of obstruction below, admitted of surgical treatment when one-sided. After detailing the various conditions of the ureter, congenital and acquired, which might give rise to this condition, the author suggested these cases should be first aspirated, then cut down upon and drained through the loin; the cyst-wall being stitched to the parietes. Finally, should the fistula fail to close, the remains of the kidney might be returned through the loin.

In women these tumors had been often mistaken for ovarian tumors and had been operated upon as such. Being movable and not forming adhesions till late, some might advocate ventral nephrectomy for these cases before drainage, but such treatment would entail more risk than the method advocated. Abdominal nephrectomy for hydronephrosis will, however, show better results than nephrectomy generally.

Large isolated cysts of the kidney having no communication with the pelvis were rare. They should be aspirated, and afterwards drained through the loin.

Hydatids of the kidney, also rare, had a tendency to discharge themselves through the pelvis. When forming tumors, they could generally be cured by aspiration or syphon-tapping.

Pyonephrosis, which resembles hydronephrosis anatomically, but contains pus instead of urine or watery fluid, when unilateral falls under renal surgery. The double pyelitis, with suppuration and distension, which commonly resulted from stricture and enlarged prostate, the author said was inappropriately named "surgical kidney." He suggested the term reflux pyelitis as better expressing this condition. Reflux pyelitis when one-sided was due to some obstruction in the ureter, and then often gave rise to a large pyonephrosis. Other causes of unilateral pyonephrosis were calculus and strumous pyelitis. After speaking of the diagnosis and stating that these tumors were more adherent, and gave rise to more pain and constitutional disturbance than hydronephrosis, he said that nephrectomy for pyonephrosis had been performed twenty-eight times, and of these seventeen recovered and eleven died, but it was most worthy of notice that among these twenty-eight cases six had previously discharged their contents through a fistula in the loin, and all these recovered. Hence, he argued, it was better to drain a pyonephrosis before performing nephrectomy.

Neoplasms of the kidney could only be treated by nephrectomy, and if this were performed early, there might be a good chance of permanent benefit. Generally they were too large to be removed except through the peritonaleum, but of five cases removed through the loin, four recovered. Out of sixteen removed by ventral incision, ten died and six recovered.

Calculus of the kidney offered an excellent field for surgical interference, but the difficulty was to make sure of the diagnosis. Many cases of supposed calculus would turn out to be strumous kidneys. Two cases were related in which the kidney was explored, and even deeply punctured, but no ill-result or rise of temperature followed, and the wounds nealed primarily. Several cases of nephro-lithotomy were recorded in the Clinical Society's Transactions, and two cases had been performed successfully at Guy's Hospital during the present year. When the kidney was much dilated and damaged, it would be a question whether it might not be better to remove it.

After briefly alluding to injuries to the kidney, which, though not included under the title of the paper, might suggest nephrectomy, the author proceeded to speak of some details in operating. He recommended for the lumbar operation a combination of two incisions which he had employed as giving the most room, viz.:—an oblique incision higher than the colotomy incision within about half an inch of the last rib and parallel with it, and a vertical incision on the outer margin of the quadratus lumborum extending from the upper edge of the last rib to the iliac crest. For the transperitoneal operation, Langenbuch's incision external to the rectus muscle was to be preferred to the median incision, as it enables the operator better to reach the kidney through the outer layer of meso-colon.

In conclusion, he urged, that antiseptic exploration of the kidney through the loin is a simple and not at all a dangerous operation, which may be undertaken without anxiety in any case where calculus is suspected; that it is generally wiser to tap and drain fluid tumors of the kidney before proceeding to remove the diseased organ; that when nephrectomy is decided upon, the extraperitoneal operation through the loin should always be chosen for any tumor it is possible to withdraw through the limited space at disposal; finally, if this course be adopted, the transperitoneal operation will be reserved for large solid tumors, and, perhaps, some floating kidneys.—*British Medical Journal.*

CASE OF BASILYSIS.—In the Section of Obstetric Medicine, at the annual meeting of the British Med-

ical Association, 1883, Dr. J. Halliday Croom described a case where this operation was found necessary:

Among the recent improvements in operative midwifery, the operation of basilysis, as a means of comminuting the fœtal basis cranii, deserves to occupy a prominent place. Devised by Dr. A. R. Simpson some years ago, and carried out by him in practice, it has, in my opinion, quite fulfilled the expectations he formed of it. I gladly take an opportunity of a recent case, which occurred under my care in the Maternity Hospital, to bring this operation under the notice of the Section. The case was as follows:

S. W., a primipara, aged 26, was sent to the Maternity Hospital on the forenoon of Sunday.

At the time of her admission she was well advanced in the second stage of labor; the membrane had ruptured early in the morning, and a loop of the cord had prolapsed in advance of the head. I saw her shortly after admission, and found the conditions as described; and further found, on abdominal palpation, a very prominent uterine tumor; the head at the brim, but unengaged, and back to the left. There were no fœtal heart-sounds to be heard.

On vaginal examination, the head was presenting, the membranes ruptured, and a loop of cord prolapsed and pulseless. The occiput was to the left, and the sagittal suture transverse. The conjugata vera diameter, gauged by the diagonalis, measured slightly less than two and a quarter inches. The pelvis was a distinct rickety one. The indications, therefore, for reducing the head were obvious. This I did with the basilyst in the following way: With the assistance of Dr. Barbour, the head was steadied thoroughly at the brim, and the basilyst introduced at the most centrally presenting part of the right parietal bone. The cranial vault was easily pierced, and the instrument pressed down through the cerebral substance to the base of the skull. While Dr. Barbour kept the head perfectly steady, I screwed the basilyst home into the base, and, closing the handle, easily effected separation of it. The head immediately collapsed, and was pushed by Dr. Barbour through the brim, with slight aid on my part with the crotchet. Indeed, the use of the crotchet was almost unnecessary, as, after the collapsed head was well pushed into the brim, its extraction was mainly accomplished by the hands *per vaginam*, aided by suprapubic pressure.

On examination of the head after birth, it was found that the basilyst had entered the right parietal bone, and then passed down to the basi-occipital, just behind the foramen magnum, and the base was found to be splintered both laterally and anteroposteriorly. The disintegration of the base of the skull was remarkably complete, as the recent preparation which I now exhibit shows; and the great diminution in the bulk of the head is obvious from the fact that suprapubic pressure was of itself sufficient, with but little aid from the crotchet, to push the head through the brim.

Remarks.—The introduction and working of the instrument are simple enough, but there is one point which, in a former case, offered some difficulty; namely, the doubt, after the basilyst has pierced the vault, as to whether it goes directly to the base. This is more apparent than real, for, if the head be well steadied, and its position distinctly made out, there can be but little risk in pushing the instrument straight on in the proper axis. Of course, in cases of extreme flexion, it will be easier to strike the center of the base than in a case of flat pelvis, where marked Naegele obliquity is combined with extension.

This is illustrated in the case I have just recorded, where the basi-occipital bone was struck instead of the sphenoid; but, as the case shows, the result was none the less satisfactory. In any case, the risk of missing the base is very slight. It has been urged against this method of comminuion and delivery, that some instrument for extraction in addition to the basilyst is required. First of all, let me point out that, in the case in point, with a head perforated at the occiput, and with a two inches and a quarter brim, suprapubic pressure was almost enough to effect delivery, and secondly, it must be kept in view that a second perforation of the base can always be performed when necessary, reducing the whole head to a veritable pulp, and allowing it to pass through the pelvis with the aid of the hands and suprapubic pressure alone. It has, therefore, the advantage over cephalotripsy and other forms of embryulcia, that delivery is accomplished without the application of any instrument external to the head.—*British Medical Journal.*

List of Changes in the Medical Corps of the Navy During Week ending January 12, 1884.

Surgeon D. McMurtrie ordered to the Naval Rendezvous, Philadelphia, Pa.

Surgeon A. F. Price detached from the Receiving Ship St. Louis on the 15th, and ordered to the U. S. S. Ossipee on the 22d.

Past Assistant Surgeon A. C. H. Russell ordered to the U. S. S. Ossipee on the 22d.

Past Assistant Surgeon H. C. Eckstein detached from the Naval Hospital, Philadelphia, and ordered to the Receiving Ship St. Louis.

Past Assistant Surgeon Howard Wells from the Naval Rendezvous, Philadelphia, and ordered to the Naval Hospital, Philadelphia.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department United States Army, from January 4, 1884, to January 11, 1884.

Brown, P. R. Captain and Assistant Surgeon: assigned to duty at Fort Huachuca, A. T. (Par. IX., S. O. 119, Department of Arizona, Dec. 27, 1883.)

Havard, Valery, Captain and Assistant Surgeon: assigned to duty in charge of office of Medical Director, Department of Texas, during the temporary absence of that officer. (Par. II., S, O, 164, Department of Texas, Dec. 31, 1883.)

Egan, P. R., First Lieutenant and Assistant Surgeon: upon reporting of relief to proceed without delay from Fort Huachuca, A. T., to Fort Apache, A. T., and report to the commanding officer for duty at that post. (S. O. 119, Department of Arizona, Dec. 27, 1883.)

OFFICERS OF

THE AMERICAN MEDICAL ASSOCIATION

AND OF ITS SEVERAL SECTIONS, 1883-4.

PRESIDENT.

Dr. AUSTIN FLINT, SR., of New York.

FIRST VICE-PRESIDENT.

Dr. R. A. Kinloch, Charleston, S. C.

SECOND VICE-PRESIDENT.

Dr. T. B. Lester, Kansas City, Mo.

THIRD VICE-PRESIDENT.

Dr. A. L. Gihon, United States Navy.

FOURTH VICE-PRESIDENT.

Dr. S. C. Gordon, Portland, Maine.

PERMANENT SECRETARY.

Dr. Wm. B. Atkinson, 1400 Pine St., Philadelphia.

TREASURER.

Dr. R. J. Dunglison, Philadelphia.

LIBRARIAN.

Dr. C. H. A. Kleinschmidt, Washington, D. C.

Place of meeting, 1884, Washington, D. C.; Time of holding meeting, first Tuesday in May.

CHAIRMAN COMMITTEE OF ARRANGEMENTS.

Dr. A. Y. P. Garnett, Washington, D. C.

ASSISTANT SECRETARY.

Dr. D. W. Prentis, Washington, D. C.

BOARD OF TRUSTEES FOR JOURNALIZING THE TRANSACTIONS.

Drs. J. M. Toner, Washington, D. C., President;
E. M. Moore, Rochester, N. Y.; Leartus Conner, Detroit, Mich.;
J. H. Packard, Philadelphia, Secretary;
H. F. Campbell, Augusta, Ga.; A. Garcelon, Lewiston, Me.;
P. O. Hooper, Little Rock, Ark.;
L. S. McMurtry, Danville, Ky.; J. H. Hollister, Chicago, Ill.

OFFICERS OF THE SECTIONS:

"Practice of Medicine."

Chairman—Dr. John V. Shoemaker, Philadelphia, Pa.;
Secretary—Dr. W. C. Wile, Sandy Hook, Conn.

"Obstetrics and Diseases of Women."

Chairman—Dr. T. A. Reamy, Cincinnati, Ohio; Secretary—Dr. J. T. Jelks, Hot Springs, Ark.

"Surgery and Anatomy."

Chairman—Dr. C. T. Parkes, Chicago, Ill.; Secretary—Dr. A. O. Walker, Detroit, Mich.

"Ophthalmology, Otology and Laryngology."

Chairman—Dr. J. F. Chisolm, Baltimore, Md.;
Secretary—Dr. J. L. Thompson, Indianapolis, Ind.

"Diseases of Children."

Chairman—Dr. Wm. Lee, Baltimore, Md.; Secretary—Dr. W. R. Tipton, Las Vegas, N. M.

"Oral and Dental Surgery."

Chairman—Dr. T. W. Brophy, Chicago, Ill.; Secretary—John S. Marshall, Chicago, Ill.

"State Medicine."

Chairman—Dr. Deering J. Roberts, Nashville, Tenn.;
Secretary—C. W. Franzoni, Washington, D. C

Committee on "Necrology."

Chairman—Dr. J. M. Toner, Washington, D. C.

ORIGINAL ARTICLES.

REPORT OF THE STANDING COMMITTEE ON METEOROLOGICAL CONDITIONS AND THEIR RELATIONS TO THE PREVALENCE OF ACUTE DISEASES.

BY N. S. DAVIS, M.D., LL.D., OF CHICAGO, ILL., CHAIRMAN OF THE COMMITTEE.

[Presented to the American Medical Association in session at Cleveland, Ohio, June 7, 1883.]

In the report which your committee had the honor of making to the Association at its last annual meeting, it was stated that the plans had been completed and the work actually commenced on the first day of January, 1882, for securing the results of three parallel series of coincident observations in twelve different localities, namely: Boston, New York, Philadelphia, Baltimore, Mayport, New Orleans, Cincinnati, Chicago, St. Paul, Pittsburgh, Denver and San Francisco. To these were subsequently added Lansing, Mich., and Lawrence, Kansas. One series consists of the observations and records made at the Signal Service stations in the several places named, full abstracts of which have been kindly furnished to the chairman of your committee under the order of the official head of that bureau of the general government. Another series consists of a daily record of the ozone or active oxidizing agents in the atmosphere in the same localities, made by competent scientific men whose names were given in the report of last year. In this series all the observers are furnished with uniform test papers, and uniform instructions with scales and blanks, under the supervision of Prof. J. H. Long, of the Chemical Laboratory of the Medical Department of the Northwestern University (Chicago Medical College) in Chicago. In most of the places this series of observations has been continued through the year 1882, the time covered in this report, with entire faithfulness, and the results neatly tabulated for each month by Prof. Long, which tables constitute a part of this report. A few of the observers, located in the central part of large cities where the results were almost entirely negative, became negligent, as will be seen by inspecting the tables in detail.

To this series was also added in Chicago a daily record of the organic or albuminoid matters in the atmosphere, as carefully determined by Prof. Long, whose complete observations commenced on the first of September, 1882, the result for the first six months of which will be given in this report as tabulated and explained by himself. So far as your committee are aware, this is the first record of reliable determinations of the quantity of organic matter in the atmosphere *daily* through an entire year, made in this or any other country.

The third series of observations consists in ascertaining and recording the date of commencement of all acute diseases by physicians in active practice in the same localities where the other series of observations are in progress.

In the report of your committee last year, it was stated that a sufficient number of active practitioners had volunteered their services in all the places selected except in New York and Philadelphia. In the latter only three, and in the former not one, out of a large number of members of the Association who were applied to, appeared willing to engage in a work of much profit to themselves, and of great importance in obtaining data for determining more accurately the real causes of disease. In using the expression "profit to themselves," we do not, of course, mean direct pecuniary profit, but what is of more value to the physician, namely, the acquisition of a habit of closer inquiry concerning the origin and progress of the diseases he is called upon to treat, and of much greater exactness of mental discipline, with a corresponding increase of professional knowledge. The whole number who did volunteer their services for this part of the work was forty-one; of whom only eleven, however, actually reported the results of their observations at the end of the year. Small as is this number, the facts they furnish, taken in connection with the other series of observations, are of much value, as will be seen in the sequel. But if the work of your committee is to be continued, the number of workers in this department can be steadily increased until the results are all that could be desired. By the three series of observations and records just described, we are placed in possession of the facts concerning all appreciable conditions of the atmosphere, including the barometric pressure, temperature, moisture, direction and velocity of winds, rainfall, sunshine and clouds, in twelve localities, in one of which is added the oxidizing and organic constituents, for every day and night of 1882. And to a limited extent, in the same localities for the same

period of time, the facts in relation to the beginning and prevalence of acute diseases. These facts, observed and recorded by independent workers, acting coincidently under uniform instructions, are capable of analysis and study in several important directions. First, we find much that is of interest and value in comparing the various items contained in the meteorological part of the records with each other, and tracing both the relations and absolute changes connected with the different seasons of the year. And when the records have been carried through a series of years, deductions of still greater interest can be made by comparing the variations of all these items in one year with those of another.

Second, by comparing the date of commencement of the several acute diseases with the atmospheric conditions, we are enabled to determine with much greater accuracy the direct agency of certain of these conditions in determining the degree of prevalence of several important endemic diseases, as typhoid fever, pneumonia, and bowel affections of children. In some of the localities we have been able to carry this comparison through three successive years, thereby ascertaining very definitely the reasons why the same disease (pneumonia, for instance) reaches its highest point of prevalence in January of one year and in April or May in another year, in the same community and under the same sanitary measures. We have also been able to find very satisfactory reasons why there were four or five times as many cases and deaths from typhoid fever in the same community in 1881, as in 1880; and 33 per cent. more than in 1882, notwithstanding the logical inference and expectation based on the popular germ theory of its propagation would be, that the extraordinary production and diffusion of the supposed germs during the epidemic of 1881, would be followed by a still greater prevalence of the disease in 1882. To give the detailed results of the analytical examination of the three series of records before us would weary your patience, as they can be appreciated only by careful reading in print. Consequently we will pass them, and only detain you with a brief but interesting statement from Professor Long in regard to the progress and results of his daily observations concerning the ozonic or oxidizing agents and the organic matters, and the relations of these two classes of agents to each other.

"Observations on the amounts of free ammonia and nitrogenous organic matter present in the atmosphere have been carried out during the past nine months by the method proposed by Chapman (*Chem. News*, 1870, page 65), and elaborated by Remsen (*Nat. Bd. Health Bull.*, Sept. 11, 1880).

In brief, the method consists in aspirating a certain definite volume of air through an absorbent tube containing coarsely powdered pumice-stone, which possesses the property of absorbing nitrogenous gases. If the contents of the tube be now thrown in a retort with pure distilled water and a little carbonate of soda, on the application of heat what is known as free ammonia distills over. This includes the ammonia existing in *ammonium* compounds.

Then, after driving off the free ammonia, if a strong solution of caustic potash and permanganate of potash be added, what is known as albuminoid ammonia distills over. This ammonia does not exist as such, but is formed by the action of the strong oxidizing solution on nitrogenous matter.

The ammonia, as it distills over, is collected and tested by the Nessler reagent, as in the examination of water by the Wauklyn method.

As to the method itself and results obtained, there are several points suggested by this long trial which might be mentioned. Prof. Remsen showed in his paper that by careful work fairly comparable results could be obtained, and in a number of preliminary experiments tried by myself a year ago, and reported on at the last meeting of the Association (through Dr. N. S. Davis), I was able to verify this statement. Subsequent work showed that the liability to error is about the same as in the testing of water by the method just referred to.

While examining these sources of error several very interesting papers appeared in print, and observations I had made were fully confirmed by them. More recently, these sources of error in the determination of free and albuminoid ammonia have been pointed out very fully by Prof. J. W. Mallet (*Am. Chem. Jour.*, Vol. 4, Nos. 4 and 6), and precautions for avoiding them as far as possible suggested. Experience had already pointed most of these out to me. The condensation of the ammonia evolved is a very important part of the process, and more difficult than usually supposed. To save the ammonia, it is necessary to distill very slowly, and to pass a good stream of cold water through the condenser.

At the commencement of the investigation (April, 1882) another source of error suggested itself. I found that in operating on artificially polluted air, the amount of ammonia obtained by treating the pumice stone in the retort directly with the permanganate solution was much greater than the sum of the free and albuminoid ammonia obtained in the usual way. I convinced myself of this fact by a number of experiments, but other duties interfering, I was obliged to drop the investigation for the time, and some months elapsed before I could take it up again.

In the meantime I learned that a similar phenomenon had been observed by Prof. Remsen, while engaged in investigating the water supply of Boston a year before, and in a paper by Mr. Marsh (*Am. Ch. Jour.* IV., 3,) experiments illustrating the same point are described. It appeared, then, that in the distillation certain nitrogenous compounds were volatilized before being converted into ammonia. In my experiments with an artificial atmosphere the amount of organic matter present was very large, and it would be hardly fair to assume that a natural atmosphere would show the same results. During the past few months I have carried out a number of parallel experiments to decide this point, and without going into details, I will simply say that very little, if any, volatible albuminous matter seems to be lost in the first distillation. In a number of tests I could observe no increase of ammonia by direct treatment with the oxidizing liquid. In other tests a slight increase was noticed, but the excess was within the

limits of error of observation. Other parallel tests are still in progress, and perhaps the atmosphere will show different results at different times.

On the whole, then, it may be said, the method is fairly accurate and gives good results, but when one takes into consideration the very minute quantities of matter dealt with, it will readily be perceived that the greatest care must always be observed in manipulation. In the hands of a single observer results can be obtained which are comparable with each other, but I fear that results obtained for free ammonia by different observers could hardly be compared with fairness, as the difficulty of measuring such minute traces with anything like accuracy is very great, and different persons would approach the true result with different degrees of sharpness. This I consider the weakest point in the method. Of course large volumes of air might be aspirated, but there are practical objections in the way of aspirating more than 100 liters daily.

A few words as to results of observations. The amounts of free and albuminoid ammonia expressed in grammes per thousand cubic meters of air are as follows:

The results are means of daily observations.

	Free.	Alb.
September	.051	.110
October	.021	.093
November	.022	.085
December	.024	.105
January	.022	.091
February	.044	.096
March	.019	.073
April	.016	.059

It will be noticed that the free ammonia is always much smaller than the albuminoid. In September a large amount of free ammonia was registered, and this I can not now account for. In February also the amount is large. On several days during the fall of sleet in this month considerable quantities of free ammonia were detected. On many occasions I have noticed that a large amount of albuminoid ammonia could be connected with a very bad odor coming from the direction of Bridgeport (a dirty manufacturing part of the city).

Another point noticed seems to me of considerable interest. Several times during the winter a certain window of the college dissecting room was left open by the janitor, and by this means the external air became contaminated immediately over the point where my aspirator was at work. I found that at such times there was a marked increase in the amounts of free ammonia, but scarcely any change in the albuminoid. These results suggested several additional experiments. I placed a piece of decaying meat in a shallow dish, covered the bottom of the dish with water (leaving the surface of the meat exposed, however), and allowed the whole to remain in a closed room for some days. A number of examinations of the air were then made by the above method, all of which showed a considerable increase in the amount of free ammonia, but very little in the albuminoid over what might be expected from the external atmosphere. Now, without removing the meat, a Siemens ozone generator was put in operation in the room, and sufficient ozone generated to give a slight reaction on test paper, Schönbein and Thallium, suspended near the aspirator.

The ozonizer was operated at short intervals during a day, and at the same time air was drawn through a pumice-stone tube for examination. This showed a marked reduction in both free and albuminoid ammonia. This experiment was followed by other similar ones, all of which went to show that the moist organic matter could be oxidized into something not capable of yielding ammonia.

About a week later the experiments were repeated. In the meantime the meat had become thoroughly dry and the stench had nearly disappeared. An examination of the air now showed a decrease in the free ammonia, and a considerable increase in the albuminoid as compared with the previous experiments. Ozone papers failed to show a reaction now, when suspended as before, although the generator had been kept at work a much longer time. These results seem to indicate that dry decaying matter is capable of producing more albuminoid ammonia than moist, a probability which has been pointed out by Dr. Carmichael and Prof. Remsen. During the summer I expect to carry out more extended experiments on this question.

JOHN H. LONG,
Chemical Laboratory of Chicago Medical College."

FINANCES.

In regard to expenditures, your committee report that, on the completion of the first six months of his work in determining and recording the organic constituents of the atmosphere, $250, being one-half of the special appropriation made for that purpose, was drawn from the treasury and paid to Professor Long, leaving of that appropriation $250 still in the treasury, to which the professor will be entitled as soon as the year's observations are completed. For the other departments of your committee's work no money has been drawn from the treasury during the past year, although bills to the amount of $108.60 have been paid by the chairman of your committee. Sixty dollars of this was for one Kilo Thallium Metal imported from Germany free of duty, the rest for printing and blanks, for all of which vouchers in the form of receipted bills accompany this report. At the date of our last annual report there remained in the treasury an unexpended balance available for the committee's expenditures of $290.28. If the sum just named as the amount expended during the past year is paid, there will still remain of the original appropriation an unexpended balance of $181.68 in the treasury. Your committee will therefore close this abstract of their report by asking the Association to adopt the following propositions:

First, That your committee be authorized to furnish their report for publication as a part of the Transactions of the Association, and to continue the investigations now in progress, with the privilege of drawing on the Treasurer for so much of the unexpended balances of former appropriations as may be necessary during the coming year.

Second, That the thanks of the Association be

tendered to the Superintendent of the Civil Service Bureau, Gen. Hazen, for the enlightened and generous aid he has rendered by causing your committee to be furnished with full abstracts of the meteorological records made at the several places selected, and that he be requested to continue the same favor during such time as the committee may desire.

All of which is respectfully submitted.

N. S. DAVIS, Chairman.

P. S. Details of observations and analysis of the same will be given in the next number of the JOURNAL.—EDITOR.

REPORT OF A CASE OF DOUBLE-HEADED MONSTROSITY.

PRESENTED BEFORE THE MARION COUNTY MEDICAL SOCIETY, INDIANAPOLIS, IND., NOV. 14, 1883.

BY JOSEPH EASTMAN, M.D., PROFESSOR OF DISEASES OF WOMEN AND CLINICAL SURGERY IN CENTRAL COLLEGE OF PHYSICIANS AND SURGEONS.

[Reported by Dr. H. I. Raymond.]

There is a two-fold interest in the subject-matter of monsters. First, as it presents itself to the mind of the practical obstetrician; and second, as it calls into exercise the subtle reasonings of the speculative physiologist.

The simple scientific investigation of the subject may in the end yield as practical results as the investigation of the matter for purely clinical purposes, inasmuch as the scientific teratologist may some day afford some rational clue to the semiology of monster formation, and the physiologist be enabled to suggest much looking toward the prevention of psychical impressions likely to modify the normal processes of nutrition and growth.

The clinical features of this subject-matter will be best brought out by simply relating the history of the present case.

The size of patient's abdomen was enormous, so much so as to excite in her own mind an apprehension of twin conception. To remove suspense, she called me in as her medical adviser ten days previous to her expected confinement. I could map out but one body, and that with difficulty, owing to the excessive accumulation of the liquor amnii.

I assured the patient that the head of the child was downwards; that nothing was wrong; no twins; simply an enormous accumulation of waters.

One week later, the patient was confined at night, the first intimation of labor being rupture of the membranes with escape of one and a half buckets of water, literally flooding the bed.

I was in attendance immediately, and found a dry labor in a primipara of nineteen. The abdominal swelling had disappeared; the uterus was reduced in size; but one child could be mapped out by external palpation, and but one head felt by vaginal examination.

The head soon advanced to the perinæum, the chin rotating under symphysis pubis; labor then only slightly progressive.

The pains were inefficient; three hours had been spent in waiting.

Forceps delivery was decided upon, and the instruments applied. On making traction, great difficulty was encountered in the withdrawal of the head.

The forceps were then removed, and the finger of the accoucheur was passed up the parturient canal, for the purpose of hooking down the child's arm. But the finger found no axilla. It detected a hard, round object, sensibly a second head. By conjoined manipulation but one body could be mapped out.

The pains were hard, but not sufficient to effect delivery. The first head was now brought up sharply over the pubis. The second head pressed against the perinæum. Forceps were applied and delivery effected.

During these manœuvers the accoucheur's attention was abstracted for the moment from the administration of the chloroform, which was done by the friends, and, as it happened, the patient passed into the third stage of anæsthesia, so that she was profoundly under the influence of the anæsthetic at the time of delivery of the second head, and it is thought this condition of complete muscular relaxation enabled the operator to deliver such heads with but a slight abrasion of the perinæum—so slight as to require no surgical treatment. There was neither any laceration of the cervix uteri. The diameter of the second head, and neck of the first head of the monster, as apposed in the genital outlet, measured a little more than six inches.

The subject of monsters in relation to practical obstetrics is treated of very meagerly in works on midwifery. It is frequently dismissed with the statement that such developments do not usually carry to full term, and no difficulty, therefore, will be met with

in their delivery, which teaching is not of much help to an accoucheur dealing with a full-sized double-headed monstrosity weighing 10 pounds.

It should be remarked further, that this particular monstrosity was not simply a fusion of two complete corporeal organisms, nor yet an abnormal development of one, but presented a perfect and entire and fully developed fœtus with an annexation of an extra cephalic extremity, with its own proper cervical vertebræ.

There was, however, blending or fusion of the respective dorsal portions of the columns.

In speculating upon such freaks or perversions of nature as are exhibited in her monstrosities, the endless subject of nævi materni or mothers' marks comes to the front, albeit no vascular connection exists between the mother and fœtus in utero.

A case, apropos, occurred in my practice about two years ago, which I will relate.

I was asked to treat a man with perineal fistula, existing in the line of incision in right lateral lithotomy.

I ordered poultices to be applied. The wife herself applied the poultices, and attended to their removal and reapplication with assiduous care.

Ten months later I attended this lady in confinement, and delivered her of a male child that presented as perfect a case of hypospadias as I had ever seen.

The urethral outlet of the child was exactly at the point on the right of the median raphé corresponding to the point at which the urethral fistula in the father existed.

REMARKS.—The American Cyclopædia informs us that Isidore Geoffroy Saint Hilaire restricted the term monster to "congenital anomalies of conformation, involving change in the form, structure, volume, position, and number of parts."

He recognized two classes of monsters. 1st, those whose make-up included the elements of only a single individual. 2nd, those whose conformation involved parts, complete or incomplete, of two or more individuals.

The present monstrosity would come under the second variety of his classification, in which were present a complete individual, with parts of an incomplete individual annexed.

Injection of fluid into the œsophagus of the neck to which the body rightfully belonged, caused meconium to be extruded through the anus, but no fluid could be made to regurgitate from the stomach up the gullet of the second head, and on dissection no œsophagus for the second head could be found.

The arterial systems freely communicated, since alcohol injected into one common carotid saturated both systems. Dissection revealed two hearts enclosed in a single pericardium.

POTT'S DISEASE.

THE MECHANICAL TREATMENT OF DORSAL CARIES WITH GREAT DEFORMITY.

BY CHARLES E. WEBSTER, M.D., CHICAGO.

[Read before the Chicago Medical Society.]

There are already before the profession a great number of forms of apparatus for the treatment of Pott's Disease. Too often the inventor claims to have discovered the only perfect machine that is universally applicable.

It is not for the purpose of adding to this list that I prepare this paper, but for the purpose of discussing the merits of a particular form of apparatus which is applicable to a particular class of cases.

On visiting the office of any great orthopædic surgeon and watching the run of his practice, it will be discovered that many with dorsal caries, however they may have been treated, grow progressively worse. In fact, one candid gentleman remarked, "We can't expect to do much with these patients." I propose to consider the mechanical problem presented by such a hopeless case, and to demonstrate the form of apparatus which is best adapted to its treatment.

In chronic non-suppurative spondylitis, when after years an indefinite number of the dorsal vertebræ have been invaded, there are both general and local causes that perpetuate the disease. The general health of the patient is bad. Whether this arises from a peculiar diathesis or is the result of the disease, is a question the discussion of which is unnecessary to the present inquiry. The local causes arise from irritation of various kinds. This may be due to the motion of the heads of the ribs, to the lateral and back-and-forth motion between the vertebræ, and to the pressure of the superincumbent parts.

It is unnecessary to detail all the resulting changes. The crumbling of the spinal column lowers the head and shoulders, pressing the sternum forward

and the spinous processes backward. The capacity of the thorax is diminished. Let us presume that this process, with the commonly resulting curvature, has progressed until the ribs reach the crest of the ilium, and the patient is anæmic and emaciated.

In the treatment of such a case we are compelled to consider the general condition of the patient; the diminished capacity of the chest; the local irritation by the ribs, by lateral motion, and by the superincumbent weight; lastly, the resulting deformity.

Whatever may have been the original cause of the trouble, the general health is undoubtedly impaired by the pathological processes taking place. If the caries can be arrested, the nutrition, circulation, and nervous condition will improve.

It is of the first importance that the treatment should permit exercise in the air, as well for the indirect advantage of having the patient occupied by pleasant pursuits as for the direct advantage to his general health. This applies with full force only to cases where the age of the patient renders his confinement particularly irksome, and his size prevents him from being readily carried out of doors. Such medicines may be given as, in the judgment of the physician, are indicated. It may be assumed, however, that the better the judgment of the physician, the less the medicine that will be given, for a good diet, fresh air, and the arrest of the progress of the disease by suitable support, are the chief requirements of the case.

The capacity of the thorax, naturally diminished by the disease, is generally still more reduced by surgical interference. Corsets, braces and plaster-splints having, by their lacing, strapping and bandaging, flattened down the sternum and twisted the yielding ribs and cartilages around each other in such a way as to materially interfere with the respiratory function.

In such a case any further restriction of the thorax is unwise.

The motion of the heads of the ribs in respiration undoubtedly acts as an irritant. It can be readily prevented by constricting the chest, but for reasons just stated, this is inadmissible, and it may even be necessary to encourage such motion at the expense of temporarily increased inflammation for the sake of additional lung room. Were the size of the chest little affected this precaution might be unnecessary.

Lateral motion is self-limited by the irregularities of the vertebræ, as well as by the production of connective tissues binding together the diseased bones. The application of a posterior splint with a view to limiting the lateral and antero-posterior motion, is inexpedient for the following reasons:

It is difficult to make a splint bear evenly around an abrupt curve.

If applied, it cannot be rendered efficient without constricting the chest.

Pressure will be unequal, and liable to cause additional irritation.

Theoretically, it is inapplicable, for the greatly deformed spine cannot be bent straight, thus throwing the weight of the superior parts on to the transverse and articular processes.

Clinically it fails.

The prime factor in perpetuating the caries is downward pressure.

It is constant while the body is in the vertical position, and the jar of every step; the weight of every article of clothing; the strain of every movement of the arms adds to its potency. This is demonstrated as well by the action of the patient as the course of the disease. The patient supports himself by the hands on the knees, the elbows on the table, by resting the head on the hands, and finally is obliged to assume the horizontal position in order to relieve himself of the weight which is grinding out the bodies of his vertebræ, and allowing the crumbling spinal column to topple over in the direction of the least resistance.

It is necessary to support the weight of the parts above the point of disease. This is best done by placing the patient in the horizontal position. As previously shown, this mode of treatment may be counterindicated.

The weight to be supported consists of the head, arms, and that portion of the trunk superior to the part of the spine which is diseased. The only part of the body affording a base of support for apparatus to sustain this weight is the pelvis. In individuals whose hips are not sufficiently flaring to give a proper base, other modes of treatment must be adopted.

For the reduction of the deformity several methods are employed. The posterior splint producing pressure on the point of curvature. Suspension by the head and axile, and rest on the back in the horizontal position. By either method the deformity can be reduced. In the first, by crowding down the spines or lateral processes of the vertebræ, and packing the diseased bones more closely together. In the second, by drawing them forcibly apart. In the third, by slight extension and the posterior splint combined.

The first method is liable to increase the inflammation by adding another cause of irritation to those already in action, althongh it may compensate by diminishing some existing causes, as the lateral motion.

The second method gives the most immediately gratifying results, markedly diminishing in a few minutes the most glaring deformity. It is likewise the most dangerous. The tearing apart of the diseased bones is liable to increase the existing inflammation, cause hæmorrhage, or lead to meningitis of the cord. Neither is it demonstrated that the reparative process can fill in the breach between the bones and thus effect anchylosis.

Lying on the back may be inexpedient for general reasons previously stated.

On account of these considerations, it seems preferable to use such an amount of extension as shall prevent pressure on the diseased surfaces, and that this slight extension should be constant through a long period of time, thus gradually permitting the bones to accommodate themselves to a more normal position without endangering the life of the patient, increasing his sufferings, or delaying his cure. In general, it may be stated, that any treatment of the deformity as such is bad surgery.

To summarize: The general condition of the pa-

tient is such that exercise is necessary. The deformity is such that constriction of the chest is inadmissible. Irritation by the motion of the ribs is unavoidable. A posterior splint may be harmful, and is unnecessary if the two ends of the spine can be kept in a fixed relation by apparatus that removes the weight from the diseased bones. The deformity itself is not a proper object of treatment. From these premises I deduce the following proposition:

In advanced cases of Pott's disease, with great deformity of the thorax, support of the weight of the parts superior to the disease, with slight extension, is sufficient treatment, while other interference may be dangerous.

In view of this proposition, I have devised, constructed, and by several years of trial practically demonstrated the usefulness of the following apparatus, which consists of the parts shown in the cut:

(*c*) The pelvic base carrying on either side crutches to support the arms and a rod at the back to support the head. (*b*) The neck piece permitting the lateral motion of the head. (*a*) The head piece permitting the nodding motion of the head.

The pelvic base is of sheet steel, hammered to accurately fit the parts to which it is applied. It extends from just below the anterior superior spine of the ilium on the one side along the crest of that bone, across the sacrum and along the crest of the other ilium, terminating at a point corresponding to that at which it commenced. For an adult the metal should be about $^1/_{16}$ of an inch (.0016 m.) in thickness.

From this pelvic base arise on either side short steel crutches, with carved wooden tops fitting the axilla, which slightly raises the shoulders, and thus supports the weight of the arms. At the back is a rod of malleable iron, double below, the parts being spread about four inches (.1 m.) to afford a firm attachment, and terminating above with a deep socket for the pivot of the neck-piece. This rod is made to follow accurately the curve of the spine without pressing upon it.

To remove the pelvic base, throw the shoulders forward off the crutches and turn the apparatus to one side, raising it slightly, when it readily slips off. The reverse of these manœuvers puts it into place.

The neck piece consists of an arc of iron, from the middle of which is a dependent stem fitting into the socket previously mentioned. At its ends are vertical screws slotted at the top for the bearings of the head-piece. The head-piece being lifted out of its bearings and drawn forward, the neck-piece can be taken out of its socket Thus the head supporter can be entirely removed at the convenience of the patient while sitting or lying down.

The head-piece may be made of copper, steel, or vulcanized rubber. *It must fit perfectly.* If of metal, it is to be tinned or silvered on the inside to prevent corrosion, and lined with some thick fabric to protect the skin from chill, and the uncomfortable sensation of accumulated perspiration. It should be stiffened by bosses opposite the mastoid processes. *Exactly in the line* of the axis of the occipital condyles should be attached metallic studs, the necks of which fit into the slots in the screws of the neck-piece. By these screws the heighth of the head can be adjusted.* The weight of the entire apparatus for an adult is about three pounds, or perhaps two ounces less (1120 grms.)

The chief advantage of this apparatus consists in its perfect adaptability to a class of cases hitherto the opprobrium of the profession. With slight modification it might be made to meet the requirements of other classes of cases now treated by other methods.

The motions of the head are of great convenience to the patient, and can be permitted in every case, except in disease of the cervical region. In fact, the nodding motion might be permitted in every case, except in disease of the occipito-atloid articulation. The parts in contact with the body are perfectly fitting and quite rigid, thus reducing the local irritation to the minimum.

I have diligently searched the literature of the subject, and as far as I can learn, the support of the spine by suspension of the head and arms from apparatus resting on the pelvis without constriction of the trunk, the head supporter permitting the free nodding motion of the head on the axis of the occipital condyles, as well as the perfectly well fitting pelvic base fully open in front, are new and original inventions, and I would respectfully invite a more extended test of their practical value.

The price of the apparatus (making a general statement) varies according to the skill of the mechanic employed, etc., and is estimated to be from $25 to $50.

---

*For detail description of head supporter see *Boston Medical and Surgical Journal*, May 18, 1882, page 469.

EXTIRPATION OF THE SPLEEN.

A TRANSLATION, WITH REMARKS,

BY A. N. BLODGETT, M. D., BOSTON.

The recent momentous strides in the science and art of surgery, which have resulted in the development of the antiseptic and the cultivation of the aseptic systems, have materially diminished the perils of operative interference, and in the same ratio have enlarged the boundaries of the legitimate domain of the surgeon, and have opened new fields, and added new diseases to the list of those formerly considered amenable to treatment by this means. The cavity of the knee-joint, formerly one of the most dangerous portions of the human body, is now incised and drained without hesitation; the thorax is opened with impunity; the pericardium is aspirated; the abdomen is laid open and its inmost recesses explored for intestinal obstruction; the ovaries, and indeed the entire internal female generative system is excised, amputated, ligated, cauterized, and subjected to treatment in many other ways which would have struck terror to the heart of many a courageous operator of a few years ago.

So rapid have been the advances in surgical science in this direction, that some enthusiastic operators look forward to the time when the cavity of the skull shall become accessible to mechanical treatment, and every organ in the body shall be deemed suitable to surgical manipulation. Already the kidneys are within their reach, the stomach is resected, and portions of the intestine excised with recovery. The spleen, however, still remains beyond the present limits of justifiable operative procedure. How long this will continue to be true is a question which is awakening increasing interest in the minds of medical men.

In this connection, the following summary of all known cases of surgical interference in the way of excision or amputation of the whole or any part of the spleen, may be of sufficient importance to warrant it a place in the columns of an American journal. It is a translation of a review upon this subject by Dr. Albert Blum, in *Archives General de Médicine*, June, 1883, and is given in full, as follows:

Deeply seated in the left hypochondrium, between the diaphragm, the kidney and the stomach, concealed and protected beneath the lower ribs, the spleen would seem to be safe from any traumatic violence. Its great vascularity, the important role which it plays among the viscera as a uropoietic organ would lead one to suppose that the spleen was outside the legitimate domain of surgical attacks. Experience and the facts derived from medical literature demonstrate, however, on the contrary, that the spleen is not exempt from accidental injury, and with the last few years certain of the bolder surgeons have deliberately attempted its extirpation by means of direct operative interference. We desire in this review to ascertain what are the chances of a favorable result from splenotomy as the result of a traumatic injury, as well as in those cases in which its removal is attempted by the surgeon on account of some disease of the organ.

(*a.*) Splenotomy consequent to injury or hernia of the spleen.

We have collected the details of seventeen observations detailed in the monographs of Magdelain, Simon and Zesas. We have arranged these cases in chronological order:

1. Franz Rousset (Traité nouveau d'hystérotomotokie, Paris, 1581,) relates that Dr. Viard extirpated the spleen successfully in two cases of wounding of the left side, in which the organ had become dislocated and partially degenerated and atrophied.

2. Clarke (Ephem. Nat. Curios. Obs., 1676). This was a case of attempted suicide in which a wound was inflicted with a knife in the left hypogastric region. A portion of the epiploön, the intestines and the spleen immediately protruded from the wound. The surgeon, who was called three days after the injury, returned the intestines to the abdomen, resected the spleen and a portion of the epiploön, and united the edges of the wound with sutures. The patient made a rapid and complete recovery.

3. Purmann (Chirurg. Curios., 1680). A man fell from the top of a house, striking upon the left side, and in his fall a knife, which he held in his hand, was thrust into the left side in such a manner that when it was withdrawn, a portion of the spleen came with it, and the epiploön protruded from the wound. This was immediately replaced. The side was much swollen and was treated by means of cataplasms. In six weeks the patient was well.

4. Nicholas Mathias (Ephem. Med. Physicæ, 1684, "*De exciso liene ex homine sine noxa*"). A man received a wound from a knife in the left hypochondrium. On the next day Mathias was not able to replace the spleen, which protruded in the shape of a hernia. After applying a ligature he extirpated the spleen, and three weeks after the operation the patient was well and able to resume his occupation.

5. Hannaeus (Ephem. Nat. Curios., 1698). A peasant received a blow from a knife in the left hypochondrium, and the spleen partially escaped from the wound. The medical attendant, who first saw the case two days after the injury, applied a dressing, and the patient recovered with no impairment of his health from the accident.

6. Ferguson (Philosophical Transactions, 1737) was called to a man who had received a blow from a knife. He found the spleen lying outside the wound, and already cold, black and devoid of vitality. He applied a ligature about the mortified part, and resected 3½ ozs. of the spleen. The patient recovered perfectly.

7. Wilson (*Chelius Handbuch der Chirurgie*, 1743) reports that at the battle of Wettingen, in 1743, a soldier received a wound from which the intestines and the spleen protruded. The intestines were returned to the abdominal cavity, and the entire spleen was removed. The patient recovered perfectly.

8. According to Baillous, (Observationes Chirurg.) a surgeon of limited experience, resected the prolapsed spleen in an individual wounded in the left

side without knowing that it was the spleen, and the patient made a good recovery.

9. Dorsch, (*Kopp's Jahrbuch der Staatsarzneikunst-Harless, Rheinisch-Westphälische Jahrb.*) Jan. 20, 1797, in a general riot an individual received several stabs from a knife. He at once started in pursuit of his assailant, and on the way he noticed a portion of flesh protruding from the wound. He became much alarmed, fainted, and was transported unconscious to his home. January 21, it was found that this man, aged 35 years, and who had previously enjoyed the most perfect health, had received a wound on the left side between the two lowest ribs, from which a large portion of the spleen of a pyramidal shape had escaped, and was projecting from the body. It was so wedged between the lips of the wound that, in spite of the fact that it was not sensitive to pain, it was impossible to return it within the abdomen. A ligature was therefore applied, and half, if not more, of the spleen was detached. The patient recovered quickly, and was still in good health 23 years after the operation.

10. O'Brien (*Medico Chirurg. Journal, 1816,*) reports the case of a man of 39 years, who received a wound from a knife Jan. 14, 1814, below the false ribs on the left side. O'Brien did not see the patient until some days had elapsed. The spleen was then already in a state of inflammation and disorganization. A ligature was applied at the margin of the wound for the purpose of restraining hæmorrhage, and the protruding portion of the spleen was ablated. Violent febrile reaction supervened upon the operation. Feb. 13 the last fragments of the sloughing organ separated, and left a smooth wound, the edges of which were united with adhesive plaster and appropriate dressings. March 10 the patient was discharged well.

11. Lenhossek reports (*Hecker's Medicin Ann., 1828,*) that in 1815 a peasant, aged 19 years, received a wound of the hypogastrium through which the spleen projected, and as gangrene had commenced, the vessels were ligated and the entire organ was removed. The patient recovered, and was seen three years after the accident, and then enjoyed the most perfect health.

12. Donnel (Transactions of the Medical and Physical Society of Calcutta, 1836,) removed the spleen from a man aged 30, who had received a wound from which this viscus protruded. Two months later the patient was entirely well.

13. Berthet. (*Gaz. Med. de Paris, 1843.*) A man received a cut from a knife in a street brawl. The wound was in the lower left side. Berthet was called to see the patient eight days afterward, and found a hernia of the spleen, which had already become gangrenous and extremely offensive. He applied a ligature and resected the entire organ. The patient recovered, and lived in good health for 13 years afterward.

14. C. Bell (Pathol. Medic. v. Allan Webb, London, 1844,) reports that one of his former pupils had resected the spleen in a native of South America. The organ was in a state of gangrene. The operation did not produce any detrimental effect upon the health of the individual.

15. Schultz (Deutsche Klinik, 1856,) gives an account of a case in a lady aged 22 years, who fell from the top of a hay stack and struck upon the step of a carriage. The step penetrated the body between the ninth and tenth ribs. There was no hæmorrhage from the wound, but a fleshy substance of a bluish color immediately appeared in the cut and protruded from the body. Schultz found between the ribs mentioned a body of fleshy consistency, of the size of half the fist, which secreted a reddish yellow liquid. The surface was smooth, of gray color, and in some places deprived of its envelope. The respiration was embarrassed, and there were chills and febrile reaction. From the topographical relation of the parts, it was thought that the protruding organ must be either a part of the lung or the spleen. Schultz concluded that it was the spleen, and not being able to return it to its place, performed splenotomy by applying a strong ligature and resecting the projecting portion. Three small arteries required to be tied. The edges of the wound were united by adhesive plaster, and the whole covered with charpie. The part of the spleen which was removed weighed four ounces. Its texture was greatly changed, having in some parts been transformed into a purulent mass. The first day the wound secreted a thick pus of a light yellow color. The pain was very moderate. The fever persisted, and even augmented for some days. The appetite was voracious. Fifteen days afterward the wound was entirely cicatrized, and the patient left the hospital in a state of perfect health.

16. Bazille (Rec. de Mem. de Med. et de Chirurg. Militaire) relates the case of an Arab, aged 35 years, of robust constitution, who was admitted to the hospital of Djelloul ben Achem, March 2, 1869. In a riot the patient had been wounded by a knife in the left hypochondrium. One hour after the injury a fleshy mass was observed to protrude from the wound. Examination showed a very soft structure which was thought to be the spleen. It was 11½ cm long, width 9 cm, circumference 27 cm. The general condition of the patient was very good, and he only complained of hunger. Excepting the first day there was never vomiting. A ligature was applied, and the mass was removed March 5. On the 15th of the same month the patient had fully recovered his former health.

17. Pietrzycki (Przeglod Ckanski, 1874), being called in the capacity of medical expert to a peasant woman, found the spleen partially prolapsed as the result of a wound. After fruitless attempts at replacement a ligature was placed about the organ and the prolapsed portion was removed. Fifteen days after the operation the patient was entirely cured.

These observations are for the most part not accompanied by full details, and relate to partial and not to complete extirpations of the organ. One cannot help noticing the striking fact that in *all* these cases the result was a cure, and that in no case were there subsequent troubles which could be attributed to a loss of a portion more or less considerable of this viscus.

(*b.*) Splenotomy in cases of tumors of the organ.

The numerous physiological experiments by Malpighi (1669), Dobson (1830), have demonstrated that the spleen is an organ which is not indispensable to life. More recently Vulpian (1855) extirpated the spleen from a dog, which lived for six years. Bardeleben, Crips, Legros, repeated these experiments, which were confirmed by Zesas, in 1881. This observer removed the spleen from six hares, under the influence of chloroform, and applied the Lister dressing. All the animals recovered.

Four months after the operation, a microscopical examination of the blood showed a diminution of the number of red globules; the white globules, on the contrary, were increased in number and augmented in size. On killing the animals there was found a hypertrophied condition of the bronchial and mesenteric glands.

Credé (Langenbeck, Arch., 1882) has collected 30 cases of extirpation of the spleen, as the result of errors of diagnosis and on account of disease of the organ itself. We give the list of cases below, together with the weight of the organ removed, and, as far as possible, the time intervening between the operation and the fatal termination.

1. 1549, Zacarelli. Hypertrophy. Cure in twenty-four days. Weight of the spleen, 1340 grams.
2. 1826, Quittenbaum. Hypertrophy. Death in six hours. The spleen weighed 5 pounds.
3. 1855, Küchler. Hypertrophy. Death from hæmorrhage in about two hours. The spleen weighed 1500 grams.
4. 1865, Spencer Wells. Hypertrophy. Death on the sixth day. The spleen weighed 3150 grams.
5. 1866, Bryant. Leucémie (Leucocythæmia?) Death in one hour from hæmorrhage. The spleen weighed 2000 grams.
6. 1867, Péan. Cyst of the spleen. Cured. Weight of spleen, 1140 grams.
7. 1867, Bryant. Leucocythæmia. Death fifteen minutes after the operation. The tumor weighed 4650 grams.
8. Kœberlé. Hypertrophy. Death a few minutes after the operation. The tumor weighed 6750 grams.
9. 1868, Bryant. Leucocythæmia. Death in about fifteen minutes. The tumor weighed 4650grams.
10. 1873, Kœberlé. Hydatid cyst. Death in seventeen hours.
11. 1873, Urbinoto. Hypertrophied and wandering spleen. Weighed 1300 grams. Death on the third day.
12. 1873, Spencer Wells. Leucocythæmia. Death from hæmorrhage.
13. 1873, Watson. Death.
14. 1876, Péan. Hypertrophy. Cure. The tumor weighed 1125 grams.
15. 1876, Spencer Wells. Leucocythæmia. Death.
16. 1877, Billroth. Leucocythæmia. Death by hæmorrhage in about four hours. The tumor weighed 2975 grams.
17. 1877, Billroth. Leucocythæmia. Death by hæmorrhage in about one hour. The tumor weighed 5280 grams.
18. 1877, Martin—Spleen hypertrophied and wandering. Cure.
19. 1877, Browne. Leucocythæmia. Death in five hours, from hæmorrhage. The tumor weighed 2,975 grams.
20. 1877, Furhs. Hypertrophy. Death in eighteen hours.
21. 1877, Simmons. Leucocythæmia. Death from hæmorrhage in two hours.
22. 1878, Czerny. Hypertrophy. Cure.
23. 1878, Czerny. Leucocythæmia. Death in a few hours. The spleen weighed 3,886 grams.
24. 1878, Volney Worscey. Hypertrophy. Death.
25. 1878, Arnison. Leucocythæmia. Death.
26. 1878, Geissel. Leucocythæmia. Death. The tumor weighed 4,500 grams.
27. 1878, Pranzolini. Hypertrophy. Cure.
28. 1878, Hayward. Leucocythæmia. Death.
29. 1878, Baker Brown. Leucocythæmia. Death.
30. 1878, Credé. Cyst. Cure. The tumor weighed 1,720 grams.

From the above table we find that extirpation of the spleen has resulted fatally in every case of leucocythæmia. Every patient succumbed, either during the operation or immediately thereafter. This operation is unjustifiable, as well from the results of practical experience as in theory. It is no more rational to remove a leucocythæmic spleen, than it would be to remove glands which were enlarged as the result of infection from some malignant growth, without extirpating the growth. These operations, however, were all performed as a desperate resort, and at a time when the patients no longer had the vigor to withstand a serious traumatism.

Leaving out case 1, which claims only historic interest, we learn from the remaining 29 cases that extirpation of the spleen has been successfully performd 6 times—twice for cysts of the spleen (cases 6, 30), four times in cases of hypertrophy (cases 14, 18, 22, 27).

CONCLUSIONS.

When, in consequence of a wound of this region, there is hernia of the spleen, the surgeon would be justified in excising the protruding portion. All the observations relating to this condition indicate the benignity of this procedure, and its uniform termination in recovery.

In disease of the spleen, its extirpation is contraindicated in the case of cancer or of symptomatic hypertrophy, either in relation to an affection of the liver or to an *intoxication poiudégenne*. The results of surgical interference have been universally deplorable.

Cysts of the spleen are curable by means of treatment more easy or less dangerous than extirpation.

In cases of wandering spleen the operation might be indicated if the symptoms were alarming. *En résumé*, it may be affirmed that splenotomy is practicable in the human subject without altering the condition of the health. This operation is indicated only very exceptionally. It is difficult to obtain a fortunate result, the chances being in favor of a rapid termination in death, due to hæmorrhage or to shock from the operation.

MEDICAL PROGRESS.

ANATOMY AND PHYSIOLOGY.

TRANSPOSITION OF THE VISCERA WITH DISLOCATION DOWNWARD OF THE LIVER.—Dr. Donald Fraser, in the *Glasgow Medical Journal*, gives the case of a middle-aged, single lady whom he had known professionally for many years without being aware that there existed in her case a complete transposition of the thoracic and abdominal viscera. The discovery of this fact was brought about in the treatment of a so-called bilious attack; tenderness and swelling of the abdomen on the left side, which was referred to the effects of a fall a month previous, led to a direct examination. A large, smooth, rounded swelling, which gave to the hand a feeling of solidity, occupied the lower half of the abdomen, lying chiefly on the left side. While it extended beyond the middle line, the greater part of it lay in the left iliac region, reaching into the hypogastric and left inguinal regions. The lower border was within an inch or so of the pubes, and the upper border was separated from the edge of the true ribs on the left side by an area of clear percussion which measured about three and a half inches. From its position and physical conditions it at first gave the impression of being a tumor of the left ovary. As its shape could be made out and the notch felt in the hypogastrinm, it was soon recognized to be the liver transposed, and dislocated downwards. Its consequent pressure on the external iliac produced a considerable œdematous swelling of the left foot and leg. A bandage and pad was so applied as to produce a continuous upward pressure on the lower surface of the liver, with the effect of, in about ten weeks, so far replacing the organ as to cause the tumor completely to disappear, the lower edge of the liver being felt underneath the edge of the left hypochondrium, with a complete subsidence of the œdema. In this case there was also effusion into the pleura at the base of the left lung, due no doubt to the dragging downwards of the diaphragm.

Further examination into the case showed a marked degree of lateral curvature of the spine, the convexity of the dorsal curvature being directed to the left. The patient was right-handed. The apex beat of the heart could be felt on the right side between the fifth and sixth ribs, at the distance of an inch and a half from the right edge of the sternum. The stomach occupied the right hypochondrium, and emitted a markedly tympanitic note. The splenic dullness could be detected on the right side.

DERMATOLOGY.

HERPES PROGENITALIS IN WOMEN.—Unna acted during four years as official examiner of public prostitutes in Hamburg. The number of these under strict surveillance is about 800, and about 25 per cent. of these suffer annually from herpes progenitalis. On the contrary, the disease is extremely rare in private practice in women. He ascribes the cause, in prostitutes, to excessive congestion of the genital organs, and believes that every herpetic eruption of the variety under consideration depends on a heightened congestion of the pelvic organs. There are men who are attacked by herpes after every act of coition, and there are prostitutes who have an eruption of herpes every time they menstruate; less frequently pregnancy and the puerperal state also induce the disposition to herpes progenitalis, which is readily explained on the same theory. It has been asserted, as a point of distinction, that pain never accompanies herpes progenitalis as it does herpes zoster. In Unna's experience, however, pain not only often accompanies the development of the exanthem, but usually precedes the eruption by one or two days. The eruption in men oftenest occurs on the second or third day, and not on the first day, after coition. He thinks compression of the nerves during penile erection may explain the pathogenesis of herpes progenitalis, much in the same way as, in Gerhardt's opinion, it accounts for the eruption of herpes labialis febrilis (*Jour. Cutaneous and Venereal Diseases*).—*Edinburgh Med. Jour.*

CASES OF THICKENED EPIDERMIS TREATED BY SALICYLIC PLASTER.—Dr. George Thin, at the Clinical Society of London, (*Lancet*), gave an account of cases of thickened epidermis, treated by salicylic gutta-percha plaster. The plaster which he used was manufactured by Herr Beiersdorff, of Hamburg, at the suggestion of Dr. Unna, who had introduced it into practice. He gave four cases.

CASE 1.—That of an adult man, in whom a tendency to extreme tylosis of the soles and palms was hereditary, being covered with an extremely thick and hard epidermis, and had been for many years in this condition, resisting very varied methods of treatment. Under the use of the salicylic plaster, which was kept constantly applied by means of bandages, and changed every third or fourth day, the hard layer of epidermis came off in one mass, leaving a delicate rose-colored epidermis behind it.

CASE 2.—A gentleman, aged 72, was unable to walk for seven months on account of an attack of sciatica. After its relief he resumed his active exercise, involving a good deal of walking on the hard pavement. The soles of both feet became hot and tender, and after a few weeks the skin of the ball of each foot became hard and horny. This lasted seven years, giving rise to much pain and discomfort. The salicylic plasters relieved the condition for several months at a time.

CASE 3.—A gentlemen, aged 43, palmar surface of right fore-finger covered for years by a thick, hard fissured epidermis. This morbid formation had been removed by the salicylic plaster, and the skin of the finger had remained normal when seen nine months later.

CASE 4.—A gentleman, aged 40, had suffered from the condition of his heels for about 20 years. It had begun by the skin being red, tender and scaly, and the hardness had gone on progres ively increasing. Amongst other methods of treatment which had been employed in vain, several antisyphilitic courses

were to be reckoned. When seen, the skin of both heels was covered by thick, hard, horny, uneven masses, which rendered walking very painful. By the use of the salicylic plaster the tendency to horny formation was not removed, yet the hard masses had been completely got rid of, and the fresh formation was avoided.

Dr. Thin regarded the condition of which these cases were examples as being essentially allied to eczema. The formative power of the epithelium was injured mechanically or otherwise, and an imperfectly formed epidermis resulted. By its solvent power on horny epidermis, salicylic acid incorporated with gutta-percha, freed the skin from an adherent, irritating mass, and the deeper layers of the rete mucosum were placed in more favorable conditions for regaining their physiological properties.

TARRY PREPARATIONS IN THE TREATMENT OF ECZEMA.—Nicale Anderson, in speaking of the use of tarry preparations, says that in many cases it is more appropriate to prescribe them in the form of ointments than of lotions, particularly when the parts feel stiff and rigid, and when there is a tendency to the formation of fissures. As a lotion he strongly advocates a mixture of equal parts of common tar, soft soap, and methylated spirits. Tarry lotions tend to discolor the parts to which they are applied and not uncommonly prove too stimulating, and then are apt to aggravate, instead of removing the eruption. The color can be rendered paler and the lotion diluted, and at the same time the combination is miscible with water, by mixing mineral tar and spirit in certain proportions and adding a little strong solution of ammonia.

℞ Picis mineralis ..... ℥ij
Sp. rectificati ..... ℥ij
Cola et adde.
Liquoris ammoniæ fort ..... m viij
Glycerine (Price) ..... ℥vj
Aquæ distillatæ ..... ℥xij

Such a mixture forms a yellowish emulsion with water in all proportions. It can be sponged on two or three times a day. Mr. Wheeler, of Ilfracombe, has informed Dr. Anderson that he has discovered that by the addition of laminaria saccharina, as prepared by him, to pix liquida, it is miscible with water in all proportions. Carbolic acid, best employed in solution, the strength varying with the degree of chronicity of the skin disease, removes at once the fœtid odor which often exhales from eczematous surfaces, counteracts the itching, and sometimes heals up the excoriations and ulcerations with remarkable rapidity. While emollient ointments, which depend almost entirely upon their oily ingredients for their beneficial effect, are best applied spread on rags, stimulating ones should, as a rule, be melted on the point of the finger and rubbed firmly into the affected part, and none should be allowed to lie undissolved upon the skin: nor, in most instances, should their color be perceptible after their application the surface should merely have the appearance of having been recently moistened. The part may occasionally be cleaned with white of egg and soft tepid water (rain water, if possible), for if layer after layer be smeared upon the skin it becomes rancid, acts as an irritant, and is calculated rather to be prejudicial than otherwise.—*Jour. Cutaneous and Venereal Diseases. Edin. Med. Jour.*

SALICYLIC ACID IN ECZEMA.—Lassar points out that salicylic acid is specially useful in eczema, and particularly when used as a two per cent. vaseline salve or vaseline zinc paste. In the common eczemas of the head in children, so numerous in dispensary practice, after two or three thorough cleansings, the daily application of the following salve nearly always suffices to obtain rapid and lasting results: ℞. acid salicylic, gr. 10; tinct. benz., m. xx.; vaseline, ℥j; m. ft. ung. On other parts, where a soft salve, which easily melts as this, is not suitable, where a firm dressing or a drying effect is desired, the following paste should be rubbed on: ℞. acid salicylic, gr. 19; vaseline, ℥j; zinci oxidi; amyli, ää ℥ss.; m. leniter terend., fiat pasta. So long as the secretion is abundant, the dressing should be daily renewed. Sometimes, when it dries hard, it tickles the skin; it should then be rendered soft by subsequent innunction with vaseline.—*Monatshefte für praktische Dermatologie* and *Ed. Med. Jour.*

RESORCIN IN A CASE OF EPHITHELIOMA.—Dr. Manino, in an article on resorcin, reports a case of epithelioma that he has treated with it. G. P., aged 64, had always enjoyed good health until about four years ago, when he noticed a small growth on his right cheek, about the size of a split pea, which caused a great deal of pain. Continued scalding caused an abrasion of the skin, and on the slightest irritation it would bleed. Cauterization and excision only caused the growth to enlarge to a size of ten centimeters in diameter. The wound had a dark red fungous appearance, with indurated edges, and gave off a profuse thin, watery discharge. An ointment of resorcin and vaseline, 1–3, was applied twice daily for eight days, when a marked change for the better could be seen; a portion of the wound was beginning to heal over. After two weeks the ointment was weakened a little, and the case continued to progress rapidly. In a short time the whole surface was bridged over, and only a red scar remained. The treatment was painless, and far more satisfactory than when caustics are used.—(*Zeitschrift f. Therap.*) *Therapeutic Gazette.*

HYGIENE.

DETERMINATION OF SALICYLIC ACID IN MILK.—The use of salicylic acid as a preservative of milk, cream, butter, and other articles of food, has now become somewhat general. This compound may or may not be an improper preservative. One would, on general principles, prefer to partake of an article preserved by means of salt, or sugar, than by salicylic acid, or boric acid, and similar drugs. It is sometimes desirable to ascertain the presence of salicylic acid in food, and for this purpose the process recently suggested by A. Remont, appears to be a good one. 20 cubic

centimeters of, say, milk are shaken up with 2 or 3 drops of sulphuric acid, when the clot which at first forms is broken up, 20 cc of sulphuric ether are gradually added, and the mixture agitated until the ether is partially emulsified. On standing for some time, 10 cc of the etherial solutions are poured off into a test tube, having a mark on it to measure that quantity. The ether evaporates and a fatty residue is obtained, which is boiled in spirit containing 40 per cent. of alcohol, and allowed to cool. The 10 cc solution now contains all the salicylic acid present in the same quantity of the milk. 5 cc are filtered into a burette, 0.015 meter in diameter, 2 or 3 drops of a 1 per cent. solution of ferric chloride are added. A rich violet color is produced, and is compared with the color produced in a liquid obtained by similar treatment from milk containing a known quantity of salicylic acid.—Dr Chas. Cameron, in *Dublin Journal of Medical Science.*

MATERIA MEDICA AND THERAPEUTICS.

Investigations into the Action of the Digitalis Group.—Drs. Sydney Ringer and Harrington Sainsbury detailed the result of their investigations into the actions of the digitalis group before a recent meeting of the Royal Medical and Chirurgical Society (*Lancet*). Digitalis is taken as the type of a group of drugs whose influence is exerted mainly on the circulatory system. The facts of chief importance in this action are: 1. The arrest of the heart in systole (if the dose be sufficiently large). 2. The raised blood-pressure which obtains throughout till close upon the final systolic arrest. Digitalis action upon the heart is defined as the production of continuous spasm of the heart-muscle by direct action of the drug on this tissue. This spasm must not be of the nature of a tetanus, *i. e.*, of a fusion of adjacent beats, and it may affect either the whole heart or a limited portion of the same. The digitalis group is thereby enlarged so as to comprehend the caustic alkalies and barium salts. Experiments were recorded of circulating these various drugs through the vessels of a tortoise, in which the brain and spinal cord had been destroyed, and simultaneously experiments were made on the excised heart of the frog. The summing up of these experiments gave for the digitalis group, which included strophanthus, dyak poison, convallarium, hydrate of potassium, carbonates of potassium and sodium, and barium chloride, 1. That a like action to digitalis obtains with them. 2. The local action on the heart serving as the definition of digitalis action. 3. Actual experiment verifies the inference that the action on the muscular tissue of the arterioles is similar. 4. So far as the experiments go, these drugs do not influence the caliber of the vessels indirectly through the nervous system. 5. Many of the digitalis group are notable muscle-poisons; the tissue of the heart, standing functionally midway between the striped and unstriped muscular tissues, may permit of the inference that a marked action of the drug on the tone of the heart would indicate a similar effect on the tone of the vessels, whereas a marked action on the cardiac beat would indicate like action on the skeletal muscles.

In the discussion which followed this paper, Dr. Lauder Brunton disapproved of grouping the cases together. If we were to group together all those substances which produced narrowing of the arterioles, we should have to include half the pharmacopœia; we should rather group only those the sum total of whose action was identical. The action of digitaline on the voluntary muscles varied not only with the species or genus, but with the individual; he did not consider it as a marked muscular poison, and did not think it wise to draw conclusions as to the action of these drugs on the skeletal muscles from their action on the involuntary muscles. Dr. John Harley, considering the fact that these experiments were made on dying animals, thought they could have no specific value as to the action of the drugs which had been used. It was not wise to argue from these experiments that such and such an action would follow on the administration of these drugs to healthy, warm-blooded animals under ordinary conditions of life. Dr. Ringer, in his final remarks, referred to digitaline, as a drug about the action of which there could not be much doubt—it strengthened the heart, it slowed the action, it regulated the beat, and it tightened the arteries. As regards its action on the heart-muscle, it was well known that, if applied locally to a bit of the muscle in which there were no ganglia, it caused contraction, thus showing that the pneumogastric nerve and ganglia were not concerned.

Kreochyle.—Kreochyle is a new preparation of meat, made at the suggestion of Prof. Barff, and intended as a dietetic remedy in cases of acute disease, vomiting of pregnancy, aggravated dyspepsia, infantile diarrhœa, and similar conditions. The following analysis has been made by Dr. North, lecturer on physiology at the Westminster Hospital:

	Grammes per litre.
Soluble albumin	35.125
Potash	14.19
Phosphoric Acid	2.016
Nitrogen, in the form of Kreatin, Kreatinin, etc.	2.4998
Chlorides	6.186

The residue of meat, after having been used for the preparation of kreochyle, consists of

	Per cent.
Soluble albumin	nil.
Phosphoric acid	.704
Potash	.181

Together with all the fat, fibrin and gelatine.

Kreochyle, therefore, is superior to beef tea, as it contains not only the extracts but a large amount of albumin. It is pleasant to the taste, and has proved valuable in the hands of many practitioners.—*Birmingham Medical Review.*

Sir Benjamin Brodies' Prescription for Gout.—℞ Pil. hydrargyri, ext. rhei, ext. colve. co., āā ℈j; ext. colchici acet. gr. xv. Ft. pil. xv. Sumantur tres hona somni pro re nata.—*Birmingham Medical Review.*

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 65 RANDOLPH STREET,
CHICAGO, ILLINOIS.

SATURDAY, JANUARY 26, 1884.

AN ETHICAL SYMPOSIUM.—Being a series of Papers concerning Medical Ethics and Etiquette from the Liberal Standpoint.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION has just been honored with a copy of a small and neatly printed volume from the press of G. P. Putnam's Sons, New York, with the above title. The object of the volume is stated in the following paragraph from the preface: "The object of this little book, therefore, is to place before the reader the motives which induced a large number of medical men of the State of New York to dissent from some of the rules (meaning the National Code of Ethics), which had hitherto controlled and guided them in their intercourse with themselves and the public."

And the *motives* set forth in the book all converge into one, namely, to get rid of certain restrictions which existed in the National Code, chiefly with regard to consultations, which is clearly indicated in the following paragraph, also from the preface of the book:

"It had been long felt that the Code of Ethics which had obtained in the State of New York, was an instrument which, however good at the time it was framed, no longer met the needs of the medical profession in the State; that its restrictions, if complied with, were embarrassing and absurd, etc."

The leading motive that impelled the action of the Medical Society of the State of New York to abolish the National Code of Ethics, which had been and still is the Code of the American Medical Association and of nearly every State and local medical society in the United States, being conceded, there are three aspects in which the movement should be viewed by every thoughtful and true lover of his profession. The first relates to the origin of the National Code of Ethics, the sources of the authority to make it, the legitimate mode by which it may be either amended or abrogated, and the essentially disintegrating and anarchial tendency of the method adopted by the State Society of New York. The second relates to a candid and direct examination of the comparative merits and demerits of the Code adopted by the New York Society. Is it in any sense a more *liberal* Code, or does it simply change one standard of restriction for that of another? Does it better protect the interests of either the patient or his medical attendant, or does it place the latter entirely at the mercy of the consultant?

The third aspect relates to the legitimate tendencies of the New York movement, and the duty of the American Medical Association and of the State and local societies in the several States in relation thereto. At the risk of wearying some of our readers, we propose to discuss these several aspects of the general subject with some degree of care; but shall have time and space for only a brief consideration of first in the present number.

In compliance with an invitation from the Medical Society of the State of New York, a convention o delegates from the medical societies, colleges, hospitals, and other permanently organized medical institutions in all parts of the United States, assembled in the city of New York in the first week in May, 1846. This convention of representative members of the profession from every section of the country, after due deliberation, appointed able committees to prepare a plan for a permanent national organization; to consider the standard of preliminary education necessary before entering upon the study of medicine; to consider the subject of medical college education; to prepare a code of ethics for regulating professional intercourse and harmonizing the interests of the profession and the public; and to prepare a nomenclature of diseases. Having appointed committees on these several subjects, they were directed to report at an adjourned meeting of the convention in Philadelphia in May, 1847.

At the appointed time the convention re-assembled, embracing much fuller delegations from the medical societies and institutions in all parts of the country, and each of the several committees presented a well considered report. A majority of the Committee on the Plan for the Permanent Organization was composed of delegates directly from the New York State

Society, at the head of whom were John Stearns, John Watson and others, some of whom are still living; while the same society was represented on the committee to report a National Code of Ethics by one of the most eminent of all her members, Dr. Alonzo Clark. We call to remembrance these facts, simply to show that the New York State Medical Society had her full share of influence in framing and adopting both the Constitution and Code of Ethics of the National Association. The declaration of the convention in 1846 that it was "expedient for the medical profession of the United States to institute a National Medical Association" was cordially sustained by the votes of her delegates in that convention; as was also the second clause of the constitution, adopted by the adjourned convention in 1847, which declares that "the members of this institution (The National Association) shall *collectively* represent and have *cognizance* of the *common interests* of the *medical profession in every part of the United States.*"

It is thus seen that the New York Society entered fully into co-operation with the State societies and medical institutions of all the other States in forming the American Medical Association, and committing to it the control of the *common interests* of the whole profession, and especially in preparing and adopting a Code of Ethics which should be uniform in "every part" of the country. Having done this, and having continued such co-operation by annually appointing her full quota of delegates to the regular meetings of the national organization, she was bound by every principle of honor, nay, even by the most common sense of propriety, if she desired changes in the National Code of Ethics or the rules for regulating professional intercourse; to formulate such changes and request or instruct her delegates to present them in due form for the consideration of the National Association. Under the rules of that Association such presentation would necessarily have been received, printed in the minutes of the meeting for the information of all the members, and have come up under the rules at the next annual meeting for full consideration and final action in open meeting of the Association. Such a course would have been, not only in accordance with the rules of the national organization, to which had been committed this most important interest common to the whole profession, but it would have been equally consonant with the honor of the New York Society, and with the mutual relations she had entered into with her sister societies in the other States of the Union. That she did not take this course so plainly open to her, and so obviously in consonance with her obligations to the profession at large, is not only well known, but fully acknowledged in the "little book" before us, as the following quotation from the preface will show: "From past experience it was felt that it would be useless to present the matter to the American Medical Association for action, and it was decided that the change should be made by the State Medical Society."

What "past experience" is here alluded to? Had the New York Society or the society of any other State ever asked the National Association to alter a single paragraph of its Code of Ethics? Had any one of the eleven contributors to this book ever presented an amendment or alteration of the Code to the Association for its consideration and action? Is there anything on record in the past history of the Association indicating an unwillingness to listen to propositions for revising or amending the Code of Ethics. On the contrary, had not the Association actually had under consideration, in the very manner I have indicated, and finally adopted, an addition to the Code only the very year previous to the independent action of the New York Society? The answer to each of these questions is obvious; and the pretence of "past experience" is a mere afterthought, as unmanly as it is destitute of any foundation in the facts of history.

No subterfuge or pretense can cover up the naked fact that in the action of the New York Society abolishing the national Code and adopting a substitute of her own, she acted in total disregard for her obligations to the national organization she had helped to create, and in which she had at the time a full corps of delegates; in contempt for her sister societies in other States, which had become joint constituencies with her; and in disrespect for her own delegates. It is this disintegrating or disorganizing *method* of action adopted by the New York Society that is more objectionable than any other feature of her work. Should her example be followed by the profession of other States, two decades would not pass before the profession of our country would be back in the same social and ethical condition so graphically described by Dr. Drake half a century ago, as quoted by our Crawfordsville correspondent in the present number of the JOURNAL—see page 108.

OHIO STATE SANITARY ASSOCIATION.—The first meeting of this proposed State organization is to be held in the City Hall, Columbus, Ohio, on the 14th and 15th days of February, 1884, commencing at 10 A. M. The programme provides for a two days session and a permanent organization. A fair number of papers on important subjects are promised, and there

are ample assurances that the meeting will be well attended, and will exert an important influence on the future sanitary interests of that wealthy and populous State.

The following railroads will return delegates at the rate of one cent per mile, upon presentation to the ticket agents at Columbus of a certificate that they have paid full fare one way, signed by the Secretary of the Association:

Indiana, Bloomington & Western.

Columbus, Hocking Valley & Toledo.

Cleveland, Akron & Columbus.

Scioto Valley.

Cleveland, Columbus, Cincinnati & Indianapolis.

Ohio Central.

The following railroads will sell round trip tickets to all persons who will attend the meeting of the Association, at two cents per mile, upon presentation to the local ticket agent of a certificate furnished for that purpose:

Pittsburgh, Cincinnati & St. Louis or C. St. L. & P. R. R.

Baltimore & Ohio.

These certificates will be forwarded on application to R. Harvey Reed, Acting Secretary, Mansfield, Ohio.

A PROPOSED NATIONAL PHARMACOPŒIA.—In the House of Representatives, January 8, 1884, read twice, referred to the Committee on Ways and Means, and ordered to be printed, Mr. Randall introduced the following bill:

"A bill to prepare and publish a national pharmacopœia for the United States:

'Be it enacted by the Senate and House of Representative of the United States of America in Congress assembled, That the Secretary of the Treasury shall, as soon as practicable, detail two officers of the Marine Hospital service, and the Secretary of War shall detail two officers of the medical staff of the Army, and the Secretary of the Navy shall detail two officers of the medical staff of the Navy, for the duty of compiling and preparing a pharmacopœia, which shall be known as the "National Pharmacopœia of the United States of America," and shall be held and accepted as the standard for the purveying, compounding and dispensing of drugs or medicinal agents, and shall be taken as authority in the Treasury Department on all questions arising under the tariff laws of the United States with regard to the nomenclature, description and purity of drugs or remedial agents, and shall further be received in evidence in the United States courts. And the matters contained in the said pharmacopœia shall be free for use by all authors and commentators for the benefit of the medical and pharmaceutical professions and of the community at large; and it shall not be lawful for any one to reprint and publish the said pharmacopœia as a whole.

'SEC. 2. That the medical officers detailed as above provided shall invite the American Medical Association and the American Pharmaceutical Association, at their next annual meetings, to form committees of not more than three members from each of the said associations, which committees, if so appointed, may co-operate with the above-named medical officers in the preparation of the said pharmacopœia, forming a board which shall have power from time to time to add to its number as may in its judgment be necessary, and which shall elect a chairman and a secretary, and adopt such rules as it shall see fit for the expediting and perfecting of the said pharmacopœia, which, when completed, shall be printed under the supervision of the said board; and an edition of not less than 5,000 copies shall be printed for use in the several Departments of the Government of the United States; and copies may be furnished to private persons in accordance with the provisions of section 3,809 of the Revised Statutes.

'SEC. 3. That for the purpose of defraying the necessary expenses of preparing the said pharmacopœia the sum of $5,000 is hereby appropriated out of any moneys in the treasury not otherwise appropriated, and the same shall be disbursed under regulations to be prescribed by the Secretary of the Treasury.

'SEC. 4. That the said pharmacopœia shall be revised once in ten years, upon the plan embodied in this act.'"

The above bill, if it becomes a law, provides for the preparation and publication of a work of much importance, both to the medical departments of the public service and to the whole profession.

The method of supervision and preparation provided in the bill secures as much freedom from local and partisan influences, and imparts to it as much of a truly national character, as is possible, while the publication by the government removes it entirely from the field of financial strife or competition. We hope individual members of the profession in every State will use what influence they have with their representatives in Congress, promptly, in favor of the passage of the above bill.

THE ARCHIVES OF PEDRIATRICS.—We have received the first number of this new monthly medical journal, devoted entirely to the diseases of infants and children. It is published in Jersey City, under the direct editorship of William Perry Watson, A.M., M.D., and an able corps of assistants or collaborators in the principal cities of this country and some in Europe. The journal contains sixty-four pages of reading matter, occupied by original articles, clinical lectures, clinical memoranda, translations, and abstracts. It devotes no space to advertisements of any kind. We wish the new enterprise an abundant

success. Terms, three dollars per annum. Address *Archives of Pedriatrics*, Jersey City, New Jersey.

MEMORIAL MEETING.—The meeting of the Suffolk District Medical Society, Section for Clinical Medicine, Pathology and Hygiene, held Jan. 9, 1884, was made the occasion for appropriate tributes to the memory of the late Dr. Calvin Ellis, who was for many years one of the most distinguished physicians and medical teachers in Boston, and was an active member of the Society.

NEWS ITEMS.

EXTRACTS FROM FRENCH JOURNALS.—Mme. Lachapelle: In *Le Medecin Praticien* Dr. Verrier gives an extended sketch of this celebrated woman. He commences by asserting that nearly all of the laity, a great many midwives, and some physicians, believe that the name of a certain Mme. Lachapelle, who advertises in the journals of the day to cure sterility, indicates the midwife in charge of the Paris Maternité, who died in 1821, and left us as a legacy her memoirs in three volumes. Marie Louise Dugès, better known as the widow Lachapelle, was born in Paris, Jan. 1, 1769. Her father was a sanitary officer; her mother a midwife at Chatelet and at the Hotel Dieu. She married, in 1792, M. Lachapelle, surgeon in charge of the service at the Hospital St. Louis. He died in 1795, leaving her childless and devoted to her calling, which she had already practiced before marriage under the instructions of her mother, and which she continued at the Hotel Dieu during her married life. From this account the accommodations for the poorer classes, during and after confinement, in the hospitals of Paris at this time, must have been of the most crude and unsatisfactory character, and the instruction to midwives was confined almost entirely to theory. In consequence of the exertions and representations of Mme. Lachapelle, seconded by the medical faculty of Paris, in 1795 the Maternity hospital was established, and she was soon joined in her work there by Baudelocque. In the school for midwives, which was a part of the institution, Mme. Lachapelle gave two or three lectures a day, illustrating her subject by the use of the mannikin, and requiring a recitation from her pupils on the matter taught.

As a practitioner, Baudelocque has expressed his admiration of the facility with which her supple, delicate hand, always intelligently directed, surmounted all obstacles, and he took pleasure in confiding to her the care of difficult cases and watching her successful efforts.

In the same journal we note the following advertisement: Mlle. ——, maitresse sage-femme of the first class, professor libre d'accouchements for midwifery students, will take to board yonng girls from the country to direct them in their studies and at the clinics. She prepares them and renders them apt, after a year of work, to pass with success the examination for midwife of the first class before the Paris Faculty. Home life. Charges moderate. Absolute morality is required. In case of a recognized inaptitude, the pupil will be returned to her family after the first three months.

JEQUIRITY — ABRUS PRECATORIUS. — Dr. C. W. Tangeman gives, in the January number of the *Therapeutic Gazette*, a systematic and exhaustive consideration of this new remedy, which has been creating such a stir, especially among ophthalmologists, on account of its reputed efficacy in curing trachoma, or granular lids. Jequirity is the name of a plant belonging to the family of papilionaceæ. It is indigenous to India, South America and tropical Africa. Although other parts of the plant have medicinal properties, it is the seeds which have been used for the purpose indicated. These seeds are of two varieties, one being of a bright red, and the other of a pale yellow color. The bright red are the variety which has found most favor as an application to granular lids. The remedy was first employed scientifically by de Wecker, the famous Parisian ophthalmologist, who received the hint from a patient whom he had unsuccessfully treated, and who on his return to his home in Brazil subjected himself to the popular treatment, as it is known among the natives of that country. De Wecker, acting on the instructions furnished him, prepared an infusion by bruising the seed to a fine powder, and then adding the proper quantity of water and allowing it to macerate for twenty-four hours. This infusion applied to the conjunctiva possesses the peculiar property of exciting a specific inflammation which, in the majority of cases, is of a diphtheritic nature. After this jequiritic inflammation has subsided it is found that the trachomatous bodies have disappeared. It will thus be seen that the seeds have succeeded in establishing a substitutive inflammation, which, running its course, smothers or otherwise overcomes the depraved process to which the granulations are due.

Dr. Tangeman details a number of very interesting physiological experiments with the jequiritic infusion on the eyes of animals, from the results of which, conjoined with his observations of the therapeutic effects of the drug in the human subject, he formulates the following conclusions:

1. Generally speaking, and judging from the results usually obtained in the treatment of trachoma, the results are remarkably good and satisfactory.
2. In the large number of cases a purulent inflammation is not excited, but nevertheless the results are favorable.
3. The strength of the infusion influences the amount of the reaction.
4. An artificial inflammation can be set up any number of times by use of the infusion, which speaks against its being an infectious disease.
5. It acts on mucous membranes other than the conjunctiva.
6. It does not seem to be necessary to produce a purulent ophthalmia to bring about about absorption of the trachomatous process.
7. An involvement of the cornea can always be

prevented by a suspension of the applications and the use of a corrosive solution, 1 : 8000, two or three times a day.

8. The reaction is much more marked if a slight amount of irritation is made with a brush while applying the infusion to the lids, so as to cause an abrasion of the epithelium.

While the jequirity bean is undoubtedly an agent of great value in the treatment of granular lids, its use should be conducted with circumspection, and the patient should be closely watched by the physician. While cases are occasionally met with which are not benefited by this treatment, it is nevertheless very uniformly successful.

By a recent order issued by the Surgeon General U. S. A., Dr. J. S. Billings has been placed in charge of the Medical Museum and Library, thus consolidating the two. While remembering his successful efforts to make the library what it has become, as the medical library of the world, and the use he has made of its material by giving to the medical profession of the world the Index Catalogue, it is fair to presume that in this new field for his labor he will find the opportunity for utilizing to the best advantage the treasures now put under his control. Now that we are at peace with all mankind, save a poor handful of red men, and the army has been correspondingly reduced in size, it is not probable that pathological specimens will find their way in any quantity to the museum cases, but there are other fields remaining to be worked that would add to the usefulness of such a museum. With the many valuable specimens in our museums of comparative anatomy, there is but little to illustrate comparative physiology—that is, to illustrate the functional development of organs and viscera, from the lower to the higher types of animals, to reach their final, not perfection, perhaps, but completion, for our studies in man. The valuable models of Auzon and his followers, and the various instruments used in research, diagnosis, and the relief of disease, would all find a place in an ideal museum.

Dr. Rochard, Medical Director of the French Marine, who some weeks since received, at the hands of a lunatic, a gunshot wound of the lung, which for some time caused grave apprehensions, has since made an uninterrupted recovery, so that he was enabled, at the last meeting of the Académié de Médicine, to thank his colleagues personally for the great interest they had taken in his progress, and to inform them that he had so completely recovered that "all that remained to him of this adventure was a small piece of lead in the right lung, and great gratitude in his heart."

The editors of the *Archives of Medicine* with the December number announce a discontinuance of the journal, after a satisfactory existence of five years. The suspension is rendered necessary, not from lack of support by contributors or subscribers, but through a combination of extraneous circumstances.

SOCIETY PROCEEDINGS.

CHICAGO MEDICAL SOCIETY.

At the meeting of this society on the evening of January 7, 1884, Dr. J. G. Kiernan read a paper on "Perverted Sexual Instinct." Upon this topic the literature of the past was reviewed to a considerable extent by the writer, of which the following extracts have been taken, a part of the phraseology not being in very common use: Casper was the first to call attention to the condition known as sexual perversion, but not until several works had been published by a Hanoverian lawyer, Ulrichs, himself a sufferer from the disease, did the matter become the subject of scientific study on the part of physicians. Westphal was the first to discuss it, and described two cases, one, a female whose history, when a child, is said, to have been fond of boys' games and the putting on of male attire. From her eighth year she had felt drawn to certain girls and liked to express her love for them, kiss them, and induce them to let her touch their genitals. She came of a neurotic ancestry, and displayed somatic signs of degeneration. She had imperative conceptions, and displayed symptoms of insanity other than the perversion. His second case was a male, who felt attracted by males. Servals reported a case, that of a male, who in addition to sexual perversion was morally imbecile. Schminke and Scholz have reported cases in males. Westphal, in addition to the two cases *above* cited, has later reported an additional male case. Krafft Ebing, after citing four cases (all males), concludes, that the main symptoms of the condition are first congenital absence of normal sexual feeling and at times repugnance to normal intercourse, although they appear sexually developed normally.

The sexual psychical phenomena are replaced by this perversion. Sexual desire appears early and extends to the same sex, or at most the feeling finds expression in mutual onanism, but as a rule pæderasty is repugnant. Tamassia and Legrand du Saulle have reported one case each, both males. Stork reports three cases, one displaying primary monomaniacal tendencies. Raggi has reported a case of what he calls sexual perversion in a male, who, from having enlarged breasts, created the delusion that he was a woman. Charcot and Mognan have reported one case. In this country five contributions have been made to this subject. One by Dr. H—— (see anonymous contribution New York *Medical Record*, April 18, 1881), who describes the case of a male; one by Spitzka, who deals with a historical case; one by Blumer, who describes in a very thorough manner the case of a male in whom the perversion had very Platonic manifestations (a kind of love of which Plato was a great expounder); Shaw and Ferris reported one case which, however, was not well observed; and one case by Wise who describes the Lesbian loves (from Lesbos, an old Greek city) of two victims of this perversion. The author has seen three cases, two of which were impure, the other, a female, aged twenty-two, whom he describes as being of

neurotic ancestry on the paternal side, her cranium and face being asymmetrical. The patient has always had a fondness to dress in male attire, and she feels at times sexually attracted by some of her female friends, with whom she has indulged in mutual masturbation. These feelings come at regular periods, and are then powerfully excited by the sight of the female genitals. In the interval she manifests repugnance to attentions from men. She is aware of the fact that while her lascivious dreams and thoughts are excited by females, those of her female friends are excited by males. She regards her feelings as morbid. At times she is troubled by imperative conceptions, such as that if she turn her head around she will break her neck, in consequence she carries her head in a very constrained position.

Regarding the cause, excluding the impure cases of Ulrich's, Dr. Kiernan stated that thus far there have been 27 cases reported, *four females, the rest males*, which would seem to appear that sex predisposed to the affection, but it should be remembered that a history of female sexual desire is not easily obtained, that in nearly every case a neurotic ancestral history was obtained, and that the condition then appeared to be congenital

Treatment.—To remove this perversion is out of the question. Dr. Wise has recommended that all such cases be sent to an asylum. Krafft Ebing proposed that these patients be exempt from legal penalties, and allowed to follow their inclinations when harmless, and when not violating public modesty.

The case recited by the author, he treated as if it were one of nymphomania, and by antaphrodisiac measures he sought to strengthen the patient's will, and at the same time by instituting a course of intellectual training. The patient has been aided by these means so far as to be able to control her perverse inclinations.

Dr. E. Andrews discussed the paper by saying, cases of this kind occurring to people living in cities situated in the southern half of Europe are not regarded as cases of insanity, and in Italy many boys open a vicious trade to travelers, which, no doubt, is due to corrupt associations there. Among the Latins, and Greeks, and people living along the Mediterranean Sea, vicious habits of all sorts were practiced 200 years ago, according to some works on ancient literature. In a certain saloon-parlor in Paris, there is exhibited a fine large picture of a nude figure to represent a hermaphrodite, for certain kinds of lascivious purposes, and both sexes view it. Prostitutes frequently are known to be affected with chancroids on the verge of the anus, and the men frequenting the place often contract specific disease in the mouth.

Dr. R. E. Starkweather inquired of the essayist if he considered the cases that the newspapers had published so much recently about, occurring in Wisconsin, a mutual or mental disease? Both the persons are said to be females, and the latest report states that one is pregnant.

Dr. Kiernan thinks there is scarcely a civilized nation in which the vice is not practiced; and this vice aspect is common in Asia, also in Naples.

Among the Pueblo Indians, one of their number is delegated as a pæderast. He, however, thinks these cases should be divided into two classes, one of which are vicious, the other perverted. Regarding the last speaker's interrogatory, Dr. K. thinks we can reject the pregnancy part of the question; and then, too, in the case he alludes to we are not assured that both are women, for the scrotum of a man may be adjusted so as to elude detection, and other things being equal, a male person may dress in female clothing and readily pass as such.

Dr. Charles E. Webster read a well prepared paper on Pott's Disease, and exhibited a mechanical appliance of his own invention, that he had manufactured for the relief and cure of dorsal caries. The apparatus was examined by the gentlemen, and many of them endorsed it as being superior to the jury-mast and head-lift, it being far less cumbersome than the former, which is apparently always in the way. The paper is an original contribution, and differs somewhat from the literature upon this subject. A description of the apparatus and mode of application which has been prepared by our reporter we omit here, as the paper in full is contained in another part of this number of the JOURNAL. L. H. M.

IOWA CENTRAL MEDICAL ASSOCIATION.

The Iowa Central Medical Association met at the parlors of the Tremont House, January 8, 1884. The President, Dr. H. L. Getz, called the meeting to order. After reading the minutes of previous meeting, the regular order of business was proceeded with.

This being the annual meeting, the following officers were elected for the ensuing year: President, Dr. Chas. Reiterman; Vice President, Dr. Wm. B. Kibbey; Secretary and Treasurer, Dr. Harriet Conniff; Censors, Dr. H. L. Getz, Dr. James Lang, and Dr. Rosa Tysson.

The retiring President, Dr. Getz, now delivered the annual address, his subject being "Medical Issues of the Day," wherein he sharply criticised the *reasons* given for change of code by the New York Medical Society, and yet urging leniency and liberality on the part of the profession in the construction placed upon it, where consultations were required in out of the way places and in localities where competent physicians or surgeons could not be induced to locate. He also pointed out the gross inconsistency in the pretended consultations between regular and homœopathic physicians. The doctor advocated and hoped that he might see added to article 1, section 3, of the present Code, a clause not only *permitting* a physician to give on his card the name of medical college at which he graduated, the city in which it is located, and the date of his or her graduation, but that it would be made as *obligatory* to do so. His reason for advocating this addition to the present Code being that it would, first, enable the public to select intelligently a competent, or at least a properly qualified physician; second, by doing this it not only protects the general public from imposition, but it likewise protects the physician who has spent his means and time in properly qualifying himself for his pro-

fession from *theft* on the part of the unqualified, or those who *claim* to have obtained regularly the degree of Doctor of Medicine and Surgery; third, that this change of Code can be easily made by the profession, and since desirable medical legislation is so difficult to obtain, the proposed change of Code would, to a great degree, take the place of desired medical laws; fourth, that the change advocated would be the cause of persons entering the profession obtaining their degree only from the best medical colleges, consequently do much toward a "so much talked about but so little accomplished" higher medical education. Other important and interesting questions were discussed.

The newly elected President, Dr. Reiterman, after a few well chosen remarks, now took the President's chair.

Dr. Getz reported the following cases of interest:

Case 1. Woman; married; aged 35 years. Cystic degeneration of kidney; cyst weighing about seven pounds successfully removed by abdominal section similar to ovariotomy.

Case 2.—Male; aged about 30 years; cut throat with large pocket knife, severing all tissues from one carotid artery to the other; severing the trachea completely, and the œsophagus about one-half; liquids taken by mouth escaped through cut on throat. The trachea and all parts were carefully approximated by deep and superficial sutures, and the patient nourished by liquid food injected into the stomach through tubes. Recovery has been steady and satisfactory, the patient now, just one month since the injury, being able to take liquids and solids in the usual way with little or no inconvenience.

Case 3.—Woman; aged about 25 years; pelvic cellulitis followed by abscess and complicated by hæmatocele; operation indicated and done; evacuating by trocar; patient recovering.

Case 4.—Railroad injury; caused by hand-car running over body; fracture (comminuted) of leg, and sustaining severe injury to spine, causing paralysis of the bladder and bowels; the latter are slightly improving; the former continues paralyzed; injury sustained six weeks ago; leg is doing well.

Other cases of interest were reported by Drs. Long, Conniff, Reiterman and Kibbey, after which the meeting adjourned.

THE MICHIGAN STATE BOARD OF HEALTH.

[Reported for the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.]

The regular quarterly meeting of the Michigan State Board of Health was held in the office of the Board at Lansing, Michigan, Jan. 8, 1884, the following members being present: Jno. Avery, M.D., of Greenville, President; J. H. Kellogg, M.D., of Battle Creek; Victor C. Vaughan, M.D., of Ann Arbor; C. V. Tyler, M.D., of Bay City; and Henry B. Baker, M.D., Secretary.

The recommendations to the Warden of the State House of Correction, by Dr. Jno. Avery, Committee on Buildings, Ventilation, etc., under date of Sept. 7, 1883, for improving the ventilation of the shops at the State House of Correction, at Ionia, were ordered printed in the next Annual Report.

The Secretary read a resumé of recent work of other boards of health; also, a summary of the work of the office of this Board during the last quarter, which showed that a successful sanitary convention had been held at Ionia; that partial arrangements had been made for holding one at Hillsdale; that the proceedings of the Muskegon, Pontiac and Reed City Conventions had been printed; that special meetings of the Board had been called at the State Reform School to examine plans for a new building; at Detroit to attend American Public Health Association; and at Ionia at the time of the convention; that a leaflet on contagious diseases had been translated into French, Danish-Norwegian and Swedish for general distribution among citizens of Michigan who speak those languages; that a very general distribution of circulars on communicable diseases and on the work of health officers had been made to the health officers of cities, villages and townships in Michigan; that similar documents were distributed at Ionia, and at the State Teachers' Association; that circulars, blanks, etc., had been sent to health officers and clerks of all cities, villages and townships in Michigan for their annual report, including that of the diseases dangerous to the public health; that notice had been sent to health authorities in several parts of the State warning of the shipment of diseased cattle into such localities; that the regular distribution of weekly bulletins of sickness and of meteorology, the yearly distribution of material for meteorological reports, and the quarterly distribution of blanks to observers of diseases, had been made.

The Secretary presented reports from Dr. Hazlewood, who as committee of the Board attended the Sanitary Convention at London, Ontario, and the meeting of the Board of Corrections and Charities at East Saginaw. In connection with the first report, Dr. Hazlewood described the water supply of that city (London), and the Secretary, who also attended the convention, described a visit to the Asylum for the Insane near London, Ontario.

By request of the State Board of Corrections and Charities, committees were appointed to examine and report on the sanitary condition of the jails, asylums, etc., in several counties in Michigan.

Drs. Avery and Kellogg were appointed a committee to investigate and report at next regular meeting on the sewerage, ventilation, etc., of the Capitol building.

A committee, consisting of Drs. Baker, Kellogg and Vaughan, were appointed to examine and report on the sanitary condition of the State Reform School and surroundings.

Dr. Kellogg presented and read portions of a very interesting report on the present knowledge respecting diphtheria, which will be published in the next Annual Report.

Considerable discussion occurred over the examination of text-books on physiology and hygiene, with reference to alcohol and other narcotics.

Only four books had been presented for examina-

tion. The committee reported relative to these books, and asked to be discharged, but the committee was continued, Professor Vaughan added to it. It was directed to confer with a similar committee from the State Board of Education, and it is to report again at the next regular meeting of the Board, April 8. It is hoped that publishers of school books will give early attention to this subject, and that more than one book can be approved at that time.

STATE OF MICHIGAN,
ATTORNEY-GENERAL'S OFFICE,
LANSING, Jan. 9, 1884.

HENRY B. BAKER, M.D., Secretary State Board of Health.

Dear Sir:—Yours relative to the proper construction of Act 167, laws 1883, entitled, "An Act to Promote Public Health," and inquiring whether physicians could lawfully register after the time fixed by Statute for the registration of physicians, is at at hand, and in reply would say, that physicians *can lawfully register at any time.*

The Act, after declaring the necessary qualifications for the practice of medicine in the State, required that persons so qualified should, within three months after the law took effect, file with the county clerk the statement therein set forth.

The three months after the law took effect, as specified in the Statute, was simply a limitation of time beyond which no person could lawfully practice medicine without being registered.

The person who failed to register within that time, but practiced as a physician, made himself liable to the penalties prescribed in the Act, and is also barred by Sec. 4 of the Act from recovering pay for professional services rendered subsequent to the time when he should have registered, and prior to the time of his compliance with the law. A removal to another county would necessitate a new registration.

Yours, truly,
J. J. VAN RIPER,
Attorney-General.

CHICAGO SOCIETY OF OPHTHALMOLOGY.

The Chicago Society of Ophthalmology and Otology held its third bi-monthly meeting on Dec. 18, 1883, the President, Dr. F. C. Hotz in the chair.

Drs. Z. Bettman, G. F. Hawley, H. Gradle and C. B. Shotwell were elected to membership.

Dr. Hotz then addressed the Society on Medicated Bougies for the Lachrymal Sac and Nasal Ducts..

The means usually adopted for the treatment of diseases invading these parts, are the employment of probes and syringe. The action of the probe is a mere mechanical one, to open the passages for the outlet of tears. The syringe, on the other hand, serves the double purpose of cleansing the tract and of introducing medicaments which are to act on the diseased mucous membrane.

A number of remedies are excluded from use if applied according to the latter method, on account of their insolubility in water, as bismuth, iodoform and boracic acid. The objectionable feature of nitrate of silver, when used in the fluid state, is the annoyance caused to patients by its staining qualities. A quantity of the fluid remedies, when injected into the sac, invariably bathe the conjunctiva, producing an unnecessary irritation. Furthermore, the action of fluid medicines is naturally of short duration for they flow rapidly through the nose.

The good results of medicated bougies was observed when introduced in other channels lined by a mucous-membrane. The thought of using them in the nasal duct, and thus combining the effects of probe and syringe, presented itself to the doctor.

Mr. Wadleigh, of the Western Suppository Co., 91 Washington St., Chicago, succeeded in manufacturing an article which has proved entirely satisfactory. The bougies are three inches long, and of the caliber of a Bowman's probe No. 6, tapering off toward the one end to the size of No. 2. It is not necessary to employ larger sizes, since they swell in warm water to a thickness corresponding to Bowman's probe No. 8. They are quite firm and elastic. The ingredients entering into their composition are, gelatine, in which are incorporated various remedies.

The following formulæ have thus far been prepared:

A. Iodoform $^1/_8$ gr. B. Boracic acid $^1/_4$ gr. C. Fluid ext. calendula $^1/_8$ gr. D. Carbolic acid $^1/_{32}$ gr., sulphate zinc $^1/_{16}$ gr. E. Subnitrate of bismuth $^1/_4$ gr.

It is introduced in the ordinary manner, with great facility and without pain. It adapts itself by virtue of its power of elasticity to the sinuosities of the passage where it is allowed to remain.

If the bougie is too long, the piece protruding may be clipped off with a pair of scissors. The medicated probe can also be cut in two before introduction, and either end inserted, according to the exigencies of the case. Several hours are reqnired for the complete dissolution of the bougie. In case of extensive strictures, Bowman's probe may precede the introduction of the bougie.

Dr. Hotz closed his remarks by saying that he had used this means of medication in but a limited number of cases with success, and asked the members to give it a fair trial. Its application in a great number of cases will decide whether it is to occupy a prominent position amongst the methods employed for the treatment of affections of the lachrymal passages. Several of the members had used the bougies, and agreed with Dr. Hotz as to the ease with which they were inserted, and as to their efficiency.

A paper on Pulsating Exophthalmus was read by Dr. Boerne Bettman. The three most important symptoms to be noted in connection with this disease are exophthalmus, the development of noises in the orbit and over a larger or smaller part of the cranium, and pulsation of the eye. This complex of symptons is produced by pathological processes existing either in the orbit or cranium.

In the following case the cause of the trouble was intracranial, an aneurisma arterioso venosum, produced by a fracture of the base of the skull. Mr. F., æt. 23, of Albuquerque, N. M., was attacked by robbers on the night of June 29, 1881. He was struck with a sand bag on the neck and back of the head and knocked down senseless. Friends found him in this state, bleeding profusely from the nose. He re-

gained consciousness several hours after the assault, when he complained of severe pains in the neck and head; during the night he vomited frequently and bled copiously from the nose. Pains in the head and left eye increased in severity, to be accompanied by the most annoying of all symptoms—a continuous hammering and buzzing in the head and ears, similar to the puffing of a steam engine. The next morning on awakening he noticed several other unpleasant features. Strabismus convergence with consequent diplopia, and exophthalmus of the left eye. Patient was confined to bed five weeks. During this time he complained of severe tension of the left eye, and of pain in this organ and in the head. Pulsation and exophthalmus increased. The diplopia disappeared after nine months, when the veins on his forehead began to swell. The vision of the left eye gradually diminished. Fifteen months after the injury a protrusion of the right eye was first noticed. Mr. F. was subjected to various methods of treatment. Electricity was for a long time applied, his complaint being diagnosed in a neighboring western city as morbus baso. The following state of affairs was found when he presented himself for examination in Chicago, September 7, 1883:

Marked exophthalmus, both eyes; left eye protrudes seven-eighths of an inch beyond the anterior orbital plane; right eye three-fourths of an inch. Conjunctiva bulbi oc. w. very much swollen; especially marked are the enlarged, tortuous, dark red blood-vessels; cornea clear; pupils normal in size; irides blue, react promptly. The prominent eye-balls can be pushed back into their sockets with ease. When the pressure is discontinued they assume their former position. Of great interest is the pulsation, which can be easily detected by the finger, which is lifted rhythmically; it is also visible to the eye. Above and to the inner side of both eyes, extending to the root of the nose, are two oval tumors somewhat larger than a hazel nut. The right one is divided into three parts by the ligamentum palpebrale mediale. A distinct purr fremissement schwirren is felt in the larger part of the right tumor; its pulsation and that of the eye are synchronous with the radial pulse. Auscultation over the head and eyes demonstrates a constant murmur, which becomes louder during the arterial pulsation. This systolic murmur can be traced along the carotis communis of the left side. Compression of the left carotid artery produces a complete cessation of the pulsation and noises on both sides; the exophthalmus is seemingly reduced somewhat. Compression of the right carotid does not affect these symptoms in the least. Strabismus convergence l. eye.

L. E. V. $= {}^{6}/_{70} +$ 2 letters of the next line.

R. E. V. $= {}^{6}/_{6}$ glasses do not improve.

Ophthalmoscopic examination.—Both sides papillitic. The veins are enlarged to double their size, and are extremely tortuous. The retinal arteries are exceedingly thin.

The constant pressure of the blood in the enlarged veins has worn deep furrows in the frontal bone. Dr. Baxter was called in as surgeon. It was decided to ligate the common carotid, since the patient endured digital compression of that artery admirably well. Dr. Baxter performed the operation at the Michael Reese Hospital, September 15, in the presence of a number of physicians. A No. 2 catgut ligature was placed around the vessel, below the omohyoid muscle. Pulsation and noises, subjective as well as objective, disappeared instantly. The eyes receded, the tumors collapsed. The patient rallied rapidly. On the 16th he had slight fever. 37. The temperature was normal the next day. He left bed and took a walk in the garden on the 20th of September. The wound healed per primam. On the night of the 26th, 12½ days after the operation, he was awakened by a sudden, loud hammering and puffing noise in the head and ears. An examination, made on the following morning, proved conclusively that circulation through the artery had been reëstablished, producing a return of all the unpleasant symptoms.

Dr. Baxter tied the artery again October 17, low down in the neck. As before, pulsation and noises ceased immediately; narcosis lasted longer this time; the pupils were dilated and did not respond to light; the right angle of the mouth was drawn upwards. These phenomena disappeared before he awakened. During the process of healing a small abscess formed (in the lower part of the wound), which discharged on the thirteenth. The wound then healed rapidly. The pulsation reappeared in a slight degree during the latter part of his abode in the hospital, but only after physical exertion. On November 5 he departed for his home, much improved; he is to return in March to have a similar operation performed on the other side. The pathological anatomy and therapeutics were then discussed. This disease is extremely rare; the most noted surgeons have not been fortunate enough to observe a single case during their many years' experience. In four cases of pulsating exophthalmus, a rupture of the carotis interna in the sinus cavernosus could be demonstrated without a doubt. Closer observation of all cases recorded, of which there are 106, will show that the majority owe their origin to such an injury. Several methods of cure have been proposed. Digital compression, injection of medicines in the pulsating growths and ligation of the common carotid artery. The latter plan is the oldest and most successful. Of fifty-six cases operated for rupture of the internal carotid in the sinus cavernosus 37, equal to 66.7 per cent., were cured; 11, equal to 19 per cent., remained unimproved; 8, equal to 14.29 per cent., died.

The interesting features of the case were then commented upon. Of special importance was the complete relapse twelve days and a half after the operation, at a time when the wound had healed completely and the patient was preparing to return home. Sattler mentions instances of the reappearance of the pulsation and noises in from one-half to two hours after the operation. In Herpin's case a relapse occurred after nine months. The recurrence of the trouble in the cases referred to was certainly due to reëstablishment of circulation in the aneurism through the widened anastomosing vessels from the opposite side, whilst in the case discussed the ap-

parently well ligated artery allowing the blood to take its former course.

During the first operation doubt was expressed as to the durability of a catgut ligature, as to its power of withstanding the action of the tissue fluids long enough to enable a thrombus to form.

Dr. Baxter quieted these fears by the following remarks: "During my long experience as surgeon to the Cook County Hospital, I never applied silk ligatures, but always used catgut, and never knew it to give way if tied sufficiently firm. Neither were the catgut ligatures destroyed by absorption before the eighth or twelfth day, and it does not require a longer time than this for the formation of a thrombus." After proving by a critical analysis of the clinical history that neither a thrombus had formed nor an extensive rupture of the interna and muscularis had followed the application of the ligature, the following conclusions were arrived at:

The artery had never been completely closed. Catgut is comparatively stiff and cannot be drawn together so tightly as silk. A thin, perhaps, thread-like stream of blood constantly flowed through the vessel, the pressure of the blood current, assisted by the process of absorption, gradually weakened the ligature, until at last it suddenly gave way.

A question of importance which arose during the second operation was the justifiableness of again employing catgut as a ligature, in the face of the first mishap.

An occurrence which often threatens the life of patients after an operation is secondary hæmorrhage. This peril, according to the essayist, is increased by the use of a silk ligature, provided a thrombus does not form or does not possess sufficient power of resistence, for silk usually cuts through the arterial coats. In view of a contravention of this statement, that such a possibility does not exist, since a thrombus capable of withstanding any pressure usually forms before silk could produce such an action, a case was cited of fatal secondary hæmorrhage, occurring 35 days after the operation, when the wound had healed perfectly. An autopsy revealed a necrotic degeneration of the interna and muscularis, and two non-obturating thrombi below the place of ligation. In order to avoid secondary hæmorrhage, Sattler says: "It is of great importance, when isolating the artery, not to tear more of the arterial sheath than is absolutely necessary to apply a ligature. In this manner the danger of necrosis of the artery is avoided. The danger of hæmorrhage is furthermore diminished by closely following the laws of antisepsis and employing a carbolized catgut ligature." If a No. 3 catgut ligature be applied double, or two adjoin each other, we secure the best chances for the healing of the wound per primam and avoid the danger of secondary hæmorrhage. BŒRNE BETTMAN, M.D., Secretary.

THE PROPOSED SIMS MONUMENT.—A committee has been formed, representing the profession in various parts of the country, to obtain funds for the erection of a monument to the late Dr. Sims in New York. Dr. Fordyce Barker is the chairman, and Dr. George F. Shrady is secretary.

BOOK REVIEWS.

A PRACTICAL TREATISE ON MATERIA MEDICA AND THERAPEUTICS. By ROBERTS BARTHOLOW, M.A., M.D., LL.D. Fifth edition. Publisher, D. Appleton & Co., 1884.

This is deservedly one of the most popular works upon this subject that the profession has. Prof. Bartholow's style is clear and pleasing. He is known to be an authority upon the matters treated. He gives with assurance his own views, and the practitioner can at once tell what has been used with benefit by the author.

The new edition is somewhat enlarged and has been thoroughly revised, so that it now agrees with the new pharmacopœia.

The work from its first appearance has been so popular and so widely read that an extended notice in regard to its scope and methods would now be superfluous.

DOMESTIC CORRESPONDENCE.

"BAKING POWDER."

FOR THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

Mr. Editor:—I send you the following comments on a very common but important subject, and hope they will attract attention:

There have been many newspaper wars pending about this article, but they have not at all enlightened the public on the subject. Dr. Hammond, of New York City, waged a war against the old time institution of the "country pie," demonstrating its indigestibility, and its consequent bad effect on the stomach; and I cannot understand why some medical authority has not agitated the baking powder question, and explained to the public its injurious effects, about which there is no doubt. To make the matter clear, it may be stated that the average baking powder is composed of bi-carbonate of soda, cream tartar, and starch, with a possible admixture of other things. The continued use of even this purest baking powder will affect the system seriously, commencing with only a slight derangement of the digestive organs, which gradually becomes chronic, changing the secretions of the stomach necessary for digestion (muriatic acid), in fact, altering the whole chemistry of the human stomach.

The continued use of alkalies in any form injures the health. Look at the alkali country west of us, where the alkali is found in the *drinking water*. The same dangers will arise from the persistent alkaline medication of our *daily bread*. The various forms of dyspepsia, bladder troubles, Bright's Disease, consumption—the newest researches speak about a wrong proportion of the alkalies in this disease—are only too often caused by this modern substitute for the old time-honored, common sense practice of using yeast.

It is a well known fact that the American nation is dyspeptically inclined, and that the New England race especially has physically deteriorated since bak-

ing powder is so generally used. The amount of baking powder made every year is enormous.

YEAST.

ST. PAUL, MINN., Jan. 7, 1884.

CRAWFORDSVILLE, Ind., Jan. 15, 1884.

EDITOR JOURNAL OF THE AMERICAN MEDICAL ASSOCIAION:

In my letter, so kindly published in your issue of January 5, an unimportant error crept in, where you say "his coat" instead of "*the cord*," in the sentence "The doctor pulled his coat off."

In reading *The Western Journal of Medicine and Surgery*, of March 1, 1847, edited by Drs. Daniel Drake, L. P. Yandell, and T. W. Colescott, I was interested to see what was expected of our Association as set forth in the following extracts: "Provided its members shall consult together with a fixed determination not to part till they have laid the foundation of an American profession. It is quite time that this was at least attempted. At present there is as little intercourse and sympathy between the physicians of the different States of the *Union*, so-called, as between those of the different kingdoms of Europe. All this is wrong, and should, if possible, be corrected. The medical profession is one throughout the world, and especially should its members, in the same confederacy of States, compose one brotherhood. As a means of promoting this interesting object, and, at the same time, giving an impulse to medical inquiry and improvement, it is to be hoped that the convention will not adjourn without taking measures to bring about, in some central city, a yearly meeting of physicians, surgeons, obstetricians, druggists, and dentists, open to all who legitimately belong to these respective departments of the profession. Such meetings could not fail to call forth many valuable papers and reports of committees, the reading and discussion of which would be a source of both pleasure and improvement; while our physicians generally would acquire a new impulse to observation and experimental research, and the publications of the association would elevate the character of our profession. Our readers will recollect that the meeting in Philadelphia will be an adjournment of that held in New York in the month of May, 1846. The minutes of that meeting are now before us, and we observe that several committees were appointed to make reports on the organization of a national association; on the primary education of students of medicine; on a higher standard of graduation; on State boards of examiners for the degree of M.D., instead of its being done by the professors; finally, on a uniform system of medical ethics. All those are important topics, which it is hoped the committees will thoroughly investigate."

In the June number I find: "The convention before adjourning resolved itself into an association, to be called the American Medical Association, and Prof. Chapman, being presented as its President, said he was greatly impressed with the honor conferred upon him, and unable to express in adequate terms the feelings which then animated his breast. It had been his good fortune, in the course of his long life, sometimes to have been complimented in the same manner, though not in the same degree. He confessed his incompetency to serve them in conformity with his wishes. He loved his profession, and should be very ungrateful did he not. Whatever he possessed in this life of any value had been bestowed by her great favors. Whenever he deserted her or any of her disciples, might Almighty God desert him! It would always be his aim to promote as far as he could the principles of the science, and do everything in his power to elevate still higher the medical profession." Yours,

T. F. LEECH, M.D.

STATE MEDICINE.

MEETING OF THE ILLINOIS STATE BOARD OF HEALTH.

We copy the following special report from the *Daily Times* of this city:

SPRINGFIELD, Ill., Jan. 18.—The State Board of Health is holding its annual meeting for the election of officers and other business, in its rooms, in the Dapitol building. There are present Newton Bateman, of Galesburg; R. Ludlam, of Chicago; A. L. Clark, of Elgin; W. A. Haskell, of Alton; W. R. Mackenzie, of Chester; A. W. Reen, of Peoria (recently appointed to fill a vacancy), and the Secretary, John H. Rauch, of Chicago.

Dr. A. L. Clark, the Treasurer, presented his annual statement for the year 1883, accounting for the receipts through the Secretary's office of $904.91, and the expenditure of $715.85, leaving a balance in his hands of $189.06, independent of the regular appropriations.

The Secretary, Dr. Rauch, presented his quarterly report, in which is also included an annual summary. The following are the more important points:

THE PUBLIC HEALTH.

Scarlet fever has continued during the quarter in many localities, but without, in any case, assuming a serious epidemic form, while the death-rate from it remained unusually low. The German edition of the Board's circular on scarlet fever, alluded to in the last quarterly report as in preparation has been published and distributed to many points. Diphtheria has been reported from several places.

Small-pox has appeared at Stone Fort, Saline county; Farina, Fayette county; McLeansboro, Hamilton county; and Alton, Madison county. The disease was also reported October 31, from Paris, Edgar county, but the case was subsequently ascertained to have been chicken-pox. At Stone Fort the disease was introduced by a woman who had been attending the St. Louis fair; took sick a few days after her return, and died on the thirteenth day of an attack of unmodified confluent small-pox. Of seven other members of her family four contracted the disease, the remaining three escaping through successful vaccination after exposure. A relative's family, liv-

ing in the adjoining township, in Pope county, also contracted the disease, and in turn infected the attending physician. Except this latter and one woman, none of those attacked had even been successfully vaccinated prior to exposure. The physician and woman above referred to had both been vaccinated in childhood, and escaped with mild attacks of varioloid. Of the remaining cases, seven in number, all died of unmodified confluent or hæmorrhagic small-pox. The situation became so serious, and so much apprehension existed in the community and neighborhood about the middle of November that the Secretary was compelled to visit the locality in person, which he did November 20-24. Reporters, Drs. W. R. Osborne and D. Bozarth, Stone Fort, attending physicians. The case near Farina was also due to contagion, contracted near St. Louis, an unvaccinated young woman, who finally recovered after a severe attack of hæmorrhagic small-pox. Fortunately the other members of the family in which the case occurred were all protected by vaccination, and no other cases resulted. Reporter, A. R. Hancock, M.D., Farina, attending physician. On the first of December an unvaccinated public scholar at McLeansboro was found in the febrile stage of what proved to be an attack of small-pox, from which, however, she ultimately recovered. Source of contagion unknown. A large number of others were exposed, and although vaccination was freely resorted to, six more cases followed, of which number two died. None of the seven had ever been vaccinated prior to exposure. Reporter, C. M. Lyons, M.D., McLeansboro, attending physician. A fatal case of small-pox occurred in Alton during the early part of December, contracted in St. Louis, notwithstanding the case was not discovered until the eleventh day, and a number of persons were exposed in the boarding house where it occurred, only one other case resulted; one of his nurses, vaccinated in childhood, but not successfully re-vaccinated until after nearly two weeks' exposure. This patient died on the fifth day, the disease being the rare form of pupura variolosa. Reporter, W. A. Haskell, M.D., Alton, attending physician.

TRICHINIASIS.

Three outbreaks of trichiniasis—one of them resulting in three deaths—have occurred, the first during the early part of November, in a family near Gardner, Grundy county; the second and third during December, in Woodburn, Macoupin county, and in Bloomington, respectively. The Gardner and Bloomington cases resulted from eating uncooked pork and sausage, and the Woodburn cases from raw smoked sausage. Specimens of the meat from Gardner and Woodburn were sent to the Secretary for examination, the character of the disease being only suspected, until the microscope showed in one case about 2,000, and in the other about 8,000 trichinæ to the cubic inch.

Dr. A. T. Darrah reports the Bloomington outbreak quite fully, and Drs. Taxis and Reid, of Gardner and Woodburn, respectively, have promised detailed reports of their cases. The matter, however, possesses little sanitary importance, except that it is well to put on record every authentic instance of the occurrence of trichiniasis, and to determine its cause. Since 1866 I have noted every such instance in this State, and of the deaths resulting, which now number 16, and, without exception, they have been caused by eating uncooked or imperfectly cooked pork in some form. I see no reason to modify the opinion expressed in 1881 in reference to an inquiry addressed to me by a committee of the Chicago Board of Trade, and by the State Department at Washington, to-wit: That, as a sanitarian, I regard the danger to human life from trichinæ as practically amounting to nothing, it being so easily prevented by thorough cooking.

The investigations which have been made during the past four years, both in this country and abroad, show American pork to be less liable to trichinous infection than that of other countries. The hog in every country is subject to the parasite; even the wild swine in European forests have been found infected, and an outbreak of trichiniasis in 1881 at the village of Khiam, near the source of the Jordan, in Palestine, was caused by the flesh of a wild boar slain in the woods near the village. Prof. Virchow is recently reported to have condemned the outcry against American pork as utterly illogical, unnecessary, and unjustifiable by sanitary reasons, and adds that "no case of trichinæ in American hog meat has been proved to exist in Germany for ten years." Neither in Switzerland nor England has it been found necessary to interfere with the importation of American hog products; and yet in these countries their reputation is higher than ever before. As previously remarked, the question is one of economic and commercial importance, and in only a very limited sense has it any sanitary interest. Proper cooking will render the most badly infected piece of trichinous meat absolutely innocuous. Exposure to a temperature of 150–160 degrees, Fahrenheit, is fatal to the trichinæ.

PRECAUTIONS AGAINST DANGER TO LIFE FROM FIRES.

The recent loss of life by fire at Belleville, suggests the point whether the Board can profitably take any further action looking to securing adequate provision for escape from, and for the extinguishing of, fires in public buildings. On different occasions within the past few years the Board has called attention to this subject—the last time in the fall of 1881, with reference to the danger from fire at seaside resorts, and this was emphasized soon after the Secretary's circular letter was sent out, by the destruction of no less than six of these inflammable structures within a very short time. Fortunately, these fires occurred at a season of the year when there were only a few, in some cases no inmates, and nothing worse than the rapid destruction of the buildings and contents happened. These events, however, served to direct attention to the subject, and there is reason to believe that this class of buildings is much improved in this respect. I think it would be well to prepare a suitable letter with necessary instructions, and address to all those having charge of public buildings in the State, with the view of publishing a report on the

condition of such structures, with reference to the number of stories, sizes and arrangement of rooms, number and dimension of staircases, doorways, windows, and other exits, special provisions for escape, and for extinguishing fires, etc. Such a report would serve a useful purpose in disclosing to what extent municipal, State, or other interference may be necessary to correct such dangers as are found to exist

CHICAGO SEWAGE.

In my last quarterly report, speaking of the solution of the various questions hinging upon the disposal of the sewage from the city of Chicago through the Illinois and Michigan canal, I observed that it was "clearly the duty of the city of Chicago, immediately upon the close of navigation, to have the Bridgeport pumps put into operation, and their capacity and the capacity of the canal determined by actual experiment." I am glad to say that this experiment is now being carried on, and I am in receipt of a telegram from Superintendent Thomas, announcing that the "Bridgeport pumps are working finely, and are holding three feet of water in the canal above the level of the Chicago river."

ELECTION OF OFFICERS.

The following officers have been elected their own successors for the ensuing year: Hon. Newton Bateman, LL.D., President; A. L. Clark, M.D., Treasurer; John H. Rauch, M.D., Secretary.

THE AFTERNOON SESSION

was devoted to executive business. The relations of colleges to the new schedule of requirements in medical education now in force by the Board was the principal subject under consideration. Among other action taken was the adoption of an order refusing to recognize diplomas of the Joplin College of Physicians and Surgeons, and of the Kansas City Hospital Medical College. Adjourned sine die.

NECROLOGY.

STODDARD, SAMSON, M.D., was born Feb. 7, 1806, at Vienna, Oneida Co., N. Y., and died August 24, 1876, at Albion, Calhoun Co., Michigan.

The subject of this sketch, Dr. Stoddard, was of the seventh generation of the Stoddard family in America—Anthony Stoddard, the founder of the same, having emigrated from England and come to Boston in 1639. The published genealogy of this family, now extending over a period of nearly two centuries and a half, shows that the traditions and practice of the ancestry were uniformly in the direction of education and scholastic culture, and that more of them were members of the liberal and learned professions than is often observed even in New England families. Thus if there be such a thing as a legacy of culture or an inherited tendency towards learning, it is quite sure that this belonged by right of birth to Dr. Stoddard.

His father, Rev. Goodwin Stoddard, was a Methodist itinerant, and therefore the doctor's boyhood life was subject to the frequent changes and genteel poverty incident to the career of a Methodist clergyman. This irregular life is not usually well calculated to advance the education or the moral training of children, and yet, despite this drawback, the doctor early manifested an intense love for study and a tireless perseverance in the acquirement of knowledge. When he was sixteen years of age he entered Wyoming Seminary, remaining there three years, excepting three months when he taught a district school. Immediately after leaving the seminary he took up the study of medicine, for the study of which he had a great passion, and a special aptitude for its practice. In October, 1825, he entered Fairfield Medical College, which was a branch of the University of New York, and the only medical school in what was then called the western part of that State. At that period there were only five chairs and five professors, showing what were the meager advantages of the medical student of that time compared with the present. He graduated at the close of the session of 1828-9, but spent only one year in the practice of his profession in his native State, when he determined to try his fortunes in the then "far West," as Michigan was called. He reached Jacksonburg, now the city of Jackson, Mich., in the early part of September, 1830. Only eight or ten families had preceded him, and he was the first physician to locate there. He became a member of the Medical Society of the Territory of Michigan, Feb. 10, 1831. In the practice of his profession his ride had a circuit of thirty miles or more. In those days the practice of medicine was no sinecure. Very many times long journeys on foot had to be taken where no horse could be rode, and over streams spanned only by a single log, and where swollen streams and wide marshes would not permit the crossing by any other means. The people were poor, drugs were dear, so doctors did not rapidly become rich.

In the spring of 1832 the doctor married Miss Sarah M. Blake, of Livonia, N. Y., who died in July, 1851. He remained in Jackson till the spring of 1836, when he moved to a large farm fifteen miles west from Jackson, where he remained till 1873, at which time he moved to Albion, where he died. While clearing up and cultivating his farm, he still carried on a large medical practice. For years it was his custom to labor on the farm all day, and then ride half or two-thirds of the night. For a long time, thanks to a splendid constitution, he bore up under this great sacrifice of needed sleep. But as the cares of a large family came on and the anxieties of a more extended farming interest occupied his attention, his health began to break down, and as early as 1854 he entirely gave up the practice of medicine and bestowed his whole attention to business pursuits. But it was always the regret of his later years that he did not remain in Jackson and devote himself wholly to his profession to the exclusion of every other interest.

Dr. Stoddard was a man of strict probity of character, a hater of shams and subterfuges of all kinds, and whose word was a bond. He never lost his love for the profession of his choice, and to his last days kept himself familiar with its literature. He did a

large pioneer work in a new country for his profession, very much of it poorly paid for, or not at all. But he gloried in his work, and was ever ready to respond to the call of the suffering and the needy, and to this day the memory of his labors and character are kept green in an extended circle of friends and grateful patients. TREATMENT OF STRICTURE OF THE URETHRA.

BY HENRY J. REYNOLDS, M.D.,

PROFESSOR OF DERMATOLOGY, COLLEGE OF PHYSICIANS AND SURGEONS, CHICAGO.

[Read before the Surgical Section of the American Medical Association, at Cleveland, Ohio, June 8, 1883.]

In no department of medicine or surgery has scientific progress been more rapid during the last few decades, than in genito-urinary surgery. The unity of hard and soft chancre is a theory no longer entertained. Tapping the bladder through the rectum with an ordinary trocar has been superseded by the superior process of aspiration above the pubes. "Tieing in" of catheters and sounds, in the treatment of various urinary affections, has been mostly abandoned. Locating stricture with a sound of even caliber, and considering every adult urethra where a No. 14 or 15 English sound could be passed, as large enough, aré fallacies no longer accepted.

I will here confine my remarks to the treatment of organic or permanent stricture of the urethra. This of itself is a very wide and comprehensive subject, and an elaborate discussion of which would occupy too much time. I shall, therefore, notice in a general way what I consider the more salient features of the same, with a report of some cases.

Only a few years ago, even among specialists, if a man was examined and found to have a capacity sufficient to admit a No. 14 or 15 English sound, he was informed that no stricture existed. The patient presented himself to the physician with some urinary trouble, which in reality was the direct result, reflex or otherwise, of a stricture of large caliber. He was possibly interrogated as to whether he had ever had a gonorrhœa, and answered in the affirmative. He was then asked if it was followed by a gleet, and answers in the affirmative. He was then possibly asked if the urinary stream had diminished in size since the attack of gonorrhœa, and, as usual in stricture of large caliber, especially when the meatus is naturally small, says it has not. The patient was then considered as entirely free from stricture, or, if any at all existed, nothing capable of producing evil consequences. But to be doubly certain as to his correctness in excluding stricture, the physician then passed a sound, possibly as large as the meatus would admit, which may not be over a No. 12 or 14 English, and found that it could be made to enter the bladder. Stricture was then supposed to be out of the question. The patient was now put under treatment for cystitis, with accompanying backache, pains in the groins or perinæum, or, if he had a gleet, he was treated for that. After six months' or a year's time had elapsed, and the physician had tried nearly all the recommended remedies, without success, he consoled himself and patient by saying that such complaints were very stubborn and unyielding to treatment, and sometimes baffle all medical skill for the time being, and he was then informed that nothing but nature and time would accomplish the desired object, and was recommended to go south. or north, or west, as the case might be. This hypothetical case is a true picture of what we often see. No importance whatever, I think, should be attached to the statement by the patient, that his stream is full size. The size of the stream *may* afford quite conclusive evidence of the *presence* of stricture, but not of its *non-existence.*

All strictures vary in the *size of the circle described by the contracting band*, in the *width* of the same, in their *location*, and in the *number* in each case, so the treatment in each case must necessarily vary to some extent. It may, however, be classed under two principal heads, viz.: that indicated in what is known as stricture of large caliber, and that applicable in those of small caliber: The object of treatment is mainly two-fold, viz.: to restore the urethra to its normal caliber, and to maintain the same after the normal caliber has been secured. The number of devices that are and have been in use to accomplish this object, are numerous. Instruments for drawing the water, making applications to the urethra, etc., have been in use for the last 2,000 years; but not until in the seventeenth century do we find any positive evidence of their having been used for the purpose of dilatation or actual stretching of the stricture, and not until the present century was internal urethrotomy practiced to any extent.

Before any mode of treatment has been adopted, the normal caliber of the urethra should be ascertained, which can be very accurately accomplished by the use of Otis' urethrometer. The size of the urethra being proportionate to that of the entire organ, however, a sufficiently accurate knowledge of its normal character may be ascertained by measuring the circumference of the penis in the flaccid state, between which and the size of the urethra a constant relation exists. For instance, a penis measuring three and one-half inches in circumference,

as a general thing may be said to have a caliber of 35 millimeters, equivalent to about a 21 English or 23 American sound. A circumference of three inches would give a urethral caliber of about 30 millimeters, etc.

After the normal urethral caliber and the size and location of the stricture have been ascertained, the mode of procedure which I adopt, when the caliber of the stricture is large enough to admit, and the patient willing, is internal urethrotomy, and for which purpose I prefer Otis' dilating urethrotome to all other cutting instruments. If the stricture is too small to admit Otis' instrument, and Thompson's divulsor can be got in, I stretch sufficiently with it to admit the Otis instrument, and then treat it the same as if it had been of large caliber, viz.: stretch to full size, and then cut each stricture with the Otis instrument. For reasons too numerous and lengthy to be given in this paper, I think this mode preferable to all others of a dilating or cutting kind. Dilatation with the conical steel sound is very painful and slow, and, I think, more uncertain in both immediate and ultimate results.

The tendencies of all strictures, I think, after being cured by any method, is to gradually decrease some in caliber if an instrument is not occasionally passed; but I very much doubt the possibility of their ever becoming as small, after internal cutting and stretching to full size in this way, with the frequent use of the full-sized sound until entirely healed, as they were previous to the operation. To insure the permanency of the cure, however, I always provide the patient with a full-sized sound, with instructions to pass it at intervals afterwards. One thing certain, in my experience, the cure of the gleet by the above process is attained in a very short time if the *full* and *complete* caliber be restored.

If the stricture be of too small a caliber to admit a Thompson's dilator, or even a filiform bougie, I think it advisable that plenty of time should be taken, and several attempts be made at different sittings, to pass a filiform and a Thompson's divulsor over it, which, if accomplished, renders the operative procedure much more simple and less dangerous to the patient than the operation of external perineal urethrotomy, which is the only resort, should an entrance to the bladder through the urethra be found impossible. If anything larger than a filiform can be passed, the strictures can generally be dilated in time so as to admit a Thompson's instrument over a filiform. A still smaller instrument, known as Maisonneuve's urethrotome, may be used if thought advisable, it being about No. 3 English in size, and Thompson's about No. 5. But it has the disadvantage of being liable to cut the urethra more or less in its entire length. As soon as successful in passing either of these instruments into the bladder, the strictures should be enlarged before they are withdrawn. Then, as in large caliber, they should be again stretched and cut to full size with Otis' instrument at the same sitting. This operation, as most all others of a stretching or cutting kind, I generally make under chloroform. When all strictures are broken up, a full-sized sound, which may be all the way from a No. 18 to a No. 24, English, should be passed in a few times to make sure that the passage is entirely free.

Should all efforts at passing an instrument into the bladder fail, the external perineal operation must be resorted to. A general description of perineal urethrotomy is not necessary. I will here report a case in practice, however, of extreme stricture, in which the operation was involved, together with some cases treated by other methods.

CASE I.—H. E., aged 34, lawyer, with good constitution, presented himself October 20, 1882, with the following history: Contracted gonorrhœa in 1873, which lasted two or three months. The attack being very stubborn and unyielding; very strong injections were occasionally used. Was troubled considerably with chordee, which, during intercourse, broke several times, giving rise to considerable hæmorrhage. Gleet continued until 1875, with frequent urination, at which time he began to have retention. A sound was then passed for the first time, and the caliber of the smallest stricture found to be about No. 8 English. From that time the retentions became more frequent, and were quite often accompanied by violent rigors. The acts of urination also became somewhat more frequent, and there was almost constantly a small amount of dribbling. To relieve the retention, patient got in the habit of going into a Turkish bath, and with a syringe, which he always kept with him for the purpose, would forcibly inject the penis full of hot water, till it would force it away through the strictures, as it were, on into the bladder. The urine would then, he states, almost invariably flow off quite freely at once. He attached much more importance, however, to the use of the syringe and hot water, than he did to the bath; the latter being resorted to more for the relief of the rigors, than for the relief of the retention. From 1878 to 1880, efforts at gradual dilatation with sounds were made by a physician of Milwaukee, where he resided. Was at one time able to get in a No. 6 English. Got married in 1880, since which time the acts of retention have been less frequent, though great difficulty is experienced in urinating, which act is preceded and followed by dribbling, for which he wears a urinal.

Examination: Penis, 3½ inches in circumference. Meatus, 20 French. From meatus to peno-scrotal fold there are three strictures, varying in size from 7 to 9 French, 2 to 4 English. Immediately posterior to this it becomes filiform, and at 6½ inches filiform is grasped and entirely arrested. Advise external perineal urethrotomy.

March 15.—Operation: The bowels having been previously moved by a cathartic, and the urine rendered alkaline by citrate of potash, patient was put under chloroform, and after half an hours' effort, failed to enter the bladder. I then, assisted by my brother, Thomas N. Reynolds, M.D., of Detroit, and my three students, made the external perineal operation without a guide. Found one very fine and long stricture near the scrotum, and another at the membranous portion. Found also a pocket at upper and front side of prostate an inch deep, and large enough

to admit the finger; the septum between which and the anterior ¾ of an inch of the prostatic portion, I was obliged to divide before a full-size sound could be passed. I then passed Thompson's divulsor from the perineal wound forwards and out at the meatus. It, being several sizes larger than the strictures, had to be forced through; which, with the manœuver of passing from behind forwards, may be more easily accomplished. This being done, the instrument was turned up to full size and then withdrawn. The operation was then completed by stretching the strictures up to 38 French, and cutting them, and incising the meatus with Otis' divulsing urethrotome. Might say right here, that by turning the Otis instrument upside-down, so it cuts towards the frænum, there is nothing better for dividing the meatus.

After-treatment: Patient kept under anodynes for a week, and bowels moved by injections every day. Citrate of potash continued till wound healed. No. 36 sound passed every other day and wound thoroughly cleansed every day with warm water and castile soap. Penis also cleansed every day till perineal wound was about to close, by forcibly injecting the same through it. No antiseptics were used.

March 31. Perineal wound closed, the sixteenth day, so that from that time no more urine escaped through.

April 13. Patient sits up and passed the No. 36 sound himself. Was able to retain urine longer immediately after the operation than he had done since first gonorrhœa.

April 26. Perineal wound has cicatrized very kindly, and no bad symptoms of any kind during the entire convalescence. Continues to pass his No. 36 sound every other day, and has completely recovered from all his previous bad symptoms referable to the stricture.

Case II.—E. G., æt. 20, laborer, with good constitution and fair habits, presented himself on March 13, 1882, with the following history: Contracted gonorrhœa seven or eight months previous, which was followed by gleet that lasted ever since. Was told by his physician, after the gleet had continued two or three months, that he had a stricture, who accordingly treated him for the same, and finally informed him that it was cured. The gleet was, however, not arrested.

Examination: Penis 4 inches in circumference, meatus extremely large, being 40 French; strictures at 4½ and 7 inches with calibers of 29 and 22 French respectively, equivalent to 17 and 13 English.

March 14. Operation: The urine having been rendered alkaline with citrate of potash, and the bowels moved by a mild cathartic, patient was put under chloroform and strictures stretched up to 38 and cut with Otis' divulsing urethrotome. Hæmorrhage slight; kept under anodynes in bed for 48 hours and alkali continued until well. No. 37 passed on third day and every other day afterwards.

March 20. Had slight hæmorrage.

March 29. Was taken with another hæmorrhage, for which I was called. Did the penis up in splints, which immediately arrested it, and there has been no more hæmorrhage since.

April 3. Gleet all stopped, and patient dismissed with instruction to pass his No. 36 sound every few days.

Case III.—June 28, 1883, R. S., æt. 33, farmer, with good constitution and good habits, gives the following history: Had gonorrhœa nine years ago, followed by gleet, which lasted several months. Since shortly after that time he has been troubled continuously with frequent micturition, pain in the back, over the pubes and in the perinæum; which condition has grown gradually worse, till at the present time he is obliged to urinate several time during the night, every hour or two during the day, and has now become almost totally unable to perform manual labor. Medicinal remedies fail to have any beneficial effect, and patient decides to have "something done."

Examination: Penis 3¼ inches in circumference; meatus 15 English; strictures at 4½ and 6½ inches with calibers of 10 and 8 English, respectively.

June 27. Operation. The bowels having been moved by cathartic, and urine rendered alkaline, patient was put under chloroform; the meatus cut, and strictures stretched with Thomson's divulsor up to full capacity, which is about 21 English, or 35 French. No. 18 English was the largest sound that could be passed immediately after the operation, but as patient objected to having any cutting done, no further operations were made.

June 29. Patient doing well. No. 16 English, which is the largest size that will *now* pass, is used and repeated every few days for two months. Patient's condition improved rapidly, and in a short time he was only occasionally obliged to pass the water during the night, and much less frequently through the day than before the operation.

April 10, 1883. Examined, and find strictures at 4½ inches, which was no doubt resilient, and should have been cut. Patient's general condition is much better than previous to the operation, however, and he might no doubt be completely restored to his former health by a cutting operation, whereby the normal caliber would be secured and maintained.

Case IV.—R. I., æt. 30, single, with good constitution and regular habits, gives the following history: Had gonorrhœa in 1880, in 1881, and in 1882. The last attack was followed by gleet, which lasted ever since, with more or less cystic irritation, pain in the perinæum, over the pubes, etc.

September 14, 1882. Examination. Penis, 3½ inches; meatus, 28 French; strictures at 2½ and 6½ inches, with calibers of 28 and 18 French respectively.

September 16. Treatment. Commenced treatment by gradual dilatation with conical steel sound, passing as large a size as the strictures would admit twice a week, and a smaller size every day.

January 20, 1883. Have carried dilatation up from No. 18 to No. 27 French. Pain and irritation less, but gleet continues, though not so bad.

February 20. Irritation and soreness in perinæum only comes on occasionally, but the gleet remains the same.

April 1. Incised the meatusup to No. 35, by put-

ting it on the stretch and cutting with Otis's urethrotome.

May 1. No. 30 now passes readily; gleet continues.

June 1. No. 32 passes comfortably, but gleet still continues.

Here is a case where nine months' treatment by gradual dilatation has not secured as good an immediate result as might have been obtained in three weeks by cutting and stretching, with no better prospects of maintaining what has already been secured.

It will be noticed by the results of the above cases, which are intended to represent about the average results from each method, that the surest, quickest, and least painful treatment for stricture of either large or small caliber, seems to be by a method that at once secures the complete normal caliber of the canal, and warrants the permanency of the same, with the continued use of the sound, at least, if not without. I believe it is not the usual custom to cut very deep strictures, but I have never yet seen hæmorrhage, or other unfavorable symptoms, resulting from the operation sufficient to give much trouble, and I now always cut, regardless of location. I will say, in conclusion, however, that I think the success of even the cutting and stretching method depends entirely upon *the completeness of the removal of all obstruction to the canal.* Even the slightest constriction left remaining may be sufficient to keep up irritation, and form a ground-work for future contraction, with perhaps a continuance or renewal of gleet; and I would, therefore, suggest that the stretching be carried even beyond the normal caliber, with the immediate and continued use till healed, at least, of a *full* sized sound. This may necessitate the manufacture of a specially large instrument, but I consider it one of the chief elements in the complete and ultimate success of the operation.

SOME RULES OF THE COMMON LAW RESPECTING THE DISPOSITION OF HUMAN DEAD BODIES.

A SKETCH OF ENGLISH LEGISLATION UPON THE SUBJECT OF ANATOMY, AND A DRAFT OF AN ACT TO PROMOTE THE SCIENCE OF ANATOMY, MEDICINE, AND SURGERY IN THE STATE OF ILLINOIS.

BY MARSHALL D. EWELL, LL.D.

So far as the writer has been able to discover, there seems in all ages to have been, in the non-professional mind at least, a peculiar aversion and horror of dead bodies of human beings. The laws of Thena, enacted, according to Sir Wm. Jones, from 880 to 1,280 years before Christ (Sir Wm. Jones' Works, pp. 79-80), contain many provisions respecting uncleanness and purification therefrom, by reason of the dead, and it seems everywhere assumed that dead bodies are unclean. Thus, among many other provisions, we find the following: "He who has touched a chandala, a woman in her courses, an outcast for deadly sin, a new-born child, *a corpse*, or one who has touched a corpse, is made pure by bathing." —Laws of Thena, ch. 5, § 85.

"Should a Brahmin touch a human bone moist with oil, he is purified by bathing; if it be not oily, by stroking a cow, or by looking at the sun, having sprinkled his mouth with water."—Ib., § 87.

Likewise, by the laws of the Franks, a person who dug a corpse out of the ground in order to strip it, was banished from society, and no one suffered to relieve his wants till the relations of the deceased consented to his re-admission.—4 Black. Com., 235; Montesq. Spir. Laws, b. xxx, c. 19.

By the common law of England—and I suppose the rule of the American common law is the same—it is an indictable offense to take up a dead body, even for the purpose of dissection, as being "*contra bonos mores*, at the bare idea alone of which," say the court in Rex v. Lynn, 2 Term, R. 733, "nature revolted." See 1 Russ. on Crimes, 629; 2 East's P. C., c. 16, § 89, p. 652; 1 Leach (4th ed.), 497; Commonwealth v. Cooley, 10 Pick. 37; Kanavan's Case, 1 Me., 226.

While it is true that at the common law there can be no property in a corpse (4 Black. Com., 235; 2 East's P. C., c. 16, § 89, p. 652; Williams v. Williams, English High Court of Justice, chancery division, reported in 21 Am. Law Dig. [U. S.], Aug., 1882, p. 508, in the note to which the cases upon the subject are quite fully collected by the writer of this paper), and, therefore, stealing it is no felony; yet it is a very high misdemeanor at the common law (2 East's P. C., 652), and at the present time "body-snatching," so-called, is made a statutory crime in probably every State of this Union.

In the case of Dr. Handyside, where trover was brought against him for two children that grew together, Lord Chief Justice Willes held that the action would not lie, as no person had any property in corpses: 2 East's P. C., 652; Haynes' case, 12 Coke, 113; 4 Black. Com. 235.

The case of Williams v. Williams, above referred to, which referred to the subject of cremation, and in which it was held that a man cannot dispose of his body by will; that it is the executor's duty to bury it, and that meantime he has the right to possession of it, is an interesting case to read in this connection.

If, however, the coffin or any of the grave clothes be stolen with the body, it was a felony at common law: 2 East's P. C., 652; 4 Black. Com. 235; Haynes' Case, 12 Coke, 113; 1 Hale's P. C., 515: 3 Coke Inst. 110.

By the common law, it is an offense against decency to take a person's dead body with intent to sell or dispose of it for gain or profit: 1 Russ. on crimes, 629; Rex v. Gilles, Russ. and Ry. 367, note. Even to sell the dead body of a capital convict for the purposes of dissection where dissection is no part of the sentence, is a misdemeanor and indictable at common law: 1 Russ. on Crimes, 629; Rex v. Cundick, D. and R. N. P. C. 13. See also Commonwealth v. Loring, 8 Pick., 370.

Even the refusal or neglect to bury dead bodies by those whose duty it is to perform the office, appears also to have been considered a misdemeanor: 1 Russ. on Crimes, 631. So, the prevention of the interment of a dead body has been considered indictable: 1 Russ. on Crimes, 637; Rex v. Young, cited in Rex v. Lynn, 1 term R. 734. To cast a dead body into a river has been held indictable at common law as an offense against common decency: Kanavan's case, 1 Me., 226.

A gaoler has no right to detain the body of a person who has died in prison for any debts due to himself, and is indictable for so doing: 1 Russ. on Crimes, 637; Reg. v. Fox, 2 Q. B. 247; Reg. v. Scott, 2 Q. B. 248.

The dissection of human bodies being necessary for the advancement of anatomical and medical science, statutory enactments were made upon the subject in England at an early date, and also exist in many of the States in this country. The statutes of every State and Territory of this country have been examined with reference to this subject, and it was the writer's intention to have incorporated a digest of the same in this paper, but it has been found that such a digest would consume more space than the merits of many of these statutes deserve, and it has been thought better to give the English legislation upon the subject, and at the close to submit a draught of such an act as seems best to fulfil the indications of the case. Access could not be obtained to the continental legislation upon the subject, but accessible legislation in this country and England furnish sufficient material to construct a bill upon the subject.

The first English statute upon the subject of anatomy and dissection that we have been able to find, is section 2 of chapter 42 of 32 Henry VIII., enacted in 1540, and entitled, "For Barbers and Surgeons." The second section of this act is as follows:

"And further be it enacted by the authority aforesaid, that the said masters or governors of the mystery and commonalty of barbers and surgeons of London, and their successors yearly forever, after their said discretions, at their free liberty and pleasure, shall and may have and take without contradiction four persons condemned, adjudged and put to death for felony by the due order of the King's laws of this realm, for anatomies, without further suit or labour to be made to the King's highness, his heirs or successors, (2) and to make incision of the same dead bodies, or otherwise to order the same after their said discretions at their pleasures, for their further and better knowledge, instruction, insight, learning and experience in the said science or faculty of surgery."

By the statute 25 Geo. II., c. 37, 1752, entitled, "An Act for better preventing the horrid crime of murder, (repealed by 9 Geo. IV., c. 31, § 1, 1828, for consolidating and amending the statutes in England relative to offenses against the person; re-enacted in substance in sections 4 and 5 of the same statute, but repealed in 1838 by section 16, of 2 and 3, Wm. IV., ch. 75, which section 16 was itself repealed by 24 and 25, Vict. c. 95, § 1,) it was enacted, after providing (Sec. 1) that murderers should be executed the next day but one after sentence passed; that (Sec. 2) the body of such murderer so convicted shall, if such conviction and execution shall be in the county of Middlesex, or within the city of London or the liberties thereof, be immediately conveyed by the sheriff or sheriffs, his or their deputy or deputies and his or their officers, to the hall of the surgeons' company, or such other place as the said company shall appoint for this purpose, and be delivered to such person as the said company shall appoint for this purpose, and be delivered to such person as the said company shall depute or appoint, who shall give to the sheriff or sheriffs, his or their deputy or deputies, receipt for the same; and the body so delivered to the said company of surgeons shall be dissected and anatomized by the said surgeons or such person as they shall appoint for that purpose, and in case said conviction and execution shall happen to be in any other county or place in Great Britain, then the judge or justice of assize, or other proper judge, shall award the sentence to be put in execution the next day but one after such conviction (except as before excepted) and the body of such murderer shall in like manner be delivered by the sheriff or his deputy, and his officers, to such surgeon as such judge or justice shall direct for the purpose aforesaid."

That the purpose of this act was less to advance the interests of science than to terrify wrongdoers, is evident from section 3, which directs sentence to be pronounced immediately, stating the time of execution and the marks of infamy above specified, "in order to impress a just horror in the mind of the offender, and on the minds of such as shall be present, of the heinous crime of murder."

The statue above quoted has furnished a model, which, with greater or less modifications, has been followed by several of the States of this Union, and among others by the State of Illinois, sec. 443 of whose criminal code provides, that "the court may order, on the application of any respectable surgeon or surgeons, that the body of the convict shall after death be delivered to such surgeon or surgeons for dissection, unless the same be objected to by some relative of the convict."

In 1832 the elaborate act of 2 and 3, Wm. IV, ch. 75, entitled, "An Act for Regulating Schools of Anatomy," was passed, the preamble of which might with profit be read by the present Board of County Commissioners of Cook County; it is as follows:

"Whereas, a knowledge of the causes and nature of sundry diseases, which affect the body, and of the best methods of treating and curing such diseases, and of healing and repairing divers wounds and injuries to which the human frame is liable, cannot be acquired without the aid of anatomical examination; and whereas, the legal supply of human bodies for such anatomical examination is insufficient fully to provide the means of such knowledge; and, whereas, in order further to supply human bodies for such purposes, divers great and grievous crimes have been committed, and lately murder, for the single object of selling for such purposes the bodies of the persons so murdered; and, whereas, therefore it is highly expedi-

ent to give protection, under certain regulations, to the study and practice of anatomy, and to prevent, so far as may be, such great and grievous crimes and murder as aforesaid, be it enacted, etc."

The act then proceeds to provide (sec. 1) for licenses to practice anatomy; (sec. 2) for the appointment of inspectors of schools of anatomy; (sec. 3) the districts they shall superintend; (sec. 4) for returns by the inspectors of subjects removed for anatomical examination; (sec. 5) for the inspection of places where anatomy is practiced; (sec. 6) for salaries of inspectors.

Sec. 7 makes it lawful for any executor or other person having lawful possession of the body of any deceased person, and not being an undertaker or other party entrusted with the body for the sole purpose of interment, to permit such dead body to undergo anatomical examination, unless, to the knowledge of such executor or other person, such person during his life expressed a desire that his body should not undergo such examination, or unless the surviving husband or wife, or any known relative of the deceased, shall require the body to be interred without such examination.

Sec. 8 requires the party having lawful possession of the dead body of any deceased person who has during his life directed the anatomical examination of his body, to direct such examination to be made, unless the deceased person's surviving husband or wife or nearest known relative shall require the body to be interred without such examination.

Sec. 9 prohibits the removal for anatomical examination of the body of any person from the place where such person died within a certain time and without a certificate of the manner of death.

Sec. 10 makes it lawful for professors, surgeons, etc., being licensed as aforesaid, to receive bodies for anatomical examination under the provisions of the act.

Sec. 11 provides that the persons mentioned in the last section shall receive with the body a certificate as aforesaid, which shall be transmitted to the inspector of the district with a return stating from whom received, date and place of death, sex, name, etc., and that the said certificate and particulars shall be by such license recorded in a book kept by him for that purpose, etc.

Sec. 12 requires notice to be given to the Secretary of State of places where anatomy is about to be practiced.

Sec. 13 regulates the manner of removing bodies for examination, provides for their interment after examination, and for the transmission of a certificate of interment to the inspector of the district.

Sec. 14 provides that the persons licensed under the act shall not be liable to punishment for having in their possession or examining dead bodies according to the provisions of the act.

Sec. 15 provides that nothing in the act contained shall be construed to extend to or prohibit any post-mortem examination of any human dead body required or directed to be made by any competent legal authority.

Sec. 16 repeals so much of 9 Geo. IV, ch. 31, as directs that the bodies of murderers may be dissected or hung in chains as ordered by the court; and enacts that such bodies shall be hung in chains or buried, as the court shall direct. (This sec. 16 was repealed by 24 and 25 Vict., c 95, § 1).

Sec. 17 limits the time within which actions for anything done under the act shall be brought, and regulates the pleading therein.

Sec. 18 prescribes the punishment for offenses against the act.

Sec. 19 defines the interpretation of certain words in the act.

Sec. 20 provided that the act should go into effect August 1, 1832.

Sec. 21 provided that the act might be altered or amended during the then present session of Parliament.

In 1871 (34 Vict., ch. 16, § 2), the Secretary of State and the chief Secretary of Ireland were empowered from time to time to vary the period limited by § 13 of 2 and 3 Wm. IV, ch. 75, for transmission of certificates of interment to district inspectors.

This appears to be the latest legislation upon the subject in England.

In this country, there is quite a diversity among the statutes upon this subject, and in many of the States, especially the Southern States, there is no legislation whatever upon the subject, other than statutes prohibiting the robbing of graves, etc. Many statutes, and among them the statute of this State (Rev. Stat. Ill., ch. 91), provide that "it shall be lawful" for the designated officers to deliver up the dead bodies, etc., or that they "may" deliver, etc., without containing words making it the imperative duty of such officers to deliver, etc. It is very possible, and in some cases probable, that the word "may" in such statutes, should be construed to mean "shall" or "must." "The words 'may' or 'shall,' when used in a statute, may be read interchangeably, as will best express the legislative intention. The rule adopted by this court [Supreme Court of Illinois] is 'the word may means *must* or shall only in cases where public interests and rights are concerned, and the public or third persons have a claim *de jure* that the power shall be exercised.'" Schuyler County v. Mercer County, 4 Gilm. 20; Wheeler v. City of Chicago, 24 Ill. 107; Fowler v. Perkins, 77 Ill. 273; Rex v. Barlow, 2 Salk. 609. S. C. Carth, 293; Newburgh Turnpike Co. v. Miller, 5 John. Ch. 112; Malcom v. Rogers, 5 Cow. 188; Hill v. Barge, 12 Ala. 693; Lovell v. Wheaton, 11 Minn. 101; Phelps v. Hawley, 52 N. Y. 27; Rex v. Inhabitants of Derby, Skinner, 370.

Where a statute directs the doing of a thing for the sake of justice or the public good, the word "may" is the same as the word "shall." Rex v. Barlow, 2 Salk. 609; S. C. Carth. 293; People v. Otsego Co., 51 N. Y. 401; People v. Livingston Co, 51 N. Y. 119; Rex v. Inhabitants of Derby, Skin. 370. See also the cases next above cited. Thus, where a statute says that a sheriff *may* take bail, it has been construed to mean that he shall do so. Rex v. Barber, *sup.*

On the other hand, if any right to any one depends

upon giving to the word "shall" an imperative construction, the presumption is that the word was used in reference to such right or benefit; but where no right or benefit to any one depends upon the imperative use of the word, it may be held to be directory merely. Wheeler v. City of Chicago, 24 Ill. 105; Fowler v. Perkins, 77 Ill. 273.

In the draft of a statute upon this subject, therefore, it is better, in order to avoid doubt, to use such words as express unequivocally the intention of the legislature to impose a duty upon the officials mentioned in the act to deliver, etc.

Many statutes contain a provision authorizing the delivery of dead bodies to county medical associations, or to some reputable physician, in cases where there is no medical school in the county. Such a provision, as well as others that might be mentioned, are doubtless very desirable in some cases, but they have not been included in this draft, for the reason that, should this draft be used as a model upon which to frame a bill for introduction into the Legislature, they might antagonize some members, and endanger the passage of the bill. If thought desirable, it will be easy to incorporate such provisions. It has not been attempted to make this bill *perfect*, but only *practicable*. It is believed, however, that all the really good features of the various acts upon this subject, which are to be found upon the statute-books of the various States of this Union, will be found in this bill, and a number of other provisions which seemed necessary have also been incorporated in it.

An Act to promote the science ot anatomy, medicine, and surgery in the State of Illinois.

Be it enacted by the People of the State of Illinois, represented in the General Assembly:

Section 1. The right to dissect the dead body of a human being, or any part thereof, shall exist in the following cases:

(1) In cases authorized by positive enactment of the General Assembly of this State, in this and other statutes.

(2) Whenever a coroner is authorized by law to hold an inquest upon the body, so far as such coroner authorizes dissection for the purposes of the inquest, and no farther.

(3) Whenever and so far as the husband, wife, or next of kin of the deceased, in case the deceased leaves no surviving husband or wife, may authorize dissection for the purpose of ascertaining the cause of death, and no farther.

(4) Whenever a person has, during his lifetime, directed that his dead body, or any part thereof, may or shall be dissected, or where any person has directed or given permission that any part of his body which has become separated therefrom during his lifetime, be dissected, such dissection shall be lawful to the extent authorized by such person, and no farther.

Sec. 2. Every person who makes, or procures to be made, any dissection of the dead body of a human being, or of any part thereof, contrary to the provisions of this act, shall be deemed guilty of a misdemeanor, and upon conviction thereof shall be fined not less than $25 nor more than $100, or be imprisoned in the county jail not less than one month nor more than three months, or shall be punished by both said fine and imprisonment, at the discretion of the court.

Sec. 3. Every superintendent of a penitentiary, State, city, or county hospital for the insane, warden of poor-house, coroner, sheriff, city undertaker, and every other public officer by whatsoever name designated, lawfully having charge of the body of any deceased person required to be buried at the public expense, shall immediately, by telegraph when practicable, otherwise by letter, notify the nearest known relative of such deceased person, if he knows or can with reasonable diligence ascertain the same, or, if no relative can be found, then some personal friend of such deceased person, if any such is known to exist, of the death of such person, and shall deliver the body of such deceased person to any such relative or personal friend, who is known to or shall prove himself to be such, and the officer or authorities having charge of the body, and who shall claim the same for interment within a reasonable time after such notice, not exceeding forty-eight hours after the death of such person; but if no such relative or friend sh all claim the body within forty-eight hours after death, it shall be the duty of such officer or authorities having charge of such body forthwith to deliver the same to the officer or duly authorized agent of any respectable medical college, of whatever school, regularly chartered by this State, making application therefor, and which has given the bond hereinafter referred to, and otherwise complied with the requirements of this act necessary to obtain its benefits; and it shall be lawful for such officer or agent to receive the said dead body, and for the said medical college, through its professors, officers, and students, to use the same as they may deem most for the advancement of anatomical, medical, and surgical science, but for such purposes only, and in this State only.

Provided, That if any body so delivered shall be subsequently claimed for interment by any such relative or friend of the deceased, it or the remains thereof shall be forthwith surrendered up for that purpose.

Provided, also, that the remains of no deceased person who is known during his last sickness to have expressed a desire to be buried; the remains of no traveler dying suddenly, the remains of no person detained on any civil process, or as a witness, shall be so delivered, but shall be decently buried in the usual manner.

Provided, also, that the bodies so delivered shall be distributed among the several respectable, regularly chartered medical colleges of this State, of whatsoever shool of medicine, according to the number of students regularly matriculated during the winter session of the college year next preceding the time of application and distribution; provided, however, that no medical college shall receive more than three (3) bodies, till every other medical college which has filed the bond hereinafter required, otherwise complied with the requirements of this act, and made application therefor, shall have received at least one (1), and no application shall be made, or if made, shall be al-

lowed, till the college so applying is ready to receive and remove the body or bodies applied for, and has given bond hereinafter required and otherwise complied with the requirements of this act. Any violation of any provision of this section shall be deemed a misdemeanor and shall be punished by a fine of not less than $50 nor more than $200, or by imprisonment in the county jail not less than three nor more than six months, or by both said fine and imprisonment at the discretion of the court.

Sec. 4. In order to facilitate the equitable distribution of said bodies, it shall be the duty of every medical college so applying to file with each and every application for a body or bodies a statement of the number of students matriculated as aforesaid, and the number of bodies received by it from all sources up to the date of such applicaiion under the provisions of this act during the current college year, which for the purposes of this act shall be deemed to commence upon the day when this act goes into effect and end on the 31st day of August next ensuing, and every year thereafter shall commence with the 1st day of September and end on the 31st day of August of each and every year, and no application shall be allowed which is not accompanied by such statements. In making the distribution and delivery of dead bodies above provided for, each and any officer or person concerned in the same shall be governed by the statements thus filed and by the principles stated in this and the preceding sections. In order to equalize any irregularity of distribution resulting therefrom, it shall be the duty of each and every medical college claiming the benefit of this act, through its clerk or other recording officer, on or before the 5th day of September, each and every year, to file with the Secretary of the State Board of Health a statement in writing and under oath, of the number of students regularly matriculated during the winter session of the college year ending on the 31st day of August next preceding, and the entire number of bodies received from all sources under this act during the same period; and it shall be the duty of the said Secretary of the State Board of Health forthwith to equalize the distribution of bodies appearing from such statements, according to the principles of this act, and to certify the results of such equalization and transmit a copy thereof under his hand and seal as soon as may be to each college which has filed the statements above required, showing (1) the entire number of bodies each college was entitled to receive under this act during the year next preceding; (2) the number of bodies each college has in fact received; and (3) the number of bodies to be delivered by each college respectively which has received an excess over the number it was entitled to receive, to each college respectively which has received a less number than it was entitled to receive; and therefore it shall be the duty of each college respectively thus appearing to be in excess, to deliver within a reasonable time after the reception of such copy of said certificate, to each college respectively which has received less than the number it was entitled to receive, so many bodies as said certificate shall specify as being necessary to equalize the distribution according to the principles hereinbefore laid down. Every medical college neglecting or refusing to file with the Secretary of the State Board of Health the statement above required, or neglecting or refusing to comply with the terms of equalization above provided for as shown by the said certificate of the Secretary of the State Board of Health, shall thereby forfeit during the the time it shall so neglect or refuse such compliance, all rights and benefits otherwise accruing to it under this act; and a subsequent compliance with such requirements shall not entitle it to the benefits which might have otherwise accrued to it during the period it was so in default.

Sec. 5. Every medical college claiming the benefit of t his act shall, before it shall be entitled to receive any dead body as aforesaid, execute and file with the clerk of the county in which such college is situated, who shall give a receipt therefor, a bond to the People of the State of Illinois in the penal sum of $1,000, with a surety or sureties to be approved by said county clerk, conditioned that each and every body received under the provisions of this act shall be used only for the advancement of anatomical, medical and surgical science, in this State only, and in such a manner as not to shock the public sensibilities, that said college will cause to be kept the record required by this act, and that the remains of every such body after use as aforesaid, shall be decently buried in some public burial ground in this State; which bond shall be renewed on the first day of September of each and every ensuing year.

Sec. 6. The person receiving any dead body under this act shall, in the name and in behalf of the medical college for which he receives it, sign and deliver to the officer or person from whom the same is received, and whose duty it shall be to demand and obtain such receipt, a receipt therefor, stating, if known, the name, age and sex of every such person, and the place, date, and cause of death, if known, which receipt shall be preserved and recorded in a book to be kept for that purpose in the institution, association, or office from which such body shall be delivered, and a copy thereof immediately transmitted to the Secretary of the State Board of Health, whose duty it shall be to file the same in his office. And every medical college receiving any dead body under this act, shall by its demonstrator of anatomy or other analogous officer, in a suitable book to be kept for that purpose, make a legible record of the time when, the name and official station of the person from whom, and the place where such body was received, and whether or not such body when so received was inclosed in any box, cask, or other receptacle, and, if so inclosed, such record shall contain a description of such box, cask, or receptacle sufficient to identify the same, together with the shipping mark, or directions, if any, on the same. Such record shall also contain a description of such body or remains, including the name, if known, sex, length and weight of the body, and the probable age of the deceased at the time of death, color of hair and beard, if any, condition of teeth, and any and all wounds, marks or scars, if any, on such body by which the same might be

identified; and whether or no such body when so received was mutilated so as to prevent identification of the same. And such record shall be preserved by such medical college through its demonstrator of anatomy or other analogous officer, whose duty it shall be to exhibit the same on demand, as also any and all such dead bodies then in his charge, for the inspection of any sheriff or deputy sheriff of this State. Any violation of any provision of this section shall be deemed a misdemeanor, and shall be punished by a fine of not less than $50 nor more than $200, or by imprisonment in the county jail not less than three months nor more than six months, or by both said fine and imprisonment at the discretion of the court.

Sec. 7. Any person who shall buy or offer to buy, sell or offer to sell, the dead body of any human being, or procure the same to be done by another; or any person who shall offer, pay, demand or receive any money or any valuable consideration whatever, or procure the same to be done by another, in consideration of the delivery for anatomical, medical or surgical purposes, of the dead body of any human being, or who shall transport the dead body of any human being beyond the limits of the State for anatomical, medical or surgical purposes, or who shall procure the same to be done by another, shall be deemed guilty of a felony, and upon conviction thereof shall be punished by imprisonment in the State's Prison not less than one year nor more than five years.

Sec. 8. Inasmuch as the law now in force upon the subject of this act is defective, an emergency exists requiring this act to take effect immediately; therefore this act shall take effect and be in force from and after its passage.

PSILOSIS (?) MUCOSÆ INTESTINI.

BY C. M. FENN, M.D., SAN DIEGO, CAL.

In a brief article which you copy from the *Practitioner*, Sept., 1883, I discover that Dr. Thin has anticipated me somewhat in the description of a lesion of the mucous membranes, which I have been studying with much interest, as often as such cases came under my observation. Having met with but few instances of it, and most of these *in transitu* (non-resident), I hesitated to announce my impressions until after further investigation. However, by contributing a few paragraphs now, I may at least assist in calling the attention of others to this peculiar disease.

The name "psilosis (loss of hair by depilation) mucosæ intestini," with which the new malady has been christened, would seem to be somewhat forced in its application to epithelial (intestinal) desquamation, but, perhaps, does not do great violence to our usual nomenclature of diseases.

Though I have not yet been able to recognize the three stages noted by the doctor, and have seen no fatal results, I have every reason to believe, from the similarity of symptoms and the indications of treatment, that the diseases are identical. Having but little to add to his graphic summary of symptoms, I shall confine my remarks chiefly to its pathology, "about which," Dr. Thin says, "little is known."

The histories thus far obtained by me have been of miners, ranchers and Chinese, all single men, who have "roughed it." They had used stimulants to some extent; and at periods more or less remote had suffered from supposed bilious troubles. Some of them had been addicted to patent pills and potions, or had consulted physicians for the relief of some prominent symptom, or general malaise. In some instances, the condition of the posterior nares and pharynx had suggested catarrhal (ozœna) trouble; or a chronically irritable throat had given rise to a suspicion of venereal excesses, syphilis, etc. In others, itching and soreness of the rectum, with or without discharge, had indicated vermifuges and pile remedies, which had been used in vain. Flatulence, diarrhœa, constipation, and other gastric and intestinal disturbances had often been overlooked in the presence of more tangible symptoms. A peculiar odor, simulating that from chronic diarrhœa or dysentery, not infrequently emanated from breath and body. If the disease had been protracted, there was a notable deficiency of adipose tissue, the dry and flabby skin covering the body like an ill-fitting mantle; the hair had become thin; the nails ribbed and horny; and the conjunctiva, especially of the lids, was irritable, if not inflamed. The appetite was always good, sometimes morbid, but food was not properly assimilated. In brief, there was an aged appearance, an obvious impairment of the general physique and system, which, in the absence of advanced age and of the usual exhausting diseases, was remarkable.

The pathology of psilosis, in my opinion, points to a defect in the formative power of the epithelium of the mucous membrane, or to some derangement of the desquamative process. To substantiate this view it will be necessary to consider briefly the function of the bile as taught by later physiologists. In the opinion of Küss, for example, the bile is especially concerned in this desquamation of the intestinal epithelium. After showing that the biliary secretion is not poured into the duodenum until several hours after the ingestion of food, in fact, not until most of the alimentary substances have already been converted into chyle; and that the desquamative process is most active when the bile comes into contact with the epithelial cells, he adds, "the chief purpose served by the bile is thus the renewal of the cellular coats, promoting the decay of the old elements and the restoration of the new." Accepting this theory, and in connection therewith recalling the symptoms of psilosis and allied diseases, as well as the physiological experiments bearing upon this secretion, I think we shall have no difficulty in discovering the *fons et origo mali*.

Bidder and Schmidt's experiments upon animals demonstrated that when the bile is carried off through a fistulous opening in the gall-bladder, the fatty elements of the food are no longer absorbed; the skin becomes dry; the hair falls off; the breath and body exhale foul odors; and the animal, with even a vora-

cious appetite, perishes with symptoms of inanition. Reverting again to the human system, the effect of opium upon all of the secretions is well known. Opium smoking especially interferes with the functions of the liver, mucous membranes and skin. (May not this national habit in part account for the large number of cases of psilosis, which, the writer says, came from China?) So, too, fatty degeneration, atrophy and cirrhosis of the liver, in which there is more or less mechanical interference with the secretion of bile, give rise to indigestion, flatulence, constipation, dry and rough skin, exhaustion and death.

In the absence of a quantitative and qualitative analysis of the bile, it is impossible to determine in what manner it affects the absorptive and other functions of the intestinal epithelium; whether there is not enough of it, as Küss suggests, "to sweep the workshop clean" of the old cells, or whether its vitiated character impairs the function of the new epithelium. But from the fact that symptoms, known to attend suppression and retention of the biliary secretion, are seldom absent at some period of the malady, and that cholagogues are often indicated in the treatment, we may rationally infer that a deficiency of bile is one of the chief factors in the ætiology of psilosis.

A CASE OF POISONING FROM A BELLADONNA PLASTER.

BY HERBERT JUDD, M.D., GALESBURG, ILL.

EDITOR OF THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION:

The case of belladonna poisoning resulting from the application of a belladonna plaster, reported in the *Medical Record* of January 19, 1884, by Martin J. Fleming, M.D., of New York, leads me to report the following case:

February 5, 1883, at 8 P. M., I was called to see C. H., at the Union Hotel, who, while descending the stairs of the hotel one hour before, had slipped and fallen upon his left side and back. His general condition was good, his habits temperate. The only treatment I advised was to apply over the seat of pain a belladonna plaster. The plaster was to be cut from a pattern I made of paper, triangular in shape, and has since been found to aggregate about twenty-six square inches in surface; the plaster was of the ordinary roll plaster, prepared by Seabury & Johnson, not porous. There had been no liniment nor any irritating or soothing lotion of any kind used. There was no abrasion of the skin. At 11 o'clock, three hours later, I was telephoned in great alarm and distress by the hotel people to hurry to my patient. Their replies to my questions concerning his condition were such that I queried with Dr. Ira Wilcox, of New York city (then a guest at my house), and Dr. Hopper and Edgerton, who were also present, if it were possible the patient was affected by the plaster; the plaster had been cut and brought to me for inspection before it was applied, as it had at first been cut wrong and would not fit the body as I had directed; in this manner the size of the plaster and the case had been brought to the notice of the above named physicians. We all thought it could not be the plaster.

I found the patient suffering in an extreme degree from the poisonous effect of belladonna; at least, such was my opinion, and explanation to the terrified attendants. The patient could not see distinctly; the face and neck were flushed to a deep scarlet; he could not swallow and was in spasm. I removed the plaster and gave a hypodermic of morphine; he immediately became quiet, and at the end of one hour was in a nearly natural sleep. The disturbance of vision lasted three days. My patient was a member of the traveling public and a favorite among them, also an old resident of this city, so that I became *famous* for not only giving *strong medicine*, but for using *strong* belladonna plaster

MEDICAL PROGRESS.

MATERIA MEDICA AND THERAPEUTICS.

HYDRIODATE OF HYOSCIN IN PHTHISIS.—Dr. Fräntzel recommends hydriodate of hyoscin in the treatment of night-sweating of phthisis, in subcutaneous doses of half a milligramme ($^1/_{140}$ gr.), or in pill, beginning with the same dose. He does not find it so universally beneficial as atropia, and it sooner exhibits a narcotic action; but he has seen good results from it in cases where atropia has proved useless, or has failed to act after being in use for some time.—(*Wiener Med. Blätter.*) *Practitioner.*

KRANKENHEIL.—Of late years a new spa in Bavaria, to which the suggestive name of Krankenheil has been given, has attained much popularity, especially in the treatment of strumous diseases, skin affections, etc. The water contains principally carbonate of soda, with a little iodine and a small amount of sulphur. Various preparations are made from it; soaps, for toilet and medicinal purposes; soap liquors also; the mother liquor of the spring; the salts in powder and made into lozenges.—*Birmingham Medical Review.*

TREATMENT OF HOARSENESS IN SPEAKERS AND SINGERS.—M. Corson advises the placing in the mouth of a small piece of borax, about two or three grains; it produces an abundant salivation, and the voice becomes clear. He also recommends the use of a couple of grains of potassium nitrate in a glass of sugar and water, or an infusion of 46 grains of jaborandi, and—shortly before using the voice—of a gargle with 6 or 7 ounces of a decoction of barley, 1 to 2 drachms of alum, and 2 drachms of honey of roses.—(Rep. de Pharmacie). *Jour. de la Soc. de Med. de la Haute-Vienne.*

EUCALYPTUS IN GANGRENE OF THE LUNGS.—Dr. Bonamy relates the case of a man, about fifty years of age, who was admitted to hospital suffering from cough, dyspnœa and fever. A few days after admis-

sion, the fœtid odour of his breath became so extreme that it was necessary to separate him from the other patients. There was dullness in the axillary line on the left side over the middle portion of the lung. At this point there was tubular respiration, and crepitant râles were audible at the end of inspiration. The sputa consisted of a black matter, detached portions of which were swimming in an abundant serous fluid. The cough was incessant, and the odor intolerable. A diagnosis was made of gangrene of the lung of superficial extent. The patient was first put upon a mixture containing carbolic acid, but no improvement following, this was replaced by tincture of eucalyptus. In two days after the last prescription the odor of the breath was much less offensive, and in less than two weeks the patient was cured.—(*Le Courrier Medical.*) *Practitioner.*

Bromide of Ethyl.—Prof. O. Berger has found bromide of ethyl useful, (1.) In neuralgic conditions of the nerves of the face and head, in megrim, and in nervous headache and heaviness. The inhalation of twenty to forty drops of the remedy several times a day has lessened headache in cases where quinine, salicylic acid, caffein and guarana had all proved useless; and in three cases of headache connected with cirrhosis of the kidney it was better than any other remedy. (2.) In neurasthenia: it is here given in doses of from one to three grammes twice or thrice a day if necessary. (3.) In epilepsy: here it is of very little use, although Brumeville and D'Ollier considered it useful. They narcotized their patients daily for ten to twenty minutes with it, but when given in doses of one gramme daily by inhalation it is useless. It is besides expensive, and causes much depression. When inhaled before or during the epileptic attack it only prevents or cuts it short in exceptional cases. (4.) In hysteria it is of more use. The attack of hystero-epilepsy may sometimes be cut short by narcotizing with it for ten or fifteen minutes, eight to twelve grammes of the drug being required. When given in doses of a half gramme to two grammes by inhalation, once or twice a day, it may avert a threatened attack of hystero-epilepsy. (5.) In several cases of psychical excitation the bromide of ethyl has proved serviceable.—(*Breslauer ärzt,. Zeitschrift.*) *Practitioner.*

Trichlorphenol, the Best Disinfectant for Gangrenous and Foul Wounds and Ulcers.—In 1879 Dianin noticed that a solution of carbolic acid, to which chloride of calcium had been added, was of great use in foul ulcers, and later he satisfied himself that this was due to the trichlorphenol thus formed. This combination was discovered in 1836 by Loran, and has the formula $C_6 H_2 C L_3 O H$; it is a phenol, wherein three atoms of hydrogen are replaced by three atoms of chlorine. It possesses the characteristics of an acid, forming well-defined salts with potash, magnesia, ammonia, baryta, lead, and calcium. The calcium salt is that which is formed by adding the chloride of lime to the solution of carbolic acid. This combination is an excellent disinfectant, being twenty-five times more powerful than ordinary phenol as an antiseptic. Experiment shows that the power of arresting fermentation, which is possessed by trichlorphenol and its potash and calcium salts, is marked alike whether in arresting the fermentation in wine, putridity in the blood, or the ammoniacal decomposition in the bladder. Clinical observations were made as to its effect on gangrenous ulcers of the limbs, gangrenous phlegmon, wounds from machinery, complicated fractures and dislocations, carbuncles, cancerous ulcers, caries, etc., all more or less gangrenous, and throwing out foul-smelling secretions. For complete purifying of the sloughing surfaces and the production of healthy granulations, usually four to six days were enough, and rarely ten to thirteen days were required. The method of application was generally to apply to the sloughing parts a 5 per cent. solution of the trichlorphenol, and thereafter to cover the parts with a bandage soaked in a 1 per cent. solution. Sometimes the dried trichlorphenol was powdered on, and the bandage allowed to remain from five to eight days. The drug was also used for soft sores, diphtheria, etc. In all cases the disinfectant and deodorizing powers were very strong. The smell of the drug may be hid by the use of oil of lavender. The soda salt has no smell. All the preparations are cheap.—(*Petersb. Med. Wochenschrift*). *Edin. Med. Jour.*

Cider and Its Anti-Calculous Properties.—A writer in the *Gaz. Med. de l'Algerie* calls attention to a recent publication by a pupil of Dr. Denis-Dumont, surgeon-in-chief of the Hotel-Dieu, of Caen, which professes to demonstrate that cider is the enemy of stone in all the varieties of calculi which, from one cause or another, affect the bladder. During a long experience in the hospitals of Caen, Dr. Denis-Dumont was struck with the almost complete absence of patients affected with stone—almost complete, because there were a few cases whose habitual beverage was wine. On treating these cases with cider, they were either considerably benefited, or entirely relieved of their malady. Struck with these facts, Dr. Denis-Dumont entered into correspondence with a large number of the medical practitioners of Normandy, principally those who practiced in localities where cider was the common and almost sole beverage. Of these practitioners, some of whom were of forty years' experience and longer, none had treated a case of stone. If they had treated any affection allied to stone, it was in cases where cider was not the ordinary drink, or it was due to some foreign cause. As a consequence, he has collected a mass of valuable observations which confirm his conjectures, and support him in formulating the proposition that cider is not only a prophylactic against the formation of stone and other affections of the bladder, but also that it is an energetic curative agent, when in the condition to be absorbed, like any ordinary drink, and brewed in the best manner. Cider, even in Normandy, is frequently improperly made—but it would seem that bad cider is not worse than bad wine. The writer, using the precaution to declare that he is not of Normandy, goes on to say, with the effusion of a Frenchman, that, if the results of Dr. Denis-Dumont are

admitted, they will furnish cause enough for the encouragement of plantations of apple-trees, and for the fabrication af a beverage which laughs at the phylloxera, which has been served on the table of a Queen of France, to Saint Radegonde; which Charlemagne did not despise; which was celebrated after the epic mode in a Latin poem dedicated to the glory of Phillippe-Augustus by Guillaume le Breton, and which Francois the First appreciated on his visit to Normandy.

MEDICINE.

LYMPHORRHŒA FROM THE NOSE IN LEUCOCYTHÆMIA.—Dr. Coniel relates the case of a patient suffering from leucocythæmia who had a discharge from the nose of a thick, transparent, glairy fluid. It flowed slowly but constantly, and was neither thin like the discharge of a commencing coryza, nor opaque like that of a more advanced nasal catarrh, but contained a large quantity of white corpuscles. The patient did not sneeze, nor were there any tickling sensations in the nose. At the autopsy the mucous membrane of the nasal fossæ was seen to be smooth, without ulceration, but thickened in places. The thickened parts presented a gray color on section. They were formed by an infiltration of the connective tissue with a mucous transparent fluid, like lymph. It was this leukæmic infiltration of the Schneiderian mucous membrane which was the cause of the nasal lymphorrhœa.—(*Revue Medicale Practitioner.*

THE HOT WATER "CURE."—The *Lancet* has some very timely remarks under this heading. It is probable that we have not yet begun to appreciate how wide-spread is the application of this so-called cure, nor how much mischief it is gradually producing. The article in question says very forcibly: There is no lack of evidence that crude or decomposing contents of the alimentary canal may be washed away by copious draughts of hot water, and that the apparatus of digestion thus cleansed at short intervals will work better than when it is coated with débris and excreta. On the other hand, it is not less well known that the mucous membrane of the stomach and intestines may become permanently congested, and the essential parts of its structure—the organs of secretion and absorption—rendered habitually swollen and turgid, with the result of impairing their functions, by too frequent "fomentation." Like everything else, the use of hot water as a "cure" needs to be determined by considerations of expediency, based on a precise judgment of the state and conditions in each individual case. If it should become popular to drink hot water largely, we shall soon be called upon to treat patients who have done themselves a lasting, and, it may be, a serious injury by this practice. If it should happen that where there already exists a tendency to congestion, the blood-vessels are denied the opportunity of contracting and relieving themselves in the intervals of digestion, or if "gastric juice"—to use a popular term—slowly and laboriously secreted in cases with impaired or debilitated glands, be ruthlessly washed away by too frequent drinking, the "advantages" of the hot water cure are not likely to prove welcome results of a "plan of treatment" which has been misapplied.

We heartily endorse these views as expressed in the *Lancet*, although we do not see how the gastric juice is to be ruthlessly washed away. As we understand it, the hot water is used only in the intervals of digestion, and as the gastric juice is secreted by the stimulus of food to be re-absorbed when it has performed its work of digestion, it could not directly be very much influenced.

OPHTHALMOLOGY.

EPITHELIAL GROWTH FROM AN EYELASH IN THE ANTERIOR CHAMBER.—This case occurred in the practice of Mr. Rockcliffe, of Hull, and is reported in the last number of the *Transactions of the Ophth. Society*. A man received a blow which lacerated the cornea and caused prolapse of the iris, and, at the same time, some slight injury to the lid. The iris receded under atropine, and the injury was not followed by much inflammation. He was first seen six weeks after the accident. At that time, what was supposed to be an eyelash was seen lying in the anterior chamber, and an attempt was made to remove it, but without success. A little more than a year later a tumor 6x2x2 mm. was removed, along with a portion of iris. The growth was examined by Dr. Brailey, who reported: "The mass consists of flattened epithelium cells, exactly like the superficial cells of the conjunctiva, and their nuclei stain very distinctly. It looks as if the cells of the root-sheath of the eyelash had proliferated in the anterior chamber."—*Edin. Med. Jour.*

PHYSIOLOGY.

ON THE ACTION OF INFUSED BEVERAGES ON PEPTIC DIGESTION.—Dr. James W. Fraser (*Edinburgh Clinical and Pathological Journal*) under this heading gives an abstract of the results of a series of experiments performed with the view of elucidating the action of infused beverages in producing the dyspeptic symptoms which so frequently follow their use, and, if possible, to find some means of reducing these undesirable actions. The beverages subjected to experiment were: As examples of the teas—mixed tea, Chinese tea, Indian tea, green tea; of the coffees—ordinary coffee, coffee with chicory, and the coffee berry very slightly roasted, broken into fragments, and the infusion prepared by very brief boiling with water; of the cocoas—Schweitzer's cocoatina, from which part of the fat has been extracted, and Epp's cocoa, from which no fat has been extracted. The artificial gastric juice employed had the following composition:

Benzer's liquor pepticus	20 c c
Dilute hydrochloric acid	12 c c
Distilled water to	100 c c

The experiments are given in detail with compre-

hensive tabular statements, the chief points of which may be recapitulated as:

(1.) All infused beverages retard the peptic digestion of albuminoid food stuffs, with four exceptions, viz.: ham and white of egg with coffee, and fish with cocoatina and cocoa.

(2.) The digestion of the meats ordinarily used at breakfast, viz.: ham, egg, and salt beef, is less retarded by the action of tea and coffee than that of other meats, and the same is true of roast beef.

(3.) That this retarding action is less, as a rule, with coffee than with tea, and less with either than with the beverages of the cocoa order.

(4.) That the retardation is caused (*a*) in the case of "teas" by the tannic acid, assisted by the volatile oil, the former precipitating the uncoagulated albuminoids of the food, and the syntonin and peptones as formed, tanning the gelatinous constituents of the meats, and removing some of the pepsin by entangling it with these precipitates, and the latter retarding the action of the pepsin. The alkaloid of tea appears to assist digestion, but its action is masked by that of the tannic acid and volatile oil. (*b.*) In the case of "coffee" the caffeo-tannic acid and volatile oil retard digestion. and the alkaloid assists it. (*c.*) In the case of the cocoas, the tannic acid, volatile oil and alkaloid all assist in retarding digestion.

(5.) In retarding the consumption of acid during digestion, tea has the greatest effect; coffee has no more effect than water, and cocoa increases the consumption.

(6.) Coffee and cocoa cause the peptic digestion of albuminoids to pass on through the stage of peptones, to the formation of leucine and tyrosine.

(7.) Tea acts on the digestion of fresh meat so as to increase the production of flatus, but has no such effect with salt meat, and coffee has no more effect than water.

(8.) The addition of cream and sugar to the beverage reduces the retarding action of tea on digestion, but increases that of cocoa; and coffee appears to have its action reversed by these additions, but this result is doubtful.

From these experimental results the following practical conclusions are to be drawn:

If at any meal containing much albuminoid matter, infused beverages be drunk instead of water, the person making this meal must either eat more albuminoid matter or be content to suffer that loss. This is, of course, undesirable, for, even if the power of the beverage to reduce tissue waste, were such as to compensate for the albuminoid matter lost, it would manifestly be more economical to take the infused beverage on an empty stomach, and then, when mealtime came, less food would be required.

If flatulence be the chief cause of trouble, tea should be avoided when animal food is eaten; coffee being the best beverage.

If the dyspepsia is of the acid form, tea is the worst, coffee neutral, and cocoa the best beverage, from its increasing the consumption of acid. This would apply to the over-acidity of the gastric juice and to its over-secretion, but if there is any tendency to the lactic acid fermentation, cocoa should be avoided, from the sugar it contains.

In the case of those who habitually eat too much albuminoid matter, which, if absorbed, would have to be eliminated by the kidney as urea, and so might cause gout or some renal complaint, tea would seem to be a useful beverage by its property of preventing the digestion of some part of the food, and causing it to be rejected unabsorbed.

The after-dinner cups of coffee and tea may have their uses, but from a digestive point of view are hardly free from disadvantages. Perhaps the ladies at five o'clock tea have chosen the best time for the consumption of their favorite beverage, for early lunch has had time to have been chymified and to have disappeared from the stomach, and the interval before dinner is long enough to allow of the digestion of the very small amount of solid food which is supposed to be consumed at "kettledrum."

The Work Done by the Heart.—Howell and Donaldson (Proceedings of the Royal Society of London) conclude that the mean ratio of the maximum weight of blood pumped out of the left ventricle at each systole to the body-weight is $\frac{1}{855}$, with a pulse beating 180? The pressure in the left auricle is about 16 mm mercury; Goltz and Gaule had estimated it for the auricle of a dog at 19.6 mm mercury. They state that variations of arterial pressure of from 58 to 147 mm mercury have no effect on the force of ventricular contractions, and within these limits, therefore, heightened blood-pressure does not increase the work of the heart. The outflow from the left ventricle, and consequently the work done, increases with the venous pressure, but not proportionally. The most direct factor influencing the amount of work to be done by the left ventricle is the extent of intraventricular distension during diastole, which is mainly owing to the auricle, since pressure in the great veins seldom has any positive value, but often a negative one. Further, a diminution in the pulse-rate, by lowering the temperature of the blood flowing through the heart, causes an increase in the amount pumped out by the ventricle, and therefore increases the amount of work done by the ventricle. The changes in the outflow from the ventricle at each systole are not, as has been previously stated, inversely as the pulse-rate. The total outflow and the total work done by the ventricle during any given period of time, decrease with a diminished pulse-rate, and increase with an increased pulse-rate. These facts have a definite bearing on practical medicine. The experiments were conducted on dogs.—*Medical Times and Gazette.*

The New York Post-Graduate Medical School, about February 1, intend to move into new quarters on 20th Street, between 2nd and 3d Avenues.

The new building is especially adapted for a hospital and school combined, and is in a convenient neighborhood to the medical centers.

The school has been well patronized during the past year.

THE

Journal of American Medical Association.

PUBLISHED WEEKLY.

THE EDITOR of this JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information, should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE..... $5,00.
SINGLE COPIES..... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 65 RANDOLPH STREET,
CHICAGO, ILLINOIS.

SATURDAY, FEBRUARY 2, 1884.

BUFFALO, Jan. 21, 1884.

THE EDITOR OF THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, CHICAGO.

Dear Sir:—Your editorial upon signing the constitution, etc., of the A. M. A., leaves something of the peculiarity of the affair unexplained.

As you quite properly say, "every *member elect* is required to sign these regulations."

That this is the rule, and wisely so, to my knowledge was never questioned. But that this rule authorized the local committee, or the Judicial Council, or any other body, to exact from *permanent members* such a pledge as was made prerequisite to registration at the late meeting I very much doubt, and upon this important point your editorial is peculiarly silent.

Perhaps the term "member elect" is used with a significance quite apart from the ordinary, and possibly it may require the official interpretation of the Judicial Council to determine who are members and who members elect. But to those who give the words their usual meaning the fact remains that there was imposed upon the permanent members at the late meeting of the A. M. A. a restriction and form intended for *members elect* only, and therefore that this restriction upon the *permanent members* was unauthorized, and, being so, was liable to be severely characterized.

As to the meaning of the term, or rather as to what is included in the term "these regulations," it may be of interest to discuss at some future time. At present it would seem to be desirable to ascertain, and as you have introduced this subject in a prominent manner I trust that you will give the required information, as to who may be the *members elect* of the A. M. A. With the hope that you may find room in the THE JOURNAL for this note, I remain a permanent member,

H. R. HOPKINS.

The writer of the foregoing letter suggests three questions, namely, first, who are "members elect," as these words are used in the last paragraph of the plan of organization or constitution of the American Medical Association relating to *members?* Second, what is included in the words "these regulations" as used in the same paragraph of the constitution? Third, had the local Registration Committee, or any other authority, the right to exact of permanent members a pledge endorsing the constitution and Code of Ethics of the Association as a condition of registration?

It is always a pleasure to aid those who are seeking relief from either mental doubts and embarrassments or physical infirmities, consequently we will do what we can to remove any doubts concerning the questions suggested by our correspondent. It must be kept in mind that the paragraph in which the words "members elect" occur is a part of the second section of the constitution defining who shall be members of the Association. The section provides for three classes of members, *i. e.*, delegates, permanent members and members by invitation. The first are to be elected annually by State and local medical societies and from the medical corps of the Army and Navy, and from the Marine Hospital Service. The second embraces such as have been not only *elected* but have *served* as delegates at least once, or have been elected directly by unanimous vote of the Association. The third, or members by invitation, are also elected, but only as members for the meetings of the session at which they are elected. It will be seen that there are no members of the Association except such as are primarily elected to that position. Consequently, all members are in the strictest sense "members elect." One class are recently elected to represent some organized part of the profession and are called delegates; another, having been elected and served their time as delegates remain as permanent members so long as they comply with the regulations of the Association. The exact question raised by our correspondent is, whether the words "every member elect," mean all the members provided for in the section of the constitution relating to members, or only those newly elected as delegates? The whole paragraph in which the words in question occur is as follows:

"Every member elect, prior to the permanent organization of the annual meeting, or before voting on any question after the meeting has been organized, must exhibit his credentials to the proper committee, and sign these regulations, inscribing his name and address in full, specifying in what capacity he attends,

and, if a delegate, the title of the institution from which he received his appointment."

If the reader remembers that the preceding paragraphs of the same section had practically provided for two classes of members, one directly representative of some organization and called delegates, and the other permanent members, and then reads carefully this paragraph, he cannot fail to see that the phrase, "every member elect," actually includes every member presenting himself for admission or registration; else why, after requiring him to "sign these regulations," require him also to "specify in what *capacity* he attends, and, *if a delegate*, the title of the institution" he represents, etc.? This phraseology clearly implies that "every member elect" applies to those attending in more than one "capacity," and even more clearly, that it applies to members who are not delegates, as well as to those who are. Otherwise the words, "if a delegate," would be both superfluous and senseless. There is, therefore, no escape from the conclusion that signing of the constitution and by-laws is a requirement of the constitution, to be executed as one of the conditions for registration or admission to the annual meeting, binding alike upon all members, in whatever *capacity* they may attend, with the additional obligations upon those claiming to be delegates that they specify "the title of the institution from which they received their appointment."

In regard to the second question suggested by our correspondent, relating to what is properly included in "these regulations," it is only necessary to turn attention to the closing words of the resolution by which the whole plan of organization was adopted in the adjourned convention of 1847, and which is published as a part of the preface to the constitution and by-laws in the several volumes of Transactions of past years. That they refer directly to the constitution and by-laws adopted for the government and practical working of the institution there can be no doubt. That the Code of Ethics constitutes a part of "these regulations," is so obvious from the use made of it in the fourth paragraph of Section II of the constitution and in the ninth by-law, that there is little room for any doubt on the subject. The third question suggested by our correspondent, regarding the *right* of the registration committee to exact of permanent members the same endorsement of the "regulations" as they do of delegates, is settled in our answer to his first. Instead of having adopted a new rule operating restrictively upon the rights of permanent members, at Cleveland, the committee only resumed the execution of a plain constitutional duty, which had been neglected by the committees of several preceding years. As every permanent member must have been *elected* to his position primarily, and it is conceded that when so elected it was highly proper that he should endorse the "regulations" of the Association by his signature, we fail to see how the repetition of that signature every time he returns for admission to an annual meeeing works any possible "restriction" upon his rights or privileges. We can conceive of only one condition in which it might cause him some *embarrassment*. If he had so far forgotten the ordinary principles of consistency and honor, as to have entered into another organization, and lent his direct aid and endorsement to rules, regulations, and ethics antagonistic to those of the Association, we can readily see how he might feel somewhat embarrassed when called upon to re-sign those of the latter. Riding two horses at the same time, with the animals going in opposite directions, is very generally acknowledged to be a feat likely to give the rider much embarrassment.

The paper on the Treatment of Strictures of the Urethra by Dr. Reynolds, contained in this number of The Journal, failed to appear with other papers read before the Surgical Section of the Association, through an accidental omission of the Secretary of the Section to make any mention of the paper in his minutes.

The paper in this number on the history of legislation, concerning the disposal of the bodies of the dead, and the making of proper legal provisions for dissections in the study of anatomy, surgery, physiology, etc., was written by one educated in both law and medicine.

The news comes to us from over the sea that Mr. William Bowman is to be made a baronet. As the *Medical Times* says, men who are now thinking of retiring from practice, when they were students read no physiology but Todd and Bowman's. It is more than forty years since he was awarded a Royal medal by the Royal Society. Then it was quite probable that he would become the leading London surgeon, but he confined himself to the limits of eye-surgery.

Among the gentlemen recently admitted, after examination, to the Fellowship of the Royal College of Surgeons of England, was Dr. W. B. Platt, of Baltimore, U. S. He is the first native of the United States who has obtained this diploma. Subsequent to his course of study in the Harvard Medical School, Boston, he studied at Vienna, Berlin, Halle, Würzburg, Heidelberg and London.—*Lancet.*

SOCIETY PROCEEDINGS.

CHICAGO MEDICAL SOCIETY.

At the regular meeting held January 21, 1884, Dr. C. G. Davis read an original paper on the action of "Gelseminum Sempervirens," recording his experience during a number of years of observation, and which contains many points of interest. His preliminary remarks were substantially as follows:

The present advanced state of medical science is due in a great measure, if not entirely, to the recorded experience and observation of thinking men. If this be true, would it not be well if all physicians engaged in the active practice of their profession would make a special endeavor to observe more closely, and record more accurately, the various symptoms manifested by the action of medicine on the human system? A neglect of this on the part of many physicians has given rise to what we may properly term the "school of skepticism." They disbelieve entirely in the action of medicine to relieve disease, and often, while manifesting a sublime indifference to the appeals of the poor sufferer before them to be relieved, they go into ecstacies over the pathology of the case, and are plethoric with theories in regard to the ultimate nerve cells or molecules wherein the disturbing action arises. Be it understood, I cast no reflections upon scientific investigation in these directions, but the true office of the physician is to prevent, cure, or alleviate disease, and inasmuch as he fails in this, he fails to fulfill his mission. Regarding gelseminum sempervirens, first described in 1640 by John Parkinson, who cultivated it in his garden, for a full description of the plant see the various dispensatories, works on botany, etc. The subjoined anecdote may serve its purpose: Some one has stated that the *medicinal* action of this remedy was discovered by accident. A Southern gentleman, who was sick with a fever, sent his colored servant into the garden to obtain the roots of a plant which he indicated, in order that he might prepare a decoction for himself and alleviate his disease. The servant made a mistake, and obtained, instead, the roots of the "yellow jessamine." The tea was drank, however, and the patient breaking out into a profuse perspiration, and recovering so soon from the fever, made inquiry as to what he had taken, and was so delighted with the result that he immediately recommended it to others who were similarly afflicted. However true this may or may not be, gelseminum owes its medicinal action to the presence of an alkaloid, the active principle gelsemina or gelsemia, and to Professor T. G. Wormley undoubtedly must be given the credit of having first isolated the alkaloid, and also demonstrated the presence of a new organic acid, which he designated gelseminic acid, of which by his process he was able to procure about 2¼ grains of the pure acid from 16 ounces of the fluid extract. The alkaloid gelsemia exists, approximately, 1 grain in 2½ fluid ounces of the fluid extract, and it is so intensely bitter that its presence to the extent of 1-1000 part by weight in solution can be readily detected.

Its physiological actions. When taken into the system it is rapidly diffused in the blood, and when administered in small quantities, sufficient to produce a sensible effect, it has a mild, soothing tendency over the nervous system, manifested by mental quietude, a tendency to drooping of the eyelids, slight muscular relaxation, slowing of the pulse and slight dilatation of the pupil, though Prof. Ringer says this dilatation is preceded by contraction of the pupil. When the dose is much increased the symptoms are all intensified, and we see manifested double vision, giddiness, pain in the forehead, increased paralysis of the levator palpebræ muscles, causing drooping of the eyelids, labored respiration from partial paralysis of the respiratory muscles, muscular weakness, and general sensibility is much reduced. If the dose is still further increased, the symptoms are still more intensified, the action of the heart becomes weak and intermittent, vision becomes entirely lost, pupils widely dilated, not responding to the action of light, consciousness may be retained until near the period of death, when it is lost from the carbonic acid poisoning resulting from incomplete respiration. The action of the heart continues for some moments after respiration has ceased. From these symptoms it is evident that the prime action of gelsemia is upon the nervous system, and its action is such as to warrant us in classifying it as a cerebro-spinal depressant, acting principally upon the motor centers, although some discussion has been held that its primary action is upon the peripheral extremities of the motor nerves. Ringer at one time entertained this view of its action primarily upon the extremities of the motor sensitive nerves. In cold-blooded animals its first effect is on the sensory center, while in warm-blooded animals the motor centers are first impressed. The reader of the paper considered this fact to be of great importance, viz.: that the remedy lowers the temperature, which he had verified in many febrile and inflammatory diseases. The theory of it being an efficient antidote to poisoning by strychnia, was according to the views expressed by the writer disproven, as was illustrated by experiments on dogs, and the contrary effect he was satisfied to announce, was the result *that it facilitated or increased the action of strychnia.*

Two dogs were selected, weighing ten pounds each, to both was administered at the same time one-fifth of a grain of sulphate of strychnia hypodermically. Five minutes elapsed, and one-eighth of a grain of the alkoloid gelsemia in the form of a sulphate was given to one of the dogs. In ten minutes convulsions appeared in this animal, while the effects were not noticed in the dog that received only the strychnia until the end of thirteen minutes. In thirty minutes the animal that had received both poisons was dead, while the other lived forty minutes, and then, too, it was noticeable in the experiment that in the animal receiving both the strychnia and gelsemia the convulsions which appeared earlier were far more violent and continuous. This experiment was repeated a number of times with almost unvarying results. As antagonistic to and incompatible with the effects of gelsemium, we may rely upon alcoholic and diffus-

able stimulants, and as an illustration, a case was cited that the author treated three years ago.

J. B., æt. 45, had been afflicted with muscular rheumatism for a number of years, was given five drop doses of the fl. ext. gelsiminum three times a day, with instructions to increase the dose one drop every day. In time he reached a dose of twenty drops per day, and, not seeing any of the usual effects of such a dose, I requested him to change his druggist. In two hours after acting upon this advice the patient was brought back to me by a worthy officer, who found the gentleman staggering on the street and supposed him intoxicated, as he showed to a very marked degree the effects of the remedy. A tablespoonful of brandy was at once administered. In fifteen minutes he was much improved. The same dose of the stimulant was repeated twice during an hour, at the end of which time the symptoms had entirely disappeared. This case serves to illustrate the antidotal action of alcoholic stimulants to the poisonous action of gelsemium; also, what is true of many other of the fluid extracts, their entire worthlessness as to medicinal action.

Therapy. In its native Southern region it has for many years had an extensive reputation as a remedy of great value in the treatment of autumnal malarial fevers. While its efficacy in this direction may have been over-estimated, yet its beneficial effects in malarial fevers are such as to merit our careful consideration. After an observation of a number of years, and administering the remedy to probably many hundreds of cases, I have arrived at the following conclusions: First, gelsemium is not a direct antidote, either chemically or physiologically, to malaria. Second, it does have a wonderful effect over the disease, owing to the relaxing influence it brings to bear upon the system, thereby increasing excretion and assisting to eliminate morbific matters. Third, it may be regarded as the great adjuvant of the salts of cinchona and in this direction, so far as malaria is concerned, lies its chief merit. The following typical case, of which the principal points only are here given, illustrates this action. A sign painter of "bilious temperament," sallow complexion, and melancholy expression of countenance, had ague at intervals for three years, of which the smallest amount of *quinine* or any other of the salts of cinchona produced unusually severe cerebral symptoms. Was called to see him while he was seized with a terrible "chill," simulating the congestive form; he refused the treatment that was suggested, and in forty-eight hours he was again prostrated with another more severe attack; when called to him again he was partially unconscious in a congestive chill. After three hours hard work, with diligent use of stimulants, external heat, etc., reaction began. During the febrile stage the fl. ext. of gelsiminum was given freely, reducing the temperature and producing symptoms denoting its other effects. After eighteen hours had elapsed ten grains of quinine were given every two hours till 120 grains had been given. Not a symptom of tinnitus aurium was manifested, nor any other unpleasant symptom was noticeable. There has been no return of the disease from that day to this, so far as is known. This is only one of a number of cases where the remedy was given to prepare the system for the action of quinine.

In convulsive diseases, particularly those where the spasm is dependent upon reflex irritation, this remedy satisfactorily fulfils the indications, especially in the various diseases of childhood where convulsions are manifested. The following illustration may not be devoid of interest: Willie S., aged 8 months, at supper partook of milk and mashed potatoes. The child was soon seized with convulsions, because the stomach failed to digest its contents. In three hours' time there had been twenty convulsions according to the statements of the attendants. Upon arriving two drops of the fl. ext. were immediately given to the child, and in ten minutes two drops more. Then ten drops were prepared in four ounces of water, and a teaspoonful of this was given every hour for twelve hours longer. No more convulsions appeared, and the next day the child was convalescent. No other remedy has such a satisfactory effect on the nervous system of a child during the period of dentition, while the entire system is disturbed from irritation of the distal extremities of the fifth pair of nerves.

As a remedy for *meningeal inflammation* of the brain and spinal cord, its efficacy in this class of cases the reader illustrated by citing a case selected from a number of similar ones that had from time to time been under his observation, and the large amount of the remedy that may be borne when the nerve centers are excited.

When called to the bedside, the case (that of a young man) had already progressed four days; his temperature was high, pulse rapid and small, tongue dry, mind wandering and there was severe spinal tenderness, the slightest disturbance in the room or jar of his bed resulted in severe convulsions, which amounted to opisthotonos, occurring once or twice every hour. Bromides in large doses had already been given. The fl. ext. of gelsemium in five drop doses was then administered every hour for three hours, at which time another convulsion came on. Ten drops of the remedy was then ordered every hour. In three hours there appeared slight symptons of another convulsion. The dose was increased to twelve drops and gradually to fifteen drops, given as often before there was entire relaxation and disappearance of all convulsive action. This dose was maintained for several hours before any toxic symptons began to be manifest. The patient was then continued under the influence of small doses for a week longer, and later he recovered. Gelsemium has been lauded as a remedy for tetanus, but the author is convinced that it is of but little use in this condition. It has no effect given alone over epilepsy, but added to bromides a desired result may be obtained, more immediately and permanently in controlling cases of epilepsy confined to children.

The writer doubts its efficacy in cases of tic-doloreux or neuralgia, and thought it quite possible that the successful cases treated by the remedy by others were not tic, but neuralgia resulting from cold, or some other eccentric causes producing congestion. Given in pneumonitis and pleuritis it is beneficial,

and will lessen or retard the inflammatory conditions by lowering the temperature, lessening the pulse rate, and it has a soothing effect over the respiratory function. It has a marked effect over the mucous surfaces in gastro-intestinal catarrh, dysentery, and inflammatory conditions of the urinary organs. In rattlesnake bites no other remedy yielded such results, while the author was living in Kansas some twelve years ago, when he treated a number of these cases. The local inflammation and pain rapidly subsided, and convulsions ceased after giving a few doses. Favorable reports from several physicians to whom the remedy was suggested, verify this. The remedy is given internally and applied locally, and in these cases its action doubtless is entirely physiological and not chemical.

In diseases of women, of which a variety were enumerated, he discussed the application of the remedy to pelvic disorders and their attendant nervous disturbances, and it applies with equal force to both the acute and chronic states, for it possesses a relaxing effect over the uterus and its appendages. In the first stage of labor where there may be present a rigid and unyielding os, a similar administration will produce many times a most happy effect. In many forms of dysmenorrhœa its beneficial effects are equally noticeable. The author pictured many typical cases classified under the head of nervous diseases; long continued congestions of the pelvic viscera; various phases of hyperæmia and anæmia of the spinal cord; hysteria; spinal irritation; neuræsthenia, etc., that were treated by all known therapeutical measures, local treatment, and while he did not claim it to be a never failing remedy—a panacea—for all these conditions, he held that a large number of female diseases could be relieved by this remedy. In using it for a number of years, continued the writer, he was prepared to positively assert that gelsemium is a stimulant or tonic to the cerebro-spinal system when long continued in small quantities. Three chronic cases were cited of local troubles (ulceration) with serious nervous disturbances, in which all were relieved by taking minute doses of the remedy. The first was where the patient had been treated for endocervicitis, retroflexion, retroversion, ovaritis, peri-uterine trouble, etc., and menstruation had ceased. She was 35 years of age; all the functions were gradually restored, and in eighteen months she gave birth to a perfectly healthy child, since which time her health has been perfect. Case second was a remarkable one. A patient aged 45, with a decidedly neurotic history. There was hemi-anæsthesia, but this was not due to any cerebral lesion, there was ovarian tenderness, bowels constipated, frequent micturition, bearing down pains, uterus enlarged and retroverted; she suffered severely with dysmenorrhœa, and sometimes the menses did not appear at all. She was approaching the turn of life; had been married twenty years, but she had never been pregnant. Her improvement was gradual and continuous by taking small doses of gelsemium, and in six months she appeared entirely well, menstruation being regular and normal. In three months longer she called again, for she was afflicted with nausea, and felt, as she expressed it, "so very strangely." Could she have conceived? Yes, possibly, and in due time "the wife and son were doing well," was the message sent me. Thus the pathological condition was removed, menstruation had returned and pregnancy occurred at the age of 44 years.

The last case, that of a lady, aged 46, consulted the writer some four years ago; her case presented a number of interesting features. For eight years she had been in a decline, and she became reduced in weight to seventy-five and a half pounds. During the past five years she had been treated for typhoid fever, which she had an attack of and continued for five weeks. She had been treated also for sciatica, bronchitis, ulceration of the intestinal canal, disease of the pylorus, cirrhosis of the liver, diseased kidneys, hyperæmia of the brain and the various flexions, versions and inflammation of the uterus. My diagnosis was told her facetiously, perhaps, saying that she was "sick." There was a general failure of nutrition, restlessness, frequent attacks of neuralgia, depression of spirits, spinal tenderness, enfeebled digestion and backache. Her menstruation had been very scant and irregular for two or three years, and it had not appeared for seven months. The gelsemium was given to her in minute doses. She began to improve almost immediately. At the end of the third month menstruation reappeared, much to our surprise. In four months she gained twenty pounds. She increased in weight thirty-five pounds in a few months longer, as also in strength, and menstruation still continues at the age of almost 50 years. As a remedy for nocturnal emissions it was simply referred to in the paper.

For "algies" and other disorders, it was also alluded to. The writer stated the following, in conclusion: This remedy, if it has any influence over the pelvic viscera which is directly due to an impression on the spinal cord, or upon the sympathetic ganglia, is doubtless a matter of some question, but it is highly probable that it has a tonic effect on the sympathetic ganglia, as well as the cerebro-spinal centers, and urged that the action of gelseminum over the disorders peculiar to women was a subject of great importance, and well worthy the attention of the profession. For a very large number of the pelvic disorders of women arise from a disturbed nervous system, which in turn produces morbid ovulation. It is in this way that I account for the action of gelseminum on these disorders. Its action is directly on the nerve-centers—spinal and sympathetic—equalizing the circulation and giving tone to cell power, and by these means permitting free ovulation and relieving the congested and inflamed condition of the other pelvic viscera. If it does have this action, then Dr. Davis propounded the question, may it not also be considered a remedy for sterility?

The merits of the paper were discussed by Drs. G. C. Paoli, A. H. Foster, L. H. Montgomery, R. Ti ley and C. G. Davis, after which Dr. R. Tilley read a paper prepared by Dr. E. F. Ingals, giving a report of A Case of Catarrh Caused by a Large Cystic Tumor, with Removal and Recovery.

Mr. V. had suffered from catarrh more or less for

the past ten years, and had been especially troubled during the past six months. There was difficulty in breathing, and obstruction to the left nasal passage, being able to inhale by considerable exertion, and unable to exhale at all through that side. His hearing was also impaired. His general health is excellent.

Upon inspecting the naso-pharynx by means of the rhinoscope, a smooth, grayish-white tumor was noticed, completely occluding the posterior orifice of the left nares, and filling two-thirds of the naso-pharyngeal cavity, which evidently sprang from the lateral wall of the pharynx, in the region of the fossa of Rosen Müeller.

An attempt was made to remove the growth with a modification of Jarvis' écraseur armed with a fine steel piano wire. After several trials, I found myself unable to pass the loop over the growth, on account of its great flexibility. A larger wire was then substituted, and aided by the rhinoscope, the growth was secured and finally detached; it fell into the mouth, and was ejected by the patient. It measured 1⅜x1⅛ inches in the largest diameter, and ¾ of an inch in thickness. A microscopic examination of the tumor was made by Dr. E. P. Davis, who pronounced it to be a mucous cyst. No after-treatment was deemed necessary.

Careful examination of cases of so-called catarrh should be made, as many are due to nasal polypi, hypertrophied turbinated tissue, adenoid vegetation in the naso-pharynx, or tumors.

The pathological specimen was then exhibited, and remarks passed upon it. L. H. M.

NEW YORK NEUROLOGICAL SOCIETY.

Stated meeting January 8, 1884. Dr. William J. Horton, President, in the chair. Notes on the use of the menthol cone as an anodyne.

Dr. E. C. Wendt showed a little contrivance, called by the Germans "*Migräne Stift*," and explained the method of its application and uses. It consisted of a piece of menthol molded into a conical shape, and secured in a little wooden box, closed by a cover to prevent evaporation, soiling, and breaking. It seemed to be very little known here, although it was much used abroad, especially for sick headache.

His attention had been first directed to the anodyne properties of menthol by a short notice published in the *Medical Record*, of April 28. 1883, by Dr. Cammann.

That gentleman had recommended an alcoholic solution of menthol (℥j. to ℥ss. alcohol), to be painted over the affected parts. Dr. Wendt had since that time often used this solution, and found it a rather reliable anodyne.

Its pain-relieving action was restricted, however, to the slighter ailments, especially those of a neuralgic character. Since his acquaintance with the solid menthol cone, he had frequently substituted the direct application of menthol by means of the latter for the solution formerly employed. He would admit that the only advantage which the solid cone or pencil had over the solution, consisted in the greater simplicity of it application, its ready portability, and the fact that its vapor was not apt to irritate the eyes of susceptible patients. He had repeatedly heard complaints in that direction from ladies, regarding the solution, which was obviated by using the cone.

In this country menthol had not yet received that amount of recognition from the profession to which its pain-obtunding properties would seem to entitle it. In fact, little seems to be known about it, and for this reason Dr. Wendt thought it might not be amiss to quote a descriptive notice which had appeared in the *Midland Medical Miscellany*, of October, 1883:

"Menthol, or menthylic alcohol, $C_{10}H_{20}O$, is a crystalline substance, deposited from the oil of peppermint, prepared in China and Japan from *menthæ arvenses var. piperascons* and *glabrate*."

It formed the chief ingredient of a much valued remedy for neuralgia, before its nature or source was generally known. Under the name of po, ho, yo, or *gouttes Japonaises*, it has been sold in small bottles, labeled with Chinese characters.

It is a white crystalline stearoptene, melting when pure at 97° Fahrenheit, and is obtained by the Japanese from the oil of peppermint, by submitting it to freezing several times in succession, until no more menthol crystallizes out.

It is also said to be contained in the American and English oils of peppermint, but probably in small quantities only. It is somewhat surprising that the Japanese peppermint plant, which is grown in England as a curiosity, has not been cultivated in that country, as a source of the drug, the supply of menthol being uncertain, the demand great, and the price, in consequence, occasionally very high.

Menthol is said to be sometimes adulterated with crystals of Epsom salts, to which it bears a great resemblance. These being insoluble in alcohol or chloroform, in which fluid menthol is freely soluble, can easily be detected. Samples of fine crystals sometimes contain essential oil, adhering to them, a fact which must be taken into consideration when the menthol is made into cones or pencils.

Menthol is but slightly soluble in water, although imparting a strong odor and taste to that liquid, and is soluble in aqueous alkalies. It is soluble in fixed and volatile oils, and in ether.

Although Dr. Wendt's experience with menthol had not yet been a very extended one, it had nevertheless been sufficient to convince him of the utility of the drug in a rather large class of cases. Thus, as already stated, he had found it a pleasant and reliable anodyne in all the lesser neuralgias, and especially in those so frequently occurring about the face. But it was also serviceable in many painful affections due to inflammatory processes. For example, in mumps, in the cervical adenitis so often accompanying sore throat, and in numerous other affections, where pain was a prominent symptom, menthol might be used to advantage. With regard to its topical action, it was similar to that of aconite, over which it had the advantage of not being poisonous.

Dr. Wendt remembered one rather striking case of

quite severe supraorbital neuralgia, which refused to yield to the oleate of aconitia, but was much benefited by the menthol. But, on the whole, in violent attacks, he had found it almost useless. In typical migraine, for instance, where the pain was at all severe, and in all deep-seated aches of more than very moderate intensity, it had no appreciable effect, except, perhaps, the indirect psychical action of distracting the sufferer's attention.

In the discussion which followed these remarks, Dr. Roberts asked Dr. Wendt if he had tried the prolonged application of menthol.

Dr. Wendt said that he had in some cases of hemicrania, though without decided benefit. Nevertheless, the patients experienced a pleasant sensation of coolness of the surface, followed by a feeling of agreeable warmth.

Dr. Norton desired to ask Dr. Wendt in what sense he used the word anodyne. Dr. Wendt said in the usual one, of affording relief from pain by blunting sensibility.

Dr. Norton thought that menthol probably acted more after the manner of counter-irritants, by insuring relief in a reflex rather than directly local way. Mustard was a typical peripheral nerve-irritant, and it seemed to him that the action of menthol could be best explained on the same principle, of procuring peripheral nerve-impressions in a reflex way.

Dr. Horton continued, that his attention had been first called to the menthol-cone by Dr. Wendt. He chanced to be at the latter's office one day when suffering from a headache. A few strokes of the menthol gave him at once a sense of relief. He felt the effects of the peppermint to be as gratefully cooling as the application, say of cold metal. In brachial neuralgia, as well as sciatica, he had been pleased with the good effects of the menthol. He thought the drug was deserving of further trials.

Dr. Ralph L. Parsons then read a paper on Detention in Asylums.

The reader spoke first of the question, whether sane persons were not often improperly or unjustly detained in asylums for the insane; and secondly, whether many uncured and incurable patients who were methodically detained in asylums might not advantageously be returned to their relatives, or placed in the care of private families under State supervision.

It was assumed in the first instance, that the detention of patients after recovery had taken place, for a longer time than might be required, was quite possible, and even probable in some instances. But he claimed such detentions were not usually of serious import to the patient; that on the other hand, too early discharge might be more injurious. It was also admitted that maliciously unjustifiable detentions were quite possible, as any other sort of injustice is possible on the part of persons holding positions of power and responsibility. But reasons were urged by Dr. Parsons, in support of the belief that such malicious detentions were at least very rare, that sentiments of honor and professional pride were strong deterrents, to say nothing of the great danger of detection in the commission of the wrong, and the ease with which patients who were decidedly insane obtained their enlargement through the intervention of the courts.

Cogent reasons were given why various classes of convalescents ought to remain under asylum care for a period of time after they appeared to be well, as, for instance, when they would be immediately subjected to the exciting cause of their insanity on their return, when the progress toward convalescence had been characterized by relapses, or when dangerous delusions had been entertained, and had faded away so gradually that there were difficulties in judging whether they had passed away entirely.

But, on the other hand, the discharge of certain uncured curables before they were well was advised, as when, after making a certain degree of improvement, this improvement stopped and the patient seemed to retrograde. It might be safe and highly advisable to discharge some of these patients before they were well.

The major part of the paper was devoted, however, to an advocacy of the discharge from the asylum of harmless incurables, and their return to the care of their friends, or placing them with ordinary families as boarders, and in some sort as members of the families. It was claimed by the reader that, however comfortable and happy such patients may appear to be in large asylums, there are many causes of annoyance and discomfort that would not be experienced in ordinary family life; that, notwithstanding the fine buildings they occupy, and their freedom from care, they are still prisoners, and exposed to many disagreeable associations and associates.

Quotations were made from Dr. Bucknill and from Dr. Maudsley, strongly supporting these views.

The question was then considered, what classes of incurables might safely and with benefit be released from asylum restraints. Since in the case of a great majority of such patients, moderate cost of maintenance would be essential, those only would be adopted who were quiet and orderly, and would require no especial attendance or supervision. Habits of industry would be favorable.

Whether such patients would do better with their relatives or with strangers would depend on the circumstances of the family, the state of health, the surroundings, the feelings or notions of the patients, etc. It would be found, however, that many patients who would not do well with their own kindred, would be happy, contented and useful with congenial strangers. It would be impossible for the patient to resume his former position and influence in his own family, and hence he would be subjected to irritating restrictions and annoyances there.

As a preliminary measure, a system of legalized furloughs was advocated, to the end that at first the patient might still be under legal restrictions and easily returned to the asylum, if the trial at large should prove a failure.

Properly constituted authorities should make the selection of patients for the trial, with the assistance and under the advice of the asylum superintendent.

The families in which the patients should be placed should be selected with great care. While at first there might be found very few suitable families who

would assume the charge, it was thought that, when a beginning had been made, plenty of suitable homes would be offered. Reference was made to the multitude of respectable and responsible families who take summer boarders for a moderate compensation and the probability that some of these families would prefer one or two permanent patient boarders to a number of sane boarders for a short season during the busiest portion of the year. A suitable system of visitation and of reports was advocated. The paper closed with the following summary of conclusions, to-wit:

1. That inasmuch as many recoveries take place in asylums for the insane, it is to be expected that some convalescent patients may at any time be found in the wards.

2. That while possibly now and then a convalescent may be detained on probation an unnecessary period of time, such cases are not of frequent occurrence, nor important in their consequences when they happen, and that when they do occur, the detention is very rarely indeed through criminal intent.

3. That many harmless incurables are unnecessarily detained in asylums for the insane; that these incurables would be happier in the enjoyment of ordinary family life and associations, and that systematic efforts should be made to secure their enlodgement and their establishment under family care.

4. That under certain circumstances curable patients should be removed from asylum restraints and associations while yet uncured.

Owing to the lateness of the hour the discussion upon Dr. Parsons' paper was postponed until the next meeting of the society.

BOOK REVIEWS.

THE PATHOLOGY AND TREATMENT OF VENEREAL DISEASES. By FREEMAN J. BUMSTEAD, M.D.,LL.D., late Professor, etc., etc., and ROBERT W. TAYLOR, A.M.,M.D., Professor, etc. Fifth edition. Revised and re-written, with many additions by Dr. Taylor. Pp. 906. Philadelphia: Henry C. Lea's Sons & Co. 1883. (Jansen, McClurg & Co., Chicago.)

In the production of the late Prof. Bumstead's fourth edition of his well known treatise on venereal diseases, Prof. Robert W. Taylor, A.M.,M.D., of the University of Vermont, acted as collaborator, with the distinct understanding that upon the death of either colleague the work should "revert to the survivor as his book, to be by him re-written, revised, or enlarged, as circumstances should require," in keeping abreast of modern discoveries.

The book before us is the fifth edition of this now celebrated work, practically re-written since the death of Prof. Bumstead.

As it now appears it is a valuable standard treatise, and one which reflects impartially the best modern opinion, a thoroughly reliable work of reference for practitioners.

The preparation of such a standard work is one of great labor, involving the study of recent medical literature in all the modern languages, and incessant study in collating the results of new physiological and pathological discoveries.

Even the preparation of a new edition, brought down to the most recent knowledge, is an editorial task requiring months or years for completion. The mere collecting and perusal of all the monographs which appear in a few years in all parts of the world, on so wide a subject, would require almost more than one man's time, while the digesting and summarizing of this diverse material, and its incorporation into the old work, would seem to call for the united labor of a corps of writers.

Prof. Bumstead, in a previous edition, recognizing this difficulty of keeping pace with so wide a subject, says: "So many specialties had sprung up within this one specialty, that the labor involved in issuing a fourth edition of this work was recognized as formidable, and even sufficient to afford some ground for the assertion made by one well versed in the subject, that 'in the future it will be impossible to include venereal diseases in a single treatise; they can only be studied and known in separate monographs.'"

From the nature of this work, which may be termed encyclopædic, we are not led to expect, nor do we find, so great originality and incisiveness as in Prof. Otis' so-called "Clinical Lessons" on venereal diseases.

The student and practitioner may put the utmost reliance in the work as it now stands, as containing a faithful exposition of modern ideas and discoveries, such as no other published work supplies.

CLINICAL CHEMISTRY. By CHARLES HENRY RALFE, M.A., M.D. Illustrated. Published by H. C. Lea's Son & Co., Philadelphia. (Jansen, McClurg & Co., Chicago.)

This books forms one of the manuals for students of medicine which are being now issued by H. C. Lea's Son & Co. The volumes are most convenient in size and attractive in appearance. The one before us is an excellent work. Its title does not give a fair idea of its scope. The author considers the chemistry of physiology as well as that of pathology. For example, in the chapter on morbid conditions of the digestive secretions, he takes up one after the other, describing their chemical and physiological action, as well as the changes that may occur in them when affected by disease, and also methods of detecting such changes. A better idea of the scope of the work can be given, perhaps, by quoting the heading of paragraphs in this chapter: Saliva; Detection of Mercury in Saliva; Gastric Juice; Reaction of the Gastric Juice; Pepsin; Peptones; Vomited Matters; Determining Amount and Nature of Acid Present in Vomit; Detection of Poisons in Vomit; Gases in the Stomach; Bile and Jaundice; Uræmia; Bile Pigments; Bile Acids, Fats and Salts; Biliary Calculi; Functional Derangements of the Liver; Diabetes; Lithæmia; Pancreatic Juice; Intestinal Digestion; Fæces; Intestinal Concretions; Gases in Intestines; Detection of Arsenic, Antimony, etc., in Viscera; Estimation of Nitrogen.

The work, therefore, gives concisely very much of chemical physiology. It is clearly and well written. It is worthy of careful study, not only by students but by practitioners. The contents are treated of under the following heads: Organic and Inorganic Constituents of the Animal Body; Chemical Reactions of the Chief Organic and Inorganic Constituents; Blood; Chyle; Lymph; Milk; Morbid Conditions of Urine; Morbid Conditions of the Digestive Secretions; Morbid Products.

SAINT THOMAS' HOSPITAL REPORTS. New Series. Vol. XII.

This handsome volume contains a number of valuable articles. Dr. William M. Ord, under the head of Some Clinical Aspects of Glycosuria, discusses it in association with, 1, conditions of nerve disease or disorder, appearing either as probable causes or as associated troubles; 2, gout; 3, errors of diet; 4, albuminuria, placing these in sequence in accordance with their relative importance.

Mr. F. Le Gros Clark, in giving Some Records of Surgical Experience, discusses a great variety of subjects in his masterly manner. Thus, forty cases of lithotomy are briefly reviewed, the operation for hernia is discussed, and a woodcut of a "guarded knife" is given, which likewise acts as a director.

John Croft gives two cases in illustration of the Treatment of Cancerous Obstruction of the Œsophagus by Permanent Catheterism.

Mr. G. Gulliver records Two Cases of Ulcerative Endocarditis Following an Attack of Acute Pneumonia.

Dr. W. B. Hadden treats of Paraplegic Rigidity in Hemiplegia.

Dr. W. H. Stone of Some Effects of Brain Disturbance on the Hand-writing, giving three cases of agraphic modifications, one of which is peculiarly interesting, as existing in his own person, and the result of sustained mental effort, and probably some indiscretion in the use of chloral. He was enabled, after the lapse of three weeks, to make his own diagnosis, which was that of syphilis, with which he had been inoculated in his hospital duties ten years before, but which diagnosis, he thinks now, was erroneous. The article is well worth perusal, from its admirable style and the thoughts it gives rise to.

Dr. Felix Lemon furnishes remarks upon the cases occurring in the throat department of the hospital, detailing specially interesting cases, and giving short tabular statistics of the whole material of the department. He speaks very highly of iodoform as a local remedy in laryngeal phthisis, using it in cases of ulceration only, in the following formula:

℞ Iodoformii.
Acid boracic āā.....grs. j.
Morph. acetat.....gr. ⅛.

M. Ft. pulv. D. S. Ad insufflationem twice daily.

Bernard Pitts gives a case of Hæmorrhage Consequent upon Suppurative Tonsillitis, with Ligature of the Common Carotid.

Dr. Bristowe records some Clinical Remarks on So-called "Painful" Paraplegia, citing five cases of malignant disease, the symptoms of which bore upon the case in question. After his paper was placed in the printer's hands the case died, and cancer was found to be present.

Mr. G. H. Makins gives a case of Spontaneous Gangrene of Toes in a Child.

Dr. John Harley gives his Treatment of four Cases of Hydatid Tumor of the Liver.

Mr. H. H. Clutton records a case of Paralysis of the Serratus Magnus following an attack of typhoid fever. Its action was restored by the use of the induced current in galvanism, and the accompanying illustrations give a very clear idea of the condition of the parts. The literature of the subject is very interesting, and on one point the writer failed in making suitable experiments, *i. e.*, to determine the influence of this muscle on respiration. Erb declares that "the serratus is not, as was believed by Bell, Stromeyer and others, a muscle of inspiration;" but Dr. Vivian Poore refutes this by the use of the leaden cyrtometer, showing that it has a very marked action.

Dr. J. F. Payne gives Two Cases of Pemphigus. In one case arsenic did no good; in the other its use was followed by complete recovery. His paper is accompanied by an interesting table of the range of temperature.

Dr. W. H. Stone communicates an abstract of his paper On the Electrical Resistance of the Human Body, which was read before the British Association, at Southport. An obituary notice of Frank Tweed Twining follows, and the remainder of the volume is taken up by statistical and tabular reports of the obstetrical, medical, surgical and ophthalmic departments. A general index to the twelve volumes of the series is added, and accompanying the whole is the calendar and prospectus of the medical school.

THE DIAGNOSIS AND TREATMENT OF DISEASES OF THE EAR. By OREN D. POMEROY, M.D., Surgeon to the Manhattan Eye and Ear Hospital, Ophthalmic and Aural Surgeon to the N. Y. Infant Asylum, etc. New York. Bermingham & Co., 1883.

As an index of the great importance which at the present time attaches to the practice of a long neglected but now important and respected branch of surgery, we have only to inspect the recent works on the principles and practice of otology.

Not the least of the achievements of this generation of physicians has been the segregation, so to speak, of the great body of medical practice into its component parts, which has become such a distinctive feature of medical progress in our time, and one which is bearing rich fruits for the enjoyment of those who are deserving of them, for specialization in practice has opened up to the physician fields of activity which have long lain fallow.

The history of otology is replete with useful lessons to the thoughtful reader, who cannot fail to find rich profit in its perusal. Regarding its scope, we observe at once that it is coeval with that of general medicine, but that a line of marked divergence may

be traced in it, taking its origin at a period within the memory of many practicing physicians of to-day.

As is usual, however, in the fields of other arts and sciences, at rare interval there appear striking features which stand out in bold relief, and in this instance we may well be amazed at the thought that Valsalva in the 17th century devoted more than a quarter of a pretty long life (59 years) to the study of the human ear, having dissected during that time above one thousand heads, and in so doing probably accomplished more than any one man in promoting anatomical knowledge in this direction.

As regards the therapeutics of otology, we have to thank an Englishman, Sir William Wilde, for striking the very key-note of successful practice when, in his work published in 1843, he drew attention to the fact that most aural diseases are the result of inflammation, which, affecting the tissues of the ear just as it does similar tissues elsewhere in the body, is amenable to similar modes of treatment. All this looks to us simple enough in the light of modern pathology, and yet, right here lay the principles which the most learned of other times failed entirely to recognize, and accordingly, just in proportion as their ideas of causation peopled the realms of the fanciful and imaginary, their efforts at cure were unsatisfactory to their patients and to themselves.

With such thoughts as these in mind, it is a pleasure to open and read such a volume as the one before us—the fruit of conscientious labor on the part of one who has applied himself to a task for which he possessed all the necessary prerequisites to render it a success. The author has addressed his work to especially satisfy the necessities of students and young practitioners, and in so doing has made it his endeavor to be brief and perspicuous, yet we think it is to be regretted that he has not seen fit to describe even briefly the anatomy of the parts discussed, and to dwell more fully upon their pathological conditions, for such introductions are particularly desirable in text-books. The greatest difficulty which one encounters in the study of otology, is an adequate comprehension of the relations of the parts in discussion, and when this difficulty is surmounted there still remains a consideration of the pathological conditions, after which the *rationale* of treatment becomes simple enough. We think, too, that in such a work a livelier interest may often be excited by making a freer use of clinical cases, which often seem to be so much more realistic to the reader than plain generalities.

Dr. Pomeroy's work is similar in size to that of his colleague, Dr. St. John Roosa. It appears in handsome form, as has been intimated, and cannot fail to prove a valuable acquisition to the literature of the subject. J. C. H.

THE circulation of the *British Medical Journal* amounts in its weekly issue to 11,650 copies, a circulation which is about equal to the combined circulation of all the other weekly medical journals published in England.

DOMESTIC CORRESPONDENCE.

POSSIBLE CAUSES OF COMA AND CONVULSIONS.

AN ANSWER TO DR. WEST'S REQUEST FOR A DIAGNOSIS.

EDITOR JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION:

Your correspondent, Dr. G. S. West, in the JOURNAL of January 12, gives a very full and interesting history of a case of suspected "malarial coma." He expresses doubts, however, as to the existence of any such disease, stating that in thirty-two years' practice he has never heard of it until now. He also earnestly asks for a diagnosis upon the facts narrated.

It would conduce much to the advancement of practical medical knowledge, if physicians, when in doubt concerning what seems to them peculiar or anomalous cases, would oftener refer the difficulty to their favorite medical journal, frankly asking a solution from the editor or other readers, and thereby inviting discussion or even criticism upon their diagnosis and treatment. The clash of mind against mind evokes thought. Such discussions might be rendered only less interesting and profitable than those which take place at the annual meetings of our societies. They would well replace some of the elaborate papers or lectures which are met with in medical periodicals.

Others, better qualified than myself, will doubtless undertake to answer the questions propounded by Dr. West, but the following comments upon his case may be of interest to some readers:

First, as to the possible existence of "malarial coma." Unquestionably there may be a comatose condition in pernicious intermittent fever. Dr. Bartholow, in his "Practice of Medicine," second edition, p. 787, says: "In this country the most frequent varieties of pernicious intermittent are the algid, the choleraic, the pneumonic and the *comatose*." In the edition of Reynolds' System of Medicine, published by H. C. Lea, the American editor, Dr. Hartshorne, calls particular attention to the congestive form of pernicious intermittent as very common in some parts of the United States. Speaking of this, he says: "Sometimes cerebral symptoms predominate; delirium being present, passing into stupor, with stertorous respiration. Tetanic rigidity occasionally exists during the paroxysm." But, according to other authors, this form of cerebral congestion may develop without delirium."

We have no experience with such malarial conditions here at Atlantic City, where even simple intermittent is exceedingly rare; but the literature of the subject is too full and explicit to leave any room for doubt that there may be such a condition as "malarial coma."

Whether or not Dr. West's patient (T. R.) died of this affection or some other, is another matter. The onset by a distinct chill and high fever (said to be about 106), followed by rapid defervescence and profuse sweating, would give color to the hypothesis of malaria. The subsequent course, however, was irregular, there being no further notable rise of tem-

perature until the fifth day, when the first convulsion took place.

The semi-comatose state graphically described in Dr. West's report is, on the other hand, suggestive of uræmic poisoning from a latent Bright's Disease. It is unfortunate that no chemical or microscopical examination of the urine was made. If the urine had been found to contain albumen and hyaline casts, even though there was no œdema, a diagnosis of chronic interstitial nephritis, with uræmic coma and convulsions, might have been made. The drinking habits of the patient rendered such a condition very probable. A physical exploration as to the existence of cardiac hypertrophy would also have helped to clear up the diagnosis. The existence of such hypertrophy would have been confirmatory of other symptoms pointing to renal disease.

The symptoms at the outset did not correspond with those of acute Bright's Disease; therefore, upon the hypothesis of uræmia, the initial fever could only be accounted for as a complication, either malarial or otherwise, supervening upon latent chronic nephritis.

Another possible view of the case is, that there may have been cerebral syphilis or other lesion of the brain. It is stated that the man had had syphilis, and his habits were such as to predispose him to cerebral congestion. Yet simple congestion would not cause a stupor lasting, with occasional short intermissions, for five days, and passing finally into violent convulsions. And a syphilitic gumma, an effusion of blood, an abscess, or patch of softening, of sufficient extent to produce such severe symptoms, would in all probability have been attended also by localized paralysis in some part, or at least, by defective speech. Nothing is said in the report of paralysis or speech defects, and it may fairly be assumed that anything of the kind would have been observed, if existing. Hence, it may be inferred that the coma and convulsions were due to some form of toxæmia, probably either malarial or uræmic.

It is stated that after the first convulsion, when two physicians were present in consultation, 45 grains of quinine were given hypodermically, between the hours of 11 P. M. and 5 A. M. It may seem ungracious to criticise the treatment of the case, but, in the interests of medical science and of humanity, I feel it my duty to venture the opinion that such an amount of quinine *hypodermically* would be unsafe in any condition possible, and particularly so in any case of cerebral congestion.

BOARDMAN REED, M.D.

Atlantic City, N. J., Jan. 19, 1884.

HOT SPRINGS, ARK., Jan. 18, 1884.

EDITOR OF JOURNAL:—

In a recent issue of THE JOURNAL, my friend, Dr. John Thad. Johnson, of Atlanta, Ga., suggested the advisability of employing stenographers to report the proceedings and debates of the various Sections of the American Medical Association. The suggestion is a good one. These Sections usually adopt resolutions requesting the members participating in the discussions to furnish the Secretaries with copies of their remarks, but said resolutions usually amount to nothing. For instance, as acting Secretary of the Section of "Obstetrics and Diseases of Women," I only got two or three of the speeches made before that body, and there were a number of valuable ones delivered. The present Chairman of the Section made some very interesting remarks on several papers, and yet they are lost save to the memories of those who had the privilege of hearing him. I hope the members of the Association will all think carefully over this matter, and at the Washington meeting take this, another step forward.

The monied cost cannot be a great deal, and yet we will have preserved by the "art preservative" all the best discussions of the body. As it is, we have scarcely anything save the papers read and a straggling speech or two.

Let us have a stenographic report of the discussions.

Yours truly,

J. T. JELKS, M.D.

FROM WASHINGTON.

The following, of general interest to the medical profession, has been introduced into Congress:

Mr. Lowry introduced the following joint resolution in the House of Representatives January 7, 1884 (H. Res. 71):

That it shall be a misdemeanor, punishable by a fine of $500 and dismissal from office, for any officer of the United States government, civil, military or naval, to make discrimination in favor of or against any school of medical practice, or its legal diplomas, or its duly and legally graduated members, in the examination and appointment of candidates to medical service in any of the departments of the government.

That all such examinations shall be open to the attendance and witness of all physicians, citizens of the United States, and that duly certified copies of the complete records of all the details of said examinations shall be placed on file in the office of the Librarian of Congress, subject to the inspection and use of members of Congress.

Mr. Tully introduced the following bill (H. R. 1807) in the House of Representatives, January 7, 1882:

A bill to prevent the use of the United States mails to advertise noxious and dangerous medicines, foods and compounds:

That from and after six months after the passage and approval of this act, no advertisement of any kind or nature or advertising device of any medical preparation, compound or prescription, or any punch, bitters, cordial or similar compound, or preparation to be used as medicine or mixed with food, liquor, wine or any other substance used a beverage or as food or medicine, shall be placed in or carried by the mails of the United States until the exact formula for the preparation thereof, together with a sample of the same, be placed in the Patent Office of the United States, with a sworn affidavit of the correctness of such formula and the genuineness of such sample, and the examination thereof by the proper officers designated therefor in said Patent Office, and

the issue of a certificate that said substance is not noxious or dangerous to health.

Sec. 2nd makes the certificate fee $20. Sec. 3d imposes a fine of from $100 to $1,000, or the penitentiary for from six months to one year, for violation of the provisions. Sec. 4th provides for the employment of experts in the Patent Office for the purpose of making the proper examinations.

THE BUFALINI PRIZE.—The Department of the Interior has issued, through the Bureau of Education, a pamphlet of five pages on this subject, which gives all the necessary information to those who may desire to compete for it. The programme is transmitted by A. Dalla Valle, Chargé d'Affaires of Italy, under instructions from his government, through the Secretary of State, F. T. Frelinghuysen.

It is issued in consequence of a resolution adopted by the Section of Medicine and Surgery of the Royal Institute for Higher Practical Studies and Improvement, at Florence.

"Whereas, the will of the illustrious scientist, Maurizio Bufalini, dated September 12, 1874, provided that a legacy should be left to the above named Section sufficient to enable it to offer a prize to the author of the best essay on the subject named by the testator, the Section has resolved:

"(1) Competition for the Bufalini prize shall be open from this 1st day of May, 1883.

"(2) The time during which essays may be presented shall expire on the 31st day of October, 1884, at 3 o'clock P. M.

"(3) The amount of the prize shall be 5,000 lire[1].

"(4) The Chancellor of the Section of Medicine and Surgery of the Institute for Higher Practical Studies and Improvement (whose address is via degli Alfani, No. 35) is officially designated to receive the essays of competitors, and to give his receipt for the same.

"(5) The notice, the problem on which essays are to be written, a list of certain works, and the rules relative to the competition, which were laid down by Professor Bufalini in his will, shall be published. They are as follows:

"NOTICE.

"The constant experience of my long life has fully convinced me of three great truths, viz.: (1) That all principles of reasoning called a priori are entirely false, or at any rate do not lead to the discovery of other knowledge, and that the philosophy called speculative or dogmatic should therefore be regarded as impossible. (2) That only the philosophy called experimental is true, and should alone be adopted. The same is true of the method which is called by the same name. (3) That nevertheless, before my efforts in that direction, this method had not been generalized into a complete system or body or doctrine which would enable it to be more correctly understood, and which would also serve to explain complex causes and the method of reasoning about them.

"Being thus persuaded, I was compelled to conclude that the sciences had not yet acknowledged the true method, had not yet invariably followed the true mode of reasoning, and had always left the way open to well known and obnoxious ancient errors. From this it appears that the use of the experimental method has always met with serious difficulty, and this I discovered was due to the habit of reasoning with words whose meaning is not sufficiently determinate, as in learning language many words still have to be used which do not stand for sensible and concrete objects; all which has favored the birth and establishment of a mode of reasoning closely resembling the dogmatic.

"Let the learned consider, therefore, whether they can pardon me for daring to appeal to them ten years after my death, and, after that, every twenty years, to solve the following

"PROBLEM.

"The necessity of the experimental method in arriving at the truth, and the relation of all the sciences being assumed, it is required to demonstrate in a first part, how far the said method is to be used in every scientific argument, and in a second part, to what extent each of the sciences has availed itself thereof during the time that has elapsed since the last competition for a prize,[1] and how they may be brought to a more faithful and complete observance of the method itself. MAURIZIO BUFALINI.[2]

"*List of the works of Maurizio Bufalini in which the subject above referred to is more particularly considered.*

"Instituzioni di patologia analitica. 6a edizione di Firenze, 1846.

"Prolegomini. Parte I. Edizione del 1863 in Firenze, tipografia Le Monnier.

"Prolegomini. Quesiti sul metodo scientifico in appendice alle instituzioni della patologia analitica, tipografia successori Le Monnier, Firenze, 1870.

"Schiarimenti sul metodo scientifico e specialmente sull' induzione. Nel giornale Lo Sperimentale, Anno XXVI, 1874.

"Sommario delle piu essenziali ragioni del metodo scientifico. Nella Nuova Antologia, Firenze. Marzo 1874.

"Agli illustri professori della sezione di medicina e chirurgia dell' Instituti degli Studj Superiori Pratici e di Perfezionamento di Firenze ed altri.—A quelli della chimica e farmacologia insegnanti nell' arcispedale di Santa Maria Nuova—Agli medicina e chirurgia. Maurizio Bufalini, Firenze, 1874, e nello Sperimentale, Luglio, 1874, esercenti medicina e chirurgia nell' arcispedale medesimo ed altri.—Agli scholari della.

"RULES.

"(1) Each essay shall bear at the top some particular motto, and shall be inclosed in a sealed en-

[1] The lira = 19.3 cents; the value of the prize is therefore $965.

[1] The subject named by Professor Bufalini in his will is to be re-assigned every twenty years, which is why the distinguished professor refers to "the time that has elapsed since the last competition."

[2] TEMA.

Posta l'evidenza della necessità di assicurare al solo metodo sperimentale la verità e l'ordine di tutte le scienze, dimostrare in una prima parte, quanto veramente sia da usarsi in ogni scientifico argomentare il metodo suddetto, ed in una seconda parte, quanto le singolari scienze se ne siano prevalso nel tempo trascorso dall' ultimo concorso fino ad ora, e come possano esse ricondursi nella piu fedeleed intiera osservanza del metodo medesimo.—MAURIZIO BUFALINI.

velope, on the outside of which the same motto shall be written.

"(2) The essay shall be written in Italian or Latin.

"(3) The envelope containing the essay shall be accompanied by another sealed envelope bearing the same motto and containing a slip of paper on which shall be written the full name, the titles, and the place of residence of the author of the essay, which is inclosed in the other envelope.

"(4) Each of the two parts into which the subject is divided may be treated separately or both may be discussed together, at the pleasure of the writer.

"(5) The authors of dissertations relating to both parts of the subject may compete for the whole of the prize; those of dissertations which treat of a single part only, may compete for but one-half of the prize.

"(6) No essays shall be accepted that are not neatly written by a single hand, or that have corrections or additions the meaning of which is obscure. Corrections or additions or changes made by another hand will not be taken into account.

"(7) Essays not considered worthy of the prize shall be returned by the chancellor to their authors, sealed as they were by the examiners.

"(8) In case of a tie in the balloting for the award of the prize, the balloting shall not be renewed, but the prize shall be equally divided among the competitors.

"(9) The President of the Board of Examiners, before the conclusion of the session, shall publicly announce the results of the ballots taken, after which he shall announce which essay or essays have been deemed worthy of the prize; he shall then, during the same session, publicly break the seal of the envelope containg the slip on which are written the name, titles, and place of residence of the author of each of the successful essays, after which the name of the authors shall be made known to the public.

"(10) If none of the essays presented shall have been deemed worthy of the prize, the President of the Board of Examiners shall immediately so inform those present, and shall announce that another competition will at once be opened, public notice of which shall afterwards be given. It shall also be announnced that the envelopes which have not been unsealed, with their contents, are ready to be returned to their rightful owners.

"The Chancellor of the Section,
"VINCENZO PUCCIONI.

"The President of the Section of Medicine and Surgery, Prof. GIORGIO PELLIZZARI.

"Florence, May 1, 1883.

"An authenticated copy of the last will and testament of Prof. Maurizio Bufalini is deposited with the Chancellor of the Section of Medicine and Surgery, and may be seen by any one.

"N. B.—Directors of Italian scientific, literary, and political journals are respectfully asked to give the widest possible circulation to the present document."

FOREIGN CORRESPONDENCE.

LONDON, January, 1884.

There seems to be no doubt that in many serious cases of diseased lungs the new form of treatment by extreme dryness of air at a very low temperature has produced wonderful results. The neighborhood of the Engadine has now become the fashionable spot in Europe where this treatment may be best put to the test. This winter there are something like 1,200 visitors now at Davos and St. Moritz, a large proportion of whom are suffering from pulmonary complaints. A system of drainage is now in partial operation at Davos, not by any means before it was wanted, and the well-known Kulm Hotel at St. Moritz has been specially fitted for the comfort of winter guests. The favorite winter amusement of toboggining is much in vogue, and the lakes afford excellent skating. When a patient goes to Madeira, there is too seldom any question of curing his malady; the only hope is that its progress may be retarded, but a residence in the Engadine really, provided the case be at all suitable, seems to hold out strong and good hope not only for amelioration, but cure and restoration to ordinary health. The cold is intense, the thermometer sometimes falling as low as to 20 degrees below Fahrenheit's zero. But Dr. Ruedi, of Davos, the great exponent of this method of treatment, does not object to any intensity of cold for his patients, though he regards a close and stuffy room as a source of the greatest danger. The atmospherical conditions of the Engadine appear to approach closely those of the heights of Colorado and Wyoming. St. Moritz is more exposed to wind than Davos, and some of the wild wintry gales that sweep up the valley of the Inn must, one would think, be trying even to robust constitutions. Moreover, St. Moritz being on the other side of the Julier and Albula passes, is somewhat more difficult to reach from London than Davos, which is within early sledge drive from a railway station. At Wiesen a new establishment has sprung into existence, between Chur and Davos; it, however, has no lake, and therefore visitors miss the exercise of skating. Another huge inn at the head of the Maloja pass is in course of erection, but is not at present actually open for the reception of visitors.

Mr. Nelson Dobson, of Bristol, has lately strongly advocated another advance in abdominal surgery, and suggests the opening of the abdomen in cases of gastric ulcer where perforation has taken place. He advises, the stomach having been exposed and the injury discovered, it should be treated in one of the following ways: either simply to stitch the viscus to the abdominal wall and establish a fistula; or, the edges of the ulcer being pared, to unite them by sutures, or simply to sponge out the peritoneal cavity and leave all to nature. Of course, during either treatment the patient's strength would be maintained by nutrient enemata. He has not yet practically tried his proposition; what led him to seriously consider the propriety of undertaking one of the steps he recommends was a case he lately had of a young

woman who, after a laborious day, was seized with pain and tenderness in the abdomen, followed by collapse and pain in the epigastrium. Death with symptoms of peritonitis took place in less than twenty-four hours. He was at the necropsy most strongly impressed by the ease with which the hole in the stomach could have been reached.

The proposed scheme of mutual assurance for members of the profession in Great Britain is in a fair way to be successfully launched at no distant date. A provisional committee has been formed; tables have been constructed, which include not only temporary and permanent sick pay, but also other benefits such as are usual among friendly societies, amongst these a permanent annuity after a certain age. It is to be earnestly hoped that the undertaking may be a means of diminishing in the future the many cases of distress in the profession that now too unhappily occur.

The forthcoming International Health Exhibition to be held in the buildings lately vacated by the Fisheries Exhibition, promises to equal, if not excel its predecessor. The practical lessons learnt in the management of such undertakings have given rise to the adoption of some rules that will be fully appreciated by exhibitors and the public alike. The things that will be collected together appear to comprise every thing that can in any way either administer to the well-being or otherwise of the human race. The various sub-committees, under the able direction of Sir Cunliffe Owen, are now fully engaged in their arduous duties.

The Register-General has published his annual returns of the mortality rate in our largest towns. It appears that Norwich, with a rate of 12.1 per 1,000, was the best record, and the port and town of Cardiff, with one of 31.3, was the most unfortunate of the twenty-eight of the largest English towns. London had a mortality of 21.6 from all causes. The annual rate per 1,000 persons living in these towns, which had been 22.6, 21.9 and 20.6 in the last three weeks of 1883, has risen to 22.2 during the first week of this year. It has caused some amusement that, in his last report, Dr. Sedgwick Saunders has found it necessary to complain to the City Commissioners of Sewers, that among the places which had offended against the principles of smoke abatement, and thus caused a nuisance, were the General Post-Office and the Bank of England.

An interesting discussion took place at the last meeting of the Pathological Society, in connection with a case shown of a pancreas from a diabetic patient with a dilated duct, containing numerous irregular calculi of carbonate of lime, associated with fatty degeneration of the tissue of the gland. Many instances were given by members present of personal knowledge of a similar state of things being found in diabetes. Dr. Norman Moore said he had carefully examined the pancreas from a number of cases of diabetes, but the results were not constant or very definite, and he pointed out that even though the gland appeared shrunken and degenerated, microscopically the structure was often unaltered. G. O. M.

MISCELLANEOUS.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, OCTOBER 1, 1883, TO DECEMBER 31, 1883.

Bailhache, P. H., Surgeon, relieved from duty at Cape Charles Quarantine Station, Oct. 13, 1883.
Detailed as member of Board to examine candidate for promotion, Oct. 30, 1883.
Granted leave of absence for thirty days, Nov. 27, 1883.

Hutton, W. H. H., Surgeon, granted leave of absence for twenty days, Oct. 1, 1883.

Wyman, Walter, Surgeon, detailed as member of Board to examine candidate for promotion, Oct. 30, 1883.
To proceed to Norfolk, Va., to investigate the conduct of the Service at that port, Dec. 31, 1883.

Long, W. H., Surgeon, leave of absence extended ten days, Oct. 26, 1883.

Murray, R. D., Surgeon, to proceed to Ship Island Quarantine Station, Oct 17, 1883.
To inspect sites for quarantine stations, Nov. 30, 1883.
Granted leave of absence for twenty days, Dec. 18, 1883.

Smith, Henry, Surgeon, granted leave of absence for twenty-five days on account of sickness, Oct. 13, 1883.
Relieved from duty at Norfolk, Va., Oct. 17, 1883.
To report to Surgeon Sawtelle, at New York, for temporary duty, Nov. 27, 1883.
Relieved from temporary duty at New York, and placed on waiting orders, Dec. 31, 1883.

Fisher, J. C., Passed Ass't Surgeon, when relieved by Assistant Surgeon Banks, to proceed to New York for duty, Oct. 29, 1883.
Granted leave of absence for thirty days, Nov. 28, 1883.

Goldsborough, C. B, Passed Ass't Surgeon, granted leaves of absence for thirty-two days on account of sickness, Oct. 12, Oct. 20, and Nov. 1, 1883.

Irwin, Fairfax. Passed Ass't Surgeon, to proceed to Norfolk, Va, and assume charge of the Service, relieving Ass't Surgeon Glennan, Oct. 16, 1883.

Mead, F. W., Passed Ass't Surgeon, to proceed to Portland, Oregon, inspect the Service, and report the condition of Assistant Surgeon Devan, Dec. 5, 1883.
To return to station, Port Townsend, Wash. Ter., Dec. 18, 1883.

Cooke, H. P., Passed Ass't Surgeon, to proceed to Charleston, S. C., for duty, Nov. 27, 1883.

Banks, C. E., Assistant Surgeon, detailed for temporary duty at Georgetown, D. C., Oct. 11, 1883.
Granted leave of absence for thirty days, Oct. 12, 1883.

Bennett. P. H., Assistant Surgeon, placed on waiting orders, Dec. 15, 1883.
Granted leave of absence for thirty days, Dec. 22, 1883.
Upon expiration of leave of absence to proceed to Detroit, Mich, for duty, Dec. 29, 1883.

Peckham, C. T., Assistant Surgeon, to proceed to Wilmington, N. C, and assume charge of the Service, relieving Passed Ass't Surgeon Irwin, Oct. 16, 1883.

Devan, S. C, Assistant Surgeon, granted leaves of absence for ninety-five days, on account of injury and sickness resulting therefrom, Nov. 15, Dec. 5 and 22, 1883.

Bevan, A. D., Assistant Surgeon, to proceed to Portland, Oregon, and assume charge of the Service, Dec. 29, 1883.

Glennan, A. H., Assistant Surgeon, to proceed to New Orleans, La, for duty, Oct. 16, 1883.

Wasdin, Eugene, Assistant Surgeon, to proceed to Mobile, Ala., for temporary duty, Oct. 11, 1883.
To proceed to Galveston, Texas, for temporary duty, Nov. 17, 1883.

PROMOTIONS.

Benson, J. A., Passed Ass't Surgeon, promoted and appointed Passed Assistant Surgeon, by the Secretary of the Treasury, from October 1, 1883. Oct. 4, 1883.

Banks, C. E., Passed Assistant Surgeon, promoted and appointed Passed Assistant Surgeon, by the Secretary of the Treasury, from November 1, 1883. Nov. 6, 1883.

OFFICERS OF

THE AMERICAN MEDICAL ASSOCIATION

AND OF ITS SEVERAL SECTIONS, 1883-4.

PRESIDENT.

Dr. AUSTIN FLINT, SR., of New York.

FIRST VICE-PRESIDENT.

Dr. R. A. Kinloch, Charleston, S. C.

SECOND VICE-PRESIDENT.

Dr. T. B. Lester, Kansas City, Mo.

THIRD VICE-PRESIDENT.

Dr. A. L. Gihon, United States Navy.

FOURTH VICE-PRESIDENT.

Dr. S. C. Gordon, Portland, Maine.

PERMANENT SECRETARY.

Dr. Wm. B. Atkinson, 1400 Pine St., Philadelphia.

TREASURER.

Dr. R. J. Dunglison, Philadelphia.

LIBRARIAN.

Dr. C. H. A. Kleinschmidt, Washington, D. C.

Place of meeting, 1884, Washington, D. C.; Time of holding meeting, first Tuesday in May.

CHAIRMAN COMMITTEE OF ARRANGEMENTS.

Dr. A. Y. P. Garnett, Washington, D. C.

ASSISTANT SECRETARY.

Dr. D. W. Prentis, Washington, D. C.

BOARD OF TRUSTEES FOR JOURNALIZING THE TRANSACTIONS.

Drs. J. M. Toner, Washington, D. C., President;
E. M. Moore, Rochester, N. Y.; Leartus Conner, Detroit, Mich.;
J. H. Packard, Philadelphia, Secretary;
H. F. Campbell, Augusta, Ga.; A. Garcelon, Lewiston, Me.;
P. O. Hooper, Little Rock, Ark.;
L. S. McMurtry, Danville, Ky.; J. H. Hollister, Chicago, Ill.

OFFICERS OF THE SECTIONS:

"Practice of Medicine."

Chairman—Dr. John V. Shoemaker, Philadelphia, Pa.;
Secretary—Dr. W. C. Wile, Sandy Hook, Conn.

"Obstetrics and Diseases of Women."

Chairman—Dr. T. A. Reamy, Cincinnati, Ohio; Secretary—Dr. J. T. Jelks, Hot Springs, Ark.

"Surgery and Anatomy."

Chairman—Dr. C. T. Parkes, Chicago, Ill.; Secretary—Dr. A. O. Walker, Detroit, Mich.

"Ophthalmology, Otology and Laryngology."

Chairman—Dr. J. F. Chisolm, Baltimore, Md.;
Secretary—Dr. J. L. Thompson, Indianapolis, Ind.

"Diseases of Children."

Chairman—Dr. Wm. Lee, Baltimore, Md.; Secretary—Dr. W. R. Tipton, Las Vegas, N. M.

"Oral and Dental Surgery."

Chairman—Dr. T. W. Brophy, Chicago, Ill.; Secretary—John S. Marshall, Chicago, Ill.

THE BACILLUS TUBERCULOSIS AND THE ÆTIOLOGY OF TUBERCULOSIS. IS CONSUMPTION CONTAGIOUS?

SECOND COMMUNICATION.

[Read before the Philadelphia County Medical Society, Nov. 14, 1883.]

BY H. F. FORMAD, B.M., M.D.,

Lecturer on Experimental Pathology and Demonstrator of Morbid Anatomy in the University of Pennsylvania; Mütter Lecturer in the College of Physicians of Philadelphia.

GENERAL CONSIDERATION.

A little over a year ago[1] I had the honor of presenting for your consideration some anatomical points in refutation of the ætiological relations of the bacillus tuberculosis.

At that time I announced some original observations regarding the histology of scrofulous tissue, tending to place the question of heredity in tuberculous disease upon an anatomical basis. These peculiarities of scrofulous tissues, I submitted as elucidating the ætiology of tuberculosis, showing that the peculiar histological condition of the individual, under the influence of simple irritants, and not the character of the irritant, is responsible for tubercular inflammation. It gives me pleasure to state that these observations have been confirmed by several competent histologists, whose articles on this subject will soon appear in print; besides which, a general interest has been manifested by favorable comments both in America and abroad.

Shortly before the publication of these observations, Koch, of Berlin, had brought forward the discovery of the now famous bacillus tuberculosis, affirming it to be the sole cause of pulmonary phthisis and other forms of tubercular disease, and claiming for it, besides exclusive pathogenetic properties, special morphological and chemical characteristics.

In my first paper, I denied some of these propositions upon grounds of personal investigation, and, subsequently, Koch's researches were also severely criticised by a number of other observers.

As interesting and valuable as the discovery of Koch is, from a biological standpoint, its practical value is, in my opinion, decidedly over-estimated, and has not nearly the significance for medical science which the enthusiastic followers of Koch ascribe to it. The influence of the discovery was, however, great in strengthening the traditional and unwarranted belief in the contagiousness of phthisis, as held by a small part of the profession and community. On the other hand, this belief led to the popularity of the discovery. In this respect the bacillus theory has perhaps been harmful, and, taking the consequences into consideration, we should not accept such a theory without the closest scrutiny.

Two practical benefits may accrue from this discovery. The first is, that the fear of the effects of the bacillus may induce greater cleanliness in hospital management, and enforce improvement in hygienic matters in general. It is doubtful whether the removal and prompt destruction of the sputum would have any influence in checking the spread of phthisis, as the disease is found as often, if not oftener, in the clean palaces of the wealthy, as in the unclean huts of the poor. The second benefit resulting from the bacillus theory may be, that physicians may become induced to make more use of the microscope in diagnosis; yet, in this respect, the general use of the microscope is hardly practicable, on account of the thorough technic and experience required.

To-day, while the bacillus is acknowledged as a common morphological concomitant of tubercle, the pathogenetic properties are denied it by the best pathologists and clinicians, on account of a want of sufficient confirmation of the evidence thus far offered.

The followers of Koch's theory are, however, numerous, but they are recruited largely from the ranks of clinical teachers, book-writers, and others possessing no opportunities for personal investigation.

It may be well to state that, upon my visit to Koch last summer, made with the purpose of doing justice to this important question, I was gratified in many respects. I found Koch an earnest and conscientious worker, and not as dogmatic and extreme in his views as would appear from his writings; nor is he as self-satisfied and as rash to jump at conclusions as are some of his followers. Koch has the coöperation of an excellent staff of assistants, all able mycologists; but it was a matter of surprise to me that there was not a single competent pathologist connected with Koch's laboratory; and such services are evidently

[1] Studies from the Pathological Laboratory of the University of Penn., xi.; "The Bacillus Tuberculosis and some Anatomical Points which suggest the Refutation of its Ætiological Relation with Tuberculosis, by H. F. Formad." Read before this Society, October 18, 1882.

much needed, to give to the observations made there the proper interpretation from a biological and anatomical standpoint. I was also pleased to learn in Berlin that the discovery of the bacillus was exaggerated, not so much by Koch himself as by the Imperial Board of Health, which employs him, and by his over-zealous followers in the profession. There is strong evidence, however, that Koch's investigations are biased by the determination to find for each specific disease a specific fungus.

Following out the various phases in the study of tuberculosis, I am sorry to see that the entire subject is now being considered from a purely ætiological basis with reference to bacteria, while the study of the anatomical and biological relations is wholly neglected.

I admire the beautiful bacteridian discoveries of Klebs, and particularly those of Koch in connection with the ætiology of tuberculosis. The accomplishment of these results is a triumph for mycology and scientific botany; but these studies are much too one-sided to have an application to scientific medicine. The bacillus is there! It is concomitant with most tubercular lesions. It is diagnostic of tuberculous change. It is, on account of its irritant properties, one of the causes of tuberculosis. But this forms no reason for asserting that tuberculosis should be considered a contagious disease, without further investigation and proof. A contagious disease can have only one cause. I cannot agree with those who define the predisposition to phthisis as being a condition of the organism which offers a favorable soil for the tubercle bacillus. Nor can I believe that inheritance is explained by subsequent infection from cohabitation; *e. g.*, that children become scrofulous by living with consumptive parents.

The latest fruits of the bacillus studies have even inspired Baumgarten (Centralblatt f. d. Med. Wis., Aug. 4, 1883) and several others to come to the conclusion, in reference to the hereditary nature of tuberculosis, that the bacillus is transmitted in its larval state from mother to fœtus in intra-uterine life! One would think, however, that one of the most wonderful effects of the tubercle bacillus is manifested by the change it produced in the direction of the reasoning of some of our pathological and clinical investigators, both at home and abroad.

Some of the younger pathologists are affected by a regular fanaticism for bacterian studies in tuberculosis. These studies now take the place of their former excellent pathologic-anatomical studies. Consideration is no longer given to the tissue changes, or the nidus which invites the bacteria and nourishes them. In fact, Koch's followers in their enthusiasm exaggerate matters, and, to Koch's own amusement, go further in their bacillus speculations than he himself thinks justifiable. It is really painful to read how some of the younger German pathologists, and a few of the prominent English surgeons, under the influence of the bacillus craze, will make, in their publications, assertions entirely unwarrantable. They describe, for instance, with the greatest ingenuity and exquisite minuteness, how "one or more bacilli" will produce certain histological changes in the lungs or in the peritonæum, designating the exact route to the same; how the different cells, the lymphatic and the blood-vessels are affected; how the bacilli convert one variety of cells into another; how they manufacture giant cells and cheesy material; how acute and chronic phthisis are produced by the bacilli, and the quantity necessary for each; how tubercles develop only and exactly in those places where the bacillus becomes lodged; how, if bacilli alone are inhaled, miliary tubercles form; and how, if the bacillus is accompanied by some other irritants, a broncho-pneumonia will ensue.

All the above statements are made by scientific medical men and pathologists, and offered as broad facts, in full earnest! I only have to say that here evidently observation is substituted by imagination and speculation; and all this is done for the sake of the convenience in explaining a disease by pretty hypotheses.

The only men who attempted to repeat Koch's experiments, besides the work done in the pathological laboratory of the University of Pennsylvania, were Spina (Studien über Tuberculose, Wien., 1883), and Watson Cheyne. Of the latter two scientists, Spina came to results entirely different from those of Koch, and they disprove beyond doubt some parts of Koch's hypothesis. From an analytical and critical point of view, Spina's studies of tuberculosis are excellent, but the technical part of his investigation is deficient, and hence not satisfactory. Watson Cheyne, to whom the "British Association for Advancement of Science by Research" had entrusted the investigation of tuberculosis, and the testing of Koch's researches, did not do justice to his mission. From Cheyne's report (*The Practitioner*, April, 1883), it is seen that he made no earnest attempt to study the nature of tuberculosis, because all he did was to study and experiment with bacteria met with in tuberculous lesions. He went to see some of the different mycologists, consulting only believers in the germ theory; obtained some French and German bacteridian material, and, after testing the same, he reports with great emphasis that Koch's bacilli are a more genuine tubercular virus than Klebs' or Toussaint's micrococci. He did not inquire, nor did he care, whether tuberculosis may have any other cause! He simply imitated some of Koch's experiments with the bacillus material in rabbits and guinea-pigs (only), and obtained, of course, the same results. Furthermore, he made some control experiments, which, as I will show, pass for nought, as they are much more deficient than those of Koch.

There are a number of excellent studies in reference to the occurrence of bacilli in the sputum and in tuberculous tissues; but the main part of Koch's hypothesis, *i, e.*, the ætiological relation of these bacilli to tubercular disease, remains still unconfirmed.

My own researches on tuberculosis were made from a standpoint different from that of Koch, and they were undertaken five years ago, being carried on continuously since that time by myself and assistants. My object was to investigate the natural history of the disease, without being influenced by any preconceived views. While due attention was paid to ex-

ternal agencies in the production of tuberculosis, the part played by the animal or human organism itself, the behavior of its component cells, and the primary changes in the tissues, were not lost sight of.

I may state that I was fortunate enough to be able to utilize the material of over four hundred cases of tubercular disease from the autopsy tables, including a number of cases studied in the pathological institutes in Europe at various times.

My present research on tuberculosis with special reference to the bacillus question, was carried on during the last year and a half, under the auspices of the Provost of the University of Pennsylvania, Dr. Wm. Pepper. This communication should not be considered a report on my investigations, as these are not yet concluded; but a detailed report of these investigations will be made next summer. Some of the positive results achieved will, however, be referred to in the present paper; otherwise it merely embodies a general critical survey of the question of the ætiology of tuberculosis, based upon a careful perusal of the literature of the subject and upon personal observation.

I may state at the outset that, while the results of my observations force me to make some concessions to Koch, namely, that his bacillus, on account of its irritative properties, can produce tuberculosis under certain conditions, I am firmer than ever in my former conclusions, from the results of repeated observations, that tuberculosis may arise from other causes. The bacillus may be one of the causes, conditionally, but it is not *the* cause. The question of predisposition stands in the way of the acceptance of the bacillus theory. Furthermore, I will try to show that tuberculosis is not a contagious disease, and it is particularly in reference to this that I am glad to bring the present subject before the Society, desiring to profit by the discussion which is to follow as a result of the experience and the clinical observation of the individual members of the Society.

The question of the contagiousness of phthisis is one of supreme importance, not only from its scientific, but also from its social aspects.

For convenience in treating the subject of the ætiology of tuberculosis, I shall speak of it under the following headings:

1. The definition, the anatomical character, and the ætiology of tubercular lesions, including pulmonary phthisis.
2. The predisposition; the predisposing conditions; scrofulosis.
3. Tuberculosis without predisposition, due to inflammation of serous membranes.
4. Question of contagiousness; clinical aspect.
5. The bacillus tuberculosis.
6. Experiments—"pro" and "contra;" traumatic tuberculosis. Conclusions.

All these considerations will have to be, of necessity, very brief.

I.—THE DEFINITION, THE ANATOMICAL CHARACTER, AND THE ÆTIOLOGY OF TUBERCULAR LESIONS, INCLUDING PULMONARY PHTHISIS.

No definite understanding concerning a disease can be arrived at unless some fixed conception of the anatomical characters and various expressions of the lesions of that disease is formed. Thus, as regards the question of tuberculosis and pulmonary phthisis, the matter would be much simpler if a general understanding could be arrived at as to the definition of tuberculosis and phthisis in its different anatomical manifestations. The pivot of the question is, what to call a tubercle or a tubercular lesion.

The traditional conception of a tubercle being a miliary node, the belief is that nothing is tuberculosis unless expressed by nodes, and that everything is tuberculosis that appears to the eye as containing nodes. These misconceptions are what bring the confusion and prevent the settlement of the question of tuberculosis, both at the post-mortem table and in the hands of the experimenter.

One of the results of this confusion is that some clinicians divide pulmonary phthisis into catarrhal, cheesy, fibroid and tubercular proper, because they do not see tubercle nodules in some of these forms of phthisis. They seem not to be aware of the fact that miliary tubercles do not belong necessarily to the picture of pulmonary phthisis; and, on the other hand, that those nodes which occasionally appear as miliary tubercles are not miliary tubercles at all; but are only miliary foci of broncho-pneumonia, due to aspiration, as will be explained later. Miliary tubercles, if at all present, usually form a part of a general disease, a tuberculosis of the whole body. In rare instances, when the miliary eruption takes its departure from the lung, the miliary nodules may be limited to the lung.

A more serious matter is the mistake that experimenters make of interpreting as tubercles the so-called inhalation tuberculosis, artificially produced in animals by means of a spray with tuberculous and other matter. The nodules produced in the lung under these circumstances are not miliary tubercles—in fact, no tubercles at all. They are simply miliary broncho-pneumonic foci, limited to those terminal collections of air-vesicles, called acini, in which some of the inhaled irritative material became lodged. The natural round boundaries of these acini correspond exactly to the usual size of miliary tubercles, and appear as such even under the microscope, although filled merely with an unorganized inflammatory exudate. The uniform distribution of these foci is due to the fact that the inhaled irritating particles are distributed only to individual and the most accessible bronchioles and acini, thus simulating a true miliary tuberculosis of the lung. Similar broncho-pneumonic foci occur in the human lung from self-aspiration of tuberculous material from a primary focus to some other portion of the lung, or throughout the whole lung. This was proven long ago, but the inhalation experimenters appear not to be aware of that fact. Careful personal observations and experiments, to be recorded in my forthcoming report, have convinced me that such inhalation experiments prove nothing, either for or against the contagiousness of tuberculosis, in connection with which they have been brought forward as the strongest affirmative proofs. Furthermore, it must also be remembered

that the so-called experimental inhalation tubercles, as a rule, remain local.

On the other hand, miliary nodes or tubercles are met with, not only in tubercular lesions, but also in a variety of similar and dissimilar lesions, such as pearl disease or bovine tuberculosis, lupus, leprosy, glanders, actinomycosis, chancre and gummata, cancer, typhoid infiltration, lymphomatous and leukæmic lesions. All these lesions, even cancer ("miliary carcinosis"), are able to give rise to exquisite miliary disseminations, or eruptions, although these are most frequently observed in tuberculosis. We already recognize leprous, lupous, glanderous, syphilitic and other tubercles, in contradistinction to tuberculous or scrofulous tubercles.

To the above nodular formations may be added a variety of minute inflammatory foci of granulation tissue, organized around minute foreign bodies introduced experimentally into various tissues; also, "false tubercles," such as mere unorganized collections of lymphoid cells, held together by some fibrine or by some artificial or natural round boundaries, such as is the case with the referred to "inhalation tubercles;" and further, also, the eruptions and follicular enlargements in the skin and mucous membranes.

The question now arises, how to distinguish between these various kinds of nodules, apart from their clinical features. They may all undergo a cheesy or a fibrous change, may calcify, and may contain giant cells. In all, bacilli may be found if a cheesy change occurs, or tends to occur, save in cancer and in leukæmic formation. Without desiring to appear skeptical, I must say, however, that it takes the skill of a Koch to differentiate sometimes the bacilli met with in the various kinds of nodes, even after applying all micro-chemical tests.

The true tuberculous tubercles occasionally do not show any bacilli whatever, as I will prove from personal observation, and from the reliable testimony of others. It will also be shown that the only test now left for determining the pathogenic peculiarity of tubercle—namely, the asserted exclusive property to produce tuberculosis—is conditional and uncertain, since substances, not tuberculous, may, under similar conditions, have the same effect.

Therefore, it is impossible to define tuberculosis, either by its anatomical peculiarity or by the pathogenic property of its nodes.

Another important point in the natural history of tuberculosis is the cheesy degeneration of its products; but here, again, we are surrounded by difficulty, if we take only the cheesy product into consideration, because all the lesions mentioned before as being characterized by, and as being capable of, nodular eruptions, have the tendency to undergo cheesy change. Besides this, simple inflammatory products have been observed to undergo a similar change, as is instanced by that form of cheesy hepatization sometimes following croupous pneumonia, and also by certain forms of rapid necrotic changes, such as occur in acute septic inflammations, designated lately by the name of coagulation necrosis. It must, however, be remembered that the total absence of cheesy masses in the body of tuberculous subjects has been observed.

To tell tuberculosis from allied lesions is only possible after a consideration of the soil in which it develops, and the location of the products, together with the clinical and anatomical manifestations.

What is the origin of tubercle nodules?

The primary occurrence of miliary tubercle nodes is, to my mind, very questionable. I have never seen it occur without the co-existence of diffuse granulation tubercle. This granulation tubercle is recognized by all as being a simple inflammatory granulation tissue, characterized by cells somewhat larger than ordinary lymphoid cells, containing usually giant cells, but undergoing very readily cheesy change on account of its deficiency in blood-vessels. This tissue is regarded by most pathologists as secondary to miliary tubercles; but I think, after careful observation, that the reverse is the case; because I have never seen upon the post-mortem table, or in animals, *primary* miliary nodes without the granulation tissue, while the granulation tubercle tissue does exist very frequently without the nodes. Moreover, primary *miliary* tuberculosis is unknown.

That tubercle is primarily a simple granulation tissue of inflammatory origin has been proven experimentally. E. Ziegler (Centralbl. f. d. Med. Wis., 1874, No. li) made the following interesting experiment: He inserted below the skin or into the peritonæum of animals, a number of pairs of glass covers, each pair glued together in such a manner that between them there existed an interspace just large enough to allow the entrance of white blood corpuscles; and these corpuscles, not being severed from the body of the animal, then formed a tissue between these plates of glass, which, upon removal after various periods, could be readily examined under the microscope, and the conditions of tissue formations traced. Under these circumstances it was observed that whenever blood-vessels had developed in the new-formed tissue between the glass plates, an organization of the cells into a perfect connective tissue took place; but, when the formation of blood-vessels had failed to occur, then a tissue simulating tubercle tissue was formed, made up of epitheloid and giant cells, and cheesy changes had occurred. Ziegler very properly declared the latter product to be tubercle tissue. I have had, and have at present, ample opportunity to corroborate the accuracy of these observations. Ziegler's experiments were repeated in the pathological laboratory of the University of Pennsylvania by Hammer, and at present are being carried on by Woodnut. By these experiments, made with but slight modification, after the method of Ziegler, under varying conditions and upon various animals, it was shown that the granulation tissue gradually gave origin to tubercle nodules. Furthermore, these experiments showed that the tubercle nodes and cheesy changes ensue without the action of bacilli, as the latter were found not to be present when proper care was taken, during the execution of the experiment, to exclude them.

From the examination of tubercular tissue from various sources, I may say that I have seldom suc-

ceeded in finding tubercle bacilli in newly-formed tubercular tissue made up of small lymphoid cells. In older tubercular tissue, made up of opaque epitheloid cells and giant cells with a nodular arrangement, particularly when this tissue is undergoing necrotic change, bacilli are quite common, except in some forms of tubercles of serous membranes, to be referred to later. Tubercle tissue that has undergone a complete cheesy change, contains the greatest number of bacilli. Cheesy matter of any source is a dead substance, and it is usually inhabited by bacilli, if these get access to it; while other bacteria are scarce on this nidus.

Examination of materials from the autopsy table shows that tubercle expresses itself in various manners. Primarily, tubercle occurs as a mere infiltration of lymphoid cells in the adventitia of blood-vessels, or as small nodular masses of lymphoid infiltration around blood vessels or ducts of any kind; or tubercle tissue may organize within blood-vessels and various ducts. Sometimes tubercle appears as a diffuse lymphoid infiltration, extending over a larger area, showing a greater or less tendency to the formation of nodes and cheesy or fibroid change, as in the lungs. Tubercle tissue may form masses of the size of a hen's egg, particularly in the brain and serous membranes. In the lungs, in racemose glands, and in mucous membranes, catarrhal changes always follow the tubercle infiltration. On serous surfaces primary tubercles appear often as flat or nodulated patches of various sizes (in peritonæum), or as fungoid vegetations (in synovial cavities), or even as large plastic masses (in omentum). In the skin and mucous membranes, tubercles produce eruptions, ulcers, or nodular indurations; in bones—caries, with abscess formation in surrounding parts (cold abscesses). Fibroid capsules, made up of connective tissue, due to reactive inflammation, enclose often smaller or larger tubercular masses, especially if these have undergone cheesy change.

Primary tubercle manifests itself quite variously in different animals. In guinea-pigs and rabbits, it appears mainly as small cellular infiltrates; in dogs, it often undergoes a fibroid change; in goats, and especially in cattle, tubercle often forms large nodular, sometimes pedunculated masses which often calcify;[1] in birds, it forms, preferably in the liver, large round mulberry masses, which, on section, appear sometimes as horny, radiating structures.

Secondary tubercle presents an aspect entirely different from primary tubercle, and it manifests itself in nearly all instances in but one form, namely, as a fine miliary eruption representing those well-known gray semi-transparent nodules of the size of a millet seed, called miliary tubercles. These seem to lie in the perivascular lymph-spaces, and are probably distributed throughout the body mainly by means of these lymph-channels of the blood-vessel walls. Tubercles do not occur in avascular tissues. There is, however, a second form of embolic or metastatic tuberculosis, which evidently distributes itself by the blood-current proper, and it appears in the form of conical masses or round nodes, which may reach the size of a walnut, and are located usually at the bifurcation of arteries. No mention of this form of tubercle is made in text-books, although upon the post-mortem table this variety of tubercle is a very common occurrence. Especially is it seen in the lung, and more rarely in the spleen and liver.

Taking into consideration the enormous frequency of local tubercular lesions (counting pulmonary phthisis into this category), the occurrence of secondary or true miliary tuberculosis must be considered a rare affection. A tuberculosis affecting the lining of even the whole peritoneal cavity, including its lymphatic glands, or that of the pleural sacs, or that involving one or both lungs, must, when occurring thus in but one locality, be considered a local tuberculosis. In such instances, the tubercle spreads by continuity of structure.

It is a fact, established by Virchow, that tuberculosis is at first a local disease, and only become generalized secondarily. This generalization does not affect the blood like in infectious diseases, but it takes place simply as an embolic process, like in some tumors. Local tuberculosis in external organs and accessible lymph-glands is often a harmless affection. It is strongly related to primary tumors. Complete early removal of local tubercular lesions is practiced successfully in Europe. Volkmann and others have removed, for instance, lymphatic glands, testes, and joints affected with fungoid synovitis, with the object of preventing secondary tuberculosis, and have thus prevented a general miliary tuberculosis.

Nor should a gloomy prognosis be given in early phthisis. It is astonishing what a large number of healed cavities and cicatrices in the apices of lungs are found on the post-mortem table, indicating the healing of phthisis in persons who long subsequently died from some other causes in later life.

We have seen that tuberculosis manifests itself quite differently as to structure, appearance, distribution and termination in the various animals, and even differently in the various organs of one individual. Our studies have shown that these variations in the expression of tuberculosis depend upon the structural peculiarities of the various kinds of animals, and sometimes even upon the difference of the structure in animals of the same species. We have also seen that even in human beings tubercle tissue may manifest itself in various forms. In some individuals it develops rapidly, and spreads over large areas, becoming generalized and undergoing speedy cheesy change; in other individuals it develops slowly, fibroid change predominating; and in others the tuberculous product may calcify. In most individuals tubercular lesions may remain entirely local.

It is well known from clinical experience that the general condition of the organism has very much to do with the healing of a local tuberculosis. A local tuberculous inflammation may heal or become arrested in its progress, if the patient "gets strong," or it becomes more developed and aggravated if his

[1] I have met with, on the autopsy table of the Philadelphia Hospital, two cases of tuberculosis in man that were identical in every respect to bovine tuberculosis. Dr. Creighton, of Cambridge, England, describes a number of cases from his own observation, and collected from literature. Bovine Tuberculosis, London, 1881.

general health "runs down." Observation has further shown that any simple non-specific wound in a weak, ill-nourished individual may fail to heal, becoming unamenable to treatment, and probably assuming a tubercular character.

In some animals spontaneous tuberculosis is unknown, and while some animals are easily tuberculizable experimentally, in others tuberculosis can not be produced.

It is in accordance with experience that in a large number of families the predisposition to tuberculosis is hereditary, and that their members die promptly of phthisis at a certain age from the effects of a simple "cold," while in the history of other families this affection is unknown. Every individual is liable to acquire syphilis, small-pox, and other contagious diseases, but it is proven that not every one can have tuberculosis. A special predisposition and a special individual are required. In such an individual, a simple inflammation resulting from any cause whatever, can produce tuberculosis.

Therefore, for the development of tuberculosis, two conditions are necessary:

1. A *definite* soil.
2. An *indefinite* irritant.

The reaction of the soil is always the same under the influence of any irritant, whether that irritant be a bacillus or not; since the result (tuberculosis) following a lesion in such a soil depends upon the character of the soil, and not upon the character of the irritant, even though one irritant, say bacilli, may act more readily than other irritants.

In view of the demonstrated fact that simple injuries of any kind can excite a tuberculosis, but only in certain individuals and tissues, it is evident that tuberculization is determined by the kind of soil and, not by a specific irritant. *Tubercle should, therefore, be defined as being an inflammatory new formation in a special individual or tissue.*

What is the place for tubercle in pathology? The anatomical criterion for tubercle is a granulation tissue made up of lymphoid or epithelioid cells, which, on account of deficiencies in the soil, does not undergo any higher organization, nor tend to heal; but tends to form nodes and undergo cheesy change. Under favorable circumstances it may heal through fibroid change. The elements of tubercle tissue may spread by continuity of structure to surrounding parts, and occasionally tend to the production of metastasis, distributing themselves by means of the lymphatic system principally, and rarely by blood-vessels; and may generalize themselves through the whole body, forming miliary nodes or tubercles.

This miliary eruption of tubercle appears to have the same relation to the primary tubercular growth as the secondary metastatic cancer eruption has to the primary cancerous growth. Like in cancer, the elements of tuberculosis may be arrested temporarily by the lymphatic glands governing the affected region.

In tuberculosis, lymphoid cells form the nodes; in cancer, epithelial cells. While secondary cancer nodes are, as a rule, much larger than tubercle nodules on account of the well-known great proliferating power of epithelium, it is also a fact that cancer may appear as a miliary carcinosis, expressed by minute nodules, not distinguishable macroscopically from miliary tuberculosis. Cancer is proven to be a local disease. It is not contagious. It is infectious only to the individual who is affected by it; *i. e.*, it is self-infectious. And so is tubercle, in every respect, a local, self-infectious disease.[1]

That local manifestation of tuberculosis in the lung, which is designated by the traditional name of pulmonary phthisis, forms perhaps nine-tenths of all tubercular lesions, and hence deserves some special consideration.

I arrange myself with those who regard all forms of pulmonary phthisis as tubercular. There are only three or four lesions of chronic wasting disease of the lung which may be excluded from phthisis. These are atelectasis, or collapse from pressure of effusions; bronchiectasis, in which the enormous dilatation of the bronchi may lead to large cavities and atrophy of lung structure; primary fibroid changes; and abscess of lung. Yet all these lesions may become tuberculous from secondary inflammatory changes which usually follow.

The lesions that are known as catarrhal pneumonia, bronchio-pneumonia, pneumonic phthisis, cheesy pneumonia, tubercular phthisis, and fibroid phthisis, are all manifestations of the one disease. Such a classification may be, however, entirely justifiable and useful for practical clinical and therapeutic purposes. Pathologically considered, phthisis is a local tuberculous inflammation of the lung, which may manifest itself in various ways, the appearance depending upon the duration of the disease, the mode of onset, and the constitution and condition of the patient. Lesions representing the different forms of phthisis, and their transition from one form to the other, are often seen in the same lung.

Virchow insists that nothing should be considered tubercular unless it shows true tubercle nodules, and hence he does not recognize cheesy pneumonia—or cheesy hepatization, as he calls it—as tubercular, although he does not object to the term phthisis for this lesion.

I was fortunate enough to attend several times the demonstrations on this point of Virchow, the father of the view of the dual origin of cheesy matter and phthisis; yet from our present knowledge of what constitutes tubercle, I cannot help interpreting all the forms of phthisis as of a unitarian origin. It is, after all, as Virchow himself says, only a matter of nomenclature. If we consider the presence of bacilli of Koch as the differentiating point between what is tubercular and what is not, we find that catarrhal and cheesy pneumonias are the most tubercular of all, because they contain, as a rule, more bacilli than any other forms of phthisis.

---

[1] Cancer and tubercle are considered analagous lesions, and classed with tumors, by a number of pathologists. This fact would not make it inconsistent to call tubercle an inflammatory product, as the distinction between inflammatory processes and tumor formation is a purely arbitrary one. Virchow pointed out that the majority of tumors are purely inflammatory products (a statement antedated twenty years by Professor S. D. Gross). A few years ago I made the question of the ætiology of tumors a subject of careful personal study, which I yet continue, and I am forced to the conclusion that *all* true tumors are inflammatory products, and that no line of distinction can be drawn where the process which we call inflammation ends and where tumor formation begins.

Although cheesy pneumonia, like all forms of phthisis, remains commonly a local affection, it is seen on the autopsy table to give rise to miliary tuberculosis at least as often as any of the other forms of local tuberculosis.

We are then at present at the same standpoint in regard to the character of tubercle and cheesy matter as Lænnec (1819); and it is, indeed, perfectly reasonable to suppose that any cheesy matter found in a scrofulous person or animal is tubercular. Of course, it is evident that tuberculosis of the lung is usually accompanied by simple inflammatory products, such as organized connective tissue (chronic phthisis), or unorganized croupous and catarrhal exudates (predominating in acute phthisis), which may undergo rapid necrotic and purulent changes, resembling cheesy material. For the latter products the name "coagulation necrosis," as applied by the Heidelberg and Leipsic people, may be employed. Tubercle bacilli are commonly found in this coagulation necrosis. True tubercular cheesy matter should, I think, be considered only that product which is derived from the breaking down of previously well organized tubercle tissue.

I need not refer to the details of the manifestation of tubercle in the lung, as these are too well known. But I would like to remark here that those small whitish or gray nodules, usually of somewhat irregular shape, which are seen more or less densely scattered throughout the parenchyma of lungs affected by phthisis, are not miliary tubercles, but minute foci of broncho-pneumonia.[1]

These minute bronchо-pneumonic foci take their origin from tuberculous matter disseminated by means of air-passages, as explained before. *Miliary* tuberculosis of the lung distributes itself by means of the perivascular lymphatics, is very rarely accompanied by catarrhal changes or hepatization, and rarely arises from a primary tuberculous focus of the lung itself; it is, as a rule, a part of general tubercular disease.

II.—THE PREDISPOSITION.

Having shown that for the production of tuberculosis we need a special soil, and that the irritant is only of secondary significance, some inquiry into the nature of this soil is necessary.

The question of the predisposition to tuberculosis, as it stands at present, must be considered from three aspects:

1. The clinical aspect.
2. The anatomical aspect.
3. The bacteridian or parasitic aspect.

The consideration of the clinical aspect of the predisposition to tuberculosis is invaluable, as it rests mainly on actual observation, on demonstrated clinical facts, and on conclusions drawn from statistics.

From time immemorial, a clinically well-defined condition of the system, known as the strumous diathesis in its various forms, has been recognized. This condition will be considered later on.

There are a number of ailments which, from the experience of clinicians, are known to have a great, direct or indirect, influence in the development of general tuberculosis and pulmonary phthisis; or are known to create conditions of the system that predispose it to this malady. Such are syphilis, inflammation of serous membranes, bronchitis, croupous pneumonia, diabetes, the exanthemata, especially measles and typhoid fever, deformities of the skeleton, rickets, cerebral and spinal diseases of various kinds, dyspepsia, the puerperal state, uterine diseases, prolonged nursing of children, onanism, change of climate, continuous loss of sleep, distress, etc.

That exhaustion, exposure, the deprivation of food, and other hardships of campaign life, etc., are prominent ætiological factors in the production of pulmonary consumption is learned from the accounts of military surgeons, who observed among young, robust soldiers a remarkable increase in the morbility and the mortality of phthisis, during and immediately after the close of a war. Such observations have been made in the Franco-Prussian and Turko-Russian campaigns. The fact that consumptive soldiers are not allowed to enter upon a campaign (certainly not in Germany and Russia) excludes here the probability of contagion.

Statistics also show the remarkable prevalence of phthisis in persons of certain occupations, such as stone-cutters, miners, cigar-makers, weavers, telegraph operators, book-keepers, and persons engaged in certain other occupations of a more or less sedentary nature. It is more natural to suppose that the disease or predisposition to it is created by the character and the conditions of the occupation, than that a contagion should affect preferably shoemakers, miners, or soldiers in the battlefield. Again, in most phthisical patients the beginning of the disease can plainly be attributed to an exposure, to a "cold."

On the other hand, there are pathological conditions or diseases which appear to prevent the development of phthisis and tuberculosis in general. It is an established clinical fact that phthisis is extremely rarely, if ever, associated with mitral heart disease; and, from my own observations, I believe that phthisis is rarely coincident with tumors. For the latter circumstance I can offer no explanation; nor is there any statement to this effect in literature. Rindfleisch has suggested that heart disease prevents the development of phthisis by inducing repeated slow congestions of the lungs, these congestions producing an overgrowth of the muscular tissue of the bronchioles and air-vesicles, which thus gains strength for repelling the exudates following inflammation.

If tuberculosis were depending upon a contagium for its development, neither heart nor tumor disease, nor any condition of the organism, could ever prevent its occurrence.

All the clinical facts above referred to prove definitely the necessity for a predisposition for the development of tubercular disease, and militate against the necessity of a contagium.

The anatomical aspect of the question—the morphology of the soil in which tubercle develops—is the most important aspect.

[1] See, in connection with this, the excellent studies of Wm. H. Mercur, from the pathological laboratory of the University of Pennsylvania, published only in abstract form in the *Phila. Med. Times*, July, 1883.

Beneke[1] tries to explain the disposition to tuberculosis by a disproportion between the size of the heart and blood-vessels and other organs to the bulk of the body.

Schottelius[2] made recently some interesting observations concerning the mode of termination of the smallest bronchioles and their relation to the lung acini in different animals. He found that in the carnivora the entrance of the bronchioles into the acini presented very small apertures, so that the air-vesicles were not easily accessible to irritants; while in the herbivora the terminal bronchial terminations were quite wide, thus permitting the free entrance of irritants. He states that in man the bronchial terminations congenitally approach sometimes those of the carnivora, and sometimes those of the herbivora. In the latter type, he believes to have found an anatomical explanation for the predisposition in some individuals to pulmonary tuberculosis.[3] Weigert, of Leipsic, (one of the most enthusiastic germ-theorists), properly remarks upon the observation of Schottelius, that it does not explain the predisposition, as the same animals will re-act, upon the introduction of the "poison of tuberculosis" into any other part of the body where the bronchioles do not come into play.

My own studies upon the minute anatomy of the tissues of man and of animals predisposed to tuberculosis, extended over a large amount of material, and gave results which, to my mind, satisfactorily explained this condition. These results I announced at a meeting of this Society in October, 1882.

The anatomical peculiarity observed in either man or animals, be it inherited or acquired, I first showed to be, briefly stated, as follows: All the tissues of the body approach somewhat an embryonal type; they are peculiarly rich in nuclei and young cells, and the lymph-spaces of the connective tissues are narrower, fewer in number, and show a great many more cellular elements in the scrofulous than in the non-scrofulous. So far, subsequent observations of others agree with mine. Objections are raised only as to the direct relation between these structural peculiarities and tuberculosis. Here I must state that I only suggested, and never asserted, the necessity of such a relation. It is quite possible that there are some other and more striking peculiarities in the morphology of scrofulous animals yet undiscovered. This much I can, however, reassert today: that tuberculosis usually ensues when a simple inflammation is set up by any kind of injury, in animals with the structural peculiarity which I have described; but tuberculosis cannot be produced in animals that do not have this structural peculiarity, so far as my experiments show, unless the injury is inflicted upon serous membranes.

For the details of my researches in this direction, I must refer to my first paper upon this subject.[4]

Koch asserts that the structural peculiarities of the tissues which I described can have no ætiological relation to tuberculosis, because an animal not possessed of such tissue peculiarity—the cat—is easily inoculable by tuberculous material. Here I must differ from Koch, as in my experience with cats this is not the case; and, again, Koch brings no proof for his assertion, and I am unaware that he, or anybody else, produced tuberculosis in a cat, except by inoculation into some serous cavity. That inoculations into serous membranes prove nothing for tuberculosis, as I have shown conclusively, Koch still seems to fail to see. But here is a way in which cats may become tuberculous, with or without the bacillus. In one instance we kept one of the cats in a close box, *deprived* of liberty, good air, the comforts of life, motion, and sufficient food; she also had been inoculated with diphtheritic material eight months previously, but had recovered. After the lapse of a year the cat was set free, but was accidentally killed, and was found to be affected by general tuberculosis in a high degree.

This, in my opinion, corresponds fully to the conditions in which a healthy young woman is placed, and finally becomes scrofulous, and then tuberculous, from a simple cold, after being the faithful nurse for a couple of years of a consumptive husband.

On the other hand, there is full reason to believe, as it is in accordance with experience, that young scrofulous persons, under proper conditions, may become normal individuals; *i. e.*, lose or outgrow the predisposition to tuberculosis. (I have dwelled upon this in my first communication on this subject.)

The scrofulous habit, and consequently also phthisis, may skip a generation, and does not invariably embrace all members of a family. It has been observed that parents may have at first healthy children without any vice, who grow old well; and subsequently the same parents, without being phthisical (but perhaps otherwise becoming deficient in health), may have other children that exhibit a full scrofulous habit. But even the reverse has been observed.

It would be highly desirable if physiologists would furnish some experimental observations on the circulation of the plasma in the lymph-spaces. This is, to my mind, a circulation or movement of the vital juices in the tissues, which, for the well-to-do of the individual, is of importance next to that of the blood. These important channels, the lymph-spaces, are known to regulate the blood-pressure, carry and breed (white blood corpuscles) food for the tissues, lubricate tissues and relieve the body, if any of its parts are damaged by injury of any character, of inflammatory exudates, dropsy, etc. These channels are nearly blocked up, nearly useless in the *scrofulous*, and hence cannot perform their functions; and thus modify materially the condition and the fate of the individual, in case of disease.

The term "*scrofulous*," which I retained for describing the above-stated anatomical peculiarity of animals and individuals, is as good as any other term; moreover it is known by all as designating the "predisposition" to tuberculosis. Scrofulosis should be called a *condition* and not a disease, as it has its

---

[1] Die erste Ueberwinterung in Nordeney, Norden, 1882.

[2] Virchow's Archive, vol. xci, 1883.

[3] The method of investigating this condition is not without interest. The vesicular structure of the lung was injected, through the bronchi, with a resinous melted mass, which, on cooling, presented molds of the bronchioles, in connection with their characteristic infundibula and acini.

[4] *Loc. cit.*

(a natural) hereditary and widely distributed type in man, and its homologue in some normal animals (rabbit, guinea-pig, etc.). It must be remembered that the scrofulous individual acquires certain lesions, such as enlargements of lymphatic glands, cold abscesses, caries, long-standing catarrhs of various kinds, skin eruption, and certain deformities of bones, only under the influence of injuries, or of the same agencies which, in the non-scrofulous individual, lead to transient and curable affections.

Virchow designates simple, permanent enlargement (hyperplasia) of lymphatic glands, with or without cheesy change, "scrofulous," in contradistinction to "tuberculous" lymphatic glands, which contain miliary tubercle nodes (heteroplasia), and which also undergo cheesy change.

There is nothing called "scrofulous" or "scrofulosis," which by others is not also called "tubercle" or "tuberculosis." There are, strictly speaking, no scrofulous products, but only tuberculous products. The traditional term "scrofulosis" is variously used and interpreted, although it is not evident that any one means by it anything anatomically well defined.

Others take matters easier, calling everything *tuberculous* that contains tubercle bacilli, and calling scrofulous all cheesy matters in which bacilli are absent.

There is still a third aspect of this question, viz.: the parasitic or bacillary theory of the predisposition to tuberculosis. As I mentioned in the early part of this paper, Baumgarten, Mordiant and several others recently brought forward that not only tuberculosis but even the predisposition to tuberculosis is to be explained by the suceptibility of an individual to bacilli! Under this hypothesis, the inherited scrofulous tendency in individuals is created through the mediation of the bacilli. It is supposed that the bacilli or their spores may be conveyed to the ovum by the organism of the mother, or in utero by the spermatozoids of the father. Furthermore, they say, inheritance is to be explained in no other way than by a bacillary infection of the infant through the milk of the nursing mother, and by subsequent living together of children and phthisical parents. We may exclude such view altogether from consideration, as it has not been proven. Besides, it is not in accordance with facts from observation. It is as contrary to biological laws to accuse parasites for the transmission of a predisposition to tuberculosis, as it would be for that of epilepsy, etc. Hence we may dispose of such view as an unfounded, absurd hypothesis.

I am not opposed to the germ theory of disease, where it has its well-founded and proper application. Bacteridian studies have contributed largely to our knowledge of a certain class of pathological processes and lesions. But misinterpretations of the significance of bacteria; bacillary speculations, without occasion for them and without any proper application to the subject, are a check to the progress of medical science. The question of the predisposition to, and the cause of, tuberculosis, demands a great deal more of solid pathologico-anatomical and experimental studies; it can by no means be regarded as settled, and least of all through the discovery of a bacillus inhabiting necrotic tubercular tissues.

III.—TUBERCULOSIS, WITHOUT PREDISPOSITIONS, DUE TO INFLAMMATION OF SEROUS MEMBRANES.

For some years I felt much interested in the question whether or not simple inflammation of serous membranes could lead to tuberculosis in the non-scrofulous, that is, in persons who have no family history of tubercular disease; and I would like to ask the opinion and experience of the members of the Society upon this question. It is well known that there may be primary tuberculosis of serous membranes, producing secondary inflammations; and, on the other hand, tuberculosis secondary to adhesive pleurisy or peritonitis is also common in serous membranes. The general belief, however, is that whenever tubercular disease in either case occurs, if not secondary to phthisis or tubercular disease elsewhere, a strumous or scrofulous condition is required.

Traumatic injuries of joints are known to lead often to fungoid (tubercular) synovitis and general tuberculosis, occasionally in individuals with good family history. Simple injuries of the eye-ball (the anterior chamber as well as joints is lined by serous membranes), under conditions as above stated, have also been known to lead to tuberculosis, as recorded by Wolfe (*British Med. Journal*, March, 1882); Gradenigo (*Annale d' Oculistique*, 1870).

Dr. M. Litten,[1] of Berlin, was the first to publish some accounts which demonstrate that miliary tuberculosis may be caused directly and primarily by pleurisy and inflammation of other serous membranes in persons with no phthisical history, and without any cheesy masses being formed in any part of the body. In his (Litten's) experience this was particularly the case when there was a rapid reabsorption of the exudates in case of chronic pleurisy, or if repeated removal of the fluid of a hydrothorax or ascites by tapping has been performed. He records several well studied cases of that kind, accompanied by autopsy records. Litten's observations at no time, however, received their well deserved attention.

Not only clinically, but also pathologically, this part of the tuberculosis question is rather neglected. In text-books of pathology the occurrence of primary tubercle in adhesive bands is incidentally mentioned, but no special consideration is devoted to its ætiology and manifestations.

Upon the autopsy table I have repeatedly met with subjects with exquisite primary tubercular peritonitis, pleurisy, or pericarditis, which, upon inquiry into the history of the cases, failed to reveal any phthisical or scrofulous history. The products of these inflammations were often plastic in character, not unlike those of fungoid synovitis. The appearances sometimes present themselves particularly strikingly in the peritonæum; all the viscera may be glued together by plastic material into a solid mass. The omentum

[1] M. Litten, Sammlung Klin. Vortrage, No. 119. Ueber acute Miliartuberose, 1877. For further references see Wiener Med. Presse, No. 36, 1882; Charite Annalen, vol. vii, Berlin; Krankheiten der Respirations-Organe, in Virchow's Handb. der Spec. Path. und Ther., vol. i; Virchow, Geschwulste, vol. ii, p. 725, etc.; also, Formad, Transactions of the Phila. County Med Society, and of the Pathological Society, for 1882-83.

is usually retracted and matted together in a solid cord or mass, which, laying parallel with the transverse colon, reaches across the abdominal cavity, and may have a thickness of from two to four inches; the mesenteric and other lymphatic glands are usually normal, but sometimes in advanced cases may be much enlarged and more or less cheesy. The perfect absence of any cheesy focus in the body is, however, often a conspicuous feature in these cases.

Some pathologists deny the tubercular nature of these formations, and of the flat, nodular masses which cover the serous surfaces in these cases. It is true that fibroid changes predominate in these formations; but numerous tubercle nodules, with all the necessary attributes, epithelioid and giant cells, and necrotic changes, were plainly seen in all cases which I had occasion to examine. Secondary miliary tubercles of quite recent date are also found thickly strewed locally in these parts, and may or may not be seen in the lungs and other organs. As a rule, there are more or less ascites in these cases. My colleague, Dr. E. O. Shakespeare, has recorded similar cases, and Dr. Morris Longstreth tells me, also, that he had seen and studied such cases. Dr. Mitchell Prudden describes (New York *Med. Record*, June 16, 1883) an allied case.

In chronic adhesive pleurisy there occur similar primary tubercular formations in the organized plastic exudate, which in some cases gives rise to secondary (miliary) tuberculosis of other organs. The lungs may be perfectly normal in all parts, and show only peripherally, just below or bordering the pleura, some indurations of gray color made up of recent tubercle tissue. These young tubercle infiltrations are in some cases seen to have penetrated into the substance of the lung, like in a pleuro- or dissecting-pneumonia, directly from the old tubercular masses of the adjacent pleural membrane.

I have also examined several cases of plastic adhesive pericarditis, and found the plastic vegetations in this lesion to contain tubercles; two of these had coincident pleuritic lesions.

Cases which came under my observation during the last eighteen months—*i. e.*, since the opening of the bacillary campaign—were, of course, carefully examined for bacilli, and the results may be summarized as follows: Bacilli were found in most of the lesions, if the tubercular disease of serous membranes was accompanied by cavities and cheesy masses in the lung, or by tubercular ulceration of the intestines, and if cheesy changes in general were prominent; but no bacilli could be discovered, even after repeated and careful search, in any of the lesions of four cases of primary peritoneal and pleuritic tuberculosis examined. In none of these latter four cases were there any conspicuous cheesy changes in any organ, and no cavities or marked hepatizations in the lung, and no intestinal ulcers, although in two there was slight pulmonary miliary tuberculosis. These cases will be recorded in detail in a future publication.

I have also seen several cases of primary tubercular pleurisy and pericarditis, and a few of primary tubercular peritonitis, in the pathological institutes of Virchow in Berlin, and of von Recklinghausen in Strassburg. I questioned these foremost men of pathology concerning the ætiology of these lesions. They, as well as Rindfleisch, of Würzburg, told me personally their opinion, stating their firm belief that these lesions often directly originated from simple chronic inflammatory changes, without the agency of any cheesy focus, or any specific agencies whatsoever.

Birch-Hirschfeld also states, in his classical pathological work (page 183), that "nearly every exudative pericarditis and pleurisy leads to a local tuberculosis, if it takes a chronic course."

How often primary tubercular lesions of serous membranes occur in non-scrofulous persons, and whether this is the only form of tuberculosis in this class of persons, is, of course, a matter of speculation, until thorough statistics and careful studies are made in this direction. Nevertheless, it is a demonstrated fact, as I will show further on, that primary tuberculosis can be produced in the peritonæum of animals, like the dog, which are proved not to have any scrofulous tendency. I have seen this myself, and seen O. C. Robinson in my laboratory succeed in this experiment, by the introduction of simple irritants into the peritoneal cavity. Koch also never succeeded, even with the bacillus, in producing tuberculosis in the dog, except when using the peritoneal cavity or the anterior chamber of the eye (which is also a serous sac) as a point for inoculation.

Here is room for hypothesis. I would prefer to believe that tuberculosis could occur only in scrofulous persons, as this would better agree with the *scrofulous anatomy*. It is, however, possible that a scrofulous anatomy of the tissues may be artificially established by the blocking up of the lymph-spaces of the serous membranes, by fibrine and molecular *débris*, suspended in the serum which is being reabsorbed. This would then be a mechanical process, and not one of infection. If an inflammation occur in serous membranes, resolution becomes difficult through the peculiarity of the exudate. This is fibrinous mainly, and forming extensive, usually permanent organized deposits, it impairs the function of serous surfaces quite materially; the reabsorption of new exudates is probably, sometimes, entirely impossible. Thus conditions may possibly be created in serous membranes, not unlike those of scrofulous tissues, and simple irritants, perhaps the fibrine, may induce in them a similar reaction.

IV.—QUESTION OF CONTAGIOUSNESS. CLINICAL ASPECTS.

The idea of the contagiousness of tuberculosis is not new, and like other unfounded views in medicine, it has oscillated, like all fashions will, from one extreme to another for many generations. At present it is entertained by a number of scientists and by a part of the profession. This view has called forth from time to time, a number of researches whose results were either pro or contra. I will refer to these subsequently.

Of late, it appears that the belief in the contagiousness of tuberculosis has won considerable ground, not so much on account of accurate observation, as on account of Koch's discovery of the bacillus tuberculosis.

Another element which seems to have had an influence in this direction, is the fact that certain experimenters, formerly believing, from their own experiments, that tuberculosis was non-contagious, were led. later on, to change their opinions on account of the results of subsequent experiments. These latter experiments will, however, be shown not to be conclusive.

Before discussing the merits of the bacillus question, I would like first to consider the question of contagiousness from clinical grounds; and should it be proven that tuberculosis is not contagious, then the necessity for a contagium surely falls to the ground.

According to the observations of the most prominent clinicians who have paid special attention to this matter, there is not a single authenticated case of tuberculosis as a result of contagium on record. Among scores of experienced men who deny thus the contagiousness of tuberculosis it is sufficient to mention the names of Virchow, V. Recklinghausen, Stricker, in Germany; Gull, Williams, Watson, Paget, Humphrey, Richardson, in England; Bennet, in France; and Hiram Corson and Traillgreen in our own midst—all men of close observation, with ripe experiences reaching over thirty to fifty years.

The statistics of the large Brompton Hospital for consumptives, for thirty-six years, with regard to the resident officials, compiled by Dr. F. Williams (quoted after the *Lancet*, 1883), shows that of four resident medical officers, one of whom had served twenty-five years, none had any lung disease; of six matrons, none were consumptive; of 150 resident clinical assistants, eight became consumptive and five died, but in only one was the disease developed during residence at the hospital. Since 1867, of 101 nurses, only one died from phthisis, and that after leaving the hospital. Before 1867, six died, three of these of phthisis, but only one became so whilst resident, and she had a consumptive sister. She died thirteen years after first joining the hospital, but was not there the whole time. Of thirty-two gallery maids since 1867, none developed phthisis whilst at the hospital. Of twenty house porters, five died, but none of consumption. Non-residents: Of nine secretaries, three were threatened with lung disease, but recovered. Of twenty-two dispensers, seven died, three of phthisis, one while at the hospital. Of four chaplains, three died, none of phthisis. Of twenty-nine physicians and assistant physicians, eight died, none of phthisis. At the Chest Hospital, Victoria Park, there have been five resident medical officers during about the last fifteen years; all are alive and well. Two matrons, neither consumptive. There were two clinical assistants appointed every three months; none known to have developed the disease at the hospital. One nurse out of fifty or sixty in the last few years became consumptive while at the hospital, and she died after a year's illness.

An ingenious plan to decide the question of the communicability of phthisis was instituted by the British Medical Association by establishing the Collective Investigating Committee. This committee sent out questions relating to this subject to all the members of the Society. Of 1,028 replies received, 673 negatived the idea of a contagium, while 261 replies favored it. According to these statistics, there is a manifest majority in favor of the non-contagiousness of phthisis; yet such a plan is unsatisfactory, as the answers may be of unequal value, as their worth must be estimated in proportion to the experience and authority of the sender.

Not without interest is the observation of Prof. Corradi, of Pavia, who noted that out of 133 families in which he had cases of consumptives, in only 25 of the families were there more than one member of the family ill of that affection.

There is no proof whatever that tuberculosis is conveyed from person to person by contagion. Seeming exceptions to this assertion can almost always be accounted for in some other way.

The assertion that the wife may contract the disease from the husband I have pointed out, in a former paper, to be untenable; and I have also indicated that a predisposition to scrofulosis may be acquired from the unwholesome mode of life led, of necessity, by such individuals. Besides, it is established statistically that nearly one third of all deaths occurring in middle life are due to phthisis. In view of the frequency with which this malady occurs, intermarriage between scrofulous individuals may be almost as common as between non-scrofulous persons.

The view taken that children become scrofulous by contagion from phthisical parents, may be met by the fact that instances have occurred where a number of young children of phthisical parents were early removed from their homes and distributed among healthy families, and yet all, sooner or later, became phthisical.

Healthy persons have even been fed on bovine tuberculous material (which is considered identical with human tuberculous material, and have thrived on it, as is proven by the interesting feeding experiments made upon man and recorded by Schottelius, (Virchow's Archives, No. 91, 1883). The circumstances which led to this experiment were as follows:

In Würzburg, the sale of meat affected by pearl-disease or bovine tuberculosis is permitted, but, as some opposition to its sale once arose, a community of country people agreed to use exclusively tuberculous meat, on account of its cheapness and in order to prove that it was harmless. From Oct., 1867, to Nov., 1868, 49 tuberculous beeves, with well-pronounced lesions, were consumed by the people while they were under the supervision of the district physicians. In many instances the meat was eaten raw in consequence of habit. Ever since then, those people have continued the use of tuberculous meat, and thus far no bad results have been noticed; in fact, the record says that the people referred to are unusually healthy.

NOTE.—The concluding chapter will be furnished at once. It refers only to the diagnostic value of the tubercle bacillus, to the deficiency of the experimental proofs for the specific action of the bacillus. and to experiments proving that tuberculosis may be induced by non-tuberculous substances and simple irritants, in support of the statements made in the body of this paper.

THE DISTRIBUTION OF THE POISON THROUGH THE BODY AFTER DEATH FROM ARSENIC.

BY V. C. VAUGHAN, PH.D., M.D., AND J. H. DAWSON, PH.C.

Some months ago we reported in this journal a series of experiments which showed the diffusion of arsenious acid through the body when suspended in water and injected into the mouth and rectum after death. We have to report some experiments on the distribution of the substance after fatal arsenical poisoning.

Has arsenic any predilection of tissue?

Scolosuboff,[1] in 1875, reported that he had found, in experimenting upon animals, the largest amounts of the poison in the nervous tissue. He poisoned the animals with the arsenite of sodium, and after death estimated the amount of poison in 100 grams each of muscle, liver, brain and marrow. Representing the amount he found in the 100 grams of muscle by 1, that found in the same amount of liver would be represented by 10.8, that in the brain by 36.5, and that in the marrow by 37.3. Scolosuboff supposed that the arsenic replaced phosphorus in the lecithin of nervous tissue. This work has been frequently referred to in trials for murder by arsenical poisoning.

Ludwig,[2] in 1879, from experiments upon animals, and from the examination of the bodies of suicides, came to conclusions quite different from those of Scolosuboff. In all of Ludwig's experiments, he found a greater proportion of arsenic in the liver than in any other part of the body. In cases of acute poisoning, he found the kidneys also rich in arsenic, while the bones and the brain contained only small quantities. However, he mentions no case where a fatal dose had been taken in which he did not find some arsenic in the brain.

In the case of a suicide by acute arsenical poisoning, the results of Ludwig's analyses were as follows:

The liver, whose weight was 1480 grams, furnished 0.1315 gram of ammonio-magnesic arseniate, while the brain, whose weight was 1481 grams, furnished only 0.0015 gram of the same compound of arsenic. From 144 grams of kidney he obtained 0.0195, and from 600 grams of muscle 0.002 gram of ammonio-magnesic arseniate. In the bones, only traces of the poison were detected.

It will be seen from these figures that while the weights were substantially the same, the former contained about 90 times as much arsenic as the latter. It will be noticed, however, that Scolosuboff used sodium arsenite, which is more soluble and diffusible than arsenious acid.

Johnson and Chittenden[3] report the analyses of different parts of the body of Mrs. Riddle, poisoned. They found in the liver, which weighed 590 grams, 0.04788 grams of arsenious oxide (As_2O_3), and in the brain, which weighed 477 grams, only an unweighable trace. From these analyses, which embraced sections of nearly every part of the body, they calculated the total amount of arsenious oxide in the body to be 5.2261 grains. This was supposed to be a case of chronic poisoning.

In the case of Mary Stannard, whose death was supposed to have taken place shortly after the administration of the poison, Johnson found 83.23 grains of arsenious oxide in the stomach, liver and other internal organs, "while the brain contained a hardly perceptible trace of arsenic.

Of course, the unknown elements in all cases of arsenical poisoning are many and important. The exact amount taken, the amount removed by vomiting, and the time of administration are often unknown.

Johnson and Chittenden also made one experiment upon a large coach dog, which was poisoned by the administration of 6.5 grams of arsenious oxide in doses of from 0.1 to 2.5 grams per day for eight days. Twenty-four hours after the administration of the last dose, the animal was killed, and the different organs submitted to analysis. 100 grams of liver furnished 0.0010 gram of metallic arsenic, while the entire brain gave only a faint mirror.

Since these questions are of great importance in medico-legal investigations, and as the evidence furnished by the experimenters mentioned above is conflicting in some points, we determined to seek, experimentally, answers to the following questions:

(1.) In what proportion is the poison distributed to the various tissues in chronic poisoning by arsenious oxide?

(2.) What is the distribution in acute poisoning by the same poison?

(3.) What is the distribution in acute poisoning by the more soluble sodium arsenite?

Of course, these questions can be answered only in a general way. If the conditions of the experiment are varied, we should expect the results to differ in a greater or less extent.

The first experiment, representing a case of chronic arsenical poisoning was conducted on a small dog as follows: 685 grams of solid white arsenious oxide were given to the dog with meat during a period of sixteen days, in doses increasing from 0.335 to 1 gram. Seventy-two hours after the last dose was administered, the dog was killed and the following parts removed, and a quantitative estimation of the arsenic which they contained, made with the following results:

	Weight taken grams.	As_2O_3 Found.	Percentage of As_2O_3
Spleen	18	.00062	.00344
Kidneys	65	.00065	.00100
Liver	260	.01040	.00400
Lungs	95	.00040	.00042
Stomach and contents	152	.02530	.01664
Large intestine	42	.01520	.03619
Small intestine	70	.00030	.00042
Muscles from thigh	116	.00031	.00026
Muscles from abdomen	95	.00020	.00021
Heart	175	.00034	.00019
Blood	60	a very faint mirror

The second experiment represents cases of acute poisoning with arsenious oxide, and was conducted as follows. Two rabbits, one large, and the other small, were given arsenious oxide. To the larger, two grams were given, and to the smaller one gram was given. They died in about ten hours, and the following parts were removed and a quantitative estimation of the arsenic which they contained was made:

Large rabbit weighed 1520 grams.

	Weight taken grams.	As_2O_3 found	Percentage of As_2O_3

In these experiments the organic matter was destroyed by chemically pure hydrochloric acid and potassium chlorate. The arsenic was obtained by the Marsh test, and weighed in the metallic state.

It will be seen that in the case of chronic poisoning, for equal weights, the brain contained about one-sixth as much as the liver. In the cases of acute poisoning by the oxide, the amount in the brain was an unweighable quantity. In the case of poisoning with the arsenite, the amount in the brain is larger than when the less soluble oxide was given.

UNIVERSITY OF MICHIGAN, January, 1884.

GENERAL PARALYSIS FOLLOWING DIPHTHERIA. A CASE.

BY CHARLES WESLEY ROOK, M.D., QUINCY, ILL.

In the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, vol. 1, page 649, two cases are noted of the rare sequel "General Paralysis After Diphtheria."

Having within my care, at the receipt of the above mentioned article, a little patient to whom had occurred this rare and distressing sequel, now that the case is terminated, I deem it a professional duty to give a report of the same.

For a brief and concise history of this pathological condition, its association, in the relation of cause and effect, with diphtheria, and for theories concerning its cause or causes, the reader is kindly referred to Trousseau's Clinical Medicine, vol. 1, p. 382, ed. 1882.

November 28, 1883, I was recalled to Stella P., æt. one year and six months, whom I had recently attended during an attack of diphtheria, together with four other members of the family, including the mother, who were also sick with diphtheria. By the close of the second week of treatment all the members of the family were convalescent, except one little girl, æt. three years, who died of diphtheritic croup at the close of one week of sickness.

On November 4, the subject of this report, though much emaciated, her pharynx being perfectly free of any diphtheritic membrane, was discharged. During the interval, elapsing between November 4 and November 28, I saw her twice and was much gratified at the rapid advances that she seemed making toward a complete recovery. When called, Wednesday, No-

vember 28, her mother said that the Saturday previous Stella did much running and playing in the yard; while playing, she was frequently observed to lie down on her back, cry for a few moments, and strike with her feet as if they were giving her pain, then getting up would go on playing as usual. On Sunday and Monday her gait became very unsteady, and on Tuesday she was unable to walk. Wednesday, when placed upon her feet, could stand for only a moment, then would sink to the floor. By inclining her body forward, while supporting her upon her feet, she would make a feeble attempt to walk, but was unable to raise her feet and bring them forward. Examination proved the muscular tissue of the legs to be soft and flabby, the skin of a pale blue color, and the feet and legs, though covered with two pairs of stockings and kept close to a stove, were extremely cold. At the same visit it was noted that the muscular and coördinating powers of the hands and arms were apparently unaffected. The appetite was poor, but the child seemed very thirsty, and at nearly every attempt to quench her thirst, she would strangle, an attack of coughing would be induced, and the greater portion of the liquid would be returned, through the nostrils, to the cup. Her pharynx was completely free of any diphtheritic deposit. The actions of the bowels and bladder were regular. Albuminuria is said to be present quite generally, but I was unable to get a specimen of the urine for examination. The respiration and pulse were somewhat accelerated.

December 1, was hastily summoned, and learned that Stella had had a convulsion, following an attack of coughing, occurring soon after eating dinner. This, I think, was due to some article of food getting into the air-passages. She was very fretful and restless, especially of nights, not even permitting a light blanket to cover her limbs. December 4, I called. Found Stella sleeping. Her left axilla and ilium were approximated several inches nearer than normal, because of a tonic contraction of the muscles of the left side of her body. The muscular power and voluntary movements of the hands and arms were becoming impaired.

Though seen daily, no marked change other than the gradual loss of power in her hands and arms was noted until December 10, when I called and found the surface of her body hot and dry; pulse 160 per minute; the respiration rapid, feeble and shallow; the pupils widely dilated; was unable to raise either hand from off her chest, and in addition to the other symptoms noted, was a tonic contraction of the cervical and dorsal muscles, so that the weight of her body was supported by the occiput and sacrum. During the continuance of this cervical and dorsal muscular rigidity, which was four days, the limbs were completely relaxed, so that we could extend or flex them into any desired position.

Also during this interval of four days there were visual disorders. The pupils remained dilated so that she did not seem to see or recognize her friends. Convergent strabismus was also present, apparently equally affecting each eye, for upon attracting her attention by the exhibition of some plaything, she would fix the object first with one, then with the other eye. December 13, she was attacked with purulent ophthalmia; the discharge, which was profuse, thick and yellowish, continued for three days, then gradually disappeared At this time she had a very troublesome cough, the attacks of which seemed to be precipitated by her attempts to swallow liquids. December 17 she was attacked with a slight diarrhœa, which was probably reflex in nature, as she was at this period cutting her superior and inferior canine teeth. The paralytic symptoms were slowly disappearing. December 21, was still improving; drinks without becoming so frequently strangled; her cough less troublesome, and she sleeps well of nights. December 28 she made her first attempt to crawl and walk since she became paralyzed. January 1, 1884, continued her efforts at walking, but because of her weak and emaciated condition the attempts were but feebly executed. Her appetite was increasing, and the excretory functions were normal. January 9, convalescence being established, my little patient was discharged.

In order to complete this report, I called January 28, and found Stella so completely recovered as to leave not a trace of her recent serious illness.

The plan of treatment adopted was the following: For the indications present when first called this combination was ordered:

℞ Tr nucis vomicæ. sp. chloroformi, āā. ℥ss; acidi nitro-muriatici dil., ℥j; inf. gentianae, q. s. ℥iij. M. S.: A teaspoonful three times a day.

This prescription was continued until December 9. December 3, being very fretful and restless, she was quieted with the $^1/_{32}$ of a grain of morphia sulphatis. This amount was occasionally exhibited to quiet her restlessness throughout the course of her illness. December 8 and 9, two applications were made, of four minutes each in duration, of a mild induced electrical current. December 10, the paralytic symptoms being greatly augmented, and because of the inability to swallow, the nux-vomica preparation and the application of electricity were discontinued, and in their stead, rectal injections of equal parts of spiritus frumenti and milk were ordered. December 13, the $^1/_{50}$ of a grain of nux-vomica was ordered twice daily. For the ophthalmia, was directed thorough and frequent cleansing with cold water. December 14, to relieve the cough the following was given: ℞ tr. chloroformi, ℥j; acidi hydrobromici, ℥ij; syr. scillæ, ℥iij; syr. simp., q. s. ℥iv. M. S.: One-half teaspoonful every six hours. December 18, the nux-vomica was increased to the $^1/_{50}$ of a grain three times a day. December 19, as a general tonic, the following was administered: ℞ tr. ferri chloridi., ℥ss; extractum malti, q. s., ℥ij. M. S.: One teaspoonful three times a day. The three latter prescriptions were continued until convalescence was attained.

AN AGED PHYSICIAN.—It is reported that Dr. Jakinoriez, of Jarvszinka, in the Government of Kiew, Russia, has just died at the age of 107, and that he was able, until nearly the close of his life, to superintend the working of an extensive practice.

MEDICAL PROGRESS.

MATERIA MEDICA AND THERAPEUTICS.

Anæsthesia by a Mixture of Morphia, Atropia and Chloroform.—Dr. C. Aubert communicates to the *Société de Biologie* (*Comptes Rendus*) the results which he has obtained in his surgical practice by preceding the use of chloroform by the injection of

Morphia chlorhydrate.....10 centigr.
Atropia sulph..... 5 milligr.
Aqua dist.....10 grams.

He uses 1½ grammes of this solution 20 or 30 minutes before beginning the inhalations. In children he uses not more than 1 gramme. He has used this method in more than 60 cases, and, as far as the atropia is concerned, has never seen the slightest disagreeable symptom, no dilatation of the pupil, perhaps a little dryness of the throat, and considers that these agents furnish great security against the danger of cardiac syncope following chloroform inhalations. The advantages claimed, are: First, the security. Second, the greater rapidity with which anæsthesia is produced. Third, the absolute quiet of the patient. Fourth, the facility of awakening. Fifth, the absence of subsequent discomfort and vomiting.

As to security, he refers to one case where in an aged subject there existed adhesions of the pleuræ, extensive pulmonary emphysema, marked mitral insufficiency, interstitial nephritis and purulent cystitis, as proven by the autopsy three weeks later; this method was followed. and there was no perceptible influence upon the pulse. It is true that there was cyanosis which required the use of artificial respiration for two minutes. He accepts, therefore, the views of MM. Morat and Dastre that atropia diminishes the excitability of the pneumogastric.

As to the rapidity of its action; out of 40 patients 4 came under its influence in 1 minute, 5 in 1½ minutes, 12 in 2 minutes, 6 in 2½ minutes, 4 in 3 minutes, 2 in 4 minutes, 4 in 5 minutes, 1 in 6 minutes, 1 in 7 minutes, and 1 in 10 minutes—giving a mean of 3 minutes.

Narcosis by Chloroform, by Ether, and by Nitrous Oxide.—Neudörfer (in the *Deutsche Zeitschrift für Chir.*) investigates the above, and comes to some highly important conclusions, which may be thus summarized. 1. Air cannot hold more than 20 per cent. of its bulk of chloroform-vapour at the ordinary temperature and pressure. 2. Chloroform acts as a poison upon the red blood corpuscles, but only slowly, even upon corpuscles at rest, whilst those circulating through the lungs are not long enough under its influence to be destroyed. 3. It has been found by Bernard, Gréhant, Hoppe-Lezler, and Hermann, that hæmoglobin has a greater affinity for carbon monoxide than for oxygen, and for nitrous oxide than for carbon monoxide. In other words, in presence of an excess of carbonic oxide the blood cannot absorb oxygen, and in presence of an excess of nitrous oxide the blood cannot take up either carbonic oxide or oxygen. Hoppe-Lezler and Gréhant think that if the weakest of these gases (in their affinity for hæmoglobin) be previously present in excess, it hinders absorption of the gases of stronger affinity. As to this, the authors think that it does not hinder this absorption, but that the latter are thus rendered innocuous, and also that the affinity of hæmoglobin for oxygen is not constant, but varies within certain limits. 4. If to an individual, whose hæmoglobin has a relatively weak affinity for oxygen, we give to narcosis a mixture of 20 volumes of chloroform-vapour to every 80 volumes of air, he breathes a mixture holding 16 per cent. of oxygen, instead of the usual 20 per cent. in the air, and it may happen that he may take up little or no oxygen, and the chloroform may exert its fatal effect. This is a simple and sustained method of explaining death by chloroform. 5. Now, arguing by analogy, since the very poisonous carbonic oxide can be rendered innocuous by the previous presence of other gases in excess, it is to be presumed that in a mixture of chloroform-vapour and oxygen, the chloroform could not exert its evil effects upon the blood corpuscles. 6. There would be no danger of oxygen poisoning, for the quantity given would be within the limits of the variations of oxygen taken up in nasal respiration. 7. The bad after-effects of chloroform would be done away with. 8. Twenty per cent. of chloroform-vapour would be unnecessary, since three to five per cent. are quite enough. 9. As to ether, it can be mixed up with oxygen up to forty-three per cent., but it cannot compete with chloroform, because it possesses no constant chemical constitution, and its behaviour to human tissues is more prejudicial than that of chloroform. 10. The mixture of nitrous oxide and oxygen acts equally as well as the chloroform and oxygen mixture. 11. Oxygen is easily administered by Simonson's apparatus, 12. Narcosis thus caused is absolutely devoid of danger.

MEDICINE.

Morphia Habitues.—Dr. Benjamin Ward Richardson (*Lancet*) read a paper on this subject before the Medical Society of London on December 10. His remarks were directed especially to the habitual hypodermic injection of morphia, the dose varying from less than a grain to fifteen grains per diem. He gave the summary of symptoms in a case of daily injection of three grains and a half for a period of two years as being as follows: (*a*) Torpidity in the action of the liver; (*b*) abscess forming at or near the site of puncture; (*c*) tendency to local induration, and (*d*) a free excretion from the bronchial surface; (*e*) difficulty, occasionally, in swallowing morsels of small substances, as if the object were arrested in its passage owing to its becoming enveloped in a layer of tenacious mucus; (*f*) a tendency at times to violent perspiration, more often present when the morphia has been almost entirely excreted, or when the system has been much debilitated; (*g*) various perversions of sensations; (*h*) occasional difficulty in articulation, like that resulting from alcoholic excess; (*i*) impotency; (*j*) difficulty of breaking off the habit owing to craving for the narcotic, and symptoms of

debility when it was left off; (*k*) mental exaltation and depression, with tendency to exaggerate dangers; (*l*) excessive excitability of the imagination when reading, *e. g.*, works of fiction; (*m*) lessened sensitiveness and receptivity with inclination to apathy, varied, it may be, with brief periods of mental exaltation.

The more serious subjective and objective symptoms induced by deeper indulgence in this habit were defined as: Increased appetite for the morphia; loss of will power; confirmed apathy from the ordinary toxic effects of opium; failure of all the mental faculties, together with general failure of voluntary and involuntary muscular power. Diminished vitality, with bending of the body and the signs of premature old age.

PULSATING LIVER.—Dr. Walter G. Smith (*Dublin Journal of Medical Science*) reports a case of this character in a soldier 35 years of age, who suffered from lung trouble and some anasarca of the legs not higher than the thighs; was a free drinker. The skin of the face and hands was dusky in color, and there was visible pulsation in the jugular veins, which were of immense size. Albuminuria; liver dullness 2½ inches below the ribs on the right side, and to within 2 inches of the umbilicus in the middle line; margin readily felt. A distinct pulsation of the liver was visible in the epigastrium, extending over the right and left lobe. Subsequently the liver increased in size, and the lungs became engorged, while at times a triple cantering sound was heard over the apex of the heart, and the systolic murmur became more distinct. The area of cardiac dullness appeared to be enlarged, and the apex beat was visible in the sixth intercostal space. In support of his proposition that the phenomenon was principally the result of a retrograde venous wave from the right ventricle, he mentions:

1. The expansile sensation communicated to the fingers when placed upon the liver.

2. The duration of the pulsation. It continued after the ventricles ceased to act.

3. As the condition of the patient improved under treatment, the hepatic pulsation became less and less. If the hepatic pulsation were due altogether to direct shock, the contrary would be the case, for steadier and more forcible action of the heart would materially increase the pulsation.

He asks the following questions: Ought pulsation of the liver to be regarded as evidence of regurgitation through the tricuspid orifice? How does the regurgitation of blood into the hepatic veins in sufficient force to visibly agitate the liver, sometimes occur? And why is it not more frequently observed in old-standing cases of mitral disease?

Respiration aids the venæ portæ in accelerating the blood-current through the liver, and this is favored anatomically by:

1. The trunks of the hepatic veins, which almost pierce the tendon of the diaphragm, to join the inferior vena cava.

2. The hepatic veins cannot collapse when subjected to atmospheric pressure (because of their parenchymatous attachment).

3. During the inspiratory descent of the diaphragm the vena cava is straightened, and the course of the hepatic veins made more direct. Conversely, during expiration the venous trunks between the liver and the heart are shortened, and the opening in the diaphragm is diminished, counteracting the tendency to regurgitation. But if, under any circumstances, regurgitation of blood from the right heart takes place, here is a condition especially favorable for communicating to the liver as a whole any pulsation caused by reflux into the inferior vena cava and large hepatic veins. The degree to which the liver can yield is regulated by the elasticity of the enveloping capsule of the liver and of its peritoneal covering. Hence, inflammatory thickening of the capsule is an obstacle to pulsation.

SURGERY.

CATHETER FEVER.—Sir Andrew Clark (*Lancet*) on a recent occasion brought this subject before the Clinical Society of London, but as the constitution of that society did not permit such abstract questions to be discussed, on December 17 he addressed the Medical Society of London, giving his views more in detail, and recounting the history of medical observations and records of catheter fever from 1800 down to the present day. He offers the following propositions:

First, that about middle life in men perfectly healthy, or with no discoverable evidence of disease, except perhaps, and even that not always, a low density of urine, the commencement of the habitual use of the catheter is sometimes followed by fever of the remittent type, which often ends in death, and that for the fatal issue in such cases no adequate structural explanation can be found.

Secondly, that it is important that such a fever, arising in the midst of apparent health from such a seemingly small cause, and leading so often (as it certainly does) to a fatal issue, should be well and widely known, lest death should take the friends of the patient by surprise, and arrangements necessary to the welfare of a family should be left unmade.

Thirdly, that although it is well known that in persons affected with renal disease, or with chronic gout, or with grave disorders of the general health, the commencement of habitual catheterism is attended with peril to life from secondary fever, the fact that this fever may arise in what seems to be good health, and without the mediation of any visible structural lesion, issue in death, is not well known.

Fourthly, that this fever is neither distinctly uræmic nor distinctly pyæmic; that although having some of the characters of each, it has all the necessary characters of neither; that probably it begins in the nervous system; that probably the disturbance of the nervous system reacts in the first instance upon the general metabolism of the body, and in the second instance upon the secretory organs, beginning with the kidney; that the effect upon the kidney may consist either in structural alterations of the kidney, or

in alteration of the constitution of the blood, that dynamic condition of its constituents in the renal vessels essential to the elaborative action of the secretory cells thereof; and lastly, that the concurrence of these conditions may be, and often is, enforced by septic reabsorption into the blood.

Fifthly, that a more complete knowledge of this variety of fever, and of the conditions of its origin, maintenance and increase may, at least we may hope, lead to a material diminution of its mortality; and that even now, by treating in a serious manner entrance upon cather life by great temperance in the use of foods and stimulants, by rest, warmth, and by other general means, such mortality may be possibly considerably diminished.

Two questions of a practical kind arise out of this study of the history of catheter fever. The first is: As there is no account of the fever following in cases where narcotics or anæsthetics have been used, may it not be that the fever is capable of being cut short by the administration, on entering upon habitual catheterism, of narcotic or anæsthetic remedies? The second is: Assuming the presence of the fever, and seeing that quinine has signally failed in controlling it, what are the drugs to be employed on such occasions? And what is the sort of hygienic management to be followed, especially in respect of food and alcohol, which are so variously used on such occasions, in order that the fever may be brought, if that be possible, to a successful ending?

Sugar as an Antiseptic Dressing.—Dr. Fischer states that Prof. Lücke, of Strasburg (*Centralblatt f. Chir.*), has since May last been making trials of sugar as a pulveriform antiseptic. He has used it mixed with equal parts of naphthaline or with a fifth part of iodoform, enclosing it in gauze bags, which are fixed over the wound after the application of sutures. When the skin is defective, the sugar is strewn over the wounded surface. The wound has been disinfected during the operation by means of a 1 per cent. sublimate solution. The dressing may remain on the part from a week to a fortnight, until the sugar becomes dissolved, the secretions from the wound diffusing themselves equally throughout the sugar. If, however, the sugar is applied too thickly (*i. e.*, more than half a centimeter), it forms into lumps. The wounds thrive under the sugar, the dressing emitting no bad smell nor exhibiting bacteria. The granulations are well developed, having no inclination to bleed, and cicatrization proceeds rapidly. In wounds united by suture, primary union has always been obtained. The experience thus far gained justifies the recommendation of further trials of a remedy so easy to obtain.—*Med. Times and Gazette.*

The Use of Hodge's Pessary in Fractures of the Lower Jaw.—Dr. W. J. Naismith (*Lancet*) describes a fracture of the lower jaw at the symphysis, with a transverse wound two inches in length over the mental protuberance. The fragments of the jaw were freely movable, and it was desirable to apply an apparatus which would fix the bone in place immovably, and at the same time allow the wound to be dressed. Accordingly, a Hodge's pessary was brought into use, by bending it so as to allow the chin to protrude through its ellipse. One bar was moulded so as to support the fracture anteriorly, the other steadied it from below, while the rounded ends afforded admirable lateral pressure on each side, at a point in front of the angles of the jaw. To the rounded ends of the pessary tapes were sewn, two on each side, over the padding, and secured over the head, or to a fillet, and around the neck by small buckles. For fractures of the inferior maxilla at or near the symphysis, with or without wound, the Hodge's pessary seems well adapted. It can be bent to fit any size of jaw, and in the qualities of comfort, lightness and coolness compares very favorably with the solid, cumbrous appliances included under the head of moulds.

TOXICOLOGY AND MEDICAL JURISPRUDENCE.

A Rapidly Fatal Case of Arsenical Poisoning. Dr. David W. Finlay gives a case in the *Lancet* of a man fifty-one years of age, in moderate health, who swallowed, by careful computation, twenty-six grains of arsenious acid; was seen and prescribed for within a half hour; had not vomited, but the stomach pump was used freely, with no benefit, for he died in just one hour after swallowing the fatal dose. His symptoms were generally those of collapse; nothing at the post-mortem indicated any particular poison, until the contents of the stomach were analyzed.

A recent non-medical French writer (A. Cels. Bibliothicaire de l'Université de Bruxelles) in reviewing the *Manuel du Bibliothecaire*, of M. J. Cousin, takes occasion to emphasize the fact that the form of the Index catalogue of the Library of the Surgeon-General's Office, U. S. A., will be universally adopted by librarians as fast as it becomes known to them. He reviews this mode of cataloguing, giving to it the name of "*Le systéme Billings*;" and concludes by addressing a request to the *savant* Dr. Billings, that he publish a new manual, which will, beyond doubt, replace all of those which have been published up to the present time.

The Wooden Leg in the Gallic-Roman Period.—Our friends the archæologists are exciting themselves in France over the discovery on pieces of ancient pottery two delineations of figures wearing each a wooden leg. M. Emile Riviere, in the *Gazette des Hopitaux*, has an interesting article on the subject which is well illustrated; one of the figures is that of a male playing on the harp, or lyre; this is supposed to be Apollo, and the writer quotes M. Maximin Legrand as follows: "Have you ever heard, my dear readers, that the grandfather of medicine had his leg broken? As for me, I am absolutely ignorant of the fact. I have heard of the death of Adonis and of the mutilation of Atys, as names which, among the ancients, personified the sun, and of whom the death or debility, always followed by a resurrection or cure, symbolized the conditions of universal life, or simply the order of the seasons. But a wooden leg! of what can it be the symbol?"

THE

Journal of American Medical Association.

PUBLISHED WEEKLY.

THE EDITOR of this JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information, should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE..... $5,00.
SINGLE COPIES..... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 65 RANDOLPH STREET,
CHICAGO, ILLINOIS.

SATURDAY, FEBRUARY 9, 1884.

WAS the New York State Medical Society "extruded from membership" in the American Medical Association, or did she take herself out by *her own act?*

In another column of this number of the JOURNAL will be found a letter from New York signed "Vindex," and written by one of the most intelligent and influential of the members of the New York State Medical Society who were active leaders in the movement that resulted in the adoption by that society of a new code of ethics as a substitute for the National Code in 1882. We invite particular attention to this letter, as it is a fair example, both in its temper and its carelessness of statements concerning facts and events, of what has been written and said by the party the writer represents during the last two years. The leading object of "Vindex" in writing his letter appears to be the correction of the impression conveyed in the leading editorial in this journal of January 26 ult., that the New York State Society had voluntarily cut herself off, or severed her connection with the American Medical Association by her own deliberate act. On this point he uses the following language: "It (the State Society) did not. It was *extruded* from membership in that body (the American Medical Association) by the action of its Judicial Council at St. Paul in 1882, which action the Association, as a body, assumed by adopting the report of said Council."

In further proof of such "extrusion," he says the State Society sent delegates to the meeting of the National Association at St. Paul; that he, as one of the delegates, presented his credentials to the Registration Committee at an early hour on Tuesday morning, June 6, and was told, in a not very polite way, that the Judicial Council had determined, at a meeting held on the previous day, which would have been on Monday, June 5, "to throw out the credentials of the delegates from the Medical Society of the State of New York" If our friend "Vindex" had ever taken the trouble to examine with reasonable care the constitution and by-laws of the American Medical Association, or even read the official record of the proceedings of the Association at St. Paul, he would not have committed the mistake of representing the Association as *adopting* the report of the Judicial Council, when the decision of that tribunal is final without further action of the Association. Nor would he have gone so far astray in his memory as to represent the registration officer as saying that the Judicial Council had decided on the previous day to "throw out credentials," instead of what the officer doubtless did say, namely, that protests had been lodged with the Registration Committee, and that under the by-laws the credentials and protests must be reported to the Association and referred to the Judicial Council before the registration could be effected.

Neither would he have represented the Judicial Council as acting upon a matter on Monday, which could by no possibility have come before it until after the papers had been presented, by the chairman of the Registration Committee, to the Association on Tuesday morning, and by that body referred to the Judicial Council. If Vindex, or any of our readers, will turn to the volume of Transactions of the Association for 1882, pages 59 and 60, he will find that the first meeting of the Judicial Council was convened at ten o'clock on Tuesday morning, June 6, at which officers were elected, and action taken on a case concerning the Nebraska State Medical Society which had been referred to the Council the year previous, and on nothing else. The next meeting was at five o'clock P. M. of the same day. At that meeting, the protests and papers in reference to the right of the Medical Society of the State of New York to be represented by delegates in the Association, were received from the Permanent Secretary, the same having been referred by the Association during its general session in the morning. They were examined, together with a certified copy of the new code of ethics adopted by that State Society at its annual meeting in February preceding. A final decision was deferred until the third meeting of the Council, held at 8:30 A. M. on Wednesday. At that meeting, after further consider-

ation, the Council arrived at the following decision, which was reported to the Association near the close of its general session on the same day:

"Having carefully considered the Code of Ethics adopted by the New York State Medical Society at its annual meeting in February, 1882 (as furnished by the Secretary of said Society), the Judicial Council finds in said revised Code provisions essentially differing from, and in conflict with, the Code of Ethics of the Association, and therefore, in accordance with the provisions of the ninth By-law of this Association, decide unanimously that said New York Medical Society is not entitled to representation by delegates in the American Medical Association." See Transactions, Vol. 33, p. 33.

The ninth by-law referred to in the above report is in the following words:

"No State or local medical society, or other organized institution, shall be entitled to representation in this Association that has not adopted its Code of Ethics; or that has intentionally violated or disregarded any article or clause of the same." See Transactions, Vol. 33, p. 629.

With this plain and explicit rule, as a condition of representation in the Association, published in every annual volume of Transactions for more than twenty years; and the equally direct statement of "Vindex" in his letter, that the Medical Society of the State of New York had actually adopted in February, 1882, a new code as a substitute for that of the American Medical Association, can any intelligent reader entertain a doubt as to whether such action of the State Society necessarily deprived her of all right to further representation in the national organization. The decision of the Judicial Council simply declared the fact ascertained, that the State Society of New York had "violated or disregarded" the Code of Ethics of the Association and in *consequence* of such action was not longer entitled to representation in that body. That the action of the State Society in repudiating the Code of Ethics of the Association directly in violation of the by-law quoted, caused the EXTRUSION, is too plain for argument.

Instead of correcting anything contained in our leader of January 26, the letter of "Vindex" contains a full acknowledgment of the fact, that the work of revising and altering the National Code of Ethics was entered upon by the State Society of New York in 1881, and completed at the annual meeting in February, 1882, without the slightest regard to the fact that said National Code had been compiled and adopted by a national organization composed of her own delegates, in association with delegates from the State societies of all the other States, and who had consequently an equal interest in it with herself.

Though a member of the committee that did the *revising*, he says he "did not hear any discussion in regard to the American Medical Association." The truth is that "Vindex" and his co-laborers in the work of ethical revising, had given very little attention to the national organization for years, and appear to have had very little knowledge of its constitution or conditions of membership.

Under the specious pretense of reforming and liberalizing the ethical rules governing consultations, they proceeded with their work without fairly realizing the undesirable position in which they were placing their State Society in its relations to the Association and all the societies of other States, until they appeared at St. Paul as delegates from a society whose right to representation had been forfeited, in part at least, through their own influence.

Their position is an awkward one, and we can appreciate the underlying chagrin that prompts their irritability when the plain facts are brought to their notice, but instead of floundering from one false position to another, until new State and local societies are formed all over their State, and their representatives admitted to the national organization, and to fellowship with the societies of other States, why not manfully acknowledge the primary error, undo the objectionable work, resume the former relations of harmony with the national and State organizations of the Union, and then propose whatever changes may be desired, and let them be considered and acted upon by the representatives of the whole profession, where such consideration rightfully belongs.

What the letter of "Vindex" says about the framing and promulgating an "iron-clad oath," is fully and correctly answered in THE JOURNAL for January 19, 1884, and is too absurd to require further notice. The resolution which he proposes for the Association to adopt, as an act of reconciliation, is more curious than important. The credentials of a delegate consist of a certificate by the proper officer of some medical organization that the bearer A. B. has been duly elected or appointed a delegate to the American Medical Association. To be "duly accredited," it must be from a society or organization entitled to representation under the constitution and by-laws of the Association. What the laws regulating the practice of medicine have to do with such certificate it is difficult to conceive.

DR. ELISHA HARRIS, of New York, died a few days since in the city of Albany. He had been many

years connected with the departments of health and public charities, and was one of the most eminent sanitarians in this country. A more extended sketch of the life and labors of the deceased will be found under the head of Necrology in the next number of THE JOURNAL.

MISSING NUMBERS OF THE JOURNAL.—We have calls for a few copies of Nos. *two* and *six* of THE JOURNAL that we are not able to supply at present. We again request anyone who may have duplicate copies of these numbers to re-mail them to this office; and if any one has received and paid for these numbers who do not care to keep them, we will pay four times the subscription price for their return in good order to us.

WINTER CHOLERA AND HOG CHOLERA.—Dr. F. Dedolph writes from St. Paul, Minn., suggesting that the so-called winter cholera, which has been noticed in various places during the last few years, is caused by the use of lard and oleomargarine prepared from hogs affected with the disease known as hog cholera. This letter contains a printed slip showing that he made the same suggestion three years since. But as he gives no facts or investigations bearing upon the subject, we give his suggestion here instead of his letter.

SOCIETY PROCEEDINGS.

KALAMAZOO ACADEMY OF MEDICINE.

The Kalamazoo District Medical and Surgical Association has recently been incorporated in accordance with the laws of the State of Michigan, under the style "Kalamazoo Academy of Medicine." The meetings of the Academy are held in the city of Kalamazoo the last Tuesday of each alternate month of the year, beginning with January. It invites to its membership all regular practitioners of medicine or surgery in Southwestern Michigan. The Secretary would be glad to receive the names of any who desire to unite with the Academy. The meeting held January 29 was a most profitable and pleasant one for all. The officers elected for the year 1884 were: President, Josiah Andrews, of Paw-Paw; First Vice-President, Foster Pratt, of Kalamazoo; Second Vice-President, O. F. Seeley, of Clina; Secretary and Librarian, H. B. Hemenway, of Kalamazoo; Treasurer, O. B. Ranney, of Kalamazoo. Board of Censors (term expires in three years): H. O. Hitchcock and W. L. Worcester, of Kalamazoo; (term expires in two years) Foster Pratt and J. W. Fiske, of Kalamazoo; (term expires in one year) L. D. Knowles, of Three Rivers, and O. F. Burroughs, of Galesburg.

THE SUFFOLK DISTRICT MEDICAL SOCIETY.

SECTION FOR CLINICAL MEDICINE, PATHOLOGY, AND HYGIENE.

ALBERT N. BLODGETT, M.D., SECRETARY.

December 12, 1883.—The meeting was called to order at 8 o'clock by Dr. R. T. Edes, chairman.

The first paper of the evening was read by Dr. E. O. Otis, entitled

THE USE OF TOBACCO AMONG BOYS.

Dr. H. I. Bowditch, in opening the discussion, said that it is high time that some measures were adopted to stop, or at least to restrain, the use of tobacco. For thirty years he has continually found a certain number of patients who have presented the symptoms of grave functional disturbance of the heart, for which no cause could be found except tobacco. There is no organic cardiac lesion, but it is a nervous weakness. This condition was very commonly observed during the late war. Nearly all the soldiers smoked, and many gradually acquired what was appropriately named the "tobacco heart." The reason why this condition prevailed so extensively at the time mentioned, is no doubt found in the fact that tobacco enables men to endure hunger, cold, hardship, and privation better than they could without its aid. The active, exposed muscular life of the army enabled the soldiers to withstand the injurious effects of this substance better than would be the case in a sedentary occupation, or where one lives as a recluse. A moderate use of tobacco may unquestionably be continued for a long time, and probably indefinitely, without harm. There are few people in adult life who would derive any injury from three cigars daily; but the danger comes from the fact that the number is increased to ten or fifteen, and sometimes even to twenty-five in a day. Nearly all boys now smoke cigarettes to an inordinate extent, and it is painful to look forward to their future condition.

In habitués of tobacco we frequently find errors of digestion, sometimes of most refractory character, though many persons commence to smoke from the supposition that the digestion is benefited by the use of tobacco. There is no question upon the fact that mental disease may be induced by the poisonous action of nicotine; and many smokers who are not insane have been rendered exceedingly nervous and irritable by the prolonged use of tobacco, and immediately give unmistakable evidences of absolute derangement if the customary indulgence is for any reason withdrawn. The duty of physicians would seem to be to endeavor to restrain the use of tobacco to an amount which shall not be injurious; for no attempt to stop its employment would probably be successful. Above all we should seek to restrict its use among students and youths generally. Punishment, such as expulsion or suspension from school, should be attached to disobedience, and all proper means shuld be employed to protect our scholars from its influence. The medical profession should take a decided position upon this important subject. Not only tobacco, but all stimulants should be restrained to a

limit within which they can do no harm. Tea and coffee should doubtless be included in the category of agents capable of harm. When in Paris, in 1854, Dr. Bowditch found the favorite *café noir* to be such a nervous stimulant that he was able to work all night without the least feeling of fatigue. On returning to America, however, he found himself unable to follow his professional duties with his accustomed energy, but felt a great sense of lassitude and depression. He now reduced the use of coffee to once a day; but after three or four months he found himself subject to attacks of palpitation and cardiac pain, which recurred with considerable regularity. Dr. Jackson examined the heart, but could detect no organic lesion, and advised abstinence from coffee, upon which all symptoms at once disappeared. After a time the use of coffee was again commenced; whereupon the previous disturbances of the heart were soon reproduced. The harmful agent was again abandoned for 15 years, when being once more in Europe, coffee was resumed in small quantity, but within a short time the old symptoms all recurred in a more intense form. Since that time no coffee has been taken, and no further trouble has been experienced. The human system seems never to fully recover after once being thoroughly saturated with any of these subsances. The same is true of alcohol.

Dr. George B. Shattuck thought it a too common habit, in speaking of these matters, to make the *abuse* and the *use* of a substance synonymous. It is also common to form general conclusions in regard to the effects of stimulants and narcotics from personal and individual experience, and to apply to our neighbors the rules we find necessary for ourselves. It is possible to be indiscreet and to commit excesses with beefsteak as with tobacco, and the individual should decide what *his* system requires. The subject of discussion before the Society, however, the speaker suggested, was the use of tobacco by *boys;* and in regard to this he felt sure that the members present would cordially agree with the paper of the reader, Dr. Otis, and with its conclusions that the use of tobacco by the immature, even in moderate quantities, is injurious and undesirable.

Dr. Harlow observed that if tobacco retards development during the years of growth, it must continue to be a harmful substance even after the body has reached its full growth, and would work injury at any time of life. If it irritates the heart in a boy, it will do so to some extent in a man. President Quincy was accustomed to advise students against the use of tobacco or stimulants while engaged in their collegiate course.

Dr. Marcy stated that when a surgeon in the army he had observed occasions when tobacco was a godsend to the soldiers in aiding them to endure hardship and privation, and cold and hunger. There are some organisms to which it may be of questionable benefit, but it is a serious injury to any growing person. There is no doubt that a popular vote would be largely against the general use of tobacco.

Dr. Prince thought a distinction should be made in the form in which tobacco is employed—whether in cigarettes, or cigars, or a pipe. Cigarettes probably make a more lasting impression upon the system than cigars, and are harder to renounce. There is a popular impression that the principal injury comes from the paper containing the tobacco. This is not true. In cigarette smoking the vapor is inhaled, and coming in contact with the delicate mucous membrane of the air passages, its active properties are at once absorbed, and produce an immediate effect, which can be perceived to the tips of the fingers. The succeeding sensation is one of ennui, malaise, indolence, and muscular hebetude, which soon becomes burdensome unless the stimulation be renewed and prolonged by a fresh cigarette.

Dr. Marcy said that the question of the *form* in which tobacco is used is really important, if we are to judge of the *effect* from the quality of the substance employed. Many cigars are made from refuse of all kinds, which is pressed into shape and inclosed in a genuine tobacco leaf for a wrapper, while cigarettes more generally contain pure tobacco, particularly when they are made by the smoker as required for use. Certainly, as far as wholesomeness and cleanliness are concerned, cigarettes must be ranked as far preferable to cigars.

Dr. Langmaid stated that the most important questions in cigarette smoking are these: Does the inhalation of the vapor induce any disease of the mucous membrane with which it comes in contact? Does the smoke act upon the mucous membrane simply as smoke, or from the fact that it contains nicotine? Does smoking increase naso-pharyngeal catarrh? To these an affirmative reply must be given. If the mucous membrane is irritated, smoking invariably makes it worse. Will smoking produce a catarrhal state when none exists, or awaken a new one in a patient who has been cured of the disease? Observation teaches that it can do this. There is an increased secretion from the membrane, and all the other features of a catarrhal condition. Singers almost invariably abstain from smoking on those days upon which they expect to sing.

Dr. Bowditch added that he will not treat a patient for sore throat unless smoking is abandoned for the time. He has, however, never observed any affection of the bronchial tubes as indicated by râles or other physical signs, which could properly be laid to the influence of tobacco.

Dr. Cutler asked if any distinction was to be drawn between smoking and chewing. He stated that a teacher told him that students became much more stupid after smoking than after chewing tobacco. Dr. Mussey has made the same observation in regard to the mental depression from tobacco.

Dr. Edes remarked, in closing the discussion, that the subject had been presented with great clearness and in a very unprejudiced manner. One of its excellent features was the absence of exaggeration upon a topic which is generally discussed in an eminently partisan manner. There is no doubt something to be said on both sides.

Dr. George M. Geddes presented the next subject of the evening, as follows:

THE TREATMENT OF FOLLICULAR TONSILLITIS.

Follicular tonsillitis is a self-limited disease, which runs its course in a certain limited time, presents a sequence of definite and successive phenomena, and finally returns to a normal condition in about the same interval of time, whether any active treatment be employed or not. Any treatment, therefore, is directed chiefly to minor points, such as (1) the rapidity of relief; (2) the time when the patient may return to business; (3) the convenience and comfort of the patient as far as the method of treatment is concerned, and the ease with which the remedies can be applied. The disease invariably presents itself in one of two types. First, there is a type in which the follicles are stuffed full, with swelling of the parts, general malaise, high temperature, and great prostration. The malaise lasts from twenty-four to thirty-six hours, and subsides entirely without treatment. I generally give some quinine and a gargle, because it seems necessary to give something in order to minister to the feelings of the patient and his friends, but the cure would take place equally well without any treatment whatever. In the second type there is high fever, considerable pain, prostration, and high pulse. The patient is in bed and appears very sick. The general symptoms far outrank the amount of disease in the throat. This variety lasts from three days to a week or fortnight, running through a similar series of changes, excepting that they are sometimes more pronounced, as are observed in the milder variety of tonsillitis. The tonsils gradually return to a state of health, and the patient is cured just as in the type before mentioned. I have seen advised and have tried some of the nastiest things which can be made in the form of gargles. There is no danger attending the disease itself, there is no necessity for treatment of any kind, and, above all, there is no excuse for anything in the shape of disagreeable treatment of this disease by dirty and nauseous mixtures. The question of treatment rests only on the plea of shortening the disease and benefiting the patient. My plan is about this: Where the temperature is elevated to about 102° F or 103° F, I first give the patient a *sweat*. I do this by means of aconite. I prescribe five drops of the tincture, and direct that one-third be taken immediately, one-half of the remainder in half an hour, and the rest in an hour. I then give five grains of Dover's powder, and cover the patient warmly up to the neck. When sweating commences I give all the water the patient desires for two hours. At the end of that time the sweating is generally pretty profuse. The patient is dried and allowed to get on the dry side of the bed, and is directed not to rise until the next day. My apology for the sweat is that it always relieves the sore throat, back-ache, pains in the limbs, and nausea. The relief to the throat from aconite is very great, so much so that the patient can generally take milk with comfort, which he could not do before. The next day there is only slight further treatment for the throat. I generally direct the patient to gargle with hot water; and by hot water I mern *very hot*, as hot as the patient can bear it. Hot water is preferable to cold. There is no treatment before the sweat, and no call for anything further after the gargle. Each time the hot water is used the patient feels better. There is do excuse for carbolic acid or any other medicament. No germicide can be used in sufficient strength to affect bacteria without being injurious to the throat. After the treatment above described there is generally constipation, which is relieved by a seidlitz powder; and I usually prescribe quinine as a tonic, to be taken for some time afterward in small doses.

My reason for introducing the subject of the treatment of follicular tonsillitis is, that many physicians do not understand that it is a self-limited disease, and will do very well if let alone. They prescribe some disagreeable or disgusting gargle, which the patient often will not use, and sometimes cannot, and which it is practically impossible to employ in the treatment of children, who do not know how to gargle, and who resist anything of a disagreeable nature in the throat.

In a recent number of a Philadelphia medical journal I find an article by a man of that city upon this subject, and I desire to call the attention of the Section to the plan of treatment there advocated. If anything more nonsensical in theory or more disgusting in character can be put together, I do not know what it is. First, the throat is gargled or swabbed with a solution of equal parts of tincture of chloride of iron and water. This is repeated every two hours. The patient is confined in the bed, and not allowed to get up. Ten grains of quinine are given, and repeated in four hours if the fever has not subsided. This treatment is followed up until the throat symptoms disappear, and is then replaced by a tonic. The writer adds, "cases usually recover in about a fortnight." Think of a child gargling the throat with a 50 per cent. solution of chloride of iron! And the rest of the treatment there advocated is fully as unnecessary as it is painful to the patient and burdensome to the friends. I claim that such treatment is not only useless but unjustifiable in any disease which is bound to get well anyway, and which we can influence by measures equally effectual and less troublesome.

Dr. Liebmann observed that in tonsillitis there is, according to the books, general malaise but no rigor; while in diphtheria there is rigor. It is frequently the case that diphtheria comes on very insidiously, and commences as a tonsillitis, often confined at first to one tonsil, but afterward extending to the other, and being followed by the usual local signs and constitutional symptoms of diphtheria. It is a mistake to suppose that the onset of diphtheria is always announced by a rigor. Tonsillitis may be preceded by a chill, while diphtheria often supervenes without any such symptom.

Dr. Langmaid said: The great interest in follicular tonsillitis consists not in what the disease *is*, but in what it is *not*; in other words, in the absence of any exanthem, or parenchymatous disease, or deep-seated infiltration of the throat or other parts, and in the freedom of the patient from any symptoms of a more serious malady. We are never sure that the sore throat, the follicular disease, may not be the local manifestation or the initial symptom of some

grave constitutional affection, and we should be ever on our guard. The patient should be watched, and the same precautions observed in mild cases which would be necessary in a far more serious disease. It is not certain that the particular process of sweating has any advantage over the aconite alone, or over the old time remedy for sore throat, nitrate of potash. The pain in the muscles is often relieved by the administration of salicylate of soda. All the older authorities speak of colchicum and guiac, and they evidently considered the pains as of rheumatic character.

Given a case such as is described by Dr. Garland, how can the physician be certain that the superficial inflammation is not to be followed by abscess of the parts? Dr. Garland does not, probably, mean to indicate that *all* cases should be looked upon as absolutely innocent. How can he know that, instead of the creamy deposit, there may not supervene a thick deposit and all the signs of a grave exudative disease?

Any one who has had the care of diphtheria must feel anxiety upon this point. A subsequent visit should always be made, in order to be certain that no dangerous condition has supervened upon the simple tonsillitis. After the exudation there is sometimes serous infiltration of the tonsil, and the symptoms of diphtheritic infection appear.

The observer in Philadelphia is not so far wrong, for he doubtless felt the apprehension of some grave complication, and was striving to ward off more serious evils.

Dr. De Blois remarked that there is tonsillitis and *tonsillitis*. In many cases the patient is unable to open the jaws; and when the throat can be examined, there may be very little observable change in the tonsil. Scarification of the gland is often a most beneficial mode of treatment.

On motion of Dr. De Blois, it was then voted that the further discussion of this subject be postponed until the next meeting, as an invited guest of the Section, who was present, had a very interesting case to show to the members.

The report was divided at this point, and the rest published one week later.

THE TREATMENT OF CLEFT PALATE.

Dr. H. A. Baker, by invitation, exhibited a patient for whom he had contrived an improved appliance for cleft palate.

Dr. Henry J. Bigelow remarked that it is quite exceptional that staphyloraphy alone without an obturator does much service to the speech. It is not difficult to get a union of the fissure, or of most of it, but the flaps are usually so tense afterward from the contraction of the dissected surfaces behind the palate that the play of the palate necessary to articulation is prevented. I have, therefore, usually recommended patients to get one of the varieties of artificial palate or obturator, whether inflexible, like Suersen's, or flexible, like Kingsley's, and to submit only to so much operation as may be necessary to keep it in place. After an operation, patients expect to talk at once, but they cannot do so. A long education is needed to show any considerable improvement in alternating the mute and nasal consonants. As a rule, there is no improvement of speech at first. Fifteen years ago I devised a short series of exercises in articulation for a patient I operated upon. It begins with the only consonant which a patient can usually best articulate, namely, "*t*" in "*tar*," and gradually leads to the rest, constantly referring to the acquired "*t*" as a point of departure. Here it is, as it was the printed for the private use of a patient:—

"The great difficulty in pronouncing correctly with a cleft palate is in distinguishing the nasals from the mutes; thus, p and b from m; pap or bab from mam; t and d from n; tat from nan; k and g (hard) from ng.

"'Tar' is well pronounced by most beginners with an obturator. When the beginner can pronounce 'stark' and 'car' he has the key to most of what here follows. The above words should be practiced carefully; not 'start' and 'tar,' but 'stark' and 'car,' and should be spoken loudly, or, as the elocutionists say, 'exploded.'"

1.	tar	artar	kar	arkar	kar
2.	kar	arkar	arkgar	kgar	gar
3.	kar	arkar	arkdar	kdar	dar
4.	kar	arkar	arkpar	kpar	par
5.	kar	arkar	arkbar	kbar	bar
6.	kar	arkar	arklar	klar	lar
7.	kar	arkar	arksar	ksar	sar

Practice all the above with the following vowels:—

8. o as in coke.

Thus, instead of kar, akar, etc., ko — oko — oklo — klo — lo.

9. a (long) as in cake.
10. i as in kite
11. e as in keep.
12. u as in suit.

13.	kar	arkar	arngar	arkar	arngar	kar	ngar
14.	tar	artar	arnar	artar	arnar	tar	nar
15.	par	arpar	armar	arpar	armar	par	mar
						bar	mar
						dar	mar
						sar	rar

(Practice reading loudly from a book.)

"February, 1870."

Dr. Geo. F. Grant spoke as follows: In the physiological treatment of cleft palate, there are many points which require the most careful consideration. I have listened to the paper of Dr. Baker with great interest, because the subject is one to which I have devoted much time and attention, and during the past 14 years have treated over 70 cases of congenital cleft palate. While I may claim to have succeeded in almost every case in securing a good articulation, there have been great variations in the degree of success, as well as in the length of time which is required for the patient to master the art of distinct articulation and enunciation.

At the commencement I made the mistake of expecting too much from the appliance unaided by proper direction to the patient in its use, that is to say, after adjusting the palate it was my practice to give the patient an exercise in sounds, simply requesting him to follow me in their pronunciation. This plan did not prove satisfactory in all cases, and I now often wonder how so many did so well under so imperfect a system of training.

It soon became plain to me that patients of this class required to be taught the art of correct articulation technically, just as we are taught any other art

which depends upon accurate technique. This fact applies also to the sister art of enunciation, and although there is quite a wide difference between these two factors of speech, they are so closely allied in this particular branch of study that they may be considered as one in speaking of them in this relation.

I found that this class of patients is almost universally deficient in the management of the breath; that in the use of the voice they speak directly from the lungs without any check at the larynx as is the case in normal speech, and where this fault does not exist, they attempt the closing of the nose by using the depressor muscles of that organ, and thereby disfigure the face greatly.

While this fault exists, the development of correct habits of speech is impossible; for many if not all the sounds of the language require for their proper enunciation that the air column be under the most perfect control. For example, most patients are quite unable to give the sounds of those letters which are classed as labials, with any force whatever after being taught the method, simply because they do not have the power of sustaining a sufficient pressure of air. The proper thing to do is first to teach them to control the breath. It is best to give them a tube of some description, and teach them to blow through one end while the other end is immersed in water; the bubbles which arise are a good indication of the progress which is being made. They are then taught to check the air in the throat by the tongue, and by distending the cheeks make a reservoir of the mouth which furnishes air to the tube while the lungs are being filled through the nostrils, so that a continuous stream of air passes through the tube. This, many of you will recognize as the method of using the blow-pipe, familiar to chemists and artisans. I know of no plan which so rapidly gives the patient that control of the breath so necessary to the first steps in articulation. This practice gives tone and strength to the lips and cheeks, the muscles of which I have observed to be much weaker than in persons of normal formation. I have seen many patients who could apparently distend the cheeks as well as any one, when in reality there was little or no pressure upon the inside, and the act was a fictitious one, as the cheeks would not sustain percussion.

After I have taught a patient to direct a column of air through the lips and to control its passage, it is much easier to instruct him in applying those modifications to the air current which constitute articulate speech. These modifications are taught singly, and the proper position and conditions of the organs employed in the production of a sound are ocularly demonstrated, first, because the patient can more quickly understand what he can *see;* secondly, because it is of the greatest importance that the best skill should assist in developing the work which the appliance is designed to accomplish.

I have only time to say that this plan or system which has been slowly and practically developed has for its basis the reduction (by analysis) of speech to its simplest mechanical principles, and no effort has been spared to bring the mastery of those principles within reach of the most ordinary intelligence. I do not agree with much that has been written and said regarding the classification of the sounds in the language. But have one remark to make regarding the most common error which, as I believe, can be shown by a little reflection. It is a common belief that patients of this class must struggle with the consonants, while the fact is that with a few exceptions the vowel sounds are much the most difficult to teach them, because the vowels are more dependent upon the quality of the voice as a whole than upon any position or local arrangement of the organs of speech, consequently a patient may be technically correct as to articulation and have a most unpleasant enunciation, due entirely to faulty location of the vowel sounds. That is, a patient may be able to give the sounds of simple single letters or elements, and yet be unable to converse or read distinctly, because the voice has not received attention.

Few of these patients have made use of the anterior portion of the mouth in their efforts to articulate. Their whole mechanism has been misdirected to an almost vertical line with the larynx, so that if the same line were followed with a normal palate the voice would pass through the nares behind the palate, instead of being thrown upon the anterior portion of the soft palate and the whole of the hard palate, and then by reflection through the lips, as should be the case.

If you have followed me to this point, you will observe that I have first taught the patient that he must have the air to make the sounds under his control; secondly, he has been taught how to employ it in conjunction with the organs of speech in forming the parts of speech; now it remains to show him where to put it. We all agree that those sounds, or tones rather, which have the best penetrative power and are most clearly enunciated have a high or sharp pitch; then the next thing to consider is how is it produced. Why are some men's voices so much clearer in tone than others? Some of it is due no doubt to anatomical causes, the height of the dome of the palate for instance. But still there are physiological reasons. The man who enunciates best, and whose voice has purity and clearness of tone, makes it better still by careful study and training. He brings the focus as far forward upon the palate as it is possible to do; the sound wave from the larynx is projected as far upon the anterior portion of the palate as possible, by holding the head in an erect position and opening the throat, thus bringing the tongue forward. It is this very point which it is important to impart to a patient with cleft palate, and which is necessary for him to master in order to complete the work which an artificial palate makes possible. No enunciation is good without it; no articulation can be secured which will repay the trouble unless careful attention is given to these points, and I have seen so much accomplished by these methods that it seems almost a possible thing to train a patient into a fair articulation without any appliance. Two quite remarkable cases have come under my notice. In both the fissure was quite large, in one patient extending through the soft palate, in the other through the soft and half

way through the hard palate. In both cases the articulation was remarkably good, and either by accident or training the method in one was almost faultless, so that I advised the patient to let well enough alone.

A word about appliances. Dr. Baker's appliance seems to me to be the addition of a hinge to a modification of the Suersen obturator made by Dr. Kingsley, of New York. The original Suersen obturator was a solid bulb of hard rubber, so shaped as to retain contact with the divided palate under all conditions, and at the same time close the opening into the nares by the contact with the superior constrictor of the pharynx. Dr. Kingsley's improvement consisted in making the bulb hollow, and placing it so as to slide upon a bar until the most effective position was determined, and then securing it in the desired position. The method of making the bulb hollow, and the conclusions at which he arrived regarding the comparative value of the Suersen and Kingsley systems, may be found in the book on Oral Deformities, by Norman W. Kingsley.

Dr. Kingsley is of the opinion that a soft rubber appliance is best to acquire articulation with, while the hard rubber might be inserted with good results after articulation had been acquired, and I coincide with that view; for when a case of cleft palate has been brought to a successful result, and the palate is then removed, the patient is in a position analagous to perforate palate.

The articulation exists, and only requires mechanical aid, so that whatever meets that requirement suffices.

There are objections to soft rubber as a material, but it has proved of much benefit as an aid in giving the best results in acquiring good articulation, and in that respect surpasses anything which I have seen. I do not think Dr. Baker did it justice in his remarks upon it, for he must have known that if it was properly made, the die in which it was made was a permanent mould, which rendered the vela capable of easy and limitless duplication, and so easy of adjustment that it could be sent to any part of the world, or, if necessary, made or duplicated by any dentist who would follow the directions which accompany it.

The cleanliness depends upon the individual, as does the cleanliness of anything worn about the person.

The best results are dependent solely upon skillful manipulation, and no appliance can be successfully adapted by an unskilled hand. There can be no fixed rule to follow; each case presents new features, which must be met as they appear. My preference is for the soft rubber, because it more readily fulfils the requirements, and because it has done better work than any appliance which I have yet seen, though I have seen a few cases in which the hard rubber obturator had proved very beneficial.

I will not intrude further upon your time than to say that one of my greatest complaints against the Suersen principle has been that it seems almost impossible to obtain a clear voice with it, a fact which I have attributed to its thickness obstructing the posterior portion of the nares, and in Dr. Baker's appliance I cannot see that the hinge obviates that difficulty.

The patient was then introduced, and the appliance could be seen in the mouth, and, by causing him to swallow, the relation of the instrument to the wall of the pharynx and to the alæ of the velum palati could be easily observed. It was evident that in the act of deglutition no communication between the nasal cavity and the pharynx existed, the posterior part of the obdurator being raised up by the superior constrictor muscle of the pharynx, and pressed firmly against the posterior wall of the pharynx at the line of the naso-pharyngeal junction. The patient now removed the appliance, when an enormous fissure was disclosed, extending from a point near the incisor teeth through the entire hard palate and velum. Upon being asked to read, it was quite impossible to understand what the patient was saying. After replacing the appliance the same sentences were read, and every word was spoken with great distinctness, and could easily be understood by every person present. After this the patient was asked to read some new selection, and opening a book at random, commenced as follows: "Physicians generally agree that the moderate use of wine is beneficial." At this point the audience, pleased with the improvement in speech, and possibly desiring to express approbation of what was read, burst into applause, and appeared to be perfectly satisfied as to the usefulness of this instrument in cases of cleft palate. The patient remarked that he found the greatest comfort and solace in the fact that with the appliance in his mouth he was able to smoke, while without it he could not draw the vapor of the tobacco from the pipe into the mouth. With it, also, he can whistle, which he cannot do without it.

On motion of Dr. Marcy, it was voted that the thanks of the Section be rendered Dr. Baker for his important communication of original studies upon a most difficult subject, and demonstration of ingenious mechanical appliances for the remedy of cleft palate.

On motion of Dr. Prince, a vote of thanks was tendered to the retiring chairman, Dr. George B. Shattuck, for the zeal and fidelity with which he has conducted the deliberations of the Section during the past two years.

Adjourned at eleven o'clock.

DOMESTIC CORRESPONDENCE.

NEW YORK LETTER.

To the Editor of The Journal of the American Medical Association:

Dear Sir:—In your issue of January 26, 1884, is a leader headed "An Ethical Symposium," in which you make animadversions upon the action of the Medical Society of the State of New York in amending its Code of Ethics in 1882.

The argument of your leader is obviously intended to propagate the idea that the Medical Society of the State of New York voluntarily and intentionally seceded from the American Medical Association. It did not. It was extruded from membership in that body by the action of its Judicial Council at St. Paul

in 1882, which action the Association, as a body, assumed by adopting the report of said Council. These and some other facts in the matter should be stated again, as your leader was evidently written by some one who either does not know them, or refrained from using them.

In 1880, New York State passed an act regulating the practice of medicine within its borders. The year following, the Medical Society of the State appointed a committee to revise its code. I was on that committee, and did not hear any discussion, if any occurred, in regard to the American Medical Association. The revision was made to conform, in its text, to the provisions of the revised statutes of the State, and the claims of public policy, and was done under the advice of some of the best legal minds of New York City. The code, as revised and reported, was adopted by the New York State Society without even a verbal amendment, in 1882.

After this action, the society sent delegates to the meeting of the American Medical Association at St. Paul. The first session of the meeting occurred on Tuesday. The writer, at an early hour on that day, presented his credentials, and was told in a rugged, not to say impolite manner, that the Judicial Council of the American Medical Association had determined, at a meeting holden the previous day, to throw out the credentials of the delegates from the Medical Society of the State of New York. The writer, on two occasions during that session of the Association, asked the President of the Association for an opportunity to be heard in regard to the action of the Judicial Council. That official declined to give him any such opportunity. It was obvious that the American Medical Association was in the grasp of a few men who, through the Judicial Council, exercised their unchecked sway. The writer, not desiring to create tumult in such a body, contented himself with quietly taking part in the affairs of the meetings in his capacity of permanent member and delegate from the Medical Society of the County of New York.

In 1883 the Medical Society of the State of New York did not elect delegates to the American Medical Association. At that meeting the Judicial Council of the Association, in the exercise of its assumed high prerogative, framed and promulgated an iron-clad oath intended to keep out of the meeting any one who would even call in question, the wisdom of its Code, or if he did call it in question to place him in so doing in the attitude of having subscribed to a code which he intended to defy or subvert.

I have no doubt that the State of New York will again be in the American Medical Association, but not till the American idea of federation is exemplified in its laws and practice.

The passage of some such resolution as the following would, no doubt, bring about so desirable a result, namely: "Resolved, that no delegate, otherwise duly accredited, shall be excluded from a seat in the Association, whose credentials are plainly consistent with the laws regulating the practice of medicine in the State or Territory from which he comes." That would carry out the American idea of federation, and throw back upon the States the responsibility of legislating for the regulation of the practice of medicine. Some prejudices would have to be set aside to make way for such freedom, but in the end those States would exercise, by common consent, the greatest influence for good in the Association, in which the profession had ripened best under the influence of good schools; aided by good laws. Every State and Territory would, as in the American system, have the moral and political weight it was entitled to, and there would be something more in the American Medical Association than a doubtful "flavor of nationality." I am, dear sir, yours respectfully,

VINDEX.

FOREIGN CORRESPONDENCE.

FROM PARIS.

PARIS, January 16, 1884.

In opening his course of lectures as Professor of Clinical Obstetrics, to which chair he had recently succeeded the late Prof. Depaul, Prof. Pajot pointed out the necessity of adjoining a chair of gynæcology to that of obstetrics, as he said that both branches were so intimately connected that he could not understand how such a desideratum was allowed to exist, and he believed that France stood alone in this respect. Under existing arrangements gynæcology is not taught at the medical schools, nor is it officially recognized as a part of the medical curriculum in this country, the consequence is, a great number of students leaving the medical schools are completely ignorant of this most important branch. It is true the students obtain a theoretical knowledge of the principles of gynæcology, but when examined clinically they display an amount of ignorance which should not be allowed to exist. Simple gynæcology could not be taught at the lying-in hospital, as patients were admitted only to be confined, and they left it on the ninth day after confinement, unless they were not considered in a fit state to do so. Professor Pajot opened his new course under the most favorable auspices. He has promised great improvements and stated that as far as lay in his power he would raise obstetrics from its present obscure and cirumscribed position to which a narrow-minded prejudice has hitherto assigned it.

There is much ado about the consumption of American pork in this country, as a short time ago a slight epidemic of trichinosis occurred at Crépy-en-Valois, which was attributed to the use of American pork, but it was ascertained that the pork was absolutely French, as the pig to which the origin of the epidemic was traced, was killed in this country. The epidemic, however, was soon got under, and did not extend beyond the above-named town. In September last an epidemic of trichinosis broke out at Emersleben, near Halberstadt in Germany, and Professor Brouardel was deputed by the French Minister of Commerce to proceed thither to study and report upon the epidemic. He was accompanied by Dr. Grancher, whose conjoint report was submitted to the Minister of Commerce, and as it was demonstrated

that the trichinosis was only caused by eating pigs' flesh in a raw or uncooked state, a practice so common in Germany, there was little fear of the malady gaining ground in France, as almost every article of food was submitted to heat or to some culinary process. Moreover, the origin of the German epidemic was traced to an English pig that had been lately imported, and as there was nothing else to incriminate American pork, the Minister of Commerce thought proper to remove the prohibition on that article, as it constituted the principal food of the working classes, particularly among the peasantry.

The question was again brought before the Chamber of Deputies by M. Paul Bert, as well known as a politician as a physiologist, who moved that the recent decree rescinding the prohibition should not be carried into effect. This was carried by a large majority at the Chamber, so that the first decree still remains law. The Minister of Commerce, however, not being satisfied with the unceremonious manner with which his orders have been treated, re-transferred the matter to the Academy of Medicine, where it has been freely discussed.

M. Bouley, the well-known veterinarian, proved that the interdiction of American pork was a mere delusion; that during the twenty years prior to the interdiction American pork was freely eaten in France, and yet he had not heard of a single case of trichinosis in it. But the ludicrous part of the affair is that since the prohibition was decreed in 1881, the importation continued all the same; only instead of coming direct to this country, the American pork passed through England and Belgium, where no case of trichinosis had been heard of. The deduction, therefore, is that the nocuity of American pork is only another scare. The French must always have one to keep their restless minds occupied, and if they have no real subject for agitation they must invent one, and this applies as much to special or general questions as it does to their politics.

The question in dispute has been consigned to a commission, and perhaps nothing more will be heard of it for some years. Meanwhile the very people whom M. Paul Bert pretends to protect (and they are the great majority of the population) will be the greatest sufferers in a commercial as well as a sanitary point of view, for as long as the prohibition lasts they must be deprived to a certain extent of a most precious and economical article of food.

At a recent meeting of the French Society of Temperance a discussion took place on the propriety of adding strychnine to alcoholic drinks, as recommended by Dr. Luton of Reims, with the view of counteracting the ill effects of these liquors. Dr. Dujardin Beaumetz, having studied the subject more closely by experiments on animals and by personal observations of the effects of strychnia in the human subject, has come to the conclusion that, whilst the drug is capable of controlling the functional manifestations of drunkenness, it had no influence for good over the effects of alcohol on the different organic tissues of the body. He would therefore recommend that strychnia be left in its proper place as a therapeutic agent of great value in certain forms of disease, to wit, those produced by the abuse of spirituous liquors, and should not be introduced for daily use under the pretence of imbibing the antidote with the poison.

The Prefect of Police has issued some strict regulations respecting lodging-houses or furnished apartments in Paris, as these have been found in a notoriously unsanitary condition. No room is to be let that did not measure two and a half meters in height, and did not have a cubic space of fourteen cubic meters per occupant. The walls and floors are to be regularly cleaned, and proper means of ventilation should be provided for each room. Cellars are not allowed to be used as dwellings. To carry out these regulations the lodging-houses will be periodically visited by a staff of inspectors, and any infringement of the above rules will be severely punished.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT UNITED STATES ARMY, FROM JANUARY 25, 1884, TO FEBRUARY 1, 1884.

Alexander, Charles T., Major and Surgeon: so much of Par. 7, S. O. 211, Sept. 14, 1883, as directs him to report in person to the Commanding General Department of the Missouri, for duty, is revoked, and he will, upon the expiration of his present leave of absence, proceed to St. Louis, Mo, and assume duty as attending surgeon and examiner of recruits in that city. (Par. I, S. O. 21, A. G. O., January 25, 1884.)

Elbrey, Frederick W., Captain and Assistant Surgeon: present leave of absence extended 6 months. (Par. 9, S. O. 24, A. G. O., January 25, 1884.)

LIST OF CHANGES IN THE MEDICAL CORPS OF THE NAVY, DURING THE WEEK ENDING FEBRUARY 2, 1884.

Passed Ass't Surgeon Robt. Whiting, detached from the Hospital, Norfolk, and to the "Colorado."

Ass't Surgeon H. B. Fitts, detached from the "Jamestown," and ordered to Coast Survey Str. Gedney.

Passed Ass't Surgeon F. Anderson, granted leave of absence for six months.

P. A. Surgeon S. W. Battle, detached from U. S. S. Gedney, and placed on sick leave.

OFFICERS OF

THE AMERICAN MEDICAL ASSOCIATION

AND OF ITS SEVERAL SECTIONS, 1883-4.

PRESIDENT.

Dr. AUSTIN FLINT, SR., of New York.

FIRST VICE-PRESIDENT.

Dr. R. A. Kinloch, Charleston, S. C.

SECOND VICE-PRESIDENT.

Dr. T. B. Lester, Kansas City, Mo.

THIRD VICE-PRESIDENT.

Dr. A. L. Gihon, United States Navy.

FOURTH VICE-PRESIDENT.

Dr. S. C. Gordon, Portland, Maine.

PERMANENT SECRETARY.

Dr. Wm. B. Atkinson, 1400 Pine St., Philadelphia.

TREASURER.

Dr. R. J. Dunglison, Philadelphia.

LIBRARIAN.

Dr. C. H. A. Kleinschmidt, Washington, D. C.

Place of meeting, 1884, Washington, D. C.; Time of holding meeting, first Tuesday in May.

CHAIRMAN COMMITTEE OF ARRANGEMENTS.

Dr. A. Y. P. Garnett, Washington, D. C.

ASSISTANT SECRETARY.

Dr. D. W. Prentis, Washington, D. C.

BOARD OF TRUSTEES FOR JOURNALIZING THE TRANSACTIONS.

Drs. J. M. Toner, Washington, D. C., President;
M. Moore, Rochester, N. Y.; Leartus Conner, Detroit, Mich.;
J. H. Packard, Philadelphia, Secretary;
H. F. Campbell, Augusta, Ga.; A. Garcelon, Lewiston, Me.;
P. O. Hooper, Little Rock, Ark.;
L. S. McMurtry, Danville, Ky.; J. H. Hollister, Chicago, Ill.

OFFICERS OF THE SECTIONS:

"Practice of Medicine."

Chairman—Dr. John V. Shoemaker, Philadelphia, Pa.;
Secretary—Dr. W. C. Wile, Sandy Hook, Conn.

"Obstetrics and Diseases of Women."

Chairman—Dr. T. A. Reamy, Cincinnati, Ohio; Secretary—Dr. J. T. Jelks, Hot Springs, Ark.

"Surgery and Anatomy."

Chairman—Dr. C. T. Parkes, Chicago, Ill.; Secretary—Dr. A. O. Walker, Detroit, Mich.

"Ophthalmology, Otology and Laryngology."

Chairman—Dr. J. F. Chisolm, Baltimore, Md.;
Secretary—Dr. J. L. Thompson, Indianapolis, Ind.

"Diseases of Children."

Chairman—Dr. Wm. Lee, Baltimore, Md.; Secretary—Dr. W. R. Tipton, Las Vegas, N. M.

"Oral and Dental Surgery."

Chairman—Dr. T. W. Brophy, Chicago, Ill.; Secretary—John S. Marshall, Chicago, Ill.

"State Medicine."

Chairman—Dr. Deering J. Roberts, Nashville, Tenn.;
Secretary—C. W. Franzoni, Washington, D. C

Committee on "Necrology."

Chairman—Dr. J. M. Toner, Washington, D. C.

EDITED FOR THE ASSOCIATION BY N. S. DAVIS.

PUBLISHED WEEKLY.

VOL. II. CHICAGO, FEBRUARY 16, 1884. No. 7.

ORIGINAL ARTICLES.

REPORT OF THE STANDING COMMITTEE ON METEOROLOGICAL CONDITIONS AND THEIR RELATIONS TO THE PREVALENCE OF ACUTE DISEASES.

BY N. S. DAVIS, M.D., LL.D., OF CHICAGO, ILL., CHAIRMAN OF THE COMMITTEE.

[Presented to the American Medical Association in session at Cleveland, Ohio, June 7, 1883.]

[Continued from No. 4, Vol. II.]

The following tables present in a condensed form the amount of free and albuminoid ammonia in the atmosphere in the city of Chicago, at a station where the population is moderately dense, of good quality, with fairly good sewerage and water supply, as determined by Prof. Long for each day of the twelve months ending August 31, 1883: *

These tabulated details giving the results of most careful daily examination of the atmosphere during an entire year in the same locality, and by uniform processes, develope several facts of value. First, they show that both free and albuminoid ammonia are constant elements of the atmosphere, at least in cities or densely populated localities, their presence in quantity capable of measurement having been found every day in the year. Second, that the free ammonia is much less in quantity than the albuminoid, and that they do not bear any uniform ratio to each other. Both vary much in brief periods of time, the quantity of free ammonia exhibiting these variations in a much greater degree than the albuminoid. Third, that the presence of decomposing animal matter directly increases the quantity of both varities of ammonia. When the decomposing material is moist, the increase of the free ammonia is greatest, and when dry the amount of free ammonia may be so small as to impart but little odor, and yet the albuminoid be greatly increased. The details mentioned by Prof. Long also show that the ammonial constituents of the air can be markedly increased at considerable distances from their source by atmospheric currents, as shown by the effects of the winds from the direction of Bridgeport, the principal packing and manufacturing establishments of which, are from two to four miles from the college laboratory where the observations were made.

Before making further application of these tables, we will give a similar tabular statement of the indications of ozone or active oxidizing agents in the atmosphere at the several stations selected for observation, as follows:

OZONE REPORT FOR THE YEAR 1882.

*Place of observation in San Francisco changed to German Hospital.

LEPROSY IN MINNESOTA, 1869-1883.

A Report to the State Board of Health of Minnesota.[1]

BY CH. GRŒNVOLD, M.D.,

Chairman of the Standing Committee of the Board on that Subject.

[1]Originally published in the *Journal of Cutaneous and Venereal Diseases*, vol. II. No. 1, 1884.

There has lately been written much about a center of leprosy in the Northwest, from where the disease is said to be spreading. It may be interesting to see how facts support this statement.

As early as in 1864, the condition of the lepers among the immigrants to the Northwest has been an object for the attention of medical men from their own country. In that year Dr. J. H. Holmboe, surgeon in charge of the Hospital for Lepers in Bergen, Norway, visited this country, to study the influence change of climate and other relations had on the development of the disease.

He found 12 cases, of which two had originated in this country, while one, who came here leprous, had got well. His impression was that their condition of health was better than it would have been if they had stayed in the old country.

In 1869–70 the settlements were again visited by a medical gentleman from the old country, the late Prof. William Bœck, of Christiania, Norway, well-known in medical literature for his writings on leprosy and syphilis. The result of his investigations in the Northwestern settlements may be read in "Nordiskt Medicinskt Archiv," Band iii., No. 1.

He found in the three States, Wisconsin, Iowa, and Minnesota, 18 cases of leprosy, all of which had come from those parts of the Norwegian Western seacoast where the disease is endemic.

Nine cases had the anæsthetic form, 3 the tubercular, while in 6 cases both forms were represented at the same time, or one superseding the other.

In regard to the time of the appearance of the disease, in 9 it commenced already in the old country, and of these, 5 had lepers in their family, while 4 did not know of any leprous relation.

In the other 9 cases the disease first commenced in this country. Of these 8 had lepers in their family, and the disease broke out respectively, 2½, 3, 3½, 5, 6, 8, 9½, and 10 years after their arrival. These 8 cases that were developed on American soil may depend upon heredity; or they may have been caused by contagion in the old country, the only place where it is possible that they could have met with other lepers; or the disease may have developed from a miasma in the old country. Either of the last two suppositions being right, the time of the incubation will for two of the cases be 9½ and 10 years. Prof. Bœck considers them all as depending upon heredity, in direct or lateral line. If he had any doubt, he says, in regard to propagation of the disease by heredity, these cases would have convinced him.

As an instance, here is one of the cases described in the above-named medical *Archiv*:

"S. S., 45 years old, came 14 years ago to America to the place where he now resides, and he was in every respect perfectly well. His father had died, about 50 years old, in the lepers' hospital at Bergen; his brother and sister died leprous in the old country, one and four years ago; his father's sister had also had the disease. S. continued to be in good health after his arrival in this country for nine and one-half years; four and one-half years ago he commenced feeling heavy and drowsy, and two years later, after a violent cold, tearing and fleeting pains announced themselves in hands and feet, and from there in the upper and lower extremities, and at the same time swelling set in in the same parts and in the face, and an eruption of red spots appeared. The pains were so violent that he was obliged to stay in bed from January to May, and when he was able to set out of bed his strength was gone, and he discovered that his sensation was much lessened along the peroneal side of the feet and legs, and on the ulnar side of hands and arms. Since that time he has always suffered from fleeting pains in the extremities, and feels heavy and drowsy. 'I will never have a day of health any more,' he says.

Sensation is at present very weak in hands and feet, as well on the outer as on the inner side, from the hands along the arms to the shoulders, and from the feet along the legs and thighs until the neighborhood of the hip. The muscles of the right hand, between the first and second finger and those of the fifth finger, are considerably wasted."

This patient left the old country in good health, and continued to be well for nine and one-half years after his arrival in this country, in a place where there were no lepers before, and where it is not known that he has had communication with any.

The last of the nine cases developed on American soil, did not know of any leprous relation, and may possibly be referred to contagion. The case is, in short, as described in the above-named *Archiv*: "B. I. is 39 years old; came to this country 14 years ago; has for 12 years suffered, and is yet suffering, from rheumatic pains in the extremities. Recently, after a day's hard work, she had, in the evening, a violent chill, and the next day there appeared spots on the arms, and successively on the lower extremities, chest, back, and face. These spots are distinctly morphea spots, in some places slightly elevated. In them there is either complete anæsthesia or very little sensation; outside of them the sensation is normal, except on the external side of the feet and legs. Her appearance is very good; she is fleshy, has good appetite, the bowels are a little constipated, menstrual flow scanty. She does not know of any leper in the family. She has once, six or seven years ago, been in the house of a leper. By others it is said that she for some time has taken care of a leper." Prof. Boeck has his doubts whether this person does not also belong to a leprous family, and the disease is then due to heredity.

The professor is of the opinion that the lepers here are better off as regards their disease than they would have been in the old country. "They have come away from the places where we see leprosy may originate spontaneously, and which certainly will favor

its development, when the disposition is there by heredity. They have settled on fertile lands, where they certainly have to work hard to make a living, but they, generally, never undergo hardships, as we, in Norway, understand the term. Here is no work that can be compared to the midwinter's fisheries in open sea off the Finmark coast, or the hardships suffered while tending the cattle on the high mountain plateaus, which causes so often bring out the latent leprosy."

Since Professor Boeck's visit in 1869-70, investigations have been continued in Minnesota regarding the occurrence and character of the disease in that State. At present six cases and their whereabouts are known, all immigrated from that part of Western Norway where the disease is endemic.

None of them are confined to bed, and most of them are able to perform their daily duties.

The following table will show some of the particulars of the cases:

		AGE.	HOW LONG LEPROUS.	HOW LONG IN THIS COUNTRY.	FORM OF DISEASE.	LEPROUS RELATIONS.
Case I....	Male.....	58 years..	18 years.....	27 years..	Anæsthetic.	Father, father's sister, brother, sister, cousin.
" II..	"	44 "	10 years.....	15 "	Do.	Probably a brother.
" III..	Female...	29 "	7 "	20 "	Tubercular.	Father, 2 brothers.
" IV...	Male.....	29 "	7 "	16 "	Do.	None. (?)
" V....	"	35 "	16 "	12 "	Anæsthetic.	None.
" VI..	"	67 "	Prodromata in the old country.....	17 "	Do.	"

[1]Case No. I. is described by Prof. Boeck—his No. 1—and is the one described above as S. S. It is the only case yet alive of those he saw in Minnesota. He has, since the Professor saw him, been tolerably well until of late years, when the disease has made a quicker advance.

It will be seen that two of them have the tubercular form, while four have the anæsthetic; in two of these, IV, VI, a little complicated with the tubercular.

Two of them, IV, V, had the disease already in the old country, but one of them did not suffer much from it before seven years after the arrival to this country.

Of the other four, three know of leprous relations, while one (III) denies that the disease has ever been in her family. She is from a district where there are many lepers, Balestrand, in Sogn. The main features of the case are:

Case III came to America when she was thirteen years old, in company with a sister of her mother, sixteen years ago, and has all the time since lived near the place she first went to. The first two years she lived with her aunt, but after confirmation she served as housemaid in the families of the neighborhood until she, seven years ago, discovered the first signs of the disease. After a severe illness, she says, caused by cold, the legs swelled, and some vesicles appeared, first on one, later on both ankles, followed by sores. At present, she exhibits the tubercular form of the disease, and presents a very repulsive appearance. The complexion is pale, or rather a dirty white, the skin of the face thickened and rough. Tubercles, some suppurating, and some torn by scratching, are seen over the eyes and on other places of the forehead, on the right nostril, and on the cheeks and chin; also on the ulnar side and back of both hands, where as well as on the outside and back of the feet, and lower part of the peroneal side of the legs there is some anæsthesia. The voice is hoarse and rough. The nose seems flattened on account of the alæ spreading out. The lobes of the ears and lips, especially the upper, are very much thickened and elongated. The eyebrows and eyelashes are gone; conjunctiva a dirty white, with a troublesome secretion; cornea somewhat opaque; her eyesight is very much impaired. She denies having any discoloration of the skin, any sores or tubercles in other places than those above named, and on the ankles, where there are deep ulcers, laying the bone bare. She does not suffer much, only once in a while she feels a little oppression and some slight pain in the chest and back, but this, she believes, is only caused by weakness. Appetite is irregular; the sleep is commonly good. Menses commenced being scanty when the disease broke out, and stopped soon. She feels worse spring and fall, but is seldom confined to bed. She takes cold easily. Like almost all lepers here, she ascribes her disease to cold. "She suffered so from cold," she explains, "in a place where she was working, that she, then and there, got the disease." It is not known by herself, or anybody else, that she ever met with a leper in this country.

She must have carried the germ of the disease with her from the old country, whether it has been communicated by contagion or miasma, if she is right in her statement that the disease has been neither in her father's nor mother's family. The disease became evident when she was 22 years old, and had lived in this country nine years. She will not remember any prodromes; has probably tried to conceal her condition as long as possible. She tries yet to put the best appearance to her miserable condition.

Ten lepers of the immigrants are known to have died in Minnesota since the settlement of the country, all of them males. Of these, seven have died in the last seven years, and the following table will show some of the particulars of the cases:

	AGE AT TIME OF DEATH.	HOW LONG LEPROUS.	HOW LONG IN AMERICA.	FORM OF THE DISEASE.	LEPROUS RELATIONS.
Case I.....	49 years.....	24 years.....	19 years.....	Anæsthetic	Brother of mother's father.
" II.....	56 "	14 "	24 "	Tubercular.....	A cousin.
" III.....	35 "	10 "	9 "	Anæsthetic	Father's brother.
" IV.....	About 30 years.....	3 "	13 "	Tubercular.....	Brother's father and bro. diseased.
" V.....	" 30 "	12 "	15 "	Do.	Do.
" VI.....	63 "	30 "	21 "	Tuberc. first seven years, afterwards anæsthetic; disease stopped before death.	Brother and father's brother.
" VII...	30 years.....	.....	10 "	.....	Mother's brother.

It will be seen that three of them had the anæsthetic form, and died 24, 10 and 30 years after they got the disease. The last case, No. VI., Boeck's observation 2, is an instance of one form changing into the other; the disease commenced in the tubercular form, and continued so for 7 years; after a violent fever it changed into the anæsthetic. Three had the tubercular form, and died after having had the disease 14, 3 and 12 years. Case II. got the disease 10 years after his arrival in this country, when he was 42 years old.

All of them had lepers in their family; three of them had the disease in the old country; three got it here—two, ten years, and one three years after their arrival.

Four of the lepers—two of them living yet—have full-grown children born in America; two have full-grown grand-children. One, No. VI. of last table—Boeck's observ. No. 2—has fifteen grand-children, aged from 2 to 22, and two great grand-children, and in none of them has any sign of the disease been discovered. The other, No. I. of the first table—Boeck observ. No. 1—who belongs to a family strongly infected with lepers—his father and father's sister, his brother and his sister were lepers—has full-grown children and many grand-children of an age up to 17, all in good health.

The suggestion of the above facts, as far as they go, seems to be that the disease is not so easily acquired here in the Northwest as in the old country, be it by heredity or contagion. The dry climate is, possibly, not so favorable for the development and the communication of the disease, that at present mostly belongs to the sea-coasts and islands. The chances of contagion are decidedly less here than in the old country; there is greater cleanliness, as a consequence of the greater economical prosperity, and the new-built houses of the first settlers in a new country furnish no filthy nests for contagion.

But, once acquired, the disease seems to run in regular course without abatement.

[1] Cases II and VI. were seen by Prof. Beock in 1870, and described by him in the above-named journal, as observations 3 and 2. Case II got steadily worse until death, 8 years after the professor saw him, but in No. VI. the disease made no advance years before his death, which occurred 30 years after he was attacked, 7 years after Prof. B. saw him, and described his case. He was, in the last years of his life, since Prof. Boeck's visit, in good health, with the exception of the anæsthesia in the already attacked places, and an always open and discharging ulcer under one foot When this discharge stopped, about 14 days before his death, vomiting set in, which became more and more distressing, so he could keep nothing in his stomach. He was not confined to bed, but moved about as usual, until just before death.

A CASE OF SUPPOSED MALIGNANT DISEASE OF THE UTERUS TREATED BY IODOFORM.

BY I. W. FISKE, M.D., KALAMAZOO, MICH.

[Read before the Kalamazoo Academy of Medicine, January 29, 1884.]

About three and a half years since I was called to see Mrs. H., who had been suffering for some time with some uterine trouble. She came here from Ionia, where she had had removed some time previous a portion of the external os uteri for supposed malignant disease. I found the uterus somewhat enlarged, with the inside roughened and uneven. She was suffering from considerable pain at this time. Some physician in Grand Rapids had applied pure nitric acid to the internal part of the organ. I applied iodized phenol to the inside and hot water injections, and also used electricity, passing the current through the pelvis, and also applying one pole to the os and the other to the lower part of the spine, and always with relief. After about two months' treatment the inside became smooth, pain was relieved, uterus was lessened in size, and she was enabled to return to her business, which was that of dress-making.

She continued in comparative good health for some months, when the pain again returned, and after some little time was obliged to give up work, and I was called again. I found the uterus very much enlarged and elongated; very hard, with an ichorous or fœtid discharge. In fact the organ felt hard like bone. The disease was confined wholly to the uterus. I again used the former treatment, with medicine to relieve pain. After treating her awhile with no apparent change, except that the uterus continued to enlarge so as to almost fill the lower pelvis, I prescribed suppositories of iodoform, hyoacysmus and conium—five grains of the former with two grains each of the latter These were to be applied direct to the uterus night and morning. My sus-

picions being aroused with the idea that I had to deal with malignant disease, I called Dr. H. O. Hitchcock in consultation. After a thorough examination of the case he confirmed my diagnosis, and advised the continuance of the treatment. Some little time after the doctor again saw the case with me. After a second examination his former opinion was only the more thoroughly confirmed. Dr. Osborne then saw the case (he having had a case of schirrhus some time previous) and he pronounced it an undoubted case of malignant disease. I continued to persevere with the iodoform treatment, and after about three months the uterus began to soften, became less painful, and after using the treatment about six months the uterus became normal in appearance, the patient entirely relieved of pain, and she was enabled to return to her work. One year ago last fall she returned to her home, and has been comparatively well ever since.

From the successful outcome of the case I was led to the conclusion that we were all mistaken as to the diagnosis. Some time last winter I received a paper from Dr. Cutter, of Boston, on the uses of iodoform, in which he gives the history of three cases of what he pronounced malignant disease of the uterus, but by the use of iodoform, topically applied, the disease had finally disappeared. He used gr. xv of the iodoform in each suppository. The patients had remained well up to the time of his article. He also added that if the patients had died there would have been no doubt but that the cause of death was malignant disease of the uterus.

I have thus given a brief history of the above case from recollection, as I kept no record of the case, simply to elicit any experience any of you may have had in the above treatment in such cases, and to ask the question: "What effect, if any, has iodoform upon malignant disease of the uterus?"

MEDICAL PROGRESS.

MEDICINE.

ZOÖGLEIC TUBERCULOSIS (A FORM OR SPECIES OF TUBERCULOSIS WITHOUT BACILLI.—Malassez and Vignol have published in the *Archives de Physiologie*, with illustrations, an article which gives the result of their investigations in the laboratory of histology in the College of France, which embrace the following conclusions:

1. There exist tubercular lesions which do not present bacilli, and which inoculated can give rise to tuberculoses equally without bacilli, and at the same time resembling bacillary tuberculoses. The same results obtain with their products of culture. If then the presence of bacilli is sufficient, according to Koch, to characterize the tuberculous nature of a lesion, the converse is not exact; or, in other words, their absence is not sufficient to negative the tuberculous nature of a lesion.

2. Among these tuberculoses of inoculation without bacilli, there are some which are characterized by the presence of zoögleic masses of micrococci, which, in the tissues which they infect, play the part of phlogogenic foreign bodies, and also produce there the so-called tuberculous lesions. These tuberculoses then should be designated by a special name—that, for example, of zoögleic.

3. There are also other tuberculoses of inoculation, non-bacillary, in which distinct zoögleiæ cannot be distinguished. They appear to be due to the same species of micrococci with those in the zoögleic masses; but, in lieu of being crowded into groups, they are disseminated in the tissue of granulation, and it is on account of this dissemination that, in the absence of a special coloring reagent, they are not sufficiently defined. As a proof of this, they can by inoculation engender the zoögleic tuberculoses.

4. These same non-bacillary tuberculoses, with or without distinct zoogleiæ, may produce after a varying number of generations of inocculation, bacillary tuberculoses; as if the zoögliæ, the micrococci diffused, and the bacilli were simply different forms, or states of development, of the same micro-organism. However, as this transformation of the zoögloeiæ into bacilli has not been directly observed, we have no right to declare them as of the same nature, whilst the hypothesis is a justifiable one.

5. Whilst these zoögleiæ and micrococci do not bear an exact resemblance to the parasites previously described by Klebs, Aufrecht, and Toussaint, it would seem as if there was a certain relation between them, but the facts observed do not decide the question.

EXPERIMENTS ON POISONING BY THE BACILLI OF THE MACERATION OF JEQUIRITY.—M. de Wecker having demonstrated the production of inflammation of the conjunctiva, as a means of curing rebellious ophthalmia by the use of this drug; and M. Sattler having determined that its active principle was due to the presence of a characteristic bacillus, MM. V. Cornil and A. Berlioz have conducted a series of experiments (*Archives de Physiologie*) on the mode of action of this substance when absorbed—through the lymphatics or by the blood. Their experiments were conducted on the guinea pig, rabbit, and frog, and are summarized as follows:

1. The action of the bacillus of jequirity when absorbed, and after having penetrated into the animal organism, varies according to the mode of its introduction, and the species of animal.

2. Whilst the local action of the microbes of jequirity on the conjunctival mucous membrane reacts but slightly on the general health, and gives therapeutic results in serious ophthalmia, their introduction into the lymph and blood produces general symptoms followed by death in the guinea pig, rabbit, frog, and fishes.

3. The subcutaneous injection into the cellular tissue of a cubic half-centimer of a weak infusion, produces an inflammatory œdema and lesions that are generally followed by death. If the dose be very small, the more or less extensive œdema terminates in a phlegmon and gangrene, and confers upon the inoculated animal an immunity against the subsequent injection of strong doses.

Injections into the peritonæum and pleuræ of rabbits of ¼ to ½ of a cubic centimer of the decoction of jequirity produced a peirtonitis and a fibrinous pleurisy, followed by death with general lesions. The living microbes were found in the sero-purulent exudation which characterizes these inflammations. These micro-organisms might penetrate into the blood and cause, through the obliteration of certain vascular territories of the liver, an infarctus with necrosis of the hepatic cells.

5. The injection of from two to three cubic centimeters of the decoction of jequirity into the veins of the ear of the rabbit is followed by death in a few hours. The bacilli of jequirity are eliminated through the stools and urine one or two hours after injection. The injection of two to three drops of the same decoction in the veins of the rabbit causes death in twenty-four hours.

6. In a general way the bacteria of jequirity live, reproduce themselves, and disseminate through the blood of cold-blooded animals (frogs, fishes) with an activity that is incompaiably greater than in the blood of the smaller mammalia. With the frog, let the dose be large (½ cubic centimeter) or small (2 drops), by its introduction into the dorsal lymphatic sac, or the peritonæum, death follows with a colossal quantity of living, moving bacilli in the blood, the lymph, and the serous cavities. While their number in the blood is comparable to that observed in charbon, there is also an elimination of the microbes by the urine. The capillaries of all the organs are more or less filled, but the cellules of the parenchymatous organs, the liver, kidney, glands; the proper elements of the connective, muscular, cartilaginous and other tissues, do not undergo any pathological modification, a fact which also increases the similarity of this infectious disease with that of acute charbon. It appears, like the charbon bacteria, to produce death by depriving the blood globules of their oxygen.

7. The blood of a frog so intoxicated has itself become septic. The subcutaneous inoculation of a portion of that blood produces a special septicæmic condition, with subcutaneous œdema, ecchymoses, etc., followed by death, which takes place in a few days. The lymph and blood are filled with bacilli, almost as numerous as when the maceration of jequirity is used; all the vessels are filled without producing thromboses. The secretions also contain bacilli which are eliminated in this way. The parenchymatous cellules are not generally altered in any marked degree.

Pulmonary Syphilis.—Professor de Renzi (de Naples) has an extended article on this subject in the *Revista Clinica e Terapeutica*, a translation of which is given in *La France Médicale*. He declares:

1. Syphilis of the lung may be hereditary or acquired. The last, which I have observed the most frequently, is not so rare as might be supposed. In a number of cases a diagnosis of phthisis pulmonalis has been made.

2. The development is favored by debility, acute catarrh of the respiratory passages, larynx, trachea or bronchi, and chronic catarrh of the same organs. These catarrhs may cause the pulmonary localization even in an apparently robust condition.

3. There are no special and characteristic phenomena. All the symptomatic and progressive peculiarities found in syphilis are also to be found in the pulmonary tuberculosis.

4. To distinguish between these two diseases we have the following symptoms:

(*a*) Absence of the tubercular bacilli in the sputa.

(*b*) Efficacy of the anti-syphilitic treatment, which produces a rapid relief, and even a cure, where syphilis is the cause. In the cases of failure of treatment the diagnosis is uncertain. This criterion remains doubtful with the iodine treatment, but with mercury a positive effect is rapidly produced.

(*c*) The existence of other syphilitic lesions, and particularly syphilitic ulcerations of the larynx.

(*d*) Syphilitic antecedents, dating from a remote period of five years or longer.

The last two arguments are less decisive than the first two, for a syphilitic is exposed to attacks of pulmonary tuberculosis.

5. Iodine and iodide of potassium act against pulmonary syphilis. Iodine may be given without fear in doubtful cases, for experiments made upon animals and clinical observations demonstrate that it retards, and, up to a certain point, prevents the development of tuberculosis. But mercury is more efficacious and deserves the preference.

SURGERY.

On Nerve-Stretching for the Relief or Cure of Pain.—Mr. John Marshall, as President of the Royal College of Surgeons, delivered the "Bradshawe" lecture on December 6, taking this subject for his theme (*Lancet*). He formalarized in a very satisfactory manner what is known to-day upon the subject. The first question is: Can a nerve be stretched? in reply, he demonstrated this stretching by the use of a 4 lb. weight, applied to a nerve and a piece of tendon by contrast; deciding the nerve to be not so extensible as an artery, but a little more extensible than a tendon. The nerves nearer the spinal cord are more extensible than those at a distance; the nerves of the upper limb than those of the lower; the longer the nerve the greater is its elasticity.

Secondly, the recoil of the nerve. According to one observer, a nerve stretched one-twenty-fourth of it length, recoiled to within one-fortieth of its original length.

How much weight will a nerve bear? The table of weights borne vary from six pounds for the supra-orbital to 288 pounds for the great sciatic. As a mean he considers 180 pounds to be the weight that the sciatic nerve will bear; recognizing the great difference between a dead and living nerve in this respect.

The effect of stretching upon the nerve structure. Illustrations given show the changing of the wavy

nerve lines to straight and paraliel ones, the epineural fibers, perineurium, and tubules are all stretched into straight lines, the fasciculi appear compressed, and the lymphatic spacè is obliterated. The natural regmentation seems to give way to an abnormal or irregular breaking up of the medullary sheath; sometimes the tubuli break, and still more rarely the axis-cylinder gives way. These anatomical changes are followed by degenerations; the sheath becomes infiltrated and hyperæmie, charged with little ecchymoses and larger hæmorrhages, degenerative changes are rapidly set up in the tubules themselves, the fine nerve tubule melts away, the axis-cylinder is broken across, the medullary matter escapes in the form of oil globules, and the whole mass of nerve becomes disintegrated, and subject to soft atrophic changes. Then restorative changes follow in the living nerve.

The physiological results of nerve-stretching are: To diminish motor properties and sensory functions, the latter more markedly, including not only that of common touch, but the sense of temperature, and the sense of pressure. Irritability is at first increased, then gradually diminishes and is finally extinguished; to gradually diminish reflex function.

Are the mechanical effects of nerve-pulling transmitted on to the spinal cord? Practically not,—the stretching effects pass to the sciatic plexus, to the roots of the nerves, where it must disturb the spinal ganglia on the posterior roots, and it must disturb the dura mater; hence it may disturb the cord a little through the ligamentum denticulatum on either side; but there is no change of tension in the intra-spinal or intra-meningeal part of the nerve, and no movement in the cord.

The therapeutic value of this procedure is shown in tables given of 252 cases of nerve-stretching in various diseases; a proper discussion of these tables gives certainly sufficient encouragement to the belief that nerve-stretching is not only available for the cure of *inveterate neuralgia*; but also for the amelioration of *tabes*. In cases of neuralgia a great proportion are due to irritation of the *nervi nervorum*, that is, fibres which come from the nerve itself to supply the epineurium and perineurium—this action of stretching paralyzes them. As to tabetic pains, here we have changes in the posterior roots and spinal cord, but it is a disease of the conductors, rather than of the receivers, of nervous impressions; the grey matter undergoes changes, but the white matter is more conspicuously affected. Now, while the nerve-stretching has been shown not go in its effects beyond the roots of the nerves in the sheaths of the dura mater, there it affects the ganglia, there it produces an excitation of the vasi-motor centers or trophic centers; and to the reaction that takes place and the changes induced in the nerve elements in consequence of that, we must look for the benefit obtained in cases of tabes dorsalis, or locomotor ataxy.

The operation consists in exposing the nerve, lifting it either with a hook or with the finger, and stretching it to a certain point. To what extent may we stretch? By translating the tabular conclusions in their application to *disease*, the conclusion is reached that no sciatic nerve should ever be stretched by a greater weight than between 30 and 40 pounds. By pulling upon a dynamometer, a very strong man, pulling with both hands, can only pull up to about 80, 90, or 100 pounds. But if you pull as you would pull a nerve, you will find that 30 pounds is about the limit of your pull.' Taking then the limit of 30 pounds for the sciatic nerve, of course this would be graduated downwards for smaller and smaller nerves. The fingers prove to be the only suitable instruments for stretching. Surgeons should educate their feeling of resistance, so as to be able safely and adequately to stretch a nerve, adequately in order to cure, safely so as not to injure the patient. The nerve yields sensibly to your traction; you feel an internal creeping movement in the particles of the nerve—of the sheath, no doubt; you feel a certain attrition and vibration going on; and you must educate yourselves to that and you will be safe.

As to the mode of pulling, and how long that pull should last, a continuous stretch of five minutes is considered as sufficient; stretch both ways for neuralgia. Stintzing says stretch downwards for tabes, upwards for neuralgia.

The cutting operation is not the only way of stretching nerves—in the case of the sciatic, by bending the thigh upon the body, so that the knee comes up to the chin, then straightening the leg upon the thigh and flexing the foot upon the leg so as to stretch the ankle joint also, the sciatic nerve, as proved on the dead body by Trombetta, can be stretched one inch. This mode has produced relief in four cases of tabes dorsalis. The use of Sayres' apparatus for suspending the body, and the consequent elongation of the body from an inch to two inches and a quarter, led Motschutkowski to experiment, finding the spine elongated to seven-eighths of an inch, although the membranes moved, he was not sure of more than a slight degree of tension on the posterior nerves. He applied this to fifteen cases of locomotor ataxy, for ten minutes at a time three times a week, succeeding in thirteen cases in relieving the pains and abnormal sensations.

The dangers are comparatively few. There are undoubtedly three or four cases where the death may be attributed to disease of the spinal cord, set up by nerve-stretching.

THE first number of the *Archives of Pediatrics* has appeared, and presents a very creditable make up. It is well printed, on good paper and in a very convenient form for reading. It contains two original articles, one by Dr. Wm. T. Plant, on Convulsions in Children, and one by Dr. D. C. Cocks, on Fifteen Cases of Tracheotomy; a clinical lecture by Dr. Louis Stair, on Chronic Gastro-Intestinal Catarrh in Children; clinical memoranda by Dr. Wm. P. Northrup, on a case of Expiratory Dyspnœa from Enlarged Bronchial Glands in a Case of General Tuberculosis and Empyema. The translations and abstracts are quite full and well selected. The editor is Dr. William Perry Watson, Jersey City, N. J.

SATURDAY, FEBRUARY 16, 1884.

The New Medical Law of Virginia.—An act for regulating the practice of medicine in the State of Virginia has very recently passed both branches of the Legislature, received the approval of the Governor, and therefore become a law. A letter from one of the most eminent members of the profession in that State gives the more important features of the act as follows:

"Let it now suffice to state that it requires all applicants, including graduates of any and every medical school, to undergo an examination before a Licensing Board, which shall consist of men learned in medicine and surgery, and shall be appointed by the Governor from a list of names to be recommended by the Medical Society of Virginia. This Society is composed of the best elements of the profession in our State, zealous for the best interests of the profession, and completely independent of the medical schools in the State, whose graduates will be required to undergo the same examination as other applicants. This system has worked well in Alabama, where most of the rejected applicants have been graduates of legally established medical schools. I have always thought that whatever might be the influence of the example of a few exceptional schools, there could be no general reform until there was an entire divorce of the schools and the licensing authorities."

We congratulate our Virginia brethren on having a law for regulating the practice of medicine that does not nullify itself by recognizing a diploma from every institution called a medical college as sufficient evidence of fitness on the part of its possessor to practice medicine. There are three, and perhaps only three, legitimate objects to be accomplished by legislative enactments for regulating the education and practice of the medical profession. The first is, to define what shall constitute the minimum of attainments necessary to constitute an adequate medical education. This would necessarily include the general education needed to qualify one to enter upon the study of medicine, as well as the minimum length of time and opportunities required in the gaining of strictly medical knowledge. The second is the establishment and maintenance of an adequate State Board of Examiners, for thoroughly examining, both theoretically and practically, all applicants for admission to the practice of medicine. In other words, establish a competent tribunal to ascertain and enforce the standard of education required. The third should consist of a simple provision by which the certificates of similar boards in other States should be recognized, so as to maintain a comity of rights and interests between the States.

A New State Medical Society in New York.—We learn through a correspondent in Albany, N. Y., that at the annual meeting of the old Medical Society of the State of New York, the friends of the National Code of Ethics and of the maintenance of harmonious relations with the National Association and the social organizations of other States, were not numerous enough to reverse the action of the Society taken at the two preceding annual meetings.

They consequently withdrew in a body, and proceeded to organize a new State Medical Society, which is to hold its first regular annual meeting in New York City in November next. A new County Medical Association was organized in New York county two or three weeks since. The work of reorganizing thus begun will doubtless go on until the great mass of the profession in that State are again represented in the National Association, and are placed in harmony with the profession in the other States.

A National Pharmacopœia.—The bill introduced into the House of Representatives, at Washington, for framing and publishing a pharmacopœia of true national character, a copy of which was published in this journal for January 26, is making favorable progress in the Committee of Ways and Means, to which it was referred, and is strongly recommended by several of the more influential medical journals. We again ask that all our readers who approve the measure, shall lose no time in exerting their legitimate influence with members of Congress from their

respective districts in favor of the early passage of the bill. For other medical matters before Congress we refer to our correspondence from Washington, in another part of the JOURNAL.

A HINT.—Dr. Clevenger, of this city, suggests as a ready means of ascertaining the existence and location of small abrasions, needing a touch of the caustic before holding a post-mortem examination, the holding of the hands over strong aqua ammonia for a moment, when the smarting will quickly reveal all the sensitive or abraded places, however minute.

CORRECTIONS.—In the list of those who attended the meeting of the Association at Cleveland, as furnished by the Secretary and published in the last number of the first volume of the JOURNAL, the name of J. W. Hoff, M.D., of Pomeroy, Ohio, appears in the list of members by invitation. The Secretary informs us that it should have appeared as a delegate from the Meigs County Medical Society.

SOCIETY PROCEEDINGS.

The Chicago Medical Society held its semi-monthly meeting on the evening of February 4, 1884. After the usual routine of business had been transacted—election of new members, etc., Dr. S. V. Clevenger gave a report of a case of "Paretic Dementia in a Female," in which there existed peculiarities to justify us in giving a synopsis of it for publication:

Kate M., æt. 37; Irish; married, was admitted to the Cook County Insane Asylum April 12, 1883. Very intemperate before insanity was noticed by friends. October, 1881, furor appeared and lasted three weeks. She remained in St. Joseph's Hospital (this city) till mania abated, when a remission occurred, lasting till December 25, 1881, when (as her family state) she had "cramps" which lasted a week. She was then sent to Detroit, Michigan, State Retreat, where she remained until the latter part of July, 1882. Little was elicited concerning her last remission, except that she was errabund. The first remission, friends claim, was complete. Just prior to admission into the Cook County Asylum, delusions of persecution were observed. Exhibited marked paretic symptoms; tremulous oral and lingual muscles from the date of admission. Speech drawling, tremulous; feels extremely well satisfied; had unsystematized delusions of grandeur; gave little or no trouble till August 30, 1883, when hemiplegia followed a convulsion, and next day she died without having been roused from stupor. It was ascertained that her father had died of consumption of the bowels, and that her mother, at the age of 60, died paralyzed; also that this patient had never borne children, nor had she ever menstruated. Any hereditary predisposition denied. Necropsy eight hours after death. Uterus very small; resembling that of a child of sixteen; left ovary atrophied. Os tiucæ imperforate; vagina patulous and large; a third nipple well developed below left breast. The brain weighed 39 ounces after preparation in solutions for microscopical examination, hence weights as here given have a relative value only. (The author is skeptical as to any importance attaching to absolute brain weights, and of late years will often omit weighing until the tissue is hardened). Cerebellum weighed 4¾ ounces. Each hemisphere weighed within a few grains of 16⅜ ounces; the left side then can be considered under weight. Cholesterin abundant, especially in occipito-basilar regions. Right antero-posterior diameter of medulla slightly less than left. Isthmus weighed an ounce; vermis of cerebellum warped toward left side, causing left aspect of the organ to appear larger than that of the right. Cortex did not pull off with pia mater loose from medullary substance, as noted in some cases by Spitzka, but in many parts of parietal and occipital regions the pial adhesions were sufficient to bring away the outer layers of cortex, imparting the ragged, ulcerated appearance to which Rindfleisch called attention. Heterotopia found in anterior parietal region. Cortical pial adhesions occurred in the lowest extremity of right occipital lobe, with connective tissue proliferations filling widened sulci.

This condition was extreme at base of first frontal convolutions on both sides. Fibrous trabeculæ, clubbed and twisted, extended downward from pia mater, covering four to five square inches, filling interstices left by shrunken gyri and atrophied gray substance. In the white substance, external to the right lobulus cuneus, a cone-shaped area of yellow softening, with apex curved forward, was found, measuring one inch in length, tapering from three lines in diameter, It was apparently the colloidal necrobiosis of a thrombosed terminal branch of the posterior cerebral artery. The gelatinous contents of the cone were mixed with detritus of the degenerated blood-vessel. Sections microscopically examined afforded views of kinked and distorted vascular channels, often twisted glomerularly. Knobbed vessels were frequent, and perivascular spaces more so, some clear, others dotted with granular masses. Evidence of capillary stasis, general and decided, while dark bodies, resembling embryo connective tissue corpuscles, abounded. No well-defined Meynert "spider-shaped cells" were discovered. The ganglionic elements were shrunken and their processes illy defined. A few large nerve cells, with granule contents, were observed lying in clear spaces, as though contracted from areas they once filled. Sclerosed patches abounded in the sections examined. With the exception of the lesions in the bregmatic region, the post-Rolandic parts were mainly involved. The ventricular endyma was nodulated in parts, affording Spitzka's "ground glass" appearance. Comparatively few healthy ganglionic bodies were discerned in over a hundred sections taken from different parts of the cerebrum.

Remarks.—The frequency of paretic dementia occurring among women, as compared with its occur-

rence among men. We have investigated thirty-nine different authorities, and have calculated the average proportion to be about one to eight. This includes Kiernan's cases. Neumann[1], from not having seen a single case, denied the existence of paretic dementia among females. Sankey[2] inclines to the belief that sexual excess plays a part in the production of the disease, but the cases he cited show that there were, in addition to the sexual excesses, great vicissitudes.

Dickson[1] favors the views offered by some writers, viz.: the liability, etc., but considers emotional mental strain as the great cause.

Luys[2] says that in existing social conditions the males lead a much more active life than the females, and they are more subject to mental and emotional overstrain than females. Dr. Clevenger thinks the emotions preponderate in women, and even though carefully housed and cared for, every woman has to bear, at certain periods, considerable tension of feeling, more probably in proportion to her possession of other mental qualities which confer endurance.

Some authors state the affection among the rural classes is markedly less frequent in females than is the case among the civic population, and is much more frequent with the hand-to-mouth, the trading and speculative classes, where the wife (Kiernan) takes an active part in her husband's business, than among the classes where she is confined at home. There is a marked relationship between the menopause and paretic dementia, as some writers have stated. There is a mental disturbance at this period predisposing to the psychosis. The prevalent type is the quiet form, which may account for the infrequency of its observation, and it is rarely met with among the female Irish in the South of Ireland.

In the discussion, Dr. J. G. Kiernan stated that, even admitting females to be more emotional than males, as they are confined to their household duties, which are more monotonous than the male class of a speculative nature, the percentage of cases among them is one to every six or eight males. In France there is a middle class (the bourgeoisie) where a wife takes an active part in her husband's business, and paretic dementia occurs in them. Regarding the ætiology, so far as alcoholic excesses go, statistics are worthless. In 160 cases reported 116 were intemperate, but this is a symptom of the affection instead of a cause. In British Guiana, where the people indulge in excesses of a sexual nature as well as the alcoholic, and also where syphilis prevails to a considerable extent, the disease is unknown, although at Berbes, where the asylum is located in British Guiana, the superintendent reported one case, that of a male who came there from Europe, who was afflicted with the malady ere he came to Berbes.

Some French authors state that syphilis is not a predisposing cause, whilst Dr. Clevenger thinks paresis is very largely due to inherited or acquired syphilis.

Dr. R. Tilley thought if emotional strain had anything to do as a cause of this debility, that a Board of Trade speculator was much more apt to have it than a mechanic who gets his pay regularly, and yet, in the large portion constituting this category (the Board of Trade), we scarcely ever hear of their being subject to it.

Dr. Kiernan stated he had no doubt that this theory is true. The easy-going (Celts) class in Ireland do not have it, as may be illustrated by their not worrying as to how to prosper. In this city the emotional strain is great on those living from hand to mouth, and they furnish the largest proportion who have this trouble, while Jessen, a Scandinavian alienist, traced all cases to congenital or acquired syphilis.

This topic being concluded, Dr. Henry J. Reynolds read, by request, a paper on The Treatment of Urethral Strictures. (See this paper published in the JOURNAL of February 2, 1884, pp. 113 to 116, to which the reader is kindly referred). A number o the gentlemen participated in the discussion that fol lowed.

Dr. W. L. Axford was much interested in the remarks embodied in the paper just read, and said the author took the extreme views as those advanced by Dr. Otis, of New York, and that the advances in urethral surgery to-day are due principally to Otis. In strictures of large caliber, the best way to treat them is to cut them, as there is but little risk in doing so. In some cases of stricture of traumatic origin, this method is hardly admissible, and Symes' operation is then preferable — external perineal urethrotomy. The value of the acorn sound is more reliable to determine a stricture than that of the urethrometer; but to use the acorn instrument, the meatus may have to be incised. I want to ask the writer if he thinks in all cases of gleet there is stricture? Answered, yes. Then in all cases of stricture is there gleet? Answered, no.

Dr. C. E. Webster cited briefly a number of cases of stricture of large caliber he had seen operated upon. The first being one in the first stage of pneumonia, subsequently died of the lung trouble. The second case, that of organic disease of the heart, who died of the heart affection, and a third case operated on having Potts' Disease. None of these patients were benefited by the operation. The same surgeon, who is a teacher in a well-known school, operated for phymosis in a case of bow-leg, expecting thereby to relieve this deformity, as no other treatment for the bow-legs was recommended; then the following two questions were asked the reader of the paper:

First, whether he would operate upon a stricture of large caliber if no local symptoms were present? and secondly, whether acorn sounds of large size, which pass by dilating the urethra, may not indicate a stricture where the condition is not pathological, but simply due to a varying degre of elasticity along the tract of a healthy organ.

Dr. C. T. Fenn gave his experience as a physician (more than that of a surgeon) in introducing the finest sound, by reciting a case that not long since had been under his care. One of our well known surgeons also saw the case with him, in consultation, but in his essaying to pass the smallest steel sound,

[1] Lehrbuch der Psychiatrie, 1859.

[1] Medicine in Relation to Mind.
[2] Maladies Mentales.

had failed, and then resorted to aspiration of the bladder over the pubes. I had previously, however, introduced a filiform bougie, and the passage was effected by "passing it around" the stricture, as was determined at the autopsy, when the stricture was dissected, and found to be "fibrous," and in connection with it there was infiltration of urine, which caused death. The speaker did not agree with the author of the paper, in wanting to operate on so many of this class of cases, and thought the operation should be approached with no little amount of temerity, as the dark urethral channel could not be seen whilst operating upon it.

Dr. R. Tilley asked the reader why he thought it was necessary, in his cases, to render the urine alkaline before operating? and why this is better than the normal urine, which is but slightly acid? Normal urine, as he believes, is practically innocuous to wounds.

Dr. G. C. Paoli's experience and observation warranted his saying that only temporary benefit was derived from cutting operations, and that we should be very careful in making these incisions. Exudation takes place in two or three years, at longest. He has treated between 500 and 600 cases of stricture of the urethra by gradual dilatation. His patients were satisfied with this continual method, and all were successful, so far as he knew, without the cutting, and he believes we should attain the object by the method of gradual dilatation, and that it is far preferable. He then gave a history of a case which was operated on thirty-four years ago in Cincinnati. There was considerable hæmorrhage at the time. Temporary success followed, but in a short time the caliber of the canal became lessened and indurated. Every fortnight for a long period of time he passes a No. 8 or 9 Otis curve sound.

Dr. L. H. Montgomery thought stricture in the male a cause of sterility, and that the power of propagation was in many instances lessened by it, and inquired of any or all of the members what their ideas about this are? and also of the writer, how long he required a patient to take an alkali before the urine became alkaline? and if bicarb. of soda in 3ss doses is not superior to the citrate of potash to render urine alkaline?

Dr. D. W. Graham said that one of our eminent men in this city stated long ago he thought a previous attack of gonorrhœa would cause sterility in the male. The gentleman now having the floor opined that to cut a stricture is malpractice—and further than this, to cut what is revealed by an acorn sound he regarded also to be malpractice.

Dr. Reynolds, in closing, said he thought it was essentially necessary to dilute the urine, to do so, a patient will not void it so frequently, and in cystic irritation it should be rendered alkaline. In answer to Dr. Webster, he thought the condition to which he alluded would be extremely rare so far as relates to his second question, and regarding his first question, a patient would not know he had stricture unless local symptoms presented. For then a patient will consult us, and I probably should then advise an operation. Regarding one speaker's interrogatory about stricture being a cause of sterility, I think this is not the case, also that the bicarb. of soda or potash, given for two or three days, is equally as good as the citrate of potash to produce alkalinity of the urine.

The resignation of Dr. D. F. McPherson was accepted, on account of his removing to Buffalo, N. Y

The Society adjourned at a late hour.

L. H. M.

DOMESTIC CORRESPONDENCE.

FROM WASHINGTON.

The following bills of medical interest have been introduced in Congress:

January 7.—By Mr. Ellis, H. R., 2211. To construct, maintain, and support a floating ward or hospital in connection with the United States Marine Hospital at New Orleans. This bill appropriates $30,000 for this purpose, and is to be for the reception, treatment, and maintenance of all United States Marine Hospital patients, and of foreign sailors admitted thereto, suffering from contagious or infectious diseases. It is to be moored in the stream of the Mississippi River, to be properly isolated, and served by a suitable steam launch, purchased for the purpose out of the balance of the appropriation.

January 7.—By Mr. King, H. R., 2219. To investigate the origin and spread of charbon in animals. This bill appropriates $5,000, to be expended under the direction of the Commissioner of Agriculture.

On January 15, a resolution was introduced in the House by Mr. Green, of North Carolina, to authorize the Committee on Public Health to employ chemical and medical experts, and to make a thorough investigation into the adulterations of food, drink, and medicine, and report thereon. The resolution was referred to the Committee on Public Health.

We have already given on page 23, vol. 2, of this journal, the text of the bill now before Congress, to provide for suitable accommodations for the Medical Museum and Library of the Surgeon-General's Office, U. S. A., but the matter is of so much importance that we take the opportunity of referring to it again, by calling attention to Ex. Doc., No. 12, Senate, 48th Congress, 1st session, which is the official title to an illustrated pamphlet embodying the views of some of our prominent medical men, the resolutions of the American Medical Association, the reports of the Committee on Public Buildings and Grounds, and the detailed argument of the late Surgeon-General Barnes, setting forth the urgent necessity for the proper care of the Museum and Library. Three large-sized illustrations give the details of the proposed structure, which, if adopted, will be a handsome, commodious and convenient building. This is a public document, accessible to all, free of charge, through their members of Congress, and should receive wide circulation; as all who read it will be convinced of the importance of adding what political influence they may be able to exert in favor of the project. We say political influence, for though it

may be a distasteful expression to many medical men, it is the most comprehensive term to apply to the situation.

January 8.—Mr. Randall introduced a bill, H. R., 2697. To prepare and publish a National Pharmacopœia for the United States. It requires the detail, as soon as practicable, of two officers of the Marine Hospital Service, of two officers of the medical staff of the Army, and two officers of the medical staff of the Navy, for the duty of compiling and preparing a pharmacopœia, which shall be known as the "National Pharmacopœia of the United States of America," and shall be held and accepted as the standard for the purveying, compounding, and dispensing of drugs or medicinal agents, and shall be taken as authority in the Treasury Department on all questions arising under the tariff laws of the United States with regard to the nomenclature, description, and purity of drugs or remedial agents, and shall further be received as evidence in the United States courts. And the matters contained in the said pharmacopœia shall be free for use by all authors and commentators for the benefit of the medical and pharmaceutical professions and of the community at large; and it shall not be lawful for any one to reprint and publish the said pharmacopœia as a whole.

SEC. 2. That the medical officers detailed as above provided shall invite the American Medical Association and the American Pharmaceutical Association, at their next annual meetings, to form committees of not more than three members from each of the said associations, which committees, if so appointed, may coöperate with the above-named medical officers in the preparation of said pharmacopœia, forming a board which shall have power, from time to time, to add to its number as may, in its judgment, be necessary, and which shall elect a chairman and a secretary, and adopt such rules as it shall see fit for the expediting and perfecting of the said pharmacopœia. It also calls for an edition of not less than 5,000 copies, and appropriates $5,000 for the necessary expenses.

Section 4 declares that the pharmacopœia shall be revised once in ten years upon the plan embodied in this act.

Mr. Young introduced a bill (H. R. 2785), to prevent the introduction of infectious and contagious diseases into the United States, and to establish a National Board of Health. It amends and enlarges the provisions of an existing act in the relations of the Board to State and municipal boards of health, to vessels and their cargoes, to consular officers, requiring of them weekly sanitary reports to the Board. The Board is required in turn to make weekly reports embodying all such sanitary information as may be at their disposal, and to issue sanitary rules and regulations. The unexpended balance in the U. S. Treasury, $127,083.50, is made available for the purpose of carrying out the provisions of the several acts, to which is added the $100,000 appropriated for use in case of epidemic.

Jan. 9. Mr. Miller, of New York, introduced a bill, Senate, 982, for the maintenance and support of the Marine Hospital Service solely by the United States Government; and,

Jan. 15, Mr. Jones, of Florida, introduced a bill, Senate, 1105, to erect a building for a marine hospital at Pensacola, Florida, appropriating $75,000 for the erection of the building.

Jan. 11. Mr. Call, of Florida, introduced a bill, Senate, 1044, to establish a University of Medicine at the Capital of the United States, in the District of Columbia, for the advancement of science and the discovery of improved methods of treatment and cure of disease.

Section 1 appropriates $1,000,000 as a perpetual endowment.

Section 2 appropriates $100,000 for the erection of buildings and purchase of ground.

SEC. 3. Provides that the interest on the one million of dollars shall be annually paid for salaries of the professors and the expenses of the University.

SEC. 4. That the professors' chairs shall be open to all schools of medicine, and all methods of treatment and cure of disease.

SEC. 5. That the allopathic, homœopathic and eclectic schools of medicine shall all be represented in the professional chairs of said University, free and impartial opportunity to be afforded for proof of the value of each of such schools of medicine, and of methods of treatment, the end and purpose of this university being to apply the severest processes of reason and experiment to all alleged discoveries and remedial agencies for the cure of disease, etc.

SEC. 6. That the Board of Trustees shall decide what professorships shall be established; and whenever any system or method of cure of disease shall obtain any considerable hold on the public mind, it shall be the duty of the said Board of Trustees to allow the professors of such system to appear at this University and submit the same to scientific examination and practical experiment and proof.

SEC. 7. That suitable hospitals for the treatment of diseases according to the methods of all systems, and for experiment with all remedial agents, shall be established, etc. etc., and if the treatment or experiment is upon a person in good health, an accurate statement shall be made of the results, etc.

We should watch with considerable interest the development of this new University, particularly as regards the establishment of allopathy. The advocates of medical dogmas, and consequently the laity generally, have for a long time been applying this term of allopathy quite promiscuously. Here is an opportunity to determine who there are among medical men to whom this term can be applied. The provisions of the bill admit of no misunderstanding, and it is necessary for the proper organization of the University that there be such a school, and that it be represented, and of course, under such circumstances, it will have to be clearly defined. Ought not the representatives of the faith cure and of total abstinence from alcohol also to be explicitly provided for in the bill? They certainly have obtained considerable hold on the public mind. Where the patients are to come from, in view of the clearly expressed determination to experiment in the severest manner, is

another question, but probably that is of secondary importance.

Mr. Hale, of Maine, on January 22, introduced into Congress Senate bill 1,223, to the effect that all appointments to medical service under the government shall be made from graduates of legally chartered medical institutions, without discrimination in favor or against any school or theory of medical practice. That any violation of the foregoing section shall be punished in the same manner as prescribed for like offenses by the act entitled "An act to regulate and improve the civil service of the United States," January 16, 1883.

It is hard to see how such a bill, if passed, is going to be carried into effect. It takes away a privilege which was at one time claimed by the Examining Board of the Army and Navy Medical Corps, that of examining all candidates without reference to their diplomas, *i. e.*, to whether they were graduates of a medical college or not, and restricts them to graduates in medicine for the future. But to say that they shall not discriminate in favor or against any theory of medical practice, is simply nonsense. For what other purpose are they appointed?

NECROLOGY.

HARRIS, ELISHA, A.M., M.D., of New York, was born in Westminster, Vt., March 5, 1824; died of peritonitis, after four days illness, in Albany, New York, January 31, 1884. He was the son of a farmer, and attended in youth the schools of the neighborhood and assisted his father at farm work. When sufficiently advanced he taught school, and Woolworth, and after attending the usual course of lec- commenced the study of medicine with Dr. S. B. tures graduated M. D. at the College of Physicians and Surgeons of New York in 1849. His love of study and the facilities which the City of New York afforded, determined him to begin practice there. Shortly after this he was united in marriage to the only daughter of the Rev. Joseph B. Andrews. The union was a happy one, but his wife died without children in 1867. The doctor never married again. Dr. Harris early gave evidence of special aptitude for systematizing reports on public health questions. In 1855 he was appointed Superintendent and Physician-in-Chief of the Quarantine Hospital on Staten Island. So acceptably did he discharge his duties that in 1859 the building of the floating hospital, to be anchored below the Narrows, facing the open sea, was intrusted to him. Dr. Harris was a man of good physique, temperate habits, of an equable temper and suave manners, capable of a prodigious amount of labor. He was all his life an extensive reader of the best literature, and was as well informed upon State and sanitary medicine as any physician in America, or perhaps in the world. Dr. Harris enjoyed a wide correspondence for many years with the most distinguished sanitarians through Europe and the United States, and his opinions on sanitary matters were held in the highest esteem. On the breaking out of the war of the Rebellion, he, in conjunction with the Rev. Henry C. Bellows and others, organized the National Sanitary Commission, and for nearly five years gave his time to that humane work. The railway ambulance was his invention, and which proved of such inestimable service during the war. The Exposition Universal in Paris awarded him in 1867 a bronze medal in recognition of its value. A silver medal was also granted him for the same ambulance by the Société des Secours aux Blessés. This railway ambulance was adopted and has been used in the Prussian Army and in the Franco-Prussian war. Dr. Harris devised the system for a record of the deaths and burials of soldiers which became general in the army. His eminent ability as a statist, and familiarity with the work of the National Sanitary Commission, led to his being selected as chief editor of the "Sanitary Memoirs of the War," which were published in several volumes. At the close of the war he again turned his attention to the sanitary condition and needs of the city of New York. And as a voluntary work he supervised a sanitary survey of the city. The study was published by the Appletons, and proved of great value to the city of New York, as well as to all students of sanitary science. On the organization of New York Metropolitan Board of Health, in March, 1866, Dr. Harris was appointed to the position of Registrar of Records, which he filled with ability until 1870, when a change of administration led to his retirement. In 1873 he was appointed Registrar of Vital Statistics, which position, by a change of city politics, was taken from him in 1876. But although Dr. Harris was relieved of office he never gave up his enthusiastic devotion to sanitary and public health studies. One of the best investigations and most fruitful of immediate advantage to the poor in the city of New York, was his thorough tenement house survey in 1869. Bad as the tenement houses are now in that great metropolis, things were a hundred-fold worse before the facts were collected and tabulated, and their danger to the public health so graphically delineated and laid before the legislature and the city authorities. Dr. Harris was a prolific writer on sanitary and reformatory subjects. The extent of his labors and writings is a matter of wonder to those who knew him best. Among his works the following were regarded as worthy of mention: Four reports on "Quarantine Hospitals, Yellow Fever, and Cholera," "An Essay on Pestilential Diseases," "Ventilation of American Dwellings," "Reviews of the Sanitary Experiences of the Crimean Campaign," "A History of the Work and Purposes of the United States Sanitary Commission," "A Practical Manual on Infectious and Contagious Diseases in Camps, Hospitals, and Ships," "The Citizen's Report on the Sanitary Condition and Wants of New York," a volume that has passed through several editions; "The Criminality of Drunkenness," "Nine Reports on Reformatory and Penal Institutions," "Six Reports of the Bureau of Vital Statistics of New York," "Reports of Sanitary Superintendent of the Metropolitan District of New York," "Four Reports of the American Public Health Association," Chapters in the Medical and

Sanitary Memoirs of the War," "Report of the Sanitary Government and Vital Statistics of American Cities," "Vaccination and Small-pox, and the Lessons of Jenner," "Reports and Transactions of the State Board of Health," "Report on a Uniform System of Vital Statistics in the United States." Dr. Harris was also widely known for his philanthropy. He was for many years identified with the Prison Association for the care and reformation of discharged convicts; a member of the society for improving the domiciles and condition of the poor, and of various other benevolent societies. Dr. Harris was a member of the County and State Medical Societies, the New York Academy of Medicine, the Physicians' Mutual Aid Association, the Society for the Relief of Orphans and Widows of Medical Men, the Medical Journal Association, and the Public Health Association of New York. He became a member of the American Medical Association in 1853, and attended meetings in 1860, 1864, 1868, 1872, 1876, 1877, and 1880. A member of the International Centennial Medical Congress in Philadelphia in 1876. He was one of the chief originators of the American Public Health Association and its Secretary for a number of years, and its President in 1879. Ever since its organization he has worked zealously for its success, and to promote its influence and advance the science of sanitation through all the States. The National Board of Health was the natural outgrowth of this organization, and for which body he also worked zealously. For some years Dr. Harris has held the position of Secretary of the New York State Board of Health, a position he was eminently qualified to fill. He fell at his post of duty. Few men have devoted themselves more zealously to their chosen path of professional labor, or have followed it with greater ability and less selfishness than has this great champion of sanitary science—Elisha Harris.

J. M. T.

In Memory of the late Dr. Benjamin Tappan.—At a special meeting of the Jefferson County Medical Society held in Steubenville, Ohio, January 21, 1884, it having been announced that Dr. Benjamin Tappan, aged 71 years, died on the 17th inst., at his home in this city, the following testimonial was ordered to be spread upon the records of the society:

Resolved: That in the death of Dr. Benjamin Tappan, one of its founders in 1858, and for many years its President, the Jefferson County Medical Society has lost a distinguished physician and surgeon, a profound scholar, a clear and independent thinker and logical reasoner, who, during his most extensive and successful medical and surgical practice, did very much to advance medical education and elevate the standard of professional knowledge. Skillful, self-reliant, persevering, and always a student, he possessed the elements of professional success, and was remarkable for the charity with which he bestowed with devoted attention, his able services among the poor. His scholarly attainments were not confined to his profession and allied sciences, his range of scientific knowledge being very comprehensive and complete, ranking him among the most learned of the profession.

With brilliant intellect and great force of character, he was often a warm friend or a formidable opponent.

The society hereby tenders its warmest sympathy to his bereaved family in their great affliction, and directs that a copy of these proceedings be presented by the President of this society to the family of the deceased, and that the Secretary furnish copies of the same to the Journal of the American Medical Association and city papers for publication.

ORIGINAL ARTICLES.

ON THE IMPORTANCE OF TRACHELORRAPHY, WITH CASES AND REMARKS.

BY JOSEPH TABER JOHNSON, A.M., M.D., OF WASHINGTON, D. C.

Professor of Obstetrics and Gynæcology, Medical Department University of Georgetown, Gynæcologist to Providence Hospital, Fellow American Gynæcological Society, etc.

[Read before the Washington Obstetrical and Gynæcological Society, Jan. 13, 1884.]

I should not be bold enough to present a paper upon so hackneyed a subject as the treatment of laceration of the cervix uteri, were I less impressed with the importance of this lesion, and the necessity, in aggravated cases, of its cure by Emmet's operation.

From some quarters we hear distant murmurs of disapproval and opposition, and nearer home we learn that from the lack of evidence to the contrary, it is concluded that this operation, which has been heralded as one of the greatest improvements of the age, does positive harm, by making the last state of the patient worse than her first.

I trust I shall be able to impress the society with the truth and justice of the claims which have been put forth for the surgical treatment of cervical laceration, and of the error of those who oppose it.

Of the importance of trachelorraphy, we have the testimony of Marion Sims, given in the discussion which followed the reading of Emmet's second paper on this subject to the Medical Society of the city of New York, in Sept., 1874. Sims said: "I have performed this operation often enough to speak in positive terms of its value. The discussion must, of necessity, be one-sided. There can be no objection, no opposition to the operation; we must accept it as Dr. Emmet has given it to us, for it is perfect—perfect in its methods, and perfect in its results. Like all new operations, it is likely to be abused; but the time will soon arrive when it will assume its place in the foremost rank of useful improvements."

Dr. Fordyce Barker, when a paper of Dr. Walter B. Chase was being discussed, in June, 1878, said: "I think there can be no doubt that the first paper of Dr. Emmet upon laceration of the cervix, associated with the puerperal state, is one of the most important contributions which have been made to gynæcology;" and Thomas, in the 4th edition of his work, says: "even if its eminent author had done nothing else to lay his profession under obligation, Emmet's paper would indelibly write his name upon the records of gynæcology. No one contribution to this department which has been made during the last half century has exerted a more marked influence upon uterine pathology than this is now doing, and will do in the future. None will have more influence in abolishing useless and hurtful therapeutical measures." And in his 5th edition, p. 352, he speaks thus: "It is surely not too much to say of it, that it constitutes one of the most important contributions to gynæcology which has ever been made."

I make no mistake then, Mr. President, in my estimate of the importance of this subject, and am in good company when I urge, with some enthusiasm, the more frequent performance of trachelorraphy than, I believe, has heretofore been the practice of surgeons in our city.

The danger has been with this, as with other important innovations, that errors in diagnosis and judgment would occur and disrepute be brought upon a very valuable operation by its unwise, unskillful and too frequent repetition.

An English Gynæcologist is quoted by Dr. C. C, Lee in his paper on "the proper limits of Emmet's operation," as follows:

"American surgeons seemed to pass their time between dividing the cervix when nature had left it intact, and sedulously stitching up the fissures which parturition left upon its surface."

Foreign gynæcolgists often misrepresent and then oppose trachelorraphy. I have conversed with several of our best American gynæcologists who have lately visited Europe, and they all agree that in plastic gynæcological surgery the English are far behind Americans in skill, dexterity, convenient instruments, neatness and success.

In ovariotomy they excel us, or have produced better results, but whether their greater success is owing to climatic influences, environment or skill, may be an open question. Thomas attributes it to the former rather than the latter.

Savage, Tilt and Duncan, Howard of Baltimore says, are still practicing gynæcology with Ferguson's cylindrical speculum, and should be forgiven for not recognizing a condition, which they cannot see or appreciate through an instrument which, according to Emmet, should never be used, except as a safe means of applying harsh treatment to the cervix, at the same time protecting the vagina.

This, and similar remarks of Tilt and Savage have been quoted so frequently against Emmet's operation,

that I desire to read a few words from Howard's Report of the Section on Obstetrics and Gynæcology, Baltimore, Md., April, 1883, in which he replies to the following remarks of Mr. Savage in the Obst. Soc., of London, March 1, 1882.

"The American school profess to believe that every disease (none excluded) incidental to the uterus may be, and generally is, the direct consequence of a cervical laceration. The English school disbelieves this on good grounds." Howard says:

"To what class of persons do these eminent English gynæcologists address themselves? Were they to attempt to verify their bald affirmations by the writings of the acknowledged exponents of the American school, they would soon find that they had not even the cobweb texture of *truth* to rest upon. American gynæcologists do *not* slit the cervix up to the os internum to cure a so-called ulceration, due to a slight cervical fissure. They do *not* believe that every disease of the uterus is generally the direct consequence of a cervical laceration; and they certainly understand the importance of judicious medical and local treatment as well as the English or any other gynæcologists, anywhere to be found, as their works amply attest to all candid and earnest inquirers after truth. * * * But the ablest American gynæcologists well recognize the conditions and indications which render trachelorraphy judicious and proper."

In speaking of Tilt's injustice to Emmet and Sims, and his criticism upon their operations, Howard says: "This is easily accounted for, as Tilt habitually uses the cylindrical speculum of Ferguson, and thinks the habitual use of Sims' speculum in uterine surgery is like using a steam hammer to kill a fly."[1] I cannot help thinking, in concluding the subject, that trachelorraphy deserves to rank among the most important contributions that have ever been made to gynæcology, and that during the past eight years the true indications for its performance have been more accurately ascertained, and its real value more correctly determined. * * * Moreover, as epithelioma often arises from local irritations, and a lacerrated cervix is constantly exposed to friction during respiration and locomotion, it is reasonable to infer, as indeed American experience amply attests, that this dreadful malady not unfrequently finds its point of departure in a cervical laceration."

In January, 1878, at the State Medical Society's annual meeting, in Albany, Drs. Barker and Jacobi, in discussing this subject, thought the operation was performed too often, and that many cases of slight laceration would recover without the knife, by observing cleanliness and the use of repeated astringent applications. This is not denied, but both gentlemen admitted that many weeks and sometimes months of treatment were required to complete a cure, and that relapses were constantly liable to occur. In the severer cases, where the laceration is at all extensive, would it not be more rational to submit a patient to a radical operation, which in three weeks would accomplish that which confessedly takes them, by medical treatment, months of expensive local applications to bring to pass? Their patients are then liable to constant relapses, the probability of abortion, and all to the development of cancer.

Goodell says this is one of the safest and most universally successful operations in surgery, and lends the weight of his name and reputation to its more frequent performance.

Writers differ as to the percentage of cases of laceration of the cervix following delivery. Emmet places it at 33 per cent.; Mundé, 22; Pallen, 45. Goodell thinks one woman in every six who has children sustains this injury. The percentage of cases requiring operative aid is comparatively small. Many lacerations heal during the puerperal period, and a certain proportion give rise to no symptoms, and require no aid; but in those instances when symptoms *do arise which are not curable by rest, cleanliness, and astringents, I contend that trachelorraphy is the most rational mode of treatment*, and should be resorted to.

The effect which this operation has been supposed by a few obstetricians to have in preventing conception, and in causing delay, difficulty, and relaceration in succeeding labors, was discussed in a paper in the January, 1883, number of the *Obstetrical Journal*, by Dr. P. J. Murphy. His arguments, which appeared to me at the time erroneous, have been so completely refuted by statements to the contrary published in the same journal, and in many personal communications from prominent operators, that I only refer to the subject in passing, and will now proceed to the narration of the cases which form the basis of this paper.

Case 1. My first case was Mrs. F.; white; age 24; mother of one child, which was delivered stillborn with the forceps. She suffered for several weeks from an attack of pelvic inflammation, but seemed to recover, and resumed her usual avocations. She soon began to complain of pains in back and loins, and was greatly troubled by a profuse leucorrhœa, which, about the time of the monthly period, became offensive. Sexual appetite was abolished; intercourse was painful, and frequently followed by a discharge of blood. She was the victim of more than usually troublesome nervous symptoms. She had the same difficulty in walking, standing, lifting, and going up and down stairs, which women complain of who were formerly supposed to suffer from ulceration of the neck of the uterus. This condition of things went on for about two years. She would get better under treatment and rest, but upon resuming exercise and neglecting treatment she would soon become as bad as ever.

I was requested to see her by Dr. B. B. Adams, and upon examination, recognized a unilateral laceration of the cervix, extending up to its junction with vagina on the left side. I explained the nature of the case, and suggested Emmet's operation as a radical cure. The suggestion was at once accepted, and the time set for the operation. While visiting my office to undergo a preparatory treatment which was considered necessary, on account of some remaining tenderness in the cellular tissue, Dr. Mundé, who was at my house for a few days, examined her. He fully confirmed my diagnosis, and thought it a typical case

[1] Uterine Therapeutics, 4th ed., p 31.

for operation, and on April 12, 1882, I operated, with the assistance of Drs. Ashford, B. B. Adams and Mallan. Four silver wire sutures were inserted. The patient remained in bed ten days, suffering scarcely any pain. Her water was drawn four times daily for three days, after which time she was allowed to use a bed-pan. Antiseptic vaginal injections were used after each act of micturition. The sutures were removed on the ninth day, and perfect union found to have occurred. Recovery was uninterrupted, and the patient is to-day entirely relieved from all the disagreeable symptoms which had so constantly annoyed her for two years. Coition occurs without pain, and the sexual desire has returned stronger than ever. She has gained about 40 pounds of flesh, and walks down town to church and back home without fatigue.

Case No. 2 Mrs. P., a widow lady with one child about three years old, consulted me on account of profuse and offensive leucorrhœa, back-ache, sick headache, menorrhagia, many nervous symptoms, and an inability to walk. Said she had not walked three squares in two years. Upon examination, I found a double laceration of the cervix. The space between its separated edges was filled in with everted and prolapsed mucous membrane, constituting the ectropion described by Emmet. This mass bled easily when touched by the finger or the speculum. I treated her some months with varying success, never succeeding in getting a healthy surface, and always having a complete return of her symptoms soon after a suspension of the local applications. I finally proposed trachelorraphy, which was readily agreed to, and after another month spent in preparatory treatment, I operated, with the assistance of Drs. Kleinschmidt, Mallan, Rice and Sumner. I had been impressed with the importance and necessity of great care in the after-treatment of these cases. My first operation was looked after with all the zeal of a young mother caring for her first and only child. I gave the most minute directions about rest in bed, the water, bowels, diet, etc. In making my visit about noon on the third day, I found my second patient up and dressed, eating deviled crabs and drinking beer. She said, in reply to my expostulations, that "she felt perfectly well, and could not afford to fool her time away in bed."

This patient could not be controlled, and spent no more time in bed. But she promised if she felt any pain or trouble of any kind to do as I advised. I removed the sutures on the twelfth day, and found perfect union, except one stitch had cut out on one side, but the patient made a good recovery. She called on me several days after, in passing, to say that she had walked from her house to the capitol—more than a mile—and was that far on her way home, and was happy to state that she was less fatigued than a walk half around the square would have made her before the operation. Her other disagreeable symptoms had all disappeared.

Case 3. My third case was a lady whose age was about 30, mother of two children. This lady had about the same symptoms which I have detailed in cases 1 and 2. She had in addition a retroverted uterus, and a continuous pain upon the same side as the laceration, which I then thought proceeded from an inflamed ovary, but which I now think may have been caused by an uncured cellulitis. She had been a sufferer from bleeding piles for seven years. Many of her symptoms were attributed by herself and friends to this cause, and with kind assistance of Dr. Lincoln I operated upon the piles. After recovery, which was perfect, the left side pain continued as severe as ever.

I put her through a month of preparatory treatment, and then denuded the surfaces and sewed up the cervix, with the assistance of Dr. Mallen, who gave the ether, and Drs. Lamb and Mary Parsons, who were friends of the family.

The patient would not have a nurse, preferring to be cared for by her tender and affectionate mother, who was very willing and very anxious to do everything for the best, but was ignorant of the proper qualifications of a "trained nurse." The patient did well until the third day, when she exposed herself to cold, not wishing to disturb her mother. She was soon after seized with a chill, and the most severe case of pelvic peritonitis and cellulitis developed which I have ever known recover.

Drs. Lincoln and W. W. Johnston saw her with me, and they were both of the opinion that she would not live twelve hours. She was confined to her bed about four months, but finally made a good recovery. She was able before leaving the city to walk about town, attend church, and go shopping with much less fatigue than before the operation.

The uterus was still retroverted at the time of departure, but she suffered very little inconvenience from it.

Notwithstanding the pain and sickness following the operation the patient expressed herself as pleased with her present condition, and able to do more walking and exercise with less fatigue and pain than before.

Union was perfect along the surface of the wound notwithstanding the inflammatory condition of the neighboring tissues. There was no cervicitis or metritis. She menstruated regularly during her four months in bed, with no increase of pain. There was rather a sense of relief at the time of each period, caused, perhaps, by the relief of the congestion of the endometrium.

Case 4. Mrs. B., white, age 22, mother of three children and had had several miscarriages. I was requested to see her on account of uncontrollable hystero-epilepsy. I recognized a chronic inflammation of the ovaries, but while requested to remove the uterine appendages by patient, as well as physician, I diagnosed a deep cervical laceration on the left side, and thinking that might be the controlling cause of the nervous manifestations, I sent her to Providence Hospital, as a private patient, and there operated, with the assistance of Drs. Leach, Bayne, Mallan and Eliot.

Suffice it to say the convulsions continued and were the worst I ever saw. She tired out all the nurses in the hospital, and exhausted the resources of the house physician. Hypodermics would control her at first,

but finally only the most profound anæsthesia would allay the ovarian pain and convulsions. The operation was a failure in every respect. The stitches tore out. When I came to remove them they were hanging from one side of the cervix,

I think now if Battey's operation had been performed she would have been cured. She has led a wretched existence since she left the hospital, and may yet be operated on.

Case 5 was a charity patient in Providence Hospital. She had been in all the hospitals and dispensaries in the city where she could gain admittance, and had exhausted the patience of several corporation physicians. She had always been treated, she said, for menorrhagia, profuse and offensive leucorrhœa, enlargement and ulceration of the womb, and this had been going on for more than three years. She had the usual symptoms formerly attributed to these conditions to perfection. Upon examination, a large double laceration of the cervix was found to exist, with ectropion. She was treated locally for a month, put upon extra diet and tonics, at the end of which time trachelorraphy was performed. More tissues than usual had to be cut away. On the 9th day the sutures were removed, union was found perfect, and in twenty-one days from the day of the operation the patient was discharged cured. Here was what some would call a brilliant triumph of gynæcological surgery over medical gynæcology. By a safe, easy and successful operation she had been cured in three weeks, when three years of local applications had failed to accomplish much, if any, good. Her condition seemed to me to be rapidly approaching the appearance of epithelioma. The large, soft, easily bleeding, vegetating mass between the everted edges of the lacerated cervix might soon have become the local focus for the development of this form of disease.

Dr. Murphy, in his paper above referred to, says: "I fear I shall never arrive at that perfection where it will be given me to appreciate why a laceration of the cervix, by being repaired, will probably prevent cancer of the womb."

Goodell, Emmet, Mundé, Albert Smith, Howard and Wilson of Baltimore, Byford, Sutton, Thomas, Sims—all held the view that these unhealed cases of laceration of the cervix may, and frequently do, terminate in epithelioma.

I am treating a private patient now, who is about 30 years of age, in Providence Hospital, who has this form of cancer of the cervix. When she came to me for treatment, I thought the disease was entirely limited to this part of the uterus, and proposed to remove the entire organ by abdominal section. She readily assented, but Dr. Lincoln, who kindly saw her with me, thought he detected sufficient evidence of the disease in the neighboring tissues and glands to cause him to advise against the operation. A laceration of the cervix was very evident in this case. The patient knows of no other instance of cancer among her relations, and, upon the evidence of the writers just named, I believe the laceration to be the cause of her cancer; and I believe, also, if it had been cured by an operation soon after it occurred, she might not have had cancer, and could have lived twenty or perhaps forty years longer.

My next three cases were similar in many particulars, and I will, therefore, not tax your patience to give them separately. In one case, however, the mental depression was much greater than in the others, so that her family, with good reason, I thought, feared her mental faculties would give way. She became very sad and morose, and did and said many little things which indicated an unsound and unbalanced mind.

She, and the other two patients were annoyed by the symptoms which Emmet, Thomas, and other authors describe as following lacerations of the cervix. They all had ruptured perinæums, and I operated upon each of them at one sitting—that is, in each case I performed the double operation at one and the same time.

In the January, 1883, number of the *American Journal of Obstetrics* is published a discussion upon a paper of Dr. J. B. Hunter, one of the surgeons of the Woman's Hospital, which took place in the New York Obstetrical Society, upon the propriety of restoring the lacerated cervix and perinæum at one operation.

While some opposed it, other speakers favored the double operation, especially for poor women who could not afford the time or expense for two operations. One speaker objected on account of the time the patient would be compelled to remain under the influence of the anæsthetic.

I found, by having everything in readiness, needles all threaded, etc., that the longest time occupied in completing the double operation was 1 hour and 4 minutes. I have assisted in a perinæum operation which alone lasted longer than that, when no special effort was made to hasten matters.

In each of these three cases the patients made a perfectly satisfactory recovery, so that I feel quite encouraged to repeat the operation in similar cases. The two difficulties to contend with are, firstly, the feeling that we are working against time, leading in the direction of too much haste and imperfect work; and secondly, the inability to remove the sutures from the cervix until the perinæum has become sufficiently firm to admit of the use of a speculum without endangering its integrity. I did not attempt their removal until after the expiration of six weeks; but Dr. Charles Carroll Lee, also of the Woman's Hospital, writes me that he has taken them out successfully in three weeks. Dr. Hunter does the same successfully in four weeks. I see no reason why the silkworm gut sutures could not be left in six months or indefinitely. I intend to try them, and not take them out at all unless I am sure they are causing irritation. Skene, of Brooklyn, uses a prepared Chinese silk suture, which he does not take out at all in some cases. He was compelled to cut two unabsorbed sutures in one case of labor where the cervix was prevented from dilating by their presence.

This operator has introduced several innovations, which, while they have succeeded admirably in his experienced hands, I would not recommend less experienced men to imitate. He has operated upon

eight cases in his private office, without anæsthesia, and allowed his patients to ride home in the street cars, and permitted them to remain up, and even to walk out during convalescence.

In two of Dr. Mundé's cases, mentioned in his journal, he found upon the third day, when making his visit, that his patients had gone down town to attend to their business, they being shop girls in a dry goods store. They both made perfect recovery. While this is all possible, still the risk of the occurrence of cellulitis is so great with some, upon slight exposure, that careful after treatment and rest in bed should be insisted npon. Fatal results have followed this operation. Mundé reported a death not long ago from secondary hæmorrhage and another from cellulitis—the only deaths, by the way, which I happen to know of as the result of trachelorraphy.

Much stress is laid by Emmet, Mundé, Thomas, Baker of Boston, Goodell, Lee, and others upon the necessity of careful preparatory treatment. This is good advice so far as relates to uncured pelvic cellulitis, but so far as it relates to cervical catarrh, it has always appeared to me better *not* to delay to cure the catarrh before operating, but to cure it by operating. Cut away the tissues from which the glairy tenacious catarrhal secretion exudes, down to the healthy parts, and bring the denuded surfaces together by sutures, and you cure your patient and do away with the discharge at one and the same time. If the catarrh continues from the canal which you construct or restore by your operation, I hold that you have it in much more favorable condition for treatment than before.

In this connection I was pleased to see an article of Dr. Van de Warker in the July number of the *Journal of Obstetrics* for 1883, in which he makes this point in his analysis of thirty-one operations. The results produced by cervical laceration form, in a measure, the indications for its treatment, and I can state these indications in no more concise way than by giving the following quotation from Thomas, p. 358:

"Nothing more triumphantly displays the value of Emmet's contribution to gynæcology in connection with cervical lacerations, than a full exhibit of the evils which result from that condition.

"Its ordinary consequences are chronic peri-uterine cellulitis; epithelioma; subinvolution of a part or whole of the uterus; sterility; menstrual disorders; cervical endometritis; granular and cystic degeneration; fungosities of the corporeal endometrium; neuralgia of cervix; dyspareunia; tendency to abortion; uterine displacements.

"There can be, on the part of those who have been properly impressed with the importance of this lesion, no question as to the truth that all the conditions mentioned may originate from this accident.

"No part of the body of a woman is so liable to the development of cancer as the uterus; no part of the uterus is so liable to it as the neck; and no tissue of the neck is so liable to it as the glandular lining membrane. Exposure of this by eversion, the result of laceration, would, theoretically, be supposed to be a fruitful cause of that affection, and practically observation abundantly supports theory in reference to the matter. My own observation has for several years made me feel sure of this, and that of Breiskey, Emmet, and Veit is recorded to the same effect. This alone affords a valid indication for the closure of lacerations attended by local engorgements and irritation."

I have endeavored, Mr. President, to state the case fairly in regard to this operation, giving the opinions of those who oppose as well as those who favor trachelorraphy.

If the conclusions reached by Murphy are correct, viz.: 1st "That repair of lacerations of the cervix is *usually* followed by sterility;" 2d. "That the character of the labor is *unusually severe* and *protracted* and that, in a large percentage, *laceration occurs a second time*," I should feel that it would be actual malpractice to operate again upon any woman who was liable to become pregnant, and thereby expose her to the dangers referred to.

The testimony in my possession is, nearly all of it, in favor of trachelorraphy in cases such as I have cited. Did the limits of this paper, already too long, permit, I could cite many cases where pregnancy followed the operation—showing that it cured sterility, instead of producing it, and that re-laceration dtd noi occur at the time of delivery, nor was the "labor unusually severe or protracted."

This, however, is a very important subject, and I shall in a subsequent paper dwell upon these points more at large.

It is somewhat difficult to follow up one's cases and ascertain the results of operations. Many patients being seen in hospital practice, when they are discharged cured, are lost sight of forever. It is only by taking the trouble to learn the ultimate effects of trachelorraphy, that these disputed points can be definitely settled. I therefore invite reports upon the effects of this operation from those who have operated; as to its effect in causing or curing sterility; its effect upon labor, if any; and whether laceration occurred a second time, and if so, whether in the same place or not.

These reports I will tabulate and publish.

The truth is all we seek to find and impress, and in the search our eyes should not be blurred by prejudice or preconceived opinions.

926 Farragut Square.

A CASE OF APOPLEXY AND APHASIA IN A BOY TEN YEARS OLD.

BY TALBOT JONES, M.D., ST. PAUL, MINN.

So unusual is it to encounter apoplexy in young children, that probably few physicians even in extensive practice, or those making diseases of the nervous system a specialty, have met with a case. Its extreme rarity is dwelt upon in all the literature of the subject. It is a little curious that every author I have consulted has not only insisted upon the infrequent occurrence of apoplexy in children, but all of them

have employed the same adjective, "rare," to express it—a hint that in the compilation of books, authors not only employ the ideas of others, but their very language as well.

Thus, West says it is "rare;" so does Steiner. Ellis remarks "it is a rare disease," with which Tanner agrees; while Sir Thos. Watson, Bouchard, Charcot, Rosenthal and others agree that it is "rare," although occasionally observed.

According to Sarmoni's statistics, of 5,678 cases of cerebral hæmorrhage (*Riv. Clin.*, December, 1872), it is rare between the ages of 4 and 22 years. The generic term apoplexy is not synonymous with cerebral hæmorrhage, and this fact should be constantly borne in mind in a study of this affection. There may be a cerebral or a meningeal apoplexy; the latter, far from being rare in infants and children, is, according to Cruveilheir, the cause of one-third of all the deaths occurring in still-born children. The case I shall report is where an extravasation of blood occurred in the cerebral substance, the interesting features being the age of the patient, the aphasia, and certain points relating to localization. H. G., a wealthy merchant of Beaver Falls, Minn., brought his son, aged 10, to my office on January 24, 1884, having been referred to me by Dr. A. G. Stoddard, of that place. The boy was rather robust, and had never been sick in his life, save from occasional constipation.

One day during the middle of March, 1883, while engaged with his brother in coasting near his home, he suddenly felt faint and nauseated, walked to his house several rods off, complained of pain in his head, dizziness, and vomited profusely. He then became rigid, partially unconscious, but when aroused would quickly lapse into a soporose state. His face was flushed, pulse slow and full, whole body flaccid, and his extremities cool. His temperature in the axilla, according to Dr. Stoddard, who was called, was below the normal (95° F.). His breathing was stertorous and somewhat explosive; reflex irritability abolished, and there was well marked conjugate deviation of the eyes. His respiration was labored and irregular; the face tumefied from venous congestion, and cyanosed. Deglutition could still be performed.

He remained in a semi-comatose state for thirty-six hours. After emerging from his unconsciousness he appeared dazed, bewildered, and experienced a confusion of ideas.

There was complete right hemiplegia, without disorders of sensation; conjugate deviation of the eyes, and lateral rotation of the head to the side of the clot, together with paralysis of the right half of the tongue. The special senses were not affected. Not all the muscles of the face were paralyzed; those chiefly involved were muscles whose nerve supply is derived from the cerebral ganglia—the elevators of the wing of the nose, the buccinator, and respiratory filament of the facial, etc. It is extremely rare for all the muscles innervated by the facial nerve to be coincidently paralyzed in cerebral hæmorrhage. The patient fully aroused, it was now discovered that he had lost the power to express his ideas in articulate language. The aphasia was complete. His ideas were evidently well stamped on the mind, but there was an inability to communicate them by language—the so-called aphasia from "verbal ideation" of Jaccoud. The boy could read but not speak. Though unable to employ language, his expressive countenance showed that there was no mental decay. When spoken to his affirmative or negative replies would be by a nod or shake of the head. This aphasia lasted for a period of five weeks and gradually passed off. His command of language constantly improved, though slowly. If a picture of a ship was placed before him and he was asked what it was, he became strangely agitated, and would probably call it a horse. Indeed, his father informed me that the boy had to learn his language over again. When I examined the patient some six months subsequent to his attack, the aphasia had about disappeared. While able at this time to walk, his right leg yet showed signs of paralysis; in bringing this limb into play it described slight oscillations from behind forward. The right hand and foot were cool, and the right thigh one-half an inch less in circumference than its fellow. The patella tendon reflex was exaggerated. Electrical reactions were apparently the same on both sides. The tongue was no longer paralyzed. The effects of the paralysis were much more pronounced in the arm than in the leg.

Owing to the paralysis of the extensors of the fingers and hand, contractures of the flexors were well marked, and the fingers were firmly drawn into the palm of the hands. It does not come within the scope of this paper to discuss the aëtiology of this so-called "late rigidity."[4] Bouchard's explanation that it depends on atropic descending changes in the pyramidal strands, has been disproven; while Todd's hypothesis that the cause is owing to cicatrization around the clot, with the loss of a certain amount of cerebral substance, is by no means accepted by all authorities. Probably the true cause is yet to be explained.

One of the most interesting features of this case was certain choreic movements of the muscles of the paralyzed side—the so-called post-hemiplegic chorea, which was first described by S. Weir Mitchell and subsequently studied by Charcot.

With regard to the aëtiology, the patient's age at once suggested an embolism as the probable cause. A careful examination of the heart, however, showed the absence of roughing, or valvular lesion, nor had he ever suffered from scarlet fever, syphilis, or an aneurism. The cause was, doubtles, owing to an extravisation of blood in the cerebral mass, due to the rupture of a minute aneurism; for Charcot goes so far as to assert that rupture of aneurisms of minute arteries is always the immediate cause of cerebral apoplexy. (Charcot & Bouchard, *Arch. de Physiol. 1868*). If what we have recently learned through the investigations of Fritsch and Hitzig, Ferrier and others concerning the localization of cerebral lesions is to be relied upon, the site or position of the extravasation in this case was in the left frontal convolution or that region connecting it with the island of Reil, and with the central and parietal convolutions.

SUGGESTIONS ON THE MANAGEMENT OF BRISME FORCE OF THE KNEE.

BY CHAS. F. STILLMAN, M.D., OF NEW YORK.

Lecturer on Orthopædic Surgery in the Woman's Medical College.

It must first be decided that the ankylosis is fibrous, and these suggestions are only applicable to such cases as are distinctly of that character. If inflammation is present to any great degree in or about the joint, the operation is contra-indicated; but there are very few cases which do not exhibit some slight existing sub-acute inflammatory state in some parts of the osseo-ligamentous structures constituting the joint. This is sometimes sufficient to give rise to reflex contractions of the muscles governing the joint, and one authority states that the indication for dividing the tendons of these muscles, as an adjunct to the operation of brismé forcé, is the reflex spasm exhibited when the tendons are pressed upon.

There are not many cases, however, where tenotomy is really necessary, if the muscular contraction be merely reflex, and not due to actual shortening of the muscular structure. It may be subdued by a much more simple process, which has the merit, also, of producing excellent results upon any inflammatory condition which may exist. The patient should be advised to assume the recumbent position for a time varying from three to five weeks, the knee to be enveloped in a large poultice during this entire period. The recumbent position should be insisted upon. Not once during this time should the foot be touched to the floor for the purpose of bearing weight.

The poultice itself should be sufficiently long to completely encircle the limb at the knee, and sufficiently broad to extend some distance above and below the joint. It may be made of oil meal and bran, flaxseed, elm and marshmallow leaves, or any other substance which is preferred by the surgeon. It is best prepared in bags, the poulticing to be inserted into the bag, after which the fourth side is sewed up. It is then to be placed upon the knee hot, and covered with oil silk and a roller bandage.

A few weeks of this poulticing renders the part comparatively free from inflammation, and the tissue about the joint cool, relieved from reflex excitement, and ready for the operation itself. This is so well described in the different text-books on the subject, that it is superfluous for us to refer to it in detail here, since this article is written with the idea of presenting the preparatory and after-treatment only prominently before the reader. Anæsthesia is, of course, required for the operation, and if the patella is adherent it must be loosened, and the joint liberated by rapid movements, the adhesions giving way usually with considerable snapping and crackling, but much more easily than if the poulticing and rest be not practiced. Instead of placing the limb on a posterior splint, or applying extension by means of the weight and pulley, the writer prefers to use a local fixation splint, which also combines local extension, and its chief advantages are that the extension is continuous without regard to position, and the changes in the angle of the limb may be effected from day to day without removal of the splint.

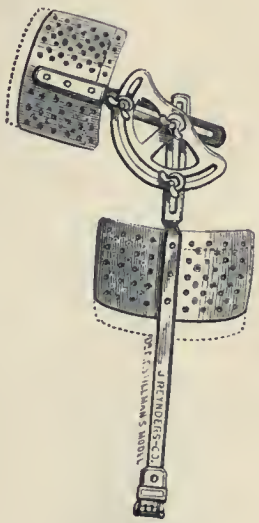

Fig. 1.

The splint shown in Figure 1 is the one employed, it being an improved form of the sector splint devised several years ago and presented to the profession through the American Medical Association at that time. But it is also provided with metal strips interiorly, which terminate in a roller and buckle. It is applied to the limb with adhesive plaster and plaster of Paris. Two pieces of moleskin plaster as fresh as possible are cut in the shape of a fan, as shown in Figure 2, and have sewed to each of them a tag of strong webbing. These are then placed, one upon either side of the limb, as shown in Figure 2, their extremities being interlaced.

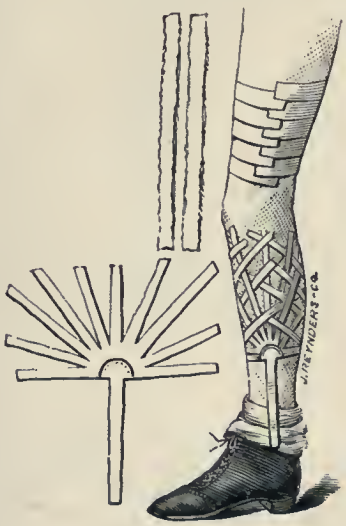

Fig. 2.

Strips of the plaster are now cut for the thigh of sufficient length to more than encircle it. These a wound around it snugly, as shown in Figure 2, and

the leg and thigh bandaged with a flannel roller. Over the leg and thigh the plaster of Paris bandage is now rolled, both above and below the knee, as shown in Figure 3, the webbing tags being allowed

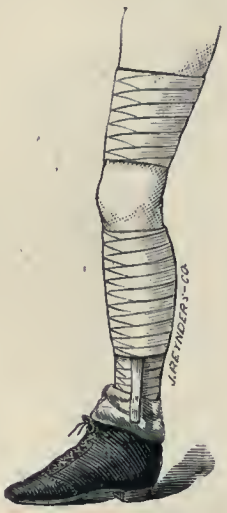

Fig. 3.

to protrude inferiorly. The brackets are now placed in position, one on either side of the limb, taking care to have them in the axis of the thigh and leg respectively, and to have the pivotal center of the splint in the pivotal axis of the knee (Figure 4). A

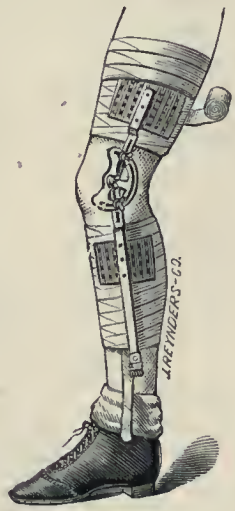

Fig. 4.

few more turns of the plaster bandage secures the splint in place, and the plaster surface is next neatly covered with a long bleached muslin roller, to insure cleanliness (See Figure 5). After the plaster has become firm, which takes but a few moments, the extension should be exerted against the muscular bulk of the thigh, and secured by the upper clamp of the sector. The other clamps should now also be tightened, which firmly fixes the limb in any desired position, and we have the surface over the joint exposed and the joint itself held securely and yet extended. A rubber bandage, cut in strips and sewed together in the centers, after the manner of scultetus, or an ordinary rubber roller, is next placed around the

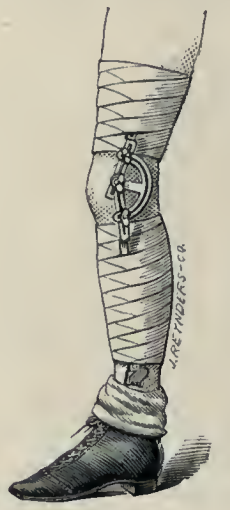

Fig. 5.

knee, exerting a moderate amount of circumferential pressure. Over this may be placed an ice-bag, which has the effect of restraining such inflammation as may arise. At the expiration of from four to six days the lower and center clamps of the sector may be loosened without decreasing the amount of extension which is held by the clamp on the upper strip. The leg may now be bent a few degrees from the position assumed after the operation, and clamped securely in a new position. It is now safe to remove the ice-bag, and replace its action with a stimulating ointment under the rubber, or in case the rubber is uncomfortable and there have been no inflammatory conditions, a large poultice may be substituted. Extension is still kept up, however, and the knee secured at various angles, day by day, until the whole range of motion, which was secured by the operation, is permanently obtained without the splint having been removed. Then the two lower clamps may be loosened, the upper one still being secured for the purpose of maintaining extension, and free motion allowed in the joint. Crutches are then supplied and the patient permitted to go about. The use of this splint during the after-treatment permits the joint to be kept perfectly under the surgeon's control, and tends to a more prompt and complete recovery of the joint functions, than by the method usually recommended in the text-books.

PROLONGED MAINTENANCE OF LIFE WITHOUT FOOD.—The *British Medical Journal* has a note from Dr. Charles J. Renshaw, describing a case of a widow, æt. 58, who, while suffering from uterine cancer, went thirty-nine days and fourteen hours, supported by morphia and water alone. She took 3 grains of morphia hypodermically injected twice daily.

DENTAL FORMATION IN THE NASAL CAVITY.

Prof. E. Fletcher Ingals, of Chicago, sends us the following regarding misplaced teeth:

Recently, in examining a patient who had for some time been troubled with nasal catarrh, I found on the floor of the left naris, four centimeters back from the nostril, a hard substance, feeling, when touched with the probe, like bone. On seizing this with forceps the patient experienced severe pain, like that caused by striking a sensitive tooth, and for several hours afterward he suffered from pain like a severe toothache.

The pain caused by touching this body was so exquisite, that it was necessary to produce complete anæsthesia before a thorough examination could be made.

Dr. R. H. Lull administered ether for me, and I then engaged the foreign body in the snare, which I use for nasal tumors, and drew it out, when it was found to be a supernumerary tooth, resembling closely the canine, and measuring two centimeters in length.

About five millimeters of the tip of the root had been exposed in the nasal cavity, and below this the tooth was covered with soft tissue, which was adhered to it down to the crown. The dentine of the crown was perfect, excepting a small perforation at its apex, but within the tooth was decayed.

How long this tooth had been projecting into the nasal cavity could not be determined, but it must have been a considerable time, for the portion of the apex of the root which was uncovered had lost by erosion about a millimeter in thickness from its entire circumference.

It is comparatively rare for teeth to grow in the roof of the mouth or nasal cavities, yet several such cases have been met with. In nearly all instances the "wild tooth," as it is called by the laity, is found to be a supernumerary tooth or a misplaced canine.

Prof. E. S. Talbott, who examined the tooth and the patient's mouth, states that, from the appearance of tartar and green stain upon the apex of the crown, it must have occupied a diagonal position in the hard palate, the crown being in the roof of the mouth, pointing toward the central incisors, and the apex of the root in the naris, pointing posteriorly. A ring of tartar encircled the crown from about three millimeters below the upper surface to nine millimeters above the lower surface, and that part of the crown below the ring was covered with a fungous growth, which proved that the part only was exposed in the mouth.

The tooth had decayed because of the imperfectly formed apex of the crown, until the pulp had become exposed and death resulted, causing alveolar abscess, the sack of which came away with the tooth. While it is not uncommon to find supernumerary teeth in the roof and anterior part of the mouth, it is very rare to find the apex penetrating the nares.

ERGOTINE prepared by the manufacturing chemists, Gehe & Co., of Dresden, costs 200 marks a gramme, or more than $3.12 a grain. That is about $21,840 a pound avoirdupois.

MEDICAL PROGRESS.

ON THE MILITARY EMPLOYMENT IN ACTIVE SERVICE BY THE FRENCH, OF SANITARY OFFICERS, APOTHECARIES, AND STUDENTS OF MEDICINE.—The principle that every citizen is a soldier is, we are told, the foundation of the military system of France; but it has received a new force and a more complete application from the law of the 27th July, 1872. According to this law, every young man of 20 years of age, free from bodily defects, owes to the country five years of active service, five years in the territorial army, and six years in the reserve of the territorial army. Independent of other exemptions, students of the Polytechnic School, of other schools not bearing upon this subject, and public teachers and ministers, are not called upon, but must serve the public in their respective capacities during a period which varies from five to ten years. The law authorizes young men who hold the diploma of *bachelier*, or a certificate bearing that their studies have been carried on at a public school to a certain fixed standard, and those who pass a certain examination held for the purpose, to engage for one year as voluntary recruits, at the end of which they are sent home, provided they can give evidence of having received a good military training; but they are always, as long as they have not served for the time fixed by law, subject to be called out again in case of need.

Many of us will remember that during the war of the Rebellion, in consequence of the repeated drafts which the country was called upon to fill, our medical colleges suffered demoralization, and our medical students were kept in a constant state of ferment, from their being liable at any moment to be called upon to do military duty. Consequently, a reference to a new law promulgated by the French Government, June 5 and July 22, 1883, (*Alger Medical*), bearing upon this subject, may be of interest to the readers of the JOURNAL.

It deals with sanitary officers, a grade which has no special meaning to us; with apothecaries of the second class—that is, those who are still in a state of apprenticeship; and with medical students who have received twelve inscriptions toward attaining their degree as doctor—that is, who have completed about three-fourths of their medical studies. These three classes are placed in the same category, but it is only with the latter that we are specially interested. Therefore we will not translate literally, but simply give succinctly those paragraphs of importance that bear directly upon the subject.

The decree of M. Grevy, the President, sets forth:

1st. The before-mentioned classes are comprehended in the category of men placed at the disposition of the reserve of the active or territorial army; they can be employed in case of active service to aid the physicians and apothecaries on active duty in the reserve or in the territorial army, by employment in the corps, in the hospitals or ambulances.

2nd. They will be termed auxiliary physicians or auxiliary apothecaries, according to their specialties.

The medical students will not receive this title until after an examination proving their aptitude according to special rules.

3rd. Their position will be that of student adjutants of the administration of the hospital service (our medical cadet). Their pay, in time of war, is the same with that of other student adjutants. Their uniform is fixed by special regulation.

4th. The auxiliary physicians and apothecaries, from the date of receipt of their nomination, are subjected to the same rules of discipline and of service as are the physicians and apothecaries of the reserve. They can also be called upon in time of peace, in the same manner.

The Minister of War, Thibaudin, in consequence of this decree, issued certain regulations. Articles 1 and 2 simply give in detail what has just been referred to, as the secretaries of faculties and of schools are required to furnish regular information to the department of their material suitable for such purposes, and after having passed their examination they are reported as ready for service. Article 3 gives a list of exempts, from causes which would exempt them under other circumstances. Article 4 defines their letter of nomination, to which is annexed the order of route they are to take to reach their place of service, which gives them free transportation. Article 5 refers to their record with recruiting officers to relieve them from such liabilities. Articles 6, 7, 8, 9 are not essential here.

Article 10. In time of peace the auxiliary physicians and apothecaries are under the same obligations with the men of the troop, as concerns the change of domicile and residence. They are assimilated, as far as the service is concerned, with the physicians and apothecaries of the reserve of the territorial army, and, like them, can be called upon under the same conditions to undergo certain periods of instruction.

Article 11 requires a personal report from them each year.

Article 12 relieves them, at their will, after twenty years of this kind of service, from all further military service.

Article 13 gives the Minister of War the power to deprive them of their grade, for cause.

Article 14 gives them the right to resign this grade and employ from personal motives, but Article 15 makes them in consequence private soldiers, remaining under the obligations imposed upon that class, with the exception that they can return to this grade if they so desire.

Article 17 requires an examination on the following subjects:

Ideas on the general organization of the army, its discipline, and of military hierarchy.

Ideas on the organization of the sanitary service in quarters and in the field.

Regimental infirmaries; the fitting out of ambulances; the providing for regimental infirmaries in the field.

Military hospitals.

Relief posts; ambulance infirmaries and litters.

Movable and stationary field hospitals.

Ambulances of evacuation; trains of evacuation.

Relief for the wounded on the field of battle. Bandages and improvised apparatus. Carrying and transportation of the wounded. Litters and conveyances.

The Geneva Convention.

Article 18 declares that these examinations are to be held before a jury composed of a surgeon of the first-class as president, and two surgeons of the second class, in any town which is the seat of a faculty or school of medicine. The members of the jury are to be appointed by the General in command of the army corps, at the suggestion of the directors of the sanitary service. The medical students can be submitted to this examination by addressing a letter to the director of the sanitary service of the locality in which they reside. In case they do not pass this examination, they continue in their previous military position.

MEDICINE.

TRICHINOSIS IN GERMANY.—Minister Sargent's report from Berlin, enclosing Consul Fox's report, has been published in the Consular Reports, No. 35, by the State Department. The place where the disease took most formidable dimensions was at Emersleben, near the Harz mountains, about five miles from the city of Halberstadt in the province of Saxony. The fully ascertained cause of the outbreak, was the consumption, mostly in an entirely raw and partly in a partially raw condition, of the flesh of three hogs raised in the vicinity, mixed with that of a Hungarian hog. The extraordinary spread of the disease through five villages in a circuit of two miles occurred because the potato harvest was in progress, and it was customary for the people to eat raw meat and bread in the fields at such times, instead of spending time to go to and return from their homes.

The inspection is alleged by the inspector and butchers to have been made in accordance with the laws, though the record required by law was not kept. The inspector was the village barber, the person habitually employed in Germany for such inspections, who passes an examination as to his fitness for the task. But the three preparations made for microscopic inspection, under the law, are not sufficient to give safe results, as trichinæ are sometimes found only after 30 or 40 trials.

The whole number of cases so far (Oct. 26) is about 438, of which 31 have died, and 19 more will probably be fatal. There are about 700 inhabitants in the village, living in about 120 houses. There are 267 sick in 85 houses. These sad scenes lead to several conclusions:

1st. American pork is exonerated from the suspicion of being the cause of this disaster, and its prohibition upon the the theory that it is more harmful than other pork is unwarranted.

2d. The inspection laws of Germany are totally inadequate to prevent such calamities so long as the people indulge the habit of eating pork raw. In the language of Prof. Hertweit in the convention of butchers of Berlin, in 1865: "You know what you

have to do in your kitchens, and if you do it properly we have no need of inspection."

An article published last spring in a newspaper of Berlin, which is usually supposed to express official ideas, held to the view that the prohibitory decree was proper, because a government must recognize in its acts the tastes of its people; that Germans like to eat pork raw and because the fact that well-cooked pork is safe, and uncooked pork is dangerous, does not make any difference. The government will keep out the American article because it is dangerous in a raw state.

Prof. Brouardel has an article on this subject in *La Tribune Medical*, in which he says:

"After studying the epidemic at Emersleben, we attempted to ascertain for what hygienic reasons the German government had prohibited the importation of pork from America. M. Virchow declared to us in the most formal manner that there was no scientific demonstration that the use of American pork had given rise to a single human case of trichinosis, either isolated or to others as an epidemic. He made this statement in the presence of M. Hertwig, Veterinary Director of the Berlin Abattoir and Chief of the Microscopic Departmemt for the examination of material in seeking for trichinæ, who confirmed the opinion. They both affirmed, furthermore, that not a single case of human trichinosis had occurred which could be attributed to the eating of American pork raw."

The declarations relating to hygiene as made by M. le conseiller aulique Koehler before the Reischstadt, Jan. 9, 1883, in answers to MM. Richter and Rickert, as to why prohibition should be continued, were in effect:

That the epidemic of Dusseldorf (1881) was, according to a communication from the Royal Prussian Government, due to American origin; 15 cases and 3 deaths.

So at Breme and at Rostock American pork was also accused. But it is excessively difficult to furnish proofs in these accusations, because

(*a*) The diagnosis of trichinosis is difficult, having been but recently studied and resembling other diseases.

(*b*) The American meat, smoked and but little salted, is mixed, dressed and sold as German sausage.

M. Koehler insists upon the impossibility of a satisfactory examination of American pork on the frontier, from the dissemination of portions, etc.

We recommend the public not to eat the flesh of American pork without cooking it, which is the surest means of killing the trichina. But if the Americans, the English and the French eat partially cooked pork with disgust, we Germans are very fond of raw or but little cooked pork. But we can not by laws change the taste of the country; those laws would be useless and would interfere with the liberty of the individual. A prohibitory law is, therefore, legitimate and necessary. It should be but temporary and subordinate to the condition of American merchandise. When American commerce examines its pork properly, then these laws would become useless. Under these conditions the arguments used are without application in France.

Pulsatile Pleurisy.—Dr. J. Cornby (*Archives Générales de Médecine*) has published the records of twenty-seven cases bearing upon the subject, and concludes by discussing the symptoms, diagnosis, pathology, ætiology, and semiologic value of this phenomenon. As to symptoms, in all the cases observed there existed a chronic pleurisy of the left side; the pulsations were synchronous with the arterial pulse over a greater or less extensive area, ordinarily the inferior thoracic portion, giving the appearance and sensation of an aneurismal pulsation, sometimes very marked and energetic, sometimes feeble and scarcely perceptible. The empyema forces out the intercostal spaces, producing one or two pulsatile tumors the size of a nut, an egg, or an orange, which may be situated near the precordial region or near the vertebral column; it may occupy the left lumbar region. There is, according to some, an absence of expansion, but according to Dr. Cornby it is present and characteristic. In all the cases published up to the present time empyema was coexistent.

The diagnosis is between this affection, pulsatile pneumonia, pulsatile cancer of the lung, and aneurism of the aorta. The onset, progress, and special signs of pneumonia would suffice to distinguish it. Cancer is difficult to distinguish. In aneurism of the aorta the thrill and the souffle must form the principal points of distinction; in other respects it remains obscure, and an exploratory capillary puncture is indicated before performing the operation for empyema.

The cause of this peculiar symptom is due to the pressure upon the lung laterally from without inwards, and adherent to the pericardium, so that the pulsations of the heart are communicated with force and directness to the pleura contained purulent fluid. In the most of these cases, where a post-mortem examination was made, phthisis pulmonalis was present.

The value of this symptom is in effect: That a certain number of pleurisies of the left side present pulsations synchronous with the heart beat. These pulsations occupy the lower portion of the thorax over an extended space, or are limited to a tumor, the seat of which is variable on the thorax, and may even occupy the lumbar region. These thoracic pulsations are due to the transmission of the heart-beat through the sclerosed lung and liquid pleural contents. They are only found in chronic purulent pleurisy with marked retraction of the lung which is adherent to the pericardium. The pulsations indicate purulence and the complete destruction of the lung.

Sounds of Fluid in the Stomach on Succussion as a Symptom of Dilatation of the Stomach — M. Audhoui is giving a clinical course at the Hospital de la Pitié at Paris, on diseases of the stomach (*Gazette des Hopitaux*), and regards this symptom, which he terms clapotage, as of importance in diagnosis. It is produced by the oscillatory movement of a liquid contained in the stomach, and is heard by succussion, by the brusk impulse of one hand, or

by the two hands, as in determining fluctuation. It can also be excited by the movements of the patient. In 1833, Duplan the elder noticed that this sign disappeared on vomiting, but recurred after the patient took something. In 1865, Chomel considered it a pathognomonic symptom of a special dyspepsia, which he called the dyspepsia of liquids, supposing that the stomach, while still capable of digesting solids, could not digest fluids,

M. Audhoui does not agree with Chomel. He considers the presence of this fluid as due in part to an exaggerated and abnormal secretion of the salivary glands and the mucous follicles of the stomach, and in part to the imperfect digestion of solid substances which liquefy in the stomach. Accepting this theory, what are the causes of retention? Inertia of the stomach or narrowing of the pylorus. The inert stomach allows itself to become dilated and distended. These sounds then, obtained on succussion in the living, are diagnostic of this dilatation, but it does not follow as a matter of course that this condition will be equally recognized after death; and three cases are given to illustrate this assertion:

1. A man who committed great excesses, dyspeptic in the highest degree, with an affection of the kidneys. He vomits bilious matter, drinks a great deal, and vomits again the greater part of the same. In his case a considerable degree of dilatation of the the stomach was determined. He dies of uræmic poisoning, and his stomach is found empty and of normal dimensions.

2. A woman taken with puerperal fever after confinement, and subject to constant and free vomiting from the commencement of pregnancy. After death the stomach is found filled with fluid, and dilated so as to extend almost to the pubis. After ligating its two orifices it is punctured, and returns to its normal dimensions.

3. A man dying from fibrous occlusion of the pyloric orifice. During life diagnosis of dilatation of the stomach. After death alcoholic injection into the stomach, which returned to its normal dimensions.

The treatment of inertia of the stomach has been successful in some cases by the use of the cold douche to the part, and by such massage as would tend to carry the liquids from the stomach into the duodenum. Electricity, so far, has failed.

It is important, in order to give this symptom its due diagnostic value, to mark the distinction between this pathological condition and the same physiological symptom, which shows itself immediately after the ingestion of fluids. Chomel denied that there was such a physiological symptom, but M. Audhoui has established the fact in a variety of ways; and the point is to determine the duration of this physiologically. It (the duration) varies according to the subject, to the quantity and to the quality of the liquid taken, from twenty minutes to two hours and thirty minutes.

So that, to make this symptom of pathological value, it must exist several hours after the taking of food or drink, and at a time when the healthy stomach would necessarily be empty—in some cases it never ceases to be present.

CHOREA DEPENDENT UPON A NASAL AFFECTION.—M. Gilli presented the notes of a case to the Societe de Biologie (Comptes Rendus) occurring in a small boy, 8 years of age, who suffered from great difficutly of respiration, nasal voice, constant blowing of the nose, snoring at night, respiration by the mouth, keeping it partly open at all times; there was a catarrhal engorgement of the naso-pharyngeal passages, with abundant nasal mucous secretion and momentary and variable obstruction of the nasal fossæ by hypertrophy of the turbinated bones, and deviation of the septum; obstruction total of the Eustachian tube on the right, and partial on the left. The pharynx was affected with a chronic phlegmatia with glandular engorgement; there was simple scrofulous catarrh.

In the treatment there was ordered two nasal injections daily of warm salt water. Three days later, the child complained of severe pains in the head, localized particularly in the frontal region, whenever the nasal injection was used, and in spite of the use of a fine rubber sound introduced into the nostril, so as to prevent the closure of the nasal orifice, or the accumulation of fluid in the frontal sinuses. At this time the mother noticed irregular movements of the right arm and hand, which she recognized as choreic, having had chorea herself in her childhood. I observed these movements also; they were not general and did not affect the right leg; there were frequent grimaces of the face and movements of the tongue from time to time, but the arm and right shoulder were particularly the seat of the characteristic oscillations.

I suspended the use of the nasal injections, and in a little time the movements were scarcely perceptible. The mother, seeing the good effect which the injections had produced upon the pathological condition, renewed them cautiously, when the same phenomena recurred; severe pain in the head, more especially frontal, and the involuntary movements of the right side, which prevented the child from writing, but not from eating. This chorea only lasted 8 to 10 days, and notwithstanding the persistence of the treatment, to which the child became habituated by degrees, it disappeared gradually; at the same time the naso-pharyngeal catarrh was relieved.

This chorea, connected with an affection of the nasal passages, and excited by the topical treatment, demonstrates the marked reflex sensibility of the naso-pharyngeal mucous membrane. A case of arthritis, which came under my notice some time since, suffered painful sensations in the left arm, with a numbness of the fingers, which was relieved from time to time on the expulsion of an enormous dry crust, moulded into contours of the turbinated bones, from the left nostril.

SURGERY.

THE EXTRACTION OF TEETH WITHOUT PAIN.—The method of placing a small rubber ring between the crown and the root of the tooth, has been used in this country and put in print, but we do not re-

member exactly where, has been revived in France, and M. Bauverd, of Geneva, has addressed a communication on the subject to M. Paul Bert, who in turn has presented it to the Société de Biologie (*Comptés Rendus*).

His method consists in placing in the position indicated the rubber ring, which varies in size according to the tooth, from a half to four millimeters; in consequence the tooth becomes loosened, and in time —about a week—will fall out ot itself. Generally about the fourth day patients request its extraction, which is done without pain. There is no pain accompanying this procedure, only a slight inflammation of the gums, which disappears when the tooth is removed. It is only applicable to those teeth with but a single root, and is especially useful in those teeth of the second dentition that are in malposition. The incisors and canines are readily removed; the molars themselves are advantageously loosened.

M. Galippe, in discussing this question, said that it had long been known that the careless employment of rubber threads has resulted in accidents of this kind. One case he referred to, in which a young girl lost her two superior central incisors, from the thread being allowed to remain too long on the lateral surfaces of the teeth. But he was surprised at the statement that there was no pain produced, knowing as he did that the ordinary application of rubber frequently produces severe pain, which it is sometimes difficult to tolerate, and is accompanied to a more or less marked degree of periostitis. Frequently a small bit of cotton pushed up accidentally during mastication between the tooth and the gum, is sufficient to give severe pain and loosen the tooth.

On the Treatment of Wens by the Injection of Ether.—M. Marcel Lemoyez (*Bulletin Général de Therapeutique*) discusses the various modes for the treatment of wens (by which he means sebaceous tumors of the face and scalp) their advantages and disadvantages. The use of the bistoury is often followed by erysipelas. The use of caustics gives rise to violent pain, a slow healing and deformed cicatrices. He then passes to the method practised by Vidal of injecting ether, which acts, like caustics, by inflaming the contents of the cyst and producing suppuration—perhaps, also, as a special solvent upon the fatty matters and cholesterine crystals. It produces no pain other than that of an exaggerated tension of the walls, nor any elevation of temperature, augmentation of saliva, or acceleration of respiration. It must be as pure as possible. In amount five or six drops at a time is sufficient; as to its frequency, in small wens every two days, three injections should suffice. In the large wens of the scalp, six or eight injections of ten drops may be necessary. The mode of injection is simple, the tumor being isolated by the fingers, the largest glandular orifice of its covering, which is generally encrusted, is selected, and the needle passed in perpendicularly; after its introduction it is moved a little freely within the cavity to break up the sebaceous matter and to irritate a little the walls of the cyst, and thereby assist in the more effective action of the ether. These injections are stopped when the tumor enlarges, becomes thin in its walls, reddens, and gives a slight sensation of pain. Then the base is pierced and a jet of pus and serum escapes, the cystic matter being eliminated as a soft whitish mass mixed with shreds, which are the detritus of the pouch. This takes place about the sixth or eighth day. During the following days the cyst suppurates, and little by little the skin retracts over the diminishing tumor. About the fifteenth to twentieth day there remains only a small, lenticular, indurated core covered by sound skin, with no visible trace of the orifice throngh which the mass of the tumor was eliminated. The case cited in illustration is that of a debilitated man, addicted to alcohol, in whom M. Vidal, after ten injections of ether, caused the complete disappearance in a month's time of a wen on the scalp of five months' standing. During the treatment there was no pain, no precautions were taken, the patient frequently exposing himself to cold without protective dressings, and remaining in the room where there were four cases of erysipelas.

MATERIA MEDICA AND THERAPEUTICS.

The Dosimetric Employment of Chloroform in Producing Anæsthesia.—M. Paul Bert presented to the Société de Biologie (*Comptés Rendus*) the method employed by Dr. Pezraud, which consists in placing a very fine small compress over the nose and mouth of the patient, and dropping upon it with each respiration one drop of chloroform; at the end of a few minutes, if insensibility does not follow, two drops are given, and by this method complete insensibility is produced at the end of seven to ten minutes. During this time the pulse and respiration remain regular, and anæsthesia obtains in a progressive manner, with only the slowing of the pulse to indicate it; there is no agitation and no hyperæsthesia, even with alcoholics or nervous women. When anæsthesia has been produced, it is maintained by three or four drops of the chloroform every minute. By calculation, it takes in this way a mixture of ten to fourteen grammes of chloroform with 100 liters of air to produce the anæsthesia.

Gout Treated by Pepsine and Pancreatine.—Dr. Girard (*Gazette Medicale de l'Algerie*) gives a case of the relief of gout by this means, to support the view that it is the result frequently of bad digestion and vicious nutrition. His case is that of a man 40 years of age; good complexion; no hereditary antecedents; who was frequently affected by attacks of the gout which kept him in bed for weeks at a time. After trying various plans of treatment, he dieted himself upon a little wine and bouillon until he became so feeble that a serious result was feared.

Dr. Girard, upon seeing him, ordered four spoonsfull of *peptone Dupesne* (?) a day, in a little warm and salt water. In two days, he had improved sufficiently to take ordinary food. For a long time he had suffered from a sensation of heaviness in the stomach, and somnolence after meals. He was put upon 60 centigrammes of pancreatine after each meal. The

sense of heaviness disappeared as by enchantment, and the inflammation of the articulations disappeared entirely after six months of treatment, since which time he has had no return of the symptoms.

INHALATIONS OF CARBONIC ACID IN WHOOPING-COUGH.—M. Campardon at the Société de Thérapeutique referred to his use of carbonic acid, as suggested to him by the practice of Dr. Petit, of Royal, who put his little patients for a few moments into a grotto, the atmosphere of which was strongly charged with carbonic acid. In the case of a child ten years of age, whose whooping cough was of five months' standing, and who suffered from frequent cough with repeated vomitings, thereby interfering with alimentation; after trying many medications without effect, he had recourse to inhalations of carbonic acid. made in the seltzer water apparatus, and discharged through a rubber tube. The cure was complete after several applications. He considered it important that the gas should be charged with water vapor.

In the discussion, M. Constantin Paul considered its action as due to an anæsthetic action on the laryngeal mucous membrane. He had used it to relieve pain in certain affections of the respiratory passages, particularly in tubercular laryngitis.

M. Dujardin-Beaumetz considered the action as analgesic, and thereby suppressing the laryngical reflex which produced the cough.—*Journal de Therapeutique.*

GYNÆCOLOGY.

CASE OF APPARENT AMENORRHŒA, AND FALSE PREGNANCY.—(Extract fron the Clinica de Saragoza, published in *El Siglo Médico*, Madrid.)

In 1874 a woman 30 years of age, married, who was accidentally separated from her husband for several months, presented herself at the clinic of Valladolid, and declared herself to be pregnant, and she did not know why. Her symptoms were, suppression of the menses for nine months, consequent enlargement of the abdomen, finally reaching the normal size of a pregnancy at term, enlargement of the breasts with pigmentation, vomiting, and movements felt of the child. There was absence of ballottement, active movements of the child, and the heart-beat. Four days after her entrance she was taken with labor pains, and passed per vaginam a large quantity of blackish blood, partly liquid and partly coagulated, accompanied with severe pains and a violent hæmatemesis. Convalescence was slow, with marked chloro-anæmia.

Feb. 4, 1877, Dr. Delgado Alba, who had attended this case, was called in haste to assist in a case of labor, and found himself in the presence of his former patient, who declared that there was no mistake this time, as her husband had been with her for the past eleven months. The supposed labor was attended with the same phenomena as before noted, the patient suffering from its effects for fifteen days.

Neither on the first or second occasion, were there found in the matters expelled from the uterus, any vestiges of moles, portions of the placenta or fœtal membranes. — *Gazette Hebdomadaire des Sciences Medicales.*

AT the recent meeting of naturalists of the Eastern United States, Dr. Benjamin Sharp described Dr. Semper's method of making dry preparations for exhibition purposes, which, while it has been previously described, may be new to many readers. The method is applicable to objects of various sizes, but is especially adapted for the exhibition of dissections. An animal, for instance a mouse, is dissected so as to show the desired organs. It is then hardened by chromic acid in the method so familiar to microscopists. After becoming sufficiently hard, it is removed from the solution and thoroughly washed with water, the object being to remove as much of the chromic acid as possible. It is then transferred to weak alcohol, and then to stronger, until at last it is placed in absolute alcohol, the object being to remove all of the water in the tissues. From the absolute alcohol it is transferred to spirits of turpentine until it is thoroughly impregnated, and then it is simply dried in the air. The result is a rather strong and slightly elastic preparation which can be safely handled, and which displays the organs in their natural condition, without any wrinkling or distortion produced by contraction in drying. The various tissues closely resemble kid in their general appearance, and are of an ashy white color. By the use of the brush, the various organs may be colored as desired; or, should it be preferable to restore the natural hues, this may be accomplished with considerable success by coating the object with a mixture of glycerine and sugar. If this is done, it is necessary that the object be kept so that the dust is entirely excluded. The time required for these several steps of course varies with the size of the specimen, varying from one or two weeks to as many months.—*Science Record.*

MEMBERSHIP OF THE BRITISH MEDICAL ASSOCIATION.—Up to the year 1867, the thirty-fifth year of the Association, the issue of the *British Medical Journal* was 2,000, the membership of the British Medical Association had increased for several years at a rate ranging from thirty to forty. The issue of the *British Medical Journal* is now 12,000, and the increase of new members to the Association has been since 1867 at the annual rate of five hundred.

PROF. REICHERT, who for many years held the chair of Anatomy in Berlin, died after a short illness on December 21. He was succeeded in his professional duties only a few months before his death by Prof. Waldeger.

ÆSTHETIC CATHETERISM.—One of our exchanges records a case of what it calls "æsthetic catheterism," where a woman introduced the stem of a small lily into her urethra; it passed beyond the reach of her fingers and had to be removed by instruments.

DURING the academic year 1882–83, 672 M.D. degrees were conferred in France—465 were conferred by the Paris faculty, Montpellier 69, Bordeaux 46, Lyons 43, Nancy 21, and Lille 20.

CHICAGO, ILLINOIS.

SATURDAY, FEBRUARY 23, 1884.

WHO ARE "MEMBERS ELECT" AGAIN?—Our Buffalo correspondent, whose brief letter will be found in the proper department, still appears to think that there are reasons for believing that the words "every member elect," commencing the last paragraph of the second article of the constitution, apply only to *delegates*, and do not include permanent members. His reasons are, that the paragraph alludes to voting and the presenting of credentials, while permanent members have no right to vote, and have "no credentials." The allusion to voting in the paragraph of the constitution would be just as applicable if only a part of the "members elect" voted as it would if all voted; and our correspondent is mistaken in his assumption that permanent members have no credentials. Every permanent member has credentials of the most satisfactory character in the printed records of the Association. And the clause of the constitution in question was not only understood to include all classes of members, but in the early years of the Association permanent members actually went to the registration table prepared to show, either by written certificates or the printed records, that they were members entitled to such registration. This practice was continued until the Permanent Secretary, to save the members inconvenience, began to have regularly at the registration table, for convenient reference, such volumes of Transactions as would enable him, or the registration officer, to verify the claims of any who might be present. And if at the next meeting, one whose name was not on the records, should present himself for registration as permanent member, he would not get very far before he would find his credentials or evidences of membership called for. If the words "every member elect" means only *delegates* elect, the reading should be just as harmonious and consistent throughout the paragraph if the word *delegate* was substituted for that of "member."

Perhaps our correspondent will be better satisfied if he makes the trial and notes the kind of agreement he would have between the first line of the paragraph and the two last. Thus, "every *delegate* elect, etc., etc., etc., must etc,, etc., etc,, inscribe his name and address in full, *specifying* in *what capacity* he attends, and, *if a delegate*, the title of the institution, etc." We do not think it requires a very "judicial mind" to see that the words "every member elect" in the constitutional paragraph, either includes members acting in *more* than *one capacity*, and some who are *not delegates*, or the two last lines are meaningless.

"VINDEX" AND THE JUDICIAL COUNCIL.—Perhaps the most striking feature in the many criticisms which have been written in regard to the organization and doings of the National Association, is the manifest ignorance of the critics concerning the topics about which they write. For instance, a member of the St. Louis Medical Society, who is also a member of the National Association, gravely presents to the first named society the two following resolutions, and by letter seriously asks us to help him to gain a consideration of them in the Association:

Resolved, 1st, That the professors and lecturers in medical schools and colleges are requested to refrain from letting their names appear in the circulars, prospectuses and cards.

2d., That the American Medical Association be respectfully petitioned to deny representation to all medical colleges which parade the names of the professors in their circulars, and act contrary to the spirit of this rule.

He seems to be entirely oblivious to the fact that the constitution of the American Medical Association has in it no provision for the admission of delegates from any medical colleges whatever, and that no college has had an official representative in the Association during the last dozen or fifteen years. But we have nowhere seen a more interesting exhibition of this quality in criticism than is furnished in the second letter of "Vindex," to be found under the head of domestic correspondence in this number of the JOURNAL. In that letter occurs the following sentence:

"Had the Medical Society of the State of New York attempted, through its delegates, to move to

amend the Code of Ethics of the American Medical Association, the motion would, under ruling, have gone to the Judicial Council, and been disposed of, by your showing, without appeal."

A man of the high character for general and professional intelligence possessed by "Vindex," must certainly know that framing and amending codes of ethics, or constitutions and by-laws, are *legislative* acts; and that among no civilized people is the work of legislation committed to *judicial* tribunals.

The latter are established to *execute*, and not to *make* laws. Had "Vindex" taken the trouble to read the eleventh by-law of the Association, by which the Judicial Council is established and its duties defined, he would have seen that it was not authorized to take cognizance of or decide any questions but those of a "*judicial* character," and more especially such as involve "personal character, including complaints and protests and all questions on credentials." And should the Association so far forget its own constitutional regulations as to refer a proposition to amend the Code of Ethics, or any other legislative proposition, to the Judicial Council, it would be promptly reported back as not coming within the jurisdiction of that body.

By the action of the Association in general session at the annual meeting in Buffalo, June, 1878, propositions to amend the Code of Ethics were placed on the same basis and subjected to the same rules as propositions to amend the constitution. If "Vindex" will glance at section 7 of the constitution, he will see that "no amendment or alteration shall be made in any of these articles, except at the annual meeting next subsequent to that at which such amendment or alteration may have been proposed; and then only by the voice of *three-fourths* of all the delegates in attendance." If our friend "Vindex" will spare a few minutes more, in looking over the proceedings of the annual meetings in Buffalo, in 1878, and at Richmond in 1881, he can see it actually demonstrated that an amendment to the Code of Ethics was presented in due form in the meeting in Buffalo; laid on the table; taken up and discussed at the next annual meeting in 1879 and laid over for further consideration, and finally taken up, fully discussed in general session, modified, and adopted by the required vote of three-fourths of the delegates present at the meeting in Richmond in 1881. How, in the face of the most plain provisions of the constitution and by-laws, and in the light of the actual proceedings of the Association of such recent date, otherwise intelligent men can hazard their own reputations by such reckless and erroneous statements as those made in the letter of Vindex, as well as by many others, is not within our comprehension.

PREPARATIONS FOR THE NEXT MEETING OF THE ASSOCIATION.—All the information we get points directly to the fact that the coming meeting of the Association in Washington is to be one of the most interesting and important ever held. Especially is this true in regard to the scientific work in the several Sections. But the remaining time for preparation is short, and all who intend to present papers should be sure to communicate the fact to the chairman of the Committee of Arrangements before the end of March.

SANITARY PROGRESS.—The recent State Sanitary Convention held in Columbus, Ohio, was well attended, and elicited much interest. A permanent State organization was effected, with a prospect of doing much good.

SOCIETY PROCEEDINGS.

SUFFOLK DISTRICT MEDICAL SOCIETY.

[Section for Clinical Medicine, Pathology, and Hygiene.]

ALBERT N. BLODGETT, M. D., SECRETARY.

January 9, 1884. The meeting was called to order at eight o'clock, Dr. R. T. Edes in the chair. A summary of the proceedings of the last meeting was given by the Secretary.

Upon motion of Dr. George B. Shattuck the business of this meeting was suspended as a token of respect to the memory of the late Dr. Calvin Ellis, formerly President of the Suffolk District Medical Society.

Dr. Edes in announcing the result of the motion made some very appropriate remarks relating to his early acquaintance with, and life-long esteem for, Dr. Ellis, a man whose character would long be a living influence in the medical element of Boston. Dr. Edes then called upon Dr. George C. Shattuck, who spoke as follows:—

Dr. Shattuck said that he could not refuse an invitation to say a few words at this time, and to bear his testimony to the worth and excellence of our late associate, Dr. Calvin Ellis. It certainly is well for us survivors, after the departure of a highly esteemed associate, to meet together and put on record our appreciation of worth and skill and our sense of loss. Excellence and distinction in our profession are the result of original endowment, of industry in training faculties, in acquiring knowledge, and of fidelity and skill in the discharge of duties. A medical man must devote years to preliminary education, and then must be constantly studying and training his powers of observation and reasoning, as well as adding to his

stores of knowledge. There are those here who were associated with Dr. Ellis in his early years and will tell us of the qualities for which he was remarkable as a young man and a student. I became associated with him when he had already acquired reputation as a teacher and a practitioner, and was looked upon as on the sure road to distinction. I noticed and admired his knowledge and skill as the pathologist of the Massachusetts General Hospital and instructor in clinical medicine in the Medical School. His ability, knowledge and fidelity were recognized by professors and students. He was evidently the coming man in his department. And yet he worked patiently in subordination, was always kindly and courteous, and ready to carry out the plans of those who had the direction of affairs. When his predecessor retired in accordance with his own wishes and ideas of duty, Dr. Ellis was chosen professor of clinical medicine and visiting physician of the hospital, without any solicitation on his own part or from his friends, but because those who had the appointing power recognized that he was the fittest man to discharge the duties. The wisdom of the appointment was shown by many years of successful work. And when obliged by painful illness to retire from work, those who appointed him, those who worked with him, and those for whom he worked, preferred to wait for three years in the hope that his health and strength might be renewed so that the same skilled labor might still be at the service of medical science and instruction.

These hopes have been disappointed. He who knows what is best for each and all of us has removed him. We must acquiesce in this decision, whilst we may cherish the example of conscientious devotion to duty, of scrupulous regard to the rights and feelings of associates, of self-sacrifice in ministering to the sick and the poor, and in efforts to teach the young and the ignorant. May we all be able to profit by his example, so that when to each of us the summons to depart comes, the plaudit "well done, good and faithful servant," may be on the lips of survivors.

The Secretary then read the following letter from Dr. Henry I. Bowditch:—

JANUARY 9, 1884.

To the Secretary of the Section of Clinical Medicine of the Suffolk District Medical Society:—

DEAR DR. BLODGETT,—I am very sorry that I am at present confined to the house, and shall therefore be unable to be at the Memorial Meeting which is to be held by the Clinical Section of the Suffolk District Medical Society at its first meeting after the death of our friend, Dr. Calvin Ellis. The Section, in which he so long labored, acts most appropriately in proposing to have this Memorial Meeting.

Dr. Ellis has just died, after a long and distressing illness, which he bore without complaint and with a manly fortitude, while, however, looking forward hopefully, as was his nature, to its ultimate result, because it was non-malignant.

He was my pupil in his days of medical study, my assistant at the Massachusetts General Hospital, and afterwards my successor there, and also in the Professorship of Clinical Medicine at Harvard University; and, finally, he was always a beloved friend. For many years past I have often sought his advice, and no one that I met gave wiser counsel than he did; for his words were uttered only after a most rigid examination of the matter in hand. To me his loss is simply irreparable; for no one can fill another's place.

But I do not write this in order to praise him or to mourn for his loss. His own life is his highest praise; and the termination of the earthly career of a really noble soul has not a particle of sorrow connected with it, which is not far outweighed by a kind of satisfaction, not to say joy. The beauty of Dr. Ellis' every-day life from the cradle to the grave seems well rounded out by his serene, uncomplaining death. If with this death we remember the years of almost hopeless and severe suffering so sweetly borne by our friend, then death has no horrors, but comes rather as an angel of divine mercy to the relief of suffering humanity.

If by his intellectual acts a man has left, as Dr. Ellis has surely done, his impress for good upon hundreds who have either sought his instruction, or have met him in the daily walks of life, then the natural sorrow which we must feel for his loss is wonderfully mitigated; and he becomes forthwith a silent, but not less effective, exemplar, to all who knew, loved, and respected him. And where is there one who intimately knew Dr. Ellis who did not love and respect him?

Since his death I have been led to inquire into the antecedents of his family and of himself before we became personally acquainted, and I have been interested and instructed to find how many of his more striking moral and intellectual traits he owes to heredity. I shall give, of course, only a glimpse of the facts, because my purpose, on the present occasion, requires nothing more.

Two hundred years ago, or thereabouts, his earliest progenitor in this country came here from the ranks of the hard-handed independent-souled yeomanry of England. He settled in Dedham, Mass., and there tilled his acres and reared his family. A home on the site still stands, and it is occupied, as it has always been, by one of the same stock and name. Calvin Ellis, our deceased associate, was the seventh descendant from this first settler. It would seem that as the generations have passed along, solid work, and a belief in the real excellence and nobility of work, has been ever a prominent trait among all his ancestry. But there was with it also a love of culture, so far as that was possible in the earlier times. The Ellis family has given clergymen, physicians, lawyers, and energetic merchants, and many honorable and excellent men and women to the world. His grandfather brought up a family of eleven children, and, aided by the thrift and economy of his wife in her wise management of his household, left as the net result of their joint lives $30,000 for their heirs. Surely here was a trait of energy, physical and intellectual, worthy of commendation. This same grandsire believed so strongly in work that he had a contempt for the bare idea of a man's having "nothing

to do." His favorite expression was, "I would rather my son should throw stones from one heap to another, and then throw them all back again, than have 'nothing to do.'"

Again, fully believing in the excellence of the intellectual, as well as the physical training of any youth, he had his youngest son prepared to enter Harvard.

Unfortunately, as the story goes, the youth was by his brothers fairly laughed out of trying a college life.

Dr. Ellis' parents moved into Boston before his birth, and the father, Luther Ellis, became an energetic and successful iron merchant. Retiring from active business with a property ample for his wants, he had his son Calvin, our associate, educated for Harvard. Both parents have left loving memories of themselves in the hearts of their children, and of others. Their home, as the story comes to me, was one of those delightful places where parents and children mutually loved and respected and helped one another.

Religion, too, was taught in and governed it. The boys and girls went, in their earlier days, regularly to church. They were not governed by tales of terror as to the future, but were led to honorable thought and action rather by the examples of loving kindness and of independence of thought given to them by their parents.

They were styled Unitarians, a term of obloquy formerly—less so of late, since science has tended to break down sectarianism, that stronghold of the devil. The mother who presided over the domestic affairs had a gentleness and firmness of purpose, combined with a bright, contented, and self-sacrificing spirit. Her example proved to the children the lovableness of these qualities. The father, after long suffering borne with exemplary patience, died during the first year of Dr. Ellis' college life. Thus we see that while receiving from his earliest ancestors the fine manly traits of love of work, and of liberality and independence of thought, with a desire for culture of the intellect, so far as was possible, his parents left him also a legacy of sweet and winning traits, that shone so conspicuously during all the years of our friend's life.

As a boy he was of a quiet character, less boisterous than most boys of this age. He was, however, intelligent and bright, and a favorite with all who knew him. His college life was uneventful. He was an athlete, and was in the first boat's crew ever organized at Harvard. He took no very high honors, but he faithfully did his allotted tasks. Upon entering the Medical School, he used to say, he first awoke to his life's work, as play had been his object during his college days. He became earnest and was ever at work, to do what the hour called him to perform.

When I met him as an assistant he had no flourish or pretense or servility about him. He was always deferential, but not crouching submissively to me, or any one, though cheerfully undertaking what was imposed upon him by his superiors. He rarely, if ever, failed in the due performance of his task; always had that bright, yet dignified manner which he subsequently bore in his professional career. In his meetings with you, his associates, I am sure you always found him simple, thorough, and true. When dealing with a professional associate he needed no "code" of by-laws to keep him fair and honest. His own well balanced mind and generous spirit forbade him to do anything to injure a brother physician's reputation, even in the smallest degree.

To do so by a word, a covert sneer, or even a smile of doubt in the presence of by-standers, as is done at times by some of the stoutest defenders of the "Code," he abhorred. I shall never forget the glee (for, among other good qualities, he heartily enjoyed a joke) with which he told me, only a few months ago, how he and others had *squelched* instantly a proposition coming from a committee of the Counselors of the Massachusetts Medical Society, a proposition, which, had it been adopted by the Society, would have violated one of the prime rules of common courtesy, and even those of simple hospitality in many of our country villages and small towns.

As a teacher of medicine I need say nothing, as most of the younger men of this society must have known him well in that capacity. His object was to teach a student the methods that should be pursued in order to come to a perfect diagnosis. I was much struck with the remark made by one of the juniors of our profession, when I asked what Dr. Ellis' reputation was as a teacher among the pupils. He paused before reply, and then, in substance, said as follows: "Dr. Ellis while unraveling any case was less brilliant than some other more fluent professors, and he was called a little 'slow,' and tedious, as some thought. But, upon our arrival at Vienna, by comparing our method of grappling with cases in the German hospitals with the desultory and imperfect examinations made by students of some noted schools in other large cities of our country, we soon found that we had been *more thoroughly drilled* than they. The result was, that we understood more quickly and fully than they did all of the intricacies of a case."

No higher praise could be given to any professor than this simple, but significant, expression of one of his pupils.

He has left an unfinished work, entitled, I believe, Symptomatology. On this he was laboring every hour that his disease permitted him to work, even to the last few days of life. I sincerely hope that it has been so far finished that his literary executors can publish it. I was visiting him one morning while he sat half erect in bed. He was working then upon it, and was kind enough, at my request, to read me a short extract. From that, I was led to feel that the work would not only add to his well-merited reputation, and serve the student and junior practitioner long after the writer's death; but that it would perhaps mark an era in the correct study and practice of clinical medicine similar to that which followed the publication of the great French teacher Louis' works. In truth, it seemed founded upon the same principle that underlies all of Louis' works, namely, the absolute necessity of making a most careful diagnosis of a case before proceeding to treat it. It was fortunate for several American students of fifty years ago, that

even Louis, the great clinical teacher of that day, whose principles are now everywhere more or less perfectly carried into practice, was considered rather "slow" by his compatriots. Consequently, our small coterie of Americans and of Swiss students had his oral instructions all to ourselves, which has, of course, been of immense advantage to every one of us during our lives.

In Dr. Ellis's connection with the Harvard School his influence was always for a higher education and better practical measures. He may be called a "conservative reformer." He never moved until his judgment approved of a plan. When once decided in his opinion, no obstruction could prevent him from boldly urging forward the cause against the opposition of even the most powerful. This was seen especially in his efforts at progress in the Medical School's late reforms. During his last illness, he told me that every step taken forward was violently and persistently opposed; and I sincerely believe that had it not been for the efficient work of Dr. Ellis, aided by his earnest young coadjutors in the Faculty, no reform would or could have been accomplished, and as Dean of the Faculty no one contributed more than our friend did to these very desirable results. During his long illness he, from love of the school, remained one of the Faculty. At length his disease compelled him to resign his position of Dean, but he still hoped, even until the end, that in the intervals of his torture be would at times be able to meet and to lecture to his pupils.

Surely I think that even with these brief hints at the various passages of the life, and allusions to the intellectual and moral qualities of our friend, we can feel in the language of Wordsworth, that

"The child is father to the man,"

and his days were

"Bound each to each by natural piety."

May this fine example of a life of true work not be lost on any of us. Yours very truly,

HENRY I. BOWDITCH.

Dr. C. D. Homans said: Probably no one present knew Dr. Ellis so long or so intimately as I did. Perhaps Rev. Dr. Bartol may have done so, but certainly no one else. We were boys together, we were in college together, we were abroad together, and we have been together ever since. When in college Dr. Ellis, though a good scholar, was not brilliant, but was a hard student and a continuous worker. He was always a favorite, and was much interested in the pastimes of those days. He was an athlete, and was a member of the first boat club which was formed at Harvard College. We bought a boat together when we were in the Massachusetts General Hospital, and in our spare hours were fond of rowing on the Charles River. The water then came up almost to the stone building which at that time comprised the entire hospital. He always kept up his love for athletic exercise, and even in his last years was very fond of walking, often preferring to go on foot rather than in his carriage to visit his patients. In some ways Dr. Ellis was particularly fortunate. He was hardly ever ill during his life until the commencement of the disease of which he died. He was fortunate also in possessing a competence, and was not obliged to trouble himself in regard to pecuniary matters. While a student in the Medical College he was one of the few who attracted the attention of the late Dr. J. B. S. Jackson, who for years made all the autopsies in and around Boston, and from him Dr. Ellis derived that love for and knowledge of morbid anatomy which was so useful to him in after life. He was a worker as long as he lived. During his last illness, in fact up to within a few days of his death, he was engaged in the intervals of his sufferings in the preparation of a medical work for the press, which he left nearly finished.

It afforded him a great deal of satisfaction to be informed that, within a few days of his last attack, a letter had been received by a friend from a young physician, at present in Vienna, who stated that as a result of the careful clinical training received from Dr. Ellis, students from Boston were able to profit much more largely from the advantages offered by European hospitals than were those coming from other American cities and schools.

The disease from which Dr. Ellis died was ulcer of the duodenum. It first commenced about nine years ago, and continued to cause him more or less suffering from that time until his death. It was at first feared that it might be malignant, but the course of the disease disproved this, and it was then supposed to be ulcer of the stomach, but finally the diagnosis of duodenal ulcer was made, and was found by the autopsy to be correct. Death finally ensued from perforation and consequent peritonitis. Dr. Ellis never was willing to make a positive diagnosis of his own case. Through all his sickness he never lost his interest in what was going on. Just before his death he was planning what he would do when he got out again. For some time he was driven in a low carriage, and he was getting tired of this, and thought of buying a coupé as soon as he was strong enough to go out. During the last year he had been obliged to keep his bed much of the time, yet he always got out a little whenever possible. At times he would leave his bed and go for a drive, and on returning would go at once to bed again. On the day of the last municipal election he rose, and was driven to the polls, and voted, and returning home went immediately to bed as usual, and never rose again. Through all his sickness and suffering he never murmured or complained, but was always patient and resigned, and when the pain became easier his cheerfulness and good-humor at once returned. He was always glad to see his friends, and seldom spoke of his own distress.

In all he did Dr. Ellis was actuated by a strong sense of duty and intense love of his profession. He had the greatest interest in the University and Medical College, which he has proved by the fact that he has bequeathed his entire estate to the University after the death of his sister, most of it for the special benefit of the Medical School. As a physician he was loved and respected; as a counselor his advice was sought far and near; as a teacher and professor and public spirited man the entire community knew

and appreciated his worth, while only those who were intimate with him can know how faithful he was to every demand which friendship might make upon him.

Dr. Sargent, of Worcester, having been requested, sent the following communication:—

"I am more than gratified, for I am also flattered, in being asked to contribute something to the testimonial of the general 'admiration of the noble and generous qualities' of Dr. Calvin Ellis, whose recent death is so great a loss to the profession and to the public.

"My acquaintance with Dr. Ellis was of long standing, but it was rather friendly than professional, for I never had occasion to have any professional relations with him whatever. It commenced in Paris in one of my periods of residence there, in the year 1850, and I see him now in his long walk from the neighborhood of the Garden of Plants to the schools and the hospitals. Then as always he was studious, sensible, thorough, faithful, and reliable. I renewed my acquaintance with him on his return to Boston, and was somewhat instrumental in his being placed on the commission for investigation of the peculiar pleuro-pneumonia of cattle, nearly twenty-five years ago. I had afterwards some other public relations with him. His sound sense always, his good judgment, and sincere convictions, and his fidelity to them, won, as they deserved, the greatest respect from the profession and the public.

"I never had the advantage of listening to any of his instructions from the professorial chair, but as I have had them described to me by young men who were so fortunate as to be his pupils, their thoroughness and richness and exactness must have been a very valuable contribution to the distinguished excellence which is so conspicuous in the Harvard Medical School.

"Commencing practice in Boston in a new era, when the microscope had just begun to peer into pathological anatomy, and its use was so seductive and engrossing as, perhaps, to warrant the witticism of our justly admired Dr. Holmes, then not more distinguished in literature than in medicine, and probably the best read American physician of that time, 'Now for an era of little men,' he recognized all that was true in what was new, and adopted all that was valuable. And so with him always. His scope was large, and great good sense directed his judgment and governed his work. His influence and his example have been a great good and an honor to the profession, and an advantage to the public.

"Let no man say that merit shall not command success."

HARVARD UNIVERSITY, MEDICAL SCHOOL.

BOSTON, MASS., January 7, 1884.

DEAR SIR:—In reply to your letter of January 4, it gives me great pleasure to express to you the sympathy of the entire Medical Faculty in the feeling which has prompted your Society to appoint an evening for holding memorial exercises in honor of our late Professor of Clinical Medicine, Dr. Calvin Ellis.

Although I am not authorized by the Faculty to promise any formal coöperation in your services, yet the individual members of that body will doubtless gladly avail themselves of the opportunity thus afforded of testifying by their presence to their great respect for Dr. Ellis' noble character, and to their high appreciation of the value of his services as Dean of the Faculty during a most important epoch in the history of the School; as a clinical teacher of rare power and enthusiasm, and as a practitioner of medicine gifted with unusual soundness of judgment.

Yours very truly,

H. P. BOWDITCH, Dean.

DR. A. N. BLODGETT, Secretary.

Dear Doctor:—I regret to say that owing to illness in my family I shall not be able to attend the meeting to-night. Very truly yours,

JAMES C. WHITE.

Wednesday.

MY DEAR BOWDITCH:—I am grieved not to be with you to-night, to show by my presence at least my appreciation of the character of our late associate and friend.

The profession will do justice to his memory.

Let me add my tribute to his fidelity as a physician, his ability as a lecturer, his integrity as a man.

Faithfully yours,

D. HUMPHREVS STORER.

Jan. 9, 1884.

Dr. Oliver Wendell Holmes, who was unable to be present, sent the following touching letter:—

CALVIN ELLIS.

My recollections of Dr. Ellis go back to the period of his pupilage. Of the large numbers of students with whom I have been in relation as teacher, I do not remember one about whose future I felt more assured. He had all the signs of promise—active intelligence, industrious habits, love of his work, a vigorous frame, a cheerful temperament, an agreeable presence stamped with every outward sign of a sincere and manly character. I looked forward to his becoming a leading practitioner with a confidence which his after career fully justified.

He united many rare qualifications. He had studied disease long and diligently, in the changes left by it in the various organs, and thus laid the foundations of his skill in diagnosis. But he never forgot that medical science is only the handle of the medical art. His assiduity, his patience, his self-devotion as a practitioner were unmeasured and unstinted, as I have known from personal observation. He forgot everything but his patient, he remembered everything for him in the chamber of sickness comforted by his quieting and commanding presence.

Every interest of the profession was very dear to him. The Medical Faculty of the University of which he was so long the Dean, found him a most willing laborer and a generous benefactor. The Boston Medical Library was indebted to him for valuable services and liberal contributions. He could not be otherwise than faithful in all that he undertook, for integrity—wholeness of character—belonged to him in its fullest measure.

Some of you knew this brother of ours more intimately than I can have known him. You will not think, I am confident, that I have exaggerated the excellencies of this wise and skillful physician, this true and goed man, whose loss will long be felt by the profession and the community. O. W. H.

NEW YORK, *January* 7, 1884.

DR. ALBERT N. BLODGETT, *Secretary*:

My dear Sir:—I beg the privilege of offering to the members of your Society my sincere condolence in the loss which they have sustained. I had not the pleasure of a personal acquaintance with the late Calvin Ellis; but he was well known to me, and to all interested in medical education, as a painstaking, conscientious student of disease, and as an able, patient, and effective clinical teacher. In his death not only the School with which he was connected, and his professional brethren in your city, but the profession of the whole country and American medicine have sustained a great loss. Cut off in the midst of his useful labors, and at an age when many more years of valuable services in behalf of medical education were to have been hoped for, our only consolation is in the reflection that he leaves a noble example which should incite others to follow in his footsteps.

Will you kindly remember me to those who will be present at the meeting on the 6th inst., with the assurance that I should have been glad to have been able to ayail myself of your invitation to be present on that occasion.

With much esteem, very truly yours,
AUSTIN FLINT,
418 Fifth Avenue.

Rev. Dr. Bartol, upon being invited to make some remarks, spoke with great feeling and emotion as follows: I am here, Mr. Moderator, through courtesy and kindness on the part of this Society. I have listened with great interest and gratitude to what has been said by those who have spoken before me. The atmosphere of this meeting seems like a new consecration to duty. This Professor of Clinical Medicine whom we have assembled to honor to-night was not a *professor* in any other way. Whatever mistakes or vices the science of medicine or its sister professions of theology and law may be liable to, Dr. Ellis was free from them. There was in him no assumption of wisdom or authority. He took no bias in any unprofessional conduct.

In speaking of what Dr. Ellis was, and did, and said, we have referred to him in the *past*, but my feeling toward him is such that I can only speak of him in the *present* tense. Whatever hope we may have of some future life, or heaven after we have left the body, is revived by such fidelity. Every word which has been uttered to-night finds an echo in my own heart.

Dr. Edward Emerson, of Concord, rose and said: "I thank you for the opportunity to say a word for the older students. The character of Dr. Ellis as a physician has been dwelt on in an appropriate and worthy manner in the remarks of those who have spoken. One special feature of his life has, however, not been touched upon, and that is his position among those who were so fortunate to be his pupils. He was a leader in the medical profession to a striking degree. He gave no long lectures on morals, delivered no tedious homilies, but his daily life exerted a gentle yet continuous influence, which was always a lesson to those about him, and was all the more powerfully felt because it was exerted unconsciously.

As a friend Dr. Ellis was always thoughtful, unselfish, and devoted, as I know from my own experience. For some time I was in the habit of going to him for advice, not professional but personal, and he always took a most paternal interest in all which personally concerned those more closely associated with him."

The Secretary then read the following resolutions, which had been prepared by one of the members, and which were adopted unanimously:—

Resolved, The Section of Clinical Medicine of the Suffolk District Medical Society at its first meeting after the death of Dr. Calvin Ellis desires to express its admiration of him as a professional associate, a great clinical teacher, and above all as a man of noble character.

Resolved, That our respectful sympathies are hereby tendered to the sister of Dr. Ellis in this her great loss.

Resolved, That the above resolutions, signed by the chairman and secretary of the Section, be forwarded to the sister of Dr. Ellis.

STATE MEDICINE.

CONNECTICUT STATE BOARD OF HEALTH SANITARY REPORT.

BY DR. C. W. CHAMBERLAIN, SECRETARY.

MORTALITY IN OCTOBER, 1883.

	HARTFORD.	NEW HAVEN.	MERIDEN.	WATERBURY.	NEW BRITAIN.	BRIDGEPORT.	NORWICH.	NEW LONDON.	MIDDLETOWN.	WILLIMANTIC.
Total deaths	102	75	17	39	16	49	30	16	28	5

In public institutions	7	9	..	..	..	..	..	..	10	..

The deaths from consumption, which always ranks high among the ten principal causes of death, indicate the usual increase that occurs during the spring

and autumn months, trying seasons for weak lungs in this climate. Thus far, however, the season has been very mild and the death rate has not so rapidly advanced from this cause. Bronchitis and pneumonia began to be somewhat prevalent during the latter part of the month. The weather has apparently been favorable to the development of malarial fevers, and an increased prevalence is quite generally reported. While perhaps rather more cases of intermittent fever, that is acute tertian ague, have been seen this season than for several years, in the districts where malaria has been prevalent for some time, yet the prevalent type generally is the typho-malarial and the less clearly defined varieties of malarial diseases. Typhoid fever, although steadily increasing in frequency, does not apparently so frequently drive out malaria, as malaria appeared to drive out typhoid fever when it first commenced to extend over the State, so that for years not a case of typhoid fever occurred over large areas, and it lost place among the ten principal causes ot death throughout the State. That the decreased frequency of typhoid was entirely independent of the malarial invasion now is quite clear. The return of typhoid is also not dependent upon the decrease of malarial diseases, as we see it side by side with all varieties of ague, not only where the latter has longest remained as one of the regular diseases of the region, but also where malarial diseases are entering territory hitherto never occupied, so far as human knowledge can determine, by any form of ague; and also where having existed quietly for several years, malarial diseases become epidemic, leaving but a small percentage of the people unaffected. The subject is too complicated to discuss here, but the increased frequency of both malarial diseases and typhoid fever are interesting features.

Stafford reports typhoid fever as more prevalent than usual. The table shows the mortality in the cities. The frequency in Waterbury is decreasing. Avon reports both typhoid and malarial fevers. Typhoid fever is reported from Hampton and like places, where malaria has not yet become prevalent; in no case any epidemic, but, as was formerly the case, appearing to a greater or less extent every autumn, the degree varying as sanitary regulations were transgressed or observed. A few cases of malarial fever are reported from Haddam and adjoining towns, from Tariffville as frequent; from Watertown and that region generally typhoid is reported, with not much malaria. From Thomaston fatal cases of both typho-malarial and typhoid fever are reported, and the former, with whooping-cough, stated to be the most prevalent diseases. Westport and New Canaan report both typhoid and malarial, the latter one fatal case of typhoid, and a death from this cause is also reported from Cheshire. This indicates the distribution of these diseases to some extent.

There was a decrease in the prevalence of diphtheria in Hartford early in October, but it was only temporary, and the mortality reached a higher point than in any month. The mortality as given last month since June was 90; the total to November 1st is 133.

In connection with the Chairman of the Board of Health of Hartford, a special study of the regions affected has been commenced. As before stated, the drainage of the houses themselves, the lack of traps and ventilation of the drains, and the storage of filth in vaults, and the like, appear to be the chief local factors. Contagion does not appear to have been the cause of the prevalence, except to a limited degree.

The city Board of Health have under advisement an ordinance for the proper sanitation of tenement houses which shall hereafter be constructed, as a measure to improve the general healthfulness of the city, as the defects of the present system, where no precautions are required, scarcely require argument to prove.

There have been quite a number of cases of diphtheria in New Hartford, three deaths from diphtheretic croup. A few cases of diphtheria are reported from North Manchester and Greenwich; cause, as usual, unsanitary surroundings.

The causal relations between filth, in its sanitary sense, including the products of putrefactive decay, and the prevalence of disease and increase of the death rate, have been repeatedly illustrated; while, on the other hand, the control rendered possible by such relations is an incentive to renewed exertions.

HEALTH IN MICHIGAN.

Reports to the State Board of Health, Lansing, by observers of diseases in different parts of the State, show the principle diseases which caused most sickness in Michigan, during the week ending Dec. 15, 1883, as follows:

NUMBER OF OBSERVERS HEARD FROM, FORTY-ONE.		For preceding week.
DISEASES ARRANGED IN ORDER OF GREATEST AREA OF PREVALENCE.	Per cent. of observers who reported the disease present.	Per cent. of observers who reported the disease present.
Bronchitis	63	46
Neuralgia	59	63
Rheumatism	59	71
Intermittent fever	51	66
Tonsillitis	51	46
Consumption, of lungs	51	46
Influenza	34	49
Pneumonia	34	32
Diarrhœa	27	27
Inflammation of kidneys	22	24
Remittent fever	20	34
Measles	20	15
Erysipelas	20	22
Scarlet fever	17	20
Typhoid fever (enteric)	15	15
Whooping-cough	15	22
Puerperal fever	15	7
Typho-malarial fever	12	15
Diphtheria	10	15
Inflammation of brain	10	5
Dysentery	10	12
Cerebro-spinal meningitis	7	0
Cholera morbus	7	2
Chicken-pox	5	3
Inflammation of bowels	5	15
Cholera infantum	5	2

For the week ending Dec. 15, 1883, the reports indicate that puerperal fever increased, and that intermittent fever, influenza, remittent fever, rheumatism, and inflammation of bowels decreased in area of prevalence.

At the State capitol, the prevailing winds, during the week ending Dec. 15, were southwest; and, compared with the preceding week, the temperature was lower, the absolute and the relative humidity less, and the day and the night ozone more.

Including reports by regular observers, and by others, diphtheria was reported present during the week ending Dec. 15, and since, at 20 places, namely, Antwerp, Big Rapids, Crystal Falls, Detroit, Duplain, Groveland, Grand Rapids, township of Grand Rapids, Howard City, Leslie, Laketown, Monroe, Niles, Pontiac, Pierson, Ronald, Sebewaing, Six Lakes, Winfield, Wheatland. Scarlet fever at 18 places, Adrian, Detroit, Eveline, Ensley, Grand Rapids, Kalamazoo, Monroe, Muskegon, Memphis, Owosso, Oxford, Plymouth, Roxand, Reynolds, Selma, Salem, Springville, Winfield. Measles at 12 places, Corunna, Cedar Springs, Charlevoix, Clinton, Detroit, Grand Rapids, Gaines, Monroe, Muskegon, North Adams, Pontiac, Swartz Creek.

HENRY B. BAKER,
Secretary.

LANSING, Dec. 19, 1883.

BOOK REVIEWS.

HEALTH, AND HOW TO PROMOTE IT. By RICHARD MCSHERRY, M.D., Professor of Principles and Practice of Medicine, University of Maryland, President of the Medical and Chirurgical Faculty of Maryland, etc., etc. Second edition. New York: D. Appleton & Co, 1884.

This is a small volume on private hygiene, the hygiene of the family, and is addressed more particularly to the non-professional reader. Avoiding scientific terms and tedious details, and dealing with his subject in an easy, pleasant style, the author has certainly presented his readers with a highly entertaining as well as instructive book, filled with valuable hints regarding the attainment and preservation of health, good morals, and happiness. Its pages are enlivened with witty remarks, pleasant anecdotes, and a kind of insinuating good humor calculated to improve the assimilating capacities of a confirmed dyspeptic, or even make an hypochondriac feel on better terms with himself. Altogether, it is one of the best books of the kind with which we are familiar.

J. C. H.

THE DISSECTOR'S MANUAL. By W. BRUCE-CLARKE, F.R.C.S., Senior Demonstrator of Anatomy and Operative Surgery at St. Bartholomew's Hospital, etc., etc.; and CHAS. B. LOCKWOOD, F.R.C.S., Demonstrator of Anatomy and Operative Surgery at St. Bartholomew's Hospital. Philadelphia: Henry C. Lea's Son & Co.

This is one of those invaluable aids to the student in his study of practical anatomy. It commends itself alike in regard to quality and quantity. While it is small enough to readily slip in the pocket, it is unusually complete in describing the steps in the process of exposing to view each successive structure to be dissected. It contains 49 excellent cuts, which are nearly all new, and which were drawn from preparations specially prepared under the direction of the authors.

J. C. H.

THE estimate now before the Municipal Council for the expenses of the Paris hospitals and hospices for 1884, sets them down at $4,046,600—being $123,300 higher than 1883, on account of the rise in the amounts and prices of the various articles of diet, and of some medicinal substances. From a comparison of the years from 1865 to 1882, the population of these establishments has increased by 21 per cent., the expense of medicines by 55 per cent., and that of diet by 41 per cent.

DOMESTIC CORRESPONDENCE.

PUERPERAL ECLAMPSIA.

On page 220, vol. I, of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, I reported a case of puerperal convulsions. I now wish to report another case that occurred in my practice since. Mrs. P. H. sent for me in the forenoon of January 7, 1884. I found her suffering from fever, frequent micturition, general anasarca, nausea, violent frontal headache, great restlessness. Diagnosis: uræmia. Gave her three compound cathartic pills as a purge; pot. bitartart. and tinct. digitalis as a diuretic; pot. bromide and chloral hydrate, as a nervous sedative. Early the next morning I was called again, the messenger stating that she was in convulsions. I hurried to the house and found her conscious. Her husband told me that she had had three convulsions during the night. I now gave her an enema of forty grains of hydrate of chloral, and continued the treatment of the day before. In the evening of the same day I found that she had had no convulsions during the day. I gave her another enema of the same quantity of chloral.

January 9, I found her much improved, and by the 12th she was so far recovered that she could sit up; had no headache and no nausea any more, but still had a little ancsarca of the lower limbs. She took no other medicines than those above mentioned. This woman was in the eighth month of pregnancy. There was no dilatation of the os, and she had no pains.

January 25 I was called again, and found her in labor. On examination I found the os dilated. On rupturing the membranes, the liquor amnii escaped, which was thick, reddish (as if discolored by blood), and small in quantity. As I knew the child to be dead I gave ergot, and she soon gave birth to a female child in the third post-mortem stage, or putrefaction. After she had had the convulsions, the woman could not "feel the child," neither could I detect the fœtal heart. This shows that the child died during one of the convulsive seizures, and was retained in utero as a foreign body for two weeks and a half. The woman has given birth to fourteen children, and has had convulsions once before.

W. F. HERTZOG, M.D.

NEW JERUSALEM, PA., February 11, 1884.

WASHINGTON.

On January 29, a bill was introduced into the U. S. Senate for abolishing the office of Assistant Surgeon-General.

At the same date a bill was introduced into the House of Representatives providing for the sale, at public auction, of the Naval Hospitals at Chelsea, Mass.; Brooklyn, New York, and Annapolis, Maryland.

The newspapers of recent date (Jan 31) give an account of an interview of two medical men in the Government Service with the committee on the District of Columbia, House of Representatives. They expressed views in favor of a bill (H. R. 1791) which reads: That any corporation in the District of Columbia which shall withhold any privileges of membership therein from any person on account of said person being in the service of the United States, shall forfeit its corporate powers, and upon complaint and satisfactory proof thereof to the District Court, said court shall declare null said corporate powers, and restrain all persons from exercising them hereafter.

From what has transpired it is evident that this bill was introduced to restrain the Medical Association of the District of Columbia from making any distinction in its membership. As it is now constituted, it is composed of members and associate members. The members with full rights and privileges are those who devote themselves to their profession; the associate members have all the privileges of members with regard to consultations, fees, etc., but have not the right to vote. This class was established for the benefit of clerks in office, and others in government employ, a large and growing class of doctors in the District of Columbia, with whom the practice of medicine is a secondary consideration, from a pecuniary point of view at least. This Association performs no social or literary work—it simply meets twice yearly, or oftener if convened by request, to consider medical ethics It is difficult to see, however, how such a bill can influence it in any way, as it is in no sense a corporate body, and simply a voluntary organization.

OLEOMARGARINE, ETC.

HOUSE OF REPRESENTATIVES, Feb. 7.—Mr. Beach, of New York, from the Committee on Agriculture, reported back with an amendment the following preamble and resolution:

WHEREAS, It is alleged that the interests of the American agriculturists and dairymen are greatly and unjustly injured by the manufacture, sale and use of oleomargarine, butterine, suine, and imitation, artificial, and adulterated butters of different kinds, and of adulterated and imitation compounds and mixtures sold and consumed as dairy products; and

WHEREAS, It is alleged that fat and oils of hogs and cattle and of other animals, and also that vegetable oils are used in the making and compounding of suine, oleomargarine butter, butterine, and adulterated and imitation dairy products, and also that such fats and oils are used, and are imported and are exported to be used for the making and compounding of such artificial, adulterated, and imitation dairy products, and that such adulterated imitation compounds are surreptitiously sold in this country and elsewhere in competition with genuine dairy products, greatly to the injury of the agriculturists and dairymen of the United States; and

WHEREAS, It is alleged that the manufacture, sale, and exportation and disposition of said compounds, materials, and commodities is so conducted as to avoid general publicity, and to prevent the obtaining of accurate or desirable statistics in relation thereto, and to mislead and deceive the consumer as to the actual character, composition, and ingredients thereof; therefore,

Resolved, That the Committee on Agriculture be, and hereby is, instructed to inquire into and investigate the said allegations, and ascertain the facts relating thereto, and the facts and statistics of the adulterated and imitation compounds and mixtures of dairy products, and of the materials composing the same.

The amendment recommended by the committee was to and to the resolution the following:

And to this end the said committee is hereby empowered to send for persons and papers.

The resolution with the amendment was placed on the House Calendar, and ordered to be printed.

MARINE HOSPITAL SERVICE.

YELLOW FEVER AT HAVANA.—The Inspector of the Marine Hospital service at Havana reports to Surgeon-General Hamilton that there were 482 deaths in that city during the month of January. Thirty of these were caused by yellow fever, and of these 25 were among the merchant, shipping and private citizens, and the remaining 5 were from the army and navy. During the same month in 1883 there were only 14 deaths from yellow fever. This year has been noted for absence of hurricanes and high winds at that point.

RAVAGES OF SMALL-POX.—The Surgeon General of the Marine Hospital service is informed that small-pox is epidemic at Louisville, Ky., and that there were seven deaths from that disease in the Marine Hospital there during the week ending January 31. He has also received a letter from the Deputy Collector at Kodiak, Alaska, stating that small-pox was raging among the Indians in the western part of the Territory, and requesting that the officer of the Marine Hospital service at Sitka superintend the vaccination of the natives. Dr. Hamilton has referred the matter to the House Committee on Public Health, with the request that provision be made for granting the request.

PROPOSED SANITARY INSPECTION ON GULF COAST.—It has been suggested by an officer of the Marine Hospital service that a thorough inspection of all the cities on the Gulf of Mexico, not only in the West Indies, but in South and Central America and Mexico, be made at once, before the onset of extreme hot

condition, with reference to the quarantine service of the United States during the coming season. The matter will be presented to the Secretary of the Treasury for action. Secretary Folger has approved the recommendation made by Surgeon-General Hamilton for an immediate inspection. A medical officer of the Marine Hospital service and a revenue marine officer will be detailed to make the inspection.

Consul-General Sutton, who is stationed at Matamoras, advocates strongly the establishment of an international quarantine in the ports belonging to the United States and Mexico that border on the Gulf of Mexico. The commerce with Mexico has been greatly hindered by the lack of proper laws in Mexico, and by the arbitrary, uncertain and inefficient manner in which the local American quarantine laws are enforced. He drew up memoranda on this subject, which he laid before Señor Romero, minister from Mexico to the United States, Gen. Cuellan, and Gov. Canales for their consideration, which has been favorable and which will probably result in some definite action being taken. He considers that quarantine stations should be established at Vera Cruz, Tuxpan, Tampico, and Bagdad, in Mexico; and Brazos de Santiago, Galveston, New Orleans, and Mobile, in the United States, to be governed by such rules and regulations as shall be agreed upon by the two countries; the quarantine being intended to prevent infection, protect commerce and the passenger traffic. The expenses to be met by both countries, and the scheme to be perfected in time to meet the exigencies of the coming season.

MEDICAL CORPS UNITED STATES NAVY.

Acting Surgeon-General of the Navy.—Since the expiration of Surgeon General Wales' term of office, there has been neither chief nor assistant chief of the bureau. Dr. Hudson will act as Surgeon-General until a new one is appointed by the President, and it is inferred that a nomination of that officer may be still delayed some time.

NEW YORK LETTER.

To the Editor of the Journal of the American Medical Association:

Dear Sir:—I am under obligations to you for your editorial of Feb. 9. It confirms my statement, if any confirmation was needed, that the American Medical Association is in the grasp of a few men. Had the Medical Society of the State of New York attempted, through its delegates, to move to amend the Code of Ethics of the American Medical Association, the motion would, under ruling, have gone to the Judicial Council, and been disposed of, by your showing, without appeal. Such modes of action may secure, for long periods even, a simulation of peace and harmony, but volcanic eruption will surely, sooner or later, give vent to pent-up opinion.

The question of the right of a State Society to change its by-laws or code of ethics, and to retain its place in the American Medical Association, was of importance enough to justify some discussion. That question, more or less varied, was inevitable when States began to pass statutes regulating the practice of medicine within their respective bounds, and therefore, to define what was the meaning of the phrase—a regular doctor.

Had the credentials of the delegates from New York been received by the clerk on presentation, and referred to the Judicial Council for a hearing, it might have been justly made to appear that the New York State Society had only exercised its prerogative in amending its by-laws so as to make them consistent with the statutes of that State and public policy.

Your statements only confirm those of my former letter in showing that, however cunningly the machinery of the American Medical Association may have been devised in the interests of harmony, it certainly is not, in its plan or working, entitled to the name of "American," and must undergo material change.

Vindex.

Buffalo, Feb. 9, 1884.

Editor of the Journal of the American Medical Association.

Dear Sir:—Permit me to thank you for your kindly interest in the subject, and for your generous treatment of my note of recent date.

You have fully explained that the term *member elect* as used in the paragraph you quote: "Every member elect prior to the permanent organization of the annual meeting, or before voting on any question after the meeting has been organized, must exhibit his credentials to the proper committee and sign these regulations," was intended to include and did include all classes of members, or as you put it, "actually includes every member presenting himself for admission or registration." Your construction being official, must of necessity be accepted. As the opinion of an individual it might possibly be criticised, but as the official utterance of the organ of the Association, it, to members, must be conclusive.

The importance of having one source of authoritative interpretation seems well shown in this case.

To the unjudicial mind the term "member elect," as used above, might be deemed to apply only to delegates chosen but not qualified, and this view might appear to be confirmed by the words of the second line, "or before voting on any question," inasmuch as it is well known that a large number of permanent members can not vote.

This impression might appear to receive still further support from the emphatic words of the fourth line, "must exhibit his credentials to the proper committee," when it is remembered that the permanent members not attending as delegates have no credentials to exhibit.

There are then three chances in the single paragraph for the unwary to be misled. He is a member elect, he is one of a class of voters, and he must have credentials.

Surely the ordinary mind may be pardoned for not seeing in this a provision for the government of permanent members, who may not vote and who have no credentials.

weather, with a view of ascertaining their sanitary

In spite of what you say of the term, "these regulations," I still have doubts upon the subject, and will send you a note upon my difficulties as soon as I can get a reply to an inquiry addressed to the Permanent Secretary some three weeks since.

Sincerely,

H. R. HOPKINS.

INEBRIETY.

HARTFORD, Conn., Jan. 22.

My Dear Doctor:—The enclosed inquiries are addressed to you by the American Association for the Cure of Inebriates, which was organized in 1870 for the purpose of studying the nature and causes of inebriety from a purely scientific standpoint.

The purpose of these questions is to gather the practical experience and observation of leading members of the medical profession, as a basis for a more accurate knowledge of the nature and character of inebriety.

Full answers to these inquiries and other facts relating to this subject are most earnestly solicited, and will be fully credited to each reporter. The results of this investigation will be sent to each one free when published.

Trusting to hear from you soon, I am with thanks, very truly yours,

T. D. CROTHERS, M.D., Sec. of Committee
and Editor of *Journal of Inebriety.*

1.

Can you give any facts from observation bearing on the heredity of inebriety; particularly as to the presence of insanity, epilepsy, phthisis, inebriety, or other neuroses in the parents or relatives of inebriates?

Give cases with histories if possible.

2.

Can you give any history of inebriates whose drinking dated from or was influenced by head injuries, sunstroke, syphilis; or could be traced to mental shock, disease or injury of any kind; also to overwork, nervous exhaustion, anæmia, and any specific causes which broke down or injured the system?

3.

Have you seen any cases in which insanity or epilepsy either preceded or followed inebriety? If so, was it traced to the use of alcohol alone, or was it due in part, or in whole, to some inherited or acquired diathesis?

4.

Have you noted any distinction between the different forms of inebriety, such as irregular, continuous, or periodical inebriety? State any facts you have noticed which relate to the periods and forms of drinking.

5.

What particular mental and physical changes have you noticed concerning the character and general health of the inebriate, that would suggest the idea of disease and the need of physical care and treatment?

6.

Have you noticed any form or condition of inebriety that seems to be produced or is largely influenced by the kind of alcoholic drink used, or the work engaged in, or the food or climate, or any other unsanitary surroundings?

Illustrative cases concerning any of these inquiries will be welcome, and a full expression of opinion from observation and experience is urgently requested.

NECROLOGY.

LEWIS, MAGNUS MEWES, M.D., of Alexandria, Va., died at his residence in that city, on the 19th day of January, 1884. By this death, society has lost a gentleman, our profession an ornament, and the community in which he lived a citizen who, "take him for all in all, we shall not look upon his like again." He was the son of Dr. Robert Lewis, and his christian name was that of his mother's grandfather.

He was born in Jefferson county, Virginia (now West Virginia), on February 8, 1824. His academic studies were finished at the school of Benjamin Hallowell, so widely and favorably known as a teacher. Leaving Hallowell's, he studied medicine, and attended his first course of lectures at the University of Virginia. From this institution he went to the Jefferson Medical College in Philadelphia, where he was graduated in the spring of 1847. Shortly after graduating, he returned to Alexandria, and devoted himself to his profession. Rightly believing that no man, in this profession, without hard study, could rise above mediocrity, he applied himself closely to the acquisition of that knowledge which, in after years, he used with so much skill and judgment. For some time, his practice was amongst the very poor of our population.

> "In misery's darkest hovels known,
> His useful care was ever nigh;
> Where hopeless anguish poured his groan,
> And lonely want retired to die"

In return for the clinical experience thus acquired, as compensation for his work, their summons were never mocked by cold delay, but were answered with promptness and attended with care; but his talents and ability soon gained him a more lucrative practice.

When the war between the States broke out, he left his home with the 17th Virginia Infantry of the Confederate service, and while at Manassas Junction, Va., he was appointed Surgeon of that regiment. He was soon made Medical Director of Gen. Longstreet's Brigade, and was afterward Chief Surgeon of Pickett's Division. In each of these positions, he acquired additional reputation. What was the limit of his ability, I cannot say; it ever seemed to be superior to the occasion. After the surrender of Gen. Lee's army, he returned home, and showed his community that

> "A wise physician, skilled to heal,
> Was more than armies to the public weal."

It was not long before his growing reputation overshadowed his predecessors. Of his successful operations, I can now recall the following: Ovariotomy, amputation of the thigh for a large exostosis of the femur, removal of an immense fibro-cartilaginous tumor from the neck of a man 70 years old, tracheotomy for removal of a foreign body, excision of an encysted tumor of the throat, previously pronounced malignant, and unsuitable for surgical interference, by eminent surgeons, and a double synchronous amputation of the legs. Of Dr. Lewis it might be quoted:

"How he solicits heaven, himself only knows, but persons strangely visited, the mere despair of surgery, he cures."

His attitude to his professional brethren was one in which the gentleman and physician were ever blended. To that native dignity which so characterized him, and to that marked observance of etiquette so necessary in our profession, he united a rare unselfishness, which often prompted him to share the success and reward of his own operations with physicians younger and less deserving than himself. The loving confidence and loyalty of his patients was something of which any man might justly boast, and this was often his only recompense. In the eyes of his lady patients he stood, "like Saul amongst his brethren, much taller than the rest," and long will they hold in tender remembrance

> "The touch of a vanished hand,
> And the sound of a voice that is still."

He was a member of the Alexandria Medical Association, the Virginia State Medical Society, and of the American Medical Association, having been a delegate to the latter in 1858.

Some eighteen months ago Dr. Lewis first suspected the cause of certain cardiac troubles which affected him. This was Bright's Disease, in the form of contracted kidney. He sought the best medical advice of the country, but from none could he receive encouragement. His disease, unhappily, was too well marked to be mistaken; but, like a true man, he submitted to the inevitable, and bore with a fortitude almost sublime the sentence passed upon him.

> "Calmly he looked on either life, and *here*
> Saw nothing to regret, nor *there* to fear."

And thus he died, in the prime of life and the height of usefulness.

> "His life was gentle, and the elements
> So mixed in him that nature might stand up,
> And say to all the world,
> '*This was a man!*'"

R. C. Powell, M.D.

Alexandria, Va., February 6, 1884.

Mme. Broca offers a prize of 1,500 francs ($300), to be given by the Anthropological Society of Paris for the best memoir on a question concerning human anatomy, comparative anatomy or physiology, bearing on anthropology. The first prize will be awarded in April, 1884.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department United States Army, from February 9, 1884, to February 15, 1884.

To be Assistant Surgeon with the rank of First Lieutenant, to date December 3, 1883:

William D. Dietz, Walter W. A. Fisher, William Stephenson, Adrian S. Palhemur, John L. Phillips, Renben L. Robertson, William C. Borden, Edgar A. Mearns, Guy L. Edie, William D. Crosby, William L. Bundler, Charles M. Gandy, Charles S. Black, James E. Pilcher, Alonzo A. Chapin. (S. O., A. G. O., Washington, Feb. 11, 1884.)

Brewster, William B., First Lieutenant and Assistant Surgeon; resignation accepted, the date From Feb. 7, 1884. (S. O., A. G. O., Washington, Feb. 11, 1884.

Changes in the Medical Corps of the Navy for the Week Ending Feb. 16, 1884.

Medical Director S. F. Cones to the Naval Medical Examining Board, Philadelphia, March 3, as the relief of Medical Director P. J. Howitz, who retires on that date.

OFFICERS OF

THE AMERICAN MEDICAL ASSOCIATION

AND OF ITS SEVERAL SECTIONS 1883-4.

PRESIDENT.

Dr. AUSTIN FLINT, SR., of New York.

FIRST VICE-PRESIDENT.

Dr. R. A. Kinloch, Charleston, S. C.

SECOND VICE-PRESIDENT.

Dr. T. B. Lester, Kansas City, Mo.

THIRD VICE-PRESIDENT.

Dr. A. L. Gihon, United States Navy.

FOURTH VICE-PRESIDENT.

Dr. S. C. Gordon, Portland, Maine.

PERMANENT SECRETARY.

Dr. Wm. B Atkinson, 1400 Pine St., Philadelphia.

TREASURER.

Dr. R. J. Dunglison, Philadelphia.

LIBRARIAN.

Dr. C. H. A. Kleinschmidt, Washington, D. C.

Place of meeting, 1884, Washington, D. C.; Time of holding meeting, first Tuesday in May.

CHAIRMAN COMMITTEE OF ARRANGEMENTS.

Dr. A. Y. P. Garnett, Washington, D. C.

ASSISTANT SECRETARY.

Dr. D. W. Prentis, Washington, D. C.

BOARD OF TRUSTEES FOR JOURNALIZING THE TRANSACTIONS.

Drs. J. M. Toner, Washington, D. C., President;
M. Moore, Rochester, N. Y.; Leartus Conner, Detroit, Mich.;
J. H. Packard, Philadelphia, Secretary;
H. F. Campbell, Augusta, Ga.; A. Garcelon, Lewiston, Me.;
P. O. Hooper, Little Rock, Ark.;
L. S. McMurtry, Danville, Ky.; J. H. Hollister, Chicago, Ill.

OFFICERS OF THE SECTIONS:

"Practice of Medicine."

Chairman—Dr. John V. Shoemaker, Philadelphia, Pa.;
Secretary—Dr. W. C. Wile, Sandy Hook, Conn.

"Obstetrics and Diseases of Women."

Chairman—Dr. T. A. Reamy, Cincinnati, Ohio; Secretary—Dr. J. T. Jelks, Hot Springs, Ark.

"Surgery and Anatomy."

Chairman—Dr. C. T. Parkes, Chicago, Ill.; Secretary—Dr. A. O. Walker, Detroit, Mich.

"Ophthalmology, Otology and Laryngology."

Chairman—Dr. J. F. Chisolm, Baltimore, Md.;
Secretary—Dr. J. L. Thompson, Indianapolis, Ind.

"Diseases of Children."

Chairman—Dr. Wm. Lee, Baltimore, Md.; Secretary—Dr. W. R. Tipton, Las Vegas, N. M.

"Oral and Dental Surgery."

Chairman—Dr. T. W. Brophy, Chicago, Ill.; Secretary—John S. Marshall, Chicago, Ill.

"State Medicine."

Chairman—Dr. Deering J. Roberts, Nashville, Tenn.;
Secretary—C. W. Franzoni, Washington, D. C

Committee on "Necrology."

Chairman—Dr. J. M. Toner, Washington, D. C.

—THE—

Journal of the American Medical Association.

ORIGINAL ARTICLES.

WHAT THE ANCIENTS KNEW CONCERNING OBSTETRICS AND GYNÆCOLOGY.

TRANSLATED FROM ÆTIUS BY G. M. B. MAUGHS, M.D., PROF. OF OBSTETRICS AND GYNÆCOLOGY, MISSOURI MEDICAL COLLEGE, ST. LOUIS.

Presented to the Section on Obstetrics and Gynæcology of American Medical Association, June, 1883.]

A short time since I was presented by my friend Dr. Dickinson with a Latin folio edition of all the extant works of the two most valuable Greek medical compilers, Oribasius and Ætius. The book itself is some 300 years old, and in a good state of preservation —never having been read,and though published only a little over 100 years after the invention of printing, could scarcely be excelled in mechanical execution at the present day. But any value that might be attached to this is utterly lost in the priceless value of its contents.

Oribasius, a learned Greek physician of the fourth century, was court physician to the Emperor Julian, and wrote his great work, the Hebdomekontabiblos or Seventy Volumes—a compilation of all that was known of medicine, at the order of Julian, who was as remarkable for his cultivation of letters as for his hatred of the Christian religion. He also wrote an abridgment for his son Eustathius, in nine books. Of the great work some twenty-five volumes have been preserved, together with all the abridgment in nine books. All of this is in my Latin edition, turned into Latin and dedicated to Cosmo Medici, Duke of Florence, by Dr. John Babtist Rasarius of Novarensus, in 1553. The work as preserved covers pretty fully the departments of materia medica, anatomy, and the practice of medicine and surgery, all of which contain many articles, instructive and well calculated to dissipate any inflated ideas we may entertain that wisdom began with us, and to inspire us with veneration for those great men who at this early age had placed the healing art abreast with the most advanced thought of the day.

In gynæcology there are many really valuable and accurate articles, such as Prolapsus Uteri, On Exciting the Menses, Fleur Albus, On Ulceration of the Uterus, etc.; but the compilation of the learned Oribasius, full and valuable as it is, was written amidst the hurry and excitement of court and camp, and lacks the fullness and accuracy of Ætius—the most learned, able, experienced and honest of all the Greek compilers, who practiced and wrote at Alexandria in the sixth century, at the time when the library in the Serapion contained at least a copy of all that was known in medicine and all other departments of human knowledge, while its dissecting rooms gave an accuracy in anatomy no where else to be obtained. And yet this great work has, I believe, never been published in any modern language, certainly it never has been in English. Had it been, it would have saved many learned assertions of modern authors concerning the knowledge of ancients, from publication.

I can not even guess why the Sydenham Society should have had the learned translator of the "Genuine Works of Hippocrates and the Extant Works of Ætius" also translate the comparatively worthless, incomplete and unreliable works of Paulus Ægineta, a Greek compiler of the seventh century, who, without ability or experience, certainly made his compillation without the aid of the Alexandrian library, and if he had any other works to compile from, than Oribasius and Ætius, certainly did not use them. A fact that leaves less regret, when we learn how bad a use he made of these, and yet this work is done in English possibly to show us how much the ancients knew of medicine, a purpose it utterly fails to accomplish. But even this would be of less consequence but for the fact that the learned translator, Dr. Adams, in his exhaustive commentaries on Paulus Ægineta, which have furnished the source from which much subsequent learned reference to the ancients has been derived—constantly does great injustice to Ætius, and thus to the world, frequently stating that Ætius agrees with his author, as though he had not lived a century before Paulus, who has stolen the article from Ætius. and through ignorance or desire to hide the real author, has done it so badly that the article has lost its value by the theft.

But scarce as are the works of Ætius, and little as they are read or quoted, they existed in the libraries of Europe, and as we shall see furnished the mine, the metals from which has been made the fortune of not a few discoveries. (?)

The works of Ætius in this edition, turned into Latin in 1512, by Dr. Janus Cornarius, Greek and Latin Professor at the Imperial city of Frankford, consist of his Tetrabiblus, or Four Books. Each book is divided into four sermons or discourses, each discourse consists of a great many chapters. The

last one of the Fourth Book of the Tetrabiblus is entitled "On the rationale of conception and parturition and diseases of women, especially those of the uterus and mamma; also of the preparation of most precious ointments, potions and perfumes." Surely, in reading this title page we might suppose the book was not of the seventh, but belonged to the nineteenth century. This fourth discourse of the Fourth Book consists of 112 chapters on Obstetrics and Gynæcology. It also begins, as all such works may be expected to, with a description of the uterus and its appendages, which we give:

"De uteri, situ, magnitudine ac forma, chap. 1.

On the situation, size and form of the uterus.

The uterus, Greek *metra*, this is called the matrix, because all life originates from it as from a mother. The same is called hystera, beause it is situated beneath all the viscera. For the uterus is placed within the peritoneal membrane lining the abdomen and all the intestinal convolutions, between the bladder and rectum, and lies upon this nearly its entire length, and upon the bladder to near the umbilicus, where is its fundus, for the most part mounting here above the bladder. But near the part stretching to the pudenda, the bladder extends beyond the uterus by its neck. Its size is not the same in all, for the uterus is much smaller in those who are not pregnant, but larger during pregnancy, but in those who have never been pregnant the uterus long continues even less, and until near puberty it is least in those who have not arrived at venereal desires, and is always smaller in those who have never had sexual intercourse.

And then the length of the uterus in women is ordinarily from near the umbilicus quite to the vagina, and is about eleven finger-breadths, but its width extends from either side between its horns. But whatever size it may attain, all that remains, the body, and more especially the fundus, is like a bladder. But in that it has nipples which spring up, produced from either side of the fundus and stretched to the loins, it is not like a bladder. These productions, which are called horns, tend at first upward, afterwards downward, and they are a little narrowed, so that their terminations are like veins; and these narrowed parts of the horns, as flexible tubes are carried to the ovaries, which are situated by either side of the uterus, by either side of the fundus near the cornua, and through these winding canals of the horns, in congress with the male the uterus draws the semen from the ovary. But the female testicles (ovaries) are small and not round, and oblong, and composed of tender flesh, as in the male, but broad and glandular and membranous. Moreover, the uterus is attached to the bladder and rectum by interstitial fibers, and attached to the sacrum by ligaments, which are strong, fibrous and muscular. There are ligaments and appendages which are inserted into the uterus, a part of which are interwoven and platted into the body of the uterus, not a small part of which are nerves originating from the spinal cord, but a part are incrementual and nutritive to the uterus itself, and made subservient to the fœtus. Such are the arteries and veins, for from the vena cava, which runs along the spine from the convex part of the liver, and from the great artery which lies upon it, two nerves and two arteries originate, indeed on either side a vein and an artery, and these four vessels are distributed to the uterus, but, before being inserted into this, give off branches to the ovaries, and afterwards are inserted into the body of the uterus and interwoven with its substance, and from these the menstrual blood in the uterus is derived. But there are other veins and arteries inserted into the uterus, a part of these are sent to the ovaries and a part extended to the neck. And, in fact, the body of the uterus consists of two membranes, an external, which is serous, and an internal, which is vascular; an external which is simple and one, but the internal is double; so that if we desired to peel it off there is seen to be two uteri (cavity of body and cervix) under one and the same membrane. Again, the neck of the uterus is muscular, and composed of hard and cartilaginous flesh, and always harder at its termination, and as time advances becomes cartilaginous, so much so in those who have had many children, and in old women, as as to resemble to the touch the upper part of the throat, and there is a meatus in the neck through which the menstrual blood is discharged and the woman receives the male semen, and through which the fœtus also passes, for, wonderful to relate, this opening is distended to so great a magnitude at this time. For the remainder of the time it is only sufficient to admit the point of a sound or a substance a little larger, and when the woman is pregnant it is closed so that it will not admit anything. But at the time when the fœtus is discharged from the womb the pains of parturition distend it to so great an extent that, wonderful to hear, the whole child passes through it. The neck ends and is terminated at the vagina or at the pudenda; moreover, the length of the vagina in women of mature age is about six finger breadths, nevertheless in labor and coitus it becomes shorter; doubtless in these states the neck of the uterus extends itself. During girlhood the vagina is soft and delicate, but in old women and in those who have had many children it becomes hard and like cartilage, because from the frequent congress and the forcible distention of labor it is hardened. It is also hardened by the presence of the menses, and not less by the abundant flow of acrid humors, by which hard ulcers and fistulæ are produced. And then at the time of menstruation the uterus is thickened and swollen, at other times it is thinner and contracted. It is also thicker and larger in those who have had many children, but thinner (smaller) in those who have never been pregnant.

It is also thickened from the first day of conception. But when the fœtus is developed, and during labor, it becomes thinnest, but thinned as a bladder becomes by being distended with air, its thickness being drawn out in its long diameter; and this much have we said as to the situation, size and shape of the uterus."

Commentary.—This remarkable description of the uterus is only wanting in our modern more distinct divisions of a subject and our more concise terms of

expression to give it a fitting place in a work on obstetrics and gynæcology of the eighteenth century. The author is not wanting in anatomical knowledge, but here, as in many other instances, the facts, though clearly known, are imperfectly communicated, for want of concise terms to express them.

The statement that the womb is called matrix because all life originates from it as from a mother, and that it is called hystera because placed under all the viscera, are facts worth stating and perhaps not known to all. The length of the uterus given is during pregnancy, and is true. The description of the oviducts and their uses left nothing for Fallopius to discover, this, together with his description of the uterine blood-vessels and their uses, of themselves, refute the assertion made and believed, that the ancients had no physiology. Now, how did Ætius know what modern science has so lately learned,—that the extremities of the Fallopian tubes were applied to the ovaries during ovarian orgasm, and that through them passes to the uterus from the ovaries whatever the female contributed to the reproduction of the species? and how did he know that the mouth of the uterus in the non-pregnant condition would only admit the point of a sound if they had no uterine sound, or only used it, as Dr. J. G. Simpson supposes, as a therapeutical agent? and how could he know that during pregnancy the canal was closed against even this? or that the uterus was succulent and thickened during menstruation? or that it beeame intumescent from the first day of conception? Such knowledge is in advance of that at the beginning of the nineteenth century, and proves conclusively that he possessed a vast fund of accurate anatomical and physiological knowledge not given here, not given because not compatible with the nature and subject of the chapter. After reading this description we suppose no one will again assert that the ancients did not know or did not discriminate the os uteri from the vagina! Surely Ætius did not suppose that the os vaginæ of a woman bearing children would only admit the point of a sound, and that after conception it would not admit even this?

"On the assistance that should be given those in whom conception is hazardous.

"Some women when they conceive are endangered in parturition, either from the smallness of the uterus, so that the fœtus cannot escape from it, or from narrowness of its neck, or because a tumor (polypus) or some such like substance is developed within its entrance, which complicates the labor, and certainly such are best served, if they are entirely guarded against parturition; and should they conceive, it is safer to probuce an abortion than to dissect and remove the fœtus at term. For these reasons we must proceed from the order of destroying the fœtus, to that of producing sterility. For that which induces sterility, differs from that which destroys the child, for it prevents conception, this done it kills and expels it. Therefore as a woman must not conceive she must first take heed not to have intercourse with the male at the time when conception is most likely to take place, namely, at the beginning and termination of the menstrual flow, and then in the act of coitus when the male semen is being ejected she must hold her breath, that the semen may not be carried within the uterine cavity, and immediately rise up and placing herself upon her knees provoke sneezing, and carefully wipe the pudenda. To prevent conception also the mouth of the womb may be smeared over with honey, or with opobalsom, or with cedar oil, either by itself, or mixed with white lead. In like manner she may use white lead mixed with liquid myrtle cerate or with alum water, or galbano with wine, also of a like nature are cold and astringents applied to the meatus, just before coitus, as they close the mouth of the uterus and prevent the semen penetrating within its cavity. But also the excitation of heat not only drives the semen of the male from the uterus, but draws and extracts the remainder of the tumors. But those things which follow prevent conception and induce sterility."

Commentary.—Here follows in the next chapter a long text of very efficient suppositories, washes and drinks for the prevention of conception, by which we are assured that the women of ancient Greece and Rome were often as anxious to escape conception as are some of those of New York and St. Louis, and also that they were provided with perhaps quite as efficient means as are those of the present day. Again in the next chapter, "On the Production of Abortion," which is credited to Asparia (by the way, there never was a female writer on midwifery by this name), shows that this accursed art had been brought to great perfection 2,000 years ago, and if less efficient than some of those of the present day, it was only because less dangerous.

"Pariendi difficultatis causæ.

"On the causes of difficult labor."

"Difficult labor happens from various causes, from that which affects the body or the mind of the puerpura, or from weakness of both at the same time; either from smallness of the uterus, or because of narrowness of the meatus, also those who, on account of age or shortness of stature generally have the uterus corresponding with the rest of the body. It is possible for difficult parturition to arise either from obliquity of the neck of the uterus, or from the growth of flesh (polypus) to the neck of the same, or from its mouth, or from inflammation, or disease or induration of the same parts, or because the fœtus cannot rupture its surrounding membranes, or because the water collected in the uterus is discharged prematurely, and at the time of labor the parts being without the water, are dry; for the waters are of the greatest service at this time, as they give easy passage to the child. Or because the puerpera has a stone in the bladder, which by compressing the neck of the uterus renders labor difficult, or it may be caused by grossness or fatness of the pregnant woman. Also, the labor may be rendered difficult by the two compact union of the pubic bones, so that they cannot dilate during labor; for the pubic bones in women are not connected as in men, alternately (serrated suleres), but are jointed by strong ligaments. The same difficulty in parturition is caused by a too great cavity of the loins (promontory of sacrum) compressing the uterus, or from the great quantity of excre-

ments retained in the rectum or bladder. Sometimes, also, the parturient patient is debilitated from age. Others begin to bear down during the first stage of labor, through ignorance, or on account of inexperience of how properly to prepare the body, or because they have not yet attained the age or strength of wo manhood, but to this time have remained as girls. Difficult labor may be produced when all or a part of the child is of extraordinary size, or the head or the thorax, or the abdomen is of undue proportion; or when the fœtus, from weakness, is not able by its leaps and movements to assist its mother; or when there are two or three children, or when twins advance and both suddenly engage in the neck of the uterus together; or when the fœtus, having perished, can give no assistance in the labor, or when being dead it is swollen; or lies præternatural, for the position of the presenting fœtus is natural when it advances so that its head is straight, with the hands extended upon either thigh, but præternatural when the head is turned to either the right or left side of the uterus, or when one or both hands is prolapsed and the legs are separated from each other. Yet less is predicted of the rest of the form in those which present by the feet, especially if they advance with a hand extended upon either thigh. But the fœtus which presents with one foot prolapsed, while the other is detained within the uterus, or doubled up resting upon some part of the uterus, requires correction, just as do those who have the hand extended. Those which present obliquely are less objectionable, and this may happen in three ways, for either one or the other side of the fœtus presents or the belly; but the presentation of the side is easiest, for then the midwife, by introducing her hand, straightens either the feet or the head of the child. And then those that present double are in the worst position, more especially if the presentation is by the pelvis. But there are three ways in which they may be doubled, for either the head and legs, or the abdomen may be in the mouth of the womb; but it is preferable for it to be on the abdomen, for these are dissected by us, and after removing the internal parts the pieces come down and the shape is readily changed.

"In like manner parturition may become difficult if the membranes, either because of their thickness do not break, or because of their thinness rupture too soon; moreover, difficult labor may arise from external causes, for the meatus may be contracted if the season of the year is cold and stormy, or it may be relaxed by the heat of summer. All of these difficulties occurring to women in labor, it behoves the physician to inquire of the midwife, and not rashly to resort to surgery, nor should the midwife be permitted to continue to dilate the uterus for any undue length of time. If therefore the labor is rendered difficult by the lumbar cavity (projecting sacral promontory), the patient should be placed in a chair, with the knees bent forward, that the uterus may lie within its neck straight; the fat and fleshy are placed in the same manner. But if the difficulty is because ot some narrowing or stupor, or contraction, assistance must be given by laxative warm hip baths or fumigation, such also as a warm room, and inserting of both actual and potential warm oil (pungent oils or those warmed), and also by the application of ointment and poultices of the same property. Relaxation may also be produced by baths, and, if not forbidden by fever or some other cause, by carrying the bed of the patient into a warm room. Some have also advised strong shaking in this condition. But for those who are prostrated by weakness in their labor, we must produce firmness by strengthening, condensing, and more especially astringent remedies, such as sprinkling them, and the use of hip baths of decoctions of myrtle, vine leaves, or roses, or aromatic decoctions with vinegar, and ointments from wine and rose oil cold. But if the difficult labor is caused by the preternatural form of the fœtus itself, it must be reduced to the natural conditions by such means as we are able to use, but if a foot or hand present, we must not draw upon it, as the greater impaction would be produced thereby, or it might be even dislocated or broken, but with a finger under the shoulder or thigh we change the position of the fœtus and bring down the presentation in a more favorable manner. But if at the same time with contraction, the entire condition of the fœtus is unfavorable, it is first lifted up from the os to the upper part of the womb, and afterward it is brought down again to the mouth of the womb straight, and that this may be done gently, safely, and without contusion, constant anointing the parts with oil must be observed, for upon this depends the safety of the child and the mother, and the uterus also remains uninjured. And if the mouth of the uterus remains closed, it must be softened and relaxed by fat ointments. But if the difficulty should be on account of a stone in the bladder, we must push this out of the neck of the bladder with a catheter—and if the bladder is distended with urine, it must be emptied with a catheter, and if the rectum should be loaded with excrements, they must be removed by a clyster; and if the woman should not be able to accomplish her delivery by reason of inflammation, or abscess, or ulcer, loose tumor (fibroid) or induration, she must be relieved from each of these by suitable treatment. But if the labor should become difficult by the springing up of flesh (polypus) in the neck of the uterus, or from some kind of congenital solidity of the membranes, as happens in imperforate women, whatever may be the nature of such impediment, we must cut it away; and if from the membranes surrounding the fœtus being too solid, so that is not able to rupture them, they must be cut open. But when from the too early discharge of the waters, by which the parts, at the time of labor, are left dry, we must inject into the vagina the white of eggs, with decoctions of mallows, or warm barley water, and if smallness of the uterus is the cause of the difficulty, the parts must be anointed with some kind of fat, also fomentations must be used, and the os uteri dilated with the finger, and the fœtus forcibly extracted; but if not successful in this, it must be dissected. This is done more especially when the fœtus is too large or dead. That the fœtus is dead we may know by the cessation of movements and from its appearing cold to the touch. And if there are twins or triplets obstructing the mouth of the uterus, we should lift the

others to the fundus of the uterus, and first deliver that one which appears nearest delivered. But if the difficult labor is caused by the great size of the head or thorax, or belly, all that is necessary is to open these. Moreover, the time for placing the woman in chair is when the mouth of the womb is open to the touch, and the membranes ready to rupture."

Commentary.—This long and interesting chapter is taken from Philumenus, a distinguished surgeon and gynæcologist of the 2d century. The next chapter, "On the Dissection and Extraction of the Fœtus," is credited to Philumenus, and constantly repeats the directions in this, showing conclusively that this is from the same author. We are then given here, not the opinions and practice of Ætius of the 6th century, but carried back to the state of obstetrical knowledge some 1,800 years ago. While some of the statements of the author are obscure or fanciful, particularly as to the position of the fœtus, which they really did not understand—and even Ambrose Pare candidly admitted that, though he had labored to determine, he did not know what was the natural position of the fœtus—yet it is exhaustive in the relation of actual causes of difficult labor, and fertile in his resources in removal of the difficulty, so much so that all Europe could not have duplicated this chapter in better the days of Smellie.

The causes of difficult labor are very properly stated to be dependent upon pathological states of the mother or that of the child. Of the mother the causes may be either physical or mental, and this is true. Of the pathological conditions of the mother he relates, smallness of the uterus (hypothetical) narrowness of the os (rigidity), smallness of stature (true), age, either too old or too young (true), obliquity of the uterus (beautifully true), the growth of flesh in the neck or os (polypus or fibrous tumor, true), inflammatory states (true), because cannot rupture the membranes (firmness of membranes cause delay), too early discharge of water, (true in fact, and why?), stone in bladder (true), too fat, too fleshy (true), anchylosis of pubic bones, (true), projecting sacral promontory (true), loaded rectum or bladder (true), bearing down in first stage (true), excessive fœtal development (true), multiple pregnancy (true), locking of twins (true), dead and intumescent fœtus(true), praeternatural positions (true), head bent upon neck (true). The means indicated for meeting these various causes of difficult labor, either caused by mother or child are often just such as a scientific obstetrician should give at the present day. The time for placing the woman in the chair is just that which we observe at the present time—to do so previous to this time would be to unnecessarily confine the patient, to defer it longer would be hazardous.

The too firm union of the pelvic bones so that they cannot dilate, or separate, is a question we are yet discussing. I, however, fully agree with Philumenus.

"Cancri Chirurgia. Leonidæ."

"On the surgical treatment of cancer, by Leonides.

"In the treatment of those cancers that arise upon the breast I (says Leonides), rely entirely upon surgery, which is done thus: "I make the patient lie upon her back, then I cut upon the sound part of the breast, above the cancer, and burn in the incision with a red hot iron until a crust is formed sufficient to arrest the flow of blood; I immediately incise again and dissect up from the deepest part of the mammæ, and again burn the incised parts, and after this I repeat the cutting following it with the red hot iron sufficient to arrest the hæmorrhage. The first burning is for the arrest of the hæmorrhage, but afterwards the burning is for the removal of every vestige of diseased tissue. But often also when the indurated cancerous tumor is situated less deep in the breast, the entire operation is performed without the cautery, for in such cases it is sufficient to amputate to the sound parts, as there is no danger from hæmorrhage.

Commentary.—This chapter on the surgical treatment of cancer of the breast, follows that description of cancer of the breast by the two great gynæcologists of the first century, Archigines and Leonides, and shows that with all our boasted knowledge we have not improved upon the skill of these immortal surgeons of 1,800 years ago. Indeed, the operation here given is better than the more artistic one of the present day, and with chloroform it might be relieved of the hideous suffering then inflicted. But in operating for cancer, as life or death hangs upon the perfection of the removal of the disease—even this is of but little moment. Some may ask, Why did they not apply ligatures to the bleeding vessels instead of burning, for the arrest of hæmorrhages? This would be answered with the statement that the ligature is of modern invention or discovery, for which we are indebted to the genius of Ambrose Pare. This is not true, as these surgeons were just as familiar with the use of the ligature to bleeding vessels as Dr. Gross or Billroth; and if any surgeons from the days of Galen, second century, to that of Ambrose Pare were ignorant of them, it was because they had not done what Pare did, read the ancients. *En passant*, we may say that Hunter discovered how to cure aneurism from Ætius. They did not apply the ligature, because the theory was that cancer was caused by black blood, and this should be permitted to run out to as great an extent as might be compatible with the safety of the patient; while, therefore, the first burning was for the arrest of the hæmorrhage, the last was for the removal of any vestige of the disease—vestiges which so constantly escape the eye and knife in our artistic operation, that one of our distinguished surgeons has nearly ceased to advise operation in this disease.

"De reclinatione, aversione æ recursu uteri Aspasia.

"On lateroversion, anteversion, and retroversion of the uterus, by Aspasia.

"In suppression of the menses, from necessity, there is repletion of the veins and arteries tending to the uterus; for the blood which runs quite to the mouths of the vessels, but is not able to pass into the uterine tissue, either because from its too great thickness it impinges against their mouths and coagulates, or because the mouths themselves are closed and their passage obstructed so that the veins, filled with fluid, are distended, and the appendages in the vicinity of

the uterus are swollen, by which distension the uterus is withdrawn; and if the drawing is equal from both sides, the lateroversion or retroversion of the uterus is equal (no displacement), but if the traction is made greater in one part than another, as is caused by the viscera, namely—the liver or the spleen, the distended veins of which overflowing with blood, draw the uterus from these parts, the veins of the liver from the right, those of the spleen from the left, as either may be more full. But to whatever part the uterus is inclined, we may know by touching with the finger and by the following signs. For if it is inclined obliquely, distension, pain, coldness, impediment, and numbness of the near thigh will disclose it; sometimes also dryness of the same groin, followed by weakness in resting upon that limb, and difficult locomotion. But if it is inclined backward (retroverted or retroflexed), or downward (prolapsed), motion of either leg is followed by numbness and difficulty. Often like movements well nigh intercepted, and violent pains harrass the patient; the bowel is likewise constipated, nor does it admit an enema unless the patient is placed upon her knees. The flatus is also retained, and pains are excited at the anus, especially if the displacement is against the anus (retroflexion); and if it is turned to the pubis (anteverted), the hypochondrium and pubis are distended, and pains invade the same parts; likewise, sometimes the urine is retained in this form of displacement. Therefore, in whatever manner the uterus shall have been displaced, it ought to be treated during the exacerbation in the same manner as inflammation. But in the remission and decline of the disease a more mild treatment may be used, but with the disease persevering we must use such things as have the property of drawing from above (cathartics), and of changing the habit of the body (alteratives), and indeed we should treat displacement against the anus (retroversion) thus: First, we should direct the midwife to lift up the uterus by introducing her finger into the anus; then she may place in the anus a suppository four fingerbreadths in length, prepared from galbanum and wax, and to the extremity of which a thread has been attached, for its more ready removal; or wool with castor diluted with water, or dry bitumen, or liquid pitch may be used in a similar manner. But on the following day tepid oil of irini or lilies may be thrown into the vagina and rectum, and the parts should be fomented with some aromatic decoctions, either horehound or fleabone, and the vagina may be washed with the same; afterwards rose cerate may be used. But if the drawing back inclines obliquely (retroflexed), first the same fomentations may be used; then the midwife, with a sound introduced with the finger, straightens the neck of the uterus; the patient is then placed in the supine position, or on the opposite side to the one affected. Moreover, a mild and aperient suppository may be used, and some of the formerly named oils should be thrown into the vagina, and washed with wine and rose oil, or flaxseed emulsion prepared with wax should be placed upon the pubis, and we may give to drink musk, anise or cumen or nigella, peonyroot or gentian or myrrh, or carrot seed, or heartworth, or elecampane from vinegar and honey. Likewise the same may be done in violent attacks of pains in the uterus, not each single and by itself, but also united together. Also, the woman should be laid with her head elevated; and if the uterus, after being properly replaced, is again drawn back, some fetid substance should be immediately placed to the nose and sneezing excited. And if the urine is retained, it should be drawn off with a catheter. And if the paroxysm should be relieved by this, there is quiet. Again, for the exacerbation of the disease, if the patient is young and plethoric we may consider the propriety of extracting blood from the arm. We may then give emmenagogue drinks and use the milder pessaries.

Commentary.—This remarkable chapter proves conclusively that the ancients not only recognized the diifferent kinds of uterine displacements, but were scarcely less apt than ourselves in remedying them, only wanting permanent supports that have become so fashionable among modern gynæcologists, to render their treatment as efficient as that of the present day. But if they were wanting in the pessary mania of the present day, whereby each and every local operator, through some lucky twist or screw of some strange device, called uterine support, hopes to attain immortality—their patients were gainers. They also, as is seen, used the uterine sound for displacement as we do. And yet the uterine sound is a modern invention? Nothing equal to this chapter was again written for more than 1,500 years.

The directions given to the midwife to do this or that prove that it was not written by a midwife, but by a physician, most probably about the time of Hippocrates, when Aspasia, the celebrated mistress of Pericles, had made the name famous.

"*De uteri abscessus Archigenis.*"

"On uterine (pelvic) abscess, by Archigenes."

"The formation of an abscess in the uterus, as in other parts of the body, is preceded by inflammation. First, therefore, the signs of inflammation are apparent, then, about the time the pus is formed, the pains are increased and a fever with rigors, most violent in the evening, a tumor is developed, and the pains become more pungent; sometimes the urine and sometimes the fæces are retained, or both at the same time, but the seat of the pain will indicate the locality of the affection. Therefore, if it is not possible to discuss it, we must use such treatment as hastens suppuration. For this purpose we apply flaxseed meal, boiled figs, althæ root and turpentine made into a poultice. These poultices are applied to the hypochondrium and loins, while the vagina is constantly fomented by means of a sponge and vapors, by means of a reed inserted in a perforated covered vessel and carried into the vagina. Frequent hip baths should be used, composed of decoctions of such things as have drawing properties, such as pennyroyal, horehound, laurel sage, wormwood, dittany or centuary, but in cases where the patient is afflicted with more violent pain, we should apply poppy heads boiled, bruised, and made into a poultice, also raw figs rubbed up in a mortar with pine resin, turpentine, and a portion of niter may be applied. We may also use a suppository prepared thus: ℞ The fleshy pulp of figs, goose grease, oil of irini

aa℥ij; turpentine, ℥jss; rue, ℥jij; ungunt iridis nitri, aa℥iv; raisins may be substituted for the figs. Wool may be made into a pessary, dipped in warm oil of irini or cypress and introduced into the vagina; but the most efficient remedy for this purpose is a composition called Cyphoides, and previously described when treating of abscess of the liver, and likewise enneapharmacum, a preparation used for indurations, also poultices of goldcup and other substances of a like nature, also pessaries may be placed in the vagina saturated with oil of lilies or telis. Likewise the lower abdomen and pubis should be constantly fomented with some select decoction. Should the abscess break, if the pus escapes into the bladder, and is discharged with the urine, milk drinks and cucumber seed decoctions are prescribed, and cataplasms are used, composed of fragrant emollient substances. But if the pus passes into the rectum, and is discharged with the fæces, or by itself, we must throw up the bowels enemas of decoctions of pomegranate rind or mastich, but if it breaks into the vagina and the pus is laudable, injections of rose oil or tetrapharmacum with fresh butter and rose oil may be used, and the parts washed with decoctions of roses or mastich. But if a thin and fetid ichor like that from noma or phagedenic ulcer is discharged, more astringent injections must be used, such as are the decoctions of myrtle berries, palm, mastich and pomegranate rind. Moreover, if after the discharge of the humor, the inflammation should continue, we must persevere also in the use of the poultices and hip baths formerly described, and if the matter discharged is unequal, fomentations and hip baths of decoctions of horehound, vetches or mastich must be used, but the parts must be washed with barley water, with honey and rose oil added; at the same time the os uteri and anus should be anointed with rose cerate or butter, to which is added some dross of tin or lead, or foam of silver (lithrage), which may be mixed with breast milk, also lead water may be used. But if the discharge should become very offensive, the vagina should be washed out with wine and honey, and we must continue in the use of these until the cure is perfected.

"*Abscessus oris uteri chirugia.*

"On the surgical treatment of abscesses of the womb (pelvic abscess).

"If the abscess is situated about the mouth of the womb, so that surgical treatment can be used, we should not be in haste to open it too early, but wait until the disease is perfected by the greater increase of the inflammation, whereby the parts containing the pus are thinned. And then the woman is placed supine in a chair, with her legs drawn up upon the abdomen and her thighs separated, with her arms brought down under the legs and properly secured by a cord passing over her neck; she is then placed before a clear light, when the surgeon, seated by her right side, separates the pudenda with a speculum (dioptra) suited to the age of the patient, and makes an examination, and with a sound measures the length of the vagina so that he may not compress the uterus with the stem of a speculum longer than the vagina. And if it is found that the stem is greater than the vagina, rolls of wool should be placed upon the labia or sides of the pudenda, so that the speculum itself is made firmer. The stem should be introduced with the screw turned to the upper part; then, while the surgeon holds the speculum, the screw is turned by an assistant, so that by separating the blades the vagina is distended. When the abscess is exposed, if it is thin or soft to the touch, its apex should be opened with a scalpel or lancet, and after the pus is discharged a thin piece of lint dipped in rose oil is placed in the incision, or rather without the incision, in the vagina, without compression, but outside the labia pudenda, to the pubis and loins, washed wool, clean or saturated with oil, is placed. Then, on the third day, the patient is seated in a hip bath of warm water and oil, or a decoction of mallows, and having cleaned the parts, we introduce gently into the fissure of the incision lint spread with tetrapharmacum, either by itself or mixed with honey, but the tetrapharmacum should be diluted with butter or rose oil, and a poultice is kept applied externally until the abscess is free from inflammation or discharge. But, if there is difficulty in cleansing it, it may be washed by means of an ear syringe with decoction of iridis, and an ointment prepared from calomine or lardano, or burnt barley diluted with rose oil may be used until cicatrization is perfected. But if the abscess is within the uterus surgical treatment must not be resorted to, but the treatment previously related is to be pursued.

Commentary.—These excellent chapters on pelvic abscess by the distinguished gynæcologist of the first century, Archigenes, would do credit to any author now living, and for excellence of treatment, both medical and surgical, require no improvement. First, the accurate description of the nature, symptoms, and termination of the disease is followed by the medical treatment with poultices, fomentations, fumigations, and injections with wine, oil and water, into the vagina and rectum, with hip baths, astringent and antiseptic washes, with an accurate description of the most common discharge of the pus—into the bladder, into the rectum, and into the vagina—with a most appropriate treatment for each of these conditions, varied according to the various conditions of the abscess and its discharges. First, the surgical treatment, which opens with an aphorism that should be remembered, that the cure is not facilitated by too prompt a resort to surgery, but that we should wait for the abscess to become perfected, when it should be opened with a scalpel or lancet, and lint smeared with rose cerate introduced into the incision. The parts kept clean with injections by means of an ear syringe and aromatic and astringent washes. I candidly confess I could not improve upon the treatment. The next chapter treats of those cases where the abscess breaks into the abdominal cavity, which leaves nothing to be discovered by later researches. But what is of perhaps the greatest interest, and the one to which we wish to call especial attention, is the mention of the dioptra or speculum vaginæ, and the uses of the uterine sound as a diagnostic means, and while not intending to describe an instrument in common use, and with which he evidently supposed every one familiar—yet in his description of the

manner of using it, he has done so so clearly as to leave no tears for the arduous labors of Racemier and other modern geniuses in discovering or inventing it, while the uses made of the sound in this and other instances greatly lessen the labors of Sir J. Y. Simpson in learning how to apply it. To show the great ignorance even now prevailing as to the history of the speculum vaginæ, perhaps no better instances could be given than the statement of the learned Professor of Obstetrics at Glasgow, in the last edition of his most excellent work on midwifery, that the first indication of the speculum vaginæ is given by Ætius in a chapter, "De Fœtus Exsectione ac Extractione," which he takes from Philumenus. Now, there is no mention made of the dioptra in this chapter, and the instrument used for separating the external parts were, doubtless, just such as we use at the present day for a like purpose—bent spatulæ. It is but fair to Professor Lieshman to state that he does not say the speculum was used here, but first indicated; by which we are evidently to understand that the instrument itself was not yet known. Philumenus was, we believe, a writer of the second century; while the speculum was, as we have seen, not only indicated but of common use in the first century—no doubt, centuries earlier.

"De uteri obturatione.

"On obturation of the uterus.

"Obstruction about the mouth or neck of the womb may be either because of previous ulceration or from inflammatory induration by which the places are so greatly narrowed that they do not sufficiently admit the semen, or this being admitted is not retained, for from the callous hardness the uterus cannot contract; sometimes, however, the semen being admitted and retained within the narrowed os, a fœtus is begotten, but such conception becomes the cause of the pregnant woman's death, as from the extensive narrowing of the places the fœtus can not escape. For this condition hip baths of oil and water and decoctions of fœnugreek are administered, and the parts relaxed by cerates and emollient pessaries, prepared from œsypus, turpentine and niter. And when the parts are soft to the touch we should, for its sufficient dilatation, introduce a sponge tent (spongiam siccam) with a thread attached, and when this is removed, we may introduce a larger one, and for this reason it behooves us to have prepared many and different sized sponge tents. We should smear over the sponge tents with the following ointment: ℞ Red orpiment, dry alum aa℥j; yellow orpiment ℥ij; rub all up with honey and paint over the sponge tents before inserting. Wherefore if it is seen that the distension of the sponge tent has not sufficiently opened the place and inflammation has been produced, the tents may be covered with the following ointment: ℞ Iridis ℥ij: goose grease, turpentine, frankincense, oil of irini, wax, aa℥j; first the iridis, then the frankincense must be reduced to a fine powder, and then sifted; then the turpentine, goose grease, and wax with the liquid oil are added and all united together; then when the inflammation has subsided and the place is open the sponges may be covered with cerate, prepared from rose oil and goose grease. The use of which is continued until the parts are cicatrized, and the places made somewhat firm.

Commentary.—This chapter and the following one on imperforate uterus, is also from the distinguished gynæcologist Archigenes of the first century, and both the causes, narrowing from inflammatory induration and ulceration; and the effects, sterility, just such as are met with and given at the present day, while the treatment is just such as is daily practiced without improvement, while the display of this surgeon's gynæocological bag, with its marvelously perfect and varied sponge tents with strings attached for their more ready removal, is calculated to gladden us, at the same time to humble our vanity, that we have just now arrived at a point where he left off 1,800 years ago. Sponge tents in great quantities and of different sizes—and when the dilatation of one failed to open the part sufficiently, the introduction of a thicker one, and when by persistence in their use inflammation was excited, antiseptic preparations until inflammation has subsided, is just what we are now doing, and yet sponge tents are of modern origin, and owe their invention to the fecund brain of Sir J. Y. Simpson. How could such knowledge have been forgotten? Of course Simpson learned their use from the very chapters I am now quoting.

"De utera non perforato.

"On imperforation of the genital canal.

"Some women have by nature, (congenital), an imperfect genital canal; of this there are three kinds, for in some the obstruction is from a membrane or flesh springing up within the pudenda itself, or from the sides of the labia; in others it is in the vagina; in others the same obstruction is about the mouth of the uterus itself. Wherefore, to cure those in whom the membrane exists in the labia pudenda, we place them in the supine position, with their legs properly placed and their thighs separated, and dissect out the obstructing membrane with a scalpel until the shape of the pudenda has attained natural dimensions; after this we fill the divided section with a roll of lint, and fasten it there, then for the cure of the suppuration, we first apply poultices for several days, then we use lint saturated with rose cerate, and if, after the division, we discover the sides of the pudenda to be united by their fleshy parts, we break them up again, and dilate them by lint tents, and use the same treatment as before. The woman, after the operation, is placed upon her back with a pillow between her thighs until cicatrization is completed, but if while the external parts of the pudenda are open, the vagina is obstructed by the development of flesh in the place, so as to leave only a narrow opening, the woman being placed in the same position, we introduce a sound into the neck of the uterus for greater safety, that we may not through error, make the section too high, and thus we dissect within the places indicated by the sound, with a broad spatula, until it is seen that the vagina is according to nature, then the dissected sides of the flesh being distended with a vulsella, we cut around to a quadrangular shape. We then stand the woman upright that the fluids collected in the vagina may readily flow away. But when

this has been done sufficiently the patient is placed back in bed, as in the first position. We then place in the divided section a roll of lint wet with wine and oil, and to the extremity of which a thread is attached for its more ready removal, then, having properly bandaged the parts, we enjoin quiet; then on the following day we wash the parts with oil and honey, and a roll of lint dipped in medicine for suppuration is placed in the vagina, and when the parts are cicatrized a tin tube is introduced and secured in place until the parts are firm; but if the parts again unite together, so that the os uteri is again closed, I introduce a sponge tent until hardness has been induced; but if the membrane obstructs the mouth of the uterus itself, the woman being placed in the same position, and the vagina distended by, the the introduction of a speculum, the membrane is seized by a vulsella and extended and twisted until it is all bound together in a cord, when it is cut off with a broad spatula, and sprinkled over with a preparation of dry flowers, and a roll of lint wrapped with a thread is introduced and the same treatment pursued as heretofore given. When any of the membrane may have been left, the cure may be completed with flowers, or with a medicine called psaro. For cleansing the parts lint dipped in this preparation may be used: wax, turpentine, goose grease, aa℥ij, iridis, frankinsence, aa℥j, saffron ℥iij, oil of irinis ℥xvj; rub up the iridum, saffron and frankincense with a pestle and mix with the liquids until liquified. But the speculum must be constantly used and the cavity not permitted to fill up with granulations, which the following preparation will prevent: ℞ Scales of copper rust, rust of copper, frankincense bark, aa℥ij, ground up, united and used; or copper rust and scales with lead water, may be mixed and used. But the use of sponge tents must not be omitted till hardness of the sides has been induced, also the introduction of the tin tube is to be continued.

Commentary.—Again this chapter from Ætius is evidently from the Marion Sims of ancient gynæcologists, and is manifestly only a fragment of a "Treatise on Operations upon the Vagina, by Archigenes." The first obstruction is an obturator hymen, which is properly treated; the next is an imperfect vagina in which Amussat's operation for the formation of an artificial vagina is anticipated by 1,800 years. The difficulties of preventing the parts again uniting and the canal again coutracting, are fully appreciated and very properly treated. Sims' vaginal dilator is used. It is thus seen that there is nothing new under the sun, and we, with all our boasted knowledge, are only now approaching the wonderful gynæcological knowledge of the ancients.

Dr. Willard Parker is eighty-three years old; Alonzo Clark, eighty; A. C. Post, seventy-seven; Isaac E. Taylor and Austin Flint, seventy-one, and Frank H. Hamilton, seventy. Some of these distinguished medical men are still in active practice, notwithstanding their great age.—*The Cincinnati Lancet and Clinic.*

MORPHIA AND ATROPIA BY HYPODERMIC INJECTION PREVIOUS TO THE ADMINISTRATION OF ANÆSTHETICS.

BY J. C. REEVE, M.D., DAYTON, OHIO.

The number of this journal for February 9, contains an article upon the above subject by Dr. Aubert, from the proceedings of the *Société de Biologie*, in which the modification of the action of anæsthetics by preceding injection of narcotics, seems to be presented as something entirely new, and his experience of the benefits resulting from it is detailed as if nothing similar had been heretofore given to the profession. The fact is that this mode of modifying anæthesia is more than twenty years old. It had its clinical birth under Nussbaum in 1863, and owes its establishment upon a scientific basis to Bernard shortly afterwards.[1] Since then it has been gradually making its way in practice. Its merits have been several times presented and urged upon the profession of this country by myself. First, in an article in the *American Journal of the Medical Sciences* for April, 1876; again in a paper read before the State Medical Society of Ohio, in 1878, and more lately, but very briefly, in the American edition of Holmes' Surgery (Vol, III. p. 556).

But the object of this article is not to claim credit for any merit in promulgating the doctrine of "mixed anæsthesia," rather to again direct the attention of the profession to it and to again urge its claims to confidence as a sure method of lessening the dangers of anæsthesia and of facilitating the administration of anæsthetics. I am impelled by the conviction that the method is not as generally known or resorted to as it deserves to be, a conviction strenthened by the appearance in a leading journal of such an article as M. Aubert's without any editorial allusion to the large amount done in the same line in this country and elsewhere.

In the papers above mentioned the theoretical arguments in favor of the method were presented, some interesting comparative cases detailed, and considerable clinical experience given. Theoretically, the arguments in its favor are the fact that atropia is a powerful stimulant to the cardiac and respiratory functions, as taught and demonstrated by Harley and Bartholow; and the obtunding and soporific influence of morphia, which lessens both physical and psychical excitement, and brings the patient to the verge of sleep before any anæsthetic vapor is inhaled. Clinically, the experience in favor of the method is quite large. My own extends far beyond that of Dr. Aubert, sixty cases. I have used it now for more than ten years whenever required, for operations of every kind severe enough to demand it, in patients of all ages. I have not in a single case found occasion to regret having resorted to it, nor seen a single bad symptom which could be attributed to it.

Desiring to be as brief as possible, I will first touch

[1] Lecons sur les Anæsthetiques et sur l'Asphixie.

on the leading points relating to anæsthesia by this method:

Safety.—This rests on the sound basis of the physiological action of medicines and on clinical experience. When it comes to speak in relative terms of the *greater* safety of this method, of course the vast experience upon which to base such a claim is wanting. Too often we see relative advantages claimed for some particular method of administering anæsthetics, based on the experience of a single administrator. Such a claim, viewed in the light of the rarity of accidents, and the widely varying experience of hospitals and armies, in which there have been large numbers of administrations, is simply ridiculous. There is one clinical point, however, to be urged in favor of this method, in regard to which there cannot be, I think, any question. It is its efficiency in lessening emotional excitement. Few of us, under the influence of almost daily use of anæsthetics, realize the momentous aspect the process assumes to the patient, especially to a nervous and impressionable female. Is not a feeble and depressed pulse a constant phenomenon at the beginning of the administration? and does it not gradually rise in force and volume as consciousness fades? The contrast, when a hypodermic injection has preceded, has been, under my observation, striking. There can be no question that deaths have occurred under anæsthetics from purely psychical causes, just as the patient shrieked and died when the surgeon drew his finger nail along the perinæum, to show the class where he would make the first incision in lithotomy. No more powerful means are at our command for allaying undue apprehension and its consequences than the benumbing and soothing influence of morphia.

Rapidity of producing anæsthesia, and smaller quantity of anæsthetic required.—It is only necessary for anyone to try this method a few times to be thoroughly convinced upon these points. I would rest a decision upon them to half a dozen observations by any candid person.

Absolute quiet of the patient.—This is a point of no mean importance; one alone sufficient to make the method worthy the attention of the operating surgeon. This feature is of especial value in all prolonged operations. Under this method the transition from profound to partial anæsthesia is not so rapid, and the patient does not so readily again begin to feel pain and move about. In some twenty cases of ovariotomy under this method, I cannot remember more than one in which a limb was moved during the operation; straps to bind the leg of the patient to the table, as used by some noted operators, are simply superfluous. Recently, I had a striking instance of the value of this point. The operation was for strangulated hernia, at night, with but one medical assistant, and he inexperienced and timid with anæsthetics. Having placed the patient, a female, under the influence, the sponge was committed to his care, while the dissection and sponging the wound was performed by myself. Anyone who operates under these circumstances will congratulate himself on having preceded the anæsthetic by a hypodermic injection of narcotics. My patient never moved, notwithstanding the irregularity and intermittences of the administration.

Upon two points my experience is not in accord with that of Dr. Aubert. I do not find that there is *absence* of vomiting upon awakening. I certainly believe that disagreeable symptom to be less in frequency and degree, but such a point is difficult to prove. To claim its entire absence would be to claim too much for the method. Decidedly, the patient does not awaken more readily after this method; the reverse is the truth, and I believe it to be an additional point in favor of the plan. And after awakening the patient drops off again easily, and passes hours in slumber or dozing under the influence of the narcotic, the pain of the operation soothed and assuaged.

For the benefit of those not having access to the papers published upon this subject, it may be stated that the amount generally used by me is seven to twelve minims of a solution of sixteen grains of morphia and one-half grain of atropia to the ounce of water. For very prolonged and severe operations the amount of atropia may be increased to advantage. Experience has taught me that *time* is an element of importance. Fifteen to twenty minutes should elapse between the administration of the hypodermic injection and the beginning of the administration of the anæsthetic. When the one immediately or soon precedes the other, the dangerous stage of excitement is *not* diminished.

Far the major amount of experience which has been published as to mixed anæsthesia, has been made with chloroform as the anæsthetic. What is here presented, and all my experience has been with the mixed vapors of alcohol, chloroform and ether, known as the "A C E" mixture: 1 part alcohol, 2 parts chloroform, 3 parts ether, by measure.

Those wishing further information upon the subject may consult, besides Bernard's work:

Recherches sur L'Anæsthesie Chirurgicale Obtenue par l'Action Combinee de la Morphine et du Chloroforme. Par H. de Brinon, Paris, 1878.

De l'Anæsthesie Mixte, ou de l'Emploi Combiné de la Morphine et du Chlorofome. These par Verriet-Litardiere, Paris, 1878.

An article by Mollow, of Moscow, a translation of which may be found in the *Revue des Sciences Medicales*, T. X.

MULLEIN IN ITS INFLUENCE ON THE BODY WEIGHT IN PHTHISIS.—Dr. F. J. B. Quinlan writes to the *British Medical Journal* of a case upon which he had before published a note, where the weight in pretubercular phthisis had increased from ninety pounds four ounces to 102 pounds twelve ounces, with corresponding benefit to the pulmonary symptoms, in a month's time. His further record of the case was to the effect that in a hospital with the advantages of the best country air and a very liberal dietary, the mullein being discarded, and cod liver oil, a tablespoonful morning and evening, substituted for it, the increase in weight during the second month was seven pounds eight ounces, as against the twelve pounds eight ounces under the mullein.

MEDICAL PROGRESS.

ANATOMY AND PHYSIOLOGY.

Abnormal Development of Olfactory Nerves.—The Paris correspondent of the *British Medical Journal* gives M. le Bec's recent communication to the Biological Society, of Paris. A woman died at the Hopital St. Antoine, from a surgical affection. The brain was removed for purposes of demonstration, and it was observed that the olfactory nerves were apparently absent. On the left side there was a nerve-stump, presenting the aspect of a small flat band, measuring eight millimeters in length and two wide. It rose at the spot where the roots of the olfactory nerves normally unite, was directed forwards, reached the inferior surface of the left optic nerve, adhered to it by means of the pia mater, and stopped abruptly. On the right side the olfactory nerve was still less developed, and was represented by a slight swelling of about the size of a pea of the gray substance behind the optic nerve, exactly on the spot where the olfactory nerve ought to exist. Backward, on a deeper plane, the olfactory nerve was represented by a gray band two millimeters long; this did not reach the optic nerve. The external roots presented an equal degree of development. The inner white root was detected with difficulty. The convolutions of the inferior surface of the frontal lobe differed from those of a normal brain. On the left side, where the nerve-stump existed, the olfactory sulcus was normally placed. On the right side, where the olfactory nerve was practically wanting, the olfactory sulcus was absent. The cribriform plate of the ethmoid bone was normal. During life the patient possessed olfactory perception as keenly as most people, enjoyed the scent of flowers, and especially disliked the smell of meat and fish. M. Mathias Duval examined the pituitary body, and discovered gray nerve fibers, apparently belonging to the olfactory nerve, which suggested the hypothesis that the olfactory nerve was reduced to fine filaments, which had adhered to the pia mater and had been removed with this membrane. This hypothesis indicates the advisability of preserving the pia mater and arachnoid membrane of the orbital surface of the frontal lobe, in order to examine it with the microscope.

MATERIA MEDICA AND THERAPEUTICS.

Hydrate of Chloral in the Treatment of Blenorrhagia.—Dr. Lopez Rodrigues, of the Brazilian Navy, being attached to a vessel which was poorly provided with medical stores, was consulted by a sailor who was suffering from a very acute blenorrhagia, with hæmaturia; he had recourse to injections of chloral hydrate in the following manner: Hydrate of chloral, 4 grammes; water, 250 grammes; for three injections a day. Much to his surprise, there was a very rapid improvement, and on the fourth day the patient returned to service. He continued to use it in twenty-one cases, of which two were women suffering from acute vaginitis. Several of the cases were of long standing, having resisted previous treatment. In two cases there was a relapse, which yielded to the renewal of the medicine. The treatment is not painful. The first injections give a slight sensation of warmth.—*Unias Medica de Rio de Janeiro, and Gaz. Heb. des Sc. Medicales.*

Paraldehyde as a Hypnotic.—Cervello was the first to produce this isomeric modification of aldehyde. After experimenting upon animals, he used it upon himself, by taking four grammes in solution in water in the course of an hour. It produced a desire to sleep without affecting the pulse or respiration, and without any headache. Using it afterwards upon others, he fixed the dose for women at 1 gramme, for strong, vigorous men at four grammes. The dose has been determined to be triple that of chloral. An adult can take ten grammes in divided doses without any bad effect. It is best given in aqueous solution with a little sugar, in the proportion of three per cent of paraldehyde.

After the publication of Cervello's observations others recorded their clinical experiences with the drug. Monselli has employed it in 350 cases of mania, melancholia, and neuropathies. Generally, he found three grammes sufficient to produce a sleep of from four to seven hours, which was induced in twenty to thirty minutes after its ingestion.

Perelti found paraldehyde to possess certain advantages over chloral in that (1) even in strong doses there is no danger from action of the heart; (2.) it has no convulsive effect; (3.) it produces sleep rapidly without any stage of excitement and without congestion; (4.) the awakening is not accompanied by any disagreeable symptoms. On the other hand, it possesses the disadvantages of (1.) a rapid tolerance, so that, much more than is the case with chloral, an increase of the dose is necessary; (2.) it communicates a persistent and very disagreeable odor to the breath; (3.) it is very expensive. This last objection has been in part overcome.

Berger has given it in eighty cases. In nineteen it produced, after ten to twenty minutes, a profound sleep of several hours; in forty-two the sleep lasted from one-half to three hours; in nineteen the result was negative. The inconveniences observed were rare and of but little importance—bad taste, nausea, vomiting, vertigo. The pulse was generally somewhat diminished in frequency; diuresis was also diminished. He prescribes it as follows:

℞ Paraldehyde, ʒj; mucilage gum acacia, ʒij; syrup of bitter orange peel, ʒj. To be taken as a dose.

He recommends its use where chloral is inefficacious.

Masius has used it for some time in his clinics. He finds the sleep produced by it to be beneficial and reparative, without leaving behind it any discomfort or headache. Some patients have complained of the bad taste of the medicine, and also of nausea and vomiting. When sleeplessness is produced by pain the paraldehyde has either no effect or affords but slight relief, and even in cases where there is no pain

the effect may be insignificant. He prescribes it as follows:

℞ Paraldehyde, 45 to 90 grains; aqua dist., ʒiij; syr. simplex, ʒv. To take at night in the course of a quarter of an hour.—*Le Progrès Médical.*

On Certain Medical Incompatibilities and Contra-Indications.—M. Rabuteau presented some of his views on this subject to the Société de Biologie (Comptes Rendus) referring especially, first, to the incompatibility of iodide of potassium and sulphate of quinine. It is well-known that pure iodide of potassium is generally well tolerated in ordinary doses, and the same can be said of sulphate of quinine. But when these two drugs are given together, or at short intervals, even in medium or small doses, such as 1 gramme of iodide of potassium and 50 centigrammes of sulphate of quinine, a remarkable intolerance is created. This intolerance is marked by disturbances of the digestive organs and other more general symptoms. The indigestion consists in anorexia, nausea, vomiting, pain in the epigrastrium and colic. The general symptoms consist of anxiety, inexpressible discomfort, slowing and diminution of the pulse, pallor and general fatigue. These symptoms, more or less marked, recall perfectly those which occur after the ingestion of pure iodine or tincture of iodine when the iodine is precipitated in the stomach.

A mixture of iodide and iodate of potassium has long been recognized as unstable in the presence, as it gives off immediately free iodine. The same thing takes place with this mixture and the gastric juice on account of the acid which is there present. This is most striking when, after giving a dog a little bread, he is given a mixture of, say, potassium iodide 1 gramme, and potassium iodate 10 centigrammes, dissolved in water. He vomits the bread, which is colored of a violet blue by the free iodine. If he took either of these ingredients singly there would be no such effect.

So in this mixture of iodide of potassium and sulphate of quinine, it decomposes in the alimentary canal, not only in the stomach, but also in the intestine, where the secretion is also acid, notwithstanding what has been said to the contrary. Free iodine is liberated. The decomposition is a slow and gradual one, which accounts for the prolonged feelings of discomfort a day at least after the ingestion, which gradual process corresponds to the time required for its elimination by the successive processes of secretion and re-absorption.

Second.—Contraindications to the use of cinchona in the woman during the menstrual period. A case is referred to under this head of a young woman suffering from malaria, who took tincture of cinchona, or small doses of quinine—30 to 50 centigrammes in a little wine—when suffering from fever. On three occasions she took these medicines during her menstrual periods, and suffered severely in consequence from severe hypogastric pains and fainting. The heart beats were lessened in force and frequency so as to be imperceptible. The drug was not abandoned, but it was never again administered during a menstrual period, and these symptoms never recurred.

Dr. Sonsa Refoios gives a case where an infusion of quassia amara given during the menstrual period produced violent uterine pains, comparable to the pains of childbirth; placing in his argument quassine among the agents modifying innervation and myotilitis. It is capable, in fact, of producing convulsions. If quassia then is to be interdicted to women during their menses, the use of beer should also be interdicted, as its bitterness depends greatly upon substances of this class, notably the beer of Surinam, so called because there is substituted for the hops a quassia which bears the official name of wood of Surinam.

The Physiological and Medicinal Action of Hydrofluoric Acid and the Fluorides.—Surgeon L. A. Waddell, M. B., the Resident Physician of the Medical College Hospital, of Calcutta, has an article on this subject, in the *Indian Medical Gazette*, which he summarizes as follows, in brief:

(1.) The corrosive action on glass by a few precautions can be overcome.

(2.) The topical action is attended by more acute pain than in other concentrated mineral acids. In contact with the skin, by combination with the lime, and other bases of the tissues, it forms a hard, horny sheath, under cover of which it continues to penetrate the deeper tissues till its energy is expended. On removal of the slough the resulting ulcer manifests a readiness to heal scarcely inferior to that produced by oil of vitriol.

(3.) Poisoning treated as with other strong mineral acids.

(4.) The fumes of the acid on inhalation provoke dyspnœa, and spasmodic cough, and if concentrated, produce intense bronchial and laryngeal irritation, with spasm of the glottis, convulsive cough, and in some cases speedy death. The inflammatory action seems to have nothing distinctive in itself; a powerful argument against its use in the treatment of diphtheria.

(5.) The alkaline fluorides are not absorbed through the skin.

(6.) The remote action of the alkaline fluorides is essentially similar to that of the dilute acid. The salts are to be preferred to the acid for ordinary medicinal use.

(7.) Fractional doses, after a time, slightly impair the appetite. Moderate doses induce nausea and tend to disorder the stomach. Large doses readily excite vomiting by direct action on the gastric mucous membrane. No vomiting occurs on subcutaneous administration of the drug, and free dilution diminishes the emetic tendency. No purgative action ordinarily attends the use of the salts even in large doses.

(8.) Nutrition is impaired by the prolonged ingestion of small doses of the alkaline fluorides or the acid, and this atonic condition is accompanied by slight loss of body-weight.

(9.) The amount of urea exereted in the urine is increased. The body-temperature is distinctly re-

duced, the pulse-rate somewhat slowed, and the arterial pressure slightly lowered?

(10.) The alkaline fluorides and the acid profoundly modify the constitution of the blood, producing an anæmia (oligocythæmia), the essential characteristic of which is that the corpuscles suffer a decrease out of all proportion to the hæmoglobin. With the provers, after a five-days' course of the drug, the general loss averaged about one-fourth of the total red corpuscles. The hæmoglobin is only slightly reduced in amount and at the same time the size of the red disc becomes slightly larger.

(11.) In the malarially enlarged spleen, where the function of disintegration of the red corpuscles is inactive, the exhibition of fluorine by stimulating this function reduces the total volume of the contained blood, and thus enables the muscular fibers (?) to regain their normal activity, and so contribute toward the further reduction of the enlargement.

(12.) Toxic doses affect frogs in a similar manner to warm-blooded animals.

(13.) Circulatory depression is a constant and characteristic effect of fluorine compounds. The cardiac contractions are slowed and weakened, and with poisonous doses the heart is arrested in diastole. The contractions are found to be arrested a considerable time before the contractility of the cardiac muscle to mechanical stimuli is lost. Under full medicinal doses the sphygmograph shows, after a time, a distinct reduction of blood-pressure.

(14.) Increased frequency of the respiratory act follows the injection of poisonous doses of the drug. The respirations soon become retarded, slightly irregular and evidently laborious. The respiratory difficulty increases, and the inspiratory efforts ultimately become convulsive (asphyxial) in character.

(15.) Even in the largest medicinal doses no narcotic effect, nor even drowsiness results. In toxic doses the pupils at first become slightly dilated, then afterwards markedly contracted. Voluntary movements cease only a few seconds before the final arrest of the respirations and general circulation. The medulla appears to be specially affected. The spinal reflex irritability persists throughout unimpaired. The voluntary muscles retain their electric excitability for some time after death.

(16.) The salivary secretion is very slightly increased, especially after large doses, which excite nausea. Bulk of urine slightly increased.

(17, 18, 19, 20.) Large, and even moderate doses cause such unpleasant symptoms as to make it difficult to keep up its use except in fractional doses; no use in epilepsy, harmful in phthisis pulmonalis, mitral disease and aortic regurgitation. Of benefit in rickets; no use in acute rheumatism.

(21, 22, 23.) Of use in soft vascular goitre, in plethoric states, such as gout, and for relieving vasaular fullness in the earlier stages of aortic aneurism. Reduces the chronically enlarged spleen of malaria readily, but do not prevent further enlargement resulting from fresh paroxysms of the intermittent. Quinetum or quinine fluorides the best. Iron fluorides of no value. Fluorine is contra-indicated in every case where grave adynamic symptoms are present.

Incompatibles, lime or lead salts, organic acids.

Dose: Of the acid, 15 minims in 2 drachms of a ½ per cent. solution of the alkaline fluorides; ¼ grain to 3 grains.

Iodoform in Its Influence on the Body Weight in Phthisis.—Dr. R. Shingleton Smith (*Bristol Medico-Chirurgical Journal*) gives a case of a man, aged 35, who used to weigh 172 pounds; six months before record weighed 152 pounds, one month before weighed 134, at date of record weighed 120 pounds with clothing. Phthisis pulmonalis was well established, and he was put upon iodoform, two grains every four hours for the first four days, weight 113 pounds without clothing; three grains every four hours for seven days, weight 113 pounds; six grains every four hours for a month, weight 110 pounds. Up to this time the improvement in strength and general condition had been marked, and the temperature ran from 98.6° to 99.2°. But now symptoms of iodoform intoxication appeared—weakness, vomiting, foggy vision, hallucinations. Drug stopped for four days, and renewed in three-grain doses for a week. The weight rose in that time from 109 pounds to 112 pounds. The renewal of the drug renewed the symptoms of intoxication, which had somewhat abated. It was again stopped for four days, and again renewed in three-grain doses, with cod liver oil ℥i three times daily. This was kept up for eleven days, with a gain in weight from 112 pounds to 115 pounds, with a temperature of 99°. It was then stopped entirely.

Dr. A. Ransome read a paper on this subject before the Section of Medicine of the British Medical Association (*British Medical Journal*), embodying the records of his experience with twenty-one complete cases in the Hospital for Consumption. He gave it in the form of a pill, one and one-half grains three times daily. It (the iodoform) caused so much nausea and disturbance of the digestive organs, that he combined it, to great advantage, with two grains of croton chloral. Of his twenty-one cases four were in the first, five in the second, and twelve in the third stage of the disease.

Of the four cases in the first stage, one gained two and one-half pounds in three weeks, the second two pounds in one month, the third gained eleven pounds in four months, the fourth *lost* eight pounds in three months.

Of the five cases in the second stage, the first was losing three pounds in a fortnight, he gained one pound in a fortnight, discontinued the drug, lost weight, gained slightly on its renewal, lost again on its omission; on its second renewal, improved and regained former weight, the second gained two and one-half pounds in ten days, third gained somewhat, fourth gained, fifth gained three and one-half pounds in the first fortnight.

Of the twelve cases in the third stage, two distinctly gained weight, six remained approximately at the same weight. The remaining four have all diminished in weight with more or less rapidity.

From a review of all the cases, Dr. Ransome is in-

clined to attribute to iodoform some slight improvement, even in cases in which it was manifestly hopeless to expect cure, and thinks that in the earlier stages of the disease it is decidedly worthy of further trial.

SURGERY.

A CASE OF PRIAPISM.—A. H. Boys, L.R.C.P., (*Bristol Medico-Chirurgical Journal*) records the case of a gardener, 65 years of age, who came to him suffering with persistent priapism of a week's standing, induced by irritation of the nates and gluteal region from unusual horseback exercise. He ordered a cold lead lotion with pot. bromid. grs. x internally every three hours. In five days there was no improvement. He then pricked the penis all over with a fine needle. Serum flowed abundantly. This, with constant hot applications, also failed to relieve the condition. Cold, in the shape of ice, and a mustard plaster to the spine, with tincture of belladonna x minims every three hours, were substituted and also failed. Finally, 15 days after its first occurrence, suppositories of one-half gr. of belladonna with a pill containing two grs. of iodoform, and one and one-half grs. of extract of conium, produced a decided improvement in three days, and perfect relief at the end of 3 weeks. There was a curious complication in the case on account of the stupidity of the patient. The belladonna suppositories were made large, and were to be inserted every four hours. On the third day after they were ordered, it was found, on complaint of the patient, that they pained him severely; that he had been trying to insert them into his urethra!

MEDICINE.

OCCURRENCE OF THREE INFECTIOUS DISEASES IN THE SAME INDIVIDUAL.—Dr. Prior, Assistant to the Royal University Polyclinic in Bonn, communicates to the *Deutsche Med. Wochensch.* a case in which three different infectious diseases occurred in the same individual in the space of one month. Three children were attended on Nov. 18 for well-marked scarlatina, with a temperature of 104° Fahr., copious eruption, and some difficulty in swallowing. Desquamation began on Nov. 21, and proceeded normally, only one child having slight renal symptoms, until on Dec. 1, the two younger were attacked with rigors, headache and malaise, and on the following day were covered with a thick eruption of varicella. On Dec. 3, in the absence of the mother, a child from the next room, intercourse with which had been carefully avoided on account of measles, was found playing with the child, and showed signs of measles next day. The first patients were now carefully watched, and on Dec. 13 the temperature was found to be raised, with photophobia and slight coryza; on the 15th the eruption of morbilli appeared. Its course was protracted, and caused some anxiety, but finally the child recovered. The cases show how the two poisons of scarlatina and varicella may be in the organism at the same time, and how measles may be conveyed by a two hours' intercourse in the prodromal stage, while the crusts of varicella are still present, the measles showing itself as soon as ten days later.—*The Medical Press and Circular.*

THE BRITISH MEDICAL ASSOCIATION MEETING AT BELFAST.—The fifty-second annual meeting of the Association will be held on July 29, 30, and 31, and August 1, 1844, at Belfast. The address in Medicine will be delivered by Sir Andrew Clark, Bart., M.D., F.R.C.P., Physician and Lecturer on Clinical Medicine, London Hospital. The address in Obstetric Medicine will be delivered by George H. Kidd, M.D., F.R.C.S.I., Master of the Coombe Lying-In Hospital, Dublin. The address in Physiology will be delivered by Peter Redfern, M.D., F.R.C.S E., Professor of Anatomy and Physiology, Queen's College, Belfast.

Visitors coming from America to attend this meeting can travel by any of the following routes: 1. A Cunard steamer will leave (*a*) New York on Wednesday, July 16, arriving in Queenstown about the following Thursday week, July 24; (*b*) Boston on Saturday, July 19, reaching Queenstown the following Monday week, July 28. 2. A White Star steamer will leave New York on Saturday, July 12, and on Saturday, July 19; due at Queenstown about July 20 and 27. 3. An Inman steamer will leave New York on Tuesday, July 15; due at Queenstown about July 23. 4. An Allan steamer will leave Quebec on Saturday, July 19, arriving in Londonderry about the 26th or 28th July. 5. An Anchor steamer will leave New York on Saturday, July 19; due at Londonderry on July 29. Londonderry is 95 miles from Belfast, and trains run daily between the two places. The route from Queenstown to Belfast is from Queenstown to Cork, Cork to Dublin (165 miles by train), and Dublin to Belfast (113 miles).

MEETING OF THE INERNATIONAL CONGRESS AT COPENHAGEN.—The time of the meeting of the British Medical Association at Belfast has been fixed so as not to interfere with the International Medical Congress, which is to begin at Copenhagen on August 10. A steamer will leave Hull (England) on August 2 and 9 for Copenhagen; and on August 5 a steamer will leave Leith (Scotland) for Copenhagen. Both these places (Hull and Leith) can be reached on any day by leaving Belfast on the previous evening by the cross-channel steamers. Visitors after attending the meeting of the British Medical Association in Belfast will have ample time to travel to Copenhagen for the Congress.

Communications in reference to the meeting of the British Medical Association at Belfast to be addressed to the Hon. Local Secretaries, John Moore, M.D., Alex. Dempsey, M.D., John W. Byers, M.A., M.D.

IT has been estimated that the loss to the producers from hog cholera in1875 amounted to the enormous sum of 1,500,000.—*Louisville Medical News.*

THE

Journal of American Medical Association.

PUBLISHED WEEKLY.

THE EDITOR of this JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information, should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE..... $5,00.
SINGLE COPIES..... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 65 RANDOLPH STREET,
CHICAGO, ILLINOIS.

SATURDAY, MARCH 1, 1884.

RUSH MEDICAL COLLEGE COMMENCEMENT EXERCISES.—The forty-first annual Commencement exercises of the Rush Medical College, Chicago, were held in Central Music Hall on the afternoon of the 19th of February, 1884, and were attended by a large audience, The regular members of the Faculty appeared upon the stage attired in long black silk gowns or robes, headed by Dr. J. Adams Allen, President of the college,and Bishop Fallows as Chaplain. After music and prayer by Bishop Fallows, the Secretary, Prof. J. H. Etheridge, read the annual report, from which we learn that the whole number of matriculants attending the college during the past year was 418, of whom 166, or about 40 per cent., passed the required examinations and received the degree of Doctor of Medicine.

The Secretary stated that for the first time in the history of the college,the Faculty required a preliminary examination at the commencement of the year just concluded. His analysis of the literary qualifications of the 166 candidates for graduation gave the number holding literary degrees 47; normal school and academic graduates, 12; graduates of High Schools, 28; registered pharmacists, 13; holders of teacher's certificates, 46; leaving 20 without any evidences of attainments, except such as were obtained by the personal examination. Although the reporters represent the Secretary as stating the number holding literary degrees to be 47, as printed on the programme, only 24 of the names have appended any titles indicating the possession of a literary degree.

As the commencement of this college year was the first time the Faculty had required a matriculate examination in regard to general education, it would have been an interesting statistical item if the Secretary had stated how many of the whole number presenting themselves, had been rejected for insufficient literary attainments. After the report of the Secretary, the degrees were conferred in the usual manner by the President of the college, Prof. Allen; and in addition to the 166 ordinary degrees, an honorary degree was conferred on Dr. A. L. Justice. A valedictory address in behalf of the class was given by Dr. D. S. McArthur, after which the regular doctorate address was delivered by Prof. Norman Bridge, chiefly on the progress of medicine.

The orchestra discoursed excellent music at suitable intervals in the progress of the programme, and the exercises closed with a benediction by Bishop Fallows.

In the evening the Faculty of the college gave an elegant banquet to the Alumni and members of the graduating class in the Grand Pacific Hotel. While the banqueting was in progress, the exercise was pleasantly varied by a presentation. Prof. J. Nevins Hyde, on behalf of President Allen, presented a life size portrait of the latter to the Faculty and College Trustees. The gift was accepted for the college by Prof. H. M. Lyman. The present was in commemoration of the twenty-fifth anniversary of Prof. Allen's connection with the college as one of the Faculty.

MEDICAL LEGISLATION IN VIRGINIA.—In a recent issue of the JOURNAL we noticed with pleasure and approval the enactment of a law by the Legislature of Virginia, establishing a State Board of Medical Examiners, and requiring all future applicants for permission to practice medicine in that State to undergo a satisfactory examination by the State Board, regardless of college diplomas.

We learn that the same Legislature has now before it a bill for appropriating an annuity of $7,500 to one of the medical colleges of the State, on condition that said college shall give *free* medical education to as many medical students annually as there are members of the Legislature (136), each member having the privilege of naming one student. This bill is bad in every respect. The idea of appropriating the public money derived from the taxation of the people, to give free professional education to the proteges of a legislative body, is positively vicious. The true line of justice and sound public policy, in regard to appropriating public money for educational pur-

poses, is so clearly stated by a non-medical writer, in a recent number of the *Lynchburg Virginian*, that we copy it entire, as follows:

"We notice a bill reported in the Senate, to grant an annuity to the medical school at Richmond, coupled with the condition of free tuition to as many students as there are members in the General Assembly.

"In the earnest absorption of the members with the multifarious work upon their hands, there is unusual danger, at the present time, that proposals of this kind may pass without the sifting scrutiny they should receive.

"We are in no sense hostile to the medical college; on the contrary, we desire to see it prosper, and become a great school of medical science. But we feel sure, that this measure does not tend to that result. If the medical college stands in need of a grant of public money to supply some essential need which cannot be otherwise attained, let such grant be made, after careful inquiry into the facts, to see that the purpose is one which justifies such application of the public funds. But we do object, out and out, to the proposal to make doctors at the expense of the State treasury. In other words, we hold that there is no sound principle on which the State should be called upon to give gratuitous professional education in the so-called learned professions. Normal schools for training the teachers of the public school system, stand on a ground to themselves. They are a preparation of the public servants for the most efficient discharge of their duties to the public, in their office. Not so with private professions. A private profession is simply a man's private business, by which he proposes to make a support for himself and his family. The public has no concern with it, beyond what it has with any other form of individual industry. It is, therefore, a misapplication of public money to give gratuitous professional education.

"If free instruction is to be given to young doctors, why not to young aspirants to the bar?—why not to clergymen?—to civil and mining engineers? If *professional* men of any class are to be furnished for their special business—equipped for their life work at State expense, why not have commercial and business colleges for clerks, and so on without end? The *principle is wrong*. Public education can be justified only on the ground that the citizen, by being taught the elements of education, is thereby better fitted to meet and discharge his duties to society *as a citizen*, in those functions which are common to all citizens. This reason utterly fails to apply to professions and professional education. They are *special*, and *individual*, by the very terms of the statement—and, therefore, outside of the reason which vindicates public school instruction for the masses.

"No one man has any claim on the public to be furnished with a business, or to be qualified for it, beyond every other man.

"Gratuitous professional instruction at the public expense, is, therefore, a violation of common right—and a misapplication of the public money.

"Besides this, one professional school cannot be placed in this position, without injury to all the others in the State—all ought to be on the same footing.

"Many other objections occur to us, which we have not space to develop. The movement seems to us to be wrong in principle; and in policy highly objectionable, for various reasons. We hope the General Assembly will not think of sanctioning it."

BIDDING FOR PRACTICE AND UNDERBIDDING.—A correspondent at Charleston, Mo., requests an answer to the two following questions through the pages of the JOURNAL:

1st. "Is it professional for a physician to propose to the authorities of a city or county to do the pauper practice of such city or county for a period of one year for a stated amount?"

2d. "If a physician had a contract of the kind just mentioned, would it be ethical for another to propose to the authorities for a sum less than the one having it, he knowing what the other was receiving for said work?"

While the National Code of Ethics contains no direct statement or rule regarding what has been called "contract practice," or offering to attend the sick poor of a city or county for a specified sum, the National Association has several times taken such action as would answer both the above questions in the negative. Sound principles of ethics, in other words, correct principles of professional conduct, undoubtedly require that all claims for pecuniary compensation should be based on two plain rules, namely, on the amount and kind of services rendered, and the rate adopted either by common consent or actual agreement by the profession practicing in any given locality. All propositions, either to families, corporations, city or town authorities, etc., to bestow ordinary professional services, either on the rich or the poor, for a specified sum per month or year, are clearly in violation of those rules. The second question involves so plain a proposition to *underbid* as to leave no doubt of its unprofessional character.

EXTRA COURSES OF INSTRUCTION.—The students in the Chicago Medical College are being favored during the present college term with some valuable instruction in addition to the usual full curriculum of that institution. Dr. J. S. Marshall is giving one lecture per week during all the last half of the collegiate year on the diseases and defects of the teeth and their appendages, which are listened to with much interest by the students. And Dr. H. J. Detmers has just closed a series of four or five lectures on such diseases of domestic animals as are liable to be communicated to the human species; in-

cluding glanders and farey in the horse; hog cholera, trichinosis, etc. These lectures were very valuable, and were listened to by the students with the greatest interest.

THE CHICAGO DENTAL INFIRMARY.—The Collegiate Department of this institution opened its second annual course of instruction on Monday evening, February 25, 1884, with encouraging indications of success.

NOTICE TO EXHIBITORS.—Manufacturing chemists, pharmacists, instrument-makers, etc., who wish space provided for their exhibition during the meeting of the American Medical Association, beginning May 6, should make application to Dr. D. C. Patterson, 919 I street, Washington, D. C., before April 1.

NEWS ITEMS.

CLINICAL CHARTS.—We note an advertisement in the *Medical Times and Gazette* of temperature and diet charts, drawn up by medical men of clinical experience, for use in hospitals and general practice. They are sold at the rate of $6 per 1,000, or 84c per 100, by Wodderspoon & Co., 7 Serle Street, Lincoln's Inn, London. We make this reference not with any desire to advertise the firm, but to call the attention of the profession in hopes a sufficient demand might be created to induce some of our own stationers to supply them. They certainly insure much saving of labor, preserve a correct record and furnish a valuable history for future reference at but little expense. It is surprising that we have never yet had a satisfactorily clinical case book issued for the use of the private practitioner.

THE MEDICAL SICKNESS, ANNUITY AND LIFE ASSURANCE SOCIETY OF THE BRITISH MEDICAL ASSOCIATION.—Some years ago this body (the B. M. A.) attempted a scheme similar to the heading of this note, and several hundred persons joined in the enterprise. It fell through from inanition. The claims made upon the funds were very few, and adequate means were not taken to make the operations of the society continuously well known and to keep it in active operation. In the end the whole of the funds were returned, and no loss was incurred by the subscribers. It has now been revived, and at the last session of the British Medical Association, documents were presented showing the written adhesion of upwards of 600 members of the Association to such a society in principle. A provisional committee was formed to consider the subject and prepare a definite plan for giving effect to the decision arrived at.

As a result it is proposed to start a society, the leading objects and general principles of which shall be as follows:

Sickness.—Payment during sickness incapacitating from professional duty of $10, $15 or $20 per week, reducible to half those amounts after twenty-six weeks' continuous sickness, the reduced rate to continue throughout the whole period of illness. After age 65, sickness pay to cease, and be replaced by absolute annuity.

Annuities.—The provision of annuities of $100, $150, $200 or $250 to commence at age 65, and be paid absolutely without reference to the health of the members.

Life Assurance.—Sums payable on the death of members of $125, $250, $375, $500, $625, $750, $875, $1,000.

Payment of all premiums to cease at age 65.

Members may join for the whole or any of the above assurances, and may relinquish, vary or retain any of them at pleasure.

The committee have power to pay a sum not exceeding 70 per cent. of the full surrender value on policies relinquished.

Members may at any time extinguish future contributions by the payment of a sum down.

The society will be managed by a committee and officers appointed by the members.

All funds and property of the society will be vested in trustees, and will belong absolutely to the members.

The management expenses will be kept separate, and are not to exceed 10 per cent. of the premium income.

The affairs and funds of the society will be examined and valued every five years, and the whole of any declared surplus or profits will be at the disposal of the members.

There are three tables given to show the quarterly premiums required up to the age of 49, copies of which may be obtained (free) of the Provisional Secretary, at the British Medical Association office, 161 A, Strand, London, W. C.

SOCIETY PROCEEDINGS.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting, Thursday, February 7, 1884. The President, R. A. Cleemann, M.D., in the chair.

A YEAR'S WORK IN OVARIOTOMY.

Dr. Wm. Goodell read a report of his cases of ovariotomy during the past year. Of these he had twenty-five, with seven deaths. Eleven of them were performed in the private rooms of the Hospital of the University of Pennsylvania, with one death. Ten were operated on at their own homes, with five deaths, and four at his private hospital, with one death. He attributed the majority of these deaths to three causes: First, that he made it a rule never to doom a woman to certain death by refusing to operate on her, however forlorn the hope of her recovery might be, and three of these fatal cases were very ill indeed at the time of the operation, from septicæmia and purulent cysts. Secondly, that the women of this country

being unwilling to go to a hospital, either insist on being tapped, which increases the risks of the radical operation; or else postpone the operation until the tumor has become very large, adhesions have formed and the health has become greatly undermined. Out of his twenty-five cases, he had but eight without adhesions, and one of these, a case of double ovariotomy, died at home, he not having seen her or treated her after the operation. Thirdly, that five of his fatal cases had been operated on at their own homes, which were so distant that he was able to see but one of them after the operation, and she did not rally, but died in eight hours, from the shock of the removal of an intra-ligamentous cyst, universally adherent. The fatal case at his private hospital was one of pelvic abscess bursting into the bladder. The operation was not a difficult one, although the lower portion of the cyst had to be separated from the two layers of the broad ligament by which it was enveloped. The sole fatal case out of eleven performed at the Hospital of the University was due to hospitalism. This he deemed a good record, for the building is used as a general hospital, with many railroad accident cases and suppurating wounds. In this hospital he always operated in one of the private rooms, where the patient was kept until all danger was over.

While acknowledging that his results were not so good as those of British ovariotomists, he said that, on the other hand, it was to be said in his favor that he never refused to operate on a woman, however slim her chances of recovery. He made this statement because, according to remarks made by Dr. Sutton at the last meeting of the American Gynæcological Society, Billroth is the only one among European ovariotomists who "refuses to operate npon nothing that deserves the chance of life," and his success amounts to about 65 per cent., whilst one of the most successful of British ovariotomists "does not remove very large tumors, viz.: those which weigh from 60 to 65 pounds, with extensive adhesions, etc."

Out of the twenty-five cases of ovariotomy, there were twelve in which both ovaries were removed. In all these cases, the second ovary was positively diseased. Yet with a larger experience he (Dr. Goodell) was becoming more and more inclined to remove both ovaries in all cases of malignant degeneration of one ovary; in all women who have passed the climacteric or who are approaching it, and in all cases complicated with fibroid tumor of the womb.

Finally, he referred to the fact that some ovarian cysts, although they may appear to the eye benign, show by their subsequent history that they are malignant; the woman dying a few months later from carcinoma of the pelvic organs, or at the site of former adhesions. Very unfortunately, there are no diagnostic criteria to indicate the character of such a cyst.

Dr. A. H. Smith feels that Dr. Goodell is hardly right in saying that in England desperate cases are rejected. In his own experience, while in England recently, several cases which were very desperate, and which would have been generally rejected here, were operated upon successfully, and were ready for discharge three weeks after operation. It occurred to him that the lower average temperature had much to do with the result. The thermometer is not allowed to rise above 65° F. in the room in which the patient is kept, and in Lawson Tait's cases it rarely goes over 60°, and never up to 65°. Perhaps this has a good effect in preventing hyperpyrexia. The English ovariotomists are also very careful in details, especially in preventing hæmorrhage, and use an immense number of hemostatic forceps. Ovarian cysts are remarkably common in London.

Dr. B. F. Dawson, of New York, upon invitation by the President, spoke of the English ovariotomists, and alluded to what he had himself seen, while on visits to England, as to very desperate cases being operated upon. His own late experience had been so good, that he was inclined to attribute it, as well as the good results of the English operators, to absolute painstaking in the most trifling details, with absolute cleanliness—not simply antisepsis, but the utmost care throughout every step of the operation. Among other things, a very large number of hemostatic forceps are used to secure each bleeding point the moment that bleeding commences. His own last six cases of laparotomy, performed this winter, two of which were very desperate in their character, have been successful, and the results he felt were largely due to the avoidance of any preventable hæmorrhage, and great care through all stages of the operation to prevent blood or fluid from the cyst escaping into the peritoneal cavity. This care is exercised throughout the "toilet of the peritonæum," and he always uses a flat sponge, as does Mr. Wells, inside of the abdominal walls, upon the intestines while introducing the closing suture, which is removed only when it becomes necessary to do so to twist the last wires.

He always uses napkins to fold over the edges of the abdominal incision, to prevent the oozing from the edges escaping into the peritoneal cavity or soiling the operator's fingers. He also enfolds the cyst in towels as it is withdrawn from the cavity, to guard against even a trace of fluid soiling the intestines or wound. He clamps the pedicle temporarily when possible, and places a napkin under the clamp before dividing and cauterizing it. Every adhesion that shows any risk of bleeding is cauterized as soon as it is separated, even when ligated. Douglas' pouch, especially, is sponged out until the sponges come away absolutely clean. In a recent very desperate case, one in which Dr. Emmett expressed his sympathy with him as to its almost certain fatality, the operation occupied two hours and forty minutes, owing to painstaking observance of the above details; and although half of the uterus was removed and adhesions were numerous, calling for many ligatures and frequent use of the cautery, yet convalescence was uncomplicated and speedy.

Dr. Goodell remarked that the quotation in his paper to which exception had been taken, referred to Mr. Tait. It was taken from a paper read last autumn before the American Gynæcological Society by Dr. Sutton, who was with Mr. Tait three months. He (Dr. Goodell) had seen about a dozen ovariotomies in Great Britain, and only one was a difficult case, and in that the patient died. There he had

seen patients refused on account of their age, while in this country they are not. Dr. Goodell had operated successfully in patients aged respectively 60, 61, 62, 64, 65, and 67 years, and some one in this city had a successful case in a patient over 83. Dr. G. had once operated upon a patient 76 years of age, of a long-lived family. This was before the days of antisepsis, and the patient died. He believes that minute attention to details is the chief element of success. One important point is to make the abdominal incision sufficiently large to see every adhesion as it is separated, and to ligate or secure immediately every bleeding point. This requires a courage which it took him years to attain. He always observes Spencer Wells' method of placing a flat sponge beneath the abdominal walls when introducing the closing sutures. He does not like wire, but always uses carbolated silk sutures, each eighteen inches long. After all have been placed, the ends are twisted together into one strand on either side, and caught in the bite of a pressure forceps. The lips of the incision are then widely separated, and a final search is made for any oozing, leakage, or accumulation of serum. They are then rapidly tied and the wound dressed. This final toilet of the peritonæum cannot be made when wires are used. He now believes in the use of a drainage tube, but he had hard work to bring himself to the point of accepting it, as he still looks upon the tube as a foreign body, a necessary evil. He had once seen death caused in a healthy man by the simple perforation of the peritonæum, without wound of the intestine, by a small stilette, and this had made him fearful of the effect of the presence of a drainage tube. But he now considered that the peritonæum, in the case of an ovarian cyst, has by thickening and attrition lost much of its vulnerability, and does not resent slight causes of irritation. He occasionally resorts to the actual cautery at a black heat to stop bleeding from torn adhesions, but he prefers the pressure forceps, the ligature, or the application of Monsel's solution. He thinks there may be some truth in Dr. Smith's idea concerning the effect of the low temperature of the operating and of the convalescent room. He was struck with the absence of ill results in one operation in London by Dr. Bantock, of which he had been a spectator. The day was cold, damp and foggy, and the operating room was chilly, the windows being open, but the patient promptly recovered. One case of his own, in which the extreme emaciation and prostration of the patient forbade postponement, was operated upon in severe winter weather; the steam pipes at the hospital had been frozen over night, and although they had been thawed out, the temperature of the operating room was only 54°. In this case the cyst had contained colloid matter, and had burst spontaneously; all that could possibly be removed was scooped, sponged and washed out. Much remained behind, yet the patient recovered and afterward became quite fat. This operation was performed three years ago; both ovaries were removed, but another tumor can now be discovered in the abdomen. The patient being fat, and also very sensitive, it is not possible to determine accurately its character, but he hopes it is a pedunculated fibroid of the uterus, and not a malignant tumor.

Dr. Dawson requested Dr. Goodell to give his opinion respecting the management of the drainage tube, and of the importance of the spray.

Dr. Goodell, when operating in private houses, has begun to dispense with the spray. Carbolic acid spray poisons some patients, and he, being afraid of it, only uses it when he does not consider it safe to omit it, as, for instance, in a general hospital, or when there are many spectators present. The year before last he lost one patient from its use; she had contracted kidneys. Only last week, in a case operated on in the hospital of the University, the patient was profoundly affected by it, and was with difficulty restored by means of digitalis, stimulants, etc. When he omits the spray he uses the drainage tube more frequently. If he finds in Douglas' pouch, after the sutures have been placed and the sponges removed, two or three drachms of bloody serum, and the source of this oozing cannot be found, he inserts a drainage tube; and he also uses it in all cases where there has been peritonitis, or when septic symptoms are present from a purulent cyst. Over the mouth of the tube he springs a piece of rubber sheeting, which is folded over a sponge squeezed out of a five per cent. solution of carbolic acid. The sponge is examined and squeezed out every few hours, and the tube moved slightly to clear the openings and allow any accumulation of serum to escape. As soon as a moderate amount of serum escapes without any tinge of blood the tube is removed. This generally happens within forty-eight hours, but in one case it was necessary to allow it to remain five days. He never irrigates the abdominal cavity, but he sometimes introduces the long nozzle of a hard rubber syringe into the tube, and draws out any serum that may have accumulated. When he operates in the country, and leaves the patient in the hands of the family physician, he tries to avoid the use of the drainage tubes as much as possible.

Dr. Dawson had given some attention to the question of the drainage tube. In New York two deaths had recently happened after ovariotomies, and in each case the surgeon had ascribed the fatal termination to the too early removal of the tube. Soon after these unfortunate cases he had operated and been obliged to use the drainage tube; on the second and third days after the operation the serum exuding from the tube was bloody. On the fourth day it was pure serum. The patient was doing well, and Dr. Dawson concluded to let well enough alone, and, with the result in the two other cases before him, allowed the tube to remain. He used a wire with a pledget of absorbent cotton attached to the extremity, to soak out the accumulated serum, and continued to use fresh pieces until they came away clean. The tube was evidently being walled in by a deposit of lymph around it. On the sixth day, after finding very little serum, the last pledget of cotton brought away a little yellow spot that might have been either lymph or pus. That night he discovered another trace of the same appearance, and the microscope showed it to be pus. The next day the discharge was fetid. A

salt-spoonful of iodoform was put into the tube every time it was cleaned, and on the tenth day it was removed, and a roll of absorbent cotton saturated with iodoform was put in its place. This was replaced in a few hours with another, until all signs of pus ceased. The opening closed in forty-eight hours. The patient recovered. He would like to ask if Dr. Goodell had ever regretted removing a drainage tube too early? Is a drainage tube more of a foreign body on the third or fourth day than it is on the first?

Dr. W. H. Parish had recently performed abdominal section for the removal of a fibroma of the uterus. In this case he used a drainage tube, although he was not able to pass it down into Douglas' pouch. On the third day he noticed that the serum escaping from the tube was cloudy and had a slight odor. On the fourth day the odor was quite objectionable, and as the tube had evidently become separated from the abdominal cavity by the formation of a canal of lymph around it, resembling in appearance diphtheritic membrane; he decided to withdraw the tube. He washed out the canal with a two per cent. solution of carbolic acid. The canal soon closed and there was no return of the offensive odor.

Dr. Goodell could not recall the loss of a case after the removal of a drainage tube. He has had, however, a number of deaths while the tube was still in position, but that meant simply that the cases were complicated and difficult ones. Was not the tube itself the cause of the pus in Dr. Dawso· 's case? Air containing germs was of course admitted into the tube in the cleaning out process, and these germs would cause decomposition of the lymph. Might not also the tube, acting as an irritating foreign body cause pus? He introduces a stitch in such a manner, beyond the drainage tube, as to make tension of the skin around the tube, and this closes the opening as the tube is withdrawn. He has occasionally followed the removal of the glass tube by the introduction of a rubber one of smaller caliber, but he has discontinued this practice, believing the glass tube to be the least irritating.

Dr. W. H. Baker reported for Dr. Walter F. Atlee a case of abdominal section. Mrs. E. C., of Erie, Pa., was brought to this city by Dr. Edward Cranch. She was forty-five years of age, married, but had had no children. Her menses were regular and very abundant. She was a stout woman, in excellent health. Four years ago she first noticed the tumor in the center of the abdomen. Dr. C. reports that the probe enters the womb the normal distance only.

Diagnosis.—A multilocular cyst with thick walls and very glutinous liquid, or a fibroid tumor of the uterus. The sense of fluctuation was not distinct.

Operation.—Feb. 4, after the usual preparation, cut down, found a solid tumor, opened it, took out as much as possible of the contents, and got out the envelopes; the incision was about five inches in length. The tumor grew from the fundus of the uterus. It was transfixed, tied and dropped. The patient never rallied after the operation, and died on the 6th of shock. There was no hæmorrhage. The operation was all over in twenty-five minutes.

Dr. R. P. Harris saw the patient prior to and assisted in the operation. The lady had an appearance of health, was quite robust, and there was nothing in the contour or expression of her face indicative of ovarian cystoma. In a conversation with her sister and family physician, he learned that the diseased growth was first noticed by this sister, who remarked upon the central prominence of the abdomen of the patient, who was at the time lying on her back on the floor, engaged in playing with a little child. When the attention of the patient was directed to the fact that her abdomen presented a central elevation even when flat upon her back, she readily detected the presence of something abnormal. Dr. Harris remarked to the physician that the history of the case indicated the existence of a tumor at the fundus uteri. When the morbid growth was exposed it did not present the appearance of an ovarian cyst; neither did percussion indicate the presence of fluid prior to incising the abdomen, except by a surface wave. There was no wave transmitted from hand to hand. The surface wave was found due to some ascitic fluid. As no fluid escaped by tapping, the tumor was opened and its contents torn away in pieces, so as to reduce it sufficiently, when it was drawn through the wound, ligated at its union with the fundus uteri, and cut away. During the shelling process a considerable loss of blood took place, and the appearance of the patient was that of great prostration. The tumor had no pedicle, being sessile in its attachment to the uterus.

W. H. H. GITHENS, Secretary.

STATE MEDICINE.

REPORT OF THE FIRST MEETING OF THE OHIO STATE SANITARY ASSOCIATION.

The first annual meeting of the Ohio State Sanitary Association was held in the Board of Trade room, Columbus, Thursday morning, Feb. 14. The meeting was called for ten o'clock, but it was nearly an hour later when Dr. J. F. Baldwin, of Columbus, rapped for order, and nominated Dr. Wm. Morrow Beach, of London, as temporary chairman. By this time about twenty members had come in, the high water having detained many; but before moving adjournment, the room was quite comfortably filled with physicians and scientific men from all over the State. The object of the meeting was to educate the peopeople by the diffusion of a more thorough knowledge of the laws of health, and the best means to be adopted for the prevention of all preventable diseases, and, finally, the securing of proper and wise legislation for the support of the same.

After the selection of Dr. Beach as temporary chairman, Rev. Dr. W. E. Moore, of the Second Presbyterian church, led in prayer, and Dr. R. Harvey Reed, of Mansfield, was chosen as temporary secretary.

In accordance with arrangements, Dr. Baldwin delivered an address of welcome, in which he re-

ferred to the sad effects of the sewerage system of this State upon the public health, and set forth a number of important topics which he deemed of importance, and which he thought should receive the attention of the student of sanitary science.

The response to Dr. Baldwin's address was made by Prof. John Simpson, PH.D., Superintendent of Mansfield Public Schools. He advocated a more thorough and general education in sanitary science, believing that a more widespread knowledge of hygiene would have a wholesome effect on the public health, and would prevent many common abuses. "Were a sound body the rule instead of the exception," he said, "the condition of the race would be materially improved in this age of stupendous progress."

The Chair, at the close of the address, appointed the following Committee on Permanent Organization: Drs. J. F. Baldwin, Columbus; X. C. Scott, Cleveland; E. H. Hyatt, Delaware; G. S. Franklin, Chillicothe; C. A. Lee Reed, Hamilton.

Dr. Beach, of London, temporary chairman, read an interesting paper on the "Importance of Sanitation." The production displayed a very intimate acquaintance with the history of sanitary science. It reviewed at considerable length the history of the plagues that swept over Europe during the Middle Ages, giving a general idea of their severity, and some of the mediums through which pestilence is spread. Dr. Beach is not in favor of fumigating bedding and other clothes after the poison of pestilence has once been retained in them, but thinks the physician should enforce positive sanitary precautions by having the articles burned. The history of quarantining against the epidemics of cholera and yellow fever was run over, and the doctor expressed himself as in favor of it. The paper closed with an eloquent peroration.

On motion of Dr. Reed, of Mansfield, it was decided to give a reasonable time after the reading of each paper, for the general discussion of the same.

Dr. C. M. Finch, of Portsmouth, being absent on account of the high water, the "Plea for the Organization of a State Board of Health," which was to have been presented by him, was necessarily omitted.

Dr. J. F. Baldwin read a letter from Dr. James E. Reeves, of Wheeling, Secretary of the West Virginia Board of Health, who was expected to address the present convention, but who said that he must cancel the engagement, as he was needed at home to help take care of the people rendered destitute by the flood, at the same time expressing his regrets at being unable to be present at the meeting, and wished it abundant success.

On motion of Dr. G. S. Franklin, Dr. Reeves' letter was accepted, and the regrets of the Association extended to him in return.

A valuable paper was presented by Dr. G. S. Franklin, of Chillicothe, on the subject of "Abattoirs," in which he expressed himself as in favor of placing the control of all slaughter-houses in the hands of Boards of Health.

The Association then adjourned until 2:30 P. M.

The first thing on the programme for the afternoon was a paper on "Drainage and Water Supply," by Professor E. H. Hyatt, M.D., of Delaware. Dr. Hyatt, however, said he would willingly give his time to the discussion of the Scott bill, and the society accepted the offer.

Dr. Scott, of Cleveland, the champion of the bill, then took the floor, and explained that it was a bill "to establish Boards of Health and Medical Boards of Examiners and Licensers, and regulating the practise of medicine and surgery in the State of Ohio, and defining the powers and duties of such boards," which he read, section by section, after supplying most of the members with a copy of the same. A spirited discussion followed, the unanimous sentiment, however, seeming to be in favor of the passage of the bill. Those gentlemen taking part in the discussion were Prof. E. H. Hyatt, of Delaware; Dr. Conklin, of Dayton; Dr. McCurdy, of Mahoning County; Dr. Reed, of Hamilton; Dr. Baldwin, of Columbus; Dr. Silver, of Sydney; Dr. Reed, of Mansfield; Dr. Beardsley, of Ottawa; Dr. Beckwith, of Cleveland; Dr. H. J. Sharpe, of London; and Dr. Franklin, of Chillicothe. No one spoke against the bill, but a number of suggestions as to how it might be changed with benefit were offered.

Dr. McCurdy feared that too much power might be given to the State Board of Health; that they might interfere with the work of local boards in matters of ventilation of public buildings, etc., and with the mine inspector in the matter of ventilating mines. It was the bill, however, which he had seen.

Dr. Reed, of Hamilton, suggested that, as the bill as now drawn up provides for a board who shall have the duties and powers of a Board of Health and of a Board of Examiners, the matter might be divided, and the question of constituting the two bodies submitted separately. This objection and another which was made were met with the answer that the Board of Medical Examiners would more than meet their expenses, and that part of their expenditure as a Board of Health would also be covered, thus entailing less cost upon the State than any other board.

Dr. Baldwin suggested that it was not desirable to create any more boards than there now are, and that the County Infirmary Board, receiving pay, could be pressed into service in the local organizations. The infirmary physician could then be utilized as the officer of the board.

Dr. Scott raised a counter objection that county physicians are generally "cheap Johns" of the profession, and would not be desirable in this connection.

Dr. Reed, of Mansfield, referred to an objection which he had heard raised against the bill, in that probably the disciples of one school would, if on the board, be compelled to sign certificates of applicants belonging to the other school. He suggested that when a new school man appeared for examination his certificate, if he passed, should be signed by the new school men alone on the board, and if an old school man by the members of he old school.

To this Dr. Beckwith, of Cleveland, made a perfect answer, saying that he, as a homœopath, was not afraid to stand the examination of the board, and

that he did not desire anyone who was afraid to stand the test to be allowed to practice as a member of his school.

There was considerable talk over this subject, and the matter was finally settled by Dr. Scott stating that it was the intention of the bill to require the signatures of the President and Secretary of the board to the certificates.

On motion of Dr. Reed, of Mansfield, it was decided to close the discussion, and appoint a committee to confer with Dr. Scott in making the necessary amendments to the bill, which should include the Chairman as a member of said committee, which consisted of the following gentlemen: Drs. Beach, of London; Scott, of Cleveland; Conklin, of Dayton; Beckwith, of Cleveland; Beardsley, of Ottawa; Baldwin, of Columbus; Franklin, of Chillicothe; Jones, of London, and James Allison, Esq., of Cincinnati.

Dr. Hyatt having given way to the discussion of the Scott bill, it was decided to have his paper in the morning.

The regular business was then taken up, and Dr. John McCurdy, of Youngstown, read a paper on "The Sewerage and Water Supply of Youngstown." He said the Youngstown people are using the Holly water system, and the large brick sewers, which (the sewers) have cost them nearly $200,000, and, notwithstanding this great expense, were a failure from a sanitary point of view. In the general discussion, the small sewer, which could be easily flooded, was unanimously considered the best, and which in towns of 10,000 seldom ever needed to be over 6 inches, except in the mains, which rarely needed to exceed 18 inches, and could be put in with much less expense.

Mr. James Allison, a delegate from the Master Plumbers' Association, of Cincinnati, read a voluntary paper on "The Plumber in His Relation to Sanitary Progress as Viewed from the College of Practice." This paper was one of the best of the meeting. The convention, after hearing Mr. Allison's paper, adjourned until evening.

The evening session was held in the House of Representatives, commencing at 8 o'clock. There were about 100 persons present, among them being a number of members of the General Assembly. Dr. Beach took occasion to return thanks for the use of the hall, and called for the first paper of the evening, the opening by Prof. Starling Loving, M.D., of Columbus, of a discussing on the resolution, "That Legalized State Sanitation has Become a Necessity in the State of Ohio for the General Protection of its Citizens." He held that thousands of deaths occur annually from preventable diseases, and referred to the Secretary of State's Report to substantiate his statements. These deaths, he argued, were a direct loss of many millions of dollars to the State, and some legislative action should be taken to prevent them. He favored the appointment of a board of competent physicians to examine all medical college students, and also a State Board to take charge of sanitary affairs.

Discussion of Dr. Loving's paper was open, and Dr. John McCurdy, of Youngstown, and Dr. Reed, of Mansfield, took part.

Prof. W. J. Conklin, M.D., of Dayton, read a paper on "The Influence of Public Schools on Brain-Building," which did not elicit discussion, from the fact that the statements coincided with the views of most members present.

The Association, after the reading of Dr. Conklin's paper, adjourned to meet in the Board of Trade rooms at 9 A. M. Friday.

The meeting was called to order by the President at 10 A. M., after which the Committee on Permanent Organization made the following report: President, Wm. Morrow Beach, M.D., London; First Vice-President, Prof. Edward Orton, Columbus; Second Vice-President, Prof. Nelson, Delaware; Third Vice-President, Hon. L. D. Brown, Hamilton; Secretary, R. Harvey Reed, M.D., Mansfield; Treasurer, Prof. John Simpson, Mansfield. Executive Committee, which, ex-officio, includes all the Presidents and Secretary, together with Prof. Starling Loving, M.D., Columbus; H. D. Beckwith, M.D., Cleveland; Prof. W. J. Conklin, M.D., Dayton; Prof. E. H. Hyatt, M.D., Delaware. Committee on Publication: R. Harvey Reed, M.D., Mansfield; J. F. Baldwin, M.D., Columbus, and Geo. A. Collamore, M.D., Toledo. Committee on Legislation: Wm. Morrow Beach, M.D., ex-officio, London; X. C. Scott, M.D., Cleveland; C. S. Van Pelt, M.D., Toledo; S. C. Minor, M.D., Cincinnati; J. R. Flowers, M.D., Columbus, and C. M. Finch, M.D., Portsmouth.

The report of the Committee on Permanent Organization was adopted, and the committee discharged.

The committee also reported a constitution and by-laws, which was read and adopted. The name of the organization is to be "The Ohio State Sanitary Association," and its object the general advancement of sanitary science, and the encouragement and promotion of local organizations throughout the State. The membership will be of two kinds, active and honorary. Active members shall form the body of the Association, and shall be selected with special reference to their interest in sanitary and allied studies. Honorary members shall be selected with reference to their general interest only in the work in hand. The association will meet at least once a year in the month of February, and unless some other city is mentioned it will meet in Columbus.

Prof. Curtis C. Howard, professor of chemistry in the Starling Medical College, read a paper on impurities and adulterations of milk, the result of a series of examinations of the milk of the Columbus market. The professor thought there was little adulteration in the way people generally suppose. As for chalk, it is insoluble, and if mixed in clear water it will be turbid for a time; but after standing a while all the chalk will settle and the water will become clear again. So also with brain matter, which some claim to have found in milk; it could not be put in without spoiling the whole of the milk. Water, however, may be added *ad infinitum*, and the quality of the milk will be in inverse proportion to the amount of

water used. The professor exhibited a chart which showed the result of his work.

The next paper was read by Prof. D. N. Kinsman, M.D., of Columbus, on "Some Reasons for the Establishment of a Board of Health." He called attention to the amount of disease arising out of ignorance of the causes of disease. Every section of country has its particular industry and each industry has its peculiar diseases. How to prevent them should be the work of the board. He referred to the importance of obtaining accurate vitality statistics, and thought a good board could do this work in a way not done as yet.

Dr. S. H. Smith, of Warren, was on the programme to read a paper on "Diphtheria," and Dr. J. W. Craig, of Mansfield, a paper on "Tobacco from a Sanitary Point of View." Both of these gen- were absent, and, on motion, a paper on "The New Fashion," by Prof. C. A. Lee Reed, M.D., of Hamilton, which had been assigned, was read in the place of these. The paper referred to the absence of athletic sports among the people in general, and hailed what seems to be the approach of an era when the pell-mell, hurry-skurry of American business life will be broken into a fair amount of refreshment and rest.

Dr. Lew Slusser, of Canton, read an able essay on "Vital Statistics," a paper illustrating the great need of correct vitality reports.

The remaining part of the morning session was taken up by Dr. Beckwith, of Cleveland, who read a paper on "Sewers and Sewer Gas." After fixing the time for hearing the paper of Prof. Orton for the first hour of the adjourned session, the Association adjourned.

F. H. Darby, M.D., of Morrow, who had prepared a volunteer paper, but could not be present, sent his regrets along with his manuscript. The paper was read by the Secretary in the afternoon. The subject of the essay was: "Blood-Poisoning from a Sanitary Standpoint." The only other paper on the programme was that of Prof. Edward Orton, of Columbus, on "What shall be done with our Sewerage and Garbage?" which at the special request of Prof. Orton was laid over until next year, as recent illness had prevented him making the desired preparation on such an important subject.

President Beach made a few fitting remarks, in which he expressed his surprise at the unexpected success of the meeting, and the great interest manifested by all in attendance, together with the high quality and marked preparation shown in the numerous papers, which were generally followed by spirited and interesting discussions.

After the President's address it was moved by Dr. Reed, of Mansfield, to adjourn, to meet February next, in Columbus, at a time to be designated by the Executive Committee.

WM. MORROW BEACH, M.D., Pres., London, O.
R. HARVEY REED, Sec., Mansfield, O.

ACCORDING to Dr. Billings, of 1,000,000 colored infants born (in Baltimore) one-half will have perished before attaining the age of two years.

HEALTH IN MICHIGAN.

Reports to the State Board of Health, Lansing, by observers of diseases in different parts of the State, show the principal diseases which caused most sickness in Michigan, during the week ending January 5, 1884, as follows:

NUMEER OF OBSERVERS HEARD FROM, THIRTY-NINE.		For preceding week.
DISEASES ARRANGED IN ORDER OF GREATEST AREA OF PREVALENCE.	Per cent. of observers who reported the disease present.	Per cent. of observers who reported the disease present.
Neuralgia	77	65
Bronchitis	62	70
Influenza	59	63
Rheumatism	59	60
Intermittent fever	54	63
Tonsillitis	54	63
Consumption, of lungs	51	53
Pneumonia	44	44
Remittent fever	33	30
Erysipelas	26	26
Whooping-cough	23	21
Diarrhœa	23	26
Diphtheria	18	14
Inflammation of kidneys	15	26
Inflammation of bowels	13	12
Typhoid fever (enteric)	8	9
Scarlet fever	8	9
Dysentery	8	0
Measles	5	7
Inflammation of brain	5	7
Cerebro-spinal meningitis	5	0
Puerperal fever	5	5

For the week ending January 5, 1884, the reports indicate that neuralgia and dysentery increased, and that inflammation of the kidneys, tonsillitis, intermittent fever, and typho-malarial fever decreased in area of prevalence.

At the State capitol, the prevailing winds during the week ending January 5 were northeast; and, compared with the preceding week, the temperature was considerably lower, the absolute humidity less, the relative humidity and the day ozone considerably more, and the night ozone the same.

Compared with the average for the month of December in the preceding six years, diphtheria, remittent fever, pneumonia, consumption, and typho-malarial fever were less prevalent in December, 1883.

For the month of December, 1883, compared with the average of corresponding months for the five years, 1879-1883, the temperature was slightly higher, the absolute humidity the same, and the relative humidity and the day and night ozone less.

Including reports by regular observers and others, diphtheria was reported present during the week ending January 5 and since at fourteen plaaes, namely, Adrian township, Burt, Calumet, Delta, Detroit, Farmington, Grand Rapids, Holly, Ithaca, Monroe, Northville, Niles, Owosso, Pontiac. Scarlet fever at nine places, Adrian township, Allen Creek, Colfax, Detroit, Grand Rapids, Jefferson, Monroe, Orleans, Washington. Measles at two places, Detroit and Owosso. Small-pox was reported in Orleans township, January 2, 1884.

HENRY B. BAKER, Secretary.
Lansing, Jan. 9, 1884.

DOMESTIC CORRESPONDENCE.

TO THE EDITOR OF THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION:

In the JOURNAL for February 16, 1884, there is an editorial on the subject of the new medical law of Virginia. The writer of the editorial says that one of the "legitimate objects to be accomplished by legislative enactments for regulating the education and practice of the medical profession, should consist of a simple provision by which the certificates of similar bodies in other States should be recognized, so as to maintain a comity of rights and interests between the States."

That such a recognition of the certificates issued by the Board of one State by the Board of another would be very desirable, there can be no question; but so long as the Boards differ so widely in their requirements as they now do, I do not see how such recognition could be made. For example, in many of the States all that is required is that the candidate should be a graduate of some respectable medical college, the question of respectability being left to the discretion of the Board. In other States—California, for instance—there are two, or possibly three, examining Boards, one representing the regular profession, one homœopathic, and probably one eclectic, though I am not sure on this latter point. When in California a few years ago, I was told by a member of the regular Board that most incompetent men had been passed by the homœopathic Board of that State. Now, would it be reasonable or proper for the Alabama Board, for instance, which is admirably constituted, to "recognize" the certificate of a physician coming from California, without subjecting him to an examination?

As a member of the committee which framed the Virginia law, I do not hesitate to say that our object was not only to put down notorious quackery, but to check that more dangerous, because less conspicuous, ignorance which is concealed behind a diploma of some medical college whose standard is wretchedly low. To do this it was necessary that every applicant for practice, whether a graduate or not, should be required to pass a satisfactory examination before a board of examiners, and it was with reference to this point that the committee had most trouble, an effort being made to allow any man having a diploma from any college to practice without standing an examination.

The medical colleges in the United States are so numerous now, and the competition for students so great, that the temptation to lower the standard required for graduation in order to attract students, becomes almost irresistible, and in view of this fact, the desirability of having an examining board in each State entirely independent of the colleges becomes apparent. Then, the next step will be to have some concert of action among the boards of the different States, so as to make the standard required by the different boards correspond. If many of the States will do this, then the colleges will be forced to raise their standard for graduation.

I hope to be able to bring this matter before those interested in the subject at the next meeting of the American Medical Association, and if you approve of the plan, I trust you will call attention to it through the columns of the JOURNAL.

Very respectfully &c.,

WM. C. DABNEY, M.D.

Charlottsville, Va., Feb. 22, 1884.

NOTE.—In the editorial alluded to in the above letter, we meant by the words "similar boards in other States," only such as were constituted on the same basis and exercised the same powers and duties. We do not regard a State Board of Examiners, who are required to issue licenses to practice to any party who may possess a college diploma, as in any sense "similar," to the board provided for by the Virginia law. Indeed, such boards are practically little more than registration offices, and the laws establishing them are hardly worth the paper they are printed on. —EDITOR.

FOREIGN CORRESPONDENCE.

PARIS, FEB. 8, 1884.

Prof. Germain Sée and Dr. Bochefontaine, his "chef de laboratoire" at the Hotel Dieu, lately undertook a series of experiments as to the physiological action of the sulphate of quinine, which were afterward compared with the results obtained clinically at the hospital. The following is a summary of their paper on the subject which was read at a recent meeting of the Academy of Sciences:

In the healthy human subject, the sulphate of quinine lowers the temperature to a very insignificant degree; the oxidations, however, undergo marked diminution; the pulse becomes slower, and the blood-pressure is lowered. In the typhic patient, the temperature is lowered after the first gramme, and particularly after the second gramme of quinine; it falls one degree and a half in six or eight hours, and the effect persists for a day and a half. The oxidations diminish in the same proportion. The pulse-rate becomes much slower than in the physiological state. The blood-pressure, which falls constantly under the influence of hyperthermia, rises to the normal condition; there is, besides, increase of the contractile energy of the heart. The sulphate of quinine alone preserves the force of the heart and increases it. Moreover, as it diminishes the febrile heat directly, without previously increasing the combustion, as is the case with cold baths, it stops dicrotism, and the arterial tension, which was considerably diminished, resumes its normal strength. It is therefore a powerful antipyretic. If, in the physiological state, it diminishes vascular pressure, it is because it does not produce a marked diminution of the normal temperature.

A very interesting exhibition of the wonders of the deep in the form of submarine animals and plants, is about to be opened at the Jardin des Plantes, which were collected by M. Alphonse Milne-Edwards during his exploration cruise along the western coast of

Africa. About the beginning of last year, M. Milne-Edwards and other naturalists who accompanied him started in a ship named "Talisman," with all the necessary engines, apparatus and instruments for soundings in the depths of the ocean, and which were placed at their disposal by the French Government. The explorations were pushed to 6,000 meters, or about 19,686 feet. They lasted several months, which enabled them to collect the most curious specimens of the fauna and flora of the great deep. Specimens of vegetables and of animals absolutely unknown to the present time, were also collected. All the different specimens have been well preserved, and will be exposed in a few days, as I have just stated. Before the opening of the exhibition, however, M. Milne-Edwards thought proper to give the result of his exploration in a most interesting communication he made at the Academy of Sciences. At the conclusion of the paper, the reading of which was listened to with intense interest, M. Boussingault, one of the oldest members of the Institute, was heard to exclaim: "And yet, for the last 30 years or more, I have been teaching that life was not possible in the depths of the ocean."

In 1873, a law was passed for the repression of drunkenness in the streets, and with the view of putting a check on the progress of alcoholism in this country. It was made applicable not only to the miscreants, but to the wine merchants, who allowed, or rather encouraged people to get drunk in their shops. The application of this part of the law was not always easy, as the drunken persons did not always recollect where they had been drinking. The police authorities have, therefore, resolved to punish severely all wine merchants whose shop any person may leave in a state of intoxication.

The following interesting report, drawn up at the office of the Minister of the Interior, has just been published in the *Journal Officiel*, showing the number of births, marriages and deaths during the year 1882. From this report it is seen that at Paris there have been 108 deaths daily, and as many or nearly as many births, or an average of 6 deaths and 6 births for each arrondissement. There were 200 marriages weekly, and it is stated that 20 per cent. of married couples have no children; 10 per cent. have more than 10; 30 per cent. have from 5 to 10; 20 per cent. have from 2 to 5; and the others have only 1 child. In the same proportion of marriages there are 15 that obtained legal separation (divorce not being lawful in this country) and it is in the first years of marriage that applications for separation are the most numerous. After fifteen years of conjugal life the applications become less frequent.

The aquarium which was established in the grounds of the Trocadero during the last International Exhibition held in Paris in 1878, has been considerably enlarged and improved. It is well provided with salt and fresh water fish, and arrangements have been made for a complete laboratory for experiments, and a staff of professors who are to give public and gratuitous lectures on pisciculture.

The late Dr. Depaul, Professor of Clinical Obstetrics in Paris, and who died a short time ago, has bequeathed his splendid collection of pathological specimens and obstetrical instruments to the Faculty of Medicine of Paris. A. B.

NECROLOGY.

Ford, Charles Mason, M.D., of Washington, D. C., was born in or near Troy, New York, May 15, 1840; died of rheumatic fever at his residence, 150 Pennsylvania Avenue S. E., February 15, 1884.

He was the son of John N. Ford, of Troy, N. Y. Having received a good academical education he, at an early age, began the study of medicine with Dr. Alfred Watkins, of Troy. He attended lectures and graduated M.D. at the University of Pennsylvania in 1861. His graduating thesis was written on "Scarlatina." Shortly after leaving college he was appointed assistant-surgeon in the Navy, and assigned to duty with the Huntsville blockading squadron, under the command of Capt. Ciciro Price. He served with reputation, but from exposure contracted rheumatism, which caused him to resign, and return home to recover his health. In a few months after leaving the Navy he came to Washington, and was at once commissioned assistant surgeon of volunteers, and assigned to duty at "Clifton Hospital," situated on the heights to the north of t he city of Washington. After some 9 months' service at this hospital, Dr. Ford was assigned to special duty at the "old Capitol Prison," where he remained until that famous institution was abolished. With the consent of the officers in charge he opened an office for private practice in the vicinity of the prison, and near where he finally located when he retired from the military service. As soon as permanent settlement in Washington was determined, he became associated professionally with Providence Hospital, and for over 14 years he served on the surgical staff of that institution. At a special meeting of the Medical Society of the District of Columbia held Feb. 16, to take action and adopt a minute expression of the feeling of the Society on the death of its member, Dr. C. M. Ford, Dr. S. C. Busy paid an eloquent tribute to his character and memory. Other members spoke in the same strain. It is to be regretted that their remarks were not reduced to writing.

Dr. Ford Thompson, who had been long associated with him in Providence Hospital, and knew intimately his character and skill as a surgeon, reduced his remarks to writing, and spoke as follows: "Dr. Ford was remarkably endowed by nature with many of the qualities which make the successful physician and surgeon, as well as the most agreeable and lovable companions. Gifted with a memory almost phenomenal in its retentiveness, he was able to keep abreast with the advance of medical science almost without an effort; and combined with this he possessed judgment to a degree that often appeared intuitive, and made his advice of the highest value to his friends as well as to his patients. He was well grounded in the essential branches of his profession, and his thorough knowledge of anatomy gave him a secure foundation

for the superstructure of surgery, for which he early evinced a decided aptness. Indeed, I have rarely seen a man upon whose judgment I would more implicitly rely than his. With a comprehension of the possibilities of the vast field of surgery he combined an insight of complications and extraneous influences which made his opinion of a case of peculiar value, upon the many occasions it has been sought by me. As a practitioner of medicine I believe he possessed the same eminent qualities to an equal degree in all the departments, for I have heard no other opinion from those who have had the fullest opportunities of judging in this field of his labor." Dr. E. C. Hagner, who had also reduced his remarks to writing, in speaking of Dr. Ford's personal and social qualities, said: "Dr. Ford had one of the most lovable dispositions that I have ever known. His heart had a southward look, and was always open to the sun. When his friends met him, however weary and exhausted they might be, it was a rest from the cares of this weary life to bask in the sunshine of his joyous nature. Quick-witted, sympathetic, large-hearted, generous to a fault, he grappled his friends to him with hooks of steel. The electricity of his temperament was indeed wonderful. I have met him when I knew the case to be visited was one which taxed every energy of his mind and sympathy of his heart, and when I expected him to show in face and manner some evidence of the strain he was undergoing. He had a most complete control over his feelings. I have marveled at the buoyancy of his greeting on such occasions, the readiness of his smile and laugh. He could beguile the time with merriment and almost boyish fun, but the moment the patient's threshold was reached the transformation of manner was complete; the strong man was there, the wise and vigilant physician had assumed control of the case, and his tender, soothing voice was heard comforting and consoling. It was no simulated sympathy that this huge man, with a woman's heart and the frame of a Hercules, gave to his patients. In the sick-room upon his brow was written 'Duty,' and all the genial elements of his nature were fused into a tender solicitude, that won the patient's confidence and gave assurance of the trust in his skill." Dr. Ford, although having a preference for surgery, had, nevertheless, a very large general practice, scattered over the eastern half of the city; and although fond of social life, was dilligent and conscientious in his attendance upon his patients. His services, too, were given freely to the poor as well as to the rich.

For some years Dr. Ford was physician to the Washington Asylum, or Almshouse, and at the time of his death he was surgeon to the Baltimore and Potomac railroad, and to the Washington and Fredericksburg railroad. He was a member of this Medical Society and also the Medical Association of the District of Columbia, and was one of the original members of the Clinico-Pathological Society of the District of Columbia. He was a delegate to the American Medical Association from the Medical Society of the District of Columbia in 1865, and attended in 1866, 1868, 1870, and 1880. Dr. Ford was an honorary member of every military organization in the District. He was at the time of his death a member of Lafayette Lodge, No. 19, F. A. A. M.; Lafayette R. A. Chapter, No. 5; and Columbia Commandery, No. 2, Knights Templar. Among all his Masonic brethren he was very much beloved, and no public occasion was deemed complete without his genial company. Dr. Ford was married in 1862 to Miss Ives, who bore him five children, two of whom with their mother survive. His domestic life was a happy one, a devoted husband and affectionate parent, and was fully reciprocated. His funeral is to take place on Tuesday, 19th inst., and the interment will be at the Congressional cemetery, where three of his children are buried. His lodge, chapter and commandery of Knights Templar will bury him with full Masonic honors; and it is announced that all the military organizations to which he was attached will join in the funeral pageant. J. M. T.

HUGHES, THOS. M., M.D., died at the residence of his mother, near Amiprille, Rappahannock county, Virginia, Jan. 29, 1884, in the 28th year of his age, of phthisis pulmonalis.

Dr. Hughes graduated from the College of Physicians and Surgeons, Baltimore, Md., in 1879, and after devoting a year to hospital practice at Bay View, began the practice of his profession in connection with Dr. John A. Adams, at Amiprille, who dying in January, 1882, the subject of this notice was required to assume the responsibilities of a large country practice, and right nobly has he discharged the duties thus devolved upon him. It has never been the fortune of the writer to see a young physician acquire the full confidence of a large and steadily increasing patronage so completely, nor to know one more generally beloved and esteemed by his professional brethren.

He was elected a Fellow of the Northeast Virginia Medical Society in 1881, of the Medical Society of Virginia in 1882, and was a delegate to the American Medical Association in 1883.

Although modest and retiring in disposition, he was accomplished in his profession, and availed himself of every opportunity of advancing its interests.

In his death the community has lost one of its most useful citizens, the medical societies to which he belonged, and the profession at large, a useful and promising member. A. H.

MISCELLANEOUS.

INDIANA STATE SANITARY CONVENTION.

SEYMOUR, IND., Feb. 15, 1884.

DEAR SIR:—You are respectfully invited to attend and participate in the labors and deliberations of the First Convention of the Indiana State Sanitary Society, to be held at the city of Seymour, on Wednesday and Thursday, March 12 and 13, 1884, under the auspices of the Committee on State Medicine of the State Medical Association.

OBJECTS OF THE CONVENTION.

The objects of the Convention are the presentation of facts, the comparison of views, and the discussion of methods relating to the prevention of sickness.

At each session of the Convention, there will be addresses or papers on subjects of general interest pertaining to the public health, each paper to be followed by a discussion of the subject treated upon. The papers are expected to be original contributions.

ADDRESSES AND SUBJECTS OF DISCUSSION.

Welcome Address—Hon. Jason B. Brown; Address by the President—Dr. N. N. Shipman.

Among the subjects which it is expected will be presented and discussed are the following:

Sewerage, the Causes of Insanity; Ventilation, Microscopical Examination of Air; Alms-Houses, Contagious and Infectious Diseases; Foods and their Adulterations, School Hygiene: Ice from Impure Sources, Disposal of Waste Water.

Programmes will be issued before the Convention.

The sessions of the Convention will be held at the Reading Room at 9 A. M., 2 P. M. and 7 P. M. of each day. The admission to all sessions will be free, and the public is cordially invited. This being the first of a series of conventions to be held at different points within the State, it is desirable that there shonld be a representative from each county of the State, of those interested in "Sanitation" in the broadest signification.

For further particulars. address the Secretary,

JOHN A. FORSYTHE,
(Editor *Daily Democrat*,)
Seymour, Ind.

NOTE.—All papers read, to be the property of the Convention.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT UNITED STATES ARMY, FROM FEBRUARY 16, 1884, TO FEBRUARY 21, 1884.

Perin, Glover, Lieutenant-Colonel and Surgeon, Medical Director; is granted one month's leave of absence, with permission to apply at Division Headquarters, Missouri, for an extension of one month. (S. O. 16, Dept. of Dak., Feb 9, 1884.)

Wilson, Geo. F., First Lieutenant and Assistant Surgeon; assigned to duty at Fort Walla Walla, W. T. (S. O. 14, Dept. of the Columbia, Feb. 5, 1884.)

CHANGES IN THE MEDICAL CORPS OF THE NAVY FOR THE WEEK ENDING FEB. 23, 1884.

P. A. Surgeon F. S. Nash, detached from the U. S. S. "Dispatch," and waiting orders.

P. A. Surgeon W. H. Rush, detached from the "Minnesota," and ordered to duty on board the "Dispatch."

P. A. Surgeon J. H. Hall to the "Minnesota."

OFFICERS OF

THE AMERICAN MEDICAL ASSOCIATION

AND OF ITS SEVERAL SECTIONS 1883-4.

PRESIDENT.

Dr. AUSTIN FLINT, SR., of New York.

FIRST VICE-PRESIDENT.

Dr. R. A. Kinloch, Charleston, S. C.

SECOND VICE-PRESIDENT.

Dr. T. B. Lester, Kansas City, Mo.

THIRD VICE-PRESIDENT.

Dr. A. L. Gihon, United States Navy.

FOURTH VICE-PRESIDENT.

Dr. S. C. Gordon, Portland, Maine.

PERMANENT SECRETARY.

Dr. Wm. B. Atkinson, 1400 Pine St., Philadelphia.

TREASURER.

Dr. R. J. Dunglison, Philadelphia.

LIBRARIAN.

Dr. C. H. A. Kleinschmidt, Washington, D. C.

Place of meeting, 1884, Washington, D. C.; Time of holding meeting, first Tuesday in May.

CHAIRMAN COMMITTEE OF ARRANGEMENTS.

Dr. A. Y. P. Garnett, Washington, D. C.

ASSISTANT SECRETARY.

Dr. D. W. Prentis, Washington, D. C.

BOARD OF TRUSTEES FOR JOURNALIZING THE TRANSACTIONS.

Drs. J. M. Toner, Washington, D. C., President;
M. Moore, Rochester, N. Y.; Leartus Conner, Detroit, Mich.;
J. H. Packard, Philadelphia, Secretary;
H. F. Campbell, Augusta, Ga.; A. Garcelon, Lewiston, Me.;
P. O. Hooper, Little Rock, Ark.;
L. S. McMurtry, Danville, Ky.; J. H. Hollister, Chicago, Ill.

OFFICERS OF THE SECTIONS:

"Practice of Medicine."

Chairman—Dr. John V. Shoemaker, Philadelphia, Pa.;
Secretary—Dr. W. C. Wile, Sandy Hook, Conn.

"Obstetrics and Diseases of Women."

Chairman—Dr. T. A. Reamy, Cincinnati, Ohio; Secretary—Dr. J. T. Jelks, Hot Springs, Ark.

"Surgery and Anatomy."

Chairman—Dr. C. T. Parkes, Chicago, Ill.; Secretary—Dr. A. O. Walker, Detroit, Mich.

"Ophthalmology, Otology and Laryngology."

Chairman—Dr. J. F. Chisolm, Baltimore, Md.;
Secretary—Dr. J. L. Thompson, Indianapolis, Ind.

"Diseases of Children."

Chairman—Dr. Wm. Lee, Baltimore, Md.; Secretary—Dr. W. R. Tipton, Las Vegas, N. M.

"Oral and Dental Surgery."

Chairman—Dr. T. W. Brophy, Chicago, Ill.; Secretary—John S. Marshall, Chicago, Ill.

"State Medicine."

Chairman—Dr. Deering J. Roberts, Nashville, Tenn.;
Secretary—C. W. Franzoni, Washington, D. C

Committee on "Necrology."

Chairman—Dr. J. M. Toner, Washington, D. C.

ORIGINAL ARTICLES.

THE IMPORTANCE OF SANITATION.

A PAPER READ BEFORE THE FIRST MEETING OF THE OHIO STATE SANITARY ASSOCIATION, COLUMBUS, OHIO, FEBRUARY 14–15, 1884.

BY WM. MORROW BEACH, M.D., PRESIDENT OF THE ASSOCIATION, LONDON, OHIO.

GENTLEMEN OF THE ASSOCIATION:—Being under the impression that we of the medical profession have failed to secure such recognition of the necessity for sanitary laws and regulations, both State and national, as we earnestly feel should be enacted and maintained, the question naturally arises as to the cause of this apathy, or carelessness, or neglect, on the part of our law-making power? I believe that this is chiefly due to the fact that our efforts have been heretofore too often misdirected, by not addressing ourselves to the people more directly, instead of to the officials, who are, in point of fact, only temporary incumbents generally. A legislator, whether in high or low official position, has one desire that is paramount to all others, and that desire is to not be relegated to private life again. He is willing, and even anxious, to do that thing that he believes the majority desire him to do, and one of his chiefest objects of solicitude is to ascertain the present and future drift of popular sentiment among his constituency.

In the presentation of this paper I shall be guided by this idea, and shall address myself toward the laity, and only indirectly to the profession, who are all supposed to be united respecting the needs and demands of a more direct recognition of the importance of sanitation.

From the frequent references to plagues and pestilences in sacred history, it is presumable that the world, in olden times, was seldom or never free from their ravages.

Whilst the armies of Romans and Gauls, under Brennus, were besieging Rome, such a pestilence appeared among them that, weary with burying dead bodies, the survivors burnt them in heaps.

In a time of profound peace, 366 years before Christ, Rome was visited by such a plague, that at its height 10,000 of her citizens died in a day; and during the siege of Syracuse, 277 years before Christ, Livy, the historian, says "the Carthagenian soldiers all perished!"

In another plague, which visited Rome 182 years before Christ, Livy says that the disease made its most fatal ravages amongst the slaves, and that their dead bodies lay unburied along the highways—"their corpses lay unburied, untouched by dogs and vultures, and wasted away by corruption."

Before Christ 126 years, historians relate that in Numidia, in Africa, 800,000 persons perished by pestilence; 200,000 on the seacoast of Carthage and Utica, and 30,000 of the Roman troops; while 1,500 dead bodies were carried out of one single gate in Utica in one day!

In the year 68 of the Christian era, when Rome contained a population of 1,000,000, Tacitus says that by reason of a plague "the houses were filled with dead bodies, and the streets with funerals."

In the year 79—the year following the first recorded eruption of Vesuvius, when Pompeii and Herculaneum were buried—10,000 citizens a day died in Rome.

In the year 88, 150,000 died in Scotland, and 45,000 perished in Wales.

In the year 165 a pestilence overspread the whole earth; but in about the year 250 commenced the most calamitous period mentioned in history, a universal plague, which lasted fifteen or twenty years. It probably had its origin in Ethiopia. One historian says, speaking with reference to the Roman provinces: "The plague in towns and villages followed the Scythians, and devoured that part of the human race which the barbarians had spared." Another says the pestilence "desolated or disfigured the whole earth." Gibbon, the English historian, says "a moiety of the human species fell a prey to this frightful epidemic."

In reference to the plague of 408, Nicepharous, the historian, says: "Almost all Europe perished, and no small part of Asia and Africa."

During the year 680 pestilence was again universal, and Rome was laid waste. "Multitudes fled to the mountains, and the streets of the city were overgrown with weeds and grass."

In the year 1005 commenced another general pestilence, which lasted three years. "Such was the weariness of those who buried the corpses, that the living, before the breath had left their bodies, were tumbled into the graves with the dead."

And again, in 1066, half the population of Egypt and Arabia perished with pestilential diseases.

In the year 1220, the plague was so fatal in Damietta, a city of lower Egypt, on the east branch of the

Nile, that out of a population of 70,000 souls, it is said that only three persons survived!

In about the year A. D. 1345, arose another pestilence of unusual severity, which became universal in its proportions. It is described as being the most general and awful in the history of mankind. It is said to have first appeared in Cathay; thence spreading to Egypt, Syria, Greece, Turkey, Italy, France, Spain, England, Ireland, Holland, Germany, Hungary and the north of Europe. It is estimated that in eight years, half the human species perished! In many cities, nine out of ten perished; and some cities were wholly depopulated. London buried 50,000 in one graveyard. Norwich lost 50,000; Florence 90,000; Lubec 90,000, and Venice 100,000. In Spain, two thirds of the whole population perished, and in the East 20,000,000 are supposed to have perished in a single year. The rights to all property were temporarily relinquished; cattle roamed at will; crops were left to perish in the fields; and houses were tenantless and ownerless, and going to decay in all the known countries of the world.

This pestilence reached to Iceland, with such mortality that the settlement there planted never recovered from the disaster. It invaded Greenland, and the Danish colony there was extinguished, for it has not since been heard from to this day. It swept over plains. Its poisonous breath rested upon the mountain heights. It spared neither age or sex. It was partial to no country or nationality. It seized upon the islands of the sea, and upon fugitives in mid-ocean, and left their vessels to drift without a human occupant or guide.

More than fifty times since the commencement of the Christian era, some of the great cities and capitals of the Old World have had to be repeopled from abroad, by reason of wasting pestilences.

Were all, or even any of these great pestilences within the power of man to avert? or was their universal spread owing to a general pestilential condition of the elements, beyond the power of human kind to localize, or control, or modify? The pestilence that swept over Iceland and Greenland in the 14th century with such devastating effects, is known to have been small-pox; and some of those described long before the time of Christ are recognized very unmistakably as having been of the same characteristic types of local epidemics of the same diseases prevailing to this day.

To ascertain the means for the prevention or avoidance of diseases that are preventable or avoidable, is the special province of the sanitarian.

Let us examine this subject for a little while.

An infectious disease is generally understood to be one that is contracted by direct contact—as *mal Francais*, hydrophobia; and the practice of vaccination furnishes a good example.

A contagious disease is one understood to be propagated without direct contact, as measles, small-pox, Oriental cholera, etc.

An endemic disease is one that arises from a local cause, as a common ague, originating in the excess of malarial poison in that particular locality.

An epidemic disease is where it becomes general in any section of country by reason of its spread from some specific contagious poison, as an epidemic of measles, whooping-cough, etc.

The mediums through which epidemics are spread are first, air; and secondly, water. It is presumable that the great pestilences to which we have alluded were generally the plague, Asiatic cholera, small-pox, yellow fever, dysentery, and typhus fever; although measles, miliary, or the "sweating sickness," angina, diphtheria, scarlatina, and other diseases might rage and have spread as pestilences.

One of the theories upon which sanitary laws and regulations should be founded, is the theory that these and many other diseases have their origin in a specific contagious principle, that will produce that specific disease and no other, and that may propagate itself through the atmosphere for a greater or less limited extent. For instance, small-pox may be contracted by exposure to a case—in the proper stage of the disease—within the limits of an ordinary room. It might be contracted by the poison—the specific contagious poison of small-pox—at the distance of 100 feet or more; but that a distance may be reached at which no possible danger can exist.

The sanitary laws of Moses (Leviticus xiii.) contain the most that is necessary to be known concerning the sanitation in leprosy even to this day.

The theory that is now most generally adopted is that epidemic diseases—and most diseases that are not epidemic—owe their origin and propagation to microscopic animal organisms. For a person to contract the disease, it may be done by contiguity or nearness to one suffering from the disease; by breathing the contaminated air of the room, which poison may come from the breath of the patient; from the sensible or insensible perspiration; from the expectoration; from the ejecta of the stomach; from the excreta of the mammary gland or kidneys; or the dejecta from the bowels. The clothing of the patient, or bedding, or rags, or any textile fabric coming in contact with him or near him; or even window curtains, paper hangings, or other porous fabrics or substances about the room, or any part of the house, may absorb or become the lodging places of the specific poison or microscopic animal organism, fungi, or bacillus; and under favorable surroundings of temperature, exclusion from air, light, heat, and so forth, these substances may retain the specific poison in a state of preservation, capable of producing a like disease in a susceptible subject, for an indefinite length of time. Cats and dogs have been thought capable of distributing these specific poisons by carrying them in their hair.

Things that become vehicles for the preservation of the specific poisons of contagious diseases, as bedding, clothing, rags, and so forth, are called "fomites."

Taking this view of infectious and contagious diseases and their origin, does it not seem plausible that it is possible to utterly annihilate some diseases that are purely and only infectious? Setting aside the possibility that there is no contagious disease that can arise without exposure to an already existing cause,

if the existing cause be removed, the disease is extinguished. This, however, as a theory cannot be looked upon as absolute, as some local idiopathic diseases, as gangrene, metritis, puerperal peritonitis, etc., may become infectious or contagious.

But leading in this direction, supposing we take a case of small-pox as an example. It first becomes the duty of the physician and sanitarian to isolate the patient; then to remove all unnecessary substances near him that can act as fomites; and after his recovery to enforce sanitary measures, such as the inexorable destruction by fire of all such substances as would act as fomites, unless we know that such as are spared can be rendered harmless by baking in ovens or by other means equally as certain.

But, not to digress too far from my special subject, allow me to say that I think the one thing most needed in the furtherance of the objects of sanitary science, is the sustaining sympathy of an enlightened public opinion. This is not only the power which lies behind the throne, but it is the throne itself.

At the time the Crusaders occupied Jerusalem they established outside the city a hospital for contagious diseases, and called it the Hospital of St. Lazarus, and from this came the name of "Lazaretto."

The first quarantine regulation promulgated in any State was by Viscount Bernabo, of Reggio, Italy, in 1374. But it was not till about the middle of the 15th century that any well-defined legal code was adopted; and this was by the little Republic of Venice, Italy, which in 1448, after having become strong enough to cross the Mediterranean with her ships of commerce, and to undertake wars of conquest, and after having suffered from no less than 63 wasting epidemics within six centuries, enacted the first digest of laws known as "the laws of quarantine." And at a later period, this little Republic established the first "board of health," consisting of three noblemen, who were at a later period given the power of life and death, or absolute power, from which there could be no appeal, in enforcing their commands.

England did not establish a regular system of quarantine until 1710; at a time when the plague was ravaging the cities along the Baltic.

The first quarantine in the United States was in the year 1700, when the yellow fever was raging in Philadelphia, and the General Assembly passed a law imposing a fine of £100 on any person landing at that port with an unhealthy vessel. Massachusetts followed in 1701, and the first Congressional enactment was in 1799—"an act respecting quarantines and health laws"—which act is yet unrepealed.

In 1851, an International Congress was called to meet in Paris; and after a lengthy discussion, a set of rules was adopted by the different national representatives present.

The second International Congress was held in Constantinople, upon a call by the French government, in 1865, and since that time, the laws of quarantine have been gradually tending more and more toward a basis conforming with the views of advanced sanitarians. The general rules now prevailing are to prevent the exportation, importation, or spreading of pestilential diseases. The means chiefly adopted are, purification, quarantine, lazarettoes, restriction, separation, seclusion, and lines of circumvallation, or military cordons; and of late years the rules have been extended to include sanitary police against the epidemic diseases of domestic animals. When a ship is about to sail, she is furnished by the consul of her country with a bill of health, which is her passport. A foul bill is given if she sails from a port where plague, cholera, or yellow fever prevail, and a clean bill if she sails from a port where no such diseases prevail. A false passport would be justly considered a very grave offense; and would be a sufficient cause for a demand for immediate explanations on the part of a government represented by such an agent or consul.

A few years ago, the cattle plague simultaneously invaded France and England. The French government immediately stamped the disease out by the destruction of about 100 head; while the English vacillated and procrastinated until over 300,000 had perished of the disease.

In 1865 our National Congress passed a law "to prevent the spread of contagious diseases among the cattle of the United States." In 1843, and again in 1850, pleuro-pneumonia was imported into Brooklyn, N.Y., and in 1847 into New Jersey, by English cattle; and in 1859 into Massachusetts by Dutch cattle. The New Jersey outbreak was immediately extinguished by the destruction of all the cattle on the farm where it first appeared; and a commission in Massachusetts, after six years of effort and the destruction of 1,146 head, besides those that died of disease, finally got rid of it in that State. But in New York State they vacillated and delayed, until by gradual spread the disease now prevails in Kings and Queens Counties, in New Jersey, Eastern Pennsylvania, Delaware, Maryland, District of Columbia, and some parts of Virginia. About the cities of Brooklyn and New York they call it the "swill-milk disease;" but it is the same disease that nearly destroyed the herds of Australia from the importation of *one* English cow; and the same that has kept some of the countries of Europe comparatively poor for more than half a century. No importation of Jerseys or other breeds into Ohio should be allowed from any of the infected regions where pleuro-pneumonia does or has existed; and the general government should follow the advice of committee after committee of its own appointment, and inexorably destroy all cattle in the infected districts that are known to be suffering from the disease, and then keep a standing force of veterinary police throughout the infected districts, to crush and wipe out all new foci that spring up. Were the tide of trade westward instead of eastward, the destruction of cattle in the middle and western portion of the country would prove a national disaster, from which we could not recover within the present century.

In the year 1878 the Russian plague appeared at Astrakhan during the time of military operations in that country. It is said that a Cossack soldier, returning from the wars, carried the specific poison in a shawl which he brought to his lady-love. The people of Astrakhan were seized with a panic, as well they

might have been, for 90 per cent. of all victims perished, and as they fled they carried the germs of the disease with them. Its general, if not universal, prevalence was probably arrested by a military cordon which was stretched in advance of the disease, beyond or through which line no person was permitted to pass.

In 1882 an epidemic of yellow fever broke out in Bagdad, Tampico, and Matamoras, in Mexico, and soon spread to Brownsville, Texas. In a few days, out of a population of 5,000 in that city, over 600 fell victims to the pestilence. The Governor of the State of Texas appealed to the Government of the United States for aid, and as the President had, under the law, already placed $100,000 in the Treasury Department to be used to prevent the spreading of epidemic diseases, Dr. John B. Hamilton, Supervising Surgeon-General of the United States Marine Hospital Service—an active, bright, young officer from Illinois, who has gained his enviable and honorable promotion to his present position by competitive examination, and with whom I have the honor of a slight personal acquaintance—immediately proceeded to establish a military cordon from Corpus Christi, on the Gulf, to Laredo, on the Rio Grande, along the line of the Mexican Central Railway. He afterwards contracted this line to nearer the line of the district infected. But in Mexico the epidemic spread from village to village, until its devastation reached up the Rio Grande for over 500 miles, and for this distance it found a sentinel in Dr. Hamilton's cordon at every available crossing; but from the Texas side of the Rio Grande the epidemic was held firmly and effectually at a distance, and was confined to the first infected district of Brownsville and its vicinity.

Eighty-six years ago, Edward Jenner, of England, taught the world how to throttle small-pox, and, in effect, to extinguish the loathsome disease from the face of the earth. Experience to this day justifies the most that was hoped for or claimed for the practice of vaccination; but in one single city of Ohio last year—Cincinnati—there occurred over 4,000 cases of this disease, with over 1,600 deaths.

A man, in his ignorance, or wilfulness, or blind prejudice, may claim he has a right to get the small-pox if he wants to; but no one can reasonably concede that he has a right to contract any avoidable disease that he knows to be loathsome and dangerous to life, and thereby jeopardize a city full of people who are afraid of and dread it. And yet in the great State of Ohio—a State for which we arrogate the claim of being the keystone to the social, political and intellectual arch of the national superstructure—in the year of grace 1872 or 1873, I had the honor of introducing a bill in the Senate, which became a law, giving boards of education the power to enforce vaccination among the pupils attending public schools, and that is all the law that now is, or has ever been, upon our statute books relating to vaccination!

Epidemic cholera is as much a native of India, as yellow fever at this day is of the West India islands. In the Bombay presidency, in India, are ninety-four shrines, to which pilgrimages are annually made as a religious rite. The religion of the Hindostanee teaches him that the waters of the Ganges have the miraculous power to cleanse him from sin. Some every one year, more every two years, more every third year, and still more every twelfth year, these misguided people make long pilgrimages to these shrines, to bathe in the waters of the Ganges. The twelfth yearly pilgrimage is called the Juggernaut pilgrimage; and at Hurdwar, below the mountain range, and near the headwaters of the river, 3,000,000 of these weary, jaded, filthy, ragged, perspiring, fanatical Juggernaut pilgrims may be congregated at one time, while the waters of the river are used for ablution, drink, and the receptacle of all the waste from 3,000,000 filthy human beings day after day, at one and the same time!

Ever since the year 1756, it has been observed by the whole civilized world that a twelvth year epidemic of Asiatic cholera has taken its rise among these congregated idolators. Some of these epidemics have been carried around the world, and our own country has several times suffered, each separate epidemic being clearly traceable to these Juggernaut festivals, and their line of march as clearly defined as the march of an army with banners. The physician and sanitarian can point out the specific remedy against its spread as an universal epidemic, but the power to enforce our plan rests with the doctors of international law—the plan of prohibiting, by military force if necessary, these Juggernaut festivals.

The different States should all have laws and regulations relating to the police power against epidemic diseases, and these laws should be so framed as to not come in conflict with each other, nor with those of municipal corporations, or those of the general government; and whatever be the form, the Governor of each State, to give dignity and prestige to the Board whose duty it shall be to enforce the regulations, and by virtue of his office as commander-in-chief of the commonwealth, should be its president.

But, with Oriental cholera ravaging China and Japan for the past three or four years; with the legions dead of it in Egypt within the closing year; with bales of rags laying on English docks, or in English warehouses, shipped direct from Egypt, and designed for the American market; and with the inter-communication between England and Egypt incident to a state of war, I ask any sane man, capable in any degree of self-protection, if it seemeth unto him any part of wisdom on the part of any State government to decline or procrastinate the officering of the unorganized battalions, and delaying all efforts at systematic organization, with the probable risk of the dark scourge in a night attack under the banner of the black flag?

A BABY WITHOUT ARMS OR LEGS.—A tetralogical case is interesting the profession of Madrid. It is one of a little girl, five months old, which was born without arms or legs. The thoracic and abdominal cavities are perfectly formed. Its first teeth have just appeared. It is healthy at present.—*Medical News.*

THE INFLUENCE OF THE PUBLIC SCHOOLS ON BRAIN-BUILDING.

BY W. J. CONKLIN, M.D., DAYTON, OHIO, PROFESSOR OF DISEASES OF CHILDREN IN STARLING MEDICAL COLLEGE.

[Read before the Ohio State Sanitary Association, February 14, 1884.]

The grandest work of the best civilization is the building of efficient brains. The school forms one of the most important factors in brain-building, and the manner in which its influence is exerted has very properly excited, during the past decade, general discussion in educational and sanitary circles.

We do not ignore the deleterious influences which surround the child in the street and home, influences which are incomparably more powerful in sapping its physical vigor than any connected with its school life. But our text to-day limits us to one phase of the question, the *effect of school work upon the health of the pupils*. We engage in this inquiry in no spirit of hostility to the schools. We know they are training up men and women who are fully competent to discharge all of the duties of State or society which may devolve upon them in the manifold relations of life.

Certainly, "no more earnest, self-sacrificing or intelligent workers gather around any labor, than those who wait on the ministry of teaching."

However, the warmest friend of the public schools will not claim that they are perfect; and it certainly behooves every citizen not only to support them, but to labor that they shall more fully accomplish the grand work for which they were instituted. In the discussion of this subject much exaggeration has been indulged by both parties. It is absurd to fasten all of the ills which befall children of school age upon the schools, and equally absurd to ignore the very general conviction of parents, physicians and sanitarians, that injury does accrue to a certain number from school work. Conditions in some degree inimical to health are inseparable from school life, as confinement, enforced quiet, vitiated air, prolonged mental effort, etc., etc.

To reduce the effect of these conditions to a minimum, and secure the best mental development, is the problem before us.

Whatever view of mind may be taken, it is sufficient for our purpose this afternoon to know that a normal brain is the essential prereqnisite of a normal mind.

Healthy cerebration requires healthy brains.

A cerebral tumor, a spot of inflammation or softening, an irregular or impure blood supply, plays sad but fantastic freaks with the sublimest minds. Again, the body is a physiological unit. Brain and muscle and bone all acknowledge the same general laws of growth, development, and functional activity. And so marked is the interdependence of the complex factors of the unit, that the integrity of any function, mental or physical, depends not only on the integrity of the specific organ, but also largely upon the integrity of all other organs and functions of the economy. If these statements are true, and to deny them is to take issue both with the teachings of physiology and the revelations of pathology, then any system of instruction which ignores them in its methods or requirements falls short of what it should be.

Judged by this standard, we proceed to point out some of the defects of our public school system—defects which impair its usefulness, imperil the health of the pupils, and which will ultimately defeat the effort to build up a perfect manhood and womanhood.

The school law of our State violates one of the plainest teachings of physiology, in fixing the age at which children shall be admitted into the schools at 6 years, and an unhealthy public sentiment demands the utmost that the law permits.

The physiological history of the child teaches unmistakably this truth; that its organism has relatively much more work to perform than that of the adult. Its nutritive organs, in addition to preserving the physical integrity of the economy and supplying force for dynamical purposes, are subject to heavy drafts for developmental needs. In infancy and childhood the brain is proportionately larger than in adult life, and so rapid is its growth, that it nearly doubles its weight during the first two years of life. Up to the fifth year, Dr. Peacock found the average weight of the brain to be one-seventh or one-eighth that of the entire body, instead of one-fortieth, as in the adult.

The brain increases rapidly in size up to the seventh year, and although it grows at a much diminished rate until between the ages of 30 and 40, at 8 years it has nearly reached its full size. The deduction, then, is plain that regular school life should not begin before the eighth year. Up to that age, let the romping, frolicsome and buoyant child nature be untrammeled by set tasks and hard discipline. Much, and enough, will be acquired without the primer. There are "sermons in stones and books in running brooks," which the child will hourly drink in, and which will place it on vantage ground for its later school work. In view, however, of the opposition of parents and of some practical difficulties in introducing the reform, it would perhaps be better to compromise upon seven as the legal school age.

By a parity of reasoning, we are forced to another conclusion: that the child having entered school, its immature physical and mental strength unfits it for long confinement and for severe daily tasks during the earlier years of its attendance. That the requirements of the public schools very frequently overstep the safety line is beyond question. After leaving the primary grades, the hot haste to secure results necessitates too many studies, excessive daily tasks, too much cram and grind, and very surely ends in overwork. This is largely the legitimate outgrowth of the times in which we live, the spirit of which the schools have imbibed. We are a fast people; live fast, work fast, demand that our children shall be educated fast, and, as a dyspeptic friend at my elbow suggests, often send them to the devil fast.

We have already referred to the very great activity of the infant organism. Now, it is a well-known pathological law, that wherever there is excessive nutritive, functional or developmental activity, there

also exists a marked predisposition to morbid changes. In harmony with this law, the nervous system of childhood presents a peculiar susceptibility to external influences. Children are very prone to "nerve storms." The convulsion which so commonly replaces the initial chill of an illness; the muscular twitchings; the wide excursions of the temperature due to a trivial indigestion; the babbling of schoolmates and lessons in fever; the impressible emotional nature; all bespeak the marked instability of the child's nervous organization. As adult life is neared, the nervous system loses its preponderance of size and activity; in part by the maturing of the nervous system itself; largely by the growth and development of the bodily organism. Notwithstanding the rapid growth of the early years, in nature's order, the nervous system is the last to reach maturity.

The lesson is obvious that during this whole period of excessive activity and immaturity, care must be taken lest its nutrition be interfered with and permanent injury result. The nervous system must be steadied and ballasted by robust bodies.

We do not mean to put brain in splints. Physiological use is one of the conditions of normal growth, whether of bone, muscle or brain. A proper amount of brain work is not only necessary to its own development, but conduces powerfully to general bodily health. The physiological condition is, however, only fulfilled when the work is fitted to the strength of the organ, and it is for this alone that we contend.

Dr. Clarke in "Sex in Education" writes: "If the schoolmaster overworks the brain of his pupils he diverts force to the brain that is needed elsewhere. He spends * * * in the brain-work of the school room force that should have been spent in the manufacture of blood, muscle and nerve; that is growth. The results are monstrous brains and puny bodies, abnormally active cerebration and abnormally weak digestion, flowing thoughts and constipated bowels, lofty aspirations and neuralgic sensations.

'A youth of study, an old age of nerves.'"

Physiology only answers the question before us in a general way. But it indicates plainly what experience confirms, that instruction should not be pushed before the age of 10 or 12, and with girls, perhaps not before 14 years. That this deduction is constantly disregarded is a matter of common observation.

We have no time to give specifications, and will only allude to two facts which have recently been impressed upon our attention.

The two lower grades, with an average age of 6½ and 7½ years, pass 5 hours each, and the higher grades 6 hours daily in the school room. I need only appeal to the experience of those here how much 6 hours of mental labor falls short of a full day's work for an adult.

Without any mental effort whatever, 5 hours' confinement for pupils under 9 years of age, with the enforced quiet and constrained positions, which the ordinary school sitting and school discipline necessarily enforce, in a room probably overcrowded and badly ventilated, is too much for growing bodies.

Arithmetic is proverbially the hardest study for young minds to master in the curriculum; it furnishes the largest percentage of failures at the annual examinations, and is the study about which children most often talk in their sleep. And yet in a neighboring city, noted for the excellence of its schools, arithmetic is completed in the 7th grade, the members of which average less than 13 years of age.

Many educators, admitting fully the bad results of overwork, maintain that there are no statistics to prove that injury results from the present system. We admit the force of the objection, but there are some things which statistics can not prove, and which they are not needed to prove.

Certain factors in school life manifest their deleterious influences in results that can be easily measured. Thus 90 per cent. of the crooked spines, not due to special disease, can be traced to improper school furniture. And statistics abundantly prove the lamentable increase of myopia among school children, due to the too prolonged use of the eyes on small type and to badly lighted study rooms.

But the injurious effects of over brain-work can not be so tabulated. It is not a question of so many studies=so many deaths; or so many hours in school =so much chorea; but much more a question of undermining the general robustness of the child; of stunting and dwarfing the physical and mental development; of building up a nervous system unable to bear the shocks and friction of later life. But the danger does not end here. Cause and effect are endlinks of a chain which not only spans the life of the individual, but the lives of the children's children.

And thus the vicious circle widens and widens, until the victims, unable to bear up in the struggle for existence, succumb to nature's law of the survival of the fittest, and the family is at last blotted out.

We are perfectly content to rest the question of overwork in the schools upon the general conviction of the medical profession, the members of which enjoy abundant opportunities for observation, and are especially fitted by education to form an intelligent and unprejudiced opinion.

The profession has spoken in no uncertain tones, and the almost unanimous opinion is that too heavy burdens are imposed upon school children, tasks disproportionate to the age and capacity of the pupils. Quotations to this effect could be multiplied from the proceedings of various local, state, and national societies, and from the published utterances of its most accomplished members.

My friend, Dr. Reeve, in a most excellent lecture before the teachers of Dayton, pertinently says: "If you ask me for my list of deaths from this cause (overwork in schools), I have none. If you inquire how many cases of insanity, epilepsy or chorea I have seen result from this cause, I have none. But if you ask me how much I have seen of disturbed sleep, disordered digestion, irritable and fretful tempers, and other evidences of the direct effect of causes injuriously affecting the health, I am obliged to say, in reply, a good deal—enough to need prompt and decided correction."

It will not do to reply that the work of the schools is no longer irksome.

It is very true that the modern teacher has well nigh discovered a "royal road to learning," and has woven around her calling a web of infatuation which holds the little ones spell-bound in its meshes, yet she has not set aside nature's law. School work is still brain work, and brain work is exhausting work. Go, enter any of the grades and see the pupils at work. Watch the class on the recitation bench. "See the anxious, working faces, over which exultation and mortification chase each other, like light and shadow, its quivering hands darted into the air at every question and after half the answers," and then say whether such concentrated attention, quick and accurate thinking, is not mental labor of a severe kind.

We are aware that *overwork* is largely a relative term. Minds vary greatly in their capacities and powers of endurance. The ideal school would adapt the work accurately to the individual capacity.

This is manifestly impracticable in the large, overcrowded public schools, but an approach to it can be made by carefully grading the requirements to the average age of the pupils, and by not permitting school work to monopolize time and energies which are needed for bodily development.

It is often urged that the schools are not hospitals; that they are founded upon "the greatest good to the greatest number," and if any child is weighted down by a vicious inheritance, acquired disease or a bad organization from any cause, it must be pushed aside in the race or struggle on into a manhood of ill health and scant usefulness. If the instances of physical injury were rare, this might pass for good philosophy, but when the testimony comes from every side that the evil is widespread and growing, and threatens the mental and physical welfare of the race, then it is certainly time to seriously consider whether the present system will *ultimately secure* the *greatest good* to the *greatest number*. That is a shortsighted policy, indeed, that refuses to look beyond the immediate horizon.

It is important in this connection to ascertain whether the number of school hours now required, and against which such vital objections exist, is necessary for the highest mental development. The length of time during which concentrated attention is practicable in early life is very limited. Experience would coincide with the deductions from physiology in placing the limit of profitable and safe study for children under ten years of age at three hours per day. It has been proven over and over again that a child under ten or twelve can receive as much mental nourishment in three hours of set tasks, as it can assimilate, and without assimilation, a mental indigestion, with its long train of sequelæ, surely results.

Perhaps the most striking proof of the truthfulness of this proposition is drawn from the "half-time" schools of England, a system provided by law for children employed in factories and workshops. These children receive daily instruction for one-half the number of hours spent in the public schools by those not at manual labor. It has now been in operation for more than 30 years, and reports of its workings, made by competent official inspectors, are found in Parliamentary documents. These prove beyond question that the half-time pupils learn quite as much as those who are in the same schools twice as many hours per day.

A few years ago, on account of the overcrowded condition of one of the schoolhouses in Dayton, it became necessary to reduce the attendance of the lower grades to one-half a day. To the surprise of every one, the examinations of the half-time pupils were as creditable in every particular as of those who had spent full time in the rooms. With these facts before us, it would certainly be the part of wisdom to limit the time passed in the primary departments to three hours a day. Other obvious advantages would result from this plan. By dividing the school into forenoon and afternoon pupils, the overcrowded condition of the primary grades would be relieved, and the teachers would have an opportunity of making an individual study of the wants of each child.

Under the present system, the girls fare worse than the boys. Their more impressible nervous systems and less sturdy physiques render them especially liable to suffer from confinement, lack of fresh air and exercise, and from over brain stimulation. Up to about the age of 13, sex has ordinarily no disturbing function; at that period, radical changes occur in the organism, upon the normal completion of which her adult health, and the ability to discharge her maternal relations largely depend. Even ordinary mental work at this revolutionary period may divert force which is needed for developmental purposes. At no other time in life is the nervous system so excitable and so much in need of protection from all worry and fret. The belief is generally entertained by those most competent to judge, that girls should be excused from set school work for a variable period, often an entire year, at this important crisis. Were this done, we would hear less of disordered menstruation, weak backs, hysteria, and the many nervous maladies which go to make up the proverbial "little health" of American women. The school life of the average girl ends at an age when, from a physiological standpoint, her serious educational work should begin. Wier Mitchell says: "At 17, healthy girls are nearly as well able to study, with proper precautions, as men; but before this time over-use, or even a very steady use of the brain, is dangerous to health, and to every probability of future womanly usefulness."

The co-education of the sexes opens up a vast field of discussion which we have no time to enter. The physical and mental differences between boys and girls are so distinctive that it is certainly questionable whether the best development of each can not be better attained in separate schools, at any rate after puberty, when these differences assume such predominant importance.

Another objectionable feature of the modern school is the very extensive and unnecessary use of artificial stimuli to study. Within certain limits personal emulation is useful, healthy and natural. Markings, prizes, honors, per cents. and examinations are now persistently used as spurs and whips to goad on to

greater effort. They exert but little effect upon the dull and sluggish, while the full force of their pernicious influence falls upon those who need to be curbed instead of urged. Examinations undoubtedly cause more fret and worry and nervousness than any other school exercise. Examination week is everywhere, according to the observation of physicians and parents, a week of disturbed sleep, capricious appetite, night study and general ailing. They usually follow a long season of close application when mind and body are wearied, and the intense excitement induced by them often proves the "straw which breaks the back of mental and physical endurance." We would not abolish examinations, but would decrease their number and limit their power. The daily record for the entire term, rather than the results of that one nervous hour, should be the test of scholarship and promotion.

We have thus briefly reviewed some of the imperfections in our public school system which are sure to result in bad brain building. The school cannot afford to cripple its usefulness by antagonizing the well known laws of physical development, nor can the State afford to have it so crippled.

We repeat our conviction that the schools are but one factor, and perhaps the least, in undermining the physical vigor of American children. The only way, however to correct the evil practices and bad hygienic surroundings of street and home is through the school house.

The shortest route to the fireside is through the school house.

When teachers become thoroughly aroused to the importance of the physical development of the young, and familiar with the fundamental truths of physiology and sanitary science, then, and then only, will education become in fact what the root signification implies—*a leading out*—a symmetrical development of all the faculties, mental, moral and physical.

Our plea is for better school accommodations, including heating, lighting, ventilating and furnishing school buildings; for a later school age, lighter tasks, shorter hours and more play during the growing period of life; a period in which children are not only most readily but most permanently affected by every influence to which they are subjected.

We place no premium upon idleness or stupidity. Good digestion and healthy brains are not antagonistic: a torpid liver and brilliant cerebration are not necessary associates, but, on the contrary, the "mens sana in corpore sano" is as true to-day as when uttered by the heathen poet.

Ohio has upon her statute books a law which points the way to a removal of many of the objectionable features of our common schools: a law, be it said, to her credit, not found in any other State in the Union. The amended section 2135 of the Revised Statutes requires Boards of Health to inspect semi-annually and oftener, if necessary, the sanitary condition of all schools and school houses within the limits of the corporation. So far as we know the law sleeps upon the statute books. It certainly comes within the province of an association such as we organize to-day, to breathe into it *new life*.

TOXIC EFFECT OF ALCOHOL IN EXSANGUINITY.

BY JOSEPH SAGER, M.D., NORTH WASHINGTON, OHIO.

[Read to the Northwestern Ohio Medical Association, December 11, 1883.]

On the third day of October, 1883, I was called to attend Mrs. B., the case proving to be placenta prævia. She was an American by birth, aged 42 years, and the mother of seven children. Upon arrival I found her almost totally exsanguinated and still bleeding. She wore the pallor of death, as much so as she did when she was dead. She could not speak above a whisper. The examination revealed a case of placenta prævia partialis; head presenting the mouth of the uterus very little dilated, with gushes of blood and no pain. The first I did I gave her a full dose of ergot, not for an oxytocic, but for a styptic; at the same time I gave her an injection of warm water followed with an injection of cold water. The opposite effect of cold water to warm water made an impression on the periphery, causing a reflex action, thereby closing up the uterine vessels. The effect was a happy one, the hæmorrhage became less and the pain came on.

The placenta occupied the right half of the lower segment, and being pushed through the os, I ruptured the membranes, allowed the escape of the liquor amnii, and forcibly dilated the mouth. The patient having been very much exsanguinated, I turned and delivered at once. The result of my labors was a male child, dead. By this time the patient being much exhausted, and from the loss of blood, she was thrown into convulsions.[1] I administered chloroform at once, kept it up at intervals for six hours, by which means I controlled them; at the same time I put hot bricks to her feet and applied warm blankets to her body. At the expiration of six hours she was comfortably warm.

The hæmorrhage had ceased as soon as the child was born.

I would say, by way of parenthesis, that this patient was of a neurotic diathesis, so that when the convulsions were controlled, she was taken violently with intercostal neuralgia. I gave her a full dose of morphia hypodermically, which effectually controlled it.

The next day, Thursday, October 4, she felt quite comfortable. Friday morning, October 5, she felt very comfortable, took some light nourishment; inquired of the Presbyterian church, and how the new minister was liked.

Saturday morning, October 6, I was called in haste to see Mrs. B., it was said she was dying. On arrival I found her in the following condition: She was crazed with neuralgic pains—facial, intercostal and sciatic neuralgia, with pain in her abdomen, some tympanitis, was very thirsty, called for water continually, very much prostrated, and difficult respiration.

On investigation, I learned that her drunken brother had consulted a friend of his—a doctor—who

[1] There being no kidney complications.

enjoined him to give his sister whiskey, whatever he did, if he wanted her life saved. Surreptitiously to myself he did it. He gave her whiskey Friday afternoon and Friday night, one pint, if not more, in tablespoonful doses. I stopped the whiskey, but it was too late. She died Sunday morning, October 7, in the greatest agony—a sacrifice to despotism and egotistic ignorance.

Whatever may be the effect of alcohol in health, the action on the nervous system, the effect it has on the circulation and nutrition, on the metamorphosis of tissues, and the arrest of the secretions, the toxic effect of alcohol is far greater in anæmia, and still more so in exsanguinity. When we take into consideration the poverty of the blood in exsanguinity, with but little reserve force, we can see at a glance that all the powers of nature must be supported by all conservative means which can be brought into play. The red corpuscles, which are so necessary to life must be cared for, and their genesis.

If we sacrifice a single red corpuscle, we hazard the life of our patient, as the force of the nervous system depends on the presence of oxygen in the red corpuscles.

It is an incontrovertible fact, that the toxic effect of alcohol in anæmia or exsanguinity is the destruction of the red corpuscles in the blood, either directly or indirectly.

It is conceded (and by good authority[1]) that alcohol favors the genesis of white corpuscles in health, which pabulum goes to form areolar tissue, muscle, etc., and every day's experience teaches us that the habitual moderate enjoyment of alcohol encourages a tendency to corpulency. Should this be the case in exsanguinity—the genesis of the white corpuscles favored, it would take the place of the red corpuscles, and prove calamitous to them.

The more probable theory is, that alcohol deoxidizes the red corpuscles. Hence their destruction.

Schulinus admits the destruction or decomposition of alcohol in the blood by way of deoxidizing the blood. He also says, by the introduction of half a drachm of alcohol into one of the lymphatic breasts of a living frog, the circulating fluid was changed from a bright red to a dark color.

Bonwetsch states that alcohol has an affinity for oxyhæmoglobin, destroying the oxygen in the red corpuscles; this he demonstrated by experimenting with ox blood.

I have myself injected alcohol into the cavity of the peritonæum of a live frog under the microscope. I could plainly notice in the circulating fluid in the web of the frog's foot, that at first the circulation was accelerated, but soon it became slower; the disks of the red corpuscles were flattened, while some were blasted or destroyed. The white corpuscles were unmolested, travelling slowly, adhering to the walls of the capillaries.

With these demonstrated declarations, let us look at the present case.

It is well known that in anæmia, we have to deal with the poverty of hæmoglobin in the red corpuscles, while in exsanguinity, we have to deal with the scantiness of the red corpuscles.

According to Flint and other physiologists, when the blood corpuscles are diminished in quantity by hæmorrhage, they are augmented *de novo* in the liquor sanguinis; this, then, is the reserve force.

Having taken care and fostered this reserve force by conservative means, our patient was in a fair way to recovery on Friday morning. The administration of whiskey not only bled our patient indirectly, but destroyed the red corpuscles of the blood and reserve force also.

The condition of the patient speaks for itself. The intense heat and thirst from the burning of oxygen, the condition of the nervous system, and hurried respiration, prove the destruction of the red corpuscles.

What else did it?

There was no other cause—I know whereof I speak.

Experience has proven it, and will prove it again, that alcohol, given to anæmic children, will produce asphyxia. Is it not reasonable, when the respiratory element itself is destroyed?

Alcoholic toxæmia will produce a constitutional tendency to inflammation. This we notice in debauchees. While in this debauched condition from alcohol, the least lesion tends to inflammation. The worst case of cellulitis I have had, was a case of this kind.

The white corpuscles are increased in the blood. At the same time the fibrin is increased largely also. These constitutional conditions will effect local changes in fresh lesions. The uterus in the puerperal state is in condition to become inflamed, if it has the least encouragement. It is a fresh lesion, although physiologically so. In addition there is hyperfibrination and degenerative changes going on.

Now let the blood become deoxidized, either by bad ventilation or a want of cleanliness, sepsis, or from any other source, there will be an inflammatory condition follow.

In my early practice I remember a physician who invariably "dosed" his puerperal patients with whisky. This physician had more puerperal fevers to contend with than any other physician in his vicinity. He finally sacrificed his own wife to this sinful practice.

I know of a bleeder, who whenever she would take wine, the hæmorrhage was increased. She finally refused to take it at all. I gave her credit for her good sense.

From the foregoing considerations, we must conclude that in alcoholic toxæmia the red corpuscles in the blood are decreased by destruction, and the white corpuscles are relatively increased, either by genesis or as the red corpuscles are relatively decreased.

In conclusion I would say, the above considerations being true, we, as a profession, should speak against this sinful practice in thunder tones, that it may be felt through the country from center to circumference.

Dr. N. S. Davis, of Chicago, in his report on the

[1] Leibig.

practice of medicine to the Medical Society of the State of Illinois, discourages the use of alcohol as a remedy in the treatment of disease, in typhoid fever, and especially so where there is a cardiac weakness.

This paper was hastily written, not having time to gather and collect statistics on the subject. I submit it to the society for what it is worth, with the earnest desire to see the theory and practice of the use of alcohol as a remedy in exsanguinated subjects perish and be for ever wiped out.

ARTIFICIAL CULTIVATION OF VACCINE VIRUS.—Dr. C. Quist, a physician of Helsingfors, Russia, announces in the *St. Petersburger Medicinische Wochenschrift*, that he has discovered a method by which vaccine virus can be cultivated in the laboratory. His claim, if true, would render vaccine farms superfluous, since all our virus should be grown in a watch-glass. It will, therefore, be examined with much interest.

Dr. Quist, by cultivating the micrococci ot the vaccine lymph found that they developed into bacilli, which in turn produced micrococci again. After many experiments he found that the two things necessary for growth were oxygen and a proper culture fluid. The vaccine bacterium is, he says, "an exquisite ærobium." The best culture-fluid he found to be egg or serum albumen, to which is added glycerine (to prevent desication) and a little carbonate of lime. The following is one of the several formulæ which were used:

℞ Blood serum, 1 part.
Glycerine, 1 part.
Aquæ distill, 1 part.
Calcii carbonat, 1-900th part.

This fluid is sterilized by keeping it at a temperature of 60° C. It is then spread upon a glass plate, a drop of vaccine lymph is mixed with it, and the whole is covered with a glass bell. The preparation is thus kept for a number of days. In six to ten days the surface is covered with the vaccine organisms. A little of this can be removed and inoculated with the result, according to Dr. Quist, of producing a perfect vaccine pustule. Our experimenter has found also that one inoculation of this cultivated virus produces immunity against a second. He does not, however, yet give evidence to show that these inoculations prevent small-pox.

It appears from reading the account of Quist's experiments that they were carefully conducted. The obvious criticism, however, is that they may only show that vaccine lymph can be largely diluted and yet retain its potency.—*New York Medical Record.*

PROF. BILLROTH'S ANTISEPTIC PRECAUTIONS.—The Vienna correspondent of the *Gazetta degli Ospitali* was recently invited to a laparatomy in Prof. Billroth's clinique in the following note: "Dr. —— is hereby invited to the operation of ——, which is to take place ——. It is understood that Dr. —— undertakes not to visit the same day, before the operation, sick rooms, dissection rooms, or other places in the Pathological Institute, and not to wear clothes which he may be in the habit of wearing in visiting these places."—*Lancet.*

MEDICAL PROGRESS.

ANATOMY AND PHYSIOLOGY.

COMPLETE ABSENCE OF JEJUNUM, ILEUM, AND THE GREATER PART OF THE COLON.—Mr. William Thomas reports a case in the *Lancet*, where in a premature birth at seven months of a female child, no anus was visible; no urethral orifice was visible, but a probe passed in the direction of the urethra for about two inches could be readily felt through the abdominal wall above the pubes. A second could be passed along the posterior wall of the vagina in the direction of the rectum for more than three inches. The child took the breast, but could not retain food for many minutes. It died in four days' time from exhaustion. The autopsy showed: no union between the pubic bones, an interval existing between them large enough to admit the finger. Stomach of normal size, connected with the duodenum by a constricted pylorus half an inch in length and rather less in diameter. The duodenum was an inch and a half in diameter in the distended state, and curved round the pancreas, to terminate on the left side of the spine by a blind extremity. There was no trace of any other part of the small intestine, nor of the cæcum, ascending or transverse colon. The intestine was recommenced by a blind portion of descending colon lying on the lower end of the left kidney, and continued by a sigmoid flexure and rectum, to terminate in the vagina.

A CASE OF GASTRIC FISTULA, WITH PHYSIOLOGICAL OBSERVATIONS.—Dr. de Cirenville (*Revue Médicale de Suisse Romande*), gives the case of a vine-dresser, 28 years of age, who suffered for some months from symptoms of gastric derangement which prevented his taking any nourishment. An examination showed an obstruction at the cardiac orifice of the stomach, with a distension of the œsophagus. It was found necessary to open the stomach on the left side, which was performed with success, a fistula established and relief afforded. The patient was fed through the fistula by means of a tube, and gained in weight in 11 days from 105 to 132 pounds. In the early treatmeut of the fistula a simple canula was used, which allowed some of the gastric juice to transude about and upon the open wound to the surface of the skin. This resulted, first, in an eczematous redness of the skin, followed by an ulceration due to a genuine digestion of the skin, but which, after the substitution of the canula used in physiological experiments for the simple canula, was readily healed. It was found impossible to overcome the resistance of the cardiac orifice, either by the sound introduced through the œsophagus or from below upwards through the stomach.

M. Herzen, Professor of Physiology, at Lausanne, adds to this record of the case, the results of some of his experiments in stomach digestion, which he intends to make more complete and to give more in detail. He notes the fact in this case that the stomach contains regularly, in the intervals of digestion, a considerable quantity of fluid, between 200 and 300 centimeters; that it contains no traces of the previ-

ous meal. Its appearance, odor and reactions showed that bile was present, but nevertheless it was sufficiently acid to redden litmus paper and to give the violet color with an aqueous solutior of tropéoline OO; it transformed starch into sugar; this too with an impermeable obstruction to instruments at the cardiac orifice which excluded the probability of saliva passing into the stomach, and rendered it possible that the pancreatic juice might be present. To test this point he gave as a drink 50 c. c. of the syrup of myrtle? strongly colored and containing the pellicles of the berry. In a quarter of an hour nothing had entered the stomach, in a half an hour the contents of the stomach were rose-colored, and in three-quarters of an hour there was a decided red color, with two or three pellicles. The test for trypsine was negative, but pepsine and zymogene were found in a very small quantity.

Calling this the first contents of the stomach, he passes to consider what he calls the second contents of the stomach. After introducing a canula and emptying the stomach completely, by degrees a fluid is formed which is entirely different from the first; it is colorless, limpid, thick like the white of egg, and in much smaller quantity than the first. It is acid in reaction with litmus paper, but not always with tropéoline, due, possibly to the varying amount present of albuminoid substances which combine with the acid. Its digestive property is appreciable only when diluted with an acid solution, but does not even then equal the active peptic gastric juice.

Digestion in this case continued for 7 or 8 hours, and after the stomach had completed its work, there seemed to be a complete relaxation which resulted in the passage of the contents of the duodenum into the stomach, the desire for more food returning some time before the stomach had emptied itself. His experiments in peptogenesis are so far limited, but he records one fact noticed, that in introducing the albumen mixed with distilled water simply, an indigestion followed which showed, with other experiments, that it was necessary to accompany it with some peptogenic liquid, as a small cup of bouillon, to insure its proper digestion. According to this, then, we should suffer from indigestion more frequently after our morning meal, were it confined to eggs, for example, and were it not, as it usually is, very peptogenic in character.

Researches into the Modifications of Temperature by Ointments Extensively Applied in Febrile Diseases of Children.—Dr. P. Colvat discusses this interesting subject at some length in the *Lyon Medical*. He dates the contradiction of the physiological view of this question, that impermeable coverings to the skin are dangerous, from the demonstrations of Fourcault in 1838, to the effect that an impermeable varnish and fatty ointments produced a refrigerant and beneficial effect in phlegmasiæ. Schlemann is generally given the credit of having introduced this method, which he employed only in scarlatina, by anointing the whole of the cutaneous surface, thereby modifying the fever, diminishing the frequency of the pulse, relieving the sensation of heat and tension of the skin, rendering less frequent the complications which accompany desquamation, and diminishing the chances for contagion. A number of writers have followed these in their favorable consideration of the subject, but Senator (1877) is the only one who has made any important researches into the lowering of the temperature in these cases. He found in the normal adult no change in the temperature after the application to the skin of a variety of impermeable substances and fatty matters; in the feverish adult there was a lowering of the temperature, but it was restricted in degree, and supposed that in children the lowering of the temperature was due to their approaching more nearly to the state of the lower animals in the great extent of their external surface. (How this reasoning applies exactly is not made very clear.)

Dr. Colvat has used this means with children in cases of scarlatina, variola, broncho-pneumonia, etc., using suet, cerate, and vaseline, preferring the latter from its never becoming rancid. He has nearly always observed after its application the symptoms consecutively of relief, calm, and sleep, and in most cases a notable and persistent lowering of the temperature, the thermometer in the rectum recording generally a lowering of 0.5° C., and exceptionally 2° C. The fall of temperature commences immediately after inunction, in five minutes to the amount of several tenths of a degree; at the end of an hour, as a rule, the lowest range is reached, to return to its former height in from two and a half to three hours. If then the ointment is re-applied, the same phenomena recur. Most of his cases were children of from one to two years of age; one was thirteen days old, another three months, and in these two was the lowering of temperature most marked.

It would seem as if to-day it was abundantly proved that no injurious effects followed this treatment. Schlemann continues the anointing of scarlatina cases for four weeks. Not only is there no albuminuria or visceral congestion produced, but they seem with the serous inflammations to have become less frequent as sequelæ. As to the now classic case of the child that was gilded to assist in the ceremonies which made Leon X. a Pope, Senator explains its death as from poisoning from some toxic material used in the gilding.

When it comes to giving the physiological reasons for the facts stated, Dr. Colvat admits with Claude Bernard that he is at fault, and can give no satisfactory explanation. He discusses a number of theories, but in a doubtful manner.

OBSTETRICS AND GYNÆCOLOGY.

On the Application of Forceps to the Breech.—Dr. Ettore Truzzi has published in the *Gazetta Medica Italiana Lombardia*, an article on the advantages and the methods of applying the forceps to the podalic extremity of the fœtus, a translation of which is given in full in the *Annales de Gynécologie*.

Dr. Truzzi recognizes the presence of certain conditions where the podalic extremity becomes immov-

able, and where it is necessary to bring down the feet or to use the finger or crochet in the groin in order to deliver the fœtus. He cites Livret as recommending the use of the forceps under the circumstances, and refers to Belluzzi as having given in full the pro and contra views on this subject. In his own practice he gives two cases where easy extraction of the fœtus was accomplished without any slipping of the forceps or injury to the child. Professor Porro assured him in their consultation upon one of the cases, that the dangers attendant upon this operation were greatly exaggerated, giving a case where the forceps were applied to the breech, in 1871, by Dr. Nonzini at the Maternity Hospital at Milan, with great success.

The recent memoirs of Belluzzi and of Ollivier tend to popularize the application of the forceps to the breech. But these two authors do not agree as to the best modes of making the application of the forceps. Belluzzi considers that the forceps, to be useful, should have a cephalic and pelvic curvature much less marked than in the ordinary forceps; the fenestrated extremities should also have a much larger opening. Ollivier considers that the forceps should not be applied to the pelvis, but to the thighs, and would be particularly applicable in the posterior sacro-iliac positions, the lower limbs being folded over the sternal plane, and corresponding to the anterior wall of the maternal pelvis, the forceps could then be applied to the thighs without exerting any pressure on the abdomen or pelvis of the fœtus.

With these points prominent in his mind, Dr. Truzzi experimented with 14 subjects where the child had died during labor or shortly after birth. He gave them first a prolonged warm bath to remove all cadaveric rigidity from the soft parts, then placed them in the pelvis in the position for a breech presentation, supporting the thighs against the sternal plane by means of cords. He was assisted by Prof. Porro, and extraction was attempted with the fingers, the crochet and the forceps. After extraction, a careful dissection was made in each case to determine the extent of the lesions. From these experiments, and from his two clinical cases, he arrives at the following conclusions:

1st. In the case of wedging of the breech in the upper or middle part of the pelvic excavation, if a rapid extraction is necessary, instead of attempting traction on the fold of the groin with the finger or the crochet, it is preferable to apply the forceps. Undoubtedly, traction in the groin admits of a better adjustment, and exercises less force than with the forceps, but these advantages are amply compensated for by the accidents which so frequently result, as fracture of the femur, and laceration of the soft parts of Scarpa's triangle.

2d. The proposition of Ollivier to apply the forceps on the thighs and not on the pelvis of the fœtus, is seductive in theory, but not in practice. In the sacro-iliac posterior position, the hold being upon the thighs, the posterior borders of the blades always compress the abdominal walls of the fœtus, and as the extremity of the forceps should, according to Ollivier, extend almost to the knees, the compression would be dangerous for the integrity of the parenchyma of the liver. They are liable to slip gradually, and after traction, lose their hold and produce an antero-posterior chafing.

3d. Much easier, surer, and less dangerous is the method of applying the forceps to the sides of the pelvis of the fœtus. The iliac bones are, at that period, quite elastic—they are protected by soft parts, which form true cushions, so as to sustain considerable pressure before appreciable lesions can be produced upon the pelvis of the fœtus. In all of the careful dissections made after these experiments, there was no fracture of the illiac bones, or lesions of the sacro-iliac or pubic articulations.

4th. To obtain a firm grasp, the blades of the forceps must reach the level of the crest of the illeum. They should be so brought together as to make these crests the points of resistance during traction, and to give the hips of the fœtus a convexity of form, thus filling in the space and preventing injury to the abdominal viscera. This mode of application of the forceps is absolutely without danger, according to Dr. Truzzi, who has never seen any contusion or laceration of the parenchyma of the liver or other viscera as a result.

5th. In his experience, the Porro forceps applied to the sides of the pelvis of the fœtus, give an excellent hold, particularly in anterior presentations. In posterior presentations, if the forceps slip, it is better to rotate the sacrum anteriorly, and then reapply them. It is well in the intervals of traction to keep up a certain degree of compression of the handles, as the iliac bones tend, by their elasticity, to return to their previous shape, and thus push aside the blades, causing them to lose their hold.

NEW INVENTION.

A SUBSTITUTE FOR STRAPPING THE TESTICLE AND THE TREATMENT OF HYDROCELE.—Dr. J. C. Warren exhibited to the Suffolk District Medical Society a chamois-leather bag which he had devised for the purpose of exerting pressure on a small collection of fluid left in the tunica vaginalis remaining after an operation for radical cure, and a woodcut of which is given in the *Boston Medical and Surgical Journal.* The bag can easily be applied by isolating that portion of the scrotum containing the testicle to be compressed and forming a pedicle, which is preserved by tightening the chamois-leather string. The bag is then laced from above downwards, and, if it has been made to fit snugly, exercises a gentle and equable pressure. If it is necessary to increase the pressure, a few turns of a common narrow roller bandage around the equator of the globular mass are all that is necessary. This bag is free from the well-known discomforts of plaster, is easily made and applied, and can be removed and reapplied by the patient himself as often as is desirable, thus avoiding excoriation at constricting points. In the single case in which it was used, the effusion promptly disappeared, and has not since returned at an interval of nine months.

MATERIA MEDICA AND THERAPEUTICS.

Fraudulent Tartar Emetic.—An article in the *Progres Mèdicale* is quite severe on the chemical products introduced from Germany into the French market, as being impure and consequently sold at lower rates. Of tartar emetic it says: The Syndical Chamber for chemical products at Paris, found the German preparations to contain 41 to 46 parts per 100 of oxalic acid. The municipal laboratory arrived by analysis at the same result. After these facts had been made public, the *Chemiker Zeitung* of Goethen declared that from different places, particularly from Saxe and from Wurtemburg, a so-called emetic salt was introduced into commerce containing oxalate of potassa and antimony without a trace of tartaric acid.

It is sufficient to consider the preparations in which this salt takes part to recognize the danger not only from replacing tartar emetic by an unknown salt, but also from its rapid poisonous effect. Tardieu cites a case where death followed the ingestion of 30 grains. Besides being used as an emetic, tartar emetic is used as a purgative, as an alterative, and as a counter-stimulant, in doses of from 8 to 15 grains during the 24 hours, (?) and persisted in for days at a time; which is much more than would be required to poison a patient with oxalic acid.

The Preparation and Application of Kephir (the New Drink from Caucasus).—Dr. W. Maximon writes from St. Petersburg to *La Semaine Médicale* concerning this new drink, which has become quite fashionable, and replaced koumiss to a great extent during the past two years in St. Petersburg. It has been carefully studied by more than a half dozen of the scientific men of Russia, and only differs from the koumiss of cow's milk in being produced, not by yeast, but by a specific ferment, which comes from Caucasus; it was for a long time a great secret among the inhabitants of that region, who have many legends to explain its origin. They prepare a drink called arian, by pouring the fresh milk of the goat into an oaken vessel with a narrow neck, placing in it a piece of the stomach of a sheep or calf; when the milk clots they shake the vessel from time to time, and then use it for drink. When the milk is used up they renew it with fresh milk which mixes and clots with the rest; this goes on indefinitely. At the bottom and walls of the vessels a peculiar sediment forms in the shape of balls or grains, which is the specific ferment in question.

If this be placed in fresh milk it produces a new fermentation, and gives a soft and refreshing drink, with an agreeable taste, called kephir, from the word *keif*, delicious. This liquid has the thickness of cream and is frothy, it is exceedingly nutritious and light, even for the weak stomach of sick persons, more so than koumiss. The grains of kephir when examined microscopically, present spores of the saccharomycetes, oidiumlactis and bacteria.

It requires a certain amount of skill and a good deal of patience in its preparation. A half a glassful of these dried grains, which are found on sale in many of the Russian towns, is put into warm water for five or six hours until they swell up. Then they are put into a glass of fresh milk, which is changed every three hours for two or three times. When these thoroughly softened grains change from a yellow to a white color, they are ready for use in making kephir, and are put into fresh unskimmed cow's milk in the proportion of a soupspoonful of the grains to two glasses of the milk: the carafe is covered with a bit of muslin and exposed without cooking to a temperature of 64° to 69° Fah., shaking it constantly. In seven or eight hours after it has commenced to ferment it is transferred to champagne bottles, being strained through the muslin and kept at the same temperature, the bottles being shaken every two or three hours. At the end of twenty-four hours it is prepared for use, but does not contain much carbonic acid or alcohol, being called weak kephir. At the end of two days it is of medium strength, and of the consistency of cream. At the end of three days it becomes more liquid, and is the strongest. To preserve it in its various stages of strength it is put on ice in the cellar, the cold arresting the fermentation, but it must still be shaken at least once every day. This ferment will serve after removal to prepare a fresh supply of kephir, or if not needed for immediate use the grains are carefully washed, dried quickly in the sun and preserved in hermetically sealed glass vessels.

The properties of good kephir are: its consistency of cream, its milk-like color, no residue, frothy like beer and a sharp sweet taste, which pricks the tongue like carbonic acid. According to a number of scientific observations, kephir is the best of all known nutrient drinks, being three times more so than koumiss; it is very easily digested and is strengthening, it is also expectorant and diuretic. Is used in general debility and deficiency of nutrition with convalescents from serious diseases, such as typhoid fever, also with children at the breast to replace breast milk, when it is made from skim milk, is boiled and mixed with water, four or five spoonsful to the bottle.

The chemical analysis gives for the unboiled milk a percentage of caseine, 85.7; albumen, 8.3; hemialbumen, 6.0. Boiled for ten minutes, caseine, 76.6; albumen, 0.8; hemialbumen, 22.6.

As boiling prepares the albuminous substances of milk for stomach digestion it is perhaps best in the boiled state. For anæmics, 0.06 to 0.12 centigrammes of lactate of iron to the bottle is useful.

As it is merely an aid to nutrition, the dose is not fixed. One glass the first day, two the second, three the third, and so on until three or four bottles are taken in one day. It is drank by mouthfuls and warm. Fresh kephir, that of 24 hours ferment, is a little laxtive; strong kephir is a little constipating.

A new medical college in Cincinnati has been organized under the title of the Medical University of Ohio.—*Louisville Medical News.*

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 65 RANDOLPH STREET,
CHICAGO. ILLINOIS.

SATURDAY, MARCH 8, 1884.

ILLITERATE DOCTORS AND MEDICAL LEGISLATION.—Under the head of domestic correspondence in the present number of the JOURNAL, will be found a short and characteristic letter from Dr. A. L. Gihon, U. S. N., which contains further evidence (of which the world had abundance already) that some graduates of medical colleges are very illiterate, and closes with an earnest request that every member of the American Medical Association will "*pray*, if nothing else, that wisdom and courage may be given the Legislature of the State of New York to enact the law that will put that great commonwealth in line of battle with Illinois and West Virginia in the war against medical ignorance and incompetence, 'regular' as well as irregular." Inasmuch as our enthusiastic representative of the medical staff of the Navy has improved every opportunity, during the last few years, to show the gross ignorance of many doctors holding diplomas from some of the oldest and most respectable medical colleges in this country, it seems a little singular that he should ask the great body of the profession to engage in *prayer* for the enactment of more laws establishing State Boards, whose members are required to accept the diplomas of these same medical colleges as sufficient evidence of qualifications for a State license to practice medicine. The war that such boards can wage against "medical ignorance and incompetence," will never amount to more than light skirmishing along the out-posts, and is hardly worth *praying* for. Had he asked the members of the Association "to pray" that the Legislature of every State may have sufficient "wisdom and courage" to enact laws similar to those in Alabama, North Carolina aud Virginia, by which every man or woman proposing to enter upon the practice of medicine, shall demonstrate his or her qualifications, under a thorough examination by the State Board, without any regard whatever to medical college diplomas, we could have joined in the general prayer-meeting with some degree of enthusiasm.

QUESTIONS AND ANSWERS.—"*Dear Sir:* Is there any little manual containing the Code of Ethics, constitution, and by-laws of the American Medical Association? Questions are frequently asked me by men much older in the profession than I am, which can only be answered by reference to those articles, but they, like many of us younger men, do not happen to possess copies of the Transactions of the society. Would it not be well to publish the articles in the JOURNAL if they are not published in manual form?

A local medical society over fifteen years ago adopted a fee table. Said society never meets now. New physicians have come in who have never subscribed to said table; some that have 'cut rates' with irregulars, though they themselves are members of the A. M. A. What is to be done about it? x."

Answers.—We know of no manual or publication containing the constitution, by-laws, and Code of Ethics of the American Medical Association, except the Volume of Transactions published by the Association itself. The Code of Ethics alone was published in a neat little duodecimo volume by William Wood & Co., of New York, and could probably be procured at most of the larger medical book stores, or through almost any book dealer. Its price is 50 cents a copy, if I remember correctly. Unless otherwise ordered, the constitution, by-laws, and Code of Ethics will be republished in the last number of Vol. II of the journal of the Association, there being a standing rule requiring that they be published with the Transactions every year, more especially for the information of new members.

If the members of the profession in any town or county, after due notice, meet in convention and adopt a *fee bill*, we suppose the rates thus established would remain binding upon all members of the profession in that locality until revised or altered by another convention. But if an organized medical society, without regard to the profession as a whole, adopts a fee bill and then expires, we think its fee bill expires also, inasmuch as there remains no active organization for its enforcement.

THE PROFESSION IN NEW YORK AND THE ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION.—We learn from a reliable source that the new State and County Medical Association in New York are prospering beyond the anticipations of their warmest friends. And through them the profession in that city and county will be well represented in the coming meeting of the National Association in Washington. As a large proportion of the county societies in other parts of that State have adhered to the National Code, and thereby preserved their right to representation in the national organization, it is probable that the whole State will be as fully represented in the National Association as in former years. There are also indications of a larger representation from the profession in the New England States than for many years past. All the circumstances indicate that the coming meeting in Washington will be one of the most important ever held.

JAMES MARSHALL AMBLER, M.D., U. S. N.—The remains of this heroic medical officer, who perished in the Polar exploring expedition of the ill-fated Jeannette, very recently arrived home under proper escort, and were buried in his native town in the interior of Virginia. Let no one fail to read the interesting obituary notice of him, under the head of Necrology, in the present number of the JOURNAL.

SOCIETY PROCEEDINGS.

CHICAGO MEDICAL SOCIETY.

Regular meeting, February 18, 1884.

Report of a case of ventral hernia in the male, with pathological specimen, by Dr. Wm. L. Axford.

Report of three cases of arrested fœtal development, in one of which there was an entire absence of the abdominal wall and the umbilical cord, by Dr. L. A. Harcourt.

We cite the important points of the first case presented as follows:

F. B., aged 56, weight 340 pounds. An enormously large and fleshy man; had been troubled for the past twenty years by a tumor situated above and to the left of the umbilicus. He did not know any cause for its appearance, having never been injured along the linea alba. At first the symptoms were those of a slowly-growing tumor. He wore a pad for a number of years, and in this way was able to keep the "mass" within bounds; but during the past five years it became uncontrollable, and had been a constant source of trouble, dating back to a very severe attack of constipation followed by severe vomiting. As near as could be ascertained at that time, he had all the symptoms of a strangulated hernia. Two years before death another strangulation occurred, and at that time Dr. Axford was invited to see him. The strangulation subsided in each instance under the use of opiates with rest in bed. In the intervals he had weekly attacks of what was described as a *hardening of the mass*. At such times it would increase to an unusually large size, and include the umbilicus in the swelling and become extremely painful, but he did not vomit. He would go immediately to bed, and after a day or two of rest it would again subside. When the writer first saw the case, at the time it was strangulated the second time, the tumor was about the size of an adult head, hard and tense, but resilient to the touch. Percussion gave dullness over the upper and left part of the mass, while over the lower two-thirds the percussion note was tympanitic. A variety of diagnoses had been made by a number of physicians, tumors of various kinds, particularly fatty tumor, hernia, hernia with fatty tumor, etc., etc. The physician who first treated the case evidently took it for hernia, as he treated it by a pad, and by this means controlled it for a long time.

The essayist believed it to be a ventral hernia when he first visited his patient, and that it contained intestine and omentum. He accounted for the dullness over the left and upper part by supposing that so large and obese a man would naturally have a thick, fatty omentum, which, from its anatomical relations, could easily occupy the left and upper portion of the hernial sac. Recently the patient died, with symptoms of strangulation similar to those of the two previous occasions. The sac of the hernia was exhibited to the society, and while no omentum was found in it at the autopsy, the sac contained a considerable portion of small intestine. As above stated, the case was one of twenty years' duration, and the tumor was always a great source of inconvenience, and at times exceedingly troublesome, aside from the two attacks of the symptoms of strangulation from which he barely recovered, while the third attack proved fatal. None of the physicians who previously attended him had diagnosed it to be ventral hernia, as these herniæ usually give rise to great gastric symptoms, which were present but a short time in the case of Mr. B. In the discussion which followed, considerable contrariety of opinion was expressed regarding the use of a rubber bandage applied in treating this variety of hernia, as well as the utility of it in femoral, strangulated femoral, and other forms of rupture that occur in both sexes. Its advantage was affirmed by some, and denied by others. It was also argued by one speaker that he personally had met a case of strangulated femoral hernia that recovered without sloughing or operation, and that, so far as he knew, little or no treatment had been carried out, which he admitted was a surprise to him; for when he was called to see the patient he was suffering acutely from well-marked symptoms of the strangulation, yet within a few days the man recovered, and resumed his duties attending a garden of which he was owner.

In the second paper, regarding "Maternal Impressions," the cited author the following cases, which constitute a synopsis only of his report:

CASE I.—On the 4th of March, 1881, attended Mrs. C. in labor with her fifth child. Some months before, she was threatened with an abortion, having had pain and hæmorrhage for several days, but rest and anodynes averted the calamity. An examination in the present case of confinement, revealed the os uteri to be about two-thirds dilated, the membranes protruding into the vagina, but only a membranous tumor could be felt by the finger. Thinking there might be a breech presentation, and that instrumental aid might be necessary in the delivery of the head, the doctor departed for his forceps two blocks away, requesting the lady to retire to bed at once. Returning in a few moments, he found her in severe pain, the membranes protruding from the vulva, and as the pain subsided, the index finger of the right hand was passed beyond the tumor, which was a spina bifida. The fœtal head was distinctly felt. The os uteri was fully dilated. He ruptured the membranes at the next pain, and almost in an instant the child was ushered into the world with extraordinary force. The warm blood was felt to gush into the operator's hand, and he feared he had a case of post-partum hæmorrhage to deal with. A glance at the woman's face banished this fear and he looked for some other explanation of the hæmorrhage. The child and placenta came into the world simultaneously. Looking at the child, which was alive, its face grew white; a second glance revealed the fact that its abdominal parietes were wanting. The anterior and part of the lateral walls of the abdomen were absent from a little above the os pubis to a little below the ensiform cartilage, leaving the abdominal viscera exposed. The intestines, of course, protruded; the bladder, kidneys, stomach and other organs could be distinctly seen and felt. The integument of the abdomen above, below and laterally *degenerated* into membrane, and a membranous fringe from three-fourths of an inch to an inch and a half in width, resembling that attached to the placenta, and from which something had been irregularly torn, encircled the opening. The lower extremities formed an obtuse angle with the body, the hips projecting to one side, as if the limbs of one fœtus had been engrafted obliquely upon the trunk of another. There was spinal curvature in the lumbar region. It was something of a monstrosity, the sex of which the writer has forgotten.

An examination of the child, the placenta, the vagina of the woman, and the bed, failed to discover the slightest trace of an umbilical cord, and the accoucheur's impression is, that the membranes were attached directly to the child's abdomen, and torn from it by the child's expulsion. The child lived only a few moments. The mother made a good recovery. She was not permitted to see the child until dressed, but knew that something was wrong, as no cord had been tied. She stated afterward, in explanation of the abnormal condition of things, that before she was threatened with the miscarriage she had seen a man who had fallen from a scaffold, whose abdomen was so torn that the intestines protruded from the rent, and who died in a few hours. The shock she received at the time, she thought, caused an arrest of fœtal development, giving rise to the condition mentioned.

In the interest of science, an effort was made to procure the child. The doctor offered to charge nothing for the services rendered, if they would give it to him. The father seemed to appreciate these motives, but the mother would not listen to the proposition under any circumstances. As nothing of this kind had ever occurred to him previously, nor within his professional knowledge, or in his reading, he was, for this reason, desirous of obtaining and keeping this specimen.

CASE II.—He was invited by Dr. Tousley, of Weyannega, Wis., 13 years ago, to see what the doctor called a headless child, recently born. Upon arriving at the house, found this statement only partially true, as the essential part of the head, *i. e.*, the brain, was there, a part of its osseous covering alone being absent. It was a case of imperfect or arrested development of the cranial vault, a part of the frontal, temporal, parietal and occipital bones being wanting. They were absent from a line beginning a little above the supraorbital arch, passing backward, arching slightly over each ear and passing through the occipital protuberance. The brain and its coverings were intact; the longitudinal fissure was well-marked, giving rise to two soft yielding tumors, which the doctor at first mistook for the breech; the face was broad and flat; the nose flattened; the eyes small, round and protruding, probably from pressure upon the brain during labor. Every feature was distorted and repulsive in the extreme, while the countenance resembled, in some measure, that of a hog. The mother was a native of Germany, and she, too, had an explanation to offer, namely: Some time after conception, she came suddenly where hogs were being butchered, and saw a number of them decapitated. She was startled, and hence, as she thought, her misfortune in giving birth to an *acephalous fœtus*.

The author gave a written report of an additional case, the principle facts of which were taken, and briefly stated as follows: The case occurred in Wisconsin under his immediate care. Some months before he confined the wife, he was called to see her husband, who had fallen from the rafters of a house, striking against the joists and sleepers in his descent, and sustaining some injury about the back of the neck and between the shoulders. The patient's shirt was removed to examine the injuries, when there was found an abrasion of the integument, and contusions extending from the occiput to the second or third dorsal vertebræ. The injuries, while not severe, looked bad at the time. The shoulders and upper part of the back were more or less spattered with blood. While undergoing this process, the wife came into the room, and on seeing her husband bleeding she became very much excited and alarmed. She was at that time in the third month of pregnancy. About four months later she prematurely gave birth to a child, on whose neck and between whose shoulders were marks, the exact counterpart of the injury sustained by its father some months before. A triangular space, extending from the occiput down-

wards between the shoulders, was covered by a reddish membrane (not skin), presenting in miniature the appearance of the father's neck when seen by the mother. Reddish spots were scattered about the back and shoulders, corresponding to the blood stains on the father. The child did not survive.

The Secretary knew that in Dr. Harcourt's experience he had seen the above cases, and at his request they have been presented to the society in this report, and are truthfully given by the author. Although scientists state, there are no such results from mental influences. Whether these impressions, or so-called mother's marks, and the attending or subsequent morbid developments, stand in the relation of cause and effect, or were mere coincidences? It was not his province to determine this, but they seem to confirm the belief entertained by many that "Jacob knew whereof he bargained, when he agreed with Laban to take as hire all the brown lambs and speckled goats and cattle born after a given date." In the discussion Dr. A. Lagorio recited briefly the main points concerning a case he saw last April, although the woman who had been confined was attended by a midwife. A baby was born having double hare lip, extending through the alæ of the nose. The nose was flattened, there was a cleft palate, the eyes were closed, and the lids could not be separated, there was no rotundity of the eye-balls. The child lived 15 or 20 days and died from inanition. At the autopsy there was discovered an entire absence of the eyes. The mother was 40 years old; an Italian. She had undergone during the period of her gestation great hardships, such as scrubbing, using a mattock to remove stumps and roots, picking up coal, carrying weights on her head, etc. The poor woman supposed the midwife to be a witch, and as such had marked her baby while "in utero." He believed there was no case on record in this country where a child was born without eyes, or where the lids could not be divided. In Vienna three cases have been reported where the eyes were missing, or where the eye-lids were closed at birth. In one of the cases the lids were separated and the eyes opened, and subsequently the child perceived objects.

Dr. S. J. Avery gave a history of a case he had seen. When called to attend a lady patient about to be confined, he ascertained that a breech presentation was the position that the child occupied; he got along very well until delivery of the shoulders, this was accomplished with more than ordinary difficulty. In the delivery of the head he discovered that it was hydrocephalic and measured, he thinks, eight or nine inches antero-posteriorly. In the delivery cephalotomy was performed. The mother recovered with no serious trouble or cellulitis.

Dr. J. G. Kiernan gave an abstract of a number of cases that had been reported in different journals purporting to be from embryologists. Some of the cases cited were very extraordinary. Men skilled in embryology have very little doubt but what a sudden and violent mental shock may arrest development in a fœtus.

The society then adjourned. L. H. M.

CHICAGO GYNÆCOLOGICAL SOCIETY.

CHICAGO, Feb. 15, 1884.—The Chicago Gynæcological Society held a regular monthly meeting, Friday evening, Feb. 15, in Parlor 4, Grand Pacific Hotel. The following paper on "Cirrhosis of the Pancreas; Pregnancy; Emaciation; Death," was read by Charles Warrington Earle, M.D.:

Several months ago I reported to the Chicago Medical Society two cases of cirrhosis of the pancreas, and before I have been able to find time to revise and re-write the article for publication, another case is presented to me, the notes of which are kindly presented by Dr. Joseph Haven:

Was first called to see Mrs. R. on Nov. 18, 1883, to relieve, if possible, the nausea and vomiting of pregnancy. She is American by birth, of nervous temperament, aged 36 years, and has been married thirteen years. She has had two children, both of whom are living, and eight years ago one miscarriage, which was followed by some uterine disease. Aside from this, she has always enjoyed comparatively good health. Up to three months ago menstruation had been regular, the amount normal, and pain not excessive. At this time menstruation ceased, and shortly after nausea and vomiting followed, for which she seeks relief. She states that six weeks ago her appetite began to fail, and she has gradually lost flesh from that time, but aside from nausea, she had experienced no pain or inconvenience of any kind; and inasmuch as she has always become very much reduced during previous pregnancies, she has paid little heed to this symptom.

I found the patient anæmic, much reduced in flesh, muscles flabby, and a general lack of vitality. Temperature normal, and physical examination elicits nothing aside from what would be caused by anæmia; the bowels are constipated.

I prescribed antacids, a laxative at bed time, and a general course of tonics and stimulants, including iron, hypophosphites, cod-liver oil, koumiss, and sherry wine.

November 23. Her husband called as directed, and reported that his wife's condition was much improved, the nausea relieved, and the appetite improving. She is ordered to continue the tonics and stimulants, and he is requested to report any change that might occur.

December 13. Was called in the night, and found patient in a critical condition; extremely emaciated, respirations slow and labored, radial pulse, scarcely perceptible, extremities cold, breath very offensive, articulation difficult, due in part to coexisting aphthæ, heavily coated tongue, sordes on the teeth. Husband states, that she has been failing several days.

December 14. Slight improvement; has revived somewhat under the use of stimulants.

December 15. Dr. Earle called in consultation; finds no symptoms other than those of anæmia and prostration, and suggests the possibility of obscure internal complications, such as disease of the pancreas.

December 16. Nourishment and stimulants by stomach and bowels give only temporary improve-

ment.

December 17. Died.

December 18. Post-mortem. Uterus enlarged to extent of three months pregnancy; all the other organs apparently normal, with exception of the pancreas, which is hard and contracted, a portion of which is removed for microscopical examination.

In the history of this case, from beginning to end, there has been a lack of symptoms other than a general failing of the powers of life. There has been no pain or other symptoms to locate the trouble in any particular organ. An analysis of urine failed to establish renal complications. It is to be regretted that the character of the fæcal dejections could not be ascertained as to presence of fat. There is no family history of scirrhus, constitutional, or wasting disease.

Discussion.—Dr. C. W. Earle: That diseases of this organ are rare, probably no one will deny, and although it is possible that affections of the pancreas may occur somewhat more frequently than we now suppose, their diagnosis must for obvious reasons always be difficult. Bartholow says that so little is definitely known of diseases of the pancreas, that many systematic works omit this subject altogether. Aitken, in his large work, does not speak of disease of this organ. Hartshorne, editing Watson, devotes about fifteen lines to the consideration of the subject. Flint and Wood have short articles, and I have looked through scores of bound volumes of journals without finding an allusion to disease of the pancreas. For anything like a comprehensive discussion of diseases of this organ we are obliged to go to Ziemssen. I cannot find a single case in all the books to which I have had access, where exhaustion from the anæmia of pregnancy has been associated with disease of the pancreas. The author of the article on diseases of the pancreas in Ziemssen's Cyclopædia, makes this one remark: "Pregnancy is believed by some authors to predispose to this (pancreatic) disease." The occurrence of three cases of disease of this organ in the practice of one individual in the course of three years, all of them proving fatal, and the diagnosis of all of them being demonstrated by microscopical examination, seems somewhat surprising. I have come to the conclusion that we have not up to this time paid as much attention to diseases of this organ as we should. I believe that a considerable number of cases that we suppose to be due to pernicious anæmia, leucocythæmia, etc., may be due to chronic disease of the pancreas. I shall place these cases on record as much to elicit inquiry and observation from other members of the profession, as from any other one thing. We frequently see cases in practice where there is very great emaciation, white color to all the integument, showing want of red blood corpuscles, and I have come to think that these changes may be due, at least in some cases, to disease of the pancreas. The functions of the pancreas, as now given by the latest authors of physiology, are as follows:

1. The pancreas digests fats and assists in the conversion of starch into sugar.

2. It assists in the digestion of albuminoid compounds.

The organ is, as will be remembered, sometimes called the "abdominal salivary gland;" and, reasoning from analagy, is it not possible that it may be disturbed somewhat as the salivary glands are disturbed?

The diagnosis wlll be difficult, if not impossible. The principal symptoms are emaciation, a flow of saliva-look ng fluid from mouth and vomiting of fatty matter, with the passage of fatty material from the bowels. During the course of these three cases I have looked up the literature very closely, and I mnst say, that even now, I do not think I would be able to diagnosticate a case. The microscopical changes are described and kindly furnished by Prof. Marie J. Mergler.

"On microscopical examination, the entire organ is found more or less altered, In some portions the connective tissue between the acini is increased, and many of the gland cells have undergone fatty degeneration, in others the broad bands of connective tissue encroach considerably upon the glands, and in place of their large polyhedral cells are found small irregular, shrivelled bodies, evidently atrophied gland cells, and still other sections do not even present a trace of gland structure, consisting entirely of connective tissue."

Dr. Merriman—Has the author in Ziemssen given any means of diagnosis during life?

Dr. Earle—Not only has none been given, but he says that no one of the possible symptoms can be relied upon as pathognomonic.

Dr. Earle then gave a brief history of the other two cases in his own practice, and also remarked that it was his opinion that frequently the pancreas was not noticed in ordinary post-mortems, and that a distinguished pathologist once told him that many medical men had never seen the organ.

Dr. Merriman—You mention in the second case increased salivary secretion. Now I should expect that, on account of the salivary glands, to a certain extent, having functions similar to that of the pancreas; for instance, changing starch into sugar. Was that symptom noticeable in the other cases?

Dr. Earle—I do not remember, but it has been noticed by others who have observed pancreatic disease; so much so that this is classed as one of the prominent symptoms.

Dr. Jno. Bartlett—When I was young I used to be accounted something of a gross pathologist. I have on several occasions made as many as five post-mortems in a day. I have made a good many post-mortems in my life, and it is my opinion that not once in fifty times is the pancreas looked at.

Dr. Sawyer—I remember being present at an autopsy that was made by Dr. Weber, the pathologist of the City Hospital of Boston, upon the body of a young girl supposed to have died from chlorosis. I remember the peculiar cast, the peculiar tint of the face presented by that corpse. I never saw anything like it. If all cases of chlorosis are as well marked as that one, then the disease can well be called chlorosis. Before opening the body Dr. Weber said to the class: "We shall probably find disease of the

pancreas, as it is one of those diseases accompanied by extreme bodily waste." I saw the pancreas in this case, and I believe it was the first time I ever saw it.

Dr. Merriman—I am more and more convinced that we don't begin to know about nutrition as we ought. I have a case of chlorosis in hand now, and this paper and discussion sets me to thinking more than ever before.

Dr. Jno. Bartlett then presented verbally a report of a "Difficult Case of Labor," which proved of decided interest and elicited much discussion.

The society then transacted some miscellaneous business, and adjourned. J. E. H.

STATE MEDICINE.

HEALTH IN MICHIGAN.

Reports to the State Board of Health, Lansing, by observers of diseases in different parts of the State, show the principal diseases which caused most sickness in Michigan, during the week ending Feb. 2, 1884, as follows:

NUMBER OF OBSERVERS HEARD FROM, THIRTY-EIGHT.		For preceding week.
DISEASES ARRANGED IN ORDER OF GREATEST AREA OF PREVALENCE.	Per cent. of observers who reported the disease present.	Per cent. of observers who reported the disease present.
Neuralgia	79	73
Bronchitis	66	68
Influenza	63	68
Rheumatism	63	70
Consumption, of lungs	63	50
Pneumonia	55	60
Tonsillitis	53	58
Intermittent fever	53	63
Remittent fever	37	28
Inflammation of kidneys	32	28
Erysipelas	29	20
Whooping-cough	24	25
Diarrhœa	21	35
Diphtheria	18	18
Scarlet fever	18	15
Inflammation of bowels	16	13
Dysentery	16	10
Measles	11	15
Membranous croup	8	5
Puerperal fever	8	5
Cholera morbus	5	3
Inflammation of brain	5	5

For the week ending February 2, 1884, the reports indicate that consumption, erysipelas, and remittent fever increased, andthat diarrhœa, intermittent fever, typhoid fever, and typho-malarial fever decreased in area of prevalence.

At the State capitol, the prevailing winds during the week ending February 5 were northwest; and, compared with the preceding week, the temperature was considerably higher, the absolute humidity considerably more, the relative humidity more, and the day and the night ozone less.

Compared with the average for the month of January in the preceding six years, neuralgia was more prevalent, and diphtheria, rheumatism, typho-malarial fever, bronchitis, scarlet fever, consumption, pneumonia, and remittent fever were less prevalent in January, 1884.

For the month of January, 1884, compared with the average of corresponding months for the six years, 1879-1884, the temperature was considerably lower, the absolute humidity less, the relative humidity more, the day ozone more, and the night ozone the same.

Including reports by regular observers and others, diphtheria was reported present during the week ending February 2 and since at eighteen places, namely, Attica, Arcadia, Belding, Detroit, East Saginaw, Flint, Grand Rapids, Hersey, Hillsdale, Linden, Northville, Newaygo, Owosso, Otsego, Pontiac, Ronald, Springfield, Saginaw. Scarlet fever at thirteen places, Detroit, Grand Rapids, Hersey, Kalamazoo, Lakeview, Mason, Monroe, Orleans, Otisco, Roxand, Saginaw, Salem, St. Clair. Measles at seven places, Elk Rapids, Flint township, Monroe, North Adams, Owosso, Pontiac and Saginaw.

HENRY B. BAKER, Secretary.

Lansing, Feb. 6, 1884.

Report of deaths in the city of Lansing, Mich., during the month of January, 1884:

Burial Permit No	Day of Death.	Name of Deceased.	Age. Years.	Months.	Days.	Sex.
477	3	Henry S. Ryan	49	1	11	M.

Deaths in the city in January..... 11
Population, U. S. census, 1880..... 8,319
At rate in January, the deaths in one year per 1,000 inhabitants (annual death rate) would be..... 15,579

O. MARSHALL, M.D., Health Officer.

THE FEEDING OF INFANTS.—Dr. V. Poulain believes that the reason that cow's milk so often disagrees with children is to be found in the fact that cane sugar is used to sweeten it. In the *British Medical Journal* he says that he has used the sugar of milk with the best results.

DOMESTIC CORRESPONDENCE.

FROM WASHINGTON.

MEDICAL CORPS U. S. ARMY.—Ordered to Europe: Lieutenant-Colonel Joseph B. Brown and Major John S. Billings, surgeons, U. S. Army, will proceed to London (England) and to Copenhagen (Denmark) to attend the International Health Exhibition to be held at the former place in May next, and as delegates to the International Medical Congress which is to meet at the latter place in August next, and will include Berlin (Germany) in their route to or from Copenhagen.

MEDICAL CORPS, U. S. NAVY.—On account of the bitterness of the fight for the Surgeon-Generalship of the Navy, it is now thought likely that the President will not make an appointment to the vacancy until after the adjournment of Congress.

MATTERS OF MEDICAL INTEREST BEFORE CONGRESS.—On February 11 Mr. Blair introduced a bill (No. 1484) to the Senate, which provides for the study of physiology and the effect of intoxicating, narcotic, and poisonous substances upon life, health, and welfare, by the pupils in the public schools of the Territories and District of Columbia. The first section of this bill simply reiterates the title, specifying in addition that the simple rules for the preservation of life and health shall be taught, and that the substances referred to are those in common use by the people. Section 2 reads: "That teachers in the public schools shall be qualified to teach accordingly, and suitable text-books shall be used to facilitate the study and instruction provided for in the first section of this act: and such text-books shall be subject to rejection from use if found to be objectionable by the Commissioners of Education. This bill appears on the face of it to be a step in advance in education, but on considering it closer one sees that its provisions will have to be carried out with great care to furnish the proper amount and character of information. To teach the physiology of the present day as regards the use of intoxicating liquors, temperance, and not total abstinence, would have to be inculcated, and it is a question as to how far that can be taught to the mass of children. Then, again, as physiology grows older it becomes less and less positive and dogmatic in its principles, which would be injurious to minds not yet formed for reasoning; so there would be danger of a race of doubters on the one hand or of positivists on the other. As to the effect of poisonous substances, if this were considered with frankness and any degree of thoroughness, there would be added a large class to those already existing who take upon themselves to question and argue the plans of treatment and the drugs used by their attending physicians, and by their preconceived notions interfere materially with their own welfare. The clauses of "simple rules" and "substances in common use," are in a measure saving clauses, but it would not be difficult for ambitious teachers to stretch those boundaries ad libitum.

Feb. 15.—Mr. Logan introduced a bill before the Senate (15591) entitled "To define the title and duties of certain officers of the Medical Department of the Army. In effect it makes the six medical officers who hold the rank of Colonel to be styled Assistant Surgeon-Generals, and to rank in the order of seniority of dates of their commissions to that rank of Colonel. This makes Dr. J. H. Baxter the senior Assistant Surgeon-General, and continues his duties as Chief Medical Purveyor located in Washington city, and also makes him incontestably the next in the regular order of promotion to the rank of Surgeon-General. The second section gives to the medical officers bearing rank as Lieutenant-Colonels the title of Deputy Surgeon-Generals.

TO THE EDITOR OF THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION:

SIR:—That I might not assume to possess a monopoly in the collection of eccentricities in medical acquirements, a friend, not in the Navy, but a man of mark in the profession, too modest, however, to wish me to print his name, gave me, a few evenings ago, these additional evidences of that "regular medical education which is presumptive evidence of professional abilities and acquirements:"

"The *oracle* was full of black clots."

"diohrea."

"Ambrose Pare was a distinguished New York Surgeon," and

"Sore eyes," the phonetic guise in which *psoriasis* appeared on a formal medical record.

I quote them as fitting companion pieces to the following:

"the mad Stone that I hav advertised is as fine a one as I ever seen I hav no use for that one as I hav got one besides as it is useful to thos who has non when they need it it is as larg as 3 inches through and very wite addres ———."

I appeal to the members of the Association whether it is not the duty of every one of them to *pray*, if nothing else, that wisdom and courage may be given the Legislature of the State of New York to enact the law that will put that great commonwealth in line of battle with Illinois and West Virginia in the war against medical ignorance and incompetence, "regular" as well as irregular.

Very respectfully, your obedient servant,

ALBERT L. GIHON,
Medical Director U. S. Navy.

U. S. Naval Hospital, Washington, D. C., February 15, 1884.

FEBRUARY, 26, 1884.

EDITOR JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION:

Notwithstanding it was distinctly announced by yourself at the June meeting of the Association of 1883, that permanent members of the Association could not vote, except they were there as elected and duly certified delegates, holding credentials from

some one of the medical societies or associations known and recognized by the American Medical Association as legally organized bodies; there are some who still hold that a permanent member has an inherent right to an equal franchise with the certified delegates.

In the 2nd section of the articles or plan of organization, adopted and embodied in the Transactions twenty-four years ago, we find the following, which I think should settle this point, both in principle and in practice. It reads thus: "Permanent members shall at all times be entitled to attend the meetings, and participate in the affairs of the Association, so long as they shall continue to conform to its regulations, but without the right of voting." Now, the principle here involved is not only an important one, but a vital one. It was placed there, I conclude, and very wisely so, to protect every possible encroachment upon the fundamental principles underlying the plan and base-work of the Association from its first inception, as a *representative* body. And most certainly, were they allowed to take place, it would put a lever under the cornerstone of its base, which very soon would put a power where it would ultimately disintegrate, if not destroy its functions as a representative body.

Not long ago, the writer was conversing with a President of one of the State societies, who stated frankly that he had always voted in all the business transactions of the Association, and he thought he had a legitimate right to do so.

As no State society is likely to have its quota of delegates full, it is proper and right that every permanent member who intends to attend the meeting of the Association, should be furnished with proper credentials, and if he goes thus armed, he is ready for battle.

If we have a great, grand principle at stake, and underlying the base-work of our Association, let us by all means protect and support it.

D. H. B.

Providence, R. I., Feb. 26, 1884.

To the Editor of the Journal of the American Medical Association.

Sir:—Your correspondent, "Vindex," makes use of an argument much in favor among the advocates of the "New Code," when he refers to State statutes as defining "the meaning of the phrase—a regular doctor," and, therefore, by implication, compelling professional recognition of all sorts of "registered" practitioners. So persistently has this one string been harped upon, that some timorous minds seem to go in dread of undefined legal penalties for a refusal to consult with any casual ignoramus who may be certificated by a county clerk. And, as a matter of course, the controversy, as brought to the gaze of the general public, is made to serve as a platform, whereon to pose the martyred attidude of homœopathy.

In fact, the New York act has no more to do with consultations than with the parallax of arcturus. It merely prescribes that every person undertaking to obtain fees from patients must be registered in a county clerk's office, and the requirements for such registration are: either a diploma from some chartered college within the State, (be it homœopathic, lobelia-inflated "eclectic," "hygeio-therapeutic," or what not); a license from the censors of any county medical society, regular or irregular, under an act passed a few years ago; or the simple circumstance of having practiced medicine or surgery, with or without education or authorization, for ten years prior to the passage of the existing law. It is, therefore, evident that the "New Code" permits, if it do not ordain, consultations with the whole army of advertising charlatans, who have fleeced the public for more than a decade, and who, from the lego-technical point of view, are quite as much "legally qualified practitioners" as the disciples of Hahnemann. And, farther, if the State law be absolute in this respect, the converse of the proposition must be equally valid, and it must be a violation of the "New Code" to consult with Gross, or DaCosta, or others whom I could name, who are not "legally qualified" in the "Empire State."

The "tempest in a teapot" which has been raised over the code question—aside from the unfortunate publicity given to the professional wrangle—is as meaningless as it is illogical. In the first place, the partisans of irregular sects are as little inclined to ask our counsel, as we to give it, even if any possible benefit to the patient could result from a discussion of irreconcilably different views; in the second place, no law in this country can deprive a physician of his free agency to give or withhold his services. He may, as he sees fit, decline to attend a patient; he may, on purely personal grounds, refuse to consult with a practitioner whose medical orthodoxy is undisputed. If a "permissive clause" in the Code is to be discussed at all, let it be as an affair of personal inclination; not under the flimsy pretext of "conformity with State laws."

I am, sir, faithfully yours,

A New York Physician.

FOREIGN CORRESPONDENCE.

London, Feb. 7, 1884.

The Anthropological Society, at their annual meeting, had an entertaining paper read by Professor Flower, F.R.S., in which he dealt with the subject of ethnography, or the discrimination of race characteristics. Its importance to those who had to rule, he said, could hardly be overestimated in an empire like this, the population of which was composed of almost every diversity under which the human body and mind could manifest itself. The physical characteristics of race, so strongly marked in many cases, were probably always associated with equally or more diverse characteristics of temper and intellect. It was absolutely necessary, therefore, for the statesman who would govern successfully not to look upon human nature in the abstract, and endeavor to apply universal rules, but to consider the special moral, intellectual and social capabilities, wants and aspirations of each par-

ticular race with which he had to deal. A form of government under which one race would live happily and prosperously, would to another be a source of unendurable misery. When they had to deal with Egyptian fellahs, African negroes, American Indians, and Australian or Pacific islanders, it seemed almost impossible to find any common ground of union or *modus vivendi*. The mere contact of the races generally ended in the extermination of one of them. If such disastrous consequences could not be averted, they had it still in their power to mitigate those evils. All the questions should be carefully studied by those who had any share in the government of races alien to themselves, and a knowledge of them meant the happiness and prosperity, or the reverse, of millions of their fellow-creatures.

The air of sunny Italy is supposed to have a beneficial effect upon the voice; however, a new invention by Dr. Carter Moffat, a connection by marriage with Livingstone, is likely to give the *coup de grace* to Italian vocal supremacy. Dr. Moffat gravely proposes to introduce at our homes the chief ingredients of Italian air. He suggests to vocalists an instrument called the "ammoniaphone," which, he explains, contains an absorbent material saturated with peroxide of hydrogen, combined with condensed ammonia and other ingredients, through which a current of air is drawn into the lungs. The doctor calls this "highly concentrated artificial Italianized air." He tried it on himself for fourteen days; his chest expanded half an inch, and his voice, which had previously been weak, became a tenor of extraordinary range. The experiments continue, and the results are awaited with interest by his many friends.

Some three years ago a hospital was instituted at 16 and 17 Fitzroy Square, for the accommodation of persons suffering from acute diseases, who were in a position to pay for their medical attendance and maintenance. The institution was called a Home Hospital, and it has been found a "home" in the best meaning of the word by many who would, otherwise, have had to go through the expense and discomfort of an illness either in an hotel, in lodgings, or in one of the large public hospitals. Here, however, each patient finds neither the noise, general bustle, or absence of privacy of an hotel on the one hand, nor the damp sheets, slipshod attendance and great discomforts of ordinary lodgings on the other. It is now proposed to raise funds to open and maintain a branch Convalescent Home Hospital at some suitable spot in the country. At the present time, when a patient becomes convalescent and he is ordered change of air, it becomes a matter of extreme worry and anxiety in proportion to the serious nature of the attack from which he is recovering, and too often much ground is lost whilst a suitable neighborhood is being sought. The committee who are working out the present scheme propose to have appliances and conveyances adapted for the removal of the sufferer from his residence to their "home." The additional capital required is £10,000, contributors of 50 guineas or 20 guineas each become eligible for election as governors and members of the association with the privileges of obtaining (1) priority of admission for themselves and their families when ill and two nominations each year, if governors, and priority of admission for themselves only if members. It is thought, that, considering the advantages gained, the amount required will be soon subscribed.

The condition of the Mercantile Marine Medical Service is again attracting attention, especially the arrangements as to the Atlantic Service. At present too often the accommodation of the medical officers is most unsatisfactory, and where "hospital room" is supposed to be provided for the use of any of the passengers or crew requiring it, it practically exists in theory only. It is considered by those who know anything of the requirements of a large ship that it is high time that Government stepped in, and by act of Parliament compelled ship owners to provide good quarters for the medical officers and suitable accommodation in case of illness or accident. The pay of the service must be increased and the medical officers made answerable only to their department, not as at present, subject to every whim of the commander of the ship and to discharge upon the termination of each voyage, should he be considered too energetic by those on shore. It would be of advantage to all were the service made so that the medical officer should have an increasing salary according to length of service, so that the Mercantile Service would be a permanent pursuit, not, as at present, an affair of a trip or two.

The well-known botanist, Dr. I. H. Balfour, F.R.S., has just died at Edinburgh. He was late Emeritus Professor of Medicine and Botany in the University of Edinburgh. He wrote much on botanical science and stood high in public estimation. Professor Bayley Balfour, who was only on Saturday last elected to the chair of Botany, at Oxford University, is a son of Dr. Balfour, and assisted his father for eight years at Edinburgh. It appears during the past year 4,732 books were published. Theology heads the list with 794 volumes, and medical and surgical treatises 163. Thus medicine and surgery are only liable for one twenty-second part of the newly issued volumes for the year 1883 in Great Britan.

G. O. M.

NECROLOGY.

AMBLER, JAMES MARSHALL, M.D., late Passed Assistant Surgeon U. S. Navy. On Sunday, Feb. 24, a hero of the medical profession was buried. The body of the late Passed Assistant Surgeon James Marshall Ambler, M.D., U. S. Navy, was on Saturday evening conveyed from the Navy-Yard, Brooklyn, N. Y., where it had lain in state from the previous day, with three of his comrades of the Jeannette Polar Expedition, to the Pennsylvania railroad station in Jersey City, for the last stage in the long journey from the mouth of the Lena to its final resting-place near his place of birth in the mountains of Virginia, and left by the nine o'clock train, under the escort of the following officers: Chief Engineer George W. Melville; Surgeon Charles W. Gravatt; Passed

Assistant Surgeons George E. A. Harmon, James H. Gaines, Presley M. Rixey, and Walter McClurg, and Lieutenants Wm. H. Jaques, John Danenhower, and Wm. H. Scheutze. They were joined at Baltimore at six o'clock on Sunday morning by representatives from the Medico-Chirurgical Faculty of the State of Maryland, the Faculty of the University of Maryland, and the Clinical Society of Baltimore, viz: Professor L. M'Lane Tiffany, M.D., of the University, one of Dr. Ambler's instructors; G. Guy Holliday, M.D., his former associate in practice; James McHenry Howard, M.D., Ridgely Howard, M.D., and Henry Howard, Esq., of Baltimore.

The body was met at the Baltimore & Potomac depot in Washington at 8 o'clock by Medical Directors John M. Browne and Albert L. Gihon; Surgeons Wm. K. Van Reypen and Charles H. White, and Passed Assistant Surgeons Thomas H. Streets, Edward H. Green and Francis M. Nash, and transferred to the special train which had been tendered by the Hon. John S. Barbour, M. C. of Virginia, President of the Virginia Midland Railroad.

It left Washington at nine o'clock, and was joined at Alexandria, Va., by Messrs. Edward C. Marshall, of Alexandria and John Ambler, of Amherst Co., Va., cousins, and C. S. Taylor, Jr., of Alexandria, a classmate of Dr. Ambler.

The funeral train was received with demonstrations of respect at Manassas and other places along the route, and at 2 P. M. reached Markham, Va., where the body was placed in a hearse and covered with the Union Jack and the floral wreaths, which had been accumulating all the way from Siberia. The following officers acted as pall-bearers: Surgeon Wm. K. Van Reypen, U.S.N., Acting Chief of the Bureau of Medicine and Surgery; Medical Director John M. Browne, U. S. N., of the Museum of Hygiene; Medical Director Albert L. Gihon, U. S. N., of the Naval Hospital at Washington; Surgeon Charles H. White, U. S. N., of the Physiological Laboratory, Washington; Chief Engineer George A. Melville, U. S. N.; and Lieutenant John A. Danenhower, U. S. N.; the surviving shipmates of Dr. Ambler, Lieutenant Wm. H. Scheutze, U. S. N., who had brought his remains from Siberia, and Lieutenant William H. Jaques, U.S.N., representing the Secretary of the Navy.

The funeral procession was very long, the line of carriages being followed by several hundred of the residents of Fauquier County, mounted, among them many of Dr. Ambler's former comrades in Ashby's corps of Confederate cavalry.

The ceremonies took place at Leeds Episcopal Church, which was about five miles from Markham, midway between it and "The Dell," Dr. Ambler's former home; the services being performed by the Rev. H. B. Lee, a classmate of Dr. Ambler at the Washington and Lee University. After the funeral his only sister and two brothers received the officers of the escort in the vestry, his mother being prevented from attending by her age and grief.

After the grave was filled, it was covered by the Russian, German, and American floral offerings, forming a floral mound under which it was completely hidden.

The late colleagues of Dr. Ambler in the medical corps of the Navy, propose erecting a monument over his grave in the Leeds churchyard, and the medical Faculty of the University of Maryland will place a memorial tablet in their hall at Baltimore.

The following tribute to his memory is from the pen of an intimate friend and classmate, and recounts in fitting terms the story of his worth and heroism:

"To those who knew his worth no word is needed to perpetuate his memory, for he possessed in no common degree the various qualities that go to make the thorough man, and was thus apt to leave a firm impress upon the memory of those with whom he was thrown in contact. It is right, however, that those who witnessed yesterday's procession should know something of him who took so sad and silent a part, and that the memory of one whose life was surrendered under such appalling circumstances as was his, should not dwell in the hearts of his personal friends alone, but he fastened upon the minds of all who admire honor, bravery, and self-sacrifice at his country's call.

"Dr. Ambler was born in Fauquier county, Va., December 30, 1848, and came of a long line of good ancestral stock—the Marshalls, the Carys, and Amblers, names intimately and always honorably connected with the history of Virginia since her early colonial days.

"As to his early boyhood, which was spent at and about his mountain home, there was nothing—so far as the writer knows—of phenomenal precocity or special interest.

"While maturing into manhood, with the development of a fine physique and much manly grace the intellectual growth kept pace. His mind was comprehensive and he read much and read well, the books found about him always being of an elevating and improving character. The knowledge thus gained, together with a ready command of language and an unusually clear insight into human nature for one of his years, put him at ease in discussions on multifarious subjects. It also enlarged his views of life and increased the liberality of his ideas towards his fellow men.

"Though possessing more of the really manly attributes than are allotted to most, there was no obtrusive display of them—no affectation.

"In casting about for life's occupation he decided upon the medical profession, and graduated at the University of Maryland in March, 1869.

"On the 1st of April, 1874, he entered the naval service as Assistant Surgeon, and was soon after ordered to the United States steamer Mayflower. In 1874–5 he was attached to the United States steamer Kansas, North Atlantic station, and in 1876 was on board the United States training ship Minnesota. He was promoted to Passed Assistant-Surgeon in 1877. During that year and part of the next he formed one of the staff at the Naval Hospital, Norfolk, Va.

"While there he received a telegram from the Navy Department, asking if he would volunteer for duty on

the Jeannette, which was to be sent in search of a passage to the North Pole. Up to that time the idea of seeking fame among the frozen seas of the north had not been entertained by him; but, not wishing to have his name coupled with a refusal where hardship and probable danger were involved, he promptly accepted. This he certainly would not have done had he known, as he soon afterward learned, that the same offer on request had been declined by others. It presented, however, an opportunity for a display of that manly stuff of which he was made. He did not, for this reason, recede from the responsibility he had assumed, but unremittingly bent every energy to secure success to the enterprise so far as in his power lay, and to his painstaking examination as to the physical qualifications of the personnel of the Jeannette's crew, to his zeal and forethought in providing the necessities of life under the peculiar conditions to which the ship's company were to be subjected, and to his wise hygienic and sanitary suggestions, may be ascribed for the most part the vigorous health of the officers and men, enabling them finally to encounter unprecedented labor and exposure. The immunity from that terrific scourge of polar travelers, scurvy, in which the Jeannette expedition stands prominently alone, were there nothing else, should be a lasting memorial to his professional capacity and foresight. But the mouths of the survivors of that ill-fated expedition have opened to testify how grandly he arose to all emergencies. They portray him as the genial companion, the skilful surgeon, the accomplished physician and sturdy officer. Melville, when asked by the court whom of the expedition he would specially commend for his behavior, promptly replied, 'Dr. Ambler,' and he was unstinted in his praise of him. During the famous retreat over the ice Ambler was one of the leading spirits. He harnessed two half-starved Esquimaux dogs to a sled of his own contriving, on which were lashed the surgical instruments, medical stores and scientific records; and leaving them to follow in the rear with the sick, the doctor took his place in advance day after day, as chief of the roadmakers. He wielded a heavy sledge hammer like a Hercules, breaking down ice hummocks to level a road for the boats. It was related of him that he invariably, when the day's work began, took up the heaviest of the sledges, thus setting an encouraging example to the men. We see see him laying this down for a moment to perform an iridectomy, one of the most delicate operations in eye surgery. After De Long's boats had reached the Lena delta, and failing to find succor for three weeks or longer, the commander decided to send two of the strongest of his party in advance to seek aid. The main body travelled very slowly, most of them being scarcely able to walk at all, and having to transport the sick. De Long was able to walk only for five minutes at a time. Ambler was the strongest of the party, and the commanding officer selected him and Nindeman to go on ahead for succor and to save their own lives, if possible, both of them being capable of a long march. When this was communicated to the doctor, he told his commander that he thought he ought not to leave his sick, as he preferred to share their fortunes to the end, and his going away would look like abandoning them. This doubtless touched the gallant De Long, whose first thought seems ever to have been his high duty to those under his command. Noros was then sent in Ambler's stead, and his life was saved. Ambler remained with his sick comrades to the last, and died with them. It is doubtful if the medical profession affords anywhere a finer example of heroism than this. Imprisonment on board an ice-bound ship for twenty-two months, a painful retreat over weary miles of rough ice, with half-frozen hands and feet, and then wandering about on an unknown shore for three weeks, reduced to a mere struggle for existence, yet not for a moment was blunted his keen sense of professional duty. Melville, who found the bodies, is of the opinion that Ambler was the last one to die. His frozen body was found in a sitting attitude, clothed in many suits of extra clothing, seizing in his right hand De Long's pistol, taken from his dead commander's pocket; in solemn and faithful guard over his dead comrades. None will ever know the dreadful extent of his sufferings during those last hours, or possibly days, of his life, alone with his dead, starving, exhausted and hopeless. Faithful messengers sent by his grateful country have brought home the mortal remains of this noble son to an aged mother, to lie at rest in his own village churchyard in Fauquier county, Va. Peace to him and her, and honor to the memory of this noble surgeon, whose life was given to his country and his duty."

A. L. G.

BEARDSLEY, LUCIUS NICHOLS, M.D., was born in Monroe, Conn., Oct. 8, 1814; died at his residence, in Milford, Nov. 22, 1880. He commenced the study of medicine somewhat early in life under competent instructors, and finally entered, as a private pupil, the office of Dr. Eli Ives, of New Haven, then Professor of the Theory and Practice of Medicine. He was graduated as M.D. at Yale College in March, 1838, and settled in Milford, Connecticut, the same month.

Dr. Beardsley was early admitted into the New Haven County Medical Society, on several occasions was chosen dissertator, and was specially appointed to prepare an account of the dysentery as it appeared in the summer and autumn of 1844. This paper was received with marked favor. Dr. Beardsley was several times elected Fellow of the State Medical Convention, and also President of the New Haven County Society. The use of ether as an anæsthetic agent was discovered after his settlement in Milford, in which subject he took great interest, being among the first at that time to give ether a trial in minor operations. He was particularly desirous, as a matter of justice, that the unfortunate Dr. Horace Wells should receive the honor as the discoverer, This appears from resolutions read by him at the State Convention held at Hartford in 1853.

Dr. Beardsley was elected delegate from the State and County Medical Societies, and attended the sessions of the American Medical Association, first in 1853, then '55, '60, '63 and 1864.

At the meeting of the National Association in New Haven, in 1860, which was the only convention of the Society ever held in the State, Dr. Beardsley served as chairman of the Connecticut delegation, and was thereby largely instrumental in securing the nomination and election of his old preceptor, Dr. Ives, to the high office of President of the American Medical Association. At the next Convention of the Association, which occurred in Chicago, in 1863, Dr. Beardsley was again preferred chairman of the Connecticut delegation, and as Dr. Ives had died since the last gathering, an "in memoriam" was offered by him, which resolutions were commended and unanimously adopted.

For a period of twenty-five years Dr. Beardsley was a subscriber to the *Boston Medical and Surgical Journal*, and an occasional contributor to its columns. He pmblished a monograph, in that journal, of the diphtheria as it prevailed in Orange in 1859. This article was copied into a number of leading journals in the country and has already been received as authority on this disease.

In 1877, owing to failing health, he relinquished practice and sought by retirement and frequent sojourns in a southern climate to regain that vigor which a constant practice had taxed so severely, but his hopes and the expectations of a wide circle of friends could not be realized.

As a practitioner, Dr. Beardsley was possessed of a remarkable measure of common sense and cool judgment. To a habit of confirming premises and cautiously reaching conclusions is to be referred the weight that his persuasions carried in medical circles. His tact as an accoucheur was widely known.

As a scholar his acquaintance with general, as well as medical literature, was extended. He was quite proficient in rendering the Latin authors, and his zeal as a student led him to follow closely every new revelation of science, as well as to verify fresh suggestions or recent appliances in medicine or surgery.

Dr. Beardsley's wit was always refined and without malice. This, coupled with an ease of declamation and a fertility of expression, made him a popular speaker. In every gathering his voice was heard in the vindication of truth and progress. Like his deeds, his words were full of benevolence, and always loyal to his belief.

CHARLES H. PINNEY, M.D., of Com.

MISCELLANEOUS.

EXTRACTS FROM FRENCH JOURNALS.

TO THE MEDICAL RECORD.—*Le Médecin Moniteur de la Policlinique* takes up the first page of its six in an amusing article under the above heading: "There is published weekly at New York a medical journal entitled *The Medical Record*. This journal contains in each number twenty-eight to forty pages of advertisements of 200 lines each. It is a veritable cocoanut in which the enormous kernel, surrounded by its filamentous husk, only contains a small quantity of rancid cream. This journal, which we have often searched in vain for something worthy of reproduction, published in one of its late numbers an anonymous article entitled 'French Medical Journals.' This consists of a formal requisition against French science. For several years it has been the fashion among foreigners to discredit France, to criticise her politics, to speak with disdain of her armies, with contempt of her literature, with injustice of her savans. However, the great nations act with us, follow the evolution of our ideas, keep pace with our works, communicate theirs to us, and are proud to see their savans take part in our institutes and academies. The little countries, on the contrary, are jealous of us, detest us, and seem to reproach us for having been for so long a time their only scientific and literary guide.

"The former respectful attitude weighs upon their pride of to-day. The children become adults, seek to bite the great nation which gave them the breath of intellectual life. Listen to this Yankee of a *Medical Record*: 'At the present time, with the great excellence of American medical journals, it is hardly necessary for a practitioner to understand French and German in order to keep abreast of the time.' This is what might be called arrogance, Mr. Yankee. It is true that an admitted preëminence in beauty and clearness of style is given to French writers, but it is impressively added, this species of superiority is of little importance in a periodical literature, and it may be said that the greater part of French journals are the worst among civilized nations. They are for the most part made up of the documents of the Paris medical societies.' And with what, then, my dear, would you have us make up our journals? Our readers desire to be kept posted in science, physiology, and clinical medicine. What do you give yours to read independent of your forty pages of advertisements? You admit that one of the most attractive parts of our journals is the *feuilleton*, in which we exhibit much wit. We cannot say as much for you, for, as you well express it: 'While as for England and America, there has not enough wit appeared for some years to spoil a single doctor.' You are mistaken, my friend; your countryman, Dr. Tanner, has given proofs of great practical wit. He has gained many dollars in laughing at his confreres and the good American public. You have all been gulled (coupé dans la fumistène) with a naive enthusiasm which proves little in favor of your judgment. You have done a fine thing in calling Locke to your aid, and in making him say that the witty man cannot have a superior judgment, and consequently the French, being men of wit, cannot be great doctors. You have proved in many circumstances that you are neither one nor the other. And if you had an ounce of good sense you would be careful how you atacked French journalism, which has the great merit of having educated you. It is due to it that you have known the works of Bichat and of Lænnec; it is due to it that you have been able to read the clinical lectures of Bouillaud and of Rostan, of Trousseau, of Velpeau, of Nelaton, of Jules Guérin, of Charcot, of Peau, and of many others; it is due to it again that you have been able to familiarize yourselves with the great

discoveries of our physiologists, Claude Bernard, Flourens, and Pasteur. Poor people! You have dared to say, 'It has been said that a French surgeon or physician must make his *mot* in order to make his mark!' You then have forgotten that it is from these physicians and these surgeons that you have learned the little that you know; it is they who have polished you, who have allowed you to translate their works, and even to plagiarize from them without shame. It may be that the number of French journals is too great; 'that only those devoted to a specialty contain anything worth reading,' as you say; but it is not for you, Americans, to be permitted to reproach us—you, a people peculiarly practical and but little scrupulous. You ask us obsequiously for exchanges; you read us; you steal from us; and you turn upon us with injurious words. You are a people without education, without wit, without intelligence. You are still Redskins.

"*Note.*—It should be well understood that this refers not to the great mass of American citizens so sympathetic with France, but to certain rapacious Anglo-Germans, who steal from us while slandering us, and who have vowed a hate of race against us."

SANITARY CONVENTION AT HILLSDALE, MICH., under the auspices of the State Board of Health, arrangements having been made by a local committee of citizens of Hillsdale, acting with a committee of the State Board of Health.

Time and Place.—You are cordially invited to be present at the sessions of a Sanitary Convention which will be held in Hillsdale, Mich., on Thursday and Friday, April 17–18, 1884.

Sessions.—There will be sessions the first day at 2 P. M. and 7:30 P. M.; on the second day at 9 A. M., 2 P. M., and 7:30 P. M., standard time. At each session of the Convention there will be addresses or papers on subjects of general interest pertaining to public health; each paper to be followed by a discussion of the subject treated.

Officers of the Convention.—President—Hon. E. L. Koon. Vice Presidents—Hon. Charles M. Croswell, Adrian; Hon. Witter J. Baxter, Jonesville; Hon. George C. Willis, Moscow; Hon. Nathan Alvord, Camden; Hon. J. H. Bennett, M.D., Coldwater; Rev. Linus Parmalee, Reading; Hon. F. M. Holloway, Hillsdale; Prof. A. E. Haynes, Hillsdale; Hon. Charles S. Veeder, Hillsdale; Hon. M. McIntyre, Hillsdale; A. R. Smart, M.D., Hudson; Prof Napoleon Clark, Ransom. Secretary—Bion Whelan, M.D., Hillsdale. Assistant Secretary—Chauncey F. Cook, Hillsdale.

Admission.—The admission to all sessions of this Convention will be free, and the public are cordially invited. The invitation is especially extended to health officers to be present and take part in the discussions.

Objects of the Convention.—The objects of the Convention are the presentation of facts, the comparison of views, and the discussion of methods relating to the prevention of sickness and deaths, and the improvement of the conditions of living.

Addresses and Subjects to be Presented and Discussed.—An address by the President of the Convention, Hon. E. L. Koon. Among the subjects which it is expected will be presented and discussed are the following: 1. The Water Supply of Hillsdale. 2. Drainage and Sewerage. 3. The Disposal of Waste Matter. 4. Coöperation of Citizens in Preventing the Spread of Diseases. 5. The Sanitary Condition of School Buildings and Grounds. 6. How Best Fulfill the New Law Respecting the Teaching of the Effects of Alcohol, etc., in the Public Schools. 7. Ventilation. 8. The Preparation of Food. 9. The Adulteration of Food. 10. Public Health Laws. The papers are expected to be original contributions, which when read are to be considered the property of the Convention, and to be left with the Secretary. Programmes will be issued before the Convention.

Committee from the State Board of Health.—J. H. Kellogg, M.D., Battle Creek; Henry B. Baker, M.D., Lansing.

Local Committee.—A. F. Whelan, M.D., Chairman; Hon. Harvey B. Rowlson; C. C. Johnson, M.D.; Hon. F. M. Stewart; R. A. Everett, M.D.; Hon. Charles S. Veeder; Chauncey F. Cook, Esq.; Rev. M. S. Burnham; C. I. King, M.D.; Prof. A. E. Haynes; Rev. J. M. Barkley; John W. Falley, M.D.; L. A. Goodrich, PH.C.

Reduced fare on railroads may be obtained by applying to the secretary of the Convention, for certificates to be presented to local ticket agents. For further information address Bion Whelan, M.D., Secretary, Hillsdale, Mich.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department United States Army, from February 22, 1884, to February 26, 1884.

Brown, Joseph B., Lieutenant-Colonel, and Billings, John S., Major, Surgeons, directed to attend the International Health Exhibition in London, and, as delegates, the International Medical Congress at Copenhagen, to be held in May and August respectively; also to include Berlin in their route to and from Copenhagen, and to be governed by special instructions from the Surgeon-General in complying with this order. (S. O. 44, Par. 8, A. G. O. Feb. 21, 1884.)

Woodward, Joseph J., Major and Surgeon, leave of absence still further extended six months on account of sickness. (S. O. 44, Par. 11, A. G. O., Feb. 21, 1884.)

Horton, S. M., Major and Surgeon, having reported at these Headquarters from leave of absence, ordered to Fort Hays, Kansas, for duty. (S. O. 40, Par. 2, Hdqrs., Dept. Mo., Fort Leavenworth, Kan., Feb. 20, 1884.)

Patyki, Julius H., Captain and Assistant Surgeon, leave of absence extended for one year on Surgeon's certificate of disability, with permission to go beyond sea. (S. O. 43, Par. 9, A. G. O., Feb. 20, 1884.)

Maddox, T. J. C., First Lieutenant and Assistant Surgeon, assigned to temporary duty at Meyer's Springs, Texas. (Per Post Orders, No. 27, Par. 1, Fort Clark, Texas, Feb. 13, 1884.)

Dietz, Wm. D., First Lieutenant and Assistant Surgeon, assigned to temporary duty at U. S. Military Academy, West Point, N. Y.

Phillips, John L., First Lieutenant and Assistant Surgeon, assigned to temporary duty in Dept. of the East. Mearns, Edgar A., First Lieutenant and Assistant Surgeon, assigned to duty in Dept. of Arizona. Kneedler, Wm. L, First Lieutenant and Assistant Surgeon, assigned to duty in Dept. of Dak. Black, Charles S., First Lieutenant and Assistant Surgeon, assigned to duty in Dept. of Texas. (S. O. 46, Par. 1, A. G O, Feb. 25, 1884.)

Changes in the Medical Corps of the Navy for the Week Ending March 1, 1884.

Assistant Surgeon H. W. Whittaker, from the "Portsmouth," and on sick leave.

P. A. Surgeon E. H. Green, from Museum of Hygiene, and waiting orders.

OFFICERS OF

THE AMERICAN MEDICAL ASSOCIATION

AND OF ITS SEVERAL SECTIONS 1883–4.

PRESIDENT.

Dr. AUSTIN FLINT, SR., of New York.

FIRST VICE-PRESIDENT.

Dr. R. A. Kinloch, Charleston, S. C.

SECOND VICE-PRESIDENT.

Dr. T. B. Lester, Kansas City, Mo.

THIRD VICE-PRESIDENT.

Dr. A. L. Gihon, United States Navy.

FOURTH VICE-PRESIDENT.

Dr. S. C. Gordon, Portland, Maine.

PERMANENT SECRETARY.

Dr. Wm. B. Atkinson, 1400 Pine St., Philadelphia.

TREASURER.

Dr. R. J. Dunglison, Philadelphia.

LIBRARIAN.

Dr. C. H. A. Kleinschmidt, Washington, D. C.

Place of meeting, 1884, Washington, D. C.; Time of holding meeting, first Tuesday in May.

CHAIRMAN COMMITTEE OF ARRANGEMENTS.

Dr. A. Y. P. Garnett, Washington, D. C.

ASSISTANT SECRETARY.

Dr. D. W. Prentis, Washington, D. C.

BOARD OF TRUSTEES FOR JOURNALIZING THE TRANSACTIONS.

Drs. J. M. Toner, Washington, D. C., President;
M. Moore, Rochester, N. Y.; Leartus Conner, Detroit, Mich.;
J. H. Packard, Philadelphia, Secretary;
H. F. Campbell, Augusta, Ga.; A. Garcelon, Lewiston, Me.;
P. O. Hooper, Little Rock, Ark.;
L. S. McMurtry, Danville, Ky.; J. H. Hollister, Chicago, Ill.

OFFICERS OF THE SECTIONS:

"Practice of Medicine."

Chairman—Dr. John V. Shoemaker, Philadelphia, Pa.;
Secretary—Dr. W. C. Wile, Sandy Hook, Conn.

"Obstetrics and Diseases of Women."

Chairman—Dr. T. A. Reamy, Cincinnati, Ohio; Secretary—Dr. J. T. Jelks, Hot Springs, Ark.

ORIGINAL ARTICLES.

RAPID LITHOTRITY OR LITHOLAPAXY, ITS LATER IMPROVEMENTS AND ITS PRESENT CONDITION.

BY EDMUND ANDREWS, M.D., LL.D., PROFESSOR OF CLINICAL SURGERY IN CHICAGO MEDICAL COLLEGE; SENIOR SURGEON OF MERCY HOSPITAL, ETC.

Lithotrity at one sitting, as planned and developed by Prof. Bigelow, has revolutionized the treatment of vesical calculus. Those most familiar with this method will agree with me that it is destined not only to supersede the slow lithotrity, but to abolish lithotomy itself in forty-nine fiftieths of the adult cases. I have now performed this operation eighteen times with only one death, though the patients averaged nearly sixty years of age, and the stones were mostly very large. In one of the successful cases the crushed fragments weighed two ounces and five drams, and the patient was about 70 years of age. No such success could have been obtained by cutting on such unpromising cases.

Passing by as irrelevant the unpleasant personal controversy between Prof. Bigelow and Sir Henry Thompson, a few words are proper respecting the newly coined word, litholapaxy. By the laws of literature, Prof. Bigelow is not entitled to inflict upon us a new technical term for a mere modification of an old operation, however valuable he may prove it; yet there are some special advantages in the new word, which will probably cause it to be permanently retained. The terms lithotomy and lithotrity by their close resemblence in sound, are an annoyance to every clinical lecturer, as well as to every one of their listeners.

Having frequently to be used in the same discourse they require a vexatious care in both speaker and pupil to prevent one word being mistaken for the other. Litholapaxy, on the contrary, is easily distinguished from lithotomy, and is moreover a smooth and agreeable word to speak, so that by its own merits it will doubtless cling to the new operation, while the old word will become obsolete with the old method.

Litholapaxy is from the Greek *lithos*, a stone, and *lapaxis*, evacuation. The latter word in Greek usage generally refers to evacuation of the bowels, but, like the corresponding English term is not necessarily limited to that meaning, and signifies evacuation of anything.

The first step towards this operation is of course an instrumental demonstration of the presence of a stone by the process of sounding. This operation, as performed with the old instruments, was sufficient to detect stones of ordinary size; but in cases of very small calculi, or in searching for the last minute fragments during the operation of litholapaxy a more delicate apparatus is required. To meet this necessity I devised in the year 1877 an attachment to the ordinary searcher, by which I was enabled to detect by the ear the smallest bit of calculous matter. The apparatus was shown to the Illinois State Medical Society in 1878, and figured and described in the Society's Transactions of the same year (p. 254). In the form there depicted the instrument consists of a light, hollow searcher, having a small rubber tube and ear piece attached. The searcher being introduced into the bladder, and the ear piece placed in the surgeon's ear, the slightest contact with sand or grit becomes distinctly audible. Having subsequently discovered that a solid searcher transmits the sound as well as a hollow one, I modified the plan and appended a small clamp screw to the rubber tube, by which I could attach it at pleasure to any metalic sound whatever.

Figure 1 shows the apparatus clamped to Sir Henry Thompson's searcher. I have one with two tubes attached for the purpose of increasing the intensity of sound by the binaural effect, as well as to assist clinical instruction by enabling two students to listen to the sound at once.

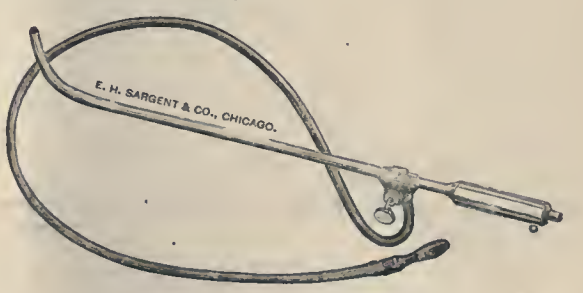

Fig. 1.—The author's Auditory Searcher.

A considerable period after this was published in the Transactions of the Illinois State Medical Society, the London *Lancet* described substantially the same device, naming it a lithophone, as a new invention

of an English surgeon, though it had been published here long before, and had been publicly used for years in Chicago clinics.

The scarch of the bladder, to be thorough, must be made with at least two forms of instruments, viz.: the ordinary searcher with a short beak, which can be rotated backward to explore the *cul-de-sac* behind the prostate, and the one with a very long beak to reach the front of the bladder near the pubis. I often clamp the tube to a simple britannia metal sound capable of being successively bent into several different curves as the case may require. Contrary to one's natural supposition, this soft metal conveys sound almost as well as steel. The auditory sounds are manufactured and sold by E. H. Sargent & Co., of Chicago, to whose enterprise and kindness I am indebted in the construction of many other new forms of apparatus made at my request.

I have practiced for some years another innovation, which I consider of still more importance, though I am unable to say whether I have any priority over others in that respect. I refer to the great value of using warm carbolized water during the whole operation of litholapaxy, both to distend the bladder during the crushing, and to wash out the fragments afterward. Carbolized water acts as a decided local anæsthetic, benumbing the nervous activity of the bladder, and seeming to me to greatly lessen the shock of prolonged operations; besides, it checks bleeding, and leaves the viscus in a thoroughly antiseptic condition, preventing the formation and the putrefaction of pus, and acting as a very powerful local antiphlogistic. I use it in the strength of about 1½ per cent., and am satisfied that it greatly lessens the danger of all operations in the bladder.

Prof. Bigelow demonstrated the fact that the bladder will tolerate with impunity much larger instruments than those heretofore used, and that the large lithotrites enable us to comminute the stone in a shorter time and with fewer movements than small lithotrites. This advantage is still further enhanced by employing very large wash tubes, which, letting out large fragments of stone, greatly diminish the amount of crushing required.

The beak of the new instrument of the usual size is shown in Fig. 2. Smaller ones are made, however, for special cases.

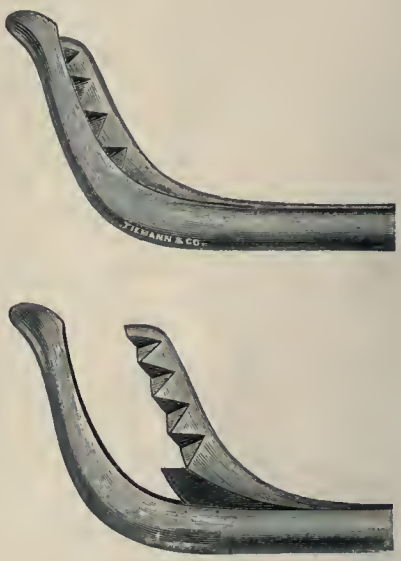

Fig. 2.—Jaws of Bigelow's Lithotrite.

The extra curve at the tip is made to facilitate the introduction through the prostatic portion of the urethra.

Fig. 3 shows the handle at one-half the actual diameter.

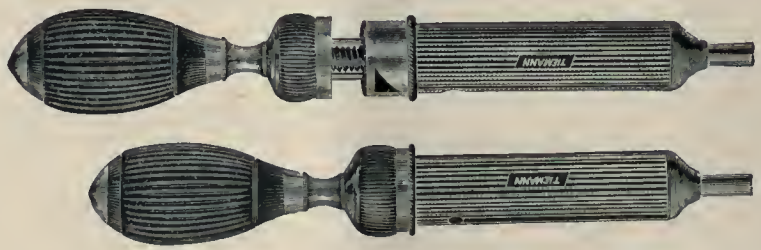

Fig. 3.—Handle of Bigelow's Lithotrite.

More important than his changes in the lithotrite are Prof. Bigelow's improvements in the evacuating instruments. This part of the apparatus was previously in such a wretched condition, that it had very little value, and many of the best lithotritists declined to use it, preferring to let the fragments of stone escape naturally with the urine. As before remarked, Prof. Bigelow greatly enlarged the evacuating catheters, some of them reaching No. 18 of the English, or 32 of the French scale, whereas the previous ones rarely exceeded 11 or 12 English, or 21 to 24 French. He also changed the form, making some straight and others curved, and all of them with a peculiar fenestrum, adapted to enter without scraping the urethra,

Fig. 4.—Beaks of Bigelow's Evacuating Catheters.

and yet to give exit to the largest possible fragments. Not every urethra will admit these great instruments, hence smaller ones must be kept at hand; but in the great majority of adult cases, they pass without difficulty, after slitting the meatus a trifle with a blunt-pointed bistoury.

The evolution of the "wash bottle," as Clover called it, or the "evacuator," in Bigelow's language, constitutes quite a history. Fig. 5 shows a French evacuator, of a complicated and inefficient sort. As it has no practical merits, it may be dismissed without description.

Fig. 5.— French Evacuator.

The apparatus of Sir Philip Crampton was simpler, but no better. It is shown in Fig. 6, and needs no special attention, as it is hopelessly obsolete.

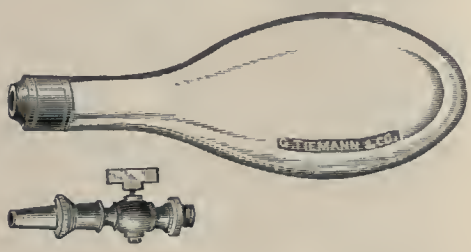

Fig. 6.—Sir Philip Crampton's Evacuator.

For a considerable time the standard evacuator was that of Mr. Clover, of London. His first one (Fig. 7) consisted of a pear-shaped rubber bulb attached to

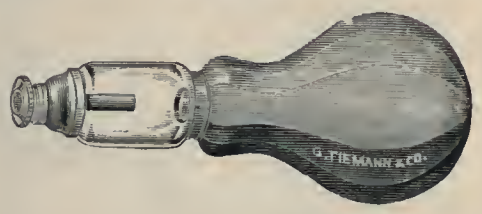

Fig. 7.—Clover's First Wash Bottle.

a glass bottle, into which a tube passed for half its length, to which tube catheters of the size of No. 12 English scale were attached. I found this apparatus very faulty, on account of the fact that a large portion of the fragments of stone drawn into the glass receiver would be swirled back again into the bladder at the next compression of the bulb. Moreover, the rubber was too weak for strong suction, and the cath-

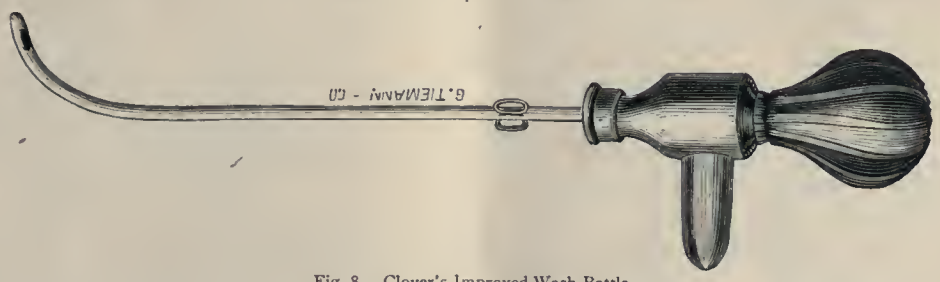

Fig. 8.—Clover's Improved Wash Bottle.

eters were too small. Clover's improved form aimed only to remedy the throwing back of fragments into the bladder. This he attempted by having a trap attached to the side of the glass receiver, into which the fragments might fall and be securely retained (Fig. 8). This plan was better, but still the catheters were too small, and the bulb too weak.

When Prof. Bigelow began to bring out improved evacuators, Sir Henry Thompson appears to have abandoned Clover's instrument, and to have made a series of improved forms, more or less in imitation of those of the Boston surgeon. His earliest one is shown in Fig. 9. F is a funnel for filling the bulb; C, the glass trap for fragments; D, a stop-cock; and B, the catheter. One of its merits was the shortness of the route from the bulb to the catheter, which left but little space for fragments to lodge half way out, where they would be again washed into the bladder. Thompson was soon dissatisfied with this, and produced another, shown in Fig. 10, having a larger trap, and a stop-cock to retain the fragments after they entered it.

Still further changes were now made by Sir Henry, and by Mr. Weiss, resulting in the form shown in Fig. 11.

In this apparatus the trap for fragments was removed from the base of the bulb and placed between the latter and the catheter. I have not used this form, but while it is evidently better than Clover's wash-bottle, the new position of the trap seems to me of doubtful value.

Bigelow saw at the outset the necessity of a better evacuator than Clover's, or any preceding one, and he set himself to the task of its production with such good purpose, that every form since devised, is either a mere modification of his, or at best strongly marked with his ideas. Fig. 12 is his earliest form.

1. is a strong rubber bulb, 2, a rubber tube, 3, 4 and 5 are the catheters, and 6 is the trap for fragments.

Fig. 13 represents a stand which received the glass trap, and held it upright whenever the surgeon wished to set it aside. I have used this evacuator consider-

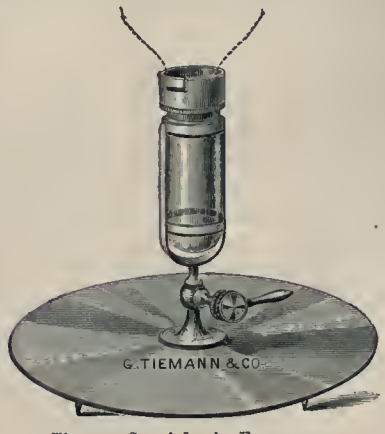

Fig. 13.—Stand for the Evacuator.

ably, and value it so much that I still keep it by me at all operations as a reserve, in case any accident should disable the one more commonly used by me. It had, however, two defects. In the first place the rubber tube, 2, is liable to become flattened a little by the curvature, or even decidedly kinked, so as to obstruct the passage of fragments. To prevent this, I have had the arch of the tube replaced by a metallic one of the same diameter, and only retain

an inch or two of rubber to make a flexible junction with the catheter. This makes a very effective instrument, but there still remains a defect. The longer the tube leading from the bulb to the bladder, the more fragments will remain in its bore, half drawn out, at the termination of each expansion of the bulb. All such fragments are driven in again at the next compression of the bulb. Hence it is better to have a shorter connection, and this led Bigelow, after some intervening efforts, to adopt the form shown in Figs. 14 and 15. In this plan the stopcock and tube enter the bulb obliquely below the middle. The tube is continued upward and inward to the middle of the bulb, and is there perforated in such a way as to arrest any swirling fragments which may approach it, but do not happen to strike into the very extremity of the tube. As there is always some blood in the bladder in this operation, the fibrinous clots very quickly catch in the perforations of the tube, so that in a few moments it is covered with them, and renders it no better than one not perforated. However, this seems scarcely to injure its action, and besides it can be unshipped and cleaned in

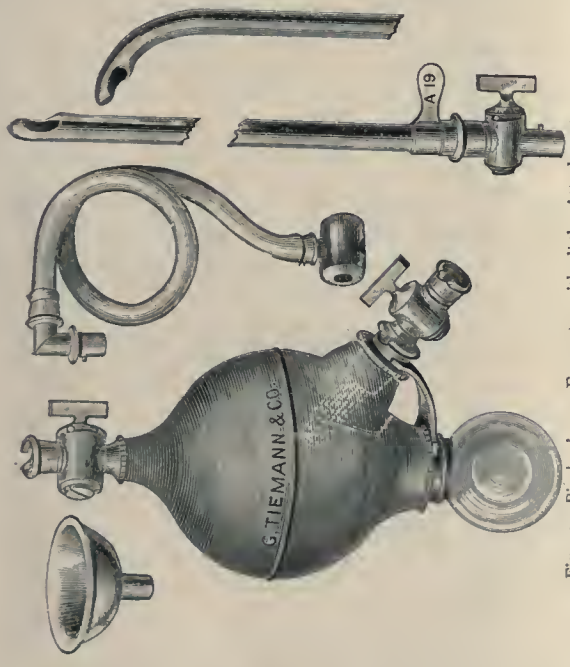

Fig. 15.—Bigelow's new Evacuator with all the Attachments.

a moment by an assistant. It is, perhaps, doubtful whether the perforations are of any use, for while they prevent some bits of stone from going back into the bladder, they render the suction current slower in the perforated part of the tube, and thus leave some fragments still in the tube at the end of the expansion of the bulb, and these pieces are of necessity at the next compression driven into the bladder again. The perforations, therefore, act both ways, and perhaps do as much harm as good. Sir Henry Thompson objects to them. On the whole this is a most excellent evacuator. It has an evil, however, that when filled it is heavy, and being fixed firmly in the catheter, it is more difficult to handle the latter delicately, so as to cause the minimum of irritation to the bladder, than when the catheter has a flexible connection. There has no way been yet devised to combine all the benefits, and at the same time exclude all the evils of stiff and of flexible connections.

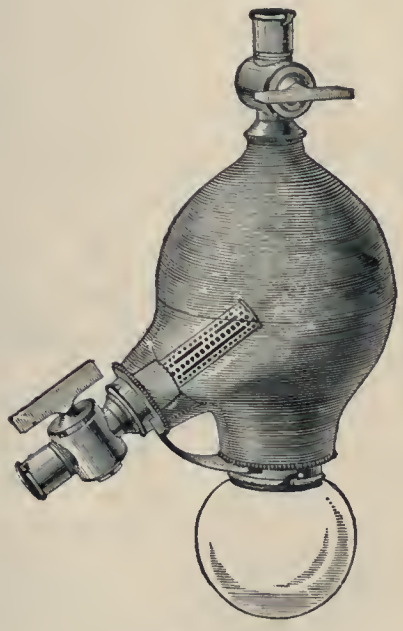

Fig. 14.—Bigelow's new Evacuator.

Much may be done by good management to diminish the throwing back of fragments into the bladder. These are mainly pieces left lying in the tubes when the current ceases at the close of each expansion of the bulb. It the surgeon commences his evacuating with the bladder nearly empty and the tube full of carbolized water, he will be able to press strongly and pass the water nearly all out of the bulb without injuriously distending the bladder. This gives a long suction, as the bulb expands again, and leaves fewer fragments in the tube than when numerous short, jerky compressions and expansions churn a little fluid to and fro in the catheter.

Prof. F. N. Otis, of New York, published in the *Medical Record*, of Nov. 3, 1883, a new form of evacuator, which is shown in Figs. 16 and 17.

I is the rubber bulb, intended to throw air instead of water. Through the rubber tube H it drives air along the metallic tube G into the top of the glass reservoir A. To the bottom of the reservoir is attached the trap F for retaining the fragments of stone. The reservoir A contains only three fluid ounces. From near its bottom the metallic tube B curves upward and outward, and is connected by a short rubber tube with the stop-cock and catheter C. To prepare it for use, Prof. Otis directs to invert the apparatus, take off the trap F, fill the bulb A with water, replace the trap, and then to return the evacuator to its regular position. As the trap holds an ounce and a half, it will now receive that amount from the glass reservoir, leaving only an ounce and a

half in the latter. The catheter being connected and inserted into the bladder, the rubber bulb is compressed by the hand, driving air through the tube H G into the top of the glass reservoir A. Here it presses down on the top of the water, forcing it to run through the tube B. and the catheter C, until the water in the reservoir sinks to the level of the inner end of tube B. Then the elastic bulb being allowed to expand, it sucks the air out of the glass reservoir A, and thus forces the water in the bladder to rush through the catheter and fill the vacuum sweeping the stony fragments along, and dropping them into the orifice of the trap F. There is, however, just here an apparent difficulty, which Prof. Otis' description does not explain. As before said, when the apparatus is filled, only three ounces of water are put in, and of this one-half runs into the trap, leaving only an ounce and a half in the glass reservoir A. Of this ounce and a half, nearly or quite half an ounce must lie below the inner orifice of the tube B, so that only an ounce can be driven into the bladder, and the same quantity drawn out again. Now, the catheter and tube C, if of full size, will hold a full ounce. It follows that the one ounce of suction provided for will simply draw up from the bladder about enough water and gravel to fill the catheter and connecting tube,

Fig. 16.—Prof. Otis' Evacuator in working position.

and then, the current ceasing, the fragments will remain where they are, until the next compression of the bulb drives them all down again into the bladder. After considerable experience with evacuators of several sorts, I am more and more impressed with the superiority of those which produce the largest currents of the longest possible continuance. The churning of a single ounce of water up and down the catheter would obviously be a total failure in its results. There must be something in the apparatus or

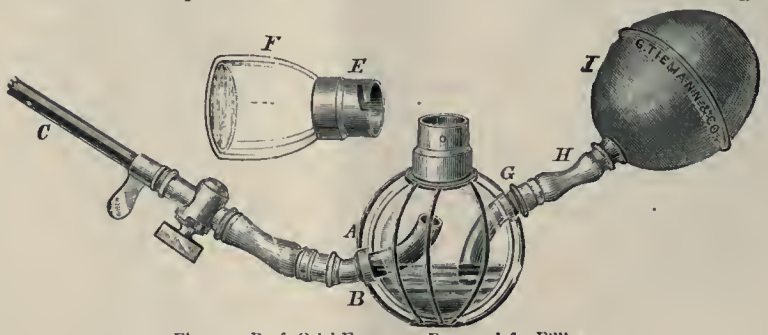

Fig. 17.—Prof. Otis' Evacuator Reversed for Filling.

in the method of using it, which the inventor has not explained in his article, or else it will disappoint his expectations.

Prof. Otis suggests that if one chooses he can dispense with the air in the bulb, and fill the whole machine with warm water. This seems to me a much better plan than the other, for it permits one to use the entire expansibility of the bulb I at each stroke, and thus, by producing currents of a longer duration, draw the fragments more thoroughly out of the catheter into the reservoir.

One of the agreeable surprises of litholapaxy is to note how little shock follows an operation of even an hour and a half duration, when performed in carbolized water. Generally the recovery of the patient is far more rapid, and the danger in adults far less than in lithotomy.

It is probable that in litholapaxy there is a little greater liability to leave behind minute fragments, than in lithotomy, but with the delicacy of search obtained by using the auditory sound, the difference is not great. After the first effects of the operation are over, the patient should be gently and repeatedly searched, and if any bits of calculus have remained, they are easily and quietly picked out in the presence of carbolized water, without much more disturbance than accompanies the passage of a catheter. For such purposes small instruments are always used, and there is no shock nor inflammation produced by these supplementary searches.

On the whole, it is safe to say that Prof. Bigelow's ideas have revolutionized the whole treatment of calculus in adults, leaving only a few peculiar cases proper for the use of the knife, but in children lithotomy will still be necessary in the majority of cases. Litholapaxy, however, is preferable even below puberty in a few cases, where the stone is quite small and the child is twelve or more years of age. In these cases of course smaller instruments must be used, but the danger of lithotomy before puberty is so slight that it leaves little need to desire any improvement in the methods of operating on young children.

No. 6 Sixteenth st., Chicago.

THE EFFECTS OF SANITATION UPON THE ORGANS OF VISION.

BY W. R. AMICK, M.D., CINCINNATI, O.,
Professor of Ophthalmology and Otology in the Cincinnati College of Medicine and Surgery.

It does not require the mind of a sage, nor the intellectual reasoning of a philosopher, to know that all effects have their causes; that disease is the cause of death, and that there is a cause for disease.

In speaking of the diseases of special organs from a sanitary platform, it is necessary first to make some general remarks. This becomes necessary especially when at least a part of those diseases are a secondary manifestation, due, however, to the same cause that produced the primary constitutional disturbance. Acting in this manner, the effect might become manifest through the system upon the kidneys, and afterward vision becomes impaired by the implication of the optic nerve and retina.

Medical science has made a grand march in the last decade. The unknown is becoming known. Many things that were buried in darkness and obscurity, now become visible when the light of science is concentrated upon them by means of the microscope. It has shown that epidemic, and even endemic and sporadic diseases, are produced frequently, if not generally, by some form of animalculæ. Then, this being the case, the question arises, What conditions are necessary for the production of these germs? If they can be discovered, then the next question is, Can they be destroyed or prevented from developing?

These questions bear the impression that it is more important to discover and remove the cause of disease, than it is to cure it after it has become manifest in the system.

Filth, in its various forms, is probably the chief factor in developing the germs of contagious diseases.

In decomposition of vegetable and animal matter, we have the effluvia arising from the decaying mass mingling with the oxygen of the air, which imparts vitality or life when submitted to the caloric rays of the sun, which rapidly converts it into carbonic acid gas, and in this is generated the germs. Their numbers are legion, and their size so small that, according to Zell, those contained in a single cup of putrid water would outnumber the population of the globe. These germs are transmitted from one place to another, either by the atmosphere or by fomites.

If the filth is located in cellars or subterranean passages, where there is no ventilation, then the effluvia arising from this process of putrescence, mingling with the confined atmosphere, produces the mephitic air which leaves disease and death in its wake.

The ancient Romans invoked the aid of this mephitic sibyl to ward off diseases, especially those of a malarious origin. But if the effluvia of decomposition gives birth to germs or poisonous gases, and they in turn produce disease, then it is evident that we will have to invoke the aid of antiseptics, disinfectants, germicides, and cleanliness.

It is not the intention of this article to speak of the general use or mode of applying these agents, except to a limited extent.

Ophthalmia neonatorum is frequently supposed to be due to a vaginal discharge existing at the time of the child's birth. This discharge may have been caused by contact with matter containing some of these germs. If so, then, as they multiply very rapidly, we will find large numbers of them in every drop of the purulent secretion. Some of this virus getting into the infant's eyes, will produce the disease. In order to prevent this, after the child's face has been carefully cleansed, the eyelids should be bathed with a solution of hydrarg. bichlor. gr. 1 to aqua oj., and a few drops allowed to pass into the eye. This, if properly used, will, in the majority of cases that have been exposed to this source of contagion, prevent the development of the disease.

Public hygiene in a country like this involves the enactment of certain laws, by means of which the safety of the community in general may be protected against the errors or the omissions of a few. It especially aims at the prevention of contagious or communicable diseases by the removal of avoidable causes. The people must be taught that a great many diseases can be avoided by resorting to the proper measures, and that knowing their duty and then neglecting to do it, they are responsible for the consequences.

Personal cleanliness and the avoidance of all excesses is the cardinal principal of health preservation.

Anything that would produce disease in one of the organs would, to that extent, be productive of inharmony. Anything that will prevent an organ from adding its portion to the general welfare of the system, interferes with the machinery of the economy. Not only that, but if an organ becomes diseased it not only does not add its *pro rata* for the maintenance of the system, but perverts the action of others. As the most perfect condition is produced by the united influence of all the organs acting in harmony, it is not only desirable that this state should be obtained, but maintained.

If the inhalation of the exhalations from decaying animal and vegetable material has a tendency to produce disease in any organ of the body, then it is detrimental to the system, and should, if possible, be prevented.

Filth, by accumulating upon the surface of the body, will prevent the normal function of the integument, and may be the cause of disease without pro-

ducing or developing microbes or animalculæ, but by compelling the system to retain mephitic products that should be cast off.

In tenement houses poverty and filth, apparently at least, go hand in hand. The children are unkempt and unwashed, and the exhalation from their bodies and clothes has a nauseating odor. The same delectable smell will sometimes greet the olfactories in every room of those buildings. Frequently this condition arises from carelessness and negligence.

We can conceive conditions where humanity is begrimed and saturated with dirt, and even filth, and not be able to remove or prevent it. Such a condition might exist especially in a prison.

But the ordinary dweller in a common tenement house has no excuse, but they are dirty and filthy, because they want to be so, or else they are unwilling or too indolent to test the efficacy of soap and water.

"As the twig is bent the tree is inclined," is an adage that is as old as the hills. As these tenement house children are reared in squalor and dirt, when they get older they do not depart from it, but follow in the footsteps of their parents. When an epidemic makes its appearance we find the largest number of cases and the greatest mortality in the filthy districts. Evidently then, there is a *something* in filth that invites disease, especially of the contagious epidemic form, to come in and take up its abode. I might also add that disease generally accepts the invitation.

In a given case a filthy neighborhood may be so poor that actual want of the necessities of life is an appreciable cause of disease. In another case the population may be so badly quartered in certain conditions, which by themselves would not be called unsanitary, yet may be so over-crowded in their apartments, or be living in such close-built houses, that this has to be taken as a cause that will produce disease.

A filthy neighborhood means an unsanitary condition; an unsanitary condition means a lowering of the powers of nature; a lowering of the powers of nature means less resistance against disease, and less resistance means a greater liability to contract any contagious malady.

This unsanitary depression not only places the system in the most favorable condition for the reception of the various diseases that wander around over the earth, but it engenders follicular hypertrophy of the conjunctiva. This condition may remain passive for an indefinite length of time, and may even disappear with favorable environments. But, as this is one of the products of a poor hygienic condition, it is not impropable to suppose that a large number of such persons are in this condition. As the fuel is already arranged, all that is necessary to have an outbreak of this disease is to apply the torch. Exposure, or a drop of a specific virus coming in contact with the conjunctiva of one of these eyes, will act as the torch to start the fires of inflammation that will spread from one person to another, until all that are susceptible will be attacked.

Children, under the same conditions, are even more liable to this disease than adults. This form of ophthalmia used to be the dread of armies, and the scourge of pauper schools, and houses of refuge.

It might be interesting to know whether the germs are transmitted from one person to another, and if so, if direct contact is absolutely neceessary.

The eye is an amphibious organ, part of the time immersed, so to speak, in a fluid, and then exposed to the atmosphere. Anything that will produce an irritation or inflammation of the conjunctiva not only increases the natural fluid secretion, but creates a new and abnormal one. This abnormal secretion is generally purulent in this form of ophthalmia. In this purulent discharge there are bacteria or germs. These are thrown into the atmosphere by evaporation from the eye-ball and lids, or by passing through the tear-channels into the nose, and are carried off during the acts of respiration. They then float around in the air, and if in ill-ventilated and poorly arranged apartments, they rapidly increase in number, so that it becomes an easy matter for some of them to come in contact with the eyes of other persons who may be present. If the eyes thus exposed have been prepared by the process already described, then the abundant crop of purulent ophthalmia will show that good seed was sown upon favorable soil.

Infants and children whose mothers have to leave home and work during the day, may suffer from disease simply from neglect and the want of proper management. An infant cannot take care of itself, and its natural tendency is to get dirty. If allowed to remain a sufficient length of time in this condition, the natural accumulation of foreign material upon the integrument not only weakens the powers of nature by closing up the avenues through which equilibrium of secretion and excretion is to be maintained, but it actually develops disease.

By closing the respiratory avenues of the skin, the system is compelled to retain mephitic products that should be cast off. These, by acting on the brain and nervous system, may produce a functional disturbance which will involve the accommodative apparatus. This may be followed by hypermetropia, and when the child gets old enough to use the eyes for regarding near objects, such as looking at letters, reading, etc., one eye will squint inwards, and as an ultimate result or effect, we have convergent strabismus or "cross-eyes."

Again, in filthy districts where the foul air which exists in alleys and streets can act with the greatest force on the inhabitants; such localities always show an increased mortality rate. The increase of mortality affects all ages, but especially the young. In a locality of this kind, if the ordinary diseases of childhood prevail, such as measles, scarlatina, etc., we find, first, that the mortality is increased, and, next, that the conjunctivitis of the former is more marked, the congestion greater, and more liable to produce inflammation or ulceration of the cornea. Chronic conjunctivitis or granulated eyelids are more apt to follow. In the latter class of cases, dullness of vision from uræmia, inflammation of the retina with a deposit of albumen, optic neuritic, and asthenopia, or a weak and irritable condition of the eyes, are among the consequences.

The organs of the body are better if they are exercised in a proper and judicious manner. Complete and continued idleness and relaxation begets disease. The eyes are no exception to this rule. Perfectly formed and normal eyes should perform their work without producing any unpleasant sensations. The best test is that we perform our work forgetting that we have organs of vision, This can very properly be taken as the guide by which to regulate the amount of work that they can perform. There is a very wide range in this respect, and what would not injure some eyes in the slightest degree, might produce fatal disease in others. Some who have good vision injure it by deliberate and rash usage, which is the result of over-confidence.

One person will say to another, "I have very strong eyes, and can look at the sun with them." He will demonstrate this to his companion by allowing the bright rays to pass directly into his eyes for a few seconds. However, he is liable to pay dearly for his experiment, as it is well known that a very bright light, whether it be direct from the sun, or the glare from a furnace, or reflected from snow, has a tendency to blunt the sensibility of the retina. Days, weeks, and months are sometimes required to restore a condition of impaired vision as the result of exposing the eyes to the direct rays of an intense light.

A Frenchman wrote a book with the title, "The Advantages of a Bad Constitution," in which he tried to prove that the tendency was to prolong life. There is at least reason in this seemingly rash statement, from the fact that having a delicate constitution, the owner would be very apt to banish all recklessness and excesses, and guard the already impaired body.

Many an old person who is blind might have preserved a fair amount of vision for the evening of their lives had they exercised the requisite care in the forenoon of their existence.

Distant vision in the normal eye is simply a sensation of passivity, while near vision means muscular exertion. If this is carried to the extent of producing fatigue or pain, then harm is likely to result, unless the proper amount of rest and relaxation are allowed for nature to, reproduce a normal condition. In reading, or studying, or writing, it is best to occasionally look across the room or out of the window, and in this manner rest the eyes by relaxing the muscular tension. When a person is in deep thought the eyes are either closed or passively turned toward some object, but not in action. In this condition all of the organs except the brain are at rest. Democritus, one of the founders of the "atomic theory," is represented as being so intense in his thinking, that he put out his eyes, that he might not be diverted in his meditations.

One of the disadvantages of living in a city is that the eyes are constantly used for near objects, necessitating a continual tension upon the muscles, hence a tendency to become fatigued.

A little girl that had been born and reared in the city, was taken to the country for the first time, and was almost bewildered, and exclaimed, "Oh, mamma, I never knew there was so much sky."

For an overstrained and weakened eye, simply from excessive tension on the muscles, before any permanent change in the refraction has been produced, there is probably nothing that gives more relief and at the same time is more soothing than looking at nature as she exists in the valleys, woodlands and hills. Especially is this true in the spring or summer, as the natural green has a very pleasant and agreeable effect on the organ of vision that has been fatigued and weakened by overwork.

It is scarcely necessary for me to say, that asthenopia is frequently developed on account of the poor quality of type that is often used. Cheap literature, quite frequently, means poor type; poor type means blurred and imperfect letters, and blurred and imperfect letters strain the accommodation, fatigue the eyes, producing congestion and functional derangement, and this in turn may be followed by inflammation and structural change, with permanent impairment of vision. Von Græfe stated, that unless the type was changed, that Germany would become a nation of blind people. Previous to his death he avoided, as much as possible, reading literature that was printed with German letters.

In addition to poor type, reading with poor illumination is another cause of disease of the eyes. As an example of the two combined, we might refer to the ambitious American youth, who has purchased a 10 cent novel, with an old gold back, and a new gold narrative. You will find him in the evening, doubled up in the corner, reading by the light of a little lamp with a smoked chimney. In this cramped and unnatural position he reads the history of the deeds of the daring desperado, Wild Fire Texas Jack, and his romantic encounters and escapades with a whole tribe of cosmopolitan Indians. During the time that he is thus storing his mind with useful knowledge, he may also be laying the foundation for a parental bill with the oculist.

Then, in addition to the foregoing, we might add that of position. If a person is lying down, or in a stooping position, or with the chin down upon the breast, it is evident that he has assumed a position that is favorable for producing congestion.

Persons, who are sleepy, sometimes make an effort to read when tired nature objects. Then, to accomplish their purpose, they place their will power against a natural law. At the same time that they may succeed in performing the self-imposed task, if often enough repeated, it will end in the production of asthenopia.

A very common error, and one which the majority of us have committed, and probably will again, is that of reading while traveling upon the cars. The constant jarring keeps the paper moving to and fro, and this requires a constant and continued contraction and relaxation of the muscles of accommodation, and the probabilities are that we know of the consequences by experience. The eyes soon become fatigued, necessitating a cessation of the strain placed upon them. In these cases, at first, all that is required is rest, nature rapidly overcoming the temporary derangement or functional disturbance. However, we may, by a continuation of the effort, change

this condition of functional disturbance into one of active congestion or inflammation, and find permanent impairment of vision as the ultimatum. This condition is generally developed gradually. The eyes at first do not appear to be unfavorably influenced, but after a while symptoms of weakness appear, so that in a very short space of time, after the effort to read has been made, there is an increased secretion of tears. This is rapidly followed by pain and blurred images. If a reasonable amount of rest does not relieve the eyes, supposing that there is no inflammation existing, an examination in the majority of cases will reveal an error of refraction. This refractive error may have been produced simply as the result of straining and abusing the organs of vision. In order to restore the impaired vision thus produced, so that the eyes can be used without producing pain, or becoming fatigued, the lens that represents the amount of error will have to be used.

"We are here to-day and *yonder* to-morrow" is trite, but true. This statement embodies our existence in this world. It signifies *change*. Life means change; it means motion, and motion means life. Nature has a few marks by means of which she designates this condition. In youth we have the rosy dimples and sparkling eye, but as decade after decade of time sweeps over the world, Nature touches the locks in the temporal region with the wand of senility, and the hair becomes white.

After we have passed the meridian and start down the declivity of life, there is a change takes place in the eye. Some of the organs lose their pristine activity, and become more sluggish in their action. There is a preponderance of the earthy over the animal matter. Senile changes take place, so that the eye that could read ordinary print with ease at a distance of twelve or fourteen inches, can now do so no longer. The paper has to be placed farther and farther away, until the distance becomes so great that the image of the object that is formed upon the retina is so small that the impression that it makes cannot be recognized distinctly. This condition means a receding of the near point of vision, and is called presbyopia. It begins at about the twelfth year, but is not sufficiently developed to need correction, as a rule, before the fortieth or the fiftieth year.

When the near point has receded beyond a given distance, then the effort to read and write produces a chain of unpleasant symptoms. In a few moments the eyes experience a burning or stinging sensation. The tears are secreted more freely; the smarting sensation gives place to actual pain; there is a congestion of the vessels, the eyes become watery and red, and a blurred image is formed. By resting the eyes a few moments, and gently pressing upon, or bathing them with cold water, all these symptoms pass away. They rapidly return when the eyes are again used.

This is the natural consequence that is produced when the refractive power is too low; when the focal point of the lens is greater than the distance from that organ to the fovea centralis of the retina.

This condition is easily corrected by using a suitable lens. A great many people will not use glasses even when the evidence is manifest that they are needed. They may imagine that it indicates that they are getting old, or that they do not look well with those frames before their eyes, or that it would not do to wear them in their line of business, etc.

Then, again, some say, I do not want to use glasses, for when I commence using them, then I will have to continue to do so. A common error is that it is better to do without glasses as long as possible.

When presbyopia has developed sufficiently to need correction, then the time has arrived to commence using glasses. By so doing the eyes will remain stronger and vision clearer than in any other way. By following this method, sharp, clear and distinct vision is preserved. On the other hand, by constantly straining and congesting the eyes in trying to read or work, without glasses, tends to produce inflammation and asthenopia. The eyes become weak, suffused with tears, and irritable. They cannot be used for any kind of fine work without becoming painful.

After they have been abused in this manner, it is sometimes very difficult to get a pair of lenses that will give satisfaction. The lens first required is generally much stronger for an eye that has been strained in this manner. They have to be changed more frequently, and do not give as good results.

It is evident, then, that there is nothing gained by trying to use a presbyopic eye for reading, writing, or any kind of fine work, without the proper glasses.

Vision for distant objects does not undergo a change in the normal presbyope. They use their glasses to read, then take them off and see as well in the distance as ever.

With the eye that has been excessively strained and congested in trying to look at near objects, we frequently find does not see well in the distance.

Then we will refer to our cardinal principle, and claim that it is as applicable to the eye as a special organ as to the body, and say that if we wish to preserve our vision we must avoid all excesses.

Then, again, there are certain agents, such as alcohol and tobacco, that have a tendency to produce an amblyopic condition. When they are the cause, the derangement is developed in an insidious manner. The external appearance of the eyes remains unchanged. There are no visible symptoms of inflammation, and generally no pain. There is a gradual reduction in the visual power. Objects are not distinct, but appear to be enveloped in smoke, and present a hazy appearance.

This condition creeps on so unsuspectingly, that it is generally well developed before much attention is given to it. Either of these agents alone may cause the trouble. The two combined are much more liable to do so.

If, in addition to any of the foregoing states, you add an unsanitary condition, you simply enhance the power of the disease.

Mens sana in corpore sano is an adage probably as old as medicine itself, yet it is not *in rerum natura* for the various organs of the body to remain in a normal condition when we are surrounded by a mephitic atmoshere, and inhaling lethal germs. And finally, may we be permitted to add, that morality does not

exist so much in a blind observance of 'isms and 'pathies, and vague creeds, as it does in submitting to the dictates of nature, and following the precepts of health.

A PLEA IN BEHALF OF A MEDICAL AID FUND.

BY FREDERICK HORNER, M.D., OF VIRGINIA.

In proof that an urgent necessity exists for an effort to provide for a Medical Aid Fund, it may be stated that for some years past the attention of the profession has been especially directed to this subject, and the facts connected with the origin and history of this movement may be briefly narrated.

The Massachusetts Medical Benevolent Society recently held its 25th anniversary, and celebrated it by a dinner. The object of the society, it was stated, is to give financial aid to widows and orphans of medical men. The funds amount to $20,000, and each beneficiary receives $80 per annum. The Mutual Benefit Association of the physicians of Kentucky, Illinois and Indiana, embracing within its fellowship hundreds of our medical brethren, was the next organization of the kind undertaken. Dr. David Keller is deserving all praise for the interest which he has manifested in this successful enterprise. In 1876, under the auspices of the Philadelphia County Medical Society, the third auxiliary Aid Society was founded, and has been nobly sustained by Professor H. H. Smith and Drs. Benj. Lee and W. R. D. Blackwood. Ere long this society is expected to have a handsome and permanent fund, the profits of which promise to secure a respectable sum for distribution to the families of deceased members.

Dr. Benj. Lee, of Philadelphia, in a late report, says concerning this Aid Society: "It has been formed for the pnrpose of providing against the recurrence among the members of the Philadelphia County Medical Society of those sad cases in which medical men, after lives devoted unselfishly to the cause of science, have died leaving their widows and orphans dependent on the cold charities of the outside world. Our efforts will be by the steady growth of the funds derived from gifts and legacies, as well as from annual dues, to save such families of deceased members from penury and distress."

The profession in the City of New York has also undertaken a like philanthropic work, and have established on a firm basis the New York Physicians' Mutual Aid Association. Dr. James Anderson is the founder of this Association, which furnishes pecuniary aid, also, to its sick members in special cases of need out of the interest of the permanent fund. Dr. M. Blumenthal, the President, in a late report, says: "The Association stands upon a sound and safe foundation, and since its organization $27,000 have been distributed among the families of deceased members." He adds, "The amount of comfort conferred and grief and sorrow assuaged by this sum, surely no figures or words can adequately express."

The committee on the formation of the Aid Society of Virginia, made its report to the State Medical Society, and urges, "while every consideration is given by physicians to promote the public weal and health, there can be no excuse any longer for them to ignore the claims of the impoverished families of deceased brethren, and the committee is unable to recognize an objection to a trial of an experiment to raise funds to be applied for the relief of the destitute within our own medical household, and of brethren who furnish no exception to the accidents, financial distress and ills referable to the chances of human life."

At the thirty-third annual session of the American Medical Association, held at St. Paul, Minn., June 6, 1882, Vice-President P. O. Hooper, in the course of his address, said "he would also call attention to the propriety of the Association organizing a relief society for the benefit of the families of physicians left in destitute circumstances, and he thought a scheme of operation might be the means of accomplishing much good, and remove an ever-present anxiety from the life of many a struggling brother."

Abroad, especially in England and on the continent of Europe, for centuries past, ample, liberal and prompt provision has been made for disabled physicians and their families. On the occasion of the writer's acquaintance with Professor Alexander C. Simpson, of Edinburgh, and Drs. Charles I. Hare and Adams, of London, these gentlemen informed him that there exist in their respective cities societies well endowed, and ensuring to the needy member the amount of £60 sterling per annum. The London *Lancet* for March 17, 1883, noticed the annual meeting of the society for relief of widows and orphans of medical men, which met in the rooms of the Royal Medical and Chirurgical Society, President, Sir Geo. Barrons, Bart.; Dr. Johnson, Vice-President, elected in place of Sir Thomas Watson, deceased; 18 new members enrolled, and 9 had died. Total, 370 out of 4,500 members belonging to the British Medical Association. Sixty widows and five orphans were on the books; £2,871 were distributed during 1882; expenses, £190; the receipts available for grants, £3,061. Regret was expressed that so few medical men avail themselves of the benefits of the society, which allows £80 per annum to each widow. The editor of the *Lancet*, commenting on the effort to raise a medical benevolent fund, says: "Dr. B. W. Richardson was the moving spirit of the 1866 experiment. It is proposed to get at least 200 new members, and to raise a subscription of two guineas a year by members under 30 years of age. After the expiration of the first year, £1 a week will be allowed for 26 weeks, and 10 shillings a week for another 26 weeks in case of total disability to work. The President, Sir George Barrons, subscribed 10 guineas toward the fund. An additional medical sick fund has been raised in England, by which a physician when totally disabled receives sufficient sick pay to keep him going. It is proposed by this society that each medical man shall subscribe to this fund £2 2 shillings annually, and in case of illness from disease or accident he will, during his incapacity from attending to his professional duties, receive £10 a week. The *Lancet* also notices the annual meeting of the Central Society of the medical men of France.

This society is intended "not only to occupy itself, it is stated, in the general interests of the profession, but to afford succor to needy members and to their widows and children who may be left without any provision." According to the reports that were read and the speeches that were made, this society in Paris is in a most flourishing state, but at the same time the melancholy fact came out that, notwithstanding the revenue so justly acquired by some of the members of the profession in France, many of them live and die in almost abject poverty.

The *British Medical Journal*, holding the relation to the British Medical Association that the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION does to the Association in America, has strongly advocated the establishment of a Medical Benefit Society. A contributor to our JOURNAL, who resides in Washington City, in a late article says: "There is great need for such a society, every practitioner will readily acknowledge; and while we see insurance companies and aid societies working successfully for special purposes, it would be the part of wisdom, if not policy, for physicians to imitate such examples, and the American Medical Association, as it stands to-day, could best foster and ensure a widespread support and sphere of usefulness to such a project."

With the facts above presented, no one can fail to admit that both in the United States and abroad medical aid societies are not novelties, and need only further development to embrace the whole profession, and especially in the rural districts, where too often a meager support is obtained by practice for the maintenance of the families of physicians. In the country, indeed, the majority of medical gentlemen neglect, or are unable to incur the expense of, the insurance of their lives; while this class located in large and metropolitan cities, more fortunate, realize usually handsome incomes, and hold professorships, and do provide for their families. An aid society conducted by ourselves would meet the wants, at least, of all who will avail themselves of its advantages. Army and naval officers may not be directly interested, because of the pension which a liberal government dispenses to their families. Yet even these classes have lately sought to provide a larger fund to meet this want. As additional evidence that this scheme for the creation of a medical aid fund has the support of the most eminent and philanthropic members of our profession, the writer will venture to take the liberty to quote from their letters on the subject. The late Dr. John Hodgin, ex-President of the American Medical Association, says: "I shall at all times and on all occasions be pleased to do anything in my power to aid the widows and orphans of deceased members of our profession." Prof. Lewis Sayre says: "It is a noble object, and deserves the favorable consideration of every man in the profession. The plan has worked admirably in this city, and would be very good to model after." Prof. Nathan S. Davis says: "The object in view is a good one. Many years since I advocated such a plan, and bestowed upon the matter some thought."

Dr. Wendle, of Murfreesboro, Tenn., writes: "Right here in this town we have an instance of an excellent physician who, after forty years' practice, died, and his children are left penniless, and his widow's home was sold last week." Dr. Blackwood says: "In Philadelphia we are fully in accord with the effort to establish both a State and National Medical Aid Society. It only requires concentration to get the matter under way." Dr. G. B. Thornton, President of the Board of Health of Memphis, writes, "that subsequent to the fatal epidemic yellow fever in that city, had not the noble and generous physicians of the city of New York sent us money, many families of the twenty doctors who died here would have suffered deplorable want." Dr. James Anderson, Secretary of the New York Aid Society, says: "Our association has been a great comfort to many a widow, yea, and four of its members, one a professor and one who once drove two horses. Our permanent fund we seek to keep intact, and it has proved the salvation of our association." With these quotations, which might be multiplied well nigh *ad infinitum*, a brief opinion of the distinguished President of the American Medical Association, Dr. Austin Flint, Sr., may be added. He says: "There can be no objection to a plan for raising a medical aid fund, to be brought before the Association at its session in Washington city in May, and I sympathize in the benevolent purpose which is proposed."

Now, in conclusion, with reference to a plan to ensure its success, the best talent, the best business and most large-hearted men of the profession of the State and National Association, should be solicited to give their moral support and coöperation to such an undertaking. Various methods might be mentioned, all of which have been tested by the Aid Societies of Massachusetts, Pennsylvania, New York, and Kentucky successfully, and have proved to be cheaper, more secure, and more permanent than is accomplished by ordinary insurance companies. For example, let $1 be added to the annual assessment of the Fellows of the Association; a committee appointed by the President of five or seven members, who shall be authorized to prepare a constitution and by-laws, and shall hold in trust the fund, and when the amount is sufficiently large, a board of directors or a Section of benevolence on the death of a member shall determine the sum to be distributed to the individual. The Mutual Benefit Association of Physicians of Kentucky is managed by an able directory and by a finance committee, the members of which have gained the confidence of the profession and of the community.

The payment of $10 for membership and a $2 annual assessment secures to the family of a deceased brother $2,500, and to one sick $5 per week for serious illness or accident. The New York Mutual Aid Association requires the treasurer to deposit all monies received from assessments in a Trust Company, and when of sufficient amount, the accruing interest to be transferred to a savings bank to the credit of the Permanent Fund, which shall be created by contributions, donations, bequests, and all other monies not appropriated. As soon as the Permanent Fund shall amount to the sum of $10,000, aid may be rendered to the widow of a deceased member and his children

under 14 years of age out of the proceeds of said fund. The Medical Aid Society of Philadelphia allows $50 per annum to the widow, and also makes provision for the children until they become of age. The graded system may also be recommended, viz.: to have payments by assessment according to the relative age of the individual member, allowing such to be confined to three distinct classes, and assessments respectively of one, two and five dollars. The investment of all funds raised for this purpose in Government, or State bonds, or in a safe bank would be desirable.

Finally, is it not wiser for physicians to endeavor to raise a Medical Aid Fund, and thereby confer a blessing on the members of their own household than to commit such a fund to corporations which tax the policy-holder, and after all may fail; agents and officials of such corporations too often, as can be shown, appropriating the larger amount of the profits. At least recent statistics show that in 1861 thirty-six insurance companies existed in New York, and in 1881 only four of these companies were in existence. Let physicians be their own policy directors. This appeal is now made to the hundreds of humane physicians of the United States, who bear the mantle of the Good Physician. He failed not even on the cross to provide for the needy. During the present era members of the Masonic Order, of the several Christian churches, and even railroad operatives, have created a sustentation fund for the benefit of the sick and disabled. The younger members of the medical profession should not fail to apprehend the advantages of a like provision for themselves, their families, and medical brethren. Nor should it be considered utopian or premature, when the testimony of prominent physicians, and various medical communities have decided the question to be a *practical* and *urgent* one. With many it is a matter of surprise that during the long and eventful career of the American Medical Association, whose fellows are possessed of wealth and influence, and even shape for good the legislation of the country, and have annually conferred upon methods for the relief of mankind, and yet have failed to devise any plan of a benevolent character for the relief and support of their medical brethren. In the words of the gifted Atlee: "Our profession should ever seek along with the advancement of medical lore, to promote every system of benevolence and humanity." As was asserted on the occasion of a late meeting of the American Sanitary Association by Gen. John Eaton: "The legislatures of the several States of our Union leave no doubt that every child among us inherits the right to an education, the right to proper food, clothing, and shelter." Will physicians in this land longer practically deny these rights to the families of their brethren? among whom, it may be declared with truth, are scores of talented youths only requiring a small help, and destined it may be in future years to rival in fame such men as Livingstone, Kane, and Barnado, and may have reared to them in the hearts of a grateful posterity.

"Monumentum dere perennius
Regalique situ pyramidum altius."

MEDICAL PROGRESS.

ANATOMY AND PHYSIOLOGY.

The Sounds of Deglutition.—The Berlin Medical Society has recently sustained an interesting discussion on this subject, which was brought before them by Dr. Ewald. He recalls the physiological statement that deglutition is divided into two distinct periods, the first being that in which, by the aid of the muscles of the base of the tongue superior constrictors of the pharnyx, mylo-hyoid, etc., the alimentary bolus is projected along the œsophogus to the cardiac orifice in less than one-tenth of a second; the second at the end of an appreciable time, consists of peristaltic movements of the œsophagus, which by degrees detaches the alimentary substances from the walls of the tube and expresses them into the cavity of the stomach through the cardiac orifice.

If the ear is applied over the stomach in the left hypochondrium, or at the xiphoid cartilage, two sounds are heard which correspond to these two periods just described. The first sound recalls that of water falling into a bottle, and corresponds to the projection of the liquid into the œsophageal space; the second is of the same character, but a coarser sound, like the *glou-glou* sound of fluids. This is produced by the liquid forcibly driven by the lower segment of the œsophagus through the cardiac orifice into the stomach.

The first sound is less constant than the second, is more marked in those who vomit easily when coughing, and constitutes a sign of weakness. In twelve cases of syphilis, the first sound was very well marked, leading to the supposition that the *cardia* was altered by the disease. Thus far these are the views of Meltzer. With regard to the cause of the second sound, Meltzer considers its presence to indicate a normal closure of the cardiac orifice, but Ewald notes that this second sound is not constant in its relations to the first as regards the time of its occurrence, and is simply the result of the peristaltic contractions of the stomach.

Ewald, after examining 500 cases of different diseases, considers that these sounds are very variable, both in health and in disease, and that they cannot be made of diagnostic value.

Fraenkel, by employing the American stethoscope, and placing the finger on the thyroid body to obtain an exact appreciation of the phenomena, supports Meltzer's theory thoroughly, and also determines the marked prominence of the first sound in cases of constitutional syphilis. In cases of paralysis of the œsophagus the second sound was constantly wanting.

Sublinski examined a large number of cases. In 40 out of 100 he could not get the first sound when he auscultated the stomach or the inferior segment of the œsophagus. He had examinied more than 60 syphilitics, and frequently established the two sounds. But the first was frequently absent as in healthy persons. This method promises little in diseases of the œsophagus, and the use of the sound and other means of differential diagnosis will always be required.

Eulenburg had observed these phenomena in a number of cases affected with nervous affections. In one case of progressive bulbar paralysis the first sound was frequently wanting, and the second was reinforced in a marked manner and the interval markedly lengthened to 9.20 seconds. In several cases of diphtheria and of amyotrophic paralysis the sounds were found to be normal.—*Gazette Hebdomadaire de Médicine et de Chirurgie.*

MATERIA MEDICA AND THERAPEUTICS.

DR. HASSALL'S INHALATION CHAMBER.—Dr. Arthur Hassall has an article in the *Lancet* entitled "My Inhalation Chamber," in which he describes a room at San Remo which has a cubic capacity of 1,170 feet, one door, one window, no fire-place, no chimney. The walls are washable, the floor tiled. It is warmed by a little hot air admitted through a grating in the center of the floor, from a calorifére placed in the basement of the house, the temperature being usually 68° F. The chief apparatus contained in the chamber consists of two chamber inhalers. No. 1, a portable arrangement of five layers of cotton fabric, is suspended from the ceiling some feet above the grating in the floor, and can be raised or lowered. This apparatus is charged with carbolic acid, 1,200 grains being the medium amount; he calculates that this will be vaporized at the rate of 100 grains per hour, under suitable conditions. The time of inhalation, commencing at first with half an hour, has varied from one to two hours daily. The amount actually inhaled is an indefinite quantity, modified by the chest capacity, the loss of material by escape through the crevices around the window and at the door, and the sensible deposition of carbolic acid on the walls of the chamber itself. Although mention is made of carbolic acid alone, a variety of disinfectants, stimulants, antispasmodics and sedatives can be used.

CHRYSOPHANIC ACID ADMINISTERED BY THE MOUTH AND HYPODERMICALLY IN THE TREATMENT OF SKIN DISEASES.—Dr. Stocquart, of Brussels, gives in the *Annales de Dermatologie et de Syphiligraphié* his experience with this drug in 61 cases of skin disease, viz.: Acne, 3; ecthyma, 5; eczema, 32; impetigo, 4; lichen, 4; pityriasis, 1; prurigo, 4; psoriasis, 5; urticaria, 3. In none of these cases was there any local treatment, even of the most simple kind; 56 were complete cures, 2 incomplete, 2 were cures with relapse, and 1 resisted all treatment, being a case of inveterate papular acne. The cases of acne, ecthyma and impetigo rapidly yielded to treatment, as also the cases of pityriasis and urticaria. In the cases of lichen and of prurigo the itching disappeared rapidly, and in the lichen cases before the eruption had completely disappeared. In one case of prurigo, however, the cure was slow, and only after continued large doses. In the 32 cases of eczema, 30 were complete cures. One case of chronic eczema of seven years' standing was not completely cured, and another of twelve years' standing, after being relieved, recurred and was again relieved. In the 5 cases of psoriasis there were 3 cures, 1 relieved, with relapse, and again relieved, and 1 which was markedly benefited.

The mode of administration of the drug was generally as a potion, mixed with water. In ordinary doses this is not disagreeable. In large doses of 20 to 30 centigrammes it forms a magma with the vehicle which is not pleasant to take. The dose for a child is 1 centigramme per day; for an adult 3 centigrammes per day. There are exceptions to this rule. In doses but little greater, symptoms of intolerance and gastro-intestinal irritation show themselves, with palpitation of the heart, vertigo, and cold rigors, followed by flushes of heat. In an adult case of eczema a dose of 2 centigrammes produced nausea, vomiting, and abundant stools, which lasted for three days. In a case of acne it required 8 centigrammes to produce nausea, and 10 centigrammes to cause vomiting and abundant stools. It does not seem to be necessary or desirable to progressively increase the dose, and children tolerate the drug with great facility.

The hypodermic use of this drug was made in 11 cases, viz.: Acne rosacea, 1; eczema, 3; lichen, 4; prurigo, 1; psoriasis, 1; urticaria, 1. It proved to be quite as efficacious when used in this way, and more rapid in its effects. Out of the 11 cases there were 9 cures, 1 amelioration of a case of acne rosacea, and 1 unaffected stubborn case of chronic eczema. The prurigo was cured in two days; the other affections in four days, except one case of chronic eczema, which took fifteen days for its relief. In four cases a single injection was all that was necessary; in the others only two injections were used. The injection is not painful, but there is a tendency to the formation of abscesses, with severe pain, even in doses of 1 milligramme in a gramme of water, which limits this mode of using it to an absolute necessity.

USE OF A SOLUTION OF CHLORAL AS A DISINFECTANT AND AS A TOPICAL APPLICATION IN WOUNDS OF THE MOUTH.—M. Perier, of the Hopital Saint Antoine, Paris, has for several years (*Journal de Méd. et de Chirurgie*) employed constantly an aqueous solution of chloral to combat buccal inflammations or to prevent the accidents which are consecutive to traumatic injuries affecting the mouth. He formerly used alcoholized water, but gave it up, as in order to have a sufficiently powerful action upon wounds, the water should contain a very large proportion of alcohol, which makes it more irritating than the solution of chloral. The latter, besides, possesses a true sedative property. If a superficial or deep wound, caused by accident or by surgical means, communicates with the cavity of the mouth, M. Perier prescribes washings and rinsings every two hours at least. Besides which a careful washing is insisted upon after each ingestion of solid or liquid food, as it is necessary to prevent putrescible material from remaining in contact with the denuded surface. If the wound is anfractuous an irrigator is used, with care not to apply any pressure. Several instances are cited to show the value of this mode of application, where after considerable loss of substance autoplasty has been facilitated and produced excellent results.

The buccal inflammation which accompanies the development of the wisdom teeth is greatly relieved by the washings and gargles with the solution of chloral. In the case of peripheral depots of pus for necroses which open at the same time on the skin and in the mouth, the washings and injections through the fistulæ diminish the inflammation and pain rapidly, and suppress the horrible odor which accompanies this species of suppuration. The irrigation is especially insisted upon after the patient has taken milk or bouillon. These two liquids are ordinarily considered to be inoffensive, but, on the contrary, the residue which they leave behind them is precisely that which is most favorable to rapid putrefaction.

M. Perier uses chloral also in other cases. It is very convenient in inflammations of the fingers and of the hand. He uses baths and compresses soaked in the chloral solution. The strength used in all is 1 part chloral to 100 of water. The compresses are made of one thickness of prepared cotton placed between two folds of tarlatan, over which is laid an impermeable rubber cloth to preserve the humidity as long as possible; the dressings being changed very seldom.

MEDICINE.

Albuminuria in Typhoid Fever.—Dr. Johannes Mygge (*Nordiskt Mediciniskt Arkiv.*) gives the result of his examination of 217 cases of typhoid fever in the hospital at Copenhagen. In a third of these cases the urine was examined every two or three days, until death or convalescence. The examination for albumen was made simultaneously by heat and nitric acid (reaction of Heller). He arrived at the following conclusions: .

1. In fifty-two (out of seventy-two) of these patients, the urine contained an appreciable quantity of albumen; in nine there was but a trace; and in eleven the result was negative.

2. The albuminuria appeared ordinarily before the end of the second week of the disease; in three cases it was present on the fourth day.

3. The albuminuria was transitory (one to three days) in sixteen cases; in thirty-six it continued for from five to eighteen days, except in several lethal cases, where it was not observed for more than two or three days; and in some other cases where it was in relation with cystitis or cysto-pyelitis, and continued for 110 days.

4. Of the twenty-six patients suffering from a considerable and persistent albuminuria, ten died, while of the remaining forty-six none died.

5. Chronic Bright's disease, as a sequence to typhoid fever, was not noted in any of the 217 patients.

6. Of the patients affected with albuminuria, more than half suffered from nephritis, as shown by the objective and subjective symptoms furnished by the urinary passages; in the greater part of those remaining the albuminuria was principally a symptom of a cystitis or cysto-pyelitis.

7. Of the eighteen patients giving evident clinical symptoms of a renal affection, ten died and eight were cured. The symptomatology in these cases did not present the characteristic clinical appearance which, according to Amat and others, constitutes the renal form of typhoid fever, although in two of the patients the symptoms of the renal affection were so marked as to mask the principal disease.

8. The excretion of urea did not diminish in a constant ratio, but the variations observed so frequently in the lethal cases could not be attributed to the accumulation of urea in the blood.

9. It would appear from the observations of other authors taken with these, that an organic renal affection and not a functional derangement, is generally the cause of albuminuria, and that this affection is most generally a parenchymatous nephritis, but that it produces from time to time an alteration in the cellular matrix.

10. When there are evident symptoms of nephritis present, the treatment requires great care in giving cold baths. The baths to commence with, should generally be of a temperature from 79° to 75,° and descend gradually to baths of a temperature of 68.° As strong doses of quinine sometimes produce a collapse, this agent must also be administered with caution.

A Case of Actinomycosis.—Mr. W. Knight Treves, in the *Lancet*, gives the first description of a case of this disease in the country. It occurred in a man 45 years of age, a brick burner, aud apparently suffering from a scrofulous affection of the glands of the neck. His illness began 16 months before his admission with inflammation about the neck and angle of the jaw. A lump by the angle of the jaw which followed the inflammation, was incised. Subsequently, other swellings formed. When first seen he was in fair general health and well nourished. Over the angle of the jaw and in the posterior triangle of the neck, were three ulcerated and fungating surfaces, those by the angle of the jaw being about one inch, and that in the posterior triangle about two inches in diameter. There were tumors over the collar bone, the second rib and the fourth costal cartilage near the sternum, each of which was in a direct line, and had followed in regular order the one described as existing in the posterior triangle. These tumors resemble each other in appearance. They are smooth and evenly formed, and are in shape as nearly as possible half a sphere; the upper one is two inches in diameter, the lower one an inch, and the middle one intermediate in size. They have an elastic, semi-fluctuating feel; the skin over the upper one is thin, red, and evidently about to give way; the skin of the middle one is also discolored, that of the lowest is normal. To the right and left of these tumors are two nodules about the size of a marble, apparently the same thing in process of formation. The discharge was thin and serous, and contained minute yellowish masses, and disintegrated tissues, and had a peculiar offensive and sour smell. These tumors broke down in the course of four

months with gradual loss of strength, and formation of lumps on the other side of the neck and in the axilla. Not being like scrofula or any familiar form of new growth, the diagnosis of actinomycosis was made, which was confirmed by the discovery, under the microscope, of bodies which resemble the fungus peculiar to this disease.

OPHTHALMOLOGY AND OTOLOGY.

INFLUENCE OF THE SEXUAL ORGANS ON THE EYE.—Dr. C. E. Fitzgerald, of Dublin, in the last volume of *Transactions of the Ophthalmological Society of the United Kingdom*, records briefly five cases in which he establishes a distinct relation between disorders of the sexual organs and a diseased condition of the eyes. His first case was one of suppression of the menses, followed by an intense neuro-retinitis, with rapid recovery on the reappearance of the menses. The second was that of a case of disseminated choroiditis, with floating opacities in the vitreous. The menses were very excessive, and she was found to have multiple fibroid tumors of the uterus. The third was a case that at first presented only a slight haziness of one of the optic discs and pallor of both. The impairment of vision was very considerable, and there was a remarkable dilatation of both pupils, though they responded to the action of light; gradually, but steadily, the vision began to deteriorate, and atrophy of both optic nerves declared itself. Examination by a gynæcologist resulted in evidences of masturbation, which she admitted having practised for two years. Complete atrophy of both optic nerves subsequently ensued. The fourth case developed asthenopic symptoms, with a hyperæmic disk and marginal haziness. Masturbation was also diagnosticated in this case. The connection between the two showing itself curiously, a rather powerful caustic was applied to the vagina, making it very tender, and during this time (for some days) there was a marked improvement in the eyesight. This patient had also enlargement of the uterus and left ovary. The fifth case is simply referred to without any details, except that it is one of masturbation and suffering from marked neurasthenia.

INFLUENCE OF THE SEXUAL ORGANS ON THE EAR.—In the *Monatsschrift für Ohrenheilkunde* is an article by Weber Siel on this subject. The affections of the sexual organs of the female, and even the physiological accomplishment of their principal functions produce a marked effect on diseases of the ear. When pregnancy, flexions of the uterus, etc., occur in the course of ear disease, the progress and character of the latter are markedly modified. A simple catarrhal otitis, which is often insignificant, may become complicated with considerable disturbance of the nervous and circulatory systems, and the treatment of the ear disease becomes useless as long as the abnormal condition of the reproductive organs is maintained. When that is relieved, the affection of the ear is healed in turn, and frequently without treatment.

When an aggravation of deafness and of morbid sounds appear to be connected with a peculiar condition of the genital organs, then, and then only, the application of electricity will cause marked pain at the last dorsal and first lumbar vertebræ, when the sponge, covering the electrode, is there applied to complete a circuit in which the other pole is introduced in the Eustachian tube, so as to reach or pass its isthmus. This effect is constant and shows itself even with a feeble continued current of 5 to 8 small elements of Leclanché. One peculiar fact is noticed in this connection; and that is, whilst this pain increases in proportion to the prolonging of the contact of the electrode, the buzzing, vertigo, and other disturbances of the ear disappear completely, or diminish very markedly. In cases that are not of too long standing, audition returns almost to the normal state, and the amelioration of all the symptoms continues for several hours. In one case, where hearing had been difficult for a year past, and attributed to a diphtheritic affection, the continued moderate buzzing in the ears became extremely intensified with painful menstruation and ovarian hyperæsthesia. The deafness was correspondingly increased, and the patient suffered from vibratory shocks to the tympanum. Among all the means employed to relieve this condition only one was beneficial, that of putting ice over the region of the diseased ovary.

The influence of sexual excitement upon diseases of the ear is particularly manifested in cases of onanism. In the case of a young man suffering from chronic otitis, with a purulent discharge, perforation of the tympanum and intratympanic granulations, who was otherwise in perfect health, the ear affection became almost entirely relieved, when suddenly the symptoms became aggravated, and the remedies were of no benefit; the change in the general condition awakened a suspicion of masturbation, which was acknowledged, and on its being stopped an amelioration in the symptoms took place.—*Annales des maladies del'oreille. Jour. de Mèd. et de Chirurgie.*

THE DIAGNOSTIC VALUE OF THE BACILLUS TUBERCULOSIS.—Dr. Austin Flint, at a meeting of the New York Medical and Surgical Society, stated that he had made this question a subject of clinical study; and, so far as his experience had gone, it confirms the value of the presence of the bacilli in the sputa as positive proof of phthisis, their absence being of more or less value iu the exclusion of that disease, and the importance of their comparative abundance and scarcity as bearing on the question as to whether the disease was or was not actively progressing.—*Maryland Medical Journal.*

SANITARY COUNCIL OF THE MISSISSIPPI VALLEY.—The sixth annual meeting of this organization will be held in the city of Memphis, Tenn., on Friday, March 21, 1884.

PROFESSOR JOHN C. DALTON has been elected President of the College of Physicians and Surgeons of New York.

THE

Journal of American Medical Association.

PUBLISHED WEEKLY.

THE EDITOR of this JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information, should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE..... $5,00.
SINGLE COPIES..... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 65 RANDOLPH STREET,
CHICAGO, ILLINOIS.

SATURDAY, MARCH 15, 1884.

THE AMERICAN MEDICAL ASSOCIATION.—Less than two months remain before the time of the next annual meeting of our national medical organization, and the inquiry arises how far all the parties interested have completed whatever work they had intended for that occasion? That the local Committee of Arrangements have their plans matured, and all needful preparations made for a most pleasant and profitable meeting, we are well assured. But have all those who intend to present papers or make reports, either in the Sections or in the general sessions of the Association, duly notified the Chairman of the Committee of Arrangements of the title and length of their papers or reports? If not, they should do this without delay. The by-laws require the officers of the several Sections to make similar reports to the Committee of Arrangements concerning all papers or reports coming to their knowledge, at least one month prior to the time for the next meeting. If individuals and officers of Sections will do this promptly, it will enable the local committee to make the printed programme of work for the coming meeting much more complete than it has been heretofore, and the practical results will be correspondingly more satisfactory and profitable. The columns of the JOURNAL are open for the publication of any notices concerning the arrangements for the next meeting that may be desired.

THE CHOLERA BACILLUS.—Dr. Koch, in his fifth and most recent report concerning the doings of his commission for investigating the nature of epidemic cholera, states that the same bacilli were found in the intestines of those examined after death from cholera in Calcutta, as were found in Egypt; while in eight bodies examined after death from other diseases, no bacilli presenting the same characteristics were found, thereby strengthening the inference that they were peculiar to the cholera.

NEW YORK STATE MEDICAL ASSOCIATION.—The new State medical society with this title was organized in Albany, New York, February 6, 1884. A brief, but excellent plan of organization was adopted, prefaced by the following resolution:

"*Resolved*, That the objects of this Association shall be the cultivation and advancement of the science of medicine."

The ninth item in the plan of Organization is as follows:

"9th. The Code of Ethics, which shall form an integral part of the by-laws of this Association, shall be as follows: The same as that adopted by the American Medical Association."

The following officers were elected:

President, Dr. H. D. Didima, of Syracuse, Onondaga Co. 3d District.

Vice-Presidents: 1st District, Dr. J. M. Crawe, of Jefferson Co.

2nd District, Dr. T. B. Reynolds, of Saratoga Co.

4th District, Dr. B. L. Hovey, of Monroe Co.

5th District, Dr. N. C. Husted, of Westchester Co.

Recording Secretary, Dr. Caleb Green, of Homer, Cortland Co.

Corresponding Secretary, Dr. E. D. Ferguson, of Troy, Renssalær Co.

Treasurer, Dr. John H. Hinton, of New York City and Co.

Councillors: 1st District, Drs. John P. Gray, of Oneida Co., and Conant Sawyer, of Essex Co.

2nd District, Drs. J. W. Moore, of Albany Co., and Thomas Wilson, of Columbia Co.

3d District, Drs. Frederick Hyde, of Cortland Co., and Ely Van de Warker, of Onondaga Co.

4th District, Drs. E. M. Moore, of Monroe Co., and M. W. Townsend, of Genesee Co.

5th District, Drs. E. R. Squibb, of Kings Co., and A. Flint, Jr., of New York.

From the State at large, Dr. J. W. S. Gouley, of New York.

One hundred and sixty-eight members were present and signed the plan of organization.

The Association adjourned to meet in the city of New York on the third Tuesday in November, 1884; having authorized the Board of Councillors to appoint the delegates to the next meeting of the American Medical Association.

EDUCATIONAL QUALIFICATION FOR COMMENCING THE STUDY OF MEDICINE.—One of the most important and encouraging signs of the times, is the increased attention given to the general education of those proposing to study medicine. A considerable number of local, and some of the State, medical societies have adopted recently regulations which, if faithfully executed by their members, will do very much to practically elevate the character and usefulness of the profession, and in a direction where it is most needed. That part of the second resolution in the following series embraced within quotation marks was adopted by the Medical Society of the State of Pennsylvania at the annual meeting in May, 1883; and the whole series were adopted by the Trumbull County (Ohio), Medical Society at its regular meeting, January 31, 1884, as follows:

Resolved, 1.—That this Medical Society shall annually elect a board of Medical Examiners, to consist of three members, whose duty it shall be to examine applicants for admission to the study of medicine.

Resolved, 2.—All applicants for admission as students of medicine under the tuition of members of this Society shall present themselves before the Board of Medical Examiners and satisfactorily pass examination in the following requirements:

"I.—A written statement, previously prepared, setting forth the candidate's course of study.
II.—An essay.
III.—Writing from dictation.
IV.—Spelling—Oral and Written.
V.—Reading.
VI.—Geography—Descriptive, Physical.
VII.—Political Economy.
VIII.—History—Ancient, Modern.
IX.—Geology.
X.—Botany.
XI.—Chemistry.
XII.—Natural Philosophy.
XIII.—Mathematics—Arithmetic complete; Algebra, through quadratic equations; Geometry, through plane geometry.
XIV.—Languages—English, standard school edition of
English Grammar;
Latin, Cæsar's Com., 4; Virgil, 4; Cicero's Orations, 2;
Greek, the Reader; Gospels; Xenophon's Anabasis, 2."

Candidates for examination may elect in French, Keetle's Collegiate Course in French, Composition, Translation and Reading, and Lacomb's History of the French People, instead of Cæsar's Com., Virgil and Cicero's Orations; and in German, Whitney's German Grammar, Composition, Translation and Reading, Schiller's Willheim Tell and Gœthe's Faust, instead of the Greek Reader, Gospels and Xenophon's Anabasis, but such elementary knowledge of Latin and Greek will be required as to enable the candidate to intelligently comprehend the etymology of medical terms derived therefrom.

Resolved, 3.—No member of this Society shall receive any person as a student of medicine unless he present a favorable certificate from the Board of Med. Examiners.

Resolved, 4.—The time of study required by members of this Society shall be five (5) years including lectures.

Resolved, 5.—Members of this Society shall recommend their students to attend only such medical colleges as either require an examination for admission similar to the one required by this Society, or make the full three-years' graded course of study obligatory for graduation therefrom, and otherwise endeavor to elevate the standard of medical education.

Resolved, 6.—That this Society requests the Ohio State Medical Society to adopt the foregoing schedule of requirements and to use its influence to secure legislation making the same obligatory upon persons entering their names as students of medicine in the State of Ohio.

Resolved, 7.—That these resolutions be printed and a copy sent to each Medical Society in this State with the request that they early report their action thereon.

CORRECTION.

EDITOR OF THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION:

I am informed by my friend Dr. Mundé, that I was mistaken in attributing to him two deaths following the operation of trachelorraphy in my article on that subject published in your journal February 23 last. His only death out of 125 cases occurred two weeks after he operated from septic peritonitis. I must have seen it mentioned in two different journals and thus fallen into the error committed.

I take pleasure in making the correction..

Very truly yours,

JOSEPH TABOR JOHNSON, M.D.

916 Farragut Square, Washington, D. C.

SOCIETY PROCEEDINGS.

CHICAGO MEDICAL SOCIETY—REGULAR SEMI-MONTHLY MEETING OF MARCH 3 1884.

The large attendance was noted and the session was an interesting one. Two important topics were discussed.

The first was a rhetorical treatise read by Dr. Charles E. Webster on "Pott's Disease as Illustrating the Principles of Early Diagnosis." It contained much original matter from which we make the following extracts:

Mr. Chairman and Members of the Society

Perhaps I, more than others, can appreciate the importance of early diagnosis in the disease to be considered this evening, and as I walk the streets I am well assured by many living proofs that in the past there has been negligence in this regard.

The busy general practitioner, with his mind harrassed by a thousand cares, is liable to overlook the critical condition of some fretful, sickly child until the golden opportunity is lost, and he is burdened with the perpetual curse of an ineradicable deformity.

In order to present a paper of sufficient scope to be of general interest, I have arranged the following notes on the diagnosis of Pott's disease, which for the most part are compiled from standard author's.

If this paper succeeds in awakening sluggish memories, and thus some child is saved by early treatment from life long misfortune, it will have well fulfilled its purpose. The treatment of a case without a diagnosis is like waging war without a fortified base of operations. It can be done, and successfully, too, but it is not the highest refinement of art by any means. The most skillful physician, like the best trained general, may be forced into action without time for intrenchment, and if the odds are not too great against him he may win the day. Uneducated doctors, like untaught savages, kill, take captive, and are victorious. The one protects his nakedness with a flimsy shield, and the other his ignorance with a fanciful diagnosis. But neither the success in emergency of the expert, or the prosperity of the quack can justify departure in ordinary cases from the common course of procedure. Therefore it may be assumed that the recognition of the disease treated is the first requisite to successful practice.

Each disease has an individuality of its own, which is preserved through all its varieties and amid all its complexity of symptoms. Were this not the fact, scientific medicine would be impossible, for classification is the first necessity of exact science, and the identification of species is the first requisite to classification. Among diseases, species may be ill-defined, may run into each other by innumerable varieties, or a particular case may present some startling anomaly, but strongly marked individual differences are not inconsistent with a specific resemblance, and the most hazy nebula has as real an entity as the most sharply defined planet.

Admitting the entity of a given disease, the question arises, in what does that entity consist? It is like the individuality of a face. Some faces have a characteristic feature, a nose, an eyebrow, a chin that is characteristic, and that face is remembered by that feature. So certain diseases have pathognomonic symptoms; as the periodicity of the attack in intermittent fever, and such diseases can be diagnosticated by their pathognomonic symptoms. In general, faces are remembered not by a process of analysis, not by their individual features, but as single units of cognition. You may know a person intimately, but cannot tell the exact shade of his hair or eyes, the shape of his nose, or the cut of his beard. Let him shave, let time furrow his face with wrinkles, and pull out half his fading hair, you will still recognize him, though not a feature, but has suffered some appreciable change. It is the same with most diseases. It is often said of such and such a doctor, he has a peculiar knack of diagnosis. In what does his peculiar excellence lie? He is old and little educated in the schools, his sight is dim, his hearing dull, he cannot appreciate fine points of auscultation and percussion. The Faradaic current is beyond his ken; he can hardly assign a reasonable cause for a single symptom, but he unconsciously coördinates those symptoms that he observes into a single unit of consciousness, giving each feature its due prominence in the picture drawn, and by taking a telescopic view of the case, and by comparing this with similar pictures of other cases he has seen, he gives his diagnosis; his view is broad, he neglects much detail, but he sees the case as a whole. In general practice it is this telescopic power of the mind that makes a diagnostician. There is more to diagnosis than this, however.

In common life recognition of an individual is sufficient. In a court of law identification becomes necessary. In ordinary practice a snap diagnosis may be sufficient. In the scientific study of disease, in commencing treatment in a fatal or chronic malady, or in a formal consultation, an exact diagnosis is necessary. This may be reached by one of two methods, either directly, by comparing the symptoms of the case with the described symptoms of the disease, or indirectly, by the differential method, considering all possible maladies that might exist in the case, and eliminating them singly by the direct method, giving the preference to the residual disease. To illustrate these principles, let us consider the early recognition of Pott's Disease.

A glance at the patient may be sufficient for the provisional or snap diagnosis. You see a sickly child with an anxious expression of face, moving cautiously, seeking support from external objects, and carrying its trunk erect. Throw some object on the floor for the child to pick up. It stoops by flexing the legs, but still carries the body erect and steady, as though the spine was made of glass, and it was afraid of breaking it. The seeking of support, and carefulness respecting jar or strain of the spine, are the most distinctive features, and may be variously modified according to the age of the patient, the location and acuteness of the inflammation, and other circumstances of the case. With the first glance you have recognized spinal caries, but in so serious a matter

an opinion should not be given until the exact diagnosis is reached, which necessitates a history of the illness and a thorough examination. If unwilling to assume the responsibility, or unable from press of business to take the trouble, send the case to one who will, for you have before you for treatment a patient destined to live in spite of the grossest negligence, but whose future happiness and usefulness alike depend upon the care and fidelity of some one who for years shall enforce those simple rules of life, and adapt with care and accuracy the appliances necessary. * * * * I can well assure you, gentlemen, that highway robbery is a much more honorable mode of obtaining wealth, than by careless diagnosis, procrastinating measures, or insufficient treatment, to rob a child of the slight chance of maintaining that normal bodily symmetry, which is a prime requisite for reaching his highest physical, mental and moral development.

The history of the case will vary according to the varieties of the disease. In this review of the subject it is not my intention to give a classification of these varieties, therefore it will suffice to mention all the symptoms likely to occur, premising that the absence of symptoms, or the inversion of their order, does not preclude the possibility of spinal caries. (The balance of Dr. Webster's paper was ably condensed from the best writers, but would occupy too much space. We give place, however, to his tabulated statement of differential diagnosis as follows):

TABLE FOR THE DIFFERENTIATION OF POTT'S DISEASE.

Pott's Disease.	Strain or Cellulitis.	Hysterical Spine.	Muscular Rheumatism.	Coxarum Morbus.
Prodromic stage..... May be months in duration.	Absent.	Absent.	Absent.	Months in duration.
Motions and attitudes.. Suggest anxiety to keep the back from hurt.	Show a stiff back.	Natural.	Not characteristic.	Suggest trouble in one leg.
Pain intermittent... Remote from spine.	From motion with local tenderness.	Very sensitive at a few points to a light touch.	Not local, at one point.	In leg.
Pain constant..... In the spine increased by pressure.	Increased by pressure.	Patient writhing in pain.	Motion painful.	In leg.
Stiffness ..... Jar and pressure.. Local. Aggravate symptoms. Relieves symptoms.	Local. No effect	Absent. Give varying results.	Absent. Negative.	Of hip. Aggravate symptoms. Relieves symptoms. Lengthening of leg.
Extension ..	No effect.	No effect.	Negative.	Negative.
Early deformity ... Angular.	Absent.	Absent.	Negative.	Absent.
Paraplegia.. After deformity.	Absent,	Hysterical.	Negative,	From abscess.
Tumor. ..... From abscess.	From abscess.	Absent.	Negative,	

Sacro-Iliac Disease.—Resembles hip disease.
Torticollis.—If from cervical caries the patient supports the head with hand. Palpation detects thickening and tenderness of vertebra.
Superficial Caries.—Constitutional or traumatic causes, abscess, no deformity.
Aneurism of Aorta.—Deformity slight, not angular, signs of aneurism.
Disease of Kidney.—Differentiate by the urine.
Lateral Curvature.—Deformity not angular; no stiffness.
Rachitis.—Deformity not angular; affects other portions than the spine.
Muscular Weakness.—Deformity obliterated by lying down.
Hernia.—Sudden disappearance of tumor, with absence of spinal symptoms.
Paraplegia.—Without deformity may be ascribed to Pott's Disease if there are spinal symptoms and no other assignable cause.
Diseases of Childhood.—With a long prodromal stage are to be differentiated by the concomitant symptoms.

Thus, a prodromal period, or period of incubation, is to be expected during this stage, which may date from some sickness or injury, or may arise without any assignable cause, and be of several months' duration. The patient shows an indifference to his ordinary amusements, and an unnatural fretfulness; he may become awkward in his movements, stumbling in his gait, or assume unlikely attitudes. There may be constitutional symptoms, as loss of appetite, anæmia, and a rise of temperature. There may be nervous symptoms suggestive of paralysis, as weakness, numbness, or tingling sensations in the lower extremities, with irritability of the bladder. If the disease is high in the column, gastric irritation, with a sensation of constriction of the chest. If upper cervical, difficult deglutition, choreaic movements of muscles of the neck, numbness of the arms, and laryngeal cough, or a choking sensation. Pain is one of the most unreliable of all the symptoms. It is generally located anywhere rather than at the seat of the disease, and many patients are entirely free from it. It is thought to be caused by the irritation of the spinal nerves, at the point of their exit from the foramina, and is referred to the ultimate termination of those nerves. When it occurs it may be constant if local, or intermittent if remote from the spine, and be increased by fatigue or sudden jar. Acute pain is suggestive of a suppurative inflammation, while a dull ache is more characteristic of dry caries. The location of the pain indicates the location of the disease. If thoracic, the disease is cervical. If in the abdomen and lower part of the thorax, the disease is thoracic; while if through the thighs, the disease is lumbar. A satisfactory history of the case having been taken, the patient is to be stripped and inspected. Flexion of the spine is avoided, and a constant effort made by the patient to support himself; he leans upon the furniture, rests his hands on his thighs, or lies across some object; his movements are constrained, in order to avoid jar; he shuffles his gait. From reflex muscular spasm there may be a partial flexure of the thighs, and a local stiffening in the portion of the spine affected. Torticollis may occur; the head may be thrown back and the shoulders raised; the respiration may be grunting in character, with limited motion of some of the ribs. The first evidence of the location of the disease visible to the eye may be a slight flattening of the normal curves of the spine, with stiffening of the affected part, an indication of little value in young children when the curves are not developed. There may be slight bulging, or a slight lateral angle in the line of the spinous processes at the diseased point, and finally, as the commencement of the deformity, there is the forma-

tion of a knuckle, produced by the tilting up of the spine of the vertebra whose body is most eroded. Follow the inspection by a physical examination to establish the diagnosis and locate the disease. Let the patient jump down from a slight elevation, as a low stool. This concussion may produce a cry of pain, a slight confusion of ideas, the child looking surprised, or even a fall.

Another method of producing the same result is to press down on the head and shoulders, producing a cry and muscular spasm; however, these are both rather dangerous experiments; rubbing the back briskly with the knuckles makes the vertebral spine stand out in red spots, this may assist in detecting any displacement; pain may be produced at the point of disease by percussion, firm pressure, compression of the chest, crowding the heads of the ribs against the diseased vertebra, a piece of ice, or a thimbleful of hot water passed down the back, and lastly by lateral flexion of the spine, the patient lying on his face and the body being grasped by the pelvis and shoulders. If, with the patient standing erect, the palm of the hand be placed against the suspected region and then the spine bent in various directions, any local stiffening can be detected, the neighboring healthy parts being felt to move; the heat of the inflammation can sometimes be detected by the hand or by the surface thermometer. There may also be slight diffuse swelling. If the patient has pain of any sort, impeded respiration, or any uncomfortable sensation, lay him across the knees, on a table, or place him in a spinal swing and make firm gentle extension or partial suspension, observe if his symptoms are relieved. If he gives a sigh of relief and breathes freely while there is a cessation of his pain, and if the reverse of these maneuvers, by pressing the diseased bones more closely together, aggravate his symptoms, the diagnosis may be considered as fully established and a plan of treatment adopted. There are cases where the first symptom noticed, is the knuckle of the commencing deformity, and others where paraplegia or abscess may occur without deformity. In obscure cases where the direct diagnosis is difficult, or in any case where especial accuracy is desired, the table for differential diagnosis will be of service. Errors in case of some of the diseases mentioned are much too common, and an occasional reference to such a table, though it be far from exhaustive, will be a valuable aid to the memory. Theories of treatment and facts of general scienee can be found in text-books. They may be held in memory, or when needed, sought by reference, as is most convenient, but it is the duty of the student ere he becomes a practitioner, to become at least tolerably expert in the snap diagnosis of common diseases, if not invincible in exact diagnosis. How are these powers to be acquired? By only one process, *i. e.*, by the study of disease, by noting the gross appearance of disease as well as its most minute features; by clinical practice supplemented by careful reading, and by acquiring the greatest possible proficiency in all those methods of physical exploration without which scientific medicine would be an impossibility. Many a young graduate enters the sick room of his first patient with trembling and abject fear. He has learned to auscultate and percuss with an instructor at his elbow, and to listen by the bedside in the hospital to an exact description of a patient's symptoms. But to interrogate and examine a patient with a view to identifying his disease and relieving his sufferings is a thing to him as strange as were mounted horsemen to the American aborigines. At the commencement of one's course, if he could learn the practical duties of a nurse and accustom himself to attendance on the sick, he would have done far better preliminary work than if he had mastered every department of natural science. For then the clinic would be real practice, the didactic lecture an illumination of intelligible pictures and not a weird phantasmagoria of the unreal. While the work of pathology would become the survey of old battlefields, the study of the historic part which is to fit him for coming victories. In conclusion the writer quoted his honored teacher in anatomy, Dr. Oliver Wendell Holmes, who from the eminence he had attained by a life of philosophical labor, sends down the clew to guide the student groping among the underbrush of routine study. "I would not undervalue the branch I teach. I recognize the incidental importance of all the subsidiary branches which form a part of the curriculum of this and other schools; do full justice to them or you will not probably do justice to your more immediately practical studies, but your hardest study must be at the bedside. To go hastily from the library of old books and the laboratory of new experiments to the bedside of disease is imitating the presumption of those rash profligates who, as Thomas Boston says, think they can take a leap out of Delilah's lap into Abraham's bosom."

In the discussion which followed, a number participated. Among those noted were Dr. W. E. Clarke, who expressed his gratification at hearing the paper, and thought the many learned points therein contained should be of much interest to the profession generally.

Dr. R. G. Bogue also was greatly pleased with the subject announced and with the views of the writer. At present he has a case under observation that has caries in the upper dorsal region, that possibly would require the greatest skill in deciding positively whether the disease could be retarded in the child and deformity prevented.

Dr. D. W. Graham had considerable experience in treating this class of troubles. The greatest number of his cases had come to him throngh the dispensary, and were charity patients. The speaker thought too much importance could not be attached to early diagnosis in these unfortunate cases, and it should be regarded as a crime for parents to neglect their children at an early stage, or who failed to have them treated. The table prepared by the author is admirably gotten up. One suggestion he desired to offer, namely, that Pott's Disease might be possibly confounded with a simple affection, such as a chronic bowel trouble with pain, rather constant, or where general debility was present, or where there was prolonged disorder of the digestive organs, and if any doubt existed as

to the malady, we should make further investigation, and insist on making careful observation of the child.

Dr. R. Tilley desired to add his testimony to the value of the paper, and that we should be fully conscientious, especially in this class of cases, to make an early diagnosis. He thought, however, that the parents of charity cases did not pay proper heed to our advice regarding the welfare of their children.

Dr. Webster, in closing, thought the first speaker's suggestion was well-timed, although, possibly, muscular rheumatism may be more likely mistaken for Pott's Disease rather than all of those in the table.

Dr. Oscar J. Price then gave a report of a case of aneurismal tumor from the arch of the aorta, with the causes, varieties, difficulty in diagnosis, treatment, history and pathology of his case, of which the following main points are given:

G. R., age 40; weight 140; temperament gouty or sanguine; married; stone contractor; was first visited by the writer on the morning of the 4th of February last. The patient had just returned from a Southern trip of some three weeks' duration, having arrived home about two hours previously. Found him sitting up and dressed, quite free from excitement, and apparently in no way entertaining serious apprehension as to his condition or welfare. He had complained more or less during the past year, and there had been constantly a dull aching pain in the muscles of the right arm, which gradually extended to the upper portion of the right chest and centered there. It had become lately quite acute and hard to bear. He also had some cough and dyspnœa; was conscious of an unusually rapid action of the heart, which particularly attracted his attention upon any exertion or excitement. He stated that his trouble had been considered by his former medical attendant as muscular rheumatism, for which was pursued constant treatment, covering a period of many months. Finally, he was advised to make this Southern trip, with hopes of recovering his health; could not say whether this advice had been given with the belief that there existed a tendency to phthisis. No benefit having occurred from the change of climate, as he was conscious of feeling worse, and became more easily exhausted upon the slightest endeavor, he resolved to return home much sooner than he at first contemplated, and while in a sleeping-car was suddenly taken with a hæmorrhage from the lungs, which was very profuse and exhausting. Receiving some temporary medical attendance at the time, he soon rallied from the shock and was enabled to pursue his journey home. In response to inquiries, he stated he had generally considered himself rugged and healthy; had led a fairly temperate life; some 12 years ago, however, he had an attack of acute inflammatory rheumatism and had also in earlier years contracted syphilis.

A careful and exact examination of his chest was fraught with considerable difficulty, owing to the fact of his having just emerged from a severe hæmorrhage, and the consequent danger of exciting another. Much percussing of the chest not appearing to be warrantable under the circumstances, I was content with as gentle an examination as possible. There was a complete absence of pectoral or vocal fremitus, and indeed a total absence of all sounds over the right thorax, as elicited by auscultation. Very gentle and limited percussion appeared to reveal the existence of a cavity of presumably large proportions. In the upper portion of left lung were evidences of bronchopneumonia, while the heart was found to be crowded considerably to the left, its valves working normally, but much accelerated in action and volume. Instructions were given for the patient to immediately take to his bed, to remain perfectly quiet, and to be given cold drinks and food with a view to avoiding, in so far as possible, other hæmorrhages presumably imminent. In furtherance of this, he was placed upon a mixture containing digitalis, ergot, sulphuric acid and opium, in proper doses, with a view of controlling the expected hæmorrhage. The next morning was called early, and found patient had just had another hæmorrhage of about one pint, and was in a state of the greatest prostration, bathed in cold, clammy perspiration, and suffering acute pain, extending from about the second right intercostal space near the sternum through to the back. One gr. of ext. ergotine was immediately injected into his back, and ¼ gr. morphia sulph. in his arm. Stimulants were exhibited, and in the course of two hours his condition had materially improved, circulation and warmth being again restored, and resting quite easily. * * *

The following day, Dr. J. P. Ross saw the case in consultation, and then a very careful and extensive examination was made. It was his opinion there was an effusion in the right chest, and acting upon this belief, an aspirating needle was thrust through an intercostal space twice at different points, but without return of fluid other than a little blood. No resistance was met with, the needle, after introduction, being tipped in different directions without obstruction.

It was thus quite evident there was no effusion worth consideration, also the existence of a cavity pretty well established presumably, from collapse of lung and accumulation of blood clot, we were now warranted in arriving at but one conclusion. When it was considered that there had been no emaciation; no hectic; no tuberculous cachexia; the character and suddenness of the invasion, with the physical signs following, led irresistibly to the conclusion of the existence of a ruptured, leaking aneurism. Remedies to control the excitability of the heart's action, to allay pain, conjoined with perfect quietude, were all that was now attempted. The following night he had another severe hæmorrhage, from which he only partially rallied, only to be plunged into yet another the succeeding day, from which he gradually sank, dying on the evening of the next, a little over one week from the first hæmorrhage.

Autopsy kindly permitted by friends. Besides the author, there were present Drs. J. P. Ross, J. A. Robinson and E. P. Murdock. Eighteen hours after death, rigor mortis well established; subject fairly nourished; skin white. Incision from upper part of sternum to ensiform cartilage, thence along course of costal cartilages. Incision into right pleural cavity

caused a small amount of sero-sanguineous fluid to flow out. Heart revealed crowded to the left, and large blood clots in right pleural cavity; blood removed to the amount of over two quarts. There now appeared a large sacculated aneurism of the first portion of the arch of the aorta, enclosing a large fibrinous mass some four inches in diameter. Pericardium adherent to heart; sac of aneurism adherent to right pleura; p. m. clot in right auricle; aneurism ruptured, opening into the pleural cavity at the lower portion of upper lobe of right lung in front, also an opening into the upper portion of the right upper lobe communicating with a bronchial tube, the lung being filled with blood, completely collapsed, and its tissue very fragile. The heart was enlarged and dilated, the walls of the left ventricle being thin and infiltrated with fat, especially toward the apex. Very slight fibrous deposit or vegetation on one aortic valve; the sac of aneurism so large as to contain a man's double fist, its distended vascular coverings having undergone such changes as to render them quite unrecognizable. The inner aspect presented a rough, uneven surface, composed of laminated fibrin and fresh blood clot. These layers of fibrin had been built upon each other into liberal proportions, so as to virtually constitute all that remained of the aneurismal sac.

(The specimen was then presented for observation). In contemplating this case it is interesting to observe the length of time the patient survived after such a formidable rupture, which evidently ushered in the first hæmorrhage, the inference being that the heart, temporaily relieved of its force and impetus, permitted a large-sized coagula to block up the opening for the time, subsequent hæmorrhages resulting from the instability of the same, which, doubtless, was considerably guarded against by perfect repose and quiet. The usual connection between aortic aneurism and ventricular hypertrophy is again illustrated in this case. There had also been, as already stated, pericarditis, which presumably took its origin from the severe attack of inflammatory rheumatism several years before, although it is perhaps questionable if the propulsive action of the heart alone is able to produce aneurism, unless of a diseased artery. It is reasonable to suppose, however, that a disease which may produce endocarditis and pericarditis may also cause endoarteritis. The history of the case also furnishes another somewhat commonly accepted cause for aneurism, negative testimony to the contrary.

Military statistics would appear to demonstrate that a large number of cases of inflammatory involvement of blood-vessels ending in atheroma or fibrous thickening of the coats of the vessels are of syphilitic origin. Admitting that this is by no means established it would still appear that it is a disease in common with rheumatism tending to impair, not only the functional properties, but the nutrition and structure of arterial walls, and is thus justly entitled to due consideration as a possible element in the case. Reasoning by exclusion, the patient had not been addicted to more than ordinary, or a very moderate indulgence in alcoholic drinks, and therefore can hardly be said to have furnished this supposedly frequent factor to the malady. Muscular effort or over-exertion also, as superinducing elements, appear to have no proper claim to consideration, as the patient had for fifteen years preceding death led a very quiet life relieved from manual labor. In estimating the general causes of aneurism, it is, of course, an open field for conjecture and capable of many and diverse illustrations. Still it would appear that the history of this case furnishes one, if not two, very reasonable and commonly accepted conditions leading to its development. Diseases which frequently terminate in a chronic inflammation of the internal coat of an artery may be properly classed as predisposing to aneurism, and such this case affords. Aside from traumatic origin, it is evident that structural lesions of a destructive tendency, involving the middle and internal coats of arteries, play an important part in the production of aneurism.

Thus we have the conditions most favorable to the formation of plastic deposits on the free surface, which are so commonly met with in the aorta or larger vessels. From this plastic inflammatory process commencing in the lining membrane morbid changes are initiated, involving the middle coat, which, becoming thinned by pressure, soon softens and yields, forming a kind of pouch or depression. Firm adhesions are now found between the two membranes, and we have the commencement of an aneurism. It is evident the natural tendency of such a destructive process would be to rupture, but, in accordance with the wonderful preservative powers of nature, conservative forces are set into action, also the external coat becomes thickened, indurated, and supported by this deposition of plastic matter going on beneath it until it becomes a firm and rugged barrier, thus preventing for a long time, and sometimes permanently, the perforation of the sac. It is, however, inelastic, and performs no proper part in the distributing of blood which passes through it. Its caliber, therefore, must gradually dilate, its pouch-like form becoming the natural receptacle for the deposition of coagula and fibrous deposit, and the specimen affords an excellent observation of the laminated type, built upon itself layer upon layer, adhering firmly to the interior of the sac, and arranged concentrically like the coverings of an onion. Its large size would seem to indicate it had been a long time in forming.

DISCUSSION.

Dr. R. Tilley thought if syphilis was a cause of aneurism (which was remote in this case, in his having the disease prior to twelve years ago), it did not establish the fact that the man had aneurism.

Dr. H. J. Reynolds asked if there were no murmurs present? Answered no. There were no sounds in the right portion of the thorax. The heart was crowded out of its place (to the left) and enlarged.

Dr. P. C. Jensen inquired of the author if there were ever present girdled pains around the patient's chest at night? Answered, would hardly regard them as such. There was a good deal of pain in the right chest, in the second intercostal space, especially when the violent hæmorrhages occurred.

Dr. W. L. Axford thought aneurism was not always easy to diagnose. The great Liston once opened what he supposed to be a boil on the chest of a man, when the patient at once sank, bleeding to death, caused by an aneurism that he had cut into.

Dr. C. E. Webster asked, if there was any erosion of any of the vertebræ, or symptoms of erosion of the sternum, present?

Answered, no, not the least.

Dr. W. E. Clark asked, how long before death was the patient aspirated?

Answered, 36 hours.

Dr. L. H. Montgomery asked, if the patient had taken iodide of potassium for rheumatism, and for the specific disease, as well, probably, as for the influence it may exert over aneurisms, and further, was there no incipient stage of the aneurism present a year ago?

Regarding the case reported. I am well acquainted with a brother of the deceased; a gentleman who is a carrier in the post-office, and whose family I have attended for several years. He told me that nearly two years ago the deceased had witnessed a sad accident, in which his 12 year old son had been killed; that his body was mangled horribly, while he stood but a few feet away at the time the accident occurred, and he saw his boy's head crushed off. The father stood apparently motionless and speechless, his features becoming very pale at the ghastly sight he beheld. If this be so, could not the heart's action temporarily intermit or cease to beat for a few pulsations, caused by a sort of paralysis, the result of what he had seen? It was from about this date that he had complained of more or less pain in the side and chest.

Dr. Price, in closing, stated in reply to the last speaker, that he had treated the patient a year ago, and gave iodide of potash in 10 grain doses to him, three or four times a day for four weeks. Secondly, he thought the accident, which has just been spoken of, might possibly have produced the starting or incipient stage of the aneurism; and thirdly, while the deceased was South some ten days before death, he engaged in violent exercise, that of jumping 8 feet 2 inches. This he did twice, and became ill shortly after.

Upon motion the society adjourned.

L. H. M.

STATE MEDICINE.

LAWS OF INHERITANCE.

BY NATHAN ALLEN, M.D., OF LOWELL, MASS.

The following extracts are from the fourteenth annual report of the Board of State Charities, of this State. The subject of the laws of inheritance is here discussed in a lucid and comprehensive manner. Few gentlemen have studied it more thoroughly than the writer of this report, Dr. Allen, of this city, with whose writings our readers are familiar.

In the second report of the Board of Charities, it was stated that one of these primary sources is an "inherited organic imperfection of the body, a vitiated constitution, or, in other words, poor stock." Since that statement was made, our conviction of its truth has been confirmed more and more by careful inspection and inquiry among the inmates of the State institutions. While many of these persons, by indolent and vicious habits, have contributed to their own degradation, still, there were predisposing causes in their constitutions which had a powerful influence in the same direction. Many inherited feeble bodies and weak minds, with strong propensities. They commenced life amid circumstances most unfavorable for developing the better qualities of their nature. In attempting, therefore, to ascertain everything that has formerly contributed to make these persons paupers, criminals, or lunatics, we must not only take into account their own agency, but must consider well the nature and amount of capital which they had to start with in life.

No fact in science is better established than that there is a most intimate mental as well as physical relation between the parent and the child—between each generation and the succeeding one. This relation has been well expressed in the proverbs, "What is bred in the bone can not be whipped out of the flesh," and "Like begets like." The hereditary relation has, we believe, a far greater agency in producing social evils than has generally been conceived. This relation extends, by transmission, not only to the form of the body and the features of the countenance, but to every part of the system—to the quality of the blood—especially to those vital organs which give stamina of constitution and beget mental predispositions. Whatever agencies, therefore, are calculated to injure the body or deprave the mind, to incapacitate an individual for self-support, or to make him a corrupter of others, should certainly be exposed by the guardians of public charity.

Among the most mischievous agents operating injuriously upon the human system, is alcohol; and whether we consider the extent of its abuse, in various forms, or the terrible effects which it produces, it certainly stands foremost as a cause of pauperism and other evils. It poisons the blood, and produces a diseased or morbid condition of almost every organ of the body. It affects the brain, impairs the intellect, perverts the moral sentiments and the will, and increases unduly the activity and strength of the worst propensities. It prostitutes the higher to the lower nature of man, changing what should be the true aims and objects of life to those of a low animal nature.

Closely connected with the alcoholic poison is another, which, though not so manifest in its effects, has a most destructive influence upon human welfare. This poison arises from habits of licentiousness, and its evil effects do not cease with the living, but extend through successive generations. The syphilitic poison operates on the human system in so covert a manner, and in such a variety of ways, that it is sometimes found difficult to trace out all these effects; but the more thoroughly the pathological and morbid conditions of the body are brought to light by modern science, the more extensively are discovered

the mischiefs which this poison has wrought. If the amount of vice, disease and pauperism produced from this source alone could be made known, it would surprise people. In some respects this poison is more destructive of health and life than the poison of alcohol.

But there are other modes of abusing the reproductive organs which injure most seriously both body and mind. A careful inspection of the inmates of our almshouses and hospitals will show a vast amount of suffering from this abuse. It is the hereditary effects of these evils that make them especially significiant in the production of pauperism and insanity. To aggravate the matter, their effects are communicated in an intensified form, from generation to generation, and it is very difficult to check or eradicate them either by human means or through the recuperative powers of nature.

Besides these two poisons. there are other agencies that injure the body and enfeeble the mind, such as narcotics, stimulants, over-medication, &c. Then come irregular habits, want of proper nutrition, and a train of diseases which either destroy their victims or make them helpless and dependent. When the physical system is impaired or broken down, the mental faculties frequently become enfeebled and depraved, so that not only poverty and temporary dependence, but habitual indolence and shiftlessness also ensue. Such a state of things makes paupers, who, by natural association, form social and domestic relations with each other. The more such persons become associated together, either in families or communities, the more unfavorable is the influence of one upon another, the whole tendency of things being to sink them lower and lower in the human scale. Worst of all, whatever offspring these persons have are pretty sure to be impregnated with vice, pauperism and crime, by the law of inheritance as well as by the habit of association. A careful inquiry into the origin, history and character of the inmates of our public institutions will abundantly prove and illustrate these statements.

So important was this subject deemed by the Senate and Assembly ot New York, that an inquiry into the causes of pauperism was ordered in 1873, which has recently been completed and its results made public. The inquiry seems to have been thoroughly made by the Secretary of the Board of State Charities, occupying his time, more or less, for several years. Over 12,000 persons, scattered in the town, city and county almshouses of the State, were examined, with reference to the leading facts connected with their pauperism. Of these, 6,566 were foreign, born in the almshouse; 3,106 could neither read nor write; 6,133 had been intemperate. Of the 4,147 chronic insane, 44 per cent. had been intemperate. Of the whole 12,000, 2,030 were homeless children, 1,750 of whom had pauper fathers and mothers. The average stay of all the paupers iu the almshouses was 4.88 years—almost five years' residence. More than 30 per cent. of the paupers had intemperate parents; many had a large circle of relatives who had been or were then in almshouses. Few persons were found to be paupers by their own misfortunes in business, or sudden loss of property. The dependence of most paupers was induced largely by immoral and sensual habits, long indulged, or by habits of idleness and shiftlessness, which in many cases might have been early arrested by proper measures.

As one of the results of this inquiry, the New York Legislature passed a law directing that children found in the almshouses of the State should be removed, and discontinued thereafter the entrance of children into such institutions—intending to provide for them in asylums, or find them homes in private families.

While this inquiry was going on, the New York Prison Association provided for a careful investigation into the causes of crime and pauperism among the inmates of the jails and prisons of the State. Among the results of this investigation, the history of a remarkable family is given, under the name "The Jukes," extending back six generations, where, from one bad woman, nearly a thousand persons, by birth, relationship, and association, became paupers or criminals. This history shows the great power and influence of heredity and early association in the production of pauperism and crime, more forcibly than ever before.

It demonstrated that the seeds, or primary causes, of these evils are connected with the great laws that govern human life farther back than has been generally supposed. This family history brings up, also, the relations between "heredity and environment," and suggests means or agencies which may be employed to prevent or check the miseries originating from these two sources. The more this whole subject is investigated, the more evident it becomes that in order to check the increase of pauperism, crime, and insanity, the remedy must be applied to their primary sources. It will be found, too, that these are, to a great extent, under the control of human agency.

A careful examination of all the facts shows that, in addition to the hereditary influence, ignorance, idleness, intemperance, and prostitution are prime factors that enter into the complex product of pauperism and crime. The hereditary agency precedes these personal factors, and predisposes to their activity and control. It is evident that the germs or predispositions originate in physical organization and development. These secondary agencies would not be called out, or would have but little influence, if the right kind of material for their operation had not been provided. This proposition may be more clearly illustrated in the case of disease and insanity. It is found, as already said, that by a thorough and systematic application of sanitary science about one-third of all disease may be prevented, and human life much prolonged. At the same time, inherited imperfections, weaknesses, and predispositions to disease already existing in the human body, stand in the way and prevent the full benefit of sanitary agencies. These hereditary predispositions or liabilities to disease are, however, very much alleviated, if not checked in their operation, by hygienic means; but if they did not exist, how much less disease would call for treatment, and how much more success would attend well-chosen measures!

Now, disease itself among the poor, especially where there is not much native energy and perseverance, is a primary cause of pauperism; and, if disease become chronic or organic, its influence is still greater. It is not the cost of illness (though this is no small item) so much as its effects in disabling the body for work, and breaking down the mental energies, which does the mischief. And to make the matter worse, the seeds of disease are communicated to offspring in an aggravated or intensified form. Besides, the preliminary stages of illness among these classes being often neglected, and the recuperative powers of nature very small, diseases of all kinds, and especially those of a scrofulous nature, are quite sure to have their run, and become chronic. A constitutional disease, becoming chronic and combined with scrofula, is a powerful factor in the production of pauperism. The fact is, hereditary influences, in a great variety of ways, enter largely into pauperism. Thus, the more extensively sanitary science can be applied among the poorer classes, in the prevention and cure of disease, the more it helps to diminish pauperism. In this way, boards of health become public benefactors, and Legislatures should provide most liberally for their support.

In the history of the insane, the deaf and dumb, the blind, the idiotic and feeble-minded, hereditary influence is still more apparent. It is well known that these defective classes afford a large number of paupers. In regard to the insane, the fact is pretty well established that the malady in fully one-half of the cases may be traced, directly or indirectly, to hereditary influences, and that in the other defective classes a still greater proportion can trace the origin of their troubles to this source. In the case of other paupers, it is more difficult to follow out hereditary influences; but the better the laws of descent are understood, the more significant become the indications of heredity in pauperism. It should be borne in mind, that it is not the mere form of an organ or similarity of construction that is transmitted by parents, but the peculiar uses to which the organs are applied, or rather the habits and character of the individual. Let those portions of the brain which officiate as the organs of the lower propensities be more active than those connected with the intellect and the moral sentiment, and kept continuously so for years, and a predominance of the animal nature is sure to be transmitted from the parent to the child. The same law holds good as to all parts of the brain or other organs of the body. Let selfishness, laziness and sensual habits control the parents, and their offspring will surely partake of the same character, provided surrounding associations do not prevent.

SURGEON-GENERAL OF THE NAVY.—The President has appointed Surgeon Gunnell as Surgeon-General and Chief of the Bureau of Medicine and Surgery of the Navy.

M. TARNIER has been appointed Professor of Obstetrics and Diseases of Women and Children in the Faculté de Médecine, of Paris.

DOMESTIC CORRESPONDENCE.

FROM WASHINGTON.

The bill to provide for the establishment of a bureau of animal industry to prevent the exportation of diseased cattle, and to provide means for the suppression and extirpation of pleuro-pneumonia and other contagious diseases among domestic animals, the provisions of which were given in No. 1, Vol 2, of this journal as having been introduced into the House of Representatives, was taken up by the House on February 5. The bill was accompanied by several reports. The report from the Committee on Agriculture was unanimous in its recommendation that the bill pass, and after considering its various clauses, it emphasized that clause which provides for the exportation of live stock from the United States under such terms and conditions as the Secretary of the Treasury may from time to time prescribe, and referred to the action of foreign governments looking towards their own protection against our want of legal enactments in the premises. The British government has given notices in both houses of Parliament of motions to be made to totally prohibit the landing of our animals on its shores. The French government recently published an edict prohibiting the importation of any of our pork product into France; this shuts us out of a trade which had already reached $19,000,000 annually and was increasing at the rate of about $5,000,000 yearly. Germany has already placed a restriction upon the importation of these products, and there are indications that other countries may follow this lead. A statement from Dr. D. C. Salmon, veterinary surgeon of the Department of Agriculture, gave the extent of pleuro-pneumonia in Connecticut, New York, New Jersey, Pennsylvania, Maryland, and the District of Columbia, as large and dangerous. Pennsylvania, by the vigorous methods used to extirpate the disease, is now believed to be free from it. The reasons for believing it to be contagious were reiterated, and the fact that the danger was greater than the extent of infected territory and number of diseased animals would indicate, was strongly put. The remainder of Dr. Salmon's argument was taken up in showing the inefficacy of State action, the advantages of the work being directed by the United States government, the fact that the presence of pleuro-pneumonia costs annually more than would be necessary for its destruction, and the importance of investigating other diseases.

The discussion seemed to turn mainly upon the interference of the Federal government with State authorities, and was continued through parts of the daily sessions of Feb. 5, 6, 23, 25, 26, 27, and 28. Mr. Belford, in his argument, gave in some detail the experimental researches of Drs. Law, Detmer, and Salmon, in investigating and determining the causes producing, and, if possible, in discovering remedies for the diseases of hogs and the other domesticated animals, which he put in a very concise and interesting form. On Feb. 28 the bill was passed as follows:

It provsded that the Commissioner of Agriculture shall organize a bureau of animal industry, and appoint a chief thereof, whose duty it shall be to investigate and report upon the number, value, and condition of domestic animals of the United States, and also the cause of contagious and communicable diseases among them, and the means for the prevention and cure of the same. He is authorized to appoint two competent agents, whose duty it shall be to report upon the best methods of treating, transporting, and caring for animals, and the means to be adopted for the suppression and extirpation of contagious pleuro-pneumonia. The bill further provides that the Commissioner of Agriculture may expend so much of the money provided by this act as may be necessary in paying for the animals it is deemed necessary to slaughter, and in such disinfection and other means as may be necessary to extirpate disease. The authorities of the States shall pay one-half of the expense of the animals it is deemed necessary to slaughter, and one-half of the cost of disinfection and care of the herds of cattle. It prohibits the transportation from one State to another of any live stock infected with any contagious or infectious disease, and provides for the prosecution of any person violating this prohibition. The sum of $250,000 is appropriated to carry into effect the provisions of the bill.

NATIONAL MEDICAL SCHOOLS BY ACT OF CONGRESS.

Mr. Editor:

In common with the profession, I am watching with a good deal of interest the development of the plan to establish schools of medicine by law of Congress, as contemplated in Mr. Call's bill for the establishment of a national medical university, and I am much pleased with your suggestion, to add chairs for the demonstration of the claims of the "faith cure," and the total abstinence from alcohol schools, and I hope your suggestion will meet with the favor of our representatives. The greatest difficulty will be in finding enough allopathic doctors to fill the chairs allotted to that school. I have been a member of the American Medical Association since its formation, and am free to say, I have never met an allopathic doctor amongst its members, or for that matter anywhere else. I have met electropathists, homœopathists, hydropathists, eclectics, faith curists, prayer curists, mesmerists, fumblers, and blue glassists, but never an allopathist. A doctor who proclaims "contraria contrariis curanter" to be the only true principle of practice, and that he pursues that practice to the exclusion of all others, or who believes in it at all as a scientific dogma, must be a rare bird, indeed. The Code of Ethics does not prohibit a member of the American Medical Association from adopting any therapeutic method that his reason or experience may suggest to him for the help of his patients, but, he may not proclaim that method to be the only rational or scientific method of treating disease to the exclusion of all other methods.

I hope Call's bill will become a law, because I think it will do more for rational medicine than can be done in any other way, simply because it will dispel a popular delusion originating in schools that have ever made their success by catering to popular credulity, and crying out against a profession that long ago cut loose from all theory, all dogmas, and adherence to the teachings of any master, only admitting a thing to be absolutely true, when proved by the general test of universal experience.

It is about time that the public should learn that personal skill is the desideratum in the practice of medicine, independently of any school or any master. There are many methods of treating disease, but the success of any method depends on the skill of the individual practitioner, and not upon any iron-clad dogma, and the chief glory of modern medicine, as represented by the profession at large, consists in its entire freedom of opinion on all questions of science and art in their application to practical ends.

Daniel Leasure, M.D.
36 Jackson st., St. Paul, Minn.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department United States Army, from March 1, 1884, to March 7, 1884.

Perin, Glover, Lieutenant-Colonel and Surgeon, Medical Director, Dept. of Dak., leave of absence extended 20 days. (S. O. 23, Headquarters Division of the Missouri, March 5, 1884.)

Bill, J. H., Major and Surgeon, granted leave of absence for one month. (Par. 1, S. O. 20, Headquarters' Dept., Platte, March 3, 1884.)

Baily, J. C., Major and Surgeon, granted leave of absence for one month, to take effect on or about March 1, 1884, with permission to apply to the Adjutant-General of the Army, through Division Headquarters, for an extension of three months. (S. O. 24, Headquarters' Department, Texas, Feb. 26, 1884.)

Bache, Dallas, Major and Surgeon, leave of absence extended 7 days. (Par. 1, S. O. 43, Headquarters' Department, East, March 5, 1884.)

Stephenson, William, First Lieutenant and Assistant Surgeon, ordered to Fort Niobrara, Neb, for temporary duty, on completion of which to return to his station, Fort Omaha, Neb. (Par. 4, S. O. 20, Headquarters' Department, Platte, March 3, 1884.)

Fisher, Walter W. R., First Lieutenant and Assistant Surgeon, assigned to duty at the Presidio of San Francisco, Cal., from 18th inst.

Polhemus, A. S., First Lieutenant and Assistant Surgeon, assigned to duty at Fort Winfield Scott, Cal., from 18th inst. (S. O. 23, Par. 1 and 2, Headquarters' Department, Cal., Feb. 21, 1884.)

Phillips, John L., First Lieutenant and Assistant Surgeon, assigned to temporary duty at Fort Warren, Mass. (Par. 2, S. O. 39, Headquarters' Department, East, Feb 28, 1884.)

Benham, R. B., First Lieutenant and Assistant Surgeon, relieved from duty at Fort A. Lincoln, D. T., and ordered to Fort Sisseton, D. T. for duty. (Par. 1, S. O. 22, Headquarters' Department, Dak., Feb. 26, 1884.)

Changes in the Medical Corps of the Navy for the Week Ending March 8, 1884.

P. A. Surgeon H. E. Ames, from the "Colorado," and ordered to the Greely Relief Str. "Bear."

OFFICERS OF

THE AMERICAN MEDICAL ASSOCIATION

AND OF ITS SEVERAL SECTIONS 1883-4.

PRESIDENT.

Dr. AUSTIN FLINT, SR., of New York.

FIRST VICE-PRESIDENT.

Dr. R. A. Kinloch, Charleston, S. C.

SECOND VICE-PRESIDENT.

Dr. T. B. Lester, Kansas City, Mo.

THIRD VICE-PRESIDENT.

Dr. A. L. Gihon, United States Navy.

FOURTH VICE-PRESIDENT.

Dr. S. C. Gordon, Portland, Maine.

PERMANENT SECRETARY.

Dr. Wm. B. Atkinson, 1400 Pine St., Philadelphia.

TREASURER.

Dr. R. J. Dunglison, Philadelphia.

LIBRARIAN.

Dr. C. H. A. Kleinschmidt, Washington, D. C.

Place of meeting, 1884, Washington, D. C.; Time of holding meeting, first Tuesday in May.

CHAIRMAN COMMITTEE OF ARRANGEMENTS.

Dr. A. Y. P. Garnett, Washington, D. C.

ASSISTANT SECRETARY.

Dr. D. W. Prentis, Washington, D. C.

BOARD OF TRUSTEES FOR JOURNALIZING THE TRANSACTIONS.

Drs. J. M. Toner, Washington, D. C., President;
M. Moore, Rochester, N. Y.; Leartus Conner, Detroit, Mich.;
J. H. Packard, Philadelphia, Secretary;
H. F. Campbell, Augusta, Ga.; A. Garcelon, Lewiston, Me.;
P. O. Hooper, Little Rock, Ark.;
L. S. McMurtry, Danville, Ky.; J. H. Hollister, Chicago, Ill.

OFFICERS OF THE SECTIONS:

"Practice of Medicine."

Chairman—Dr. John V. Shoemaker, Philadelphia, Pa.;
Secretary—Dr. W. C. Wile, Sandy Hook, Conn.

"Obstetrics and Diseases of Women."

Chairman—Dr. T. A. Reamy, Cincinnati, Ohio; Secretary—Dr. J. T. Jelks, Hot Springs, Ark.

"Surgery and Anatomy."

Chairman—Dr. C. T. Parkes, Chicago, Ill.; Secretary—Dr. A. O. Walker, Detroit, Mich.

"Ophthalmology, Otology and Laryngology."

Chairman—Dr. J. F. Chisolm, Baltimore, Md.;
Secretary—Dr. J. L. Thompson, Indianapolis, Ind.

"Diseases of Children."

Chairman—Dr. Wm. Lee, Baltimore, Md.; Secretary—Dr. W. R. Tipton, Las Vegas, N. M.

"Oral and Dental Surgery."

Chairman—Dr. T. W. Brophy, Chicago, Ill.; Secretary—John S. Marshall, Chicago, Ill.

"State Medicine."

Chairman—Dr. Deering J. Roberts, Nashville, Tenn.;
Secretary—C. W. Franzoni, Washington, D. C

Committee on "Necrology."

Chairman—Dr. J. M. Toner, Washington, D. C.

THE NEW SCIENCE OF MEDICINE.

[Being the Doctorate address delivered at the Forty-first Annual Commencement Exercises of Rush Medical College, February 19, 1884.]

BY NORMAN BRIDGE, M.D., PROFESSOR OF HYGIENE AND ADJUNCT PROFESSOR OF THE PRACTICE OF MEDICINE IN RUSH MEDICAL COLLEGE.

Graduation day is an epoch in the life of a man. To the reflecting mind it is crowded with suggestions for thought, while to many it is full of the romantic and of castles in the air. To all who graduate this thought comes, that the world still has for us subjects for study, which, up to this point, we have been unable to touch.

The undergraduate's experience in a medical college is sober and fatiguing. In acquiring the medical degree we have studied the science and art of medicine as represented in certain books; by means of lectures and quizzes, by laboratory exercises and practical work; and by the observation and contact of the sick. So far our work has been one of preparation in a very direct and practical way for a particular present object and for a larger ulterior purpose in the labor of life.

Necessarily many subjects of great interest and quite essential to the fully equipped man have been neglected. One of these is the history of medicine.

The several branches of medicine and surgery have been given to us out of condensed text books or out of the mouths of teachers, and as to portions of them, whether they are new or old, we might often be in doubt.

Both the text-books and the teacher have been obliged to be, in the main, silent as to when and where all this mass of facts became known, how the science grew and developed; where it came from: whether it did not, some of it, drop down from the clouds full grown.

No one can even approach the study of the history of medicine, without being forcibly impressed by the great number of differing views and theories that have been held in the past.

Even before our pupilage began we knew—no observing person fails to know—that doctors disagree, and that there have been so-called schools or sects of medicine for a very long time. In our early studies too it was a perplexity to our minds how there could be so much disagreement and yet any truth or foundation facts in medicine at all. And we may have been even worried by some lack of agreement among the faculty who taught us.

It is only by mental growth that we appreciate fully that on every subject on which men think there are and must be various opinions. Men thoroughly agree on no subject that seriously engages their study. This is a fact in the history of thought and in the composition and physiology of the mind. Brains and minds differing, men who think must disagree more or less. Religion, politics and all the arts and sciences have, since the beginning of history, been perpetual examples of this truth.

When a man reaches the serene belief that his views are past improvement, he ceases to reason further, and gives himself up to the exercise of faith and is happy.

There is an innate property of the mind, varying in different individuals, which manifests itself in a desire for more knowledge and better methods, both for the love of innovation and for the practical results that may follow. In a few minds among the multitude this is a dominating impulse. These are restless spirits; experimenters, innovators, who hate present ways and things, if better are possible. It is through the labor and thought of such minds that the arts and sciences and all thought have progressed through the ages.

In many directions the progress has been slow, and successive contributions have added to what already existed and a gradual moulding and a steady growth have ensued. Politics, the law and religion are examples in point. In the arts and sciences, however, progress has been made in a very different way. Here growth has been marked by occasional long strides, and a single step has often changed a science or revolutionized an art. Each great step has added something and destroyed much. The record is one long story of iconoclasm. An important discovery has often been less startling to the minds of men than the crash of cherished idols which it has caused. A new fact disturbs the foundations of existing ideas and theories and compels the recasting of a science. Thus chemistry, physiology and pathology have with fresh additions, become new sciences. The discovery of oxygen destroyed a hundred beautiful theories. The Copernican theory threw into commotion the old philosophers who saw their doctrines of the construction of the universe tottering.

The discovery of the circulation of the blood had a hard struggle, against the beliefs of the time, for recognition. It was necessary to surrender all the accumulation of alleged science with which it conflicted. This was sacrilege to the old doctors and they fought against the innovation, automatically. Every discovery that has run against any long held notions has encountered the same mental automatism on the part of those who ought to welcome every new truth. But with hesitation and haltings, and in the face of difficulties, progress has been made, step by step, in all sciences, and not least in that of medicine.

Of old, when medicine was mostly theory and hypothesis, all the doctors naturally ranged themselves into sects and schools, each held together by some dogma. As the inductive method of study came into vogue gradually the sects became fewer, till now they have, among the real students, nearly disappeared.

The schools, as well as the laity, have thought they found it necessary to designate by some name the students of medicine who, since they study this as they would any other science, can belong to no sect. As these are of the race of the seekers after demonstrable truth through all time, they have been called the "*old school.*" Physicians who believe the science of medicine is too broad and grand to be labeled by the name of a sect, are continually referred to as the "old school," as though they must be ancient in thought and practice—the very type of fossilization.

But the public is not alone in confusing the profession of to-day with that of a period long past. Many within the profession are unable to free themselves from the notion that they belong to some ancient order, in thought as well as name. They worship the past. Writers of medical books affect erudition by a familiarity with the medicine of the ancients, and quote what Hippocrates and Galen believed on a particular point, as though it was of the smallest practical consequence to us what they believed. We all regard with pride the honorable position of our profession at times in the past, and applaud its fidelity to the cardinal principles of ethics. We point to the oath of Hippocrates and say: "behold what manner of man the physician was before the Christian era." For more than twenty centuries the rules of conduct of our guild have not changed.

But human nature and weaknesses are the same in all ages, and the principles of ethics endure forever. Plato and Emerson sang the same song, only in different tongues and to different listeners.

The glory of the ancient profession is that it did grope after truth, and that it was loyal to the ethics of all time and loyal to the sick. The few facts of science which the ancient doctors gathered are but a handful to the harvest of this later day, while their errors about disease and their good-intentioned, but awful inflictions upon the sick for their supposed benefit, make a chapter that is positively sickening to contemplate. Volumes have been written to show the wisdom and knowledge of the ancient profession. I ask you to-day to contemplate how much of the science of medicine is the product of the closing century.

I would not say a word to lessen the glory of the early profession for its actual attainment and work. But it is a fact that the science of medicine as an agency that actively and forcefully aids mankind to live longer, with more comfort and less pain, and to recover from disease, is new. A hundred years ago the circulation of the blood had been known more than a century. Gross anatomy was well understood; this study had been advanced to a laudable degree. A few of the drugs of that day are among the most valuable in our materia medica, but most of them have long since fallen into neglect, and the few had not been studied systematically or scientifically as to their action.

When the idea originated that a substance to be medicinal must be disgusting I do not know, but it was early in the history of medicine. For the ancients vied with each other in search of things horrible to be called medicine. Down to the eighteenth century, in acknowledged use were the teeth of boars; the jawbones of fishes; powders of blood from various animals; excrements of animals and people; flesh of human beings and animals, and from particular parts of the body for particular diseases.

The appearances and symptoms of many diseases were well described many centuries ago. Ignorant of pathology, the ancients had devoted the most patient study to symptoms, and in this particular some of their descriptions are masterpieces.

The practice of medicine in early times was based almost entirely upon absurd theories of the nature of disease. Disease was due to the astral influence of the planets, Saturn, Jupiter and Mars. Or it was a depraved condition of the humors, called cacochymia—a humoral pathology that was like the play of fancy to children. Another theory was that all diseases had their origin in the soul.

The doctors were divided into contending sects, each of which generally had a single potion or measure of treatment, which was its only resource. One sect tried to cure all complaints by cataplasms; with another wine was the only remedy; plasters and ointments constituted the armamentarium of another; a fourth used oils and wool externally, various potions internally, and charms generally; while a fifth are said, by way of contrast, to have been "ignorant practitioners" and "silly old women." But, as already shown, it is not possible to break away entirely from what we are pleased to call the delusions of the ancients. Mental tendencies were the same a thousand years ago as now, and promise to remain the same through all time, and nothing shows this more than that men *tend* to think and believe in the same fashion in all ages. Thus a great and learned physician of the fifth century recommends for epilepsy a charm consisting of the nail taken from the arm of a malefactor who had been crucified. To cure a stye, "the points of nine barleycorns were to be rubbed upon the part," and on each application were to be uttered the words, "*Fuge, fuge, Koithe se diokis.*" But if the stye was on the right eye it was to be rubbed with three fingers of the left hand, three

times the patient was to spit, and three times to utter: "*Nec mula porit, nec lapis lanam fert,*" etc. The educated "veteran leader" of a modern sect of physicians, writing less than ten years ago, says that in typhoid fever, if a patient desires to get out of bed, give him bryonia; if to change beds, arsenicum; if to escape from bed, belladonna; if to jump out of bed, hyoscyamus; but if he springs up from bed suddenly he must have bel. and nux. For "pain in the joint of the lower jaw give baptesia; for dropping of the jaw, luchnau; for falling of the jaw, arsenicum; for hanging of the jaw, lycopodium, mur. ac., etc.; and for sunken jaw give secale." Thus the fifth century and now![1]

Medicine, as a consistent, coherent science, could not exist till the nature and composition of substances could be intelligently studied and the minute structure of bodies explored. It had been patiently waiting for two aids, the key to the science of chemistry and the means of seeing the universe of the minute. One of them came a little over a century ago in the discovery of oxygen. This explained a thousand problems, opened a vast field for research, and was the key to the chemistry of the animal body. The atomic theory came naturally after the discovery of oxygen, and from this point chemistry made rapid growth. Chemistry is so vital a part of our medical science that it may truly be said that without it the science of medicine of to-day would be non-existent; nor will it do to compare modern chemistry with ancient chemistry. The ancients had no chemistry. Modern chemistry is all there is, and it can only be contrasted with the midnight darkness of the days of alchemy.

The gross anatomy of the eighteenth century had left little to be added in that direction. But the minute anatomy of the human body, of animals and plants, was well-nigh a sealed book. This field was waiting for the perfection of the microscope, and this instrument, for effective use, may almost be said to have been born in the present century.

The medicine of to-day depends upon histology, and the microscope was the road and the way to this study.

Take away from medicine the achievements of the microscope, and we should lose our knowledge of the structure of the tissues, the function and behavior of the cell in all its manifold forms, mutations, and migrations; the vast subject of cellular pathology; all the parasites and parasitic affections; the history and behavior of the micro-organisms of disease, and many other quite as vital parts of the science.

Within the century our knowledge of nearly every disease of common occurrence has been greatly enlarged by microscopical and chemical study of the organs involved, and their products, and by comparison with conditions of health.

Before the microscope we were in deep ignorance of nearly all the diseases of the kidneys, and of many disorders and symptoms which they produce. The discovery by Dr. Bright of the true nature of some of the disorders known by his name, and other discoveries in the same direction, have given us a fair insight into the diseases of these organs.

The present practice for the relief of these maladies is all based on recent discoveries. None of it is ancient, or even old. By practical hygiene, another modern department of medicine, many cases of Bright's Disease are relieved or held in dormancy for years.

A century ago, typhoid fever was confounded with several totally different affections, one of which was the contagious and very fatal typhus fever. Now it is established that typhoid fever is not contagious at all; that it is a disease of the intestines, and that it runs its course as regularly as does small-pox, in the main, regardless of treatment.

With the better understanding of this disease has come treatment that is more rational and more successful. Formerly the mortality was very high; forty years ago it was probably 18 to 20 per cent. of the cases. Now the per cent. of deaths is 10 to 12.

More than fifty parasites attack the human body. Each variety produces symptoms which we call a disease. Nearly all the knowledge we have of the parasites and of the symptoms has been acquired since the advent of the microscope, and is thus thoroughly modern.

The sickness produced by the trichina spiralis has existed for two centuries—probably much longer. It was confounded with typhus fever; it was called dropsy, epidemic erythema, epidemic œdema, and other names quite as unintelligible. Twenty years ago the microscope swept away the fog, and we behold a little worm coiled up in a muscle. Following closely upon this discovery came, most naturally, the annunciation: Cook your pork in every part, and no trichiniasis. In the study of other parasitic diseases, quite as much progress has been made as in this.

Almost the whole of the now most formidable department of cutaneous medicine—which deals largely with these parasites—is the growth of the present century. It could not be the product of a time before the microscope.

The achievement with which the century began was the discovery of vaccination.

In every civilized community the world over it has entirely changed the practice as to the *variolous* diseases. Its benefits have been incalculable. Although attacked by all shades of fanatics, it has saved and is destined to save thousands of lives, and it has relieved mankind from measureless anxiety and regret.

Near the middle of the century artificial anæsthesia was accomplished, by the use of nitrous oxide, ether, and chloroform.

This must remain through all time a marvel of discovery and invention. That it is possible to produce such a phenomenon as anæsthesia artificially is a marvel, and it is amazing that, being possible, the means for its easy, controllable and safe accomplishment should have been found. The lessening of suffering and the saving of life which this discovery has induced have been the talk of a generation. Not only is the current practice of surgery and medicine adapted to the use of anæsthesia, but, what is frequently overlooked, anæsthesia has broadened the

[1] Russell, p. 96.

field of operative surgery, by making many operations possible which without it could never be made.

Hygiene or sanitary science, the most beneficent in saving life, and in prolonging it the most potent, is a thing of comparatively recent years. It is a new revelation. Most of its facts and laws are the fruit of years that living men remember.

It has reduced the danger of death from certain diseases; with it alone certain diseases, formerly thought dangerous, are self-limited and without danger, and it has caused the average human life to increase in length.

Through organized efforts in society it has lessened the ravages of epidemics in many cases, and warded them off in others.

Never before did it enter so intimately and so thoroughly into the daily practice of the doctor as it does now.

If there is a single feature that, more than another, distinguishes the practice of the present from that of a former time, it is the use of numerous instruments of precision. Nearly all these instruments are the product of the present period.

The stethoscope and plexímeter, and the use of them in auscultation and percussion, are all modern, and these methods of study of the diseases and conditions of the thorax and abdomen are now everywhere used. Nobody now even professes to prescribe intelligently for diseases of the chest without the aid of auscultation and percussion.

The clinical thermometer was known three centuries ago. It was neglected till about ninety years since, and has of late grown into such favor that now it is used by the profession almost without exception. Whether it is of as much value as is claimed may well be questioned, but it has grown into the methods of thought and into the literature of the profession to such a degree that now no man would think of reporting a case of acute sickness for a first-class medical journal without giving the records of the thermometer.

The ophthalmoscope, invented a few years ago for the study of diseases of the eye, and now quite indispensable in that branch of work, has overstepped its original field, and is fast coming to be indispensable in any thorough study of diseases of the brain.

The diseases of the ear cannot now be diagnosed without the otoscope, yet this instrument is not fifty years old.

The laryngoscope and rhinoscope are the newest of modern inventions, and have made a new art of the treatment of the larynx and nasal cavity.

The hypodermic syringe as an instrument of exploration is emphatically one of precision, and it is refreshing to see it coming into vogue in this direction.

The dynamometer and æsthesiometer are in daily use, while we have to aid us as occasion demands; the sphygmograph and the cardiograph, the thoracometer, stethograph, spirometer and pneumatometer, the hæmacytometer, the perimeter, the palorimeter, the sacchorimeter, and never to be omitted, the urinometer, the test-tube, and the microscope, to say nothing of a half dozen others occasionally used, and a multitude of specula for exploration of the internal organs of the body.

Hypodermic medication has come into general use within our own memory, and now nearly every practitioner carries his hypodermic syringe. It enables him often to give relief and comfort more promptly and surely than by other methods, and it has enlarged the field of his resources, for it frequently happens that by this means he can give a remedy and save a life when all other expedients have failed.

In 1850 and afterward, Dr. Bowditch, of Boston, compelled the profession to believe, what they believed with reluctance, that serum and pus in the thoracic cavity may be safely evacuated. He employed for the purpose a trocar and tube to which was attached a pump. This we have amplified in the aspirator of to-day, which is extensively used for evacuating fluid from all sorts of natural and unnatural cavities to the saving of manifold valuable lives. Few instruments ever invented have in the same time had the fortune to accomplish so much for good, while doing so little harm, as this.

The expression, abdominal surgery, has a meaning that is entirely modern.

To have learned that the abdominal cavity may be opened with comparative safety, and to have done ovariotomy thousands of times, as well as other formidable operations upon the abdomen, with a large majority of successful results, would appear to be glory enough for a century. But the splendor of the achievement cannot be appreciated till we attempt to compute the saving of life in years. It was probably fully ten years ago that the scholarly Peaslee wrote these words: "It may be shown that in the United States and Great Britain alone, ovariotomy has, within the last 30 years, directly or indirectly, contributed more than 30,000 years to the active life of woman, all of which would have been lost had ovariotomy never been performed." And it reads like a fairy tale or the story of a dream that Keith, of Edinburgh, has done this operation a hundred times successively with only three deaths, and more than sixty times successively without a fatal case.

Before the modern period, the reduction of some of the more formidable dislocations was clumsy, difficult and often barbarous. The surgeon, with his retinue of robust assistants and his block and tackle for multiplying power, as he went to a case of this kind, suggested a gathering in the olden time for raising the timbers of a building. The tackle and block were used for pulling the joint into place, and the performance resembled a refined form of ancient torture by which the victim was torn asunder.

Now, by the simple and rational method of manipulation these dislocations are reduced by the easy movement of the surgeon's hands, without ado, without pulleys, and without torture:

Two pictures are brought to my mind vividly by this topic—one of childhood, the other of the present. The first is the picture of an aged and beloved woman who had sustained an injury of the hip. Just the nature of the lesion was uncertain, but it was recent, and she received the delicate attentions of the

pulleys for an hour or more without anæsthesia, when, from sheer pity, those responsible for her, begged that she be allowed to die if she must without being rent in twain. She was a cripple the few remaining years of her life.

The other picture is of an humble woman here in Chicago, and of her eloquent tribute to rational surgery. Her ehild had received some injury of one of its bones. She sent for a surgeon. It was night; and he returned word that she must call some other doctor. Again she sent, begging him to come; again he refused. She did not call another attendant, but watched by her charge till daylight, and then made her way to the surgeon's house, and with ineffable pathos begged him "for the love o' God" to come to her child. Prompted by curiosity, he asked her to tell him why she had allowed her child to go unattended all night rather than call another surgeon? "When I was a girl," said she, "I saw enough of common doctors for bones. My poor father put out his hip, and the doctors came and nearly killed him a pulling him with ropes all night, and then could not set it. In the morning a doctor o' the name o' Brainard came. I s'pose you never heard of him; he died a long time ago, but he was a great surgent, and he took the leg in his hands and turned it first one way and then the other, and so easy all the time, and it just went in with a snap."

In the departments of ophthalmology and otology the most remarkable advances have been made within fifty years.

Till the invention of the ophthalmoscope by Helmholz there was only a misty sort of knowledge of the diseases of the inside of the eye, and it was impossible to diagnose any of them. Now their discovery is easy and certain.

The subject of errors of refraction and their corrections has, chiefly by the labors of Donders, been placed on a "basis of mathematical demonstration" that seems unlikely to be disturbed by future researches.

No branch of medicine has grown more in favor and usefulness in a hundred years than dentistry. Preservation of the teeth has come to be almost synonymous with preservation of health, and the converse is strictly true, no good health with bad teeth. Dentistry is all modern; it cannot even plead age for the sake of respectability.

Antiseptic surgery is the last great achievement and the present wonder of medicine. It is all so recent and fresh in the minds of all students that either a description of it, or extended reference to its advantages, is not called for here. To a friend who, a few weeks ago, visited Prof. Nussbaum of Munich, the latter said, that during the forty years preceding 1876, at all times there was pyæmia in the Hospital of Munich, and during 1875, of the surgical cases 87 per cent. had hospital gangrene, and a large percentage died. From the introduction of antiseptic surgery in 1876, they have not had a case of gangrene, and pyæmia is almost unknown.

Dr. Weir, of New York, only last month called attention anew to the fact, that formerly the mortality from compound fractures was from 26 to 60 per cent. Now, by antiseptic management, the death rate from these injuries is reduced to 6 per cent., and by some surgeons this figure is even lowered.

Litholapaxy is a surgical procedure, introduced very recently by Prof. Bigelow of Boston, which threatens to supersede other methods of dealing with vesical calculus.

Bloodless surgery is another new realization whereby, with the rubber bandage, the surgeon is enabled to do many operations more easily, quickly, and successfully than formerly, as well as to avoid the loss of blood.

More different splints and appliances than could be named in an hour have, within my memory, been invented for the purpose of giving comfort to surgical patients and efficiency to their treatment.

One of the most beneficient and humane departments of surgery is that which deals with deformities of the body. Orthopædic surgery has hardly attained its majority in years, but it has accomplished a work in the relief of the crippled, and correction of deformities, as well as in the saving of life, that deserves the perpetual gratitude of mankind.

Electro-therapeutics is each year more and more becoming a recognized and necessary aid in the practice of medicine and surgery. Of course it is not new, but its recognition as having a legitimate field of usefulness, and the careful survey of that field, are the work of the last thirty years. In the hands of the profession it is, then, a new science.

The practice of medicine and surgery was never before on so rational a basis as it is now. Never before were practitioners so careful to do those things for the sick that are known to be helpful, and to refrain from everything else. Meddlesome practice—which means unnecessary, if not harmful practice—was never in such disfavor as it is to-day, to the unutterable gain of suffering humanity.

The most common condition of sickness that physicians are called to is that of fever. The modern methods of treating this state differ from the old very widely, in ministering more to the comfort of the patients, in attempts to reduce excessive heat, and in the free use of water for both of these purposes.

It is a recent discovery—and one made possible by modern means of investigation—that high temperature alone is a source of danger to the tissues, and puts the patient in peril if long continued. By various means, only lately well established, most high temperatures may be reduced without harm, and usually without discomfort, and by these methods the mortality from febrile diseases is perceptibly lessened.

Rest of the disordered organs, now rapidly growing in favor, as a systematic process in treatment to be emphasized, is quite new. Modern methods enable us to know much more exactly than formerly the organs diseased, and physiological chemistry and mechanical ingenuity have put us in possession of means not previously known whereby the labor of an organ may be dispensed with.

Now, dyspepsia, inflammation of the stomach, intestines, lungs, pleura and liver, Bright's Disease, typhoid fever, all the results of injury and many other

conditions of sickness are powerfully alleviated by this process.

How to put the sick part at rest as far as is possible, and cause the other organs of the body to still carry on the processes of life with the diseased organs out of duty, is a new art, as it is a very grand one.

Within a century a multitude of medicinal agents now in constant use, have either been discovered or come into favor for purposes that are new. Quite as many have been consigned to forgetfulness. Quinine, ether, chloroform, chloral, salicylic acid, ipecacuanha, the bromides, cannabis indica, carbolic acid, iodoform, corrosive sublimate, podophyllin, jequirity, duboisia, eserine, nitrite of amyl, veratrum viride, aconite and ergot, with a hundred more have swelled the resources of the art.

Probably in the choice of medicines on which to rely the profession has not always been wise, but the choice has been made, and fixes on the therapeutics of the day the stamp of newness.

In many more directions than I have cited may medicine, as it is now practiced, be shown to be modern. In science it is recent, in methods it is new. Verily it is a new profession into which you, gentlemen, have to-day been inducted.

Let it not be inferred from these laudations of the work of this century that we have occasion to rest or be satisfied. There is a great, undiscovered country in science. That misty domain holds a thousand secrets of the cause, nature and remedy of disease. The whole class of zymotic diseases, often now referred to as preventable diseases, because, I suppose, we *ought* to be able to prevent them, and many others which cut us off early and refuse to let us die of old age—all these have waited long and still wait a solution.

Medical education partakes of the spirit of progress and is modern. It differs widely now from what it was formerly. Among us the change has been greater than in the older countries. There innovations come slowly, but change has come everywhere. Of old the writings on medicine were all in Latin. Every liberally educated physician was obliged to spend years in study to become able to read and write this language readily. The literary was the major part of his education; it was the least useful directly, and it took the place of science. Science was poor in facts worth knowing, and yet the student must learn a new language before he could read the little of science there was. No northern tongue was fit to be the bearer of such knowledge. Now we reverse the order. Science is rich and nothing can usurp her place; any language is fit to convey her treasures to us, and it is wastefulness of human energy and time to learn science by a hard method and a rugged road when there are easier ways.

Literary studies are only blessed tools and instruments. I know a great discussion of the last decade in this country has been medical education, and that there are plentiful complaints that it is defective. Both in and out of the profession the question has been widely agitated, and the complaints are, many of them, just. The standard ought to be raised, particularly in the matter of study and drill preparatory to the medical college course. The medical course itself ought to be improved by the addition of more practical work and observations.

The agitation has provoked an improvement, so that to-day the curricula and requirements of the best colleges in this country are higher than they were ten years ago. But the claim that because the undergraduate period of the last century was longer than ours, therefore these modern times have fallen into degeneracy, is not good. The educational methods of the ancients can be no guide for us. With them the term of study was long by reason of the literary incubus already referred to. There never was a time before when so much of the *science* of medicine was taught and learned during the undergraduate period as now.

The medical heroes of antiquity wrote medical books by the hundred. Beyond the anatomy and some descriptions of disease, they are most of them as truly rubbish as the stories of the alchemists—to be read by those who have the leisure as historical curiosities. In a single term of college now, a student learns more of the essential science of medicine than all the medical tomes of antiquity contain.

Bad as our course of study may be, if a long course was ever exchanged for a short one to the unspeakable advantage of everybody concerned, it was in this instance.

As to the course of study in your Alma Mater, she does not pretend that it is perfect; she does not believe any course can be perfect, and therefore does not even undertake to establish one that will be permanent and not change. In the past her course of study has changed, and it will doubtless change in the future, as the needs of the public and the profession seem to require.

The college has had in your behalf a higher purpose than merely to have you earn and receive the degree of Doctor of Medicine. She has worked, and wished, and hoped, and hopes to-day that you may become good practitioners and successful men. Hence the course of instruction has been practical in the extreme. It has been shorn of speculation and confined to demonstrated paths as far as possible, and it may have been barren of some fascinations on this account. But, mindful that the consummation of our efforts is to be useful doctors, and therefore true servants of the public and proper professional men, it has been the constant purpose of Rush College to make her courses of study contribute to this end. The experience of her alumni has completely vindicated this position. Scattered over many States and Territories of the Union, and in other lands, your fellow alumni have met with a success as physicians and surgeons that is phenomenal. No higher test of usefulness than this can be possible.

May the class of 1884 add to the honor and high standing of the alumni of the college! You, gentlemen, have as a class a peculiar responsibility, for, measured by the usual standards, your Alma Mater has found that your aggregate of attainments is higher than that of any recently preceding class. Cultivate a pride in your classes, in all that is best in the profession. Create for yourselves an ideal, and strive to

realize it in your lives. Let a few qualifications and adornments be indispensable. Your ideal is a constant student; his life at college has only intensified his ambition to study. He can observe a phenomenon himself and know it as well and truly as though he read of it in a book. Fertile in resources, he is never surprised or disconcerted. He is patient, attentive, and upright in his intercourse with his patients. He is a student outside of the field of medicine; a lover of literature and all the ennobling arts; a many-sided man, indeed. The public know him, not only as the highest type of good breeding, but as one who, throughout the years of life, is steadfast in rectitude and immovable in a high purpose; who is exemplary in industry and patient in waiting.

Such an ideal is possible, and it is possible for you to realize it.

TREATMENT OF RINGWORM WITHOUT EPILATION.

A CLINIC BY JOHN V. SHOEMAKER, M.D., IN THE PHILADELPHIA HOSPITAL FOR SKIN DISEASES.

[Reported by Charles S. Means, M.D.]

GENTLEMEN:—At the close of the last clinic, I pointed out to you the circular patches on the heads of these three children. The girl has two spots, the younger boy one, and the scalp of the older boy is entirely involved. The appearance and symptoms of these patches, together with the cause of their development, the pathological changes which had taken place in the hairs, their follicles and the skin, as well as the diagnosis, all received due consideration.

Before proceeding to the treatment of these patients, let me again recall the appearance of the fungus of this disease—the trichophyton in the specimens beneath the class microscopes, which will again be passed around for your inspection. Beneath the first microscope you will again see a hair filled with this growth, and under the second and third instruments are sections of the skin, showing how the epidermis, as well as the hair follicles deep down, are also invaded. The hair in the first specimen was taken from the acute case of the young girl, while the sections of skin in the other two were made from the older boy, having the ringworm for the last four years. Now that I have recalled an important part of this affection, the removal and thorough destruction of the parasite which has brought about these lesions should command our attention. In beginning the treatment these children should, if possible, be isolated, in order to prevent them from spreading the contagion. Constitutional treatment should next be administered, as the experience of several years has taught me that care and attention to the general system is a great factor in bringing about a more speedy change with topical remedies. Proper hygienic surroundings and the use of good, nutritious food are essential and necessary for their systemic effect. As the first two cases appear to lack nourishment, the following tonic and nutritious combination will no doubt be very advantageous: Compound syrup of the phosphates and the fluid extract of malt, two ounces of each, mix; two teaspoonfuls in water three times daily, after meals. In the third case, the boy is especially anæmic, and will respond to treatment much better by using one of the salts of iron internally. A most excellent preparation, particularly well borne by children, is the syrup of the lactate of iron, which will be ordered in two teaspoonful doses after meals. It is also of equal importance that the local treatment should be carefully and persistently carried out.

The failure of many local remedies to act is due often to the negligence and careless manner in which they are used by patients and attendants. Special apparel, towels, bed linen, combs and brushes, should be used, provided they can be obtained by these patients. During and after the treatment every thing used by the patient should be thoroughly cleansed by an anti-parasitic remedy. The hairs upon and around the diseased patches should never be disturbed either by cutting, shaving, epilating or endeavoring to extract them. I desire to refer especially to these points, which I have again and again dwelt upon for some years in my clinics, in the treatment of all vegetable parasitic affections of the skin.

While cutting the hair in this girl's case might expose more of the diseased surface, yet it would also make the hair shafts shorter, and the movement of applications over these short hairs will often add to the irritation. It will be no especial advantage to cut the hair to expose the diseased surface, as the same purpose can be accomplished by separating the hairs and making the application. Shaving the hair is for the same reason a disadvantage, and will often cause cuts and abrasions of the skin which will increase the ravages of the parasite. Epilation is even more useless, and is painful and tedious to perform. I have ceased to resort to it, and find that vegetable parasitic affections improve much better without it. I believe I was the first to treat ringworm and other parasitic diseases of the same class *without epilation*. I commenced my new departure from the old method of extracting the hair laid down in all the text-books some years ago in a discussion before the Philadelphia County Medical Society, which can be found in the proceedings published by that organization. Look at those microscopic specimens now passing around the class, see how the hair and follicles are invaded with the fungus growth, and tell me if you could successfully extract such diseased hairs. The fungus has made the hairs brittle, and they will break off upon an attempt to extract them either on the surface or beneath in the follicle. The diseased hair or a part of it remains, and the parasite continues its ravages, even more active, owing to the irritation set up by an attempt to remove the hair. The wisest and best course in all cases will be to leave the hair undisturbed.

I will recommend that the heads of these children be washed every day or two with the following antiparasitic mixture: One ounce and a half each of

sulphuric ether and alcohol, with ten grains of thymol. Another good remedy to use in place of the latter in the same mixture is boracic acid, or dilute sulphurous acid alone can be sponged over the parts once in two days. Cleanliness can be carried out perfectly by using one or the other of the preparations just enumerated. I would advise that no water be applied to these patches until all evidence of the disease has disappeared. Water applied to the surface of the skin places the organic carbon compounds in a more favorable state for the nutrition of the parasite. In addition to the mixture just mentioned to keep the parts clean, I will order for the first and second cases the copper oleate ointment in the proportion of thirty grains of the salt, to one half an ounce of recent lard. The patches should be rubbed two or three times a day with this ointment until all evidence of the disease has disappeared, and the parasite cannot be detected by the microscope. This remedy, which I have used very largely and successfully, was reported two years ago for the first time in a paper to the Pennsylvania State Medical Society. It has the power not only of destroying the parasite upon the surface, but also deep down in the follicle.

In the third case, the boy having the ringworm over the entire scalp, which is covered with abrasions and deep infiltration of four years' standing, I used the mercury oleate ointment; 20 per cent. has been used for the past six days with great benefit to the parts. The same application will be continued; the attendant being instructed to rub in the half an ounce of 20 per cent. mercury oleate ointment every day. The latter remedy has been selected in order to lessen the great infiltration of the parts, as well as to destroy the vegetable parasite. You need not fear to use such a large quantity of strong mercury oleate ointment. I have and am now applying this oleate in even a larger quantity and a stronger per cent. over the scalp in ringworm and upon the general surface of the skin, without the least untoward effect. I have yet to see with the use of the mercury oleate ointment the first case of salivation.

BACKWARD TRACTION IN TREATMENT OF CARIES OF THE SPINE.

BY CHARLES F. STILLMAN, M.D., NEW YORK.

MR. EDITOR.—I thought you might be interested in some medical matters which sometimes occur in New Jersey. Therefore I send you a partial report of the transactions of the Hudson County District Medical Society, held in Jersey City March 4, 1884. After the regular business was completed, Dr. Charles F. Stillman, of New York, who had been previously invited, delivered a scientific and interesting lecture upon "Backward Traction in the Treatment of Caries of the Spine," illustrated by clinical material.

Dr. Stillman prefaced his lecture by describing the various methods of treatment in general use and classifying them according to the principles upon which they are founded. These are, 1st, simple Fixation; 2nd, Symmetrical Traction, which included the principles of suspension and application of the plaster jacket, and 3rd, Backward Traction, upon which he dwelt more at length.

The origin of this principle, which consists in curving the spine slightly backward, so that the bodies of the vertebrae are relieved of superincumbent weight, which is transferred to the posterior process, was ascribed to Dr. H. G. Davis, although the first effective instrument was devised by Dr. Taylor. A later instrument was invented by Mr. Chance, of London, and has lately been much advocated by Noble Smith, but the application of the principle in all of these braces was defective. In each the bending point of the spine, if the patient leaned forward, was still at the seat of disease, so that great strength on the part of the apparatus was required to successfully oppose the bending

Dr. Stillman advocated a new form of *lever* brace, which completely overcomes this tendency, and gives *fixation*, *backward traction*, and *forward pressure* at the seat of disease, these being the three indications necessary to successful mechanical treatment. The principle on which they were founded was illustrated by placing patients with well marked kyphrotic knuckles, face upward, upon a padded table so placed that the head and upper extremities were allowed to hang over the edge upon which rested the kyphos. In this manner the weight of the head and upper extremities produced backward traction upon the spine, causing an extension at the seat of disease, the result being seen in a diminution of the knuckle angle. By this method the superincumbent weight which caused the knuckle to form was thus used as a traction agent for its reduction.

If the disease was in the dorsal region, the short arm of the lever extended from the site of the disease to the sacrum, and the long arm from the neck to the sacrum, the two being connected at the sacrum by an adjustable clamp which fastened them together in the form of a V. The force was thus so graduated that if leaning forward was attempted the shorter arms of the lever pressed firmly upon the parts adjacent to the knuckle and exerted forward pressure, which prevented the spine from yielding at the seat of disease. Dr. Stillman claimed that in no other brace known was this accomplished, and for the dorsal region it secures a much greater degree of fixation than any of the braces or splints in use. If the lumbar region be involved, the short arm of the lever passes from the diseased part to the second dorsal vertebræ, and the long arm from the sacrum to the second dorsal vertebræ. They are secured together opposite this point by an adjustable clamp and connected to the trunk by a T plate in front which allows the brace to be tightly strapped to the dorsal portion of the spine without exerting injurious pressure upon the arms or chest.

The effects of these braces could not be changed by alteration of position in the patient, as the peculiar action of the lever is automatic and compensatory.

Cases were shown and braces applied to patients, the demonstration being complete and satisfactory.

After Dr. Stillman's interesting and very able discourse the subject was open for discussion by the members of the society. Dr. Paul remarked that he had been greatly profited by Dr. Stillman's interesting and practical discourse; especially in the exhibition and application of the various kinds of mechanical appliances for the cure of caries of the spinal column, and hoped he would have the pleasure of hearing the gentleman again at some future time.

Dr. Quimby remarked that there were many interesting, and some novel ideas advanced by Prof. Stillman in his treatment of spinal caries. The great number of different mechanical appliances exhibited only goes to show how difficult is the treatment of this serious disease, with its accompanying deformities. Dr. Quimby observed that he thought the general practitioner, and even the specialist, in the treatment of this disease, did not always exercise a sufficient amount of caution in the use of mechanical appliances, and did not sufficiently guard against the use of too much pressure. He had seen several cases in which great damage had been done by the use of too much long-continued pressure. We should ever remember that we are operating on a formative being, whose tissues are soft and yielding.

After Dr. Quimby's remarks, a vote of thanks was passed to Dr. Stillman for his very interesting and instructive lecture.

MEDICAL PROGRESS.

SURGERY.

The Operation of Estlander (Thoracoplasty).—Dr. Bouilly (*Bulletins et Mémoires de la Socéité de Chirurgie de Paris*), having presented before the Société de Chirurgie a patient who, having suffered from chronic empyema, with a pleuro-cutaneous fistula of five years standing, was relieved by the resection of a portion of the sixth and seventh ribs. M. Paul Berger gave a very full and detailed report upon this operation of Estlander's, this thoracoplasty. The report embraces the details of five cases which illustrate fully the mode of treatment, after which Berger proceeds to discuss the operation itself, and the previous modes of handling chest wounds, which led to the establishment of this mode. Resection of the walls of the chest for the more thorough evacuation of pus and for the application of remedies to the cavity has been long practised; but the object which Estlander has in view in his operation is to assist in the work of spontaneous obliteration which results from the traction that the pleuritic adhesions exercise on the thoracic walls, and in the effacing of the corresponding side of the chest, and the narrowing of the intercostal spaces. This produces a gradual obliteration of the suppurating cavity and occlusion of the fistulæ, which are consecutive to the incision in empyema. This process is limited by the form and resistance of the costal arches, so that the application of the lung against the parietal surface of the pleura is subordinated to the force and extent of the adhesions which have fixed that organ in the abnormal situation where the pleural discharge has taken place. So that in cases of empyema, where the discharge is abundant, where the opening and evacuation of pus has been made late in the disease, and at a time when the mobility and flexibility of the sides are at their minimum, the incision made to evacuate the pus would frequently result in a permanent pleural fistula; this in turn leads to amyloid degeneration or to tuberculosis. To relieve this, Estlander, by submitting the costal walls to a loss of substance, produces a certain degree of sinking in, which allows of the contact of the parietal and visceral layers of the pleuræ.

The position selected for the operation depends principally upon the location of the cavity and that of the fistulous opening. The most favorable position being upon the lateral portion of the thorax on the axillary line, the intercostal spaces being there covered by the serrations of the serratus magnus. The opening, whether spontaneous or made by the surgeon's knife, nearly always corresponds to an intercostal space between the fourth and ninth ribs. The first operation for resection should be so thorough and complete as not to require a second, the osseous reparation being so rapid that a second resection presents all the difficulties of the first. If the fistulous opening is very oblique and the cavity is above it, it is simply necessary to resect a sufficient number of the ribs to correspond with the vertical dimensions of the intra-thoracic depot; if it be below, the lower ribs should be similarly resected. By reason of their connections and mechanical functions, the first two and the last two ribs are to be avoided, although Schneider performed with success a resection of the second rib and a part of the clavicle. The amount of bony structure removed depends upon the dimensions of the cavity. Sometimes, however, small cavities require a large amount of destruction of the osseous tissue. The surgeon need not hesitate to resect four, five, and six ribs, removing as much as 11 or even 13 centimeters of their substance. Of course, auscultation and percussion, and the use of the sound will limit the operation to that portion of the pleuræ provided with adhesions. The incision of the soft parts should be large, and the costal resections should be subperiosteal. The details of operating, instruments, etc., are given with much precision. The question of removal of a portion of the pleura is answered negatively, unless it be so much thickened as to interfere with the mobility of the parts. The pleural cavity is better not disturbed other than by careful washings and injections of zinc. sulph., 5 to 8 per cent., before the operation, closed by a sponge during the operation, and, if necessary, after the operation drained by a drainage tube, until retraction of the passage takes place or pus ceases to be discharged.

After the operation the thoracic wound, united by sutures, is covered by antiseptic dressings, disinfectant injections are regularly used, suppuration diminishes, the quantity of fluid used in injections becomes less, and the walls shrink together. If, at the end of six or seven weeks, on testing with a needle the spaces between the osseous fragments, a resistance is met with indicative of a rapid reformation of bone, and there is still an appreciable cavity present, the operation is imperfect and a new one will have to be performed. Considerable time must be allowed to pass before the operation can be considered as successful, and compression exercised over the chest by means of an elastic bandage facilitates greatly the healing process.

MATERIA MEDICA AND THERAPEUTICS.

A NEW PREPARATION OF MERCURY.—Dr. Sigmund Lustgarten describes (*Wiener Medizinische Wochenschrift*) a new preparation of mercury as made by him in Ludwig's laboratory, and as demonstrated in its therapeutic effects in Kaposi's clinic, which he calls hydrargyrum tannicum oxydulatum, and which is in the form of a dark-green, tasteless and odorless powder containing about 50 per cent. of mercury, that is not soluble while undecomposed; that is not readily attacked by diluted muriatic acid, but which is changed in a measure by very dilute alkalies, ammonia and alkaline carbonates, so as to form in a short time a sediment composed of extremely minute particles of mercury, the greater part of which are so small as to present under the microscope the so-called molecular movements. The question whether the alkaline secretion of the intestines is capable of performing this reduction process sufficiently to allow the superficies of the mucous membrane of the intestines to absorb this substance, as does the skin after inunction, has not before been answered with precision, until these experiments proved that the preparation passes so quickly into the circulation as to be detected within 24 hours in the urine.

The drug was given in two or three doses per day, to the amount of 0.1 gramme, and in spite of this proportionately large dose, there were no disagreeable symptoms exhibited on the part of the stomach and intestinal canal. There was neither the indigestion nor the constipation so frequently following the use of tannic acid, nor were there any of the disturbances which are generally shown after taking such preparations of mercury as are included in the calomel and sublimate groups. The same may be said with regard to salivation, as so much as six grammes have been given without stomatitis or salivation following. Up to the time of the writing of the paper 10 cases had been treated with this drug, representing pretty nearly all the grades of syphilis; the greater part were relapses, and presenting the severer and more stubborn forms, as in the papular and pustular syphilides, in which such a prompt and ready retrogression of the marked symptoms took place, as to warrant the assertion that the hydrargyrum tannicum oxydulatum is the most efficacious of the mercurial preparations known at present, inclusive of the mercurial ointment which it displaces.

GUACHAMACA A SUBSTITUTE FOR CURARE. — Dr. Gomez de la Mata, in *El Siglo Médico*, is quoted by E. Gayraud in the *Gaz. Hebd. des Sc. Med.* as describing this drug as belonging to the family of apocynies. The active principle is found particularly in the outer bark and in the different layers of the inner bark. It is used in the form of a resinous extract, which is of a sómber gray color, having the outward appearance of curare, but little soluble in water; completely insoluble in alcohol, chloroform and ether. Its reaction is that of the alkaloids in general. The marked resemblance between this substance and curare, in their physical and chemical relations, is reproduced in the physiological effects which are obtained in frogs, by injecting under the skin 10 milligr. of the watery extract. The strength of the extract varies according to the time of year; during the rainy season the juice is most abundant and at its maximum of intensity. Its effects have been studied by Schiffer and Sachs.

The differences between the action of this substance and of curare are the following:

1. The poison paralyzes all the skeletal muscles, whilst the respiratory muscles act perfectly.

2. It acts perfectly upon the nervous centers, which are affected more tardily by curare.

3. Curare, which acts in very small doses when hypodermically administered, is without action when introduced into the stomach.

Sachs observed that the ingestion of the extract of guachamaca in very small doses killed chickens and dogs. Schiffer was obliged to employ doses twenty-five times the strength of those used subcutaneously in killing rabbits.

In man it has been used hypodermically in doses of 10 milligr. of the dried extract. In one of three cases the insertion of the needle was followed by a slight phlegmonous swelling, which disappeared the next day. The specific action of the drug does not appear until forty minutes after the injection, when a sleep follows, which is light in its onset, but soon becomes more profound, and continues for two or three hours. In a robust patient, 20 years of age, who suffered from spasmodic contractions of the muscles, the sleep was natural, and on his awakening there was no heaviness or dizziness of the head. The circulation and respiration remained normal. Reflex irritability was maintained throughout sleep, but the dose was too small to produce any beneficial effect.

This drug is applicable to cases of muscular contraction, and in all diseases in which curare has been recommended. The dose is 10 to 15 milligr. in hypodermic injections.

MEDICINE.

ON THE TRANSFUSION OF BLOOD IN BRIGHT'S DISEASE.—A very interesting discussion on this subject took place January 11, at the Société Médicale des Hopitaux de Paris (*Bulletins et Mémoires*). The

subject was introduced by M. G. Dieulafoy, and was considered by M M. Dujardin Beaumetz and Albert Robin. M. Dieulafoy related two cases of hæmatophilia, one where it manifested itself through persistent and abundant epistaxis through the left nostril, and the other following the removal of a tooth. In both cases every means known to surgery was employed to check the hæmorrhage, but without avail. The conditions became alarming, and transfusion to the extent of 120 grammes of blood was practised; with the result of quickly arresting all further hæmorrhage. Here, then, a beneficial result was obtained in a dyscrasic condition, in which perhaps the structure of the smaller vessels was at fault, but in which certainly the blood did not possess its normal properties. These cases were relieved not alone in the sense that one applies oil to the empty lamp which is about to burn itself out, but the blood infused played also the part of a hæmostatic agent.

It was in studying these relations that M. Dieulafoy was led to consider the usefulness of transfusion as a therapeutic agent in such dyscrasic conditions, where the changes in the blood appear to play an important part; that is, would transfusion prove beneficial in uræmia, Bright's Disease, diabetes, acetonæmia, gout, and rheumatism? In uræmia and Bright's Disease he brought forward the details of three cases, which demonstrated that the transfusion of 100 to 120 grammes of blood was inoffensive, even when practiced in the later periods of the disease, with cardiac, renal, and pulmonary lesions; and also that the transfusion had a salutary influence upon such uræmic symptoms as the cephalalgia, vomiting, convulsions, and coma.

M. Dujardin-Beaumetz could not see in these statements any positive conclusion that the transfusion of blood could act as a curative agent in albuminuria. It is true that of late the humoral doctrine, of which Semmola is one of the strongest advocates, has been revived to account for the renal changes in this disease; but he considers that when once a renal sclerosis has been produced, transfusion could have only a temporary effect, relieving the patient for the moment, like the inhalations of oxygen, which sometimes cause the momentary disappearance of albumen from the urine. Transfusion is not only of no use except to repair losses of blood, but it is contra-indicated in all diseases where there exist organic lesions or septic blood poisoning.

M. Albert Robin discussed the part played by the blood as a hæmostatic agent in these cases of hæmophilia given by M. Deulafoy. Its action was certainly not due to renewing the blood in the vessels, for only 120 grammes were used, and possibly a less amount would have sufficed, therefore its presence must have exerted a qualitative influence.

The alteration of blood in hæmophilia is not well understood, we must admit that it consists in a peculiar modification of the plasma as shown by a diminution of the fibrine. For the precipitation of fibrinogen the intervention is necessary of a peculiar ferment belonging to the class of soluble ferments; perhaps the transfused blood remedies the insufficiency of this ferment and allows the serine to be transformed into fibrinogen, and then into fibrine, and thus restore the plasticity of the blood. According to Hazen, it is not the globules that are the active agents in transfusion, but the serum or rather the plasma, as defibrinated blood acts much less beneficially than complete blood, and the infused globules are destroyed with a variable degree of rapidity. Therefore, a minute analysis of the blood showing the amount of ferment and albuminoid substances before and after transfusion, and a comparative analysis of the blood transfused would give the chemical explanation of the effects produced.

If this test should fail, we can still apply to the question the curious facts recently made known by M. Grimaux, the influence of certain salts and their dilutions on the coagulability of albuminoid matters.

Nephritis After Varicella.—Prof. E. Henoch (*Berliner Klinische Wochenschrift*) reports four cases of varicella, in which the symptoms of nephritis supervened. The first case was that of a ten year old boy, in whom the nephritis appeared six days after the eruption of varicella manifested itself, and continued for twenty days. The second case was a two year old girl. November 13 varicella appeared with moderate fever. November 16, œdema of the eyelids and dorsum of the feet. Urine albuminous with a few tube casts and epithelium 7, 33, 1. Treatment with sweat baths, decoction of bark with pot. acet. Œdema and albuminuria diminishing. December 3, suddenly severe vomiting, collapse, cyanosis, in the evening death. Autopsy—Moderate hypertrophy and dilatation of the left ventricle, valves normal. Pulmonary œdema, fresh parenchymatous nephritis, and slight fatty degeneration of the liver. The third case was that of a five year old girl. November 10, a free eruption of varicella with fever (37, 8). November 18, œdema of the face and feet and albuminuria. Treatment by sweat baths. December 19, there were still some traces of albuminuria, the œdema had entirely disappeared. The fourth case a four year old girl. December 19, marked fever. December 20, free eruption of varicella. December 30, marked pallor of the skin and facial œdema. Headache and lumbar pains, slight fever. Urine markedly albuminous. Treatment, purgatives, Biliner water and sweat bath. January 2, face markedly œdematous, urine contains albumen, tube casts, epithelium and blood corpuscles. January 7, considerable improvement. January 13, perfect relief.

Henoch having failed to find similar cases recorded in the literature of the subject, recommends that the urine be examined in all cases of varicella, within eight days of its onset, with the expectation that many more instances of albuminuria will be developed.

Notes on Acholia.—M. V. Hanot, in the Société de Biologie (*Comptes Rendus*), referred to a case reported by him in 1881, where, in making an autopsy in a death from sclerosis of the stomach, he found a fibrous transformation of the hilum of the liver; microscopic sections

showed the ductus communis choledochus and the cystic canal to be completely obliterated, and the same was the case with the hepatic artery and its branches into the hilum. The obliteration of the portal vein was not complete, but its lumen was markedly constricted. The absence of icterus in the case could only be explained by considering that in consequence of the complete obliteration of the hepatic artery, and the incomplete obliteration of the portal vein, the biliary secretion was almost, if not completely, abolished, and the obliteration of the duct would not cause icterus, because the liver produced no bile. This then illustrates acholia in the literal sense of the word, and explains the absence of icterus in spite of the complete obliteration of the ductus communis choledochus. The atresia of the bile vessels must have progressed so gradually that it was difficult to ascertain from the clinical history of the patient, when the acholia was first established. In another case, under observation at the time of making the report, a man, 46 years of age, who has suffered from a chronic affection of the liver for the past three years, there is a complete want of color in the fæcal matters, without the slightest icterus. He presents an hypertrophy of the liver and spleen, with considerable tympanitis, but no ascites. He is weak and emaciated, but the appetite is good, and there is no indication of any serious change in the organism. There is no leucæmia, he has never had any hepatic colics or icterus, no symptoms to indicate an interference with the discharge of bile into the intestine; nevertheless there is this permanent want of color to the fæcal matters. For this condition there seems to be but one plausible hypothesis; the hepatic lesion has diminished the biliary secretion, and has more or less completely suppressed it; just as the protoplasm of the hepatic cells under certain pathological conditions increases or diminishes the quantity of glycogenic matter with reference to its normal amount, so does it increase or diminish the quantity of bile secreted. With polycholia, we have had oligocholia, and now complete acholia. Its pathogenesis remains obscure, it presents these two clinically paradoxical peculiarities:—the obliteration of the ductus choledochus without icterus; the decoloration of the fæcal matters without icterus, the biliary passages remaining permeable. It would seem as if this acholia could exist for a considerable length of time, and that it produced the marked tympanitis present from withdrawing the antiputrescible qualities of the bile.

Tamponning the Larynx to Prevent Pneumonia as a Sequence of Diphtheria.—Langenbuch of Berlin, according to Bouchet (*Paris Medical*), believes that pneumonia, which is so common in diphtheria, is always produced by the infection of the lungs through the secretions of the larynx and of the pharynx which pass into the trachea. To prevent this after tracheotomy, he places small pieces of sponge in an etherial solution of iodoform aud allows the ether to evaporate. These little pieces of sponge are fastened to a strong silk thread. After opening the trachea, he introduces one of some size into the cavity of the larnyx with a pair of curved forceps, and fixes it there so solidly that it cannot descend further spontaneously. This done he inserts the tracheal canula, and either fastens the thread of the sponge to it or about the neck. The sponge can be allowed to remain in place as long as is considered necessary without inconvenience.

Bouchet, in his comments, thinks it would not be possible for these secretions to pass into the trachea without producing terrible attacks of suffocation. The pneumonia of croup may depend upon the action of cold air and of dust particles, which can be modified by the wearing of a muslin cravat about the neck, but this pneumonia results more especially from cardiac thromboses, which convey, by means of the pulmonary artery, microscopic granules of fibrine into the lungs, forming embolic pneumonia. It is then that we observe at first these nuclei of pulmonary apoplexy, sometimes greyish or softened in their centers, and following them, the areas of hepatization caused by a small infectious embolus.

Expected Visitors to the International Medical Congress.—The *Lancet* has received information that the following men of eminence in the profession will be in attendance upon the meetings of the International Medical Congress at Copenhagen, Aug. 10, viz.:

From France: Pasteur, Paul Bert, Rannfer, Charcot, Verneuil, Cornil, Hazen, Mallassez, Chauveau, Ollier, Trippier, Lepine.

From Italy: Bizzozero, Mossa, Golgi, Peromento, Novaro, Reymond, Giacomo, Baccelli, Tomasi, Condelli.

From Holland: Douders, Guze, Engelmann, Heinsius.

From Germany: Virchow, Ludwig, Esmarch, Volkmann, His, Braune, Kronecker, Munk, Kühne, Heidenhain, Voit, Bernstein, Grohe.

A letter from the President, Professor Panum, concludes in the following business-like way: "We do not, however, intend to mention in our programme any festivities, solemnities, and such like. We would rather emphasize our intention to make the Congress a meeting for strictly professional and scientific work.

Hydrobromic Acid must be used in much larger doses than has been customary if any benefit is to be derived from it. Such is the opinion of Dr. H. C. Wood (*Medical News*, Feb. 23), who has been using this drug recently in epileptic cases. He found in three cases that half-ounce doses of the officinal hydrobromic acid was much more effectual than equivalent doses of bromide of sodium or potassium, and not nearly so liable to produce symptoms of bromism. He gives the acid after meals, with syrup, and diluted with half a pint of water.—*Medical Review.*

CHICAGO, ILLINOIS

SATURDAY, MARCH 22, 1884.

EXPERT TESTIMONY AND COMPENSATION THEREFOR.—Dr. T. J. Turpin, of Alabama, sends us the following resolutions touching this subject, and requests our views through the JOURNAL. The preamble and resolutions are as follows:

"WHEREAS, The Supreme Court of Alabama, in 1877, decided that a scientific expert must attend a subpœna, and that his testimony can be forced without allowing special compensation for his evidence as an expert, and

WHEREAS, This decision bears hardly upon the members of our profession in this State, and is an injustice for which a legal remedy should be found, therefore be it

Resolved, That the Medical Association of Greene County recommends to the Alabama State Medical Association that they use all available and proper means to procure the enactment by the General Assembly of Alabama of a law similar to the law contained in the Iowa Code of 1873, which provides that 'witnesses called to testify only to an opinion founded on special study or experience in any branch of science, or to make scientific or professional examinations, and to state the results thereof, shall receive additional compensation, to be fixed by the Court, with reference to the value of the time employed and the degree of learning or skill required.'

Resolved further, That our Secretary be instructed to transmit, at an early date, copies of the foregoing preamble and resolution to the President, Secretary and Senior Censor of the State Medical Association; and that it shall be the duty of our Delegates to the next Convention of the State Medical Association to bring the matter before the Association, and urge upon them the great importance of prompt action and persistent effort upon their part in order to procure the enactment of the law desired by us.

The above resolutions were adopted by the Greene County Medical Association by the unanimous vote of all members present at the meeting."

That a physician or medical man must obey the summons of a court so far as to present himself as a witness at the proper time and place, the same as any other witness, is universally conceded. Such obedience is due and necessary for maintaining the just authority of the court, and promoting justice between man and his fellow.

And so far as the medical witness is in possession of facts or personal knowledge relating to the case under investigation, he must testify on the same terms as any non-professional witness. But when called simply as an expert, to give opinions or facts that constitute a part of his professional acquirements, for the purpose of enlightening courts and juries on questions of medical science and practice, the medical man is as much entitled to just compensation for his time and knowledge, as is the attorney at the bar or the judge on the bench. The professional knowledge and time of the physician or attorney are his capital stock, and as much his personal property as is the horse or cow the property of the farmer. And there is no principle of equity, and no emergency of justice which will justify the taking of such professional knowledge and time without just compensation therefor. If it is said that there are many cases in which the ends of justice cannot be attained without the aid of such knowledge, and consequently that its extortion in courts is a public necessity, we grant it. But if the public good requires that I should leave my private business and make a post-mortem examination, or go to the court-room and spend time in imparting professional knowledge that has cost me months of time and more or less money to obtain, then surely the public treasury should afford me a fair compensation for that time and knowledge. The public good, as well as the interests of clients, often requires the services of a judge or attorney, but we are not aware that any court has ever extorted such services without some compensation therefor. Public necessity may require the opening of a highway through a man's farm; and the public authorities may enforce the necessity by seizing the necessary amount of land and opening the road. But they must return to the owner a just compensation for the land taken. So the court may issue its summons and compel the medical man to leave his patients and repair to the jury box, or become liable to severe punishment for contempt of court. But if it compels him to impart his professional knowledge, either for the public good or private interests, without awarding

him just compensation therefor, it simply robs the witness of his personal property as plainly as if it had caused the seizure of his horse and buggy and converted them either to public or private uses. We think the foregoing views have been sustained by the rulings and decisions of a large majority of the higher courts in this country during the last twenty years. They are also in accord with the views expressed by the best writers on medical jurisprudence both in this conntry and Europe.

Medical College Controversies in Louisville.—For some months past, we have been receiving circulars and newspapers containg most disparaging comments on the Faculty of the University of Louisville, apparently emanating from parties connected with the Louisville Medical College. On the other hand, our attention has been recently called to a supplementary paper in the February number of the *American Practitioner*, written by Dr. D. W. Yandell, Professor of Surgery and of Clinical Surgery in the University of Louisville, in which he shows most clearly that from the Faculty of the Louisville Medical College has come the numerous letters to students in all parts of the country directly soliciting their attendance in that institution at half the published rate of charges, under the pretense of issuing "beneficiary scholarships," etc., some of which have attracted the attention and been commented upon by the Secretaries of the West Virginia and Illinois State Boards of Health. The letters given in full by Dr. Yandell, with names and dates, are sufficient to show that the Louisville Medical College during the last year has been reviving the disgraceful practices so freely indulged, in former years, by what was known as the double-head Louisville–Kentucky School of Medicine. How men of education, and sometimes of rare talents, can allow themselves to pursue policies and indulge in practices in the name of a medical college, which they would instinctively shrink from as disgraceful in their individual professional capacity, is a mystery to us. There is only one item of comfort to be gleaned from all this unprofessional scrambling and bidding for students; which is that it is rapidly maturing a public sentiment, both in and out of the profession, which will soon lead to the enactment of such laws as will effectually separate from medical colleges the right to grant diplomas conferring the right to practice medicine.

Ancient and Modern Medicine.—The address of Dr. Bridge, in the present number of the Journal, on the more recent progress and modern character of the Medical Sciences, forms a good counterpart to the paper of Dr. Maughs in a recent number, on "What the Ancients knew of Obstetrics and Gynæcology."

Medical College Commencements.—The annual Commencement exercises of the Medical Department of the Arkansas Industrial University, located at Little Rock, were held on the evening of the 3d inst., at which thirteen candidates received the degree of M.D. An honorary degree was conferred on James A. Dibrell, Sr., M.D., of Van Buren, Arkansas. The occasion was honored by the presence of the Governor and many other prominent citizens, and the proceedings were such as to indicate that the Faculty of this young institution are honestly endeavoring to maintain a fair standard of education.

The second annual Commencement exercises of the College of Physicians and Surgeons of Chicago were held on Tuesday, the 11th inst., and were witnessed by a large audience. The degree of M.D. was conferred by the President of the College, Professor A. Reeves Jackson, upon fifty-two students who had passed examinations satisfactory to the Faculty. The doctorate address was delivered by Prof. C. W. Earle, who discussed the importance of Chicago as a center of medical education, and criticised justly the illiberal action of the Board of Commissioners of Cook County in obstructing the proper execution of the law for supplying material for the study of anatomy and surgery. The address was received by the audience with frequent demonstrations of approval. A banquet was given to the alumni and graduating class, at the Sherman House, in the evening.

Death of Lunsford P. Yandell, M.D., of Louisville, Ky.—We were pained by the announcement a few mornings since of the sudden death of this prominent member of the profession of Louisville. Dr. Yandell was a physician of high attainments and of good reputation as a writer and teacher. He has been cut off in the middle period of adult life.

Dictionary of Practical Surgery.—A "Dictionary of Practical Surgery" is in preparation, and is to be published by Messrs. Smith, Elder & Co., of London, within two years from the present time. The work will be produced on the lines of "Quain's Dictionary of Medicine," and will be edited by Mr. Christopher Heath.

SOCIETY PROCEEDINGS.

CHICAGO MEDICAL SOCIETY.

At the regular meeting of March 17, 1884, the following important topics were discussed: "On the Ætiology of Typhoid Fever," a paper read by Dr. J. F. Todd; and a second paper forwarded by Dr. Roswell Park, of Buffalo, N. Y., Second Vice-President of the Society, wherein he has deduced interesting conclusions concerning the following topics:

I, Suture of Nerves; II, Elongation of Nerves; III, Exploration of the Brain by the Hollow Needle.

It will be seen by a perusal of the following review of our former resident colleague's paper, that he has cheerfully responded to a request made to contribute his mite, and to furnish with needles and pen numerous thoughts on some of the select topics in the surgery of the nervous system, and we therefore present the main points embodied in the paper furnished by the Secretary, who, at the above date, read the article for the author.

We read[1] that Guillaume de Salicet, Lanfranc, Guy de Chauliac, and others, recommended the sutures of divided nerves. But when we remember that nerves and tendons were often confounded in those days, this interesting item loses part of its importance. In 1776, Cruikshank demonstrated the possibility of cicatrization of nerves. After him Fontana proved this cicatricial substance to consist, more or less, of true nerve tissue, and recommended its union by suture, when divided, and which was further advised by Dupuytren. But the first to actually practice it as a physiological experiment on human patients were Baudens, Langier and Nelaton, the two latter having each within a single week, in 1864, a case which each for his own part reported.[2] It happened very curiously that in each of these cases it was claimed that sensibility and motility had returned within 24 hours after operation. This seemed incredible, and Richet[3] cleared up the matter by reporting a case. This author claimed, and most properly, that a similar state of affairs had obtained in those cases in which Langier and Nelaton had claimed such surprising results, and that they had not accurately studied their cases before operating. Since that time the subject has been studied experimentally and clinically, until now the indications to the surgeon are perfectly clear. In the literature on this subject may be found among others the views of Arloing and Tripier, Langerfeldt, Lemke, Kraussold, Page, Brown-Sequard, Tillmanns, Nicaise and Holmes.

The exact statistics of all cases reported to date, as nearly as the writer could estimate, is 30 that are on record, nearly all of which have been gratifyingly successful. To these he would add two more never yet reported, along which may be also added some features of the operation.

Case I.—Rupture of the Sciatic Nerve—Immediate Union—Restoration of Function.—H. R., æt. 13. In 1881 the surgeon excised the hip joint of this patient (who was then 11 years of age) for long standing and extensive disease. He made a good recovery from a severe operation. In time sinuses burrowed in the region of the buttocks, along with other evidences of new and extensive disease, and Feb. 9, 1883, radical operative measures to remove the disease were again undertaken, the patient being admitted to the Michael Reese Hospital, Chicago. He was assisted by Drs. Lackner, Tracy and McAuliffe, and proceeded first to explore the parts. He found caries of the tuberosity and other parts of the ischium, sinuses leading inside the pelvic cavity and around the rectum. In brief, aggravated tuberculous disease of the bony pelvis and contents was present. In order to secure access to the parts, and to permit the necessary manipulation, a flap composed of the buttocks had to be laid up on that side, owing to the cicatrization following the previous operation, and the present local disease and induration. The sheath of the sciatic nerve had contracted firm adhesions to the overlying parts. The nerve was unmistakable, but the tissue was in the way. So one of the gentlemen present undertook to hold up the flap with a powerful retractor, while the operator dissected the tissues from the nerve. Being short of sufficient assistance, the patient, inadvertently, was permitted to so far recover from his chloroform that he gave a violent wrench and turned partially around, when it was discovered that the nerve had been torn completely through, the ends, while not exactly ragged, being anything but smooth. The ends were dissected free and the operation proceeded with as had been originally contemplated, *i. e.*, by resection of a good portion of the ischium, scraping out of the sinuses leading into the pelvis, inserting drainage tubes, etc., after which the nerve ends were united, first snipping them off evenly with the scissors, and then sutured as accurately as possible by two catgut threads passed entirely through the nerve trunk and about a quarter of an inch from the line of section. After this, the soft parts were closed as usual, proper provision was made for drainage, and a Lister dressing applied, the whole having been done under the carbolic spray.

For about a week there was absolute paralysis of sensation and motion throughout the region supplied by the great sciatic. Thirteen days after operating there was but a small area of integument near the external malleolus, which was not sensitive as usual, while he could move his leg as well as before the operation, and, judging by his progress, regeneration was practically complete in a day or two more.

Case II.—Division of Radial Nerve and Certain Tendons—Suture of same after Two Weeks—Restoration of function. C. D. G., aged 16. April 1, 1883, patient cut his right wrist with a cheese knife, in such a way that severed the radial nerve and artery, and the tendons of the extensor ossis metacarpi pollices and extensor primi internoidi pollicis. The physician who saw him at the time of the accident contented himself with checking the hæmorrhage. At

Reese Hospital, Chicago, on the 16th, the following condition was noted: Hand dropped to the ulnar side, with sensibility of those parts supplied by the radial nerve extremely impaired, and indeed in the central portions of that area practically lost.

After anæsthetizing him and dissecting down upon the part, found the tendon ends retracted within their sheaths so as to be an inch apart. Opened the sheaths and carefully united the tendons by catgut suture, and their sheaths over them by interrupted sutures of the same material. Then the ends of the radial nerve were found, and freshened and brought together by a single catgut thread. Over all iodoform dressings. By May 8 sensation was restored to the area supplied by the radial nerve; by the 25th it was evident that the tendons had firmly reunited, and, except as limited by partial adhesions in their sheaths, were capable of reassuming their functions. In course of time these adhesions became stretched, and the hand became very nearly as useful as before.

Commentary.—Suture of nerves is known as *direct* when the suture material is passed directly through the nerve trunk, and as *indirect* when only the nerve sheath is included; the former is usually preferable. There is fair prospect of success even months after the original injury, as witness the case in which Wheelhouse[1] united the sciatic fully nine months after the accident which severed it, the patient in four months more being able to do all manner of hard work; while Jessop, according to Tillmanns[2], has recently operated *nine years* after the injury, and with fair success. Nevertheless, the sooner it is done the better, and the quicker will be the result.

If, on dissection, the nerve ends prove to be clean cut (in recent cases), they need no further attention before uniting them, and the ordinary full curved surgical needle will suffice for the operation, taking care to insert and pass it flatwise between the bundle of nerve fibers until the broader cutting part is through, and then to turn the needle half round and let the carbolized catgut slip through the little slit. It may be necessary to introduce two or three sutures, especially in the larger trunks. To avoid tension of the limb, the part must be dressed accordingly and immobilized. Observe full antiseptic measures. Evidently, primary union is only such in appearance. It is cicatricial, not physiological. Immediate suture does not prevent degeneration, but simply permits regeneration to take place much more rapidly than it otherwise would. But immediate union of divided nerve tissue does not occur. Letiévant has suggested autoplastic operations on nerves, and Gluck in 1882, at the Congress of German surgeons, reported some astonishing successes in neuroplasty by transplantation. While the writer has not as yet performed this operation, he would not hesitate to make the experiment of transplanting nerve from some animal into a patient did a suitable case present.

It may be well to add, no case yet known has had neuritis or tetanus, or have any untoward consequences resulted from this sort of surgery of the nerves. The operation deserves much more cordial recognition and acceptance than it has yet received.

II.—Elongation of Nerves.

Upon this portion of the paper the writer dwelt considerably upon the literature, and many were the authorities quoted. Its application has apparently, therefore, not been restricted to neuralgia and contractures, but has been extended to anæsthesia and paralysis, great atrophy, convulsive affections, tetanus, to locomotor ataxia, and even to anæsthetic leprosy, etc.

To Nussbaum, says the writer, we owe a debt of gratitude for making the way clear, and first putting "nerve stretching" into practice. While resecting an elbow in 1860, his assistant accidentally but forcibly stretched the ulnar nerve, and it was noticed the tetanic cramp with which the arm was previously affected totally disappeared, which made a strong impression on his mind. In 1869 it happened that Billroth had a patient who had received a violent contusion of the buttock, and subsequently developed epileptiform paroxysms. Under the impression that there was nerve irritation from some bone splinter, he denuded the nerve, without finding anything wrong; but the nerve had been disturbed, and more or less stretched, and recovery followed. Acting on these hints, Nussbaum for the first time practiced intentional elongation in 1872, the case being one of contracture of the upper extremity consecutive to contusion. Recovery followed the operation. Without discussing the general merits of the operation, or the statistics, or extent of stretching that nerves will bear, nor yet the changes resulting therefrom other than clinical results obtained, we will be content in making synopses of the five cases reported by the writer, that have not heretofore been placed on record, in three of which elongation was made on purely empirical grounds, and merely as physiological experiments.

CASE I.—Chronic Sciatica—Elongation—Recovery.—W. L., æt. 25. Has suffered severely from sciatica for some five months; has lost considerable flesh; has been all this time under medical care, and for the last six weeks in the County Hospital, Chicago. A most varied internal treatment has been resorted to, as well as the use of electricity, part of the time intelligently applied. Patient was admitted into the Michael Reese Hospital, Chicago, and on June 15, 1883, he was anæsthetized, and the sciatic nerve of the affected side was stretched. The operation was made under the spray. By the 20th, when the dressings were changed, the wound was found to have healed per primam, pain was relieved at once, and at this date sensation and motion were found to be nearly normal. There was now and then a twinge during the next month. July 20, when he was discharged, he simply noticed an occasional pain in one small spot in the calf of the leg. September 1, he called to say he was perfectly well.

CASE II.—Toy-Pistol Tetanus—Elongation of Brachial Plexus—Amelioration of Symptoms.—A. G., æt 10. On the 4th of July, 1883, patient injured

[1] *Brit. Med. Jour.*, Aug. 5, 1876.

[2] Loc. Cit., case 11.

his left hand with a toy-pistol. On the 11th, at 4 A. M., he developed the first symptoms of tetanus. He was at once brought to the Michael Reese Hospital. Saw him at 11:30 A. M. At that time there was moderate clonic spasm of the muscles of back of neck, with tonic exacerbations; found a suppurating wound in palm of left hand. The patient was anæsthetized, operated under the spray. The palmar wound opened, found it foul, and containing a piece of wadding, which was removed and the cavity scraped. An incision along the inner border of the biceps brachii was made, the nerves isolated and stretched in each direction, including the median, ulnar, and internal cutaneous nerves, and that of Wrisberg. Wound was closed over a small drainage tube, and iodoform dressings applied. The patient improved decidedly after this procedure. ℞. Squibbs' ext. physostig., gr. $\frac{1}{5}$ hypodermically every two hours, also sodii bromid., gr. x every two pours, and chloroform inhalations during any tetanic seizures. Evening, condition very satisfactory. Next morning about 7 o'clock he complaiued of pain about the heart, and died within an hour, apparently from spasm of the diaphragm. Autopsy not allowed.

Case III.—Motor Paralysis of Right Leg, following Spinal Meningitis—Elongation of Sciatic Nerve—Negative Result.—A. K., æt. 40. In July, 1881, was seriously sick, which was probably spinal meningitis. At present he suffers from monoplegia, the right lower extremity being the part involved; has been under the care of several physicians, and recently a patient in the medical department of the Michael Reese Hospital, where, along with electricity, various other remedies were tried. Elongation of the sciatic as an experiment was proposed, patient accepted it as such. Sept. 15, 1882, operation under the spray. The limb was suspended by the nerve and stretched from above downward and *vice versa*. Heart's action momentarily disturbed. Union per primam.

October 17, patient acknowledges perceptible improvement. Very little improvement was made in several weeks longer that he remained in the hospital.

Cases IV and V.—Paræsthesia and Dysæsthesia of Unknown Origin—Elongation of Sciatic, and later of Crural Nerves—No Result.—H. K., æt. 32, has suffered fourteen years from perverted sensations, causalgia, etc., referred to integument of lower extremities, especially the right one. Of late, complains of a feeling of intense cold, referred particularly to the area of distribution of the right sciatic and peroneal nerves. His intelligence is not of high order. Patient has been under the observation of Dr. Ernst Schmidt for years, who finally suggested elongation as a pure experiment, and admitted him to the Michael Reese Hospital, June 22, 1883. Sciatic and peroneal nerves were stretched with the usual precautions. July 1, no improvement, and at patient's urgent request, the anterior crural nerve was stretched, and yet no benefit seemed to accrue. Each time the nerve was stretched downward in this case, and also an irregularity of the heart's action occurred for a few seconds.

Commentary.—Case I exhibits the happy effects to be obtained in obstinate cases of sciatica, resisting medication. That the operation has a wide sphere of usefulness in this form of complaint, of which not a few cases are already on record.

Case II exhibits at least the temporary relief to be obtained by this measure in cases of tetanus. That we cannot afford to reject this method of treatment, for amelioration of symptoms is better than no impression at all, although in this case, an error may have been committed in omitting also to stretch the musculo-spiral nerve, and possibly, that too much sedative treatment was given the patient, and not sufficient stimulating nourishment; a not infrequent mistake.

Cases III., IV., and V. were undertaken, as already remarked, on purely experimental grounds, and the patients accepted it as such. It further serves to prove that we usually learn more by our failures than from our successes.

III.—Exploration of the Brain by the Hollow Needle.

Perhaps there is no special literature on this subject. To illustrate the ease with which it may be done and its harmlessness, the author cited the following cases:

Case I.—Gunshot Wound of Brain—Trephining—Repeated Exploration for Pus—Extrusion of Fragment of Bone—Recovery.—J. L., æt. 20. On the afternoon of July 4, 1883, received a bullet wound of the left parietal eminence; brought to the Michael Reese Hospital. The house surgeon abstained from exploring the wound, but clipped the hair short and made antiseptic occlusion with iodoform cotton; also applied ice-bags. At evening there was complete right hemiplegia, pulse 90, pupils normal, patient conscious and rational; continued the ice-cap, and gave directions to use catheter.

Next morning learned of patient having two convulsions during the night; he also lost consciousness; pupils normal and respiration natural.

Exploration under the spray revealed a comminuted gunshot fracture; trephined; removed several small fragments, some of which were partially imbedded in the brain; removed also a piece of the small pistol bullet; compression was then made, and dressings of napthaline gauze applied. For several days patient's condition was satisfactory, except that the hemiplegia persisted.

July 13.—Answered questions rationally.

July 18.—There was free discharge of pus.

July 20.—Symptoms of central irritation; fear of abscess forming; dressings removed; introduced a well cleansed needle of a hypodermic syringe through the cicatricial tissue. Explored in different directions by its full length, never completely withdrawing the needle point; no pus and but a few drops of blood entered the barrel of the syringe. No anæsthetic was given, nor pain complained of; no unpleasant effect of any kind followed.

July 23.—Has some control of right leg, but the arm was in a contracted condition.

July 26.—Patient very fretful and irritable, discovered a hard substance under the integument tie. Upon cutting down (without anæsthesia), removed a piece of bone of the size of a silver half-dime and the full thickness of the skull. To be certain that no abscess was forming, exploration was again made with the hypodermic needle as before, and again with negative results.

July 28.—Patient discharged, wearing a lead plate to repress a tendency to hernia cerebri.

Aug. 3.—Patient steadily improving, and regaining the use of his arm.

CASE II.—Suspected Abscess of the Brain—Exploration.—This case presents a humorous side. H. H., æt. 38, admitted to the Buffalo General Hospital during the first week in January of the present year; no accurate history elicited. Patient had facial paralysis of right side of the face; gave a very indefinite history of suppurative trouble of right middle ear, dating back for years. Had also further paretic symptoms in the limbs, incoördination of ordinary movements; incontinence of urine and fæces; pupils unequal, but sensitive to light; pulse and temperature normal. He gave no history of convulsive seizures of any kind; syphilis denied.

Jan. 7.—Was summoned to a consultation concerning the case; others present, Drs. Wyckoff, Rochester, and Gay. For several hours patient had been comatose; pulse had been as low as 48; and his general appearance was as of one suffering from compression of the brain. Bearing in mind the trouble in his middle ear, and the other part of the history of the case, an abscess of the right side of the brain, or a collection of pus in that neighborhood, was suspected, and exploration was resorted to over the mastoid region, first trephining high enough to escape the lateral sinus. The longest needle of a hypodermic was then used, passing it inward, upward, downward, backward and forward, getting thereby only a few drops of blood. Wound was irrigated with sublimate solution, closed over a drainage tube, and a napthaline dressing applied. Spray not used; very little ether required. The succeeding day, Jan. 8, patient perfectly conscious. In short, this had been an epileptic seizure.

Jan. 16.—Wound perfectly healed over where the button of bone had been removed, and his general condition was improved.

Feb. 5.—Patient went home perceptibly better than when he entered.

Evidently here was an error in diagnosis, but an excusable one, as the man had not been in the hospital long enough to make a diagnosis possible, and where no history was obtainable, especially regarding his previous seizures. It is, moreover, obvious that the epilepsy in his case was secondary to some serious organic change, and a case of this kind, with its post mortem revelations, was still fresh in the surgeon's mind, which possibly also influenced him unduly to operate. In spite of error, however, the patient was benefited rather than injured by the operation. Exploration of the brain, at least of the upper and enveloping portions, by the hollow needle is harmless, and it should find a recognized place both in our surgical practice and in our text-books.

DISCUSSION.

Dr. J. G Kiernan said that Johnson (a Norwegian physician) had experimented on suture of nerves in fowls, and reported that to do so by the direct method it required 45 days before the animal regained the normal function of the affected part, and 60 days when it was performed by the indirect method. Regarding the second part of the paper, nerve-stretching, there is not much benefit to be derived from the operation, except in cases of neuralgia. The operation is not unattended by danger. During 1882, of 25 cases of locomotor ataxy reported where nerve-stretching was performed, five cases died from the operation. The same year, Graeme Hammond reported a case where the operation aggravated the disease. In a case of multiple cerebral sclerosis in which he was personally cognizant of the facts in the case, he reported the following result: The patient (a man) having previously been treated for a long time, visited an Eastern city, and returned markedly improved. Upon inquiry, I was told by him that the posterior cord of the brachial plexus had been stretched. I examined the surface over the region of the clavicle, and at once saw that only the integument had been cut through. Now here is a case of imaginative improvement, and the man really believed himself improved because, as he supposed and believed, the real operation had been done to relieve him. Regarding the case of tetanus reported in the paper, he did not think nerve-stretching was warranted after the source of irritation had been removed, the wound cleansed and dressed antiseptically, and the patient treated with physostigma. Regarding exploration of the brain, the speaker thought it an unjustifiable procedure, unless based on symptoms localizing the lesion in some portion of the brain.

Dr. J. J. M. Angear arose and debated the subject quite extensively. Regarding the vicarious action of nerves that the author alludes to, and their anastomoses, he did not fully understand. For it is a fundamental principle that nerves are continuous, and thought these words should not apply here, as we do to the circulatory system.

Regarding the cases of suture of nerves after long standing injuries, the speaker said:

When a nerve is severed and does not at once heal, that nerve or portion of it passes into fatty degeneration, and it is then no longer a nerve, and we might as well talk of restoring arteries after ligating them as of restoring nerve function after this manner.

To illustrate. We may have a painful stump after an amputation, and why? Because the ends of nerves supplying the parts have not passed through this degenerative process, but instead, little fibrous cords or bulbs, or a tumor has formed, and oftentimes may require to be removed to relieve the increased

sensibility. We do not have that immediate physiological action from suturing nerves. It takes weeks, or many months before physiological action is established.

With reference to elongation of nerves, great damage may be done by this procedure when this operation is performed. A surgeon often does look into the details, or the minutiæ, to see further what is wrong, about the nerve to be stretched, but proceeds to the stretching of it; and I very much doubt if peaceful, harmonious nerve action follows this operation, or at least, in but one or two exceptional cases.

Exploration of the Brain.—This we cannot endorse as a society. If we operate on the cerebrum of a patient fatal harm may result. I cannot see how it is the "harmless operation" the surgeon states it to be, and I think that death more frequently occurs than beneficial results following such procedures. Certainly there is great danger in probing the human brain, for a minute clot may form from the hæmorrhage that may ensue, and this carried along a vessel may close it. He cited a case of this kind where the man died. When the cerebrum of pigeons, *i. e.*, portions of it, are removed, they are greatly incapacitated after this has been done.

Regarding trephining for confirmed epilepsy, I do not think we are justified in doing this. A case of this kind is under my care now, that of a woman where trephining was performed, and the case is on record to-day that a cure was effected thereby, whereas the truth is, before the printer's ink was dry the woman grew worse, and has remained more so than was her condition previous to the operation.

Dr. G. C. Paoli. Let us admit for the sake of argument that suture of nerves and nerve-stretching will relieve suffering humanity. But no statistics that he knows of are yet published of what the percentage of successes are. He does not doubt but what in a very few cases nerve-stretching may prove beneficial. We often admire the boldness of a surgeon, but what a surgeon does today he would years ago have been branded for as committing murder. Some of our colleagues that are old in the practice of the profession are for like reasons, perhaps called "old fogies," because we do not go ahead and cut, but nature heals our cases, and ere long it may be that the operation of nerve-stretching will be performed in acute neuralgia, as it is now done to relieve chronic forms of it. The operation for sciatica has been in vogue during the past ten or fifteen years only.

Dr. D. A. K. Steele thought the discussion thus far had been quite severe in criticizing the paper, and thought immediate nerve suture to be justifiable. It should be done oftentimes where only the integument is sutured. Nerve stretching, he thought, useless in tetanus and locomotor ataxy, whereas in obstinate sciatica it cures, and is a justifiable operation.

The last portion of the paper, on Exploration of the Brain, is as yet certainly a mooted question. It seems to me that it cannot be done without a blood clot forming, or wounding a blood-vessel, or that paralysis may ensue. If such is the case, then it is not a justifiable operation. Some portions of the paper merit much praise, and as such I have been much interested.

Dr. R. Tilley thought the surgeon was not justified in doing more at the first consultation in the case of toy-pistol tetanus cited in the paper, than the removal of the piece of wadding and the mere cleansing the wound and dressing it properly, and using antiseptic measures, etc., etc.

Regarding suture of nerves and union of nerve tissue, experiments have been tried where crossing the nerves has been done—by crossing the distal end over the central portion, (X, thus) and then it took from two to ten weeks before they become adherent and function restored. Complete paralysis has occasionally resulted.

Motion that the Society do now adjourn prevailed.

L. H. M.

Among those from this city and Springfield, Ill., who attended the "Sanitary Council of the Mississippi Valley," at its sixth annual meeting, held at Memphis, Tenn., on Friday, the 21st, were: Drs. John H. Rauch, Ralph E. Starkweather and Liston H. Montgomery.

OBSTETRICAL SOCIETY OF PHILADELPHIA—STATED MEETING, MARCH 6, 1884.

The President, R. A. Cleemann, M D., in the chair.

Dr. Wm. Goodell made the following correction of a misstatement.

"At the last meeting of this Society I made a misstatement with regard to that distinguished ovariotomist, Mr. Tait, which I greatly regret, and which I wish here to correct. I was misled by some remarks made by Dr. Sutton at the last meeting of the American Gyncæological Society. These were so reported as to convey to my mind the impression that Billroth was the only European operator who did not refuse any case of ovarian tumor, however unpromising it was, and that Mr. Tait—to borrow Dr. Sutton's language—'does not remove many large tumors, those which weigh from sixty to sixty-five pounds, with extensive adhesions, etc.' In quoting this, by a careless slip of the pen I changed the word 'many' into 'very,' and in addition I wholly misapprehended the purport of the above sentence. Dr. Sutton has since, in the *Medical News* of February 23, explained that he did not mean that Mr. Tait selects his cases, for he was 'not aware that this British ovaiotomist refuses to remove a tumor because it is large,' but that Mr. Tait has the largest line of ovary and tube-cases and the shortest line of big ovarian cysts of any man I (Dr. Sutton) visited in Enrope.' In making this correction here, I wish to repair the injustice which I unwittingly did Mr. Tait before this Society."

Dr. Goodell then exhibited an extra-ovarian cyst with the following history: The lady, aged 28, and the mother of four children, had a miscarriage early in last October. At that time her family physician discovered the tumor. It slowly grew, but gave the

lady so much inconvenience from pain and pressure that she was brought to his office late in the following December. It was not large but was very sensitive, and was diagnosticated to be an ovarian tumor.

Both ovaries were removed early last February and the lady recovered promptly. The peculiarities of the cyst were to him unique. The ovary lay to one side of a thick-walled cyst, and at such a distance from it that the cyst could have been removed without injury to the ovary. The latter was, however, extirpated along with the cyst because it was diseased. Hitherto all parovarian cysts which he had encountered were thin-walled and contained a clear fluid. But this one had thick walls and contained a turbid, brown fluid. It started from the left broad ligament and was adherent to the bladder, omentum and abdominal wall. Another point of interest was the fact that the right ovary had doubled its size from follicular degeneration, and yet pregnancy had taken place.

Dr. Robt. P. Harris suggested the possible existence of a third ovary as the starting point of the tumor. He also thought that the presence of a third ovary might explain the persistence of the menstrual flow in some cases, after the operation of double ovariotomy.

Dr. Goodell also exhibited a coceyx removed for coccygodynia. The patient had met with a fall down stairs some years previously and the injury was followed by a vaginal abscess of some kind. She had all the classical symptoms of a very bad coceygodynia, and had fallen into a nervous condition which bordered on insanity. Dr. G. had intended merely to sever the nervous attachments of the coceyx by the sweep of a tenotomy knife, but after the patient had been put under ether, the tip of the bone was found unnaturally movable and giving distinct crepitation. The loose bone was therefore removed, and as the articulating surfaces were found rough and denuded, the whole coccyx was removed by bone forceps. Great relief followed this operation.

Although he had seen very many cases of coccygodynia, this was the first case on which he had operated. In a very few traumatic cases he had wished to operate, but was not permitted to do so. The vast majority of these cases are, in his experience, those of nervous or neuralgic coccyx, and they get well in his hands under rest, massage, electricity and appropriate constitutional treatment. The great difficulty, in cases of severity, is to decide between the nervous mimicry of the disease and pure coccygodynia in which positive lesions have been sustained, and their effects have not yet passed away, as for instance, in a sprained or a fractured coccyx, or in a rheumatic, a gouty, or an inflamed coccyx. There is yet another difficulty in the way of diagnosis, for sometimes an injury received in an hysterical woman is followed by local nervous phenomena, which will last long after the original lesion has been cured. For instance, on one occasion he had been so greatly deceived in the diagnosis of traumatic and nervous coccygodynia as to make him very cautious in resorting to the use of the knife. A highly intellectual lady, who spent her leisure in reading metaphysical works, received an injury to her coccyx by the sudden "backing" of the horse on which she was mounted. She was at that time suffering from nervous prostration, and the blow started up very exacting coccygeal symptoms. Dr. Goodell found retroversion and a prolapse of both ovaries. These dislocations were remedied and the patient put on a vigorous constitutional treatment; but she grew no better and an operation was proposed and agreed to. As soon as the day and the hour were decided upon, she lost all pain in her coccyx, and has not since had a return of it. This happened about six years ago. On another occasion he saw a very obstinate and severe case of coccygodynia, which he had been treating unsuccessfully for a long time, and which had a traumatic history, quickly disappear under an exciting family jar. In view of this experience he believed it always safer at first to consider coccygodynia as a local expression of a general neurosis, and to treat it accordingly.

Dr. J. H. Packard asked why Dr. Goodell had preferred the bone nippers to disarticulation in the first case.

Dr. A. H. Smith asked if Dr. Goodell had removed the entire coccyx. (Dr. Goodell was not sure, but thought so. There had been an abscess in connection with the injury and the bone was dead and somewhat necrosed, he had cut off one piece with the nippers and then disarticulated the remainder.) Dr. Smith continuing, said, there had been suppurative action probably followng anchylosis. Such a condition might result from injuries received from labor or from falling astride a chair back or a rail. Most cases were reflex hysterical or uterine pains, as will be proved by the freedom from tenderness when the finger is pressed on the coccyx when making a vaginal examination. He has never removed one, because he has seen such poor relief from the operation in any cases that have come under his observation. Why should relief come unless all the nerves and other painful tissues be also removed? He will be glad to hear the result of the operation in the case reported by Dr. Goodell this evening.

Dr. Packard demonstrated to the society a new method of applying axis traction to any ordinary obstetric forceps. The device consisted of two steel hooks arranged to catch in the fenestræ of the blades of the forceps, and terminating in rings through which a wooden handle is to be passed. The handles of the forceps are to be lashed together.

Dr. Smith remarked that Dr. Tarnier's first suggestion was to pass a cord through the holes drilled through a widened portion of the blades at the point at which handles are now attached. The hooks exhibited by Dr. Packard did not draw from the right point, and he thought there would be difficulty in adapting them when the head was high up.

Dr. Goodell thinks that Tarnier was anticipated in the cord attachment by another French physician.

Dr. B. F. Baer read a paper on The Significance of Metrorrhagia About and After the Menopause. (See *Amer. Jour. Obstet.*) Metrorrhagia recurring about the menopause is as likely to be the result of disease of the uterus or its appendages, as it is at any period previous to that time. The popular belief that flood-

ings at the change of life are physiological, often results in harm. That the blood-loss is depuratory or critical, and that it protects the vital organs from injurious congestion, is erroneous Where health exists the cessation of menstruation will be attended by no more aberrations of function than are seen in its establishment. An analysis of 2,200 cases treated in hospital and private practice, show that nearly the same number of women sought advice during the establishment and the decline of menstruation, and it further shows that the numbers rapidly increase as the period of greatest fecundity is reached, and decline after it is past.

Epithelioma of the cervix may result from injury of that organ, but also requires some peculiarity in the structure of the tissues which renders them susceptible to an induced dyscrasia. When a woman in the midst of the fertile period suddenly ceases to bear children, there is often some local cause for it. There is some causative relation between acquired sterility and cancer. It is safer to believe the disease of local origin, for we will then endeavor to discover and remove all sources of irritation, and possibly prevent its development. Detailed histories of a number of cases are given, to illustrate the truth of the positions assumed. Where the menopause is retarded beyond the usual period, the cause can often be found in some diseased condition connected with the sexual system, and as a rule it is an old standing trouble. When metrorrhagia recurs after the menopause has been fully established, it is almost invariably the result of a pathological change in the tissues of the uterus.

Dr. Goodell agrees almost wholly with what Dr. Baer has said. He thinks the dangers of the menopause much overrated. Cancer and fibroids of the uterus occur more frequently at that age than any other, and have caused the popular dread. Although hæmorrhage is always pathological, its cause cannot always be discovered, and in this dodging period serious hæmorrhage may occur and no dangerous condition exist. He would like to believe that cancerous growths had a benign incipiency, but cannot go so far. The microscopists make many mistakes in ascribing malignancy to growths removed from the uterus. Dr. Goodell then gave a number of cases in which experienced microscopists had given prognosis of early fatal termination, based upon the cell formation of growths removed from the uterus, but these cases had recovered, and now showed no evidence of any diseased condition. With regard to the small proportion of cancerous growths following laceration of the cervix uteri, the doctor called attention to the large number of Irishmen using clay pipes, and the small number of lip cancers, and yet it is universally acknowledged that the use of a clay pipe is the principal cause of such growths.

Blood-letting is practiced very freely in Turkey and the East, and women, as a consequence, get very stout. Such are more liable to profuse hæmorrhage at the dodging period.

Dr. Wm. T. Taylor reported a case of malarial poisoning in a newborn babe. We have frequently observed fevers of a malarial type in very young children, in some even during the first year, which were ushered in by a convulsion or other prodrome, without a rigor, as occurs in older persons, and their character is only recognized by a repetition of the attack in a day or two. But the youngest subject of this disease which I have met with is the following case:

Mrs. A. R., during her second pregnancy was affected with malarial fever, and although she was then residing at the seashore, was obliged to take occasional doses of quinine to control it. She returned to her city residence at the end of the season, but continued using quinine from time to time until the end of her uterogestation, which was completed in November last, when her babe was born. Her labor was natural and easy, and she had no unfavorable symptoms. The child appeared healthy, was of good color, but was smaller and feebler than her first born at its birth. As she had a good supply of milk it soon drew the breast quite vigorously.

About one week after its birth the nurse called my attention to "weak spells" which it had occasionally, accompanied by coldness of the skin, a feeble circulation and prostration, which continued for fifteen or twenty minutes, and were followed by a clammy perspiration. By the application of heat to the body and giving it a little brandy and water or other stimulant, it would revive.

I observed that these "spells" had a periodicity, occurring every two or three days, and considering them malarial, I gave the mother quinine and valerianate of iron, which, acting therapeutically through the milk, soon caused the "spells" to cease, and the babe became well and fat. I also gave it small doses of the elixir of cinchona for several weeks.

This child must have contracted this disease whilst in utero through the placental circulation, for being born in a perfectly healthy locality it was not exposed to any external malarial influence.

When labor began the quinine was stopped and was not resumed until the condition of the child required it, when it soon showed its anti-periodic action by completely arresting these "weak spells," for now the child is perfectly well.

Dr. R. P. Harris related a case of parallel character, which had occurred some years ago in a malarious neighborhood. The mother was under treatment before labor. The child had chills and fever when quite young and was treated through the mother.

W. H. H. Githens, Secretary.

Discontinuance of the "Proceedings" of the Medical Society of the County of Kings.—As a circular tells us, with the completion of the eighth volume, this publication is discontinued by order of the society. Many will regret this action, for although it was always a quiet, unpretending publication, confining its material to its own proper work, its readers looked for its regular monthly appearance with the confidence of finding well-selected, vigorously put and valuable matter in its pages.

STATE MEDICINE.

STATE BOARD OF HEALTH OF CONNECTICUT.

BY DR. C. W. CHAMBERLAIN, SECRETARY.

MORTALITY IN JANUARY, 1884.

With the exception of Hartford, the sanitary history of the month is exceptionally good. The highest death rate is 16, the percentage of zymotic diseases not large, nor the percentage of deaths of those under 5. The increase in the relative frequency of typhoid fever over malaria is shown by the ratio of deaths, 14 to 5. The cold weather is, perhaps, equally unfavorable to the causation of both types of disease, although the falling off in malarial diseases as the severe cold weather comes on is more marked than in typhoid, but the latter is not considered as a winter disease. No report has been made of winter cholera, although it reappeared in Providence early in the winter.

The death rate of Hartford is not materially decreased from that of December. The ratio of deaths from zymotic diseases and of infantile deaths also continues unfavorable. The mortality from diphtheria continues at the same rate it has steadily maintained since November, a little over 20 a month, and thus far in February the ratio has been the same. In 1883 there were 200 deaths from diphtheria, 234 from croup and diphtheria, now generally classed together.

Total mortality to date is 270, which is larger than the deaths from the whole State for some years, and, excluding the cases of croup, equal to the deaths from diphtheria in 1879 in the whole State. The epidemic of scarlet fever in 1882 and 1883, caused 90 deaths, and the disease has reappeared as shown by the table. If the deaths from diphtheria had been crowded into a few months instead of extending over the year, the impression would be so great that immediate action would result. That would have been a better showing for the city, for this steady persistency indicates unmistakably the existence of unsanitary conditions that cause it, rather than any epidemic influence, except such as has been caused by the local conditions that have favored its spread.

The mortality in 1882 from diphtheria was 47, or 63 from croup and diphtheria, showing that there has been an unusual prevalence for a long period. These epidemics are found associated with unsanitary conditions. An ordinance embodying the opinions of the city board of health upon some of the causes that can be remedied, which are also favorable to the spread of zymotic diseases generally, has been submitted to the Common Council for its action. The reappearance of scarlet fever is not an encouraging feature.

Typhoid fever is reported from Berlin; also from Willimantic, one case fatal. Diphtheria and scarlet fever are also reported, with one death from each from the latter place, and also measles as very prevalent. Measles are also reported from Ashford and Saugatuck, and as epidemic in Willington and Stafford. Whooping-cough is reported from Bloomfield, Hampton, Union, Thomaston, Saugatuck, South Manchester, and Avon, but not unusually severe.

Scarlet fever is more prevalent than last month. Cases are reported from New Canaan, one fatal, Robertsville, Westport, Greenwich, one fatal, Berlin and Haddam, and as quite prevalent in North Haven. From Dr. Griswold, of North Manchester, five cases in two families, of a very malignant type, are reported, three of which were fatal, in a neighbouring village. The doctor's opinion was that the infection was conveyed by paper rags. The cases are discussed more fully in another connection.

Diphtheria is reported from Manchester, Thomaston, Avon, New Canaan, Hampton, Westport, and Bloomfield—six cases, two of which were fatal. The only death from whooping-cough is also reported, but the cases were quite numerous.

Diseases of the nervous system have been unusually prevalent, as shown in the mortality table and in the different reports. Erysipelas is also reported much oftener than usual.

While lung fever is reported as prevalent quite generally, the indications are that the mortality will be prolonged into the spring months, as has been the case of late. Bronchitis is also more prevalent than usual. Lung diseases generally are reported as quite prevalent in Oxford. Lung fever is reported also from Greenwich, Berlin, New Canaan, Cheshire and other places. Malarial fevers show rather an increase over last month, as reported from Haddam, New Canaan, North Manchester, Thomaston, Willington, Westport, and Bloomfield, the frequency of cases somewhat in the order named, increasing from the first onward. Avon also reports a decided increase, and there is no decrease in the cases reported from the part of South Manchester where there has been so marked a prevalence for some months past. There appear to be more cases proportionately in that region than elsewhere during the cold weather, although much less than during the summer and autumn.

New Hartford reports only one death for the month, a child of four months old that inherited consumption. An instance of death from freezing is reported from Saugatuck. A case where a child was killed by soothing syrup is stated to have occurred in Willington. An unusual number of deaths from old age are reported from all parts of the State. Bridgeport reports six over 70, four of whom were over 80.

One singular feature is the unusual prevalence of diarrhœal diseases. Should this continue it would be an intimation to look out for cholera next summer. It is a bad time to clear up filth when an epidemic is present. The time, if prevention is to be accomplished, is before the appearance of the disease.

MEETING OF THE STATE BOARD OF HEALTH OF KENTUCKY.

The State Board of Health held its regular quarterly meeting at Frankfort on January 16, and had a joint meeting with the House Committee on Sanitary Regulations, in the hall of the House of Representatives. The members present were Dr. Thompson, of Henderson; Dr. Holland, of Louisville; Dr. Shackleford, of Maysville; and Dr. McCormack, of Bowling Green.

In his report as Secretary, Dr. McCormack reported that in 85 of the 117 counties of the State, efficient boards of health were organized, and are now engaged in making sanitary surveys of their respective counties. Small pox had been reported from five counties, and in each instance prompt restrictive measures had been resorted to, and the disease checked. The Committee on Legislation reported a bill giving increased powers to and defining more clearly the duties of local boards of health, and providing for the appointment of a health officer in each county. Also a bill providing for instructions in hygiene in all the public and incorporated schools of the State, and a bill amending the present law regulating the practice of medicine, requiring physicians to procure licenses from county judges, based on proper evidences of qualification, and have the same recorded in the county clerk's office.

These bills were presented to and examined by the above named House committee. The Board also asks an increase in its annual appropriation—from $2,500 to $7,500. It claims that its work is no longer an experiment, and that having demonstrated its usefulness in preventing and restricting epidemic and contagious diseases, and in diffusing information amongst the people in regard to the preservation of health, it should be furnished with a sufficient amount of money, that it may multiply its methods of collecting information, and enter fully upon the enlarged sphere which increased knowledge has opened up. New York gives its Health Board $20,000; Michigan gives $15,000; Illinois $12,000; some of the other States, $10.000; no State, excepting South Carolina and Kentucky, appropriating less than $5,000. As the members of the Board receive no compensation for their services, and use the money in sanitary investigations, and to pay actual expenses, the demand seems reasonable.

BOOK REVIEWS.

Diagnosis of "Functional Murmurs." By F. C. Shattuck, M.D.

We have received the interesting paper of Dr. F. C. Shattuck on the above subject, and as a whole can commend it for the care which has been exercised in collecting facts, and for the clear statement of the differential features between organic murmurs and those of inorganic origin; but we cannot coincide with him in the following statement, which we fear may mislead some who are not thoroughly familiar with the various cardiac murmurs.

He states: "As regards prognosis and treatment, a murmur, even if persistent, is of no importance to the patient, unless it either is, or after a reasonable time, say six months if you choose, becomes associated with other well-marked evidences of a disturbance of the balance of the circulation, above all, enlargement of the heart in some or all of its divisions."

In this the author has overlooked those numerous cases in which, for years, organic disease of the heart causes murmurs, without any evidence of a disturbance of the balance of the circulation, but in which the heart finally undergoes the same changes as in the more rapidly progressing cases.

These cases are certainly of importance to the patient, as, sooner or later, serious symptoms will be developed, though they may be delayed for five, ten, or even twenty years after the murmur has been discovered. During this time, the author's statement that "the murmurs are of no importance to the patient," might sometimes hold good just so far as the symptoms of any serious disease, which symptoms were not of themselves a source of inconvenience, might be of no importance to the individual (as it would not benefit him to know of them); but in other cases, a knowledge of the impending danger might greatly prolong life, by enabling the patient to avoid excitement and excessive exertion which would throw an unusual amount of strain upon the heart, and thus hasten hypertrophy and final dilatation.

E. F. I.

64 State St., Chicago.

DOMESTIC CORRESPONDENCE.

MICHIGAN COLLEGE OF MEDICINE.

Editor Journal American Medical Association:

The fourth annual Commencement of the Michigan College of Medicine was held at Whitney's Opera-House, March 3, when 27 young gentlemen received the degree of Doctor of Medicine. The address was given by the Rt. Rev. S. S. Harris, Bishop of Michigan. He explained to the audience the duties and nature of the physician; demonstrated the virtues of the Hippocratic oath and told the large audience that they had also a duty to perform not only to their personal medical adviser, but to the profession

at large, and above all, that they should always pay their bills promptly. The degrees were conferred by the Hon. Sydney S. Miller, President of the Board of Trustees. The address to the graduates was given by Prof. Gastin, who, after reciting the education they had received, closed with practical advice for their future government.

The music for the occasion was furnished by Prof. Spiel, and was excellent. Floral gifts were given by the friends of the graduates, which were profuse in quantity and beautiful in arrangement.

After the close of the exercises, an elegant entertainment was given the alumni and invited guests by the Faculty, at the conclusion of which short speeches were made encouraging and giving good advice to the graduates.

The graduates were all males, and all were three course students. They had passed a thorough examination, both written and oral.

This college, although a junior, is determined that her graduates shall be well educated before being received for medical instruction, and equally determined that they shall be thoroughly educated in medicine before receiving the degree of doctor.

B.

EDITOR OF THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION :

Sir:—It is so very gratifying to be reproved by the venerable editor-in-chief of this journal for not having asked the prayers of the members of the Association for *more* than I did, that I am almost loath to suggest that if he will carefully read the proposed law I was so anxious to have the legislature of the State of New York given wisdom and courage (by prayer or otherwise) to enact, he will find that is "worth praying for."

As many others of the members of the Association may not know the precise scope of this contemplated law I present it herewith for publication. It is indeed a surprise for me to learn that the war that such boards as those of Illinois and West Virginia "can wage against medical ignorance and incompetence will never amount to more than light skirmishing along the outposts, and is hardly worth praying for;" nevertheless, I shall be very well satisfied if I can live to see skirmishing boards not only in New York, but in every other State as effectively armed as by the following:

AN ACT TO ESTABLISH THE MEDICAL FACULTY OF THE UNIVERSITY OF THE STATE OF NEW YORK, TO REGULATE THE LICENSING OF PRACTITIONERS OF PHYSIC AND SURGERY, AND TO FURTHER REGULATE THE PRACTICE OF PHYSIC AND SURGERY.

The People of the State of New York, represented in the Senate and Assembly, do enact as follows:

SECTION 1. On or before the first day of June, 1884, the Governor shall appoint the Medical Faculty of the University of the State of New York, to consist of nine (9) members, who shall be authorized practitioners of physic and surgery in this State, but none of whom shall be connected with any medical school or college; provided, that in the appointments made the representation of the several systems of medical practice recognized by the incorporated medical societies of this State shall be in the proportion of six, two and one, that is to say, the system having the largest number of practitioners to have six, that having the next largest to have two, and the remaining system to have one representative; and all persons desiring to enter upon the practice of physic and surgery in this State, after November 1, 1884, shall before doing so, comply with the provisions herinafter prescribed and obtain the license hereinafter provided.

SEC 2. Of the nine members of the said medical Faculty, three shall serve, in the first instance, for three years, three for four years, and three for five years; and these terms shall be severally distributed by lot at the first meeting of the said Faculty. All appointments made in the Faculty at the expiration of the several terms fixed above shall be made uniformly for the period of five years each. All vacancies occurring in the said Faculty, from whatever cause, shall be filled before the next semi-annual meeting of the same, by the appointments by the Regents of the University of a practitioner of the system of practice that had previously been represented by the person occupying the seat so vacated; and in case the several State medical societies shall nominate physicians to fill such vacancies, the Regents shall appoint some one of the physicians so nominated.

SEC. 3 The said medical Faculty shall examine all applicants for license to practice physic and surgery in this State. The members thereof shall meet at least semi-annually, and at such meetings shall faithfully examine all candidates referred to them for that purpose by the Chancellor of said University, and each furnish him a report in writing of his opinion as to the qualifications and merits of each candidate, referring briefly to the degree of proficiency evinced by the applicant in all the several branches in respect of which he was examined; which opinion shall be by him denominated favorable or unfavorable. The President or Secretary of the Faculty shall have authority to administer oaths, and the Faculty to take testimony in all matters relating to its duties, and any false statement made under an oath so administered shall subject the offender to prosecution for, and on conviction, to punishment for perjury.

SEC. 4. Such examination shall be in anatomy, physiology, histology, pathology, theory and practice of medicine, chemistry, surgery, obstetrics, materia medica and therapeutics, and such other branches in the several departments of medical science as the said Faculty may agree upon, subject to the approval of the Regents of the University. The questions forming such examinations shall be the same for all classes of candidates offering themselves, with the exceptions of the departments of materia medica and therapeutics, in which branches the questions for each candidate shall be prepared by the representatives in the Board of Examiners, of the system of practice to which such candidate wishes to be licensed.

SEC. 5. The orders of the Chancellor addressed to the medical Faculty and the decision of the Regents of the University in each case shall be attached to the written reports of the examiners, and shall thereupon become, and forever after be a part of the public records of said University.

SEC. 6 Any person, on paying twenty-five dollars into the treasury of the University, and on applying to the Chancellor for the aforesaid examination, shall receive an order addressed to the aforesaid medical faculty, instructing them to examine the candidates at one of the regular semi-annual examinations, provided that proof satisfactory to the Chancellor is first given that the candidate is over twenty-one years of age, of good moral character, and has received a diploma issued to him or her, conferring on him or her the degree of doctor of medicine from some legally incorporated medical college held to be in good standing by the said medical faculty.

SEC. 7. The Regents of the University, after finding that the members of said faculty participating in the examination have given an unanimous opinion in favor of a candidate, and that such examination has been a satisfactory test of the qualifications of said candidate, shall issue to him or her a license to practice physic or surgery in the State of New York, for which license the candidate shall pay to the University the further sum of fifteen dollars.

Said faculty may refuse to recommend a license to individuals guilty of unprofessional or dishonorable conduct, and for like

cause, after giving the accused an opportunity to be heard in his or her defense, the Regents of the University shall revoke said licenses.

SEC. 8. The moneys paid to the University under the provisions of this act, shall be appropriated by said Regents for, and shall defray the expenses incurred under the provisions of this act.

SEC 9. The medical faculty shall meet on the first Monday of November, 1884, at the University in the city of Albany, and seven members thereof shall then and thereafter constitute a quorum, and shall at once organize by the election of a president and secretary, and such other officers as may then be determined, and then and thereafter adopt such rules and regulations, not in conflict with the provisions of this act, as may meet with the approval of the Regents of the University; and shall forthwith proceed to the examination of all such applicants as shall then present themselves with the order referred to in section six of this act.

SEC. 10. Subsequent to the first day of November, in the year 1884, every person (except such as have before such date lawfully registered pursuant to the laws of the State in force at the time of the passage of this act), after complying with sections 6 and 7 of this act, shall, before commencing to practice physic or surgery, register in the clerk's office in the county where he or she practices or intends to practice physic or surgery, in a book to be kept by the said clerk, his or her name, residence and place and date of birth, together with the date of his or her diploma and by what institution granted, with the date of his or her license to practice physic or surgery within this State; at the same time the person so registering shall exhibit both the license and the diploma herein required to the clerk, and subscribe and verify by oath or affirmation, before a person duly qualified to administer oaths under the laws of this State, an affidavit containing a plain statement of all the facts as aforesaid, including his or her age, and shall file said affidavit and copy of said diploma with said clerk; said county clerk to receive a fee of twenty-five cents for such registration, payable by the person so registering. Nothing in this section shall be so construed as to prohibit medical consultation in the different counties of the State between legally qualified and registered physicians of this and neighboring States.

SEC. 11. A person who shall willfully swear falsely to any statement contained in the affidavit required by the tenth section of this act shall be deemed guilty of and subject to conviction and punishment for perjury; and a person who violates any of the other provisions of this act, or who shall practice physic or surgery in this State under cover of a diploma unlawfully issued or illegally obtained, or without a license as provided for in this act, shall be deemed guilty of a misdemeanor, and on conviction thereof shall be punished by a fine of not less than two hundred and fifty dollars nor more than five hundred dollars for the first offense, and for each subsequent offense by a fine as aforesaid and by imprisonment for not less than thirty days and not more than six months. The fine when collected shall be paid, one-half to the person or corporation making the complaint, the other half into the county treasury of the county where such conviction shall be had.

SEC. 12. For the purpose of this act the words "practice physic or surgery" shall mean to annex the letters "M. D." to one's name or to suggest, recommend or prescribe, direct or employ, as a matter of business or for a fee, for the use of any person, any drug, medicine, appliance, apparatus or other agency, whether material or not material, for the treatment, cure, relief or palliation of any real or supposed ailment or disease of the mind or body, or for the treatment, cure or relief of any wound, fracture or other bodily injury or infirmity, or any deformity.

SEC. 13. Nothing in this act shall apply to commissioned medical officers of the United States army or navy, or of the United States marine hospital service, nor to any members of the house staff of any legally incorporated hospital during the term of their service as such.

SEC. 14. So much of chapter seven hundred and forty-six, laws of eighteen hundred and seventy-two; chapter five hundred and thirteen, laws of eighteen hundred and eighty; chapters one hundred and eighty-six and six hundred and seventy-nine, laws of eighteen hundred and eighty-one, as are inconsistent with this act, and all other acts and parts of acts inconsistent with this act, are hereby repealed.

Very respectfully, your obedient servant,

ALBERT L. GIHON, Medical Director U. S. Navy.

U. S. Naval Hospital, Washington, D. C, March 15, 1884.

NECROLOGY.

BATEMAN, BENJAMIN RUSH, M.D., was born in Cedarville, Cumberland county, N. J., on March 4, 1807, and died July 23, 1883, in his 77th year. He graduated from Jefferson Medical College in 1828, and immediately commenced the practice of medicine in his native town, succeeding his father, the Hon. Ephraim Bateman, M.D., who was at that time United States Senator from this State.

Dr. Rush Bateman, as he was generally known, by his energy and zeal soon built up a very extensive practice, and for forty years, day and night, cheerfully responded to *every* call for his professional services. He was an invaluable citizen, and always foremost in every good work, always leading in every benevolent enterprise. He was widely known throughout the State, and occupied at different times many positions of honor and trust. As a wise and successful practitioner he ranked among the first. He became a member of the American Medical Association in 1853, and was a Fellow of the New Jersey Medical Society, having been its President in 1866, and was an honorary member of the Cumberland County Medical Society. The latter Society, at his death, passed the following resolution:

"*Resolved*, That this Society here record a sense of their great loss of one who, though he had reached a ripe age, was ever young, ever genial and companionable, and who always added interest to our meetings."

A letter written by the distinguished Dr. Gross to Dr. Ephraim Bateman, after the death of his father, will convey some idea of the impression the latter's character always made upon his friends and acquaintances:

"PHILADELPHIA, Aug. 1, 1883.

"MY DEAR DOCTOR:—I am grieved to hear of the death of my kind friend, Dr. Bateman. I saw him only a few years ago, and he was then in excellent health, with a countenance benignant, genial, and beaming with kindness. He must have been essentially a good man, and his death must be regretted by his many friends and fellow citizens. Thus we go. All must die; none can escape the inevitable lot.

Very truly, your friend,

"S. D. GROSS."

GEO. T. WELSH, M.D., New Jersey.

DR. C. H. VON KLEIN, formerly of Hamilton, has removed his residence to Dayton, Ohio.

MISCELLANEOUS.

To the Members of the Medical Profession of the State of Tennessee:

The fifty-first annual session of the Medical Society of the State of Tennessee will convene at Chattanooga, Tuesday, April 8, 1884.

The attention of the members is called to the fact that at the last meeting there were no essayists appointed for this meeting, and the society will expect the members to come prepared with volunteer papers to present to the meeting.

The committee on changes in the constitution will recommend that permanent members and delegates present at the sessions of the society pay a tax of $2, and permanent members not in attendance pay $1 and be entitled to receive the Transactions. These fees being in lieu of the present tax of $3 which has heretofore been collected whether the members were in attendance or not.

Reputable members of the profession throughout the State are invited to become members. Every physician who values his own interest and that of the people who trust their health and lives in his care should take every legitimate method of advancing the individual and general intelligence of the profession, and this can be done to a large degree by these pleasant re-unions and discussions of our every day work at the bedside. The earnest coöperation, therefore, of every physician in the State is needed and should be given to the State Medical Society, whose laudable object is to elevate the profession and advance the medical reputation of the State. The Society, now grown old in years and honors, has an enviable history, and the future should equal if not excel the past.

The N., C. & St. L. railroad will sell round trip tickets at four cents a mile on April 7, 8 and 9, good for return passage until the 12th.

The L. & N. railroad will sell round trip tickets at same rates at their stations to Nashville. These tickets must be shown at Nashville to purchase the tickets over the N., C. & St. L. railroad to Chattanooga.

The L. & N. will, however, sell round trip tickets at Memphis via McKenzie and Nashville to Chattanooga.

These reduced rate tickets can be purchased during the business hours of the day at stations in Tennessee only. These tickets must be purchased in all cases, as no certificate of membership will be recognized as claim for reduced return passage.

For further information address the Chairman of the Committee of Arrangements, Dr. G. A. Baxter, Chattanooga. C. C. FITE, Secretary.

Nashville, Tenn.

INTERNATIONAL OTOLOGICAL CONGRESS.—The next international congress of those interested in the treatment of diseases of the ear, is to be held in Basle, from September 1st to the 4th, 1884. Communications concerning it may be addressed to M. le Dr. Burckhardt-Merion, at Basle.

ORIGINAL ARTICLES.

ON PULMONARY SURGERY.

[Read before the Second Congress for Internal Medicine at Wiesbaden, April 20th 1883. Translated from German by T. Bernauer.]

BY DR. FR. MOSLER.

O. Oe. Professor, and Director of the Medical Clinic in Greifswald.

The principle of modern medicine is that of localization. All real progress made in our science is due to its tendency to local treatment. One by one the cavities of the body are brought within its reach. It will, of course, remain for accumulated clinical experience to decide how far we shall be permitted finally to carry the extension of local treatment. The responsibility of the surgeon has certainly become greater since the introduction of the antiseptic method. Many a difficult operation is now deemed admissible, nay, necessary, for the cure of even internal affections. The advanced practice of antiseptic surgery renders us, in many instances, also less sensible how narrowly our diagnostic knowledge is limited. An exploratory puncture or incision may be made with impunity, and a more accurate judgment thus formed of the nature of dubious cases.

Who could enumerate all the improvements which, thanks to the antiseptic method, have, during the past decades, been made on the old plans of treating so many diseases, and especially those attacking the abdominal organs?

Let us but call to mind the tortures produced by floating kidneys, and our former impotence in affording relief to our patients. In two cases in which this complaint had reached an unusually high degree, Hahn made incisions in the lumbar region, drew forth the kidneys and fastened them to the parietes of the abdomen by sutures. Both patients owed their recovery to treatment by Lister's method. In desperate cases of impacted gall stones, cholelithectomy has been performed with good success. Hepatic surgery may boast of the most brilliant results in affecting the removal of echinococci which so frequently infest that organ.

We were all recently astonished at the successful resection of parts of the stomach; and resection of the intestine is already counted among the regular operations.

We need add no further examples to show the high value of abdominal surgery. Can intra-thoracic, and especially pulmonary surgery, claim the same results?

It is true the local treatment of pleurisy has been greatly advanced during the latter decennia. The antiseptic method has also rendered the performance of several exceedingly bold intra-thoracic operations possible. Schneider and Esthlander have resected as many as nine ribs and the clavicle in addition, with a view to attain complete healing of empyema cavities.

In a case of large hepatic echinococcus, which projected into the thoracic cavity, and was covered anteriorly and laterally by thick layers of hepatic parenchyma, Volkmann resected the seventh rib and opened the pleural cavity, which was healthy and free from adhesions. Having caused a wide gaping of the thorax, he divided the thinned diaphagm with a knife, and extracted the echinococcus cyst *in toto*. A perfect recovery followed.

However, all experienced surgeons will admit that the field for operative interference is much more circumscribed in the thorax than in other parts of the body. This is especially true of pulmonary surgery, where for anatomical, physiological and, I should almost say, for purely individual reasons, the operator cannot be cautioned too much against overbold proceedings.

With regard to the question, What is to be comprised under the term pulmonary surgery? we shall, of course, be guided by the standpoint of the internal clinic. As the most simple and superficial method of surgically treating phthisis in its various stages, we might mention the application of the red hot iron to points of the skin corresponding to the affected portions of the lungs. This method was recommended by Guerin as early as 1830, and has of late been modified by Vidal. In 37 cases of phthisis out of 44, Vidal obtained good results. He thinks it possible that by this procedure the disease can be completely cured in its early stages, and that in more severe cases slowing of the destructive processes is thereby caused. I tried this method on twenty patients who presented themselves at my clinic. Nearly all of them expressed themselves well satisfied with the treatment. They were conscious that energetic and extraordinary measures were taken in their behalf. Like all energetic derivations to the skin, such superficial cauterization with the thermo-cautery is not without value as a symptomatic remedy. I have seen it followed by disappearance of pleuritic pains, catarrhal complaints, and dyspnœa for a considerable time. In a number of cases where the disease had not yet progressed too far, I succeeded in attaining a slowing of the destructive process. I cannot report

a case of complete cure. I do not, however, as yet venture to pass judgment on this method. I reserve further communications.

At all events the method of derivative cauterization, which, by the way, is older than is generally supposed, deserves further consideration. It certainly may claim the merit of having suggested deeper penetration with the cautery, even down to the pulmonary parenchyma. This method was adopted recently by Wm. Koch and Leyden in opening cavities in the lungs.

Before speaking of this method, however, I shall mention another direct interference with the lungs, viz.: parenchymatous injections. As is well known W. Koch performed acupuncture in the lungs of rabbits and dogs by means of Karlsbad needles; later on he injected an aqueous solution of iodide of potassium with Pravaz' syringe. He ascertained that by injecting into the lungs iodide of potassium solutions of various strengths, he could transform any extent of pulmonary into connective tissue. Eugen Fraenkel and Jablonowski continued these injection experiments on animals. They were considered valuable therapeutically, as it was thought that in chronic inflammatory processes with a tendency to softening and destruction, the character of the pulmonary inflammation could be altered by such treatment, and that the production of a cicatricial barrier would effectually check the spreading of the disease. A good deal of zeal and scientific treatment have been expended upon these experiments, but the fair hopes based upon them have not hitherto been realized at the bedside.

Without possessing any knowledge of Koch's experiments, I began to try a similar treatment in my clinic in November, 1872. In all sorts of cases of bronchial and pulmonary affections, I pierced the thoracic walls with the needle of the syringe and then injected variously strong solutions of carbolic and salicylic acids into the diseased portions of the lungs. These trials were discontinued but a short time ago. The injections were as a rule, borne without inconvenience in cases where all antiseptic precautions were observed. From fear of hæmorrhage I never ventured to inject directly into the cones, but confined myself to the middle and lower portions of the lungs.

Now, what has been my reward for all the perseverance and labor spent, during the past ten years, upon this method of treating "pulmonary affections?"

In not a single instance, cases of pulmonary echinococci excepted, did the results obtained justify my expectations. I was never able to alter the character of the inflammation, to induce cicatricial shrinking, nor to bring about a termination of the process by complete healing.

In putrid bronchitis, and in one case of pulmonary abscess, continued injections of a concentrated solution of salicylic acid produced a temporary change in the fetid sputa, which, however, soon regained their former offensiveness. In acute pulmonary gangrene no effects whatever were perceptible; probably because the quantity of fluid injected was insufficient for disinfection of the affected parts. I warmly wish that others who have tried this method may report better success. From Koch and Hiller's experiments, it appears that even tincture of iodine can exert no shrinking influence on tuberculous tissue.

Pravaz' syringe, cautiously introduced into the pleural cavity and lungs, has rendered excellent service in diagnosing the affections of these parts; but it can no wise be stated that the injection of medicated solutions into infiltrated and cavernous lungs has proved a therapeutic success.

Just ten years ago, at the congress of German naturalists and physicians held in Wiesbaden, I read a paper on the local treatment of cavities in the lungs. In order to accomplish healing of bronchectatic cavities, I first aspirated the contained secretion, and subsequently injected medicated solutions. In some cases I allowed the canula to remain in the wound for several days, intending to wash out the cavity with frequent injections. Pepper tried the same simple method, but neither he nor myself have succeeded in rendering it efficacious in the healing of pulmonary cavities.

On this account I began to lean more favorably towards the old idea of opening pulmonary cavities by incisions through the chest walls. I reported such an operation in the above mentioned paper.

This idea of treating cavities in the lungs according to surgical principles is as old as is the science of medicine. Wm. Koch, in an excellent historical essay, has given us a review of the past achievements of thoracic surgery, and I shall therefore omit all mention of historical data.

Fenger and Hollister have recently pointed out as a merit of my paper, that it more than any preceding communication on the subject, has called general attention to the local treatment of pulmonary cavities, and that it has encouraged the making of further attempts in this direction. It is true that during the past ten years, pulmonary surgery has been advanced more in an experimental way than at any time before; but therapeutic effects are as yet exceedingly sporadic. The patient on whose lungs I operated ten years ago, and whose case I reported, likewise died a short time afterwards. The autopsy showed that in spite of the surgical treatment of the bronchectalic cavities, the disease had spread to the neighboring lungtissue and produced general tuberculosis.

In another case treated in my clinic there was a large bronchectatic cavity in the upper lobe of the left lung. On the 14th January, 1875, my colleague, Dr. Hueter, whose early death we all deeply deplore, made a somewhat extensive incision through skin and muscles down to the pleura. The anterior wall of the cavity was carefully bored with a pair of forceps (Kornzange), the contents evacuated, and a canula inserted. Through it solutions and powders were introduced for a considerable length of time. The granulations developing in the depth of the cavity, necessitated gradual shortening of the canula, till finally it could no longer be introduced.

Air and secretion now had ceased to pass through the wound, which healed up completely. All tym-

panitic sounds and râles had disappeared. A gradual contraction of the thoracic wall was noticeable in the region over the cavity. Percussion was endured without any pain being felt whatever. The retraction of the lung caused a greater extent of cardiac dullness, and the sounds of the heart had become louder. As patient had, in a great measure, recovered his former strength and weight, and as he complained no further, he was dismissed from my clinic towards the end of March. His condition was such as to enable him to resume his occupation.

This result seemed to justify our hope that pulmonary cavities would prove amenable to local treatment. Unfortunately, before the lapse of eight months this patient applied for re-admission to my clinic. He was again troubled with complaints of the chest, want of appetite, and insomnia. On auscultation of the left supra and infraclavicular regions, tympanitic sounds and râles were again detected. Commencing dullness showed that the cone of the right lung had likewise become affected. The patient expectorated an abundance of purulent substance, and had a tormenting cough, poor appetite and albuminuria. Profuse diarrhœa, acceleration of the destructive process in both lungs, accompanied by intense fever and dropsical symptoms, caused patient's death on March 25, 1876. The post-mortem examination revealed general tuberculosis, with amyloid degeneration of various organs.

This ill success of a case of surgical treatment of a bronchectatic cavity, all circumstances being apparently so favorable, will always be considered of importance as an interesting therapeutic problem. Who will henceforth venture to decide whether a bronchectatic cavity in the cones of the lungs is still perfectly circumscribed? whether the remaining pulmonary parenchyma is still perfectly intact?

Balmer and Fraentzel's valuable examinations of sputa may be considered a first attempt to distinguish, during the life of the patient, between all the manifold processes which are still confounded with tuberculosis and tuberculous phthisis. Let us hope that R. Koch's great discovery will, in this direction, continue to grow in fertility.

For all pulmonary cavities resulting from tuberculosis, or such as are usually complicated thereby, will have to remain a *noli me tangere* to operative interference, until proofs will have been produced of the existence of antiseptic agents which will destroy or arrest the growth of specific pathogenous fungi, and in particular of the bacillus tuberculosis.

In the meantime, however, we need not wholly abandon our endeavors to advance the department of pulmonary surgery.

A number of non-tuberculous cavities are found in the lungs, and these, if judiciously selected, promise amply to repay the labors of the operator.

I shall first mention echinococcus of the lungs. I am at present occupied with a monograph on this subject, as fourteen cases of this affection have come under my treatment and observation. In the treatment of this disease the value of local treatment has become strikingly apparent. A Ruegen landholder, whose left lung was the seat of an echinococcus, came to my clinic in 1875. He was treated for a considerable time with injections of carbolic acid. A year and a half later, desiring to let me know how completely he had been cured, he wrote to me that a child had been born to him, and that both father and son enjoyed the most vigorous health. They have enjoyed it up to the present day.

George Wisee, æt. 24, whom you here see sitting before you, was admitted to my clinic on July 6, 1882. The symptoms were fever, pain in the chest, bloody expectoration and spasmodic attacks of coughing, during which large cysts of echinococci were thrown up. On percussion I discovered a tract of dullness, about the breadth of a hand, stretching over the back from the right axilla to the spine. The stethoscope applied to the same region revealed, indistinct in some places, bronchial breathing, and at the end of the inspiration, a small mucous tinkling. The liver was of normal size. I ordered inhalation of oleum eucalypti. Between the 7th and 13th of July patient coughed up nineteeen echinococcus cysts varying in size from that of a pea to that of a hen's egg. I have the honor of laying them before you.

I concluded to have the patient operated upon. On the 18th of July my colleague, Dr. Vogt, resected, in the tract above described, apiece about four c. m. in length, of the sixth rib.

We could easily satisfy ourselves of the existtence of adhesive pleurisy. A trocar of the length of a finger and of medium diameter was thrust into the pulmonary parenchyma in three different directions. We hoped thereby to evacuate the contents of the echinococcus cyst, but all that escaped was a small quantity of frothy blood. We interfered no further for the present. The part was dressed antiseptically, and, consequently, the process of healing went on wholly unattended with fever. No other secondary hæmorrhage nor hæmopsis occurred. After 24 days the wound had healed completely. Patient coughed less and expectorated no more echinococcus cysts. A local examination showed but slight alterations.

As patient was apparently cured, he was dismissed from my clinic on August 28. We were, however, disappointed in our hopes of his full recovery.

About the middle of September, Wiese again coughed up a pretty large cyst of echinococci, and this was repeated twice during the following week. Being directed to return to my clinic, he was readmitted October 2. The symptoms were similar to those existing before the first operation. As this had taken so favorable a course the patient willingly consented to a repetition. This time we employed the thermo-cautery. On October 20, my colleague, Dr. Vogt, resected the seventh rib, near the seat of disease, and, perforating the bared pleura with the cautery, pushed it into the lung. We enlarged the opening in shape of a funnel with our carbolized index finger, and believed we were feeling a tensely filled cyst. We therefore burned deeper with the cautery, hoping thus to empty the cyst of echinococci. This, however, we failed to accomplish. We carefully washed out the large funnel-shaped canal we had

made in the lung, and inserted a drainage tube, expecting a subsequent evacuation of the cyst contents.

All precautions of antiseptic treatment were observed. The patient had been kept under the influence of the anæsthetic for about an hour, and the operation was borne as easily as the first one. Temperature in the axilla towards evening, 37.8° C.; pulse, 88; breathing 20. The temperature did not rise a single time during the following days. The pulmonary fistula was washed out daily with a one per cent. solution of salicylic acid, and antiseptic dressings were applied. The wound had an excellent appearance, and granulations soon developed in its depth. No echinococcus cysts have since been evacuated through the wound, nor have any been coughed up.

The wound was closed by December 1, and on the 10th of the same month Wiese was dismissed. Since March 1 he has been employed as nurse in my clinic. Notwithstanding the hard work he performs, he has no chest complaints. I have brought him with me from Greifswald, that you may all be convinced of the good results obtained by the operative treatment of pulmonary echinococcus. In this case I suppose the cyst was obliterated by cicatrical contraction of the inferior lobe of the lung. According to my views this clearly proves that the future will derive great benefits from pulmonary surgery.

Fenger lately reported a case where he opened an ichorous abscess in the middle lobe of the right lung by an incision, and through it extracted the echinococcus cyst which had caused the suppuration. He effected a complete cure.

Such operative results obtained in cases of pulmonary echinococcus, indicate that canals may also be burned into the lungs with the actual cautery, and subsequently enlarged in shape of a funnel with the index finger, for the purpose of removing such foreign bodies as fail to find an exit by the natural passages of the bronchi, and by their presence induce putrid bronchorrhœa, suppurative infiltration, or even gangrenous destruction of the neighboring pulmonary parenchyma. Wm. Koch has made a similar suggestion, but no case of an actual trial has as yet come to my knowledge. A recollection of my youth induces me to renew this suggestion. When "practicant" at Wernher's clinic in Giessen, I had occasion to observe a case where a woman had had a tooth pulled, which slipped into the trachea and became lodged in the lungs. The accident was followed by attacks of spasmodic coughing, a painful sensation at a certain spot on the right side of the chest, dullness over the lower lobe of the right lung, frequent chills with purulent fetid sputa, violent dyspnœa, intense fever, sweats and profuse diarrhœa. The patient presented a picture of disease which, by its excess of tortures, produced a lasting impression on my mind.

Twenty-four hours before death, which occurred on the twenty-third day of the disease, she expectorated the tooth she had swallowed, together with numerous coagula of discolored blood. Unfortunately, it was too late.

The autopsy showed a suppurative spot, where the tooth had probably been arrested, in the depth of the right bronchus, diffuse putrid bronchitis and numerous gangrenous foci in the right lung. At that time nobody did think, nor could anybody have thought, of operative interference. But if I should to-day be called upon to treat a similar case of pneumonia (Schluck-pneumonie), the experience I have since had would induce me seriously to consider the advisability of an operation. In cases of acute pulmonary abscess, and for other reasons in cases of acute pulmonary gangrene where there is mortified putrid tissue which has not yet been sequestered and discharged, I agree with Wm. Koch in advising complete cauterization of the gangrenous portion of the lung as soon as possible.

The operation is likewise indicated in cases of chronic pulmonary gangrene, especially in that variety of the disease in which the existence of bronchectatic sacs is, after some time, followed by expectoration of large quantities of putrid secretion. The internal treatment, as is well known, has effected absolutely nothing in the advanced stages of the disease, which was looked upon as incurable.

I was prevailed upon by this consideration to try the operative treatment on a boy of fourteen, who for a number of years had suffered from sacciform bronchectasia. He was admitted to my clinic October 19, 1882, on account of septic fever and expectoration of large quantities of pus mixed with dark black shreds of gangrenous lung tissue. All internal medication had been tried in vain. After some hesitation we determined to operate on him on December 23. The operation was entrusted to the masterly hand of my colleague, Dr. Vogt.

A cavity had been detected in the superior lobe of the left lung. Over this cavity, in the anterior portion of the third intercostal space, an incision running parallel with the ribs was made through skin and muscles. We then resected a three cm. piece of the seventh rib, perforated the thickened pleura with a Schede's trocar, and employed Paquelin's thermocautery in boring the lungs. A brownish red liquid escaped, which was of carrion-like odor. Having dilated the opening in shape of a funnel, we discovered by digital exploration a cavity of the size of an apple, with a number of recesses. Several bronchi, which were so large as to admit one finger, entered this cavity. The tissue surrounding it was exceedingly flabby. The gangrenous portions were cauterized as completely as possible, and after we had washed out the cavity repeatedly with a solution of salicylic acid we introduced a pair of very long forceps in a direction backwards and downwards. Opposite the point of the forceps, about three c.m. below the angulus scapulæ, having cut through the integument and muscles, we resected subperiosteally two pieces, each two c.m. in length, of the eighth and ninth ribs respectively. The forceps (Kornzange) were now used as a guide director for the cautery, which soon entered a large cavernous space. About 300 c.c.m. of an extremely fetid, semi-liquid mass together with numerous shreds of necrosed lung tissue ran out of this cavity in a stream. We cauterized the gangrenous walls of the

space and then pushed an elastic drainage tube of medium size along the forceps through both pulmonary lobes in a direction forwards and upwards as far as the third intercostal space. The cavities could now be washed out and disinfected perfectly. All precautions were observed in applying an antiseptic dressing.

The condition of the patient was very satisfactory during the following afternoon; coughing and expectoration had ceased entirely. Temperature towards evening 37·5; pulse 116; breathing 30. Patient had recovered from the operation, and complained merely of the inconvenience of the dressing and of stitches in the wound. Patient's condition remained favorable up to Dec. 24. He then grew suddenly worse, after the cavity had been washed out through the tube with a solution of thymol and boracic acid, besides salicylic acid. It seems that the bronchi and lungs possess an idiosyncrasy with regard to thymol and boracic acid. Their application was immediately followed by laryngitis, tracheitis and bronchitis. In spite of all remedies employed to neutralize these effects, death occurred on Dec. 30. I lack time to communicate to you the detailed results of the autopsy; I shall merely state that it revealed the important facts of a correctly formed diagnosis and of a technically successful operation. Under similar circumstances Ed. Bull, of Christiania, attained a favorable termination. In a girl aged 23, who suffered from putrid bronchitis, he succeeded in completely healing a gangrenous cavity by the operative treatment. In his case the cavity was likewise situated in the left lung. This seems to support my assumption that the unfortunate issue of our case is not to be attributed to the operation, which, as such, was successful, but to the antiseptics employed, which seem to possess properties injurious to the lungs and bronchi. It is therefore an important task to ascertain a technical procedure by which we shall be enabled to protect our patients from the above mentioned evil consequences.

The technics of pulmonary surgery deserve special consideration. For obvious reasons I omit, in this place, to discuss them fully. I shall merely remark that besides incision and subsequent penetration with a pair of forceps, my experience so far has led me to regard cauterization with the thermo-cautery and washing out with salicylic acid as of prime importance. I do not think that pulmonary resection is suitable to the human subject. It is to be rejected entirely in cases of phthisis. The first attempt of this kind turned out so exceedingly sad that every sensible surgeon will desist from further trials.

I have come to the end of my paper. Looking backwards into the past decade, it seems to me that pulmonary surgery has been somewhat advanced. Where will it stand ten years from to-day?

Others will then report its development. For this important question must and will be grappled with. I merely wish to add one warning, and that is not to hope too sanguinely nor to proceed too boldly in the domain of pulmonary surgery. If anywhere, we may certainly here apply the old adage, *Non cito sed tuto.*

STRAIGHTENING THE NASAL SEPTUM.

BY DUDLEY P. ALLEN, M.D.

Lecturer on Minor and Orthopedic Surgery in the Medical Department of Western Reserve University, Cleveland, O.

A case of displaced nasal septum successfully operated has seemed of sufficient interest to be reported. The patient, aged 23, had, when a boy, fallen, striking his face upon a beam. His teeth were loosened and his nose badly injured. When I saw him, some months since, the right nostril was wholly closed by the septum being pushed over to that side, so that no air was inspired through that nostril. Both the cartilagnious and anterior portion of the bony septum were thus displaced.

Rhinoscopic examination showed the posterior nares to be in a normal condition. The septum was firmly fixed in its displaced position, so that it could not be forced back by the thumb pressing firmly upon it.

The same injury which had displaced the septum to the right had displaced the extremity of the nose to the left, so much so as to disfigure the face. The patient's voice also had a nasal quality.

An operation was undertaken, having for its chief object to straighten the septum, and thus remove the obstruction to respiration.

For the operation a pair of forceps were obtained patterned after those described by Dr. Wier, of New York, in the *N. Y. Med. Record* of March 13, 1880. These are forceps with long handles, about the size and strength of small tooth forceps. The blades are about two inches long and one and one-half inches wide at the shank, tapering toward the tips. The blades are flat, so as to slip into the anterior nares, one on either side and their inner surfaces are smooth, so as not to lacerate the mucous membranes covering the bony septum. The blades do not close entirely together. I had the shanks spread a little apart, so as not to injure the anterior portion of the septum, as the blades grasped the inner portion.

The patient was etherized, and with these forceps forced into the anterior nares the septum was grasped and broken over to the left side.

A space was thus easily gained, so that the finger could easily be inserted into the right side. There was scarcely any hæmorrhage.

A rubber tube was then placed in both nostrils, and the right side was firmly packed with lint soaked with oil, thus holding the septum well over to the left side. Enough lint was placed in the left nostril to hold the tube on this side in place. The dressing was left in place three days. It was then removed, and an abundance of air entered through the nose. The nose after this was syringed out daily, and a small amount of packing was constantly replaced to hold the septum in its new position.

The patient was obliged to leave the hospital at the close of one week, so that after this time the packing was not efficiently kept up, and as a result, after about one month the cartilaginous portion of the septum

began to bulge somewhat into the right nostril again.

At this time, without ether, the portion of the cartilaginous septum projecting into the right nostril was transfixed with a pointed bistoury and cut away. The bony portion of the septum showed no tendency to resume the position it occupied before operation. The removal of the projecting cartilaginous portion of the septum in this manner made a small opening between the two sides of the nose. It allowed, however, the free passage of air through both nostrils. The operation accomplished more than was anticipated. It had not seemed practical at the time of operation to force the septum to the left and the point of the nose at the same time to the right, so that the latter was not attempted. As the opening which had been made by the bistoury between the two nostrils contracted during cicatrization, however, the effect was to pull the point of the nose back to its normal position. After nine months the result of the operation is that the patient breathes with perfect freedom through both nostrils. The point of his nose is much nearer the median line than before the operation, resulting from the contraction of the opening made in the septum.

The voice still has something of the nasal quality, but the improvement in this respect is perceptible.

MALARIA.

BY ERWIN F. SMITH.

In connection with the recent discussion of malaria by the American Public Health Association, it is interesting to note the conclusions reached by Prof. C. Tommasi-Crudeli, of the University of Rome, as to the causation and prophylaxis of fever and ague. These conclusions, first published some years since, have beeen reaffirmed recently in a study on "The Preservation of Man in Malarial Regions," published by the Italian government.

Tommasi-Crudeli believes malarial fevers are caused by a bacteric ferment which grows in the soil, and thence finds its way into the air. Both he and Klebs think they have discovered a specific intermittent fever germ, which they have christened bacillus malariæ. This germ is not of necessity paludal in origin. He seems to have established beyond a doubt that there is no cognate relation between marshes and malaria—some marshes, though filled with decomposing vegetation, are innocent, while many comparatively dry and even barren districts give forth rank malarial emanations.

The essential factors in the production of malaria are three: (1) Moisture in the surface soil, a slight amount being sufficient, if the ferment is present; (2) A temperature of at least 36° C.—it is well known that malarial regions become wholesome whenever freezing weather sets in; (3) the presence of cold air, upon the oxygen of which the ferment depends for growth. If any one of these three conditions is wanting, the development of the malarial poison stops.

The methods suggested for preventing the growth of the malarial ferment are: (1) A high cultivation of the soil, which in some places has proved highly successful, while in other places it has been a partial or complete failure, if not a cause of increased production of malaria; (2) Some system of drainage, which to be successful must be extensive and thorough, the ground water being lowered and kept at such a level that the surface layers of the soil are always practically dry; (3) The covering of infected layers of soil with earth or water, so that the ferment shall not be in contact with the oxygen of the air. If the district is marshy, the latter may frequently be best done by flooding. The entire marsh should be kept completely and continuously under water. If this be done, the production of malaria ceases, but recommences whenever any portion of the infected soil is again exposed to the action of the air. Here, no doubt, is an explanation of the otherwise inexplicable sudden increase of malarial fevers, in summer and fall, in the vicinity of certain lakes and millponds, whenever the waters are drawn off and the sides and bottom left exposed for some time to the action of sun and air. If the malarial district is not marshy, and cannot be conveniently flooded or covered with layers of non-malarious earth, the same end (the starvation of the bacteric ferment by the withdrawal of the oxygen of the air) may be attained by allowing the soil to become grassed over with a thick turf; or in towns by the construction of buildings and pavements, as demonstrated in certain quarters of Rome.

If none of the foregoing preventive measures can be adopted, partial immunity from malarial poisoning may be obtained by avoiding exposure to infected air in early morning and in the evening when malarial influences are believed to be most active; and by sleeping in upper stories of buildings, or, if this be impossible, by securing air for the ventilation of sleeping apartments from some distance above ground (4 to 5 meters). The habit of sleeping at some distance from the ground is common among the modern Greeks and some Italian races, who are compelled to live in malarial places, and there is reason to believe that in infected districts those who sleep some distance above the lower stratum of atmosphere enjoy a greater immunity from malarial fevers than those who sleep on or near the ground.

The malaria of the Roman Campagna is so virulent that whole districts are practically uninhabitable during the warm months, and bad seasons are marked by many deaths. The number of deaths, however, is not a proper criterion for judging of the miseries of the rural Italian population. To appreciate their condition one must be conversant with the great and pitiful physical deterioration going on in whole communities under the influence of chronic malarial cachexy. Any method of removing this scourge would be a great boon to Italy. Various medicinal agents, as quinine and eucalyptus, have been tried with but limited success. Quinine is often injurious, and much too expensive; while the euclayptus, so much vaunted as a preventive, especially in the vicinity of Tre Fontane, where there are extensive groves

under the care of the Trappist monks, has entirely failed to meet expectations. For some years after the groves were planted, Tre Fontane enjoyed an immunity which was attributed to the eucalyptus, but in 1880 the locality was terribly scourged by fever under the very shadow of the groves, and again in 1882. Last year, however, the experiment of using white arsenic as a prophylactic was tried on a large scale, and with the happiest results. In districts of the Campagna where experience has shown it to be well nigh impossible to remain during the warm weather on account of the fevers, by the daily use of small quantities of arsenic, large bodies of railroad employes were enabled to work almost interruptedly throughout the bad season. No ill effect was experienced from the use of the mineral. Experiments on a large scale will be continued to determine the exact value of arsenic. Italy experiences great financial loss on account of malaria, and the Italian government, aware of this has, with commendable good sense, set her *savants* to discover the remedy. The report of this year's investigations will be awaited with interest.

A CASE OF TRIPLETS.

BY C. W. COOPER, M.D., BATAVIA, ILL.

About 8:30 on the morning of May 13, 1882, I was called to attend Mrs. N. in confinement. She was a Swede, age 40, a multipara. I found the membranes protruding from the vagina, and a foot just within. Her pains were not very severe. From all appearances I was satisfied there were twins. I ruptured the membranes, when a large quantity of fluid escaped. The pains now became stronger, but the foot did not descend much. The mother was weak from the burden she had been carrying, and from her inability to lie down, which had now existed nearly a month. By pressure upon the abdomen and slight traction upon the foot I assisted the delivery, which was accomplished a few minutes after nine. The child was a boy weighing 6½ pounds. The second child presented the vertex and was delivered naturally at 9:45. This also was a boy, and weighed 7½ pounds. Placing my hand upon the abdomen to insure uterine contraction, I was not a little surprised at the size and hardness of the uterus, and by vaginal touch I detected a third child lying directly across the pelvis, with membranes intact. The head was to the left and too far away to warrant the hope of getting it down. I introduced my hand into the womb and had the good fortune to readily seize both feet. This third child was delivered at 10:30. It was a girl weighing 5¾ pounds. A single dose of ergot was followed by good uterine contraction, and Mrs. N. recovered from her confinement promptly. The children are all living, hearty, robust, and as forward in every respect as the average of children of their age.

BATAVIA, ILL., Mar, 20, 1884.

MEDICAL PROGRESS.

MEDICINE.

INTRAVENOUS INJECTION OF MILK.—Dr. Miglioranza gives the results of a series of experiments on dogs in the *Archives Italiennes de Biologie*, which are referred to in an editorial by the *Lancet*. He takes the ground that milk must be first digested to be properly prepared for the blood, and if it be injected as milk it will simply give up its albuminoid and fatty matters to the kidney, to pass out by the urine. He says that transfused sugar of milk passes in part into the saliva, as dogs afterwards lick their lips on account of the sweet taste. The butyric element of milk, transfused without a previous digestion, produces fatty infiltration of the kidneys and chyluria. In the treatment of cholera the serum of milk may be used to advantage, but not pure milk. The sudden introduction of a large quantity of milk into the circulation produces great diminution of blood pressure, due to collapse of the force of the cardiac systole, and unless the milk be filtered to prevent corpuscles larger than those of the blood from entering, obstruction may ensue in the pulmonary and cerebral circulation. As to the injection of the serum of milk, Albertoni has injected from 9 to 100 grammes into the veins of dogs without observing any ill effects. Casein, after being digested, if introduced directly into the blood is more apt to be transformed into urea than into nutrient material. Fresh urine may be directly injected into the blood without causing poisonous symptoms, but if decomposition has commenced serious symptoms immediately follow. Carbonate of ammonia introduced into the blood, notwithstanding the opposite statement of Ritter and Feltz, produces symptoms that precisely resemble those of uræmic fever, viz.: tetanic convulsions, dyspnœa, excitement of the circulation, hyperæsthesia, and coma.

CALCIFICATION OF THE PLEURA COSTALIS.—At the post-mortem examination of a man who had died of cancer of the stomach at the Hôpital St. Antoine, M. Gilbert found a thick plate of bone-like material covering the internal surface of the ribs on the right side, from the sternum to the vertebral column. This plate measured 12 centimeters in height, and 20 in breadth. Its external surface was smooth and separated from the ribs by connective tissue, while the internal was rough, and adherent in some places to the lung. Chemically, the plate had very nearly the same composition as bone, but the microscopical examination showed that it was only fibrous tissue loaded with lime salts.—*British Medical Journal.*

THE MICRO-ORGANISM OF BERI-BERI.—M. de Lacerda, in examining drops of blood from individuals suffering from beri-beri, has found long, cylindrical branched filaments with genuine joints, and sometimes with refracting brilliant points, which are believed to be spores. These filaments have been cultivated in bouillons prepared after Pasteur's method

with all the proper precautions. Rabbits have been inoculated from the artificial cultures, and have succumbed with all the symptoms of beri-beri. The microscope has shown the organisms in the blood, urine, muscles and spinal cord of the rabbits. M. de Lacerda believes that the parasite is originally obtained from rice which has undergone a peculiar alteration.—*Lancet.*

The Medulla Oblongata in its Relations With Sexual Disorder, and on Local Blood-Letting as a Means of Treatment.—Dr. Alexander Harkin, in the *Practitioner*, discusses this question by first calling attention to the centers already located in the medulla by physiological research, giving it as the seat of what he calls instinct, then refers to observations in hanged persons, irritation in idiopathic mania, and in injuries of the part, where erections and emissions have occurred; and to experiments by galvanic stimulation where in pregnant guinea pigs movements of the uterus or tubes, in the dog and in the rabbit erections, have been produced. He considers it to be established that the proximate cause of epileptic convulsions lies in the pons and medulla oblongata, and calls attention to the prominent place which sexual excesses hold in the ætiology of epilepsy and a large class of allied neuroses and neuropathic disorders. The saying of the older observers that "*coitum parvam esse epilepsiam*" contains a certain amount of truth; almost every fit of epilepsy terminates with seminal emission, and Nothnagel asserts that it is known that in some individuals the first coitus provokes a seizure, which is subsequently repeated every time.

Taking all this and more into consideration, he thinks it not difficult to demonstrate the existence of a mutual causal relation between a congested condition of the medulla oblongata and that disease denominated "neurasthenia spinalis" and also that of "abnormal seminal losses." Pathological demonstration is difficult, as no one dies directly from either, and the hyperæmias and congestions of the bulb are often of a transitory nature, and do not always present a perfectly satisfactory autopsy; but reasoning from analogy, and taking into account the nature of the microscopic appearances frequently presented in a disease in the same category, viz.: epilepsy, we may fairly assume, along with the congestion of the medulla common to both during life, the co-existence in its structure of the histological changes found in fatal cases of epilepsy. Thus he appeals to the results of clinical observation, to a pathology founded on the patent phenomena of the disease, and to a plan of treatment in accordance with the pathological view. That this mutual casual relation is in operation we may satisfy ourselves by reviewing the order observed in the development of the phenomena under consideration: how at one time the lower sexual center situated in the lumbar plexus, stimulated by peripheral irritation of the organs, reacts upon the higher center in the medulla oblongata; at another the higher center originates the force and evokes the functions of the lower center, which in their turn, often independently of the will and while the patient sleeps, are in ever frequent activity in the neuropathic constitution. There is thus established a vicious circle of cause and effect.

In illustration of these views, Dr. Harkin gives three cases in which relief to symptoms so commonly recognized as following after excessive masturbation was afforded by local treatment to the regions about the medulla, such as wet cups to the nape of the neck close to the occiput, and the cold douche to that region, bromide of potassium and belladonna being given in the general treatment. Dr. Harkin ignores the local and mechanical surgical treatment as applied to the genital organs, as being barbarous and false in pathology.

SURGERY.

A Case Where a Piece of Rabbit Bone Passed from the Intestines into the Bladder.—Mr. Reginald Harrison reports, in the Liverpool *Medico-Chirurgical Journal*, the case of a man 50 years of age, who for several months had suffered from intestinal irritation; for six weeks he had noticed that his stools were not formed, and that his bowels were more or less loose. Three weeks previously his bladder became exceedingly irritable, and he often experienced severe pain in the lower part of the abdomen. Urine coutained a considerable quantity of matter. The act of micturition terminated with a sort of fizzing sound, and bubbles of air were largely mixed with the urine. Palpation detected a hard, cricket ball sized tumor at the fundus of the bladder; the sound revealed nothing. Urine contained striated muscular fiber and vegetable cells, then pus-crystals of phosphates and uric acid, bacteria, and fungi spores. Later the urine was slightly discolored with fæcal matter, and contained many of the elements of food. At this time a mass about the size and shape of a bean three-quarters of an inch long was passed by the urethra, was followed by relief, but air continued to pass out with each act of micturition. The mass was examined, and found to be the expanded end of a rabbit's femur. This occurred in June, 1883, and improvement was marked to November, 1883, when the only inconvenience was the presence af air and a varying amount of fæces in the bladder, which fæces sometimes obstructed the urethra, thus causing inconvenience. To relieve this the patient was directed never to hold his water longer than two or three hours. The bowels were kept slightly under restraint with opium, and a soft rubber catheter was occasionally introduced, and the bladder and urethra washed out with a small quantity of tepid water. October 27, 1883, he gave every indication of being perfectly well.

Mr. Harrison concludes that the piece of rabbit bone had probably become impacted in the transverse colon? there kept up a chronic inflammation and thickening, which eventually resulted in the gut becoming adherent to the bladder. The constant contraction of the bladder for purposes of micturition, precipitated events by drawing down, and possibly pouching, that portion of the intestinal wall in

which the bone was impacted. In this way it is almost certain that the foreign body became, as it were, sacculated, with but little communication with the general cavity of the intestine. Then suppuration took place, and in turn the bone remained fixed in the bladder wall, where it set up and maintained a constant state of urinary irritation. After a lapse of some little time the foreign body fell within the cavity of the bladder, from whence it was expelled through the urethra.

Congenital Absence of Uterus, Ovaries and Vagina.—Temulji Briekaji reports a case to the Medical and Physical Society of Bombay, (Transactions), in a married woman 19 years of age, stout, fat, but of stunted growth. Breasts well developed, but no glandular structure in them. External parts normal; in the place of a vagina a mere *cul-de-sac* half an inch in length. A finger in the rectum touched a round, bony tumor of the size of an orange projecting from the promontory of the sacrum; the finger touched readily the point of a female catheter introduced into the bladder. No uterus or ovaries could be made out. The patient having come for the purpose of having a passage made, was told it would be death. Three months later she reappeared, saying that a Mahomedan midwife had made a passage, and wanted to know whether everything was all right. It seems that the midwife came daily for three months and forced a small wooden plug into the orifice. There was a great deal of watery discharge, but no suppuration, and for the first time, they said, she passed menstrual blood. On examination the finger passed through the *cul-de-sac* into the bladder, the urethra being so much dilated as to allow the entrance of the finger in that direction, also into the bladder, where it touched readily a finger passed into the rectum. The menstrual blood came, of course, from the laceration of the parts. The girl seemed very fond of her husband and said she had sexual desires. Her sister had a normal development of the genital organs, but the breasts were absent.

Case of Supposed Prolonged Gestation.—Dr. James Arnott reports a case to the Medical and Physical Society of Bombay, (Transactions), of a patient whose mother had fourteen pregnancies, all extended beyond their natural term. The patient herself, was in her seventh pregnancy, and was delivered twelve months after menstruation had ceased. Quickening took place at the fifth month. She was delivered of a twelve-pound, still-born, malformed child, the malformation consisting of an arrest of development of the bones at the vertex of the skull. Of her previous pregnancies, her first was a girl, born at the normal time, her second was a boy, born after ten months' gestation, and of unusual size. The third and fourth, also boys, were born after ten months' gestation, but presented no unusual appearance. Her fifth child, also a son, was born at 10 months. Her sixth was born a little after full time.

A Living Child after Craniotomy.—At the meeting of the Royal Society of Physicians of Berlin, Dr. Breus exhibited a living child, 18 days old, on whom craniotomy had been performed. The conjugate diameter of the mother was 9 ctm., (3½ in.). On extraction by the forceps the left frontal bone was fractured during its passage over the promontory, the child, born asphyxiated, quickly recovered without any paralysis and without pyrexia. The mother also made a good recovery.—*Medical Press.*

TOXICOLOGY AND MEDICAL JURISPRUDENCE.

Recovery from Chloral Poisoning.—Dr. Paolo Rossi publishes (*Gaz. degli Ospitali*) a case of poisoning by ʒvij of chloral hydrate, which is chiefly interesting on account of the recovery of the patient. The patient was a young man, aged 25, who took ʒvij of chloral hydrate dissolved in water half an hour after eating. About half an hour afterwards ʒj of cherry laurel water was given. Two hours after the ingestion of the drug the patient was seen by Dr. Rossi. At that time the patient had the appearance of one attacked by severe cerebral hæmorrhage. The face was congested, the respiration stertorous and 32 per minute, pulse small and 132. The temperature was normal. Cutaneous anæsthesia; muscular relaxation was complete; the pupils were contracted, but mobile. There was no vomiting or purging. The cherry laurel water had had no effect. Vomiting was produced by titillation of the fauces. Twenty-eight sinapisms were applied, and ♏xv of ether were injected hypodermically; an ice-bag was applied to the head, and a clyster of ʒvj of alcohol was administered. About two hours afterwards he began to move his arms. Little by little he began to move his body, and finally sat up. On the next day a large dose of the citrate of magnesia was administered, which produced four or five evacuations.—*Medical News.*

ANATOMY AND PHYSIOLOGY.

The Chorda Tympani Nerve.—Dr. Sapolini, of Milan, considers that this nerve contains motor and sensory fibers. Its deep origin is placed about the posterior end of the floor of the fourth ventricle. It leave the surface of the pons quite close to the auditory nerve, with which it exchanges many filaments. It is composed of two filaments, which pass in close union with the portio mollis and portio duram through the internal auditory meatus.

Arterial Pressure.—The *British Medical Journal* refers to the address of Dr. C. S. Roy at a recent meeting of the Royal Medical and Chirurgical Society, upon arterial pressure, in the experimental analysis of which he has been engaged during the past few years. He exhibited a group of instruments used for the purpose, and especially one for measuring arterial elasticity, one for measuring the volume of organs, and a cardiometer. His conclusions are that there exist in the vagus nerve-fibers decreasing the

force of cardiac contraction distinct from the fibers that diminish the frequency of the beat, and, similarly, that there exist in the accelerans cordis fibers augmentative of force distinct from fibers increasing the heart's frequency.

PHYSIOLOGY.

ON A "RENNET" FERMENT CONTAINED IN THE SEEDS OF WITHANIA COAGULANS.—Professor Michael Foster communicates to the Royal Society of Soudan the experiments made by Sheridan Lea on this subject (Proceedings). It seems that in India cheese made with animal rennet is unsaleable among the natives, so attempts have been made to discover a suitable vegetable rennet to meet this objection. This has been found in the fruit of puneeria, now withania, coagulans, a shrub common in Afghanistan and Northern India, an aqueous extract of the seed capsules of which does somewhat rapidly coagulate milk.

The material supplied to Mr. Lea consisted of an agglomerated dry mass of seed-capsules and stalk fragments. On proper preparation the seeds, enveloped in a coating of resinous material, the dried juice of the capsules, could be separated from the rest. It was then found that a 5 per cent. sodic chloride solution was the most efficient in the extraction of the active principle from the seeds, which is soluble in glycerine, and possesses strong coagulating powers even in small amounts. Alcohol precipitates the ferment body from its solutions; and the precipitate, after washing with alcohol, may be dissolved up again without having lost its coagulating powers. The coagulation is not due to the formation of acid by the ferment. If some of the active extract be made neutral or alkaline and added to the neutral milk, a normal clot is formed, and the reaction of the clot remains neutral or faintly alkaline. The clot formed by the action of the alkaline is a true clot, resembling in appearance and properties that formed by animal rennet, and is not a mere precipitate.

A deep brown coloring matter pertaining to the seeds was with difficulty got rid of. When 40 grms. of the prepared seeds were treated with 150 cub. centims. of 5 per cent. sodic chloride solution, they gave an extract of which 0.25 cub. centim. clotted 20 cub. centims. of milk in 25 minutes, and 0.1 cub. centim. clotted a similar portion of milk in one hour; the curd formed being quite white.

A portion of the extract given to a professional cheese-maker, was used satisfactorily as a substitute for animal rennet in the preparation of cheese.

THE INFLUENCE OF BODILY LABOR UPON THE DISCHARGE OF NITROGEN.—Prof. J. S. Burdon-Sanderson has communicated to the Royal Society of London (Proceedings) the results of the experiments of W. North on this subject. He took for his aids the researches of Dr. Parkes, and of Dr. Austin Flint, Jr. Flint's methods of research he considers as insufficient. Parkes' researches leave undecided the question of whether the increase in the discharge of nitrogen as the immediate effects of bodily labor occurs at the expense of stored material independently of any concomitant or subsequent increase of intake. This was the question which was the object of his experiments.

He reduced all his food-stuffs to fluids or powders, these being the only accurate way of sampling and analyzing them. Thus he took: Meat (dried and ground to powder); flour; vegetables (dried); potato (Edwards' patent dessicated); condensed milk. He regulated his diet for some four or five days before beginning an experiment, and took rather more exercise than usual in order to get rid of any possible surplus in the body. The first day of the experiment he abstained from food, and then placed himself upon a regulated diet of accurately known composition for nine or ten days, and about the middle of the period performed a certain amount of muscular labor. This labor consisted in walking a known distance and carrying a load whose weight was accurately determined (about 27 pounds). He gives several tables to illustrate the result of his experiments, and reaches the following conclusions:

The results, while they confirm those of Dr. Parkes, show that the disturbance produced by severe labor is much more immediate and of much greater intensity than that which Dr. Parkes observed. With Dr. Parkes they show that "an insufficient supply at one time must be subsequently compensated" whether the insufficiency be due to privation of food or to exercise. This storage of nitrogen is the expression of a tendency of the organism to economise its resources, which is much more constantly operative than has hitherto been supposed. As regards the phosphates and sulphates, unless the exertion be very severe the phosphates are not increased, whilst the output of sulphates is distinctly increased in every case, the increase being in general terms proportional to that of nitrogenous material. The total sulphur of the food was not estimated, but it is known that the percentage of sulphates contained in the food was insignificant as compared with that excreted in the urine, and consequently almost all the discharge must have been a product of oxidation.

THE "CRANE-AGRAFE."—Mr. J. D. McCan, of Portlenone, Belfast, Ireland, has invented an instrument, which is illustrated in the *Midland Medical Miscellany*, for holding the skull while sawing off the calvaria. It consists of a firm handle screwed into the base of two flexible arms which, at their extremities, are provided with two semicircular metal bands. These bands encircle the skull on either side, are made to press firmly by the screw of the handle acting upon the hinges of the arms, and are fastened in place by the joints which are attached to them. When not in use it can be folded up so as to occupy very little space in a case of post-mortem instruments.

CHICAGO, ILLINOIS.

SATURDAY, MARCH 29, 1884.

THE OBLIGATION OF MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION TO SUBSCRIBE TO OR SIGN THE CONSTITUTION, BY-LAWS AND CODE OF ETHICS, AS A CONDITION OF REGISTRATION.—In a previous number of this journal we referred to this subject, more particularly for the purpose of explaining how and why the Registration Committee at the meeting in Cleveland last year placed in the blank card which every member was required to fill up and sign, a clause signifying that the signer "had adopted the Constitution, By-Laws and Code of Ethics" of the Association.

We fully explained in the former article that this method was adopted as a substitute for the literal signing of these fundamental regulations or laws in a large book, as was done in the earlier history of the Association.[1] But as a correspondent in Buffalo seems to be still troubled in his mind about the rights of several thousand members of the profession in his State, and still more, as the action of the Registration Committee in Cleveland has been grossly misrepresented, and the Association itself denounced in unmeasured terms on account of that action, we propose to examine the subject sufficiently in detail to enable every reader to judge for himself. In doing so, we think it will appear obvious to every candid reader that the Association, through its registration officers, has neither required its members to take an "iron-clad oath," nor to sign "a pledge to support a code of exclusion," nor even "rudely shut its door in the faces of members who were entitled to enter," but on the contrary, has simply resumed the performance of a constitutional duty which should never have been neglected. Perhaps there is no one custom more universal connected with the formation and support of society organizations of every kind, than that of requiring those who become members to signify their approval of the organization and objects of such society by signing its constitution and by-laws.

Indeed, so general is this custom that the mere *acceptance* of membership in a society is regarded as presumptive evidence of approval of its constitution and regulations. For a society without a definite plan of organization or written constitution and by-laws to define its objects and regulate its transaction of business, would be merely an unorganized meeting of independent individuals. And a society having a constitution that should admit an indefinite number of new members, from year to year, without any regard to their approval or disapproval of that constitution, would soon be practically in the same condition as though no constitution existed. The resolution by virtue of which the American Medical Association was formed at the adjourned meeting of the first National Medical Convention, in 1847, is as follows:

"Be it *Resolved*, In behalf of the medical profession of the United States, that the members of the Medical Convention held in Philadelphia in May, 1847, and all others who, in pursuit of the objects above mentioned, are to unite with or succeed them, constitute a National Medical Association; and that, for the organization and management of the same, they adopt the following *Regulations:*" Then follows, first, the title or name of the Association; second, the provision for members, of which three classes are made, namely: Delegates to be elected by State and local medical societies and by various other medical institutions; members by invitation, to be elected by the Association; and Permanent members, to consist of those who had once served as delegates. The latter were allowed to "continue such so long as they remain in good standing in the body from which they were sent as delegates, and comply with the *requirements* of the By-laws of the Association."

Then follows, as the closing paragraph of that section of the constitution relating to members, the following provision:

"Every member elect" (not every delegate elect, nor every member by invitation elect) "prior to the permanent organization of the annual meeting, or before voting on any question, after the meeting has

[1] See Vol. 2, No 3, page 70.

been organized, must exhibit his credentials to the proper committee, and *sign these regulations*, inscribing his name and address in full, specifying in what capacity he attends, and if a delegate, the title of the institution from which he had received his appointment."

This plain provision of the constitution has existed from the first organization of the Association in 1847 to the present time without alteration or amendment. And in direct compliance with its provisions, the Permanent Secretary and Registration Committee, at the meeting in Cleveland last year, had the following blank card or slip prepared for members applying for registration to fill and sign:

"American Medical Association,

"CLEVELAND, OHIO, JUNE, 1883.

"In acknowledgment of having adopted the Constitution, By-laws and Code of Ethics of this body, and of my willingness to abide by them, and use my endeavors to carry into effect the objects of this Association, I hereunto affix my name.—Extract, vol. xxxiii, p. 623.

"Name (in full) .....
"Post-office .....
"County .....
"State .....
"Delegate from (name of society)....
"If not a delegate, state in what capacity you attend ....."

It will be seen that the much talked of "pledge" or "iron-clad oath," is the simplest form of acknowledgment of the adoption of, and obedience to, the organic laws of the Association, and a promise to aid in carrying into effect the *objects* of the Association. And lest there might be a suspicion of something covered under the word "objects" as here used, we will quote them as set forth in the preamble to the constitution itself.

Said preamble declares as follows:

"Inasmuch as an institution so conducted as to give frequent, united, and emphatic expression to the views and aims of the medical profession in this country must, at all times, have a beneficial influence, and supply more efficient means than have hitherto been available here for cultivating and advancing medical knowledge; for elevating the standard of medical education; for promoting the usefulness, honor, and interests of the medical profession; for enlightening and directing public opinion in regard to the duties, responsibilities and requirements of medical men; for exciting and encouraging emulation and concert of action in the profession, and for facilitating and fostering friendly intercourse between those who are engaged in it, therefore." Surely no right-minded member of the profession need hesitate about promising his aid to carry into effect such objects as these.

The only possible ground for objection to the card provided by the Registration Committee, as quoted above, is its including the Code of Ethics as a part of the "regulations" mentioned in the constitution.

Both the original Constitution and By-laws, and the Code of Ethics were reported by separate committees to the adjourned meeting of the National Convention in Philadelphia, May, 1847, and both were adopted by that convention on the same day, as preliminary steps to the final resolving of the convention into the Association under the constitution and Code of Ethics thus adopted. It is true that the constitution as then reported and designated "these regulations," contained no direct allusion to the Code of Ethics. But only eight years thereafter, namely, at the meeting of the Association in Philadelphia in 1855, attention was called to the fact that the Ohio State Medical Society had taken some action contrary to that provision of the Code which forbids the holding of patents for surgical instruments, etc., and it led to the prompt adoption of the three following resolutions at that meeting:

"*Resolved*, That no State or local society shall hereafter be entitled to representation in this Association, that has not adopted its Code of Ethics.

"*Resolved*, That no State or local society that has intentionally violated or disregarded any article or clause in the Code of Ethics shall any longer be entitled to representation in this body.

"*Resolved*, That no organization or institution, entitled to representation in this Association, shall be considered in good standing, which has not adopted its Code of Ethics." [See Transactions, Vol. viii, pp. 56 and 60.]

Two years later, the Committee of Publication was directed to have these and other resolutions that had been adopted as by-laws, appended to the constitution and published in each volume of Transactions of the Association. And at the same meeting, the committee was also directed to "append the Code of Ethics of the American Medical Association to each volume of the present and future annual Transactions." [See Vol. x, p. 603.]

In 1874, when the Constitution was so altered as to restrict the appointment of delegates to State and local medical societies and to the medical staffs of the Army and Navy, the three resolutions quoted above were consolidated into the form of the ninth

by-law as now published in the Transactions, and at the same time (1874) the section of the Constitution in relation to the appointment of delegates was so altered as to make the adoption of the Code of Ethics an element in determining the number of delegates that could be sent from any given locality. Again, at the meeting of the Association in Buffalo in 1878, when an amendment to the Code of Ethics was proposed in due form, it was promptly decided by the President, Dr. T. G. Richardson of New Orleans, that the Code of Ethics was a part of the fundamental law of the organization, and that the proposed amendment must lie on the table one year for the consideration of members, and come up in order at the next annual meeting in the same manner as provided for amendments to the Constitution. No one took exceptions to this ruling. It is very plain, therefore, from the foregoing historical facts, that the Code of Ethics was framed and adopted originally as a part of the organic law of the Association; that part, indeed, which was especially designed to constitute a basis of union and harmonious action for the profession of the whole country; that its adoption by State and local medical societies and institutions was made necessary by positive by-law regulations during the first ten years of the history of the Association; and that from the early period named to the present time, now thirty years, it has been recognized and amended as a part of the organic law, and with the Constitution, appended to every annual volume of Transactions of the Association. Indeed, the Code has been so recognized, both in the Constitution relating to the election and appointment of delegates, and in the by-law relating to the eligibility of societies, that signing the Constitution and by-laws necessarily carries with it approval of the Code of Ethics on the part of the signer. Consequently, if the registration committee in Cleveland had omitted naming the Code of Ethics with the Constitution in the blank form provided for members to fill and sign, and thereby had led any to suppose that in signing they were not endorsing the Code of Ethics, it would have been a deception.

And we trust the Registration Committee and Permanent Secretary will present the same full and proper acknowledgment for every member to sign who presents himself for admission to the coming meeting in Washington, only substituting the word *see* for that of "extract," where reference is made to the clause of the Constitution requiring such acknowledgment on the part of members.

If there are any members who desire alterations in the Code or the Constitution, let them propose their amendments in due form under the perfectly fair provisions made for their reception, consideration, and final adoption or rejection, in open session of the assembled representatives of the profession in all parts of the country. But let the Association maintain its own self-respect, and the respect of the profession in all the States, and preserve the unity of our medical society organizations, by firmly refusing admittance to its annual meetings of all such persons as are unwilling to acknowledge obedience to its Constitution, By-laws and Code of Ethics.

American Medical Association and Railroads.—We are authorized by the Chairman of the Committee of Arrangements, at Washington, to state that arrangements are being made with all railroads reaching Washington from every section of the country, looking to a reduction of fare for delegates to the Association, which meets in that city on the first Tuesday in May next. Those who desire further information upon this subject can apply to Dr. D. W. Prentiss, of Washington, D. C.

Notice to Exhibitors.—As requested, we repeat the following notice: Manufacturing chemists, pharmacists, instrument makers, etc., who wish space provided for their exhibition during the meeting of the American Medical Association, beginning May 6, should make application to Dr. D. C. Patterson, 919 I street, Washington, D. C., before April 1, 1884.

Sanitary Council of the Mississippi Valley.—The sixth annual meeting of this organization was held in Memphis on the 21st inst. Thirty members were present, representing eight States, extending from Minnesota to Louisiana. The officers elected for the ensuing year were as follows: For President, Hon. D. P. Hadden, of Memphis; Vice-President, Dr. J. A. Dibbrell, of Arkansas; Secretary, Dr. J. H. Rauch, of Springfield, Illinois. A more full account of the proceedings will be found under the head of State Medicine in the next issue of the Journal.

Picric Acid as a Test for Albumen.—Drs. Cooke and Watkins, at Bay View Asylum, Baltimore, found that in malarial cases in which quinine and cinchonidine were being given in large doses, these alkaloids were excreted in the urine and gas, with picric acid, a reaction simulating albumen. Solutions of the alkaloids were found to give similar precipitates.—*The American Practitioner.*

SOCIETY PROCEEDINGS.

SUFFOLK DISTRICT MEDICAL SOCIETY.

SECTION FOR CLINICAL MEDICINE, PATHOLOGY, AND HYGIENE. ALBERT N. BLODGETT, M.D., SECRETARY.

February 13, 1884. Meeting called to order at 8 o'clock, Dr. R. T. Edes, Chairman, presiding. The records of the last meeting were given in summary, and approved.

The paper of the evening was then presented by Dr. S. W. Abbott, Health Officer, Massachusetts State Board of Health, Lunacy and Charity, on Modern Legislation in Regard to the Adulteration of Drugs.

Dr. B. F. Davenport, State Analyst, then described the means employed in the detection of impurities in various medicinal substances as follows:—

As analyst under the Adulteration Act I have, as the result of my first year's work, reported to the State Board upon 680 samples of of about 100 different kinds of pharmacopœial drugs, of which I found 284, or 41.76 per cent., to be adulterated within the meaning of that act. This defines as an adulteration in drugs, including all medicines for internal or external use, antiseptics, disinfectants, and cosmetics (1) if when sold under or by a name recognized in the United States Pharmacopœia, it differs from the standard of strength, quality, or purity laid down therein; (2) if when sold under or by a name not recognized in the United States Pharmacopœia, but which is found in some other pharmacopœia or other standard work on materia medica, it differs materially from the standards of strength, quality, or purity laid down in such work; (3) if its strength or purity falls below the professed standard under which it is sold.

Those drugs have principally been selected for examination which were of the greatest importance as medicines, and which were known to be especially liable to vary from the standard quality, the profit of debasement being great, and detection thereof difficult from requiring special technical knowledge.

Of chiefest importance, therefore, are opium and cinchona bark with the many preparations made therefrom.

Of the forty-six samples of powdered opiums examined hardly one of the not evidently reduced samples fell below the twelve per cent. of morphine, the minimum limit of variability allowed by the United States Pharmacopœia, 1880, and but one exceeded the maximum limit of sixteen per cent. Thus the limits of the United States Pharmacopœia seem to cover all fair samples likely to be found in our market, of which the average morphine content is about fourteen per cent. The 1880 Revision of the United States Pharmacopœia seems, upon a superficial view, to have raised the minimum limit of morphine strength of powdered opium two per cent., but it is not really so. The minimum limit of twelve per cent. required by the Revision of 1880 is by an excellent process of assay, in which all the requirements are given in full detail, while the minimum of ten per cent. required by the Revision of 1870 is by a totally different process, in which many of the details needed for obtaining any definite results are totally omitted. For instance, the concluding sentence of the method is, in speaking of the crude crystals which have been obtained, "To purify these boil them with two pints of alcohol until they are dissolved, filter the solution while hot through animal charcoal, and set aside to crystallize." Now according to my own experience, in working upon an average opium, this amount of alcohol of that strength will not dissolve all the morphine crystals obtained, but it requires about half as much more alcohol. Then the amount of the animal charcoal to be used is not mentioned, a very material point considering that it absorbs quite a per cent. of the morphine, which cannot be afterwards all recovered from it even by repeated additions of boiling alcohol, yet the 1870 United States Pharmacopœia does not provide for the addition of the alcohol even once. Then there is no limit given of the time to set it aside to crystallize, another very important defect, considering that the given amount of alcohol would hold in solution, even when cold, about one-quarter of all the morphine obtained from a ten per cent. powder. All this would be lost to the assay unless the alcohol be set aside long enough to deposit it by evaporation. It can thus be very readily seen that the process of assay by which the United States Pharmacopœia, 1870, required a powdered opium to yield at the least ten per cent. of morphine, might be honestly conducted so as to require a considerably higher morphine per cent. than the United States Pharmacopœia, 1880, requires for its twelve per cent. by a very definite method. Conducted, however, even to the best advantage for the sample of opium, I think that the two standards will be found to be just about the same. In other words, that although the revision of 1880 seems to have raised the minimum standard for powdered opium two per cent., it has not really raised it at all.

Now in regard to tincture of opium there prevails much unfounded apprehension on account of the great supposed increase in its strength. This, according to the last edition of the United States Dispensatory, is not sustained by the real facts. It is founded, I believe, principally upon the assertion of Dr. E. R. Squibb that he shall, since the last revision of the United States Pharmacopœia, put now six grains of morphine in one fluid ounce of his laudanum instead of only four grains as formerly, thus making an increase of 50 per cent. in *his* morphine strength, according to the Dispensatory, "allowing the opium to be wholly exhausted of its active principles, one grain would be represented by very nearly eleven minims, according to the United States formula of 1880, while in the United States Pharmacopœia, 1870, one grain was represented by 12.8 minims." This represents an increased strength of only 14 per cent. of morphine between the tincture opii, United States Pharmacopœia, 1870 and 1880, that is, the grain dose is given in about twenty-two drops instead of twenty-five as formerly. This dif-

ference of three drops only is a less variation in quantity than would probably by made by successive attempts of the same or different persons to drop out the old twenty-five drop dose. So that I think physicians need not under *ordinary* circumstances have any anxiety as to whether it will be a tincture made according to the United States Pharmacopœia, 1880 or 1870, that will be dispensed in their prescriptions. Yet it would be well, for a while at least, to write (U. S. P., 1880) after the name of any pharmacopœial preparation which physicians particularly desire to be *surely* of the full strength, as what would thus be likely to be dispensed would more probably be of the proper quality, and the writing thus would show the pharmacist that the physician was observant and particular in such details. This is a much more reasonable way than writing the name of any particular manufacturer after pharmacopœial preparations, for it allows the pharmacist to put up his own or any one's make that he is ready to guarantee, but holds him to the full responsibility of that which he dispenses. He could not, however, be thus held if he put up a particular make which was ordered, even if this was not more than a quarter of the full proper strength.

In my examination of 100 samples of laudanum collected from all over this State, the pharmacopœial limits being between 1.2 and 1.6 per cent. of morphine, I have found samples containing all the way from 0.33 to 1.87 per cent. of morphine, thus one six times as strong as another, and with specific gravity varying from 0.921 to 0.997. Four samples exceeded the 1.6 per cent., and eighty-two fell below the 1.2 per cent. The average per cent. was 0.965, and the specific gravity 0.953. Forty-five samples contained about 1 per cent. of morphine, as was required by the United States Pharmacopœia, 1870, if assayed by the modern process of United States Pharmacopœia, 1880. The best pharmacists of this city are now generally making up their tincture to the average United States Pharmacopœia standard of 1.4 per cent. morphine, or about the six grains to the fluid ounce. The ten samples of morphine salts examined have all come up to standard.

Of citrate of iron and quinine forty samples were examined, and were found to contain all the way from 3 per cent. to 14.37 per cent. of quinine, the present United States Pharmacopœia requiring 12 per cent. only, while the previous one required 16 per cent. Of these samples 82.5 per cent. fell below the present standard, two makers alone having been found to have their preparation generally fully up to standard. Of about thirty samples of quinine salts examined, 28.5 per cent. contained an excessive amount of the cheaper cinchona alkaloids.

Only two out of a dozen samples of powdered jalap contained the proper amount of resins; while out of ten samples each of the bromide and iodide of potassium not one came up to standard. Trade absurdly demanding that the crystals should be, not translucent and colorless, and therefore *possibly* pure, but opaque and porcelain white, and therefore *of necessity* impure, with excess of alkali, which renders them unfit for use with alkaloids, syr. ferri iod., or any other like combination which might be desired.

Dr. Edes remarked that by employing the more recent manufactures by Squibb the physician would obtain a much larger dose than in the earlier preparations. In the case of tincture of opium, the present preparation contains 50 per cent. more opium than the former tincture.

Dr. George B. Shattuck asked what were the poorest results obtained by analysis of laudanum and citrate of iron and quinine.

Dr. Davenport stated that the most common result was to find a content amounting to from one-fourth to three-fourths the amount required by the Phamacopœia in analysis of tincture of opium, and in citrate of iron and quinine any amount from one-third to the normal quantity.

Dr. Morton Prince suggested that if the firms who manufacture and dispense standard goods were made known to the profession, it might be the means of protection from imposition on the one hand, and aid in driving the spurious articles out of the market on the other hand, both of which objects it would seem desirable to accomplish.

Dr. C. Harrington, of the Harvard Chemical Laboratory, gave a somewhat detailed account of the analyses of various articles of food under the auspices of the Board of Health as follows:—

About 300 samples of milk have been subjected to analysis. The milk was obtained from all parts of the State, and was secured in each instance from the regular supply furnished to customers. Milk should contain under normal conditions about 13 per cent. solids. In some specimens the solids were present only to the extent of 9 per cent. The first 100 samples of milk and the greater part of the second and third hundreds were obtained in Boston, and of these samples more than 70 per cent. were adulterated. The milk from the western parts of the State, particularly from Berkshire County, was found to be nniformly freer from adulteration than that from the eastern counties. The poorest samples of milk were invariably those obtained from the shops and groceries in which it is sold at retail. Milk directly from the cart was always of better quality. In certain large towns the milk supply was far superior to that in certain other towns of equal population. Thus, Lawrence, Worcester, and Springfield enjoy purer milk than do Lynn, Chelsea, and Somerville. In Worcester the solid constituents of milk averaged from 12 to 16 per cent., while in ten cases which were prosecuted the proportion of solids was in none more than 9 per cent.

Various articles of food were found to be adulterated in 50 per cent. of the samples. Butter was occasionally found adulterated with oleomargarine. Tea was adulterated to a greater or less extent, one sample containing 26 per cent. of sand. One specimen of coffee was found to contain 20 per cent. of chiccory. Two hundred samples of spices were examined, and all were found to be bad. Of 24 samples of mustard, only two were found to be good. Fifteen different brands of mustard in boxes were found to consist of wheat, flour and tumeric in a greater or less degree. Various samples of pepper

were analyzed, and found to contain chiefly only dirt. Spice mixture is found to consist mainly of similar material, and sells for 40 cents per pound. Several specimens of pure olive oil from Leghorn were analyzed, and were found, without exception, to consist entirely of cotton-seed oil from the Providence Oil Company.

In cereals and bread no adulterations were detected. Bread contained neither alum or copper. Some specimens contained an excess of moisture, but this can hardly be called an adulteration. Cocoa and meals, sago and tapioca were not found to be adulterated.

Dr. J. C. White asked the minimum standard of milk solids in cases which were prosecuted.

Dr. Harrington stated that no case had been prosecuted in which there was a solid content of 11½ per cent.

Dr. White alluded to a case in which no adulteration could have possibly taken place, in which the amount of solids reached only nine per cent.

In reply to a question, Dr. Harrington stated that none of the milk examined was rendered in any way injurious by adulteration, that nothing but the cream had been removed, and nothing but water had been added to it. Neither of these changes would make the milk injurious or dangerous.

Mr. G. F. Piper, Attorney to the State Board of Health, who was present by invitation, spoke as follows:

Prior to the passage of the statute of 1882, entitled "An Act relating to the Adulteration of Food and Drugs," the legislation upon that subject was confined to fraudulent adulterations and adulterations injurious to health. The fraudulent conduct, or the guilty knowledge, or the fact that the adulteration was injurious to health, therefore became elements, upon a complaint, which the government was bound to prove, and the great difficulty of proving these elements virtually made the statutes upon that subject a nullity. Very few prosecutions accordingly resulted. This form of legislation was not broad and stringent enough to reach the many cases of substitution of one article for another, or, as in the case of a drug, its manufacture below the ordinary standard of strength and purity usually adopted and recognized, or a case where some valuable constituent may have been removed and a poorer one substituted, and the many other various forms of commercial frauds existing. The statute of 1882 broadened and extended this class of legislation, its purpose being to reach all cases which the previous legislation did not reach.

In the case of drugs it adopts a standard, and makes it an offense if the party selling sells an article varying from that standard if sold under a name which carries with it a recognized standard. If the drug sold is one recognized in the United States Pharmacopœia, it adopts that standard. For instance, tincture of opium, according to the Pharmacopœia of 1880, contains 1.20 percentage of morphine. A druggist, therefore, who sells tincture of opium of less morphine strength than that standard is liable to prosecution.

If the drug is sold under a name not recognized in the United States Pharmacopœia, but which is found in some other Pharmacopœia or other standard work on materia medica, it would be an offense under the statute if it differed materially from the standard of strength, quality or purity laid down in such work. And again, it would be a violation of the statute if the strength or purity of the drug fell below the professed standard under which it was sold.

In the case of food, the statute defines also what shall be deemed an adulteration; for instance, mixing any substance or substances with the article so as to reduce, lower, or injuriously affect its quality or strength; substituting any inferior or cheaper substances; abstracting any valuable constituent, or selling an article under the name of another article.

The statute absolutely prohibits the sale of any article of food or any drug adulterated within the meaning of the act.

The element of fraudulent conduct, or guilty knowledge, or criminal intent, does not enter into the offense. If the party selling violates any of the provisions of the statute he is liable to the penalty therein set forth, without regard to the question whether he knew or did not know what the article was he sold, For the protection of the public, the statute imposes upon the tradesman the most extreme caution in selling his goods. He is bound to know what he is selling. This, certainly, is no injustice, for the purchaser buying and paying for a pure article is entitled under the law to the greatest protection.

The tradesman by the exercise of proper caution can inform himself of the nature of the article sold, while the purchaser must rely, and does rely, wholly upon the good faith of the tradesman. There is every reason, then, why the burden should be placed upon the seller and not upon the purchaser.

The statute imposes the duty of enforcing the provisions of the statute upon the State Board of Health, Lunacy, and Charity. The enforcement of similar laws, for example, the laws against the adulteration of milk, and the laws against the adulteration of vinegar, have heretofore been left with local inspectors, appointed by the different towns and cities throughout the Commonwealth. This mode of enforcing a law has proved generally to be an utter failure.

The local inspector is usually some individual who has been appointed for some political service rendered, who may have no qualifications for the office, and whose only purpose and desire often are to make the greatest money's worth out of his office. The salary is usually very meager, and no appropriation is generally made for the expense of enforcing the law. Accordingly little work is usually done and the adulterator flourishes.

The milk inspector of Boston recently testified before the Legislative Committee on Public Health that he had made six hundred examinations of milk during the past year, and thirteen persons had been convicted of selling adulterated milk. His practice was, he said, to go around the city early in the morning, carrying with him his lactometer and placing it in the milk; he in that way decided whether the milk was

adulterated. It is well known that this method of determining whether milk is adulterated is very unreliable and unsatisfactory. This may to some extent account for the few prosecutions and the condition of the milk market in Boston, in which, according to the statement of Dr. Charles Harrington, chemist to the State Board of Health, ninety per cent. of the milk sold during the past year was adulterated, and badly adulterated.

The State Board of Health, Lunacy, and Charity, by reason of the qualificaiions of its members and its freedom from local and political influences, is more likely to be a much more efficient agency to be intrusted with this work.

In November last the State Board commenced its prosecutions. The first prosecutions were against grocers and provision dealers in Boston for selling adulterated milk, and these were subsequently followed up by others.

Ten convictions have been secured.

Complaints were entered during the same time against several parties for selling adulterated tincture of opium, and in one case for seliing adulterated citrate of iron and quinine.

The analysis of the tincture of opium sold showed the following percentages of morphine: .38, .63, .79, .72, .81, where the Pharmacopœia standard of 1880 required 1.20. They were all convicted, with one exception, and in that case the adulteration was clearly proved, but the firm prosecuted testified that the tincture was sold by a young man in their employ who had no authority to sell, his duties being not those of a salesman, but pertaining to another department. This firm escaped conviction in that way.

The first prosecution for selling adulterated tincture of opium was before the Central Municipal Court of Boston, and developed the question which Pharmacopœia was the standard by which these cases should be governed, whether that of 1870 or that of 1880.

The Pharmacopœia of 1880 was not published and in use in August, 1882, when the Food and Drug Act took effect. It was accordingly contended by the parties prosecuted that the legislature must have had in view the standard of 1870, and that these cases should by tried and judged by that standard. On this first prosecution the tincture of opium was, in its morphine strength, below both the standard of 1870 and 1880, and the judge who tried the case found as a fact that the drug was adulterated, but did not rule upon the question which standard was in force. On the next prosecution before the chief justice of that court the question was again raised and presented, and a decisive ruling was made to the effect that the Pharmacopœia standard by which the drugs sold should be judged was that which was in use at the time when the sale was made, and accordingly ruled that the standard of 1880 must govern existing cases. This ruling has been followed by the other judges of that court.

On the prosecution for selling adulterated citrate of iron and quinine, it appeared that the article sold varied from the standard percentage of the quinine according to the formula of the Pharmacopœia of 1880. The parties were convicted.

A prosecution was made against a dealer in vinegar in Somerville, for selling a vinegar as a pure cider vinegar. The statute makes it an offense to sell as cider vinegar a vinegar that is not the legitimate product of pure apple juice, known as apple cider.

The chemist for the government testified that in his opinion, the sample sold was a cider vinegar which had been watered. The chemist who was summoned by the defendant before the trial had been given full opportunity to test the sample. Upon the witness stand he testified that he had had a large experience in the manufacture and analysis of cider and cider vinegar, but he had in his experience never seen a cider vinegar with the small amount of acetic acid and residue which this sample contained. He further testified that the sample was to him very suspicious.

The judge, contrary to all precedents, ruled that it did not appear that any criminal intent existed, or any fraudulent conduct. The counsel for the government suggested that it was not necessary for the prosecution to prove either elements; that the sale itself, under the statute, was a violation of law, and that no criminal intent, or guilty knowledge, or fraudulent conduct need be shown. He replied that that would be unconstitutional.

The defendant was discharged.

This principle has been decided time and again by our Supreme Court, and the ruling of the Somerville court in that respect was clearly and beyond question wrong.

I have been very much surprised at the position taken by the press of Boston in reference to these prosecutions. The reporters of three of our newspapers have told me that they have received orders not to report facts in reference to these prosecutions, and that articles that have been written by them for publication have been refused publication. I had supposed that in a matter of this kind that it was the duty of the press to advocate what seems to me to be the cause of the people. The purity of food and the purity of drugs should and must be a matter of great moment and importance. The reason of this course pursued by the press of Boston we may not know, but I think we can, each one of us, very clearly draw our inferences what that cause may be.

The physician is largely interested in the enforcement of this law. When he writes his prescription, it is of the greatest moment to him, as well as to his patient, that it shall be filled out as he has written it, and according to the existing standard. A fixed standard is absolutely necessary, and the physician and the druggist must in unison adopt that standard.

At the recent hearing before the Legislative Committee on Public Health, it was testified by one who had been a defendant in one of the prosecutions for selling adulterated tincture of opium, that he did not believe in the Pharmacopœia, and he would leave it to the discretion of each druggist to fill out a prescription. Comment upon such a statement is unnecessary. Let, then, the physicians of Boston give their strong moral support and encouragement to the

State Board of Health, Lunacy, and Charity, in the enforcement of this law, and make it an efficient law, and not a dead letter.

Mr. S. M. Colcord, PH.G., a former President of the American Pharmaceutical Association, was called upon by the Chairman and responded as follows:—

I was not expecting to be called upon to speak. I am not now in the drug business, consequently not an adulterator; not personally interested in the law, but am in the milk business, making pure milk. I am interested in this question as a matter of public welfare, and consider it a question of vital importance. More than 30 years ago I served on committees to detect, expose, and prevent adulteration. The American Pharmaceutical Association had its birth in a convention of the best apothecaries in the United States, called for the purpose of exposing and preventing the importation of inferior, adulterated, or spurious drugs. A law was already upon the statute book, and this convention was called to state the facts to the government, and pray for the enforcement of the act for the public welfare. The convention found it to be a work of time, and that home adulterations were equally important, and that patent medicines seemed to be exerting a controlling influence. And after two annual conventions a constitution and code of ethics were formed, and the convention adjourned to meet in the city of Boston as the American Pharmaceutical Association, with a Boston man for president, and here in the city of Boston we fought the great battle of adulteration. On the question of "admitting all drugs good of their kind," it was decided, mainly by Boston votes, that the large class of spurious, adulterated, and sophisticated goods was to be admitted no longer through our custom houses. The consequence was that the distributing ports of the world soon found out that the United States was no longer to be the market for their worthless trash. Orders went out for goods of quality that would pass the custom houses, and it soon came about that foreign consignors sent no more poor goods to this country, and our dispensers became acquainted with a class of drugs heretofore unknown in our country, and now every one is satisfied with the law; no one is oppressed; dispensers, *well informed*, have no trouble in finding pure articles of fine quality, and everything is lovely in that direction. But how about patent medicines and home adulterations? Well, the new Association found itself born of "poor but honest parents," and not having arrived at a fighting age, voted that patent medicines or secret remedies were not a legitimate part of the dispenser's business, and as this was too big for them to handle, and as they had so much other useful work to perform, that they would have nothing to do with this question. Home adulterations continued to be reported year after year, the Association growing more critical and severe (without accomplishing anything) until the committees making the reports were threatened with private prosecution. It was then voted to change the committee so as to serve the drug market, and the Association has since done what it could by fostering investigation, science, and education, as a preventive and controlling influence upon home adulteration.

As I am now out of the business, I do not fell like talking upon this subject. The fact is these people are all my friends,—the wholesale druggists, the retailers and dispensers, the prescribers, and the patients who have patience to take these adulterations, and my experience has been that I cannot shoot an unknown enemy at long range without finding it a fratricidal onslaught with poniard and pop-gun.

This matter of home adulteration is not a thing that has grown up in the drug business. You might as well say the drug business grew out of adulteration. I presume in the beginning they started in the race together, but I think now that adulteration may be a little ahead. It has always seemed to me that many honest and honorable men in the drug business have come to think that what many people call adulteration, sophistication, and substitution, is an unavoidable and legitimate part of the business, and that having adopted the business, they adopt these side issues as annexes to the law and the *profits*.

Now, this law was not put upon the statute-book by any action of the drug trade, neither was any remonstrance made to it that I am aware of, and the drug trade has had very little interference from the law, and it only desires to be let alone, and to do as it pleases, and feels abundantly able to settle points of quality with its customers without the interference of law But still the fact remains that the United States Pharmacopœia is nearly a perfect standard of quality, fully recognized as a legal standard, with nothing ambiguous or undefined, and very easily conformed to by all persons qualified (even very poorly) to do an ordinary drug business; that by enforcing this law all are freed from disloyal and dishonorable competition in quality, and can have no reasonable objections to the law.

If we try this law fully enforced for awhile, we shall find relief from all conflictions between honesty, conscience and profit; we should have the confidence of our customers, and all parties would be benefited commercially, and the mercenary taint that clings so tenaciously to the drug business will be so far removed that few, if any, would be willing to have the law repealed or become a dead letter.

Henry Canning, PH.G., President of the Massachusetts College of Pharmacy, spoke as follows:

Experience has shown that the President of the College of Pharmacy cannot be too careful in acting as its mouthpiece, for the reason that the institution was apt to be held responsible for all sorts of legislation touching the pharmacist.

As an individnal, however, I trust that if any modification of this law must be made, it may be only in the direction of making it stronger. It is eminently a law for the better protection of suffering humanity.

I was somewhat chagrined on hearing the report of the various adulterations in the line of food and drugs, to find that so large a percentage of the pharmaceutical products examined had been found wanting, but the feeling was a little softened when I learned that

the same report showed a much larger percentage of adulteration in important articles of food.

Again, I trust that if any change in this law be made, it be only in the upward scale.

Prof. G. F. H. Markoe spoke in favor of the present law as follows:—

Mr. President,—I am heartily in favor of the law for the prevention of adulteration of food and drugs, and would be sorry to see it changed except in the direction of greater efficiency.

The remarks by the gentlemen who have spoken before me place the subject of adulteration of drugs in its worst aspect. More than twenty years of practical familiarity with the drug market enables me to affirm that during all that time there never has been, and there is not now, any serious difficulty in getting good drugs, pure chemicals, and well-made, full strength pharmaceutical preparations from all reputable wholesale druggists or manufacturing chemists, provided the pharmacist or physician is willing to pay a fair price for choice drugs and standard preparations. The sharp competion in the prices of goods, mainly introduced by unscrupulous dealers, who care nothing for quality, has a great deal to do with the adulterations and substitutions that are found in the drug trade, especially in the line of powdered drugs, which may be quite worthless, and yet appear equally as good as the powder made from a pure drug. A skillful drug miller can transform worm-eaten or rotten rhubarb into a nice-looking powder quite as handsome as that furnished by a prime article of Chinese rhubarb. Citrate of iron and quinine may contain two per cent. or twelve per cent. of quinine, and yet the two samples may appear to be alike; a careful assay will alone show the true character of the article. But although citrate of iron and quinine with less than the standard quantity of quinine is quite common in the market, and is bought by those who will not pay the price for the official article, yet I feel sure that a very large portion of all that is sold is of good quality; because the chemists who produce the largest part of all that is used in the country make an honest preparation, and also because the great bulk of all the dispensing business is in the hands of honest and capable pharmacists, who demand a guarantee of quality from those of whom they buy, and who know enough to reject that which is not fit for use.

The wholesale drug trade of the country, with but few exceptions, is in the hands of honest and honorable men, who would much rather deal only in the best grades of drugs, and only in the products of the most reputable and skillful manufacturing pharmacists and chemists. The efficient enforcement of the drug law will compel the few firms who wilfully force poor goods upon the market to mend their ways; and since there is little chance for underselling on goods of equal quality, the ruinous competition which compels an honest man dealing only in honest merchandise to meet the prices quoted by dishonest dealers for articles bearing the same name and label, but far below the standard of purity and quality, this sort of unfair and unjust competition will be kept well in check by the law in question, and I feel sure it will receive the hearty support of all well-meaning dealers.

A few words with regard to the pharmacist, as distinguished from the druggist or wholesale dealer in drugs. I hold it to be his duty to closely watch all his supplies, and to assure himself of their proper quality. The United States Pharmacopœia of 1880 contains concise and accurate descriptions of all officinal drugs and chemicals, together with statements of the adulterations and impurities to which they are liable; also giving good tests for purity, and practical methods for the recognition of sophistications. This part of the work is so well done, that no intelligent pharmacist has any excuse on the score of the lack of a sufficient guide and standard. Those who do not know enough to use this excellent standard, must either employ some one competent to interpret and employ it for them, or run the risk, under the law, of being ranked with those men who willfully transgress for the hope of greater gain.

W. W. Bartlett, PH.G., Vice-President of the College of Pharmacy, spoke as follows:

Mr. Chairman:—I am very much interested in this adulteration law, and have attended many of the trials and hearings that have grown out of it.

I am First Vice President of the Massachusetts College of Pharmacy, but come here in my individual capacity only. It is contrary to the policy of the college to take part in anything of a political nature, it being strictly an educational institution. I believe that the law should remain on the statute books just as it is. The changes now sought to be made in it are in the interests of those who have been detected in adulterating their goods, and aim to make the law totally inactive. The best druggists in Boston favor the law as it is, and many have been present at the public hearings, and have so expressed themselves openly.

The action of the Boston Druggists' Association in the matter of adulterations has not been clearly understood by all. By your leave I will read the following resolution, offered by myself, and unanimously adopted by that body November 27, 1883:

Resolved, That the Boston Druggists' Association heartily condemns the practice of adulterating drugs and medicines, and will give its earnest support to any fair and legitimate means for suppressing the obnoxious business.

Physicians will have no difficulty in obtaining drugs and pharmaceutical preparations that are fully up to the standard of the United States Pharmacopœia of 1880, if they demand them. I make a practice of assaying my opium before making tincture of opium, and have found in every case the opium fully up to the requirements of the United States Pharmacopœia, 1880, when procured from a reliable source. I have also examined a sample of citrate of iron and quinine for a wholesale druggist in this city, which was the product of the laboratory of a reliable manufacturing chemist, and found it fully up to the standard of the United States Pharmacopœia, 1880.

These facts show that it is quite an easy matter to get reliable drugs and pharmaceutical preparations. The greatest difficulty that the retail druggist has to contend with is unfair and dishonest competition. The dealers in fancy goods having taken from us a

part of our business, and established ruinous prices for the articles so taken, the public immediately based the prices of prescriptions and drugs on these prices, regardless of purity and quality, and many unscrupulous druggists have met these prices, and furnished correspondingly bad goods.

I think that physicians should discriminate in favor of those stores where only strictly pure and standard goods are dispensed.

I believe that much trouble comes from the millers. I had occasion not long since to have a white preparation ground, and I found a cubeb and some gum arabic in the tailings. On requesting the miller to allow me to visit his mill, he objected, and I found that he did his grinding under lock and key.

In conclusion, I would state that I think that the law as it is can be safely left in the hands of the Board of Health without working hardship or oppression to the honest pharmacist or wholesale druggist.

Dr. Davenport, in reply to a suggestion that drugs from some reputable manufacturer should be specified by the physician in prescribing medicines, stated that he considered it better to demand a good article and leave it to the discretion of the pharmacist to supply the drug from any manufacturer he might think proper, or from medicines manufactured by himself if he should choose to do so. In this way, the responsibility for the quality of the goods is taken from the prescriber and placed upon the dispenser, who is also stimulated to the selection or preparation of articles of standard quality and reliability.

Wm. C. Durkee, PH.G., spoke as follows:

I am especially glad to hear the last remarks of Dr. Davenport. The practice of specifying a particular manufacture of pharmacopœial preparations does not seem to me a good one, but one which, should the custom largely increase, will produce injury to both apothecary and doctor.

The apothecary having little occasion to practice by manufacturing, the knowledge which he may once have acquired, will become less inclined or able to apply the pharmacopœial tests for purity and quality to those few drugs or preparations which are not ordered by the name of some manufacturer or dealer. The responsibility of the apothecary ceases when he complies with the order of a physician who indicates the maker of the preparation he wishes dispensed, and the physician assumes all the responsibility for quality, as the manufacturer may reside in another State or country, and not be amenable to Massachusetts law. Whereas if medicines are ordered by the officinal name only, the pharmacist is wholly responsible for quality, and if able to properly assay the officinal preparations, he is competent to manufacture them, and is entitled to a portion of the profit which would otherwise often go to any irresponsible foreign manufacturer who creates a demand for his preparations by advertising or otherwise.
