Bromide of silver can be obtained in a form markedly different from any of the preceding by boiling a collodion emulsion with a large excess of nitric acid. In this state it is distinctly green, but may be brought back to the orange state by rubbing. This form of silver bromide, which Captain Abney uses for photographing the ultra-red rays, has two maxima (Fig. 8, No. 5), the ordinary maximum near G, and another an octave below it. With this form, the ordinary photographer is hardly likely to have anything to do, but it will be as well to note that it differs entirely from gelatino-bromide emulsions which have been prepared for photographing the red end. With these latter we do not get the formation of a second maximum, but merely a continuation of sensitiveness towards the less refrangible portion of the spectrum, a fact which must be borne in mind when considering what light it is advisable to use to illuminate the dark-room.

ON LENSES.

BY W. E. DEBENHAM.*

IN treating upon the subject of photographic lenses, certain optical terms have to bo introduced, which will, therefore, be explained without going more deeply into the scienee of optics generally, than is necessary for the intelligent consideration of the subject in hand.

Planes of Definition.—It is to be regretted that in such a science as optics, where the calculations are made upon very exact bases, such an incorrect term as "plane of definition" should have come into uso. The surface upon which true definition is projected is almost always a curve. It must, therefore, be borne in mind that, if the expression, "plane of definition" be employed in what follows, it is only to bc understood in the conventional sense.

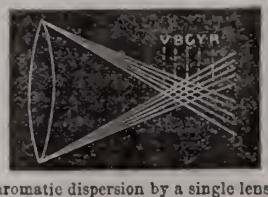
Focus, Equivalent Focus, and Conjugate Foci.—The focus of a lens is the place at which the rays proceeding from it meet to form an image. The word "focus" is also employed to mean focal length for parallel rays, and in the ease of a single plano-convex or double-convex lens, is ascertained by measuring the distance of the image which it gives of the sun, or any very distant object, from some point in the lens itself. With a double combination the expression "oquivalent focus" is used to denote the focus which would be possessed by a single lens, giving an image of the same size, as that produced by the combination. There are various means of ascertaining the equivalent focus of a combination. A very common one is to focus some object of the same size as itself, and then to take one-fourth of the distance from the ground glass to the object, as the focus required. This method is not quite accurate, for it takes no account of the effect produced by the separation of the lenses, and is not always practicable, as there may not be a camera extending sufficiently to give an image of the same size as the original. A method which I published in 1879, in connection with a proposal to introduce a standard of rapidity for lenses; which standard has since been adopted, is, I think, to be preferred. Focus an image of some definite proportion; then measure the distance from the ground glass to the original, multiply by the number representing the proportion, and divide by the square of a number larger by one, than the number which has been used as a multiplier. Thus, if marks twelve inches apart are made, or a foot-rule be planted with a head-rest against the background, and these marks or the length of the rule be focussed to be three inches apart upon the focussing-sereen, measure the distance from the background to the sereen, multiply by four (the number of times that the image is smaller than the object), and divide by twenty-five. This will give the equivalent focus with only one-quarter of the error that exists when focussing the object of full size, and is quite near enough for the purpose required. Conjugate foci are the distances respectively of the object and the image from what is known as the optical centre of the lens.

Aperture, Angular Aperture, and Rapidity.—The aperture of a lens is its working opening as limited by the diaphragm. The angular aperture, often spoken of simply as "aperture," is the proportion between this opening and the equivalent focus of the instrument. It has been customary to denote this aperture by means of a fraction *f*, the focus of the lens being the numerator, and the relation of the focus to the aperture being the denominator. Thus, $\frac{f}{4}$ describes the opening of an ordinary portrait lens, which, having a focus of twelve inches, has an opening of three inches. The rapidity of lenses is in inverse proportion to the square of the number used as denominator; but as the calculation of this is rather involved, it has been decided to accept $\frac{f}{4}$ as the standard or unity, and to reekon diaphragms by the length of exposure required in comparison with this unity. Thus, with a diaphragm of $\frac{f}{4}$, requiring au exposuro of four times that required with $\frac{f}{4}$, the diaphragm is, on the universal system, numbered four.

It might seem unnecessary to add (but that I know it is not universally understood) that when from any reason a small stop must be used, the most rapid lens is no more rapid—disregarding any variation due to colour or difference of reflecting surfaces—than the slowest one of the same length of focus which is capable of having the same-sized stop; so that if, in order to get what has been called "depth of focus," a small stop has to be used, there is no object on the score of rapidity in using a rapid, lens, and, perhaps, a slow lens may, from its other properties answer the purpose better.

Achromatic, Actinic.—The various rays which, compounded, make up white light, are refracted or bent aside in different degrees. They are, therefore, dispersed as well as refracted; and those rays which possess the greatest chemical power, or produce the most effect photographically (particularly the violet), are more refracted than those, such as the yellow, which give the greatest visual power. The effect of this is that, with any simple lens, a series of images of different colours is formed at different distances from the lens itself. The image will be most distinct to the eye when the yellow rays aro in foeus, but will give the sharpest photograph at or near the place where the violet rays come to their focus. In a lens which is not corrected, therefore, the camera back has to be shifted a little in, after focussing. The extent to which this will be required varies with the kind of glass used, but may be taken as from one-fortieth to one-thirtieth of the focal length. In tho diagram, as in other diagrams, the amount is exaggerated, in order to make it easily seen.

Fig. 1.



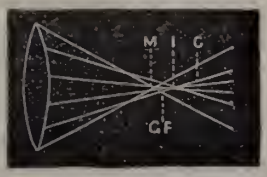
Chromatic dispersion by a single lens.

* A communication to the London and Provincial Photographic Association.

In uncorrected telescopes the evil is seen in coloured fringes surrounding light objects. Newton thought that the defect was irremediable; but it was afterwards found that different refracting substances dispersed the light in different proportions from those in which they were refracted, and, therefore, by uniting a convex lens of a substance of low dispersive power, with a concave one of a substance of high dispersive power, it was possible to let the dispersive forces balance each other, and leave a surplus of refractive power in the convex lens to form an image. Acting upon this discovery, Dollond, more than a century ago, constructed the achromatic (without colour) telescope. There is a slight difference between the amount of correction given to lenses for visual purposes and those for photographic use. The word "actinic" applied to lenses means that they are corrected for photography.

Spherical Aberration.—Spherical aberration is so important that it is well to understand clearly what it means. It is that characteristic by which the different parts of a lens uncorrected for this defect, bring the same object to different foci. It is evident that this must result in confusion or want of sharpness.

Fig. 2.



Spherical aberration. C. Focus of central rays. M. Focus of marginal rays. I. Focus of intermediate rays. G F. General approximate focus of the whole lens.

When an image is projected by an ordinary uncorrected lens, the marginal portions of the lens bring the rays which pass through to a focus nearer the lens than the focus of those rays which pass through the centre of the lens, and the rays passing through the portion of the lens between its centre and its margin are focussed at an intermediate place. This is called "spherical aberration," and where it exists perceptibly, no truly sharp well-defined image can be obtained, as every point is represented by a circle. The nearest approach to a distinct image is where the circle of confusion is small, and the concentration of rays great, as marked in the diagram. If a stop or diaphragm be now used, cutting off the marginal rays, the focus will be lengthened to the point where the central rays meet.

Aplanatic means without spherical aberration.

Astigmation or Astigmatism.—If a cross be distinctly marked upon a card and focussed in the centre of the field of a lens, the two arms will be seen with equal distinctness. If now with an ordinary portrait lens the camera be swung round or tilted, so that the cross appears near the margin of the field, it will not be found possible to focus both arms of the cross at the same time. If that arm which is in a line with the diameter of the field be focussed, the other will be wanting in sharpness. By turning the lens outwards, this other arm may be brought to a focus; but then the first one will be no longer distinct. The image of a point of light falling near the margin of the field of a lens possessing considerable astigmation, cannot be focussed sharply. On moving the lens it will be seen that the point takes the form of an oval, or an approach to a short line, either in the direction of the diameter, or the circumference of the field, accordingly as the lens is racked in or out. If a line happen to be in the same direction that the point is elongated it appears sharp, but if the elongation be across the line the latter will be blurred. This characteristic is called "astigmatism" or "astigmation."

Distortion is caused by different portions of the lens engaged in forming the various parts of an image, acting as prisms in bending aside the ray of light. Thus, with a single lens and a diaphragm at a distance from it, the axis of the ray coincident with the axis of the lens is not bent aside at all, but those rays coming from parts of the object towards the margin of the field, impinge upon portions of the lens possessing the form of a wedge or prism, and the nearer the margin the more this is the case. The images of those portions of the field are, therefore, turned aside, and, whether the stop be in front of the lens or behind it, proportionally more so the farther they are from the axis. Distortion is avoided by having an additional lens upon the other side of the diaphragm, giving a like amount of distortion, but in the contrary direction.

Curvature and Flatness of Field.—With an ordinary lens the focus of different parts of an image of equally-distant objects, will be at something like the same distance from the lens, and to get them all sharp at the same time, therefore, it would be

Fig. 3.

Curvature and flatness of field.

necessary to employ as the focussing-screen or the sensitive film a portion of a sphere instead of a flat plate. When the oblique rays have their focus lengthened out, as shown in the dotted lines, so as to fall upon a flat surface, the lens is said to have a flat field. Lenses corrected in any degree for this evil are said to be more or less flat-fielded. The great difficulty has been to get flatness of field without introducing an intolerable amount of astigmatism.

Absolute flatness of field must not be expected. The sacrifice of other good qualities in order to obtain this characteristic, over any but a small portion of the centre of the plate, is so great that, except with lenses where a very small diaphragm is used, it is only attempted approximately. It is, however, so valuable a quality that those lenses in which it has been made a particular point of, are for most purposes to be preferred. It is, perhaps, the one quality to obtain which, opticians would be justified in making greater sacrifices in other directions, than they have generally been disposed to do. A lens may be examined for it in the following manner:—Focus some object sharply in the centre of the field; then swing the camera round, so that the same object comes to points on the ground glass, at regularly-increasing distances of (say) one inch from the centre, and mark how much the lens has to be racked in, at each distance. Now draw a straight line, and at distances upon it equal to those upon the ground glass, make uprights corresponding in length, with the amount which the lens has had to be racked in at each distance, to get the best focus. Join the tops of these uprights by a line, which line will describe the curvature of field of the particular lens. This line should be compared both with the straight line from which it diverges, and with the circumference of a circle having a radius equal to the focus of the lens for the object that has been focussed. In order to reduce to an insignificant minimum any error arising from not having swung the camera accurately upon the optical centre of the lens, some distant object should be selected for focussing.

Flatness of field only implies the delineation upon a flat surface, of objects at equal distances, and, therefore, even if absolutely attained, would still require for even definition, that the various objects included should be placed in a semicircular curve round the lens, unless these objects were all so distant, that the rays proceeding from them are indistinguishable from parallel ones. To delineate upon a flat field the image of a flat surface, such as a map or a newspaper, would require the marginal rays to be so much lengthened, that the field for parallel or distant rays would be actually curved the other way—that is, convex instead of concave.

By those unacquainted with the science of optics, curvature and flatness of field have often been confounded with spherical aberration and aplanatism; and, indeed, a diagram showing only the former characteristics, has actually been given by a professed teacher of the subject, in illustration of the word aplanatic.

Diffraction has been spoken of in connection with photographic optics. If it were really necessary to take it into consideration in the calculations for the construction of a photographic lens, these calculations would be even more complicated than they are at present. Fortunately, this is not the case, and, as no scientific optician has admitted it as an element into such calculations, it may be dismissed.

(To be continued.)

Notes.

The funeral of the late Mr. Statham, Rector of Walworth and president of the South London Photographic Society, takes place on Saturday next, at 4.15 p.m., at Norwood Cemetery. Service at St. Peter's Church at 3 p.m.

The Royalist party in France have apparently much faith in the efficacy of photography to stimulate feelings of loyalty. In the Department of the Gard a wholesale distribution of photographs of the present head of the Royal Family is going on, greatly to the disquietude of the authorities of the Department, who have given information to the Government.

We have not yet elevated the photographer to the rank of the newspaper interviewer. In America this seems almost to be the case. Mr. Moncure Conway, writing in the *Pall Mall Gazette* on the Cincinnati riots, tells how a youth charged with murder was goaded into a confession by policemen, reporters, and *photographers!* It does not appear that the accused was really guilty, and his confession was exceedingly unlucky, as it was over this identical criminal that the Cincinnati populace went mad.

It is a pity the sizes of the standard flanges recently fixed by the Photographic Society are not expressed in millimetres. It is of importance to British photographers that its standards should become international, and there is little chance of this, however much foreign countries may desire to adopt them, if we express measurements in inches and fractions of inches. The Belgians and Germans for the most part prefer our dry-plate measurements to the French because they are more convenient, but they get sadly bothered in consequence.

Now several opticians on the Continent are taking up the Photographic Society's standard screws and flanges. Herr Suter, of Basle, whose instruments are favorably known in this country, is one of these firms, but it is not an easy task converting sixteenths of an inch into metrical measurements. Whereas, if our Society had elected to call its flanges by millimetres, we should have had such simple figures to deal with as, say, 15, 25, 36, 72; and these, while quite as intelligible to our opticians, would be perfectly understood throughout Europe and America.

The conditions of photographic copyright in America seem to have been in a very hazy condition, and a recent decision in the Supreme Court at Washington does not put the question on a much firmer footing. A lithographic company copied a portrait of Mr. Oscar Wilde taken by Napoleon Sarony, who thereupon sued the company for an infringement of copyright. The Circuit Court decided in favour of Mr. Sarony, and the case was then brought before the Supreme Court, the question raised being whether Congress had the constitutional right to protect photographs and negatives by copyright. From this we may assume that there is no especial Act for the protection of photographs, and that consequently the question turned upon the point as to whether photographs are works of art or not. The decision of the Supreme Court, which affirmed the decision of the Circuit Court, is instructive. It held, "first, that the Constitution was broad enough to cover an Act authorising copyright of photographs, so far as they are representations of original intellectual conceptions of their authors; second, that the finding of the facts shows that the photograph sued on was an original work of art, which was the product of the plaintiff's intellectual invention, and of which the plaintiff was the author."

So far, this is satisfactory, if it may be admitted that the posing of a sitter or the selection of a landscape is always an operation involving "intellectual invention." But the Supreme Court evidently has doubts on the subject, for it declines to "express an opinion as to whether this protection would extend to a mere mechanical reproduction by the photographic process of the physical features of an animate or inanimate object involving no intellectual effort in its execution." This decision was of course sufficient for Mr. Sarony's purpose, but it really establishes very little, as in all future copyright disputes it will always be open for the copyist to argue that the photograph he copied "involved no intellectual effort in its execution."

Our contemporary the *Standard* seems never to have heard of photography in connection with bicycling; yet before the days of the modern tricycles, many two-wheeled machines carried an amateur photographer in the saddle. A party of American bicycle riders, numbering between thirty and forty, are to visit the United Kingdom this summer, it appears, and afterwards they cross the Channel for a run as far as Venice. The *Standard* allows that the scheme is not an extravagant one, "but even if the machines were of the best, there are portions of the programme that are impracticable. For instance, some members of the party are to carry bijou cameras, and such "bits" as please the eye of the American artist in the company are to be photographed." If the 'cyclists will confine themselves to a "bijon" camera, there is nothing infeasible about the matter that we can see; the pictures would be but winks and snatches, it is true, but they would be pleasing reminiscences to their owner.

The Austrian photographers are exercised in mind on the subject of trade guilds. Every calling has its "union,' very much as in this country, and the effort is being made to attach the photographer to some of the existing guilds. Unfortunately, the modern photographer makes use of many applications in his art, and the guilds set their face against pluralists. Thus a lithographer dare not, without permission, work from zinc as well as from stone, as this might injure other guilds. Photographers are not sufficiently numerous to constitute a guild by themselves, or the obstacle might be overcome; meanwhile the difficulty gives rise to some curious incidents. Because the photographer employs paste for mounting, he is sometimes classed with the bookbinders, and in one instance,

even, was bracketed with brush-makers, because, forsooth, he made use of a brush.

We have lately received no less than three handbooks of photography issued by different firms of photographic dealers. We should very much like to say a few words in favour of them, but hesitate to do so, since we fear to praise one at the expense of another. When, however, we mention, that these columns have been heavily laid under contribution, the volumes must necessarily contain much that is good, their value, moreover, being in no way marred by any tedious repetition to the source whence they derive their information.

According to the *Journal de Liège*, the forgery of bank notes goes on as merrily as ever, one clever set of operators being in a position to split into two, new notes that have never been folded. Blue ink, which was adopted by reason of the difficulty involved in reproducing it by photography, is not now relied on so much by bankers abroad; some of them have recently taken another means of defeating the photographic forger. This is no other than the employment of an invisible actinic ink, of which no trace can be seen on the bank paper nor upon the image on the focussing screen. As soon, however, as you come to develop your plate bearing a reproduction of the bank-note, the word "forgery" appears in bold letters right across the negative.

Mr. R. A. Proctor's theory, put forward in this month's *Longman's Magazine*, that most of the recently-discovered planets may be referred to sun-spots, will not be acceptable to the discoverers. Photographers, however, will be interested in knowing that Mr. Proctor's statement is substantiated by photography—if, indeed, photography did not suggest it to him. He observes that the chief interest of the lesser markings on the sun's surface is, that to the unpractised observer they look very much like small planets in transit, and expresses his conviction that every recorded case of intra-mercurial planets seen in transit is to be thus explained, from the case of Lescarbault's Vulcan, down to the case of Vulcan's supposed return as seen in China. This "return," however, was unfortunate for the discoverer of the so-called planet, as a photograph of the sun happened to be taken at the right moment, and proved unmistakably that what had been described as unquestionably a planet, moving like a planet, and unlike a sun-spot, was nevertheless a small sun-spot after all!

The general public have advanced somewhat in their knowledge of photography since the days when Mr. Boucicault wrote *The Octoroon*. The drama has lately been played at the Grand Theatre, and there was nightly presented to the audience the spectacle of a murderer being traced through a sensitized plate being left in a camera where the murder was committed. Despite the fact that the lens is uncovered for some time both before and after the murder, the impression of the scene remains on the plate, the sensitive film cleverly contriving to be sensitive only at the precise moment when its assistance is required. This is a "detective" camera with a vengeance! But really this portion of the play should be re-written to bring it to the scientific requirements of the age. As it is, the incident is simply ridiculous.

Novelists are continually making use of photographs as a means for developing their plots. The latest idea is to utilise them to delineate character. Thus the author of "Eugenia," one of the orthodox three volume productions just published, to show the utterly vulgar and brutal disposition of a certain personage, makes him tear out of his album the photographs of his parents and family because he thought they were ungenteel, or, as he expresses it, because they were "a fiddle-headed lot." But may not the gentleman have been unjust to his family? Supposing, for instance, the "fiddle-headed" attribute, whatever that may be, had been due to bad photography?

Few photographers realise how much the electric light is now-a-days utilised in photography. They know that certain studios in various European capitals employ electricity, and that it has from time to time been used to produce enlargements and Woodbury relief plates. But they will be surprised to know that every photo-etching establishment in London, and in the big cities of the United States—and these may now be counted by the score—have the electric light installed. These establishments have little chance of existence unless they can produce a printing block in twenty-four hours—that is, take a negative, print it, and etch a metal impression—and some energetic firms there are, who will do the work from first to last in three or four hours. Obviously, this would be impossible without the electric light.

We have not heard much lately about spiritualistic photographs. Perhaps those who investigated the subject will be interested in hearing that mesmeric power can be transmitted through the medium (no joke intended) of a photograph. Mr. J. N. Langley, who lately lectured at the Royal Institution on Mesmerism, told a story of a woman who had been accused of stealing photographs. The woman was an employée in an hospital, and had been charged with the theft by one of the doctors. There was, however, little proof forthcoming, until one day, while taking a photograph out of a drawer, she heard the hospital gong sound, and became mesmerised, according to Mr. Langley's theory, by "sudden fears." She remained like a statue with one hand plunged in the drawer, and thus she was found by the doctor who had been the accuser. This is a very pretty story, but we do not care much about Mr. Langley's explanation. Why should not the mesmeric state have been caused by "unconscious cerebration" on the part of one or more originals of the photographs? Then we are not told what the photographs were. If they consisted of a collection of the inartistic monstrosities of a quarter of a century ago, with their bye-gone fashions, it is easily understood how the woman became paralysed with a sudden horror.

Patent Intelligence.

Applications for Provisional Protection.

6443. Thomas Percy Graham, 5, St. Mary's Buildings, Bedford, Bedfordshire, Photographer and Artist, for "An improved folding ship photographic accessory."—Dated 17th April, 1884.

6491. Lucy Mallock, wife of Major T. J. R. Mallock, the Royal Fusiliers (City of London) Regt., care of Messrs. Williams and Co., Dorsetshire Bank, Axminster, Devonshire, at present of 1, Queen's Place, Southsea, Hampshire, for "An improvement in menu or programme or photograph holders, which she calls the floral menu or programme or photograph holder."—Dated 18th April, 1884.

Patents Granted in America.

296,391. Ezra Cope, Hamilton, Ohio. "Art of printing by sunlight or other light, and apparatus therefor."—Filed Jan. 5, 1884. (No model.)

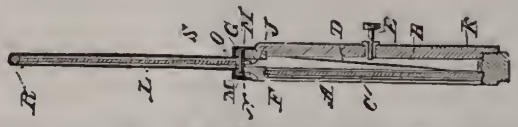
Claim—1. In a sun-printing apparatus, an envelope provided with an exhaust-aperture, and having one of its layers of proper transparency, and one or both of its layers of collapsible limpness, substantially as and for the purpose specified.

2. In a sun-printing apparatus, an envelope provided with an exhaust-aperture, and having one of its layers of proper transparency, and one or both of its layers of collapsible limpness, and adapted to receive a sensitive sheet or a negative, or both, substantially as and for the purpose specified.

3. The improvement in the method of securing close contact between the negative and sensitive sheet in the art of sun-printing, which consists in connecting them together and exhausting the air from between them, substantially as set forth.

296,443. Sebastian S. Peckinpugh and George Jeffery White, Big Rapids, Mich., assignors to said White. "Photographic plate-holder and case."—Filed September 25, 1883. (No model.)

Claim.—The combination, with a plate-holder, of the plate or strip D and the adjusting-screw E, substantially as herein shown and described.



296,578. Robert H. Jones, Marcus B. Smith, and Lars J. A. Roswall, Clarence, Mo. "Apparatus for cleaning photographs."—Filed Jan. 9, 1884. (No model).

A washing tray worked by clockwork.

Review.

Picture-making by Photography. By H. P. Robinson (*London: Piper and Carter*), 2s. 6d.

Mr. Robinson's capital volume, which appears so opportunely with the spring weather, is likely to send many of us into the country "picture-making." There are few things more pleasant than working in the open air in fine weather, and until it is fine, the reader will find it almost as pleasant reading Mr. Robinson's book, and looking at the many pictures it contains. By-the-way! why do not all authors write pleasant books. Or rather, why do readers read books that are not pleasant; it is a sin of which we ourselves are never guilty, except perhaps when we read something of our own. Some people have an idea that when you want to teach, you must be prosy; yet look at Ruskin, and at Darwin, and at Huxley, and other great masters. Mr. Robinson, we are glad to say, has taken a leaf out of their books—he has taken several from Ruskin—and the result is, he has produced a very readable work, which every art student will read with interest.

Mr. Robinson's earlier book, "Pictorial Effect," has run through three English editions, two American editions, and is translated into French and German. We make bold to prognosticate a still greater success to "Picture-making by Photography," of which every line is agreeable reading, and every page full of valuable teachings, the result of life-long study by an artist who has won for himself a name in painting and etching no less than in photography. Mr. Robinson's teachings will be none the less valuable because they are personal, as he tells us in his little editorial speech. Here it is:—

It has been said of Gibbon, the historian, that he did not always sufficiently distinguish between his own personality and that of the Roman Empire. I am afraid that the following chapters may be open to a similar objection. I fear that a great deal more will be found concerning my own personality and productions than a modest writer would willingly admit; but this cannot easily be avoided. The nature of the information to be conveyed, and the lessons to be inculcated, demand that I should teach the results of my own experience, and suggest that the pictures which have been the outcome of that experience would be the most suitable illustrations. It will be evident that pictures which have been actually produced by photography will better show the peculiarities and limitations of the art than any other method of illustration.

That photography should be not only the recorder of bald prosaic facts, but also the means by which something akin to imagination or fancy—real live art—may be worthily embodied, has been the one aspiration of my life. To this end, my aim has been, in the following chapters, to induce photographers to think for themselves as artists, and to learn to express their artistic thoughts in the grammar of art. It is not the fault of the art of photography itself that more original pictures, exhibiting many of the qualities shown in other arts, are not produced. The materials used by photographers differ only in degree from those employed by the painter and sculptor.

We only wish we had space for more extracts from Mr. Robinson's volume, but we select one which will give some idea of the value of "figures" in landscapes. Figures, if judiciously introduced, not only impart life into a picture, but, as Mr. Robinson shows, will very often balance a composition most effectively. What too often comes under the name of "photographic landscape," is a very dull bit of country indeed, forsaken of man and beast; and Mr. Robinson will have done much, if he can teach some of his brethren how to lighten up these deserted spots with a figure, artistically handled and posed. Of course this introduction of life is a risky matter, for a figure as often mars as makes a picture, and for this reason the matter is generally shirked. Here is what Mr. Robinson says:—

I now propose to give one or two slight examples of how a subject which would be otherwise uninteresting may be rendered pictorial by the introduction of a figure or figures. It is difficult

in small wood-cuts or block illustrations to give an idea of photographs, and, in the present illustration, I must trust a good deal to the imagination of my readers aided by description. The subject of the first illustration consists of a pool of water, with an overgrown hedge-row partially over-hanging it, and a bit of distance. In itself there was nothing in this of which a picture could be made; but the arrangement of the lines, and the breadth

of light and shade, suggested possibilities which should not be neglected. All that was wanted was a point of interest which would first attract and gratify the eye, give a meaning to the subject, and collect together and harmonize the scattered light and shade. It was obvious that a figure or two would easily do all that was necessary if they were well placed, and could be made to look as if they were in their natural and right places. It was not necessary that they should be large (indeed, in this case, I have chosen an example showing how valuable small figures may be), but they must be, above all things, conspicuous. Two figures were therefore chosen, and dressed in the extremes of black and white. They were placed at the balancing point of the angle of the composition, to give it support, and in opposition to the greatest distance, so as to throw it back and give space. The figures are occupied in "Watching the Newts," which provided a title."

I will now give an example of how an uninviting bit of coast may be turned to pictorial account by the addition of appropriate figures. This time I have purposely chosen a subject in which the figures are larger, and form a more important part of the composition than in the first illustration. In this case, I give the bit of coast without the figures, in contrast with the completed

picture in which the figures are introduced. The subject is that of a girl looking into the basket of a friend who has been shrimping, and asking the question: "What luck?"

The work is illustrated by between thirty and forty illustrations, including four whole-page pictures by the photo-ink process.

ON THE PREPARATION OF GELATINE PLATES.

BY H. A. HOOD DANIEL.*

In taking up this subject upon which to read a paper before the Association, I do so with a considerable amount of diffidence, as it has been so fully and ably treated in the journals by those who have been able to devote, not only their spare time, but the whole of their time to it, both theoretical and practical students.

* Read before the Bristol Photographic Association.

However, as I have, ever since I adopted the gelatine process, made almost all the plates I have used, I am perhaps somewhat qualified to offer some few remarks upon this subject, and which remarks I shall endeavour to make of as practical a nature as possible. In this determination I am perhaps somewhat strengthened by the belief that much assistance can be given by verbal explanation and occular demonstration, which written treatises will not adequately convey; and by certain enquiries made by various members which have seemed to imply a desire that I should give such demonstration. This being so, I cheerfully accede to the request, if by so doing I can impart information or render any help, even in a small degree.

I shall endeavour to treat the subject under three heads, viz., "Formulæ, and what to avoid;" "Modus operandi, and dangers incident thereto;" "Peculiarities in development, and their accompanying circumstances."

Firstly.—Formulæ, and what to Avoid.

Primarily I would say, hereon, "Adhere to what is simple, and when you get a good formula that suits you in all respects, stick to it."

Gelatine plate-making requires much system and as much uniformity as is possible, so that by often searching for novelties, or being led away by much-belauded formulæ, when one is already working a process which gives certain and reliable results, there is great danger of sacrificing a certainty for an uncertainty, and wasting much valuable time, which, in the present day, I am sure no one can afford to do.

The formulæ may be classed under two heads, viz., those involving digestion, and others, boiling. The former has been a very favourite method for somewhat slow plates, but I cannot help recommending those desirous of making plates to adopt the latter course, viz., boiling where possible, because much time is thereby saved, half-an-hour or so taking the place of twelve or fourteen hours; greater certainty is assured, the temperature during digestion sometimes creeping up in a most unsatisfactory manner during the operator's absence, the emulsion being thereby damaged; and for a business man, it is far more convenient, as the whole operation can be completed during the leisure of an evening, when in the other case the stoppage of the digestion arrangements for setting, &c., &c., have to be conducted very often at a time when one's thoughts are being drawn towards the shortly-to-be-encountered business of the day, resulting in hurry and a want of deliberation, not conducive to careful and satisfactory manipulation.

Of course in a paper such as this it is impossible to go into the thousand and one varieties of modes of getting more or less at the same end, especially as, to a certain extent, one must perforce be guided by the difference of taste regarding speed, colour of plate, mode of development, &c. I may, however, give my own ideas as to the class of formula which is, taken altogether, the most desirable.

I do not feel at all drawn to those formulæ which include amongst their ingredients chloride, for my experience has been that the result is a cold, grey colour, neither pleasing in appearance, nor facilitating the judgment of density. I have found the most reliable plates, and those possessing most vigour in every respect, accompanied by clear shadows, and a general appearance of pluck, together with a rich warmth of colour in the resultant negative, have been prepared with an emulsion containing iodide; and, so far as my own practice is concerned, I see no prospect of my omitting this from my emulsions. The negatives I have brought for your inspection are those from which my pictures exhibited at the Bristol International Exhibition were printed; and I think I may say that they are more of the wet-plate class of negative than a good many gelatine negatives one sees, alike as regards colour, clearness, and general pluck. They were all prepared with an emulsion containing iodide.

Another important point—in fact, the all-important one—in the make of the emulsion is the complete, rapid, and yet steady admixture of the bromo-iodide and silver. For this purpose, various nicely-constructed rapidly-revolving whisks and emulsion vessels have been constructed; but I consider we are all of us greatly indebted to the mode lately introduced by, I believe, Mr. Burton, and which method commends itself to me as being the most perfect, and almost automatic, that we could possibly possess. Instead of pouring the solution of bromo-iodide into that of the silver, the dry silver in crystals is placed in a hot stone bottle, all the bromo-iodide solution is poured into it, and it will at once suggest itself to you that only as the crystals

dissolve can the compound be formed, and thereby a steady and complete mixture is formed, only requiring vigorous shaking till the crystals are heard to rattle no more. I have been exceedingly pleased with this new idea, and can most certainly say that the results, as regard fineness of film and regularity, have been in my hands all I could desire.

We next come to a point upon which it is quite impossible for anyone to make any definite statement, with reference to what is correct or what is incorrect, each class being most desirable and suitable in its respective sphere—I mean the rapidity of plates.

For my own part, I prefer for general landscape work a plate of about five times the rapidity of an average wet plate; but I am inclined to think that much beyond this involves the danger of a probable loss of pluck and clearness in the shadows; also an absence of latitude in exposure and treatment very desirable as qualities in a plate for general landscape work. Of course, I do not for a moment under-estimate the great value in frequent cases of rapid plates, and always take a few with me when out for a day's photography.

MODUS OPERANDI, AND DANGERS INCIDENT THERETO.

Under this section I shall have to say but little—that is, not accompanied by demonstration, so that if it be somewhat disjointed, I must beg you to excuse it.

I need hardly say that one of the most important points in connection with the actual operations is extreme cleanliness. This requires more care and promptitude than in many other branches of the art, as particles of old emulsion are very liable to stick to and remain on dishes, vessels, &c., thereby causing mischief to fresh batches of emulsion, and being in frequent cases the cause of the failures so exercising the minds of operators. Great care is necessary in the choice of gelatine, and samples containing any grease (a most general defect) should be discarded in favour of those of purer quality, which should be both hard and soft, and mixed in the proportions which a few experiments will soon determine as the best suited to the manipulation and requirements of the operator. I find no brands of this material superior to Heinrich's and Nelson's X for hard kinds, and Nelson's No. 1 for soft; there is, I believe, another of this latter class made at Wintherthur, in Switzerland, which is also very good, but I have not tried it. There are three things which a would-be plate-worker should have arranged at the very outset of his endeavours, as being absolutely necessary for convenient comfort in working (and I maintain no man will succeed who is not comfortable in this work). These are a good levelling-cupboard, a spacious drying-cupboard, and a light-tight cupboard. You may say, why a cupboard for levelling? Would not a large slab do equally well? A slab would answer the purpose, but would not do anything like so well, for if on any emergency you should be called from your room when coating, you have only to close your levelling-cupboard, when everything is perfectly safe till you return to complete the operation; this is a matter of great convenience. And while on the subject, I may say that such cupboards should open and close easily, and with no make-shift fastenings, for it sometimes happens that one wants to get out a plate from the drying-box to test it in a hurry, and unless the fastenings are simple and sure, it is very probable that the result will be a number of plates fogged whilst in the drying-box.

I may, perhaps, with advantage, describe these two boxes. My drying-box is a little above the ground, say one-and-a-half feet, and the levelling-box above. The latter is fitted with six shelves, each accommodating six 10 by 8 plates, making a total of three dozen. The shelves are arranged in such a manner that on closing the box it at once becomes an additional drying-box. As it is connected with the drying-box, and the air, after passing through it, passes over shelf after shelf, from alternate ends, the upward current being caused by a Bunsen burner in the outlet at the top. The drying-box proper holds nearly sixty 10 by 8 plates on edge, in two rows.

I will now make up a small quantity of emulsion, remarking, as a caution, that before commencing this operation the manipulator must be careful to see that he has everything well arranged and at hand, so that when in the dim light necessary to success, but none the less awkward for working by, he shall not have to hunt and grope about for things with the certainty of breaking not a few.

[Mr. Daniel then fully described the mode, and gave a demonstration of the making of gelatine emulsion and coating plates with his revolving coating machine, and concluded with a few remarks on the development of gelatine plates.]

FERRO-OXALATE FOR COLLODION DEVELOPMENT.

BY H. L. T. HAAKMAN.

SHOULD there still be any photographers, amateurs or otherwise, practising dry collodion plates, it may perhaps interest them to know that the ferro-oxalate developer is excellent to initiate the development.

On Saturday I prepared some dry coffee plates, to experiment with on Sunday. As a rule, I always started the development by immersing the plates in a solution of plain pyrogallic in water, and gave them the necessary strength by after-treatment with acid pyrogallic and silver. My first plate was evidently much under-exposed. It then struck me to try what ferro-oxalate would do. I took a second plate, prepared with the same collodion, exposed it as long as the first, and immersed it in an old ferro-oxalate solution, restored by placing it for some time in sun and daylight in a well-stoppered white bottle, tartaric acid in water having been added to the original solution. The image sprang up almost immediately; it was, however, too weak for printing, but after having been washed, it intensified rapidly with acid pyrogallic and silver. I then took a few more comparative trials, and found that wherever the exposure had been sufficient to give a good image with the old method, the negative developed with ferro-oxalate looked much "riper." But in no case did I succeed in getting in the first instance a negative of sufficient printing density. My success with ferro-oxalate for dry plates emboldened me to try it this morning with wet plates, but to little or no purpose. My first plate, treated with the plain ferro-oxalate, was, as I expected, a perfect failure—one mass of fog, and all sorts of deposits and streaks over the plate, with, however, a rather strong negative underneath. The solution was almost blackened by a somewhat voluminous silver precipitate.

Plate No. 2 was first thoroughly washed after it had been sensitized, and then exposed. It gave an under-exposed rather foggy picture. Plate No. 3 was sensitized and exposed in the usual way, but not washed. It was developed, not by immersion, as No. 1, but by flooding it from a developing cup with ferro-oxalate to which plenty of acetic acid had been added. Result, nearly as bad as No. 1. Plate No. 4, exposed for the same time as No. 2, developed with a strong sulphate of iron developer, gave a perfect picture. These experiments prove:—

1. That ferrous oxalate is a bad developer for wet plates when free silver is present, and only an indifferent one when the same has been eliminated.

2. That it is a good developer for dry plates where no free silver is present.

To conclude, I hope I may live to see the day when collodion, either by a new mode of sensitizing or a more powerful developer, will stand in the front rank again, and leave gelatine behind it. Collodion negatives have undoubtedly a beauty of their own unsurpassed by gelatine; with only common care they keep for years. This is more than can be said for gelatine; the so-called instantaneity, which finds its application in exceptional cases, does not always work for good, and is just as often an evil. Moreover, the plates are troublesome to prepare, and very expensive to buy.

Correspondence.

PROVINCIAL EXHIBITIONS.

SIR,—I do not know why the "By-the-Bye" in your last week's issue was headed *Provincial* Exhibitions, for the criticisms it contained were quite as applicable to the London exhibition as to provincial ones. However, I am not going to quarrel over this, or I could say something on the other side. There is a question raised as to the definition of a "landscape," but I should like to know what the

definition of an enlargement is. There is very often a medal given for the best enlargement, and it would be interesting to know who is legally entitled to such an award. At Bristol, Mr. Donkin was awarded a medal for an enlarged Alpine scene, but as it turned out that only the original negative was Mr. Donkin's, and he had not done the enlarging, the medal, I believe, was afterwards withdrawn.

Now I do not think Mr. Donkin was entitled to the medal, if this was "for the best enlargement," but I ask, who is? I apprehend if I take a fine negative and afterwards make a fine enlargement of it, that I could then justly take such a medal; but I want to know if I can take the medal if I only do the fine enlargement and not the fine negative. What do your readers say to that?

If it is meant that the medal is given "for the best process of enlarging with an illustration," then I contend that undoubtedly I am entitled to the medal if I only do the enlargement successfully. I have but to look out for a friend who has taken a very fine negative, borrow it for a few days, and enlarge it. But what I want to know is: Shall I be entitled to the medal in these circumstances, if it is given "for the best enlargement"? The jury then might want it back again; they might say, "Yes, yours is a very fine enlargement, it is full of power and harmony, but, you see, the original negative is not yours. A negative is at least as essential in the making of an enlargement as are enlarging apparatus and manipulative skill, and therefore as only the latter are yours, and not the former, we cannot give you the medal." Now is the negative an element in the enlargement? is the point that is at issue. One answer to this is undoubtedly yes, because no jury ever yet gave a medal for an enlargement in which the negative was not a first-rate one. My own humble opinion is that honours should be divided; the taker of the negative is not entitled "wholly" to the medal, but neither is the person who does the enlarging "wholly" entitled to it, for he would never have received the medal had he not had an excellent negative. But possibly some of those who have more experience of exhibitions entertain a different view to yours truly,

An Exhibitor.

MICRO-PHOTOGRAPHY.

Dear Sir,—I beg to thank Mr. Jennings for his lengthy exposition of the errors in my paper, most of which, however, are not due to myself, and they would have received correction had a "proof" been sent me.

"As regards the practical part of my paper," I have found my bellows-camera, eighteen inches long, quite sufficient for recreative purposes with the microscope. The paper in question being addressed to beginners, and, in the first place, to the amateurs of this district, as a hint towards utilizing long winter evenings, I considered that directions for using a quarter and half-inch focus would meet all the requirements of the case.

Funny, too, as it may seem to my critic, I have even had occasion to expose two whole hours before getting anything like an impression from a dense logwood-stained slide; but, of course, an exposure like this is the exception, and not the rule.

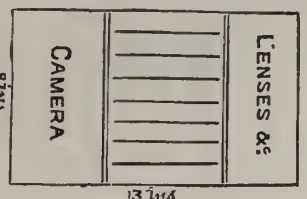
To conclude. As I do not suppose that the amateurs of North Staffordshire intend coming out as professional photo-micrographers, perhaps, while greatly appreciating Mr. Jennings' good intentions, the few hints which I gave towards making an occasional evening agreeable may be as useful as the long list of his glorious achievements.—I am, dear sir, yours, &c.,

W. B. Allison.

North Staffordshire Infirmary.

A TOURIST CAMERA WANTED.

Sir,—It may assist your correspondent Mr. Waghorn, who asks about a tourist camera for 8 × 5 plates, if I describe one that size which I have just had made by Meagher. It is strongly made for use, nothing having been sacrificed to obtain excessive lightness. With eight double backs, box containing six symmetrical lenses, tripod-top, and focussing-cloth, packed in a strong leather case, two all-round straps and handle, lock and key, it weighs fifteen



Plan of Case.

pounds, and measures 13 × 8 × 11 inches. For the benefit of tricylists I may also mention that it is carried very comfortably on a Rudge Coventry Convertible, either in its single or double form, the stand being strapped on the side bar. Of course it might be made four or five pounds lighter, but for work in distant countries, out of reach of repairers, I do not think that it is too strong or heavy. It can also, if wished, be packed in two nearly similar cases, the backs in one, and the camera, lenses, &c., in the other.

Russell Sedgfield.

THE ETHER-OXYGEN LIGHT.

Sir,—In reply to the letter of Mr. Frank Ives, I thought it was clear, from my phraseology, that I was writing of his ether generator solely from the description in the catalogue; but if not, I hasten to put that beyond doubt. The paragraph which occasioned my remarks reads as follows:—

If, when the oxygen key is closed to turn out the light, the lime continues to give a bright light, even after the saturator is turned on its side, it is an indication that the supply of ether is almost exhausted. This need not occur, because the saturator *will hold more than enough* to supply a suitable proportion for an ordinary size bag of oxygen; but if it does occur, the flame will give a harmless "snap" when turned out, or retreat into the saturator and blow off the rubber caps if the pressure of oxygen is insufficient. In the latter case the flame could be instantly smothered with a handkerchief, and no damage would be done.

I must leave it to the reader to decide whether my comment amounted to any "misrepresentation," intentional or otherwise; adding that the operator is further cautioned to commence with a full supply of ether, and "do not waste it by burning the ether flame alone." I happened to know that porous generators have been abandoned by several experimenters in this country from the deficiency of supply; and with this caution, the assurance that there was "more than enough for an ordinary size bag" brings the supposed accident, to me, uncomfortably within a measurable distance. I stated the superior safety of the porous method in one point, against what seemed to me its special danger in another; and whether I am right or wrong, the whole case is now before the reader.

As regards the latter part of Mr. Ives' letter, we must remember that with any apparatus, no accident will happen unless *something* has been forgotten, or has gone wrong.

Lewis Wright.

WANTED, A PRINTING PROCESS FOR INDIA.

Sir,—I am an amateur photographer in the jungle in India, and am rather puzzled what printing process to use. I work two sizes, usually 4¼ by 3¼, and sometimes 10 by 8, and generally want only six to twelve prints off each negative. My duties necessitate my continually moving about, and I am generally half the year living in a small tent, and consequently want a simple process.

I have tried silver, but I believe it fades out here; besides which, it is messy. I failed with carbon chiefly on account of the difficulties of drying the tissue, hav-

ing no proper room, and not being able to carry any heavy or bulky drying-box. Platinum I have tried with but moderate success, and could not get pure whites, owing, I believe, to the paper not keeping in this trying climate, and the difficulties of sensitizing appear to be as great as those of carbon.

Under these circumstances I would be much obliged for suggestions. It is too much to ask for details of a suitable process, but I would be glad if anyone would let me know what process is likely to do, and where I can get full information about its practical working,—Yours faithfully,

ASSAM.

Gauhati, Assam, India, March 20th.

GLASGOW PHOTOGRAPHIC ASSOCIATION.

SIR,—Allow me to correct a misstatement in last week's issue. Mr. Lang's paper on "Poitevin's Photo-Reliefs" was read before the above Association, and not the Amateur Society.—Yours truly,

J. CRAIG ANNAN.

RAPID PLATES FOR PHOTO-MICROGRAPHY.

DEAR SIR,—In support of my assertion last week, that rapid plates answer well for photo-micrography, I beg to send you specimens taken on very rapid plates.

The photographs are as follows:—No. 1, palpi of garden spider, ¼-plate size, Swan's "30 times collodion;" exposure one minute, small microscope lamp, two-inch lens, and eye-piece. No. 2, wing of midge, *Psychoda*, same plate, lens, and exposure. No. 3, a very small *Triceratium*, 5 by 4 plate, also Swan's, lens $\frac{1}{16}$ inch imm., without eyepiece, camera expanded about five feet; the intercellular dots are shown sharply; exposure about ten seconds to magnesium ribbon supported in a holder; × about 800. The minute size of this *Triceratium* may be imagined from the fact that it did not half fill the field of the $\frac{1}{16}$ inch. No. 4, male flea, *Pulex irritans*; rapid ½-plate—too rapid in my hands for landscape work—by Messrs. Mayfield, of Nottingham, lens 2 inch, and eye-piece. A very yellow object, so an exposure of seven minutes was necessary. In all these photographs, I think you will find that the definition has suffered neither from the rapidity of the plate, nor from the size of the enlargement.

Judging the correct exposure certainly presents difficulties in this, as in any other branch of photography; but when one's "hand" is well in, and when using familiar lenses, one is rarely wrong, for artificial light is far more uniform in actinic quality than daylight. Were I asked what is the most difficult part of microscopic photography, I should unhesitatingly reply, *the proper illumination of the object*, especially with high powers. Anyone can put on a blaze of light, even with a $\frac{1}{12}$ inch, or $\frac{1}{16}$ inch; but that is not illumination.—I am, sir, yours faithfully,

I. H. JENNINGS.

[The micro-photographs Mr. Jennings sends us are excellent.—ED. P.N.

Proceedings of Societies.

THE PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

A MEETING was held in the small room attached to the Gallery, 5A, Pall Mall East, on Tuesday, the 22nd inst., Mr. WILLIAM BEDFORD in the chair.

Some interesting examples of platinotype printing on linen were handed round by Professor Donkin. The prints were made by Dr. Huggins, and after having been moistened with glycerine, they had been mounted between glass plates so as to ensure optical contact. They resembled ordinary silver prints mounted on glass with gelatine in the usual way.

Mr. COWAN exhibited a plate-book very similar to that figured on page 58 of our second volume (1859), except that the leaves consisted simply of thick paper instead of light frames. The closed book is fitted into a paste-board case, and this first case slides into a second, so that light is effectually excluded.

After some general conversation on the subject of packing plates,

Mr. LYDDELL SAWYER read some notes on the recent exhibition of lantern slides, and it was afterwards suggested that it would be interesting for the Society to obtain some slides from the extensive educational series published by Dr. Bruno Meyer, of Carlsruhe, his series comprising more than 4,000 photographs.

The CHAIRMAN asked if anyone present had acquired further experience as to the methods of slide-making, illustrated at the last meeting, and he made special reference to Mr. Wellington's method of obtaining various tones on gelatino-bromide plates (p. 79). He rather thought that Captain Abney had broken ground in that direction some years ago.

Captain ABNEY remarked that it was easy to go farther back, as Colonel Stuart Wortley had long ago noticed something of the kind in connection with collodio-chloride plates, the colour of the image being brownish or greenish, according to the rapidity with which development was carried on.

Professor DONKIN had not been very successful in obtaining variation in colour on gelatino-chloride plates; but

Mr. COWAN suggested that he had not varied the exposures so as to accord with the different methods of development. Mr. Cowan said that, even when 280 times the normal exposure had been given, it was possible to control the development by 16 grains of bromide to the ounce of developer.

The production of reliefs on gelatino-chloride plates, as described by Mr. Francis Cobb (page 175), was then referred to.

Mr. PEEK said he had not only obtained well-defined reliefs, but he had been successful in inking them up after the fashion of a collotype plate.

Captain ABNEY referred to the analogous method with a bromide plate, which had been suggested by Mr. Swan, and to Warnerke's method, in which the gelatine of a gelatino-bromide film is washed away from the unexposed side, after the fashion of carbon printing.

Mr. B. P. LASCELLES, who is now engaged in carrying out some experiments on phototype work for the *Clarendon Press* at Oxford, made some remarks as to the progress of photo-mechanical printing, and said that practical men would welcome any improvement which enabled a relief or fatty transfer to be made with increased speed and certainty.

The meeting was then adjourned.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

A MEETING of this Society was held on Thursday, the 17th inst., Mr. W. K. BURTON in the chair.

After the usual routine business had been disposed of,

The CHAIRMAN called upon Mr. W. E. Debenham to deliver his lecturette (see page 262). He (the Chairman) said Mr. Debenham had been very explicit; while avoiding slovenly statements, he had also drawn the line in the other direction, by avoiding mathematical formulæ, which was like the dead languages to the ordinary photographer. There were a few points on which he would touch. To determine the focus of a lens precisely enough for practical purposes, he focussed a distant object, generally a row of electric lights; he then measured the distance between any two lights, removed the lens, and inserted a diaphragm $\frac{1}{16}$ of an inch in diameter. The camera was then racked out until a similar image is obtained, the distance between the ground glass and the stops representing the equivalent focus of the lens. He endorsed Mr. Debenham's remarks on flatness of field; opticians sacrificed flatness for microscopic sharpness, leaving marginal rays out in the cold.

Mr. J. TRAILL TAYLOR understood Mr. Debenham to say that flatness of field, along with comparative freedom from astigmatism, was not possible when using large angular apertures. But there was a means of overcoming the difficulty, which he would illustrate on the blackboard. About eleven years ago Prof. Piazzi Smyth studied the problem, his desire being to get an absolutely sharp picture on a small scale with the full aperture of a quick-acting portrait-lens, and afterwards enlarge it further. The manner in which Prof. Smyth overcame the difficulty was by placing a plano-concave lens close to the plate, by which marginal rays which, under ordinary circumstances, had a focus short of the plate when the axial rays were in focus, were received on the concave side of the lens, and transmitted in a more or less parallel manner, afterwards converging to a focus, and thus becoming lengthened. He found the effect of a lens so placed was to

immediately obtain good marginal definition on a flat plate. The cost would operate against very large size plates being used. The path taken by the rays was shown on the black-board. Speaking on lenses generally, Mr. Taylor was of opinion that the lens of the future would partake of the nature of a dialyt, one example of which was to be found in Petzval's orthoscopic combination as constructed by Voigtlander, and now supplanted by others. Only a few days ago he was engaged in some experiments in which a bi-concave crown and a meniscus flint, the combination being negative, was so arranged in a tube that these glasses could be easily separated. By very small degrees of separation, they gave an image on either a hollow or a flat field; not only so, but by separating them still further, the field of delineation became bellied. He exhibited the lens referred to, and said that he had just adapted it to a mount along with some other lenses, by combining which he obtained any focus from three to seventeen inches, thereby reducing the weight of his outfit to a minimum. Pictures taken with a fifteen-inch lens gave about the same effect of a scene as when examined by the eye in nature; beyond this focus the picture would be telescopic. Large pictures could be taken with a small expansion of body if the posterior lens were concave, and constructed according to the dialytic principle to which he had alluded. In connection with spherical aberration, he said that the large amount of glass in objectives of the modern rapid type requisite to secure deep contact surfaces suggested the subject of American lenses of the same type. In 1861, Sir John F. W. Herschel published a paper in which he gave a series of diagrams with curvatures showing how to obtain lenses free from spherical aberration, and it was interesting to know that, subject to certain obvious modifications, one form has been adopted by Morrison, of New York, for his rapid group lens; while another had been adopted by Dallmeyer for the back of his patent portrait lens. The Morrison lens was the American rival of all those formed on the Steinheil aplanatic system, whether designated rectilinear, symmetrical, or Euryscope; but it differed from those in being constructed with shallower curves, and of ordinary crown and flint glass. The wide angle lens of Morrison's was the outcome of the Harrison globe-lens, its front being formed of a deep achromatic meniscus, while the back was a single crown lens of similar form.

M. J. Cadett was of opinion that very few lenses would be found to do practically what is theoretically expected of them. Even theory, as published in the text-books, was sadly wanting. He had searched in vain for definite information in the works of recent date. The best information he could find was in a treatise by Monckhoven. A thoroughly practical treatise was badly wanted. He believed, with the Chairman, that marginal definitions might be improved. Those who made mathematics a study did not seem much better off as regards lenses. Ninety-nine out of every hundred photographers know nothing of mathematics, and those who profess to teach them, know very little more about it. Mr. Warnerke, who is a good mathematician, recently went through laborious calculations, and finally came to the conclusion that mathematical calculations were so much useless labour; he now trusts to practice. He did not think the Chairman could see more than one or two degrees sharp with the eye; 30° would be a general outline not sharp.

Mr. F. Hart would not like the discussion to pass without calling attention to Mr. Taylor's diagram of the plano-concave lens. He did not suppose it would be constructed for whole or half-plates; but if it were practical to get three inches absolutely sharp, an immense power would be gained. When lenses do not give sharp definition over the field, presentable enlargements cannot be expected.

Mr. A. L. Henderson asked what effect would be obtained if the plano-concave lens was brought nearer the negative?

The Chairman: It is doubtful if the same result would be attained; it must be borne in mind that rays once brought to a focus would not disperse afterwards.

Mr. Henderson questioned the lecturer as to the effect of introducing the front combination of a whole-plate lens on the back of a small portrait lens—hung on, not centred.

Mr. Debenham should expect to get confusion.

Mr. Henderson had thousands of negatives taken in that way. Working a short studio some years ago, he used to take half-length cartes with a 1B, and hung the front combination of a French whole-plate lens on to get full-length figures without having to move the camera further back.

Mr. A. Haddon said that among those who had studied mathematical science, it was surely possible to find a sub-committee who would study lens-grinding and polishing, and report thereon.

Mr. W. Coles: Does the Chairman get an image sufficiently sharp for practical purposes in his method of ascertaining the equivalent focus of a lens?

The Chairman: It is not necessary that the image be sharp for this purpose; it will be sharp enough.

Mr. Cowan said Mr. Warnerke's method is to mark the tube, taking the sun as the object; then turn the lens, taking the same object the other way; dividing the two would be the equivalent focus of the lens.

The Chairman said they had received, what he anticipated, a most instructive and interesting paper from Mr. Debenham, and he moved a hearty vote of thanks to Mr. Debenham, which was carried unanimously.

It was announced that the next lecturette will be given on May 8th—"Science of Polarized Light," by Mr. C. Darker.

Glasgow Photographic Association.

The twelfth general meeting of the session was held in the Religious Institution Rooms on Thursday, the 10th inst., Councillor Robertson in the chair.

The minutes of the last meeting were read and confirmed.

Mr. Wm. Lang, Junr., then read an interesting paper on Poitevin's photo-reliefs, and showed a number of very fine specimens of work, which were much admired and freely criticised.

The President, in a few words, thanked Mr. Lang for the great trouble he had been at in getting up the paper and illustrations.

The next business was the nomination of office-bearers for the ensuing session, to be elected at the next meeting. This having been done,

Mr. McGhie exhibited a number of magic lantern and window transparencies, printed by contact on Cowan's gelatino-chloride dry plates. Mr. McGhie said the process was exceedingly simple. The specimens before the meeting were the first experiments he had made with the plates, and they were satisfactory in every respect. In his experience he had found magnesium to be the most suitable light to print with. One and a half inches of ribbon, burnt at seven inches from the frame, was sufficient exposure for an ordinary negative. He also showed a new combined shutter and sky-shade by Guerry. The shutter had two flaps, one of which covered the sky for a certain part of the exposure, which time is regulated by a little lever.

The meeting terminated with a vote of thanks to Mr. McGhie and the Chairman.

Photographic Society of Ireland.

The usual monthly meeting of this Society was held on Friday, the 18th inst., in the Royal College of Science, Stephen Green, Mr. Mayne in the chair.

The minutes of the previous meeting having been read and confirmed, Dr. Robert Brown and Mr. James Robinson were elected members.

The Chairman then called on Mr. Watson for a communication entitled "Retrospect." In his remarks, Mr. Watson gave a short *resumé* of photography from its earliest stages, tracing out the various improvements that had from time to time taken place up to the present time. Mr. Watson's paper was most interesting, and elicited a well sustained debate.

Mr. J. V. Robinson gave some valuable information on the various methods of enamelling. In Mr. Robinson's hands the process of coating a previously chemically clean plate of glass with collodion, then applying a coat of best negative varnish, and over that a thin layer of gelatine, and lastly pressing the print on same and squeegeeing the air-bubbles out, had worked the best, the enamel proving tougher, the surface of collodion apparently not being so easily damaged as when the application of varnish is omitted.

Dr. Scott exhibited and explained a very simple and ingenious form of actinometer which he had made. He had taken two pieces of sensitized albumenized paper, and exposed one to the action of the light for thirty seconds, and the other for one minute. The colours thus procured were then accurately imitated on a piece of glass. The *modus operandi* is as follows. When an exposure is to be made in the camera, take out a small piece of paper and expose same until one or other of the colours

has been obtained, noting the time necessary to secure the change. The paper thus acted as a standard, thirty seconds on one occasion having been found to be the correct exposure for the plate, and by making a simple calculation each time the proper exposure for the plate was secured. Dr. Scott had tried this on several occasions, and had never found it to fail.

Mr. J. V. ROBINSON exhibited a whole-plate camera made by himself, also a new camera-stand, the chief merit being the method of shortening the legs, the bottom or single lath sliding between the two upper laths, and being clamped by a band of brass.

Mr. WATSON also exhibited a new 7½ by 5 camera—the various movements, as also the method of extending the base-boards, attracting a considerable amount of interest.

The next and last meeting for this session will be held May 9th.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

THIS Society held its monthly meeting at 181, Aldersgate Street. The minutes of the previous meeting were read and confirmed.

Mr. J. R. Nisbett and Mr. J. F. Lattimer were proposed and elected members of the Association.

Attention was called to a paragraph in the PHOTOGRAPHIC NEWS of March 14th, suggesting that paid canvassers should be engaged. The matter received the consideration of the Board, but no action was taken.

The other business having been dealt with, the meeting adjourned until May 7th, at 8 o'clock.

Talk in the Studio.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—At the next meeting of the above Society, to be held at the Society of Arts, John Street, Adelphi, on Thursday, May 1st, at 8 o'clock, Norman Macbeth, Esq., R.S.A., has kindly promised some "Notes on the Composition of a Picture;" when it is hoped that not only will the members attend to welcome this eminent artist, but also make use of their privilege to introduce a friend.

PHOTOGRAPHIC CLUB.—At the next meeting of this Club on April 30, the subject for discussion will be, "On the Preparation of Lantern Slides." This being a Lantern night, members and visitors are invited to bring slides.

To Correspondents.

*** We cannot undertake to return rejected communications.

E. A. T.—If you copy a photograph without knowing whether it is copyright or not, you do so at your own risk.

R. M. L.—We should recommend you to melt the size, and then stir in one-fourth of its weight to a cold saturated solution of bichromate of potassium.

J. W. MORPETH.—1. We are inclined to think that the second lens you mention will be more suitable, as the figures will come out somewhat larger than if the first were used. 2. The lens already referred to, or some other instrument so nearly allied to it as to be practically identical, is generally used; but some prefer to use a portrait combination when small pictures are required.

J. W.—We quite agree with you that extremely beautiful pictures can be, and indeed often are, produced by the process you name; but we do not know of any means by which similar positives can be obtained on ordinary gelatino-bromide plates. It is quite true that you may make a thin negative and whiten it by immersion in a solution of mercuric chloride, but those clear shadows which form a peculiar charm of the old glass positive are likely to be wanting.

D. G. A.—Messrs Trübner and Co., of Ludgate Hill, will obtain the book for you. We do not know the cost, but the firm referred to will inform you as to this.

F. W. M.—It may be sufficient or insufficient according to the activity of the toning elements; but the method you refer to is of necessity uncertain. Why not adopt the usual plan of carrying on each process separately?

T. P.—It appears to us that all your pictures are over-exposed. Be careful to use a safe light in your dark-room.

F. COLBOURNE.—Ready-sensitized paper very frequently contains free acid, and this often prevents the toning. Add a few drops of ammonia to the last water in which you rinse the prints previously to toning them.

F.—The idea is absurd, but you should register the picture so as to secure the copyright properly.

E. J. RUSSELL.—If you tell us what the solution is composed of, we may be able to give some kind of an opinion as to whether it is likely to have caused the mischief.

MOUNTER.—No doubt some of the prints have been cut across the sheet, while others have been cut in the direction of the length, and the unequal contraction of the paper has occasioned the difference which you notice.

K. R. F.—1. The idea is perhaps a good one, only you should have made the negative sufficiently vigorous to give a white ground.

CHAS. GREENISH.—1. Judging from your description, we should think it is not a photographic objective at all, but a lens made for a magic lantern. 2. A mere trace of free nitrate of silver will do no harm, but you must be very careful not to have too much present. 3. Long heating has doubtless quite destroyed the setting properties of the emulsion. 4. Methylated spirit will answer very well.

H. P. C (Bradford).—The "stained red" glass can be obtained from Williams and Co., Glass Merchants, 36, St. Martin's Lane, Charing Cross, W.C.

THOS. GARSIDE.—1. We cannot but think that you either over-expose, or that diffused light reaches the plate. Examine your lens tube and the edges of the glasses with a view of detecting any surfaces which may reflect light. 2. Litmus paper will serve if you obtain a delicately-tinted sample, and observe carefully. Acids redden it, and alkalies change the tint to blue. You should select paper which is neither red nor blue, so that either condition may be detected. 3. Lay them one by one on a hard surface, and vigorously stroke the backs with the edge of a smooth and hard object, such as a paper-knife.

F. BENNETT.—Use a stronger solution of nitrate of silver for sensitizing.

ASPIRANT.—Judging from your description, we suppose that the lens is imperfect, and we would advise you not to purchase. If the local jeweller tells you that he can cheaply replace any glass which may be missing, it is probable that he is mistaken.

WHITE LEAD.—The idea is ingenious, but hardly practicable.

CARBON.—You will find all the information in the "Lessons on Carbon Printing" which are now appearing in the NEWS. 2. Add ten drops of sulphuric acid to each pint of the water used for mounting the exposed tissue.

MR. ROBINSON'S NEW BOOK.

PICTURE-MAKING BY PHOTOGRAPHY. Being No. V. of "Photographic Handy-Books" (See page 266, PHOTOGRAPHIC NEWS.)—Price 2/6, per post, 2/8.—PIPER and CARTER, 5, Castle Street, Holborn, E.C.

Employment Wanted.

Operator & Retoucher.—A. D. Thissack, 1, Woodside-ter., Douglas, I. of M.
Retoucher (German), first-class.—30, Stean-st., Haggerston.
Assistant, well up in dry plates.—Photo., 148, St. James'-rd., Holloway.
General Assistant.—Z., Mr. Gregory, High-st., Marboro'.
Printer and Toner.—F. Knight, 40, Brooksby-st., Liverpool-rd., N.
Reception Room Lady in Lond.—M. A. S., 17, The Drapery, Northampton.
Operator & Retouch., first-class.—W. H. H., Art Studio, 3, Cheapside, E.C.
Operator & Ret., mod. salary.—Operator, 58, Campden-st., Kensington, W.
Photo. Colourist, gen. useful.—G. Manton, 49, Hurley-rd., Kennington-la.
Operator & Ret. in good house.—D. Prodger, The Broadway, Ealing, W.
Operator and Retoucher, could manage.—Artist, 1, Hove-st., W. Brighton.
Youth, as Assistant in dark room.—H. Eckhardt, 12, Bath-st., Brighton.
Mounter & Cutter (lady).—B., 1, Great Coram-st., Russel-sq.
Recep.-Room, Printing, Colouring.—E. M., 1, Benhill-rd., Camberwell.
Improver, can Tint well.—A. H., 15, Arlington-rd., N.
Reception-Room, Spot, Mount, &c.—E. H. H., *Photo. News* Office.
Ret. & Assist. Operator.—M. G. A., 1, North-pl., Montrose-st., Glasgow.
Print., Spot., Toner, Mounter, &c.—Miss Smedley, 45, Gt. North-ter., Linc.
Photo. Colourist and Retoucher.—Photo, *Photo. News* Office.
Recep.-Room, 7 years' experience.—E. Smith, York House, Cheltenham.
Spotting, Mounting, (lady)—K. B., 67, Colvestone-crescent, Dalston.
Retoucher, Recep.-Room, Spotting.—2, Marion Villas, West-st., Bromley.

Employment Offered.

Assistant in Stock-dealer's Warehouse.—Ruby, *Photo. News* Office.
Oper., clever with children & retouching.—Clayton, 6, Lond.-rd., Leicester.
Printer, with first-class references.—Stiles, 8, Kensington High-st., W.
Operator, Retoucher, manage branch.—C. Keeping, 1, Exe-bridge, Exeter.
Out-door Operator, first-class.—Taylor, 70, Queen Victoria-st., E.C.
Operator for Studio.—Hills and Saunders, Eton, Bucks.
Ferro Oper., to travel.—Mr. Griffith, 5, Northampton-bldgs, Clerkenwell.
Lady, exp., Recep.-room.—Hughes & Mullins, Regina House, Ryde, I.W.
Printer, well up in vignetting.—Winter, Midland-rd., Derby.
Oper. & Retoucher, good at lighting & pos.—Shrubsole, Davy-pl., Norwich.
Printer & Gen. Assist.—E. R. Gyde, Cheltenham House, Aberystwith.
All-round Hand (single).—Cuckney and Co., Rochester.
First-class Floater.—Tavistock Works, Tavistock-pl., Kensal-green.
Printing, Toning, &c.—Personally, 67, Pentonville Road, N.
Assistant Silver Printer.—W. N. Malby, Chichester.

THE PHOTOGRAPHIC NEWS.

VOL. XXVIII. No. 1339.—*May* 2, 1884.

CONTENTS.

PHOTOGRAPHY OF YELLOW, BLUE, AND OTHER COLOURS IN THE TRUE PROPORTION OF THEIR INTENSITY.

BY DR. H. W. VOGEL.

THREE weeks ago I communicated the fact that I had been able, after some eleven years of investigation, to prepare collodion plates which were at least eight times more sensitive to the yellow of the spectrum than to blue, and in support of this statement I forwarded to the Editor of this journal a photograph of the table of colours in my Manual, in which the blue, the yellow, and the rose were reproduced in the true proportion of their brightness. This solution of a problem that has been so long encompassed with difficulty created a good deal of interest in scientific and photographic circles, and its importance in connection with the work of reproduction was at once recognized. The Berlin Society for the Advancement of Photography, in consequence, decided to acquire the process for the purpose of publishing it for the general good.

In accordance with the above understanding, I now communicate the whole process. I will begin with purely practical details, leaving aside the scientific aspect, which has several times already been discussed by me in these pages. At a later period I will describe my experiments in more detail.

Ordinary portrait collodion shows the greatest sensitiveness in the dark blue region of the spectrum, falsely termed the indigo-blue region; only after a very long exposure is there any sensitiveness evinced in the green, yellow, and red.

In accordance with a principle which I was the first to expound, this sensitiveness for green, yellow, and red may be increased by certain bodies which absorb these particular rays. The greater number of these bodies act best on dry collodion, very few being suitable for the wet process. Eosine, however, is one of these bodies, but as in commerce there exist two kinds of eosine, it is necessary to make a distinction. The one is the yellow shade of eosine (the potassium derivative of tetrabromofluorescein), and the other the blue shade of eosine (the potassium derivative of tetraiodofluorescein); there are besides methylated, chlorinated, and nitrated products, which I have also examined. The nature of the action of these bodies I will remark upon later, merely premising that they are now in everyday use as dyes, although seldom met with in a pure state, being frequently mixed with dextrine, &c.; the impurities they contain acting prejudicially upon the silver bath.

A firm in Berlin—the Actien Gesellschaft for aniline products, whose address is: Schlesien Thor, Berlin—has been good enough to prepare some of these dyes for me in a purified form for photographic use. Both the yellow and blue eosine have been supplied to me, and I find that the latter gives rather more intensity than the former. Combined with an alkali, both of them show a magnificent fluorescence when in dilute solution; they dissolve easily in water, less easily in alcohol, and absorb very vigorously yellow-green and blue-green rays. Added to collodion in suitable proportion, they render this very sensitive to the above coloured rays, and upon this depends the principle of their sensitiveness to colour.

Besides these bodies, one termed cyanosine, which I have to thank Dr. Martius for, I have found exceedingly good as a sensitizer for yellow. This resembles eosine in so far that its absorption bands lie more towards the red of the spectrum, and for this reason not only produces a sensitiveness for green (as does eosine), but also sensitiveness for orange rays. Unfortunately, this substance cannot yet be obtained in a pure state in commerce. The Actien Gesellschaft, the firm I previously mentioned, only furnishes at present for photographic purposes the yellow shade of eosine, which is twice recrystallized; and this I would recommend in the meantime to all who desire to make experiment with colour-collodion. Very shortly the same firm will produce for photographic purposes also, erythrosine and pyrosine, and these will then be preferable to eosine.

If these colouring matters are tried with gelatine and collodion dry plates, it will soon be found that the former is at most only double as sensitive for the yellow of the spectrum as for the blue. Practically, this would be of little advantage, for the yellow in colouring matters is so dark in comparison with the yellow of the spectrum; as I have already shown, the sensitiveness for yellow must be, not twice, but twenty-five times more than the sensitiveness for blue, if, in the resulting photograph, the yellow is to appear more brilliant than the blue. Fortunately, more favourable results are obtained with collodion plates than with gelatine. Already, my first experiment showed me that it was possible to produce plates from eight to ten times as sensitive for yellow as for blue, and for this reason I naturally turned at once to the collodion process to reproduce colours in their true intensity.

My experiments with gelatine plates I will describe later.

The action of the colouring matters depends, however, as I have previously said, very much upon the composition of the collodion. If you take ordinary iodized collodion, and add to it about 5 per cent. of a solution of eosine or cyanocine (the solution containing one part by weight of eosine or cyanocine) it will be found under ordinary circumstances that there is but a slight increase of sensitiveness for yellow. For this reason I made experiment with iodized collodion containing various proportions of bromine, and these showed me that the sensitiveness for yellow increased with the proportion of the bromine salt added to the collodion. Obviously, therefore, success lay in the employment of a bromized collodion,

At the same time, I found that a small proportion of iodine was an advantage for general sensitiveness. When the silver bath from long use contains much iodide of silver, then a sufficient quantity of iodide of silver is deposited upon the plates, so that pure bromized collodion may be emptoyed. In the case of a freshly-prepared silver bath, however, containing a minimum of iodide of silver, it is well to add 5 per cent. of pure iodized collodion to your bromized material.

As a general rule, it may be said that the sensitiveness of bromized collodion plates containing eosine, and prepared in a fully iodized bath, is only one-third as sensitive for white light as ordinary portrait collodion.

Working Details.

No. 1. *Colour Solution.*—At present only two colouring matters can be recommended as obtainable in commerce, the yellow shade of eosine, and the blue shade of eosine. Half-a-gramme of the material is dissolved in 100 cubic centimetres of alcohol of 95°; considerable agitation is necessary to effect the solution. The undissolved residue is not used, but the clear solution must be decanted off.

No. 2. *Collodion.*—Two grammes of bromide of cadmium are dissolved in 30 cubic centimetres of alcohol; this is filtered, and one volume of the filtrate is mixed with three volumes of neutral normal collodion made with 2 per cent. of pyroxyline. For some purposes a denser film is more advantageous. This is obtained by dissolving 2½ grammes of bromide of cadmium in 30 cubic centimetres of alcobol, filtering, and mixing in the above proportion, but with 2½ per cent. collodion. A collodion of this kind flows with more difficulty, and is slower to sensitize in the bath. To 95 cubic centimetres of the above collodion are added 5 cubic centimetres of the eosine, or *colour solution*. The collodion keeps best in yellow bottles, and should be brought into daylight as little as possible. I may mention that an increase of eosine brings about no increase of sensitiveness for yellow, while it decreases the general sensitiveness of the plate. A lesser proportion of eosine decreases the yellow sensitiveness.

Silver Bath.—This is made up of crystallized nitrate of silver, 50 grammes; water, 500 cubic centimetres; iodide of potassium solution (1 : 100), 13 cubic centimetres; and glacial acetic acid about 6 drops, or until there is an appreciable acid re-action. Nitric acid is not to be recommended for acidifying the bath, as it acts too strongly on the colouring matter. It must be distinctly understood that eosine is decomposed by acid, and converted into a yellow pigment, which does not increase the sensitiveness for yellow. For this reason an excess of acid is to be avoided.

By reason of the danger of introducing impurities from the colouring matters now obtained in commerce, I do not recommend the sensitizing of these collodion plates in a bath used for other purposes. I prefer the horizontal bath, as it does not require so much liquid.

Developing, Intensifying, and Fixing.—The solutions in ordinary use for collodion will suffice here. The plates are treated like ordinary wet plates, and it is an advantage o the process that no strange operations are introduced. Those who can work the ordinary wet collodion process can work the colour collodion process. Pyrogallic intensifiers, mercury intensifiers, uranium and lead intensifiers, may all be employed.

Manipulations.

Preparation of the Plates.—It is best to gelatinise the glass plates first of all. One gramme of gelatine is dissolved in 300 grammes of warm water, filtered, and on cooling there is added 6 centimetres of a cold prepared chrome alum solution (1 : 50). The glass plates are first soaked in dilute acid, washed, put in a dish of distilled water, and then twice coated in the gelatine solution.

The coating with collodion is done in the ordinary manner, but the plates must remain rather longer in the silver bath, as the formation of bromide of silver is very slow. At least five minutes' sojourn in the bath is necessary, although in a stronger solution the operation is quicker. Before work, the dipping bath should be tested with litmus paper, and acetic acid added, if necessary.

In respect to the illumination of the dark room, one need not be very anxious. I recommend an orange lamp-shade. Eosine renders the collodion but little sensitive to red; if you keep your plate in the shadow, you may even use yellow light in the dark room.

Exposure.—As before mentioned, the sensitiveness of eosine bromide plates is about one-third that of ordinary iodized collodion plates. This affords the operator sufficient data to go upon. In the reproduction of coloured pictures—as, for instance, the table of colours in my Manual—the sensitiveness for yellow is not so apparent as one might suppose. Chrome yellow and ultramarine blue come out equally light. On the other hand, the action of the eosine in reproducing rose tones is very obvious. These are reproduced in their true tone value, or intensity. In other tints, such as the green, the action of the eosine is also very apparent.

If it is desired to lessen the action for the blue still more, then you have to photograph through yellow glass; only in making the choice some care is necessary. Yellow window glass, by reason of its defective manufacture, gives rise to unsharpness, and therefore I recommend yellow patent plate; with this, pictures of faultless sharpness may be obtained. But to secure the right shade of yellow is also an important matter. If you use too dark a yellow, the exposure is very long, while too light a yellow does not act upon the blue sufficiently. My plan is to test the glass with the spectroscope; but to those not accustomed to spectrum work, I recommend the testing photographically.

I do not mean to say that every picture should be taken through yellow glass. After some experience the photographer soon learns which medium is the more suitable. At the worst, a few experiments will settle the matter. It must be mentioned, however, that the yellow patent plate prolongs the exposure (often three-fold), as the best glass of this character absorbs not only blue, but also a portion of the yellow light.

I am in the habit of employing an aplanatic lens with colour collodion, which, with a full opening, gives me a sufficiently sharp and detailed picture. In the case of long exposures, a dark slide may be employed with advantage, which allows a second plate to go in front of the prepared one, and thus prevent the drying of the latter; this forward plate might be a yellow one.

The Second Silver Bath.—The plates, like those in the ordinary wet process, could be forthwith developed, if the bath was free from so-called organic defects; but, unfortunately, these are apt to arise by reason of impurities in the colouring matter which have been introduced into the bath. Plates sometimes show fog, and sometimes show a cloudy unequal deposit, running in streaks from margin to centre. The latter are worse than the former; they may be avoided, or at any rate diminished, by moving the plate vigorously in the bath. If, however, the bath is very strongly afflicted with organic matter, the only means of avoiding the action of these impurities is to employ a second bath, which may be termed the developing bath. The plate is dipped into this bath after the exposure, but before development. It is made up of:—

Nitrate of silver	50 grammes
Water	500 ,,
Nitric acid, sp. g. 1·22	4 to 6 drops

The plate is moved vigorously to and fro in this for two minutes, and thus the impure silver attached to it is washed off, and the eosine decomposed by the presence of the strong nitric acid. After this, development can be proceeded with without the chance of any of the above-mentioned defects. After a time the developing bath becomes impure, and then

it may be used as a sensitizing bath, first being neutralized, and again acidified with acetic acid. Care must be taken to test this bath also with litmus paper before use.

The Development.—As a rule, the plates are developed with the ordinary iron developer used in the wet process. But the same success may be obtained with an alkaline developer, and the latter has, moreover, the advantage that the organic impurities are less liable to give stains. In the case of alkaline development, only one silver bath is used. The exposed plate is first washed with distilled water, then put under the tap for five minutes, and then once more in the distilled water. It is best developed in a dish with the following solution :—

Carbonate of ammonia solution	(1 : 6)	2 cub. cents.
Bromide of potassium	,,	(1 : 4)	½ cub. cent.
Alcoholic pyrogallic	,,	(1 : 10)	1 ,,
Water			30 cub. cents.

If the exposure has been too short, the amount of carbonate of ammonia, which must always be freshly prepared, may be augmented.

THE MEISENBACH PHOTO-BLOCK PROCESS.

Our readers have already heard a good deal about the phototypic blocks which are made, under the direction of Herr Meisenbach, by the Autotype Company of Munich, and a most striking example of the excellence of the work was afforded by the portrait of Sarah Bernhardt, which we issued during November in last year. Dr. Pick informs us that the block from which the accompanying impression is printed, was made and printed from within five hours of the time the negative was finished.

That photo-blocks will, in the future, largely supersede wood engraving, there can be no doubt whatever ; and now that the photo-typographic blocks from ordinary gradated negatives are likely to be made on a large commercial scale, one may consider that photography enters on a new phase.

Hitherto the Meisenbach blocks have all been produced at the parent establishment in Munich ; but the necessary delay in production, consequent upon the distance, has not prevented their use by several illustrated publications in

London. We understand, however, that preparations are being made for opening a branch establishment here, and we can have but little doubt as to the success of the undertaking.

It is scarcely necessary to observe, that the quality of the prints obtained from an engraved block depends largely on the manner of printing, and as the large circulation of the Photographic News renders it necessary to print it on a quick machine, after the fashion of a newspaper, our readers will understand that we cannot put before them the best print which the block is capable of yielding.

THE WOODBURYTYPE PROCESS.

(Sixth Article).

The block and paper having been provided, the next step is to prepare the pigmented gelatinous ink in which the pictures are to be printed; or, indeed, to speak more accurately, cast or moulded.

The ink to be used varies considerably in its constitution, both as regards the amount of colouring matter which should be present, and also as to the quantity of gelatine to be used in relation to the water. The circumstance which will primarily influence the amount of pigment required is the depth of the mould, it being obvious that when the relief on the printing mould is considerable, a smaller proportion of colouring matter or pigment will be required than when the degree of relief is small. As regards the proportion of gelatine to be used, we may remark that not only will it vary according to the setting powers of the gelatine itself, but that in summer it is necessary to use a solution richer in gelatine than that which will serve well in cold weather.

The gelatine which we have found most suitable for the Woodburytype process is that known as "*Coignet's Silver Label*," and a jelly formed by melting one part of this in five parts of water may be taken as the basis of the gelatinous ink. Indian ink is ordinarily the main constituent of the pigment used, and the tone of an ordinary photograph may be imitated very satisfactorily by the addition of indigo and alizarine lake. Much trouble may be obviated by purchasing these pigments already ground, and in the moist state; but it is still more convenient to obtain Newman's "Colour for Carbon Printing" (24, Soho Square) all ready mixed to the required tint and tone.

In very hot weather, or when it is desirable to remove the prints from the mould rapidly, the gelatinous ink may be used of the full strength mentioned (1 and 5); but it will, in all ordinary cases, be better to dilute it with about half its bulk of water. Having melted some of the gelatinous mixture, the moist colour is gradually to be stirred in until it is estimated that a layer of the mixture as thick as the greatest depth of the mould, possesses just the depth of tone required for the dark shades of the picture. Of course, one can only make a very approximate estimate; but some kind of judgment must be exercised at this stage before testing the ink upon the mould.

We must now mount the leaden plate or mould ready for printing, and some kind of a press is required; but the beginner cannot do better than to use an ordinary Albion press, such as is used by letter-press printers, especially as such a press can be obtained without difficulty in any large town. A piece of moderately thick plate glass should be cemented over the platen of the press, ordinary elastic cement or marine glue being used; but of course it is necessary that both the glass and the platen should be well warmed, and the glass must be retained in position by pressure until the cement has set. A little plaster of Paris is now mixed to a stiff paste with water, and a bed is made of this in the central portion of the carriage of the press; this bed having been levelled off as evenly as practicable, the mould is set down upon it face upwards, and a sheet of the printing paper is laid over the face of the mould, after which the platen of the press is brought down steadily upon the mould. Under these circumstances, the excess of plaster is forced out, and the lead mould becomes set firmly in such a position that its upper face accurately corresponds with the plane of the glass-covered platen. The pressure should be retained on the mould until the plaster is thoroughly set. The pressure being now removed, the carriage is run out, and the mould is carefully inspected with a view of ascertaining if there are any projections corresponding to accidental defects of the negative. Such can readily be removed by scraping with the sharp edge of a piece of glass, and if there should be a plain border of more than a quarter of an inch round the negative, it is advisable to scrape out, through this border, some six or eight channels through which the excess of ink may freely escape.

Olive oil is now thoroughly rubbed over the surface of the mould with the finger, care being taken that at the moment of applying the oil, the face of the leaden mould is quite free from any trace of dew or moisture. After all excess of oil has been removed by careful wiping with a piece of oily flannel, all is ready for a trial with the gelatinous ink. A pool of the warm ink, sufficient to cover about half the diameter of the mould, is poured on, and a sheet of the prepared paper is steadily laid face downwards upon this, after which the pressure is applied. The excess of ink is forced out, and that included between the paper and the mould soon sets, and in a few minutes the paper may be stripped from the mould, carrying the cast with it, and it is now quite easy to judge as to any alterations which may be necessary as regards the composition of the ink.

If the extreme whites of the picture are tinted, it is probable that the pressure has been insufficient, or that the ink contains too much gelatine; while if the whites are clear, and the picture generally is too dense, the amount of pigment must be reduced by adding more gelatinous solution of the same strength as that just used. In actual practice, there is not the least difficulty in adjusting the composition af the ink to the special requirements of the occasion.

As regards the printing but little need be said, except that it is necessary to keep the ink melted by means of a water-bath, and before each impression is taken the block should be wiped over with the oily flannel. All the superfluous ink which exudes can be collected and re-melted, when, after straining through fine muslin, it is ready for use again.

When many prints have to be made it is usual to provide a number of presses, and to charge them in succession, so that by the time the last has been closed down upon the mould, the cast or print in the first is sufficiently set to be removed. When the presses are small, they are arranged on a circular table, which can be made to revolve before the person who is printing. It should be noted that in printing it is necessary that the paper should always be a little larger than the mould, and a mould will ordinarily yield from 250 to 300 good impressions. Before the prints are dry it is convenient to scrape off the accumulation of gelatinous ink which will be found round the edges, as this can be used again; and for drying the prints large sheets of canvas stretched on frames are convenient, the pictures being laid side by side on them, and the frames can be stacked up on each other.

The dried prints are immersed for a few minutes in a three per cent. solution of alum, rinsed for an instant in water, and once more dried. It is scarcely necessary to say that the object of the aluming is to render the gelatinous impression insoluble.

As regards trimming and mounting, we need say nothing, as no special precautions are required. Woodburytype prints are much improved by heavy rolling, as it is not desirable that any relief should be visible on the picture.

By-the-Bye.

LANTERN DISPLAYS.

Thirty years have gone by since Albert Smith was at the zenith of popularity, and attracted the *élite* of London to his popular entertainment at the Egyptian Hall. We have still among our dramatic relics a programme of his "Mont Blanc," with outline sketches of the "Grands Mulets," "Mur de la Côte," and other points on the route, sketches which represented the charming panoramas exhibited during his lecture, that so vividly helped the spectator, in his warm and cosy seat, to follow the mountaineer's risks and perils in search of the beautiful among the high Alps. Thoughts of Albert Smith came back to us the other night as we saw Professor Donkin's fine snow pictures upon the screen; you could have risen from your chair, and in two paces have mounted some of those huge blocks of crystal glacier, or have taken a turn up the tempting smooth snow slopes that stretched to your very feet. Here was the glittering region of crystals, that sad snow kingdom where the silent tread of mortal rarely penetrates, with its hoary-headed giants and white-headed peaks, brought down from its distant fastness, and placed before you in Pall Mall. Professor Donkin takes you an excursion round the Dent du Géant, now ascending some slippery peak to get a view, now crossing a rugged glacier; he actually bids you turn round and look at the track you make over the white satin-like slope, where your shoes have kicked up the snow.

On the same occasion, we were witness, too, of some charming scenes from leafy Devonshire, as well as several bold views of rugged hills in Wales, while interspersed were other illustrations more or less interesting. The avowed object of the exhibition was, indeed, more for the purpose of showing the results obtained in slide-making by different processes; and although this end was served but imperfectly—since slides of different quality were used to exemplify the different processes, and no close comparison could be made—it afforded a salutary lesson to all those who occupy themselves with lantern displays. And their number is legion, for there is no more delightful plan of exhibiting good photographs than by showing them in a lantern.

In fact, so important is the matter of lantern photography, that we cannot but think the time is not far distant when a popular entertainment not less famous than that of Albert Smith will be launched in the metropolis. Of course, the exhibition must be on very different lines to be successful now-a-days, and it must be something more than an ordinary Mechanic's Institution lecture. Given a clever and versatile comedian like the Mont Blanc explorer, some good music, and good decorations, an exhibition of photographs would be welcome both in town and in the provinces.

But this by the way. What we wish to do on the present occasion is to point out in a few words certain collateral matters which do as much to make or mar a lantern exhibition as do good and bad slides. A lantern exhibition is perforce an entertainment. It may be for instruction, it may be for amusement: but it must be interesting. An audience is readily moved, and is proverbially good-natured; it will forgive anything so long as it is not bored, and a lecturer, in conducting his entertainment, may do pretty well what he likes, if he is not dull and prosy. This fault an audience never refuses to condone.

The easiest way to escape offence in this respect is to be brief. During the winter and spring months there is at the Royal Institution every Friday evening a lecture at nine o'clock, the speakers being chosen, not because they can lecture, but because they are men known to the world. Some of these gentlemen are very sad prosers, but still the worst among them will come off with éclat if he makes an end of it punctually as the clock strikes, while an otherwise successful discourse is frequently wrecked by the lecturer keeping his audience half-an-hour beyond their time. Like a man who foolishly takes an encore after singing his best song, he is led on by the applause of a good-natured audience, and outstays his welcome. To be brief, then, and to be brisk if you can, are qualities that should be well remembered, if your object is not to bore an audience.

It is sometimes thought that if you have good lantern slides to show, anybody will do to explain them. In this case, it is the usual thing to enlist into the service a gentleman who can talk, and then leave the matter in his hands; this is a common cause of shipwreck. He talks, and talks, and talks, for he has now a most excellent opportunity, and the consequence is, a dull and monotonous flow of language that dazes the audience, and makes your slides a nuisance. Much better have some one who makes no profession to talk at all, and who, if he does stumble occasionally, is at any rate understood, and does not extinguish the interest of your slides with his garrulity.

Good slides are naturally indispensable, but as authors are usually kind to their own faults, it is well to take the advice of a small committee on their excellence rather than trust to your own judgment. Some people think every good photograph will make a good lantern slide; and others, again, believe that no matter by what process they are produced, they may all be put in the same series, as if uniformity were of no consequence whatever in respect to density of film or proportions. Portraits make excellent slides, but must be used sparingly, otherwise they grow wearisome; put in here and there, however, they are very welcome.

We have said that good photographs do not necessarily make good slides. The fact is, that until you see a picture actually in the lantern you cannot well appraise its value as a slide. It must have breadth, and details, and interest. Therefore, the best plan of judging is, we repeat, by means of a small jury who are shown the enlargement itself. That it is in every respect a successful photograph will not suffice. At the exhibition to which we have alluded there were some marvellously good transparencies shown, printed by the Woodburytype process, perfect in every detail. But as lantern slides they were out of place altogether; counters laid out with curious shells and fossils and sponges followed one after another, and tried the temper of the audience sorely. The inside of a four-wheeled cab, with its vulgar plush-lining and damp straw, might be depicted in the same faithful manner; but what would be the good of looking at it? The weakest point about photographic slides is, that they grow monotonous after a while, and therefore, if you choose monotonous and uninteresting subjects, you court failure from the outset.

It is well, indeed, to bear in mind the advantages and disadvantages of lantern photographs. The old painted slide had colour to recommend it, and although photographs may sometimes be toned or even tinted with advantage, most of them are shown in black and white. The virtue of photographs lies in their graphic character and their truth, and in a lantern display, therefore, these virtues should be accentuated. To prevent monotony, avoid prosiness in describing your pictures, and, if possible, make a break in your display now and then by lighting up the room, if it is only for a few minutes, to relate an anecdote or to enter on some brief description. In a word, do not keep your audience looking at the screen for too long a time together.

One other point as to securing the interest of an audience: describe your picture *before* showing it rather than afterwards. Expectation is then on tip-toe, and your picture, when it appears, is already invested with interest, if not with romance. A mediocre photograph in these circumstances will attract a hundred-fold more than the best slide in the world, about which no interest is awakened. Let us give an example or two. We show a bare hill-side

covered with ruins, and after it has been before the audience some seconds, and become stale in their sight, we mention that it is the remains of a Roman town, and that an inscription on one pillar shows it to have been built by the third Augustan legion. Can anything be more uninteresting? Now let us suppose that the lecturer proceeds the other way about, and does his best to raise the expectation of the audience first. He will refer to history being half-fable, and speak of the Roman emperors and Roman conquests as hidden behind the veil of centuries. "Now," he says, "I will bring you face to face with these Romans. I will show you some proof of the mightiness of their legions, and how, hundreds of miles from home, they established Roman cities with magnificent public buildings, and elegant temples of carved stone, such as are the envy of our modern architects. Nay, I will show you more. I will show you the noble arch still standing of the palace where dwelt the governor, surrounded by his Pretorian guards, and an inscription upon its walls, 'Legio tertia Augusta,' telling us how it was the third Augustan legion that built this city, whose ruins speak far more plainly of the grandeur of the Roman empire than a dozen chapters of history." What if we now show our slide; surely the audience will feel more interest in it?

Of course, if you can narrate an interesting anecdote, all the better. Here is a picture showing a little crowd of people on a pier on the island of Patmos in the Mediterranean. It is an ordinary photograph enough, but let us invest it with a story. The picture represents a scene twenty years ago, before the Mediterranean had a telegraph cable, and the incident exemplifies very vividly how London is truly the centre of commerce and how its financial pulsations are felt all the world over. Those people on the pier on that little island in the Mediterranean are Greek merchants, and they are looking out to sea, some of them with telescopes even, anxiously scanning the horizon. They are watching for the first signs of smoke from a London steamer which is to bear to them news of the change in the bank rate that issues from the Bank of England parlour once a month.

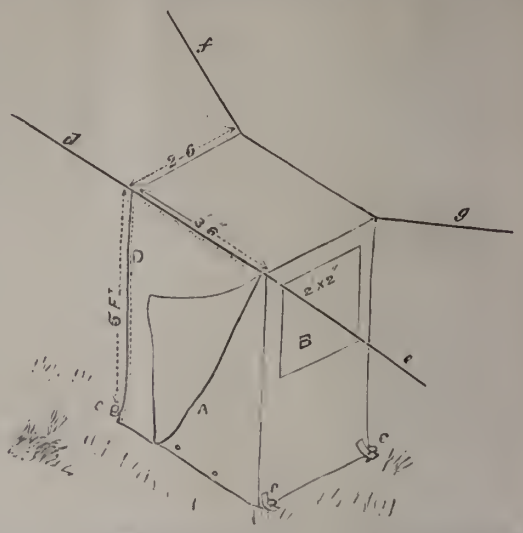
A TENT FOR CHANGING AND DEVELOPING DRY PLATES, ETC.

BY W. FRED. MAYES,
Assoc. M. Inst. C.E.

THE tent which I am about to describe is one I have had in use myself for some time, and for portability, ease of erection, and general usefulness, it leaves, in my opinion, little to be desired. It is a modification of one I saw in use for the wet process by the photographer of the Maharajah of Johore, when sojourning in the Malay Peninsula a few years ago.

Its form and dimensions are best seen by the annexed sketch. It is composed of one thickness of black satin—a very close material—lined with one thickness of best red Turkey twill, and one of yellow calico. The entrance, A, is rendered light-tight by an inner curtain of the same materials as the rest of the tent, running by means of rings along the cord, *d e*, which passes inside the tent, and made full enough, when drawn out, to leave one or two folds in the corner at D, where it is hooked to keep it in place when closed. At its lower edge are eyelet-holes to allow of its being pinned down by wire pins. The window is two feet square, and made by cutting away the outside material to this size, leaving the light to enter through the red and yellow linings and a sheet of orange paper, which, as a further protection, is suspended from a roller inside, the ends of which fit into loops on each side of the window. The paper is strengthened round the edges with tape, and at its lower edge is glued a thin strip of wood to keep it taut when down. When it is required to pack away the tent, the paper blind is rolled up and taken out.

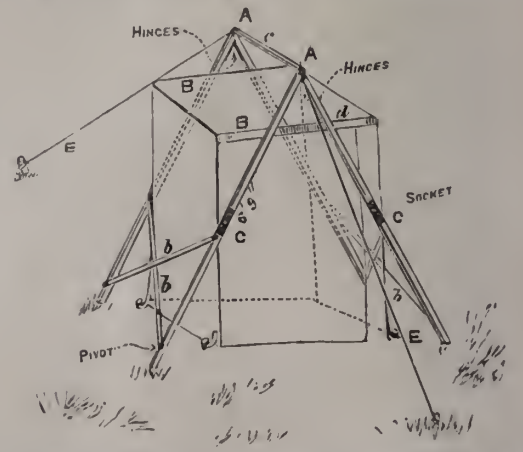
The cords by which the tent is suspended run through from front to back, the tent being, so to speak, slung on them. The curtain rings are threaded on one. The bottom edge of the tent is weighted with shot, and at the four corners are sewn strips of black canvas with eyelet-



A, curtain closing entrance; B, window; *c c c*, wire pins to hold tent down; *d e f g*, cords supporting tent.

holes, through which stout wire pins hold the whole firmly to the ground.

I use my tent indoors or out of doors. It can be suspended from hooks or nails in walls or from trees, or, two sticks being tied across the top from corner to corner, the whole can be suspended from a point overhead. It would, however, be necessary, if hanging from one point only, to steady it by fastening the cords from the four corners to pegs driven in the ground, or to weights, if indoors. I have also devised a stand, but have had no opportunity as yet of getting one made. As in many cases it might prove useful, I annex a sketch.



The stand is hinged at A A. At C C are metal sockets. The cross-ties *b b b* are of brass, pivoted at one end and hooked at the other. At B B laths passing through loops on the outside of the tent-hooks on the stand as shown in small sketch, and hold the tent in position. The cross-piece C fits on two iron pegs at A A, to which also are looped the cords E E, which support the stand laterally. (These are only necessary out of doors in a breeze).

The whole of the stand should fold up into a space of about 3′ 5″ × 0′ 2″.

On the advantages of such a tent I need hardly enlarge. Its portability is, however, its chief point, for when rolled up and fastened with a couple of rug straps, it takes up no

more room than an ordinary overcoat, and can be carried as easily, though when erected it can take the place of an ordinary dark-room for indoor work, for which I generally use it when away from home. A small table and chair can be accommodated inside, if made of the dimensions given,

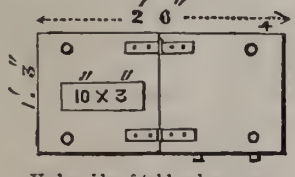
Hook at *d* to hold lath B.

Pin for holding down tent.

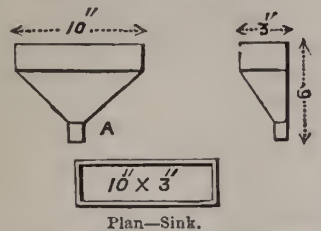
Cross tie *b*.

viz., 5 feet by 3′ 6″ by 2′ 6″. This, if it should not be convenient to carry its own table and fittings with it. As the table is likely to be a new feature in tent work, and the sink is altogether different to the one in common use, I append a short description of them. The rest of the fittings are such as may be found in ordinary use.

The table is 2′ 6″ long by 15″ wide, folding in the middle of its length, and forms, when closed, the top of the box carrying developer, dishes, &c. For this purpose, two pegs at the back fit into corresponding holes in the box, thus obviating hinges, whilst an ordinary lock in front renders it secure when in place. The legs screw in place about 4″ from each end, so as to relieve the hinges of as much weight as possible. The sink is of zinc 10″ by 3″ by 6″, having a rim on the upper edge, and is of the form shown in sketch. An india-rubber tube fits on the nozzle A; it is let in near the middle of the left half of the table, and being simply a slit 3″ wide, it deprives the table of



Under side of table when open.



Plan—Sink.

none of its usefulness when used for other purposes than developing. I have used one for years, and found it a great improvement on the old shallow form. When developing, the tray is placed over it, and when required to be emptied, it is simply drawn back a little and the contents tilted over. No splashing is possible with it. The chemical box forms a seat when turned up on end.

FRENCH CORRESPONDENCE.

Congress of Scientific Societies—The Submarine Soundings Commission—M. Audra's Emulsion and Coating of Plates.

Congress at the Sorbonne.—The usual réunion of all the French scientific and fine art societies was held in Easter week at the Sorbonne. There were no communications presented relating to photography, except two of my own—one, concerning my pocket apparatus, the model of which was completed by M. Français; and the other upon the progress of typography. With regard to the former, the great interest evinced showed that it supplied a great want. Geologists, naturalists, archæologists, physicians, chemists, &c., understand now how desirable it is to have a photographic *vade mecum*, and they appreciated the existence of a veritable pocket camera, the stand formed within an ordinary walking-stick. Of course it is also desirable that such an apparatus should cost as little as possible. For my own part, I affirm that it is always best to pay a good price for an accurate instrument capable of giving really excellent results, and scientific men and artists do not think it money wasted when expended on an instrument required to assist in research or careful observation of nature, and not treated as a child's plaything.

In the Fine Arts Section my paper on typography ought to meet with due appreciation, as the subject treated is not sufficiently familiar to our artists and even our printers. I explained how—thanks to the researches, and their results, of Pettit of Paris, Ives of Philadelphia, Meisenbach of Munich, and Goupil and Co. of Paris—wood engraving was surpassed. Even in those drawings of objects to be engraved the graver's work is useless, for nothing is easier, with the aid of paper and special drawing processes, than to obtain these designs transformed into typographic engravings by the intervention of a chemical engraving process, of a photographic reproduction transferred to copper or zinc coated with bitumen of Judea or bichromated albumen. Wood-engraving will cease to exist when these applications of photography to typography are recognised and are practised with as great a success as by our excellent and clever colleague, Mr. Bolas, in London. He may well say that, in general, great ignorance prevails of most of those processes capable of executing better and cheaper work than by the old methods, the chief merits of which lie in their being old.

Work of the Commission of Submarine Soundings.—The good work of the Commission of Submarine Soundings, presided over by M. Milne Edwards, Junr., was the subject of special mention and praise in the speech of the Minister of Public Instruction. It is a striking fact that, in making explorations at the bottom of the sea, observations relative to light have been entirely omitted. It would have been important to ascertain at what depth luminous rays, visible or invisible, cease to penetrate. It would have been interesting, also, to photograph the sea bottom at such depths as were accessible by special apparatus, and it is to be hoped that further explorations will be made in this direction. It is said to be astonishing what brilliant colours clothe beings living beyond all luminous action; it would be useful to know scientifically what is the submarine depth beyond which physical darkness exists. Moreover, one would like to see reproduced the effects of sea botton with its vegetation; and could it not be possible with the aid of electricity to illuminate these zones so as to observe and photograph at the same time? It would be of interest to obtain visible proofs of depths which, although inaccessible to any human being, would give as faithful a representation as if it resulted from direct observation. No doubt we have all dreamed about it. Meanwhile, I will endeavour to give a general idea as to the lines to be followed necessary for measuring the degree of actinism at various depths, so as to photograph the fauna and flora in their natural abode, which, hitherto, we have only seen in the isolated forms caught in the drag in sounding. With the aid of electricity and the sensitiveness of our apparatus, surely something ought to be effected in this direction without any other difficulty other than that of the immense pressure brought to bear upon the surface of the sensitive film. The main thing to be considered is to ascertain to what maximum depth apparatus capable of resisting the vertical pressure of the column of water can attain. It is altogether a question of calculating the pressure, and, to my mind, a solution must soon be found.

M. Audra's Demonstration of his Emulsion Process.—

M. Audra gave an experimental demonstration of his process in the preparation of gelatino-bromide emulsion, and the method by which the plates were coated, before the members of the Photographic Society of France. This demonstration attracted a large audience, who were delighted with the simplicity of the process and its excellent results, and the clearness with which it was explained It is of great use to many people desirous of knowing how to prepare a good emulsion to make it popular, as M. Audra is, undoubtedly, a great authority on the subject, as instanced by the number of years devoted by him to the study of so interesting a subject to the photographer. Leon Vidal.

Notes.

The Royal Academy has opened to the inspection of those privileged to take a private view, and to-morrow we shall have our newspapers filled with the usual long and tedious descriptions of art in 1884. We must say this much, however, of the present collection at the Burlington House: the pictures, taken all round, appear of a more robust school this year, and there is less of the nursery and the perambulator about them. Chubby babies and short-frocked little girls are very nice—especially on canvas—but we don't want every rising young painter to paint them. Visitors to the Academy lately have seen little else.

Nor is the Academy this year over-done by the namby-pamby school. Mr. Hodgson, R.A., asks us to admire in "Church Afloat" (484) a devout clergyman in a beautiful white surplice, standing in front of a body of open-mouthed sailors and marines, chanting the Psalms, two to a prayer-book; but there is little romance in the scene, for it could only happen in harbour. They do not have rows of thirty-twos on 'tween-decks at sea now-a-days, as Mr. Hodgson will find out if he enquires. Another ambitious picture equally open to the charge of false sentiment is "Mabel's Pensioners" (No. 804). This shows us a collection of decrepit old men who have come to receive the bounty of a priggish little miss of five or six, who presides at a table filled with loaves, and is assisted at her benevolent duties by a trim town maid-servant, who stands respectfully at attention. Can mawkish sentiment be carried further? We presume it was painted for the young lady's papa, who naturally wanted some return for the money that the loaves cost him.

Still, British painters can do one thing well, at any rate—they can paint the sea. We could give our French and German brethren long odds here, and beat them. Let the visitor look at the changing scenes of Mr. Henry Moore (577, 1626), of Mr. J. Brett, A.R.A. (1,574), of Mr. Colin Hunter, A.R.A. (389)—by the way, why is not Mr. H. Moore an Associate by this time?—of Mr. J. Faed (752), of Mr. W. J. Shaw (760), and other of our sea painters, and they will witness a school of art of which we may well feel proud. But of these pictures, as well as the Academy in general, we will speak next week.

The Photographic Society of Ireland announce an Exhibition of Photographs and Photographic Appliances in November next, in Dublin.

A diminutive weekly publication, called the *Nutshell*, has just appeared. It consists wholly and solely of reduced copies of newspaper or magazine articles and illustrations, the ordinary phototype or zinc etching process being doubtless employed for making the reductions. The production of a periodical entirely by photography in this way marks a new era in journalism.

Our readers will be glad to hear that Dr. Vogel has consented to make public the full details of his process for rendering collodion sensitive to various colours. In his communication to these columns three weeks ago, our colleague stated his ability to prepare a film that was many times more sensitive to the yellow than to the blue, and on that occasion he forwarded for our inspection a photograph of various colours, in which the yellow was represented by a light tint, and blue by a comparatively dark tint. This process Dr. Vogel now describes on our first column.

The Berlin Society for Advancement of Photography, over which Dr. Vogel has so ably presided for many years, has decided upon recognizing this act of Dr. Vogel's in a handsome manner. The worthy doctor is to receive a diploma of honour, together with a present of one thousand marks, in recognition of his discovery, which, as a matter of course, was laid before the members of the Society in the first place. We have reason to know that in the brief period that has elapsed since Dr. Vogel communicated the circumstance of his discovery to the press, he received several tempting offers to part with it, one firm alone offering the sum of two hundred pounds for the secret. Obviously, in the reproduction of paintings, a branch of photography that is now exceedingly important, this process of Dr. Vogel's will be of great value.

Those among us who believed the wet collodion process already dead and buried, will experience something of a shock in reading Dr. Vogel's practical details of his new method. Briefly put, he uses bromo-iodized collodion containing a solution of eosine, photographing through yellow glass to humour the yellow rays at the expense of the blue.

M. Gustave Hermite calls attention to a pretty experiment that may be worth trying in an idle half-hour. It is simply to take a landscape photograph on luminous paint in the camera instead of upon a dry plate. Two or three coatings of the luminous paint are applied to a glass plate or metal plate, and this is put into a dark slide and exposed thoroughly on a sunny landscape. The result, M. Hermite says, is very charming, the picture being capable of revival to a certain extent by warmth. By the way, what has become of M. Warnerke's and Captain Darwin's processes of enlarging by means of luminous paint?

M. Scamoni, the chief of the photographic branch of the State Paper Office of St. Petersburgh, will, in all probability, be entrusted with the reproductions of the Hebrew manuscripts of the Old Testament which Dr. Harkary is now

laboriously translating. Photography always renders a most valuable service in connection with antiquities of this description; it permits a hundred students in different countries to study the MS. at the same moment, and this, too, without risk of danger to the original.

On the occasion of the International Exhibition at Zurich last year, some interesting statistics were collected by M. Boissonas, concerning photography and photographers in Switzerland. It appears that last year there were as many as two hundred studios in the Helvetian republic, employing from five to six hundred assistants, and turning over three millions of francs annually. M. Boissonas divides these studios into three classes, and finds that in the first class there are 20 studios, employing from six to ten hands, 50 studios in the second class, with from three to six assistants, while the other studios, between 120 and 130, give employment to less than three persons.

No doubt photography has extended of late years elsewhere in much the same proportion as in Switzerland, and therefore the following facts are of general interest, viz.:—In 1860 there were 46 professional photographers, and few amateurs. In 1870 there were 101 professional photographers, and few amateurs. In 1883 there were 204 professional photographers, and many amateurs.

The combination of photography with the lantern is rapidly growing into favour with amateurs. A correspondent of a contemporary, in a letter on the magic lantern at home, says: "If I chance to get a day out, and have been lucky enough to secure, say, a dozen quarter-plate views, the first thing I do is to make lantern transparencies from them." Towards this end the tricycle will doubtless be made use of.

A propos of amateur photographers, and the ease with which they can now-a-days acquire practical knowledge and obtain practical results, a good many professional photographers are rather alarmed. The rush of amateurs will, they assert, still further encroach upon the narrow field which remains to professional photography. We are inclined to think such fears are groundless. Of course it is possible to take portraits at home, but to do them satisfactorily requires very different apparatus from that which the majority of amateurs employ. The best days of photography were when the amateurs dabbled largely in the art, and the re-wakening of interest in photography, though it may only amount to the taking of photographic "bits," ought to lead ultimately to the benefit of the professional man.

Vanity is the downfall of many a good man, aye, and woman too. A sailor absent from home for some time recently returned to his friends in Brittany, and accounted for his solitary absence by a Robinson Crusoe sort of story. He had been wrecked in the West Indies, and after living as an hermit for many months, was rescued and brought home. The man became a sort of hero, and all went well with him for some time, until, at an unluckly moment, he consented to sit for his portrait, and the pictures got circulated with the story. One of the portraits happened to come into the hands of an astute police officer, and it then turned out that the sailor was right, so far as he had described his life as one of enforced seclusion, but this had been passed in no more romantic locality than a Brest prison.

It will be remembered that Jean Luie, the wonderful witness in the Tichborne case, who gave himself out as the mate of the *Osprey*, came to grief in a similar manner. He also had a plausible account to give of his absence from England, and he, too, having blossomed into an hero, was foolish enough to permit himself to be photographed. The consequence will be recollected; his portrait was recognized by a prison warder as a convict recently in confinement, and Jean Luie was convicted of perjury.

The results of some curious experiments on the bleaching action of solar and electric rays have just been communicated to the Industrial Society of Mulhouse by MM. Depière and Clouet. It would seem that electric as well as solar rays bleach; that the bleaching takes place in air or in vacuum; that the yellow rays are the least active, and the red rays the most active; and that of all artificial lights the electric light has the most bleaching power.

Silver stains on linen or other fabric, most photographers know how to get rid of. Make a solution of iodine (by dissolving a few scales of iodine in iodide of potassium solution), and after rubbing the silver stains with it, immerse the fabric in hyposulphite of soda solution. But other stains are not so readily attacked. Iron stains and ink stains, for instance, are sometimes very obstinate, and an efficient means of removal is always welcome. The following advice is from the *Industrial Record*.

For ink stains, dilute hydrochloric acid, which must subsequently be carefully washed out, will generally be found effectual. For the same purpose oxalic acid or salts of sorrel may also be employed most economically by sprinkling it in fine powder over the stains, which are moistened with boiling water. The action of these solvents may be hastened by gentle rubbing, or, still better, by placing the stained portion of the fabric in contact with metallic tin. If there is much iron rust to be removed, dyer's tin salt (stannous chloride) will perform the work at less expense than the oxalic acid compound. Another solvent for such stains consists of a mixture of two parts argol with one part of powdered alum.

A novelty was introduced into the proceedings at one of Metropolitan Police Courts last week. A charge of cruelty to children was brought against two persons, the important point to be established being alleged starvation. After some evidence was taken the case was adjourned, the children being sent to the workhouse, where they were to be weighed and photographed, so that their present condition might be seen hereafter.

Patent Intelligence.

Applications for Provisional Protection.

6688. Samuel Dunseith McKellen, 18, Brown Street, Manchester, Watch Manufacturer and Jeweller, for "An improvement in cameras for photographic purposes."—Dated 23rd April, 1884.

6743. Norman Macbeth, Victoria Foundry, Bolton, Lancashire, Engineer, for "Improvements in the production of printing surfaces by the aid of photo-reliefs."—Dated 24th April, 1884.

6826. Peter James Charles, 26, Milk Street, Cheapside, London, Warehouseman, for "An improvement in photograph frames."—Dated, 25th April, 1884.

6898. Henry Joseph Redding, 53, Godolphin Road, Shepherd's Bush, London, W., Optician and Photographer, for "The 'Perfection' pocket ruby lantern."—Dated 28th April, 1884.

Specification Published during the Week.

4471. Richard Brown, and Robert William Barnes, and Joseph Bell, all of Liverpool, in the county of Lancaster, for an invention of "Improvements in means for and method of producing designs upon paper or other fibrous or soft material."—Dated 19th September, 1883.

We take a sheet of hard metal such as steel, and we cover the surface of this steel or other hard metal with a coating of what is known to photographers as sensitive bitumen, or with an equivalent composition. We then expose the so prepared steel or other hard metal to light under a photographic negative or positive picture upon which the required design has been obtained in the usual way. The result is that the design is reproduced on the sensitive surface, viz., it is printed by light in the sensitive surface, the action of the light having hardened the exposed portion, while that portion which has been covered or protected by the shades of the picture or design remain soluble. We then take the steel or other hard metal and develop the photograph thereon as usually practised, and wash away the soluble portions. We thus have the steel or other hard metal with the picture or design on its surface. After the picture or design is so developed, namely when the soluble portion has been washed away, we take the steel or other hard metal and etch the exposed parts by suitable acids or chemicals as usually practised in the art of photo etching. This operation causes the picture or design to be engraved, so to speak, on the steel or other hard metal. We then remove the bitumen or other medium from the sheet, and we have the picture or design in relief or in intaglio upon the steel or other hard metal. To produce pictures or designs from half-tone pictures or designs upon the steel or other hard metal, we prepare the negative or positive photograph in a manner such as patented to us on 15th March, 1883, No. 1380, namely, we give the photograph a grained, lined, or hatched surface, which is transmitted with the picture or design, and photo etched upon the steel or other metal. Having thus produced the picture or design upon the steel or other metal plate, either in relief or in intaglio, we pass the steel or other metal plate, in combination with such sheets of paper, leather, metal foil, or the like, as we wish to impress with the water mark effect, or embossed effect, as the case may be, through a pair of, preferably, hard steel rollers, and where large quantities of the subject have to be produced, the steel or other metal plate or sheet, having upon its surface the design, is affixed upon one of the rollers so that the paper, leather, metal foil, or the like may be passed rapidly through, either in single sheets, or from the web or roll. In lieu of applying the pressure by rollers, the pressure can be obtained by a screw or other press, but the process is slower.

Patents Granted in America.

296,913. Auguste Bissen, Paris, France. "Method of colouring photographs."—Filed Jan. 15, 1884. (No specimens.)

Claims.—1. The treatment of the translucent bodies for the reception of photographic impressions, consisting in subjecting them to the action of a bath composed of benzine, resin, and linseed-oil, in or about in the proportions herein specified, substantially as herein described.

2. The improvement in the art of printing photographs in colours, consisting in first obtaining stencil-plates or sheets cut out in the contours of the different colours, next applying said plates or sheets to lithographic stones coated with bichromate, then exposing the said stones and plates or sheets together to the action of the light and pressure under a glass, then removing the sheets and coating from the stones, and afterwards printing from said stones in flat tints, substantially as herein described.

297,017. J. Julius Sachs, Manchester, county of Lancaster, England. "Method of producing roller-surfaces for printing, stamping, or embossing."—Filed July 1, 1880. (No specimens.) Patented in England July 4, 1879, No. 2,724.

Claim.—In the preparation of metal rollers for printing, the improvement consisting in covering the roller with chrome-gelatine, placing around it a curved or flexible pattern adapted to transmit light to certain parts and prevent the transmission to others, exposing the roller to light, and revolving it to present each portion to the light, and removing the soluble portions of the chrome-gelatine coating, substantially as described.

PHOTOGRAPHY IN BRITISH BURMAH.

BY A. W. LONSDALE.

I have no doubt you and your numerous readers will be glad to hear from one who dabbles in the "Black Art," even in so remote a place as Tavoy. Before entering upon matters photographic, I must first of all briefly tell you something about Tavoy and its people. Perhaps some of you have never before heard of the place. It is a charming little town in British Burmah, situated about thirty-five miles from the mouth of the river known by the same name. Large ships and steamers are not able to come up to town, as the river is only navigable to vessels of small draught. The steamer from Rangoon anchors about half-way up the river, and the mails and passengers are brought up by a steam launch. Tavoy has been in the hands of the British for upwards of half a century, during which time it has made rapid strides in civilization. It was founded in 1751, though the country is noticed much earlier. In 1752, the ruler of the country made overtures to the British to establish a factory in or near his capital. During the first Burmese war, the garrison rose against the commander on the appearance of the British at the mouth of the river, and handed the place over to the English, together with the person of the second in command, and his family, whom they had taken prisoners. According to one tradition, the name of this town is a corruption of a Siamese word meaning a "landing-place for rattans," and according to another it was so named because it was celebrated for its armourers, people coming from a long distance to buy swords (*dha* a sword, and *wai* to buy). Which of these two traditions is reliable it is difficult to say. The town is laid out in straight streets, and the houses are for the most part built of timber or bamboos, and thatched with *dhavee* leaves. To the East and West are ranges of hills running nearly North and South. The surrounding land is under rice cultivation, and during the season is rendered swampy by the small embankments raised to retain the raised water on the fields. It contains court-houses, police-stations, a custom-house, post-office, hospital and dispensary, market, a middle school, and a gaol, besides numerous pagodas, monasteries, and zayats or rest-houses. The inhabitants are mostly Burmese, there being only a handful of Europeans and natives of India. The "Heathen Chinee" and the Israelite are also to be met with here. The European residents are principally those in Government employ. There are a few others who are merchants and coffee-planters. The Burmese are, as a rule, an indolent and vain race, very fond of amusements, and so happy-go-lucky are they that some one has deemed it fit to term them "the Irishmen of the East." Photography is greatly appreciated by them, as nothing pleases them better than to admire self, and photography enables them to do that.

Being only an amateur, my practice of the art is confined to leisure hours, and I am, therefore, entirely a "dry plate man."

My outfit consists of a beautifully-made 10 by 8 camera and double dark slides, by Messrs. Wratten and Wainwright, Ross' symmetrical lens, and a portrait combination. I have a "glass-house," which, however, has not a bit of glass in it. It may seem a novel affair to some, but it answers my pur-

pose admirably. I have an opening on one side of the ridge roof, which has a frame-work hinged on to the ridge of the roof, and covered with roofing material. This frame is lifted when the studio is to be used, and it gives me a splendid top light. Screens and curtains are freely made use of. Of course this sort of studio, however well it may suit an amateur like myself, who takes portraits for mere amusement, will not do for a professional, as he will be debarred from working on wet days. Talking about the studio reminds me of an amusing incident which took place in it the other day. A couple of Burmans came in, one of them desiring to be photographed. Having got everything ready, I began to focus the sitter while his friend walked about the studio. His eye caught a glimpse of the picture on the ground-glass, and, being emboldened by a smile from me, he came closer to examine it. You should have seen him! He stared at the picture, and, with a look of astonishment and disgust, he exclaimed, addressing his companion the sitter, "I say, this is not good; look out, you'll come out upside down." You may depend upon it, I turned the Tavoyan philosopher out of the room. After a deal of trouble in explaining and getting the man to sit quietly, I managed to secure a picture. On showing it to him the right side up, he opened his mouth wide, and said in his tongue, "Tay koung-dai!" ("Very good!")

Now a few words with regard to developers. The ferrous oxalate is in great favour with me here. The alkaline developer, strange to say, does not at all answer in this climate. I have tried Mr. Newton's carbonate of soda developer. I don't approve of it, as it tends to frilling. The plates, which had never frilled before, did so under its influence. I have adopted M. Audra's method of preserving the iron solution. It is a first-rate idea, and every photographer using the iron developer who has as yet not tried this, should do so without delay. Tavoy abounds in beautiful sceneries. I hope to take a photographic tour round the country some day.

Before concluding, I must make it a point to say that your valuable News finds its way here to me. It is my photographic companion and guide.

Goot School House, Tavoy, B.B., 10th March, 1884.

ON LENSES.

BY W. E. DEBENHAM.*

When, in January 1839, Daguerre in France, and Fox Talbot in England, announced that they had succeeded in fixing the image of the camera, that instrument at once acquired an importance that could not otherwise have belonged to it. The lens with which it was furnished, although considered sufficient for a toy, or for occasional use to assist a draughtsman, had several characteristics which made its work as an instrument for the photographer very inferior to what a scientifically-designed instrument would give. Taking an ordinary double convex lens (say) of two inches diameter, and twelve inches focus, the following four faults had to be corrected:—1. Difference of the chemical and visual foci, necessitating an alteration or adjustment of the position of the plate, varying in amount with the distance of the object to be photographed, after each focussing. 2. Spherical aberration, in consequence of which the image was more or less confused, and wanting in sharpness everywhere. 3. Curvature of the field, in consequence of which objects at equal distances, but upon different portions of the field, would be out of focus unless the plate were cup-shaped instead of flat. 4. Slowness of action.

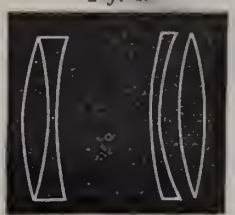
The difference of chemical and visual foci could be corrected upon the lines already laid down. Daguerre himself, indeed, used an achromatised lens, but in England some of the earliest cameras were made for uncorrected lenses, and had graduations marked upon them for adjustment after focussing. The second mentioned fault—spherical aberration—was the most important, and the discovery of the remedy for this involved the cure of the fourth defect, or that of slowness of action; because spherical aberration increases with the aperture of the lens—that is, with the proportion of the size of the lens to its focal length—so that a lens which was scarcely tolerable in its definition could not afford to have its rapidity increased by making it of larger aperture.

The want of a suitable lens being perceived, opticians and mathematicians in several countries set to work to try and cure the evils above-mentioned. One of these—Professor J. Petzval, of Vienna—succeeded in calculating the formula for an instrument which has always, and justly, been considered a triumph of mathematical science. So complete did it come into the world, that in more than forty years it is questionable whether any very important improvement or modification has been made upon it. This Petzval lens is the well-known portrait combination, which, with some differences of detail amongst themselves, has been made by photographic opticians in all parts of the world. The essential and most striking characteristic of this lens is the elimination of spherical aberration, and the means by which this is achieved is particularly, the separation of the components of the back combination. This separation allows the flint negative lens to possess so much negative spherical aberration as to correct the positive aberration of the whole system; and so perfectly is this accomplished, that it was possible to have the lens much larger in proportion to its focal length—quicker acting, that is—and, at the same time, give far finer definition than could be obtained with the then existing lenses, unless a very small stop had been used. The focus, at the same time, was somewhat lengthened towards the margins, so that the field although not flat, was yet of a flatter curve, and did not for some distance on each side of the axis depart far from the flat plate.

By tolerating a certain amount of astigmatism it is possible to make the field of the lens flatter, and the amount of sacrifice that should be made of possible marginal definition to flatness of field, is a question upon which opticians have differed. I have said "possible marginal definition," meaning the definition that can be obtained towards the margin of the field if that part only be focussed; but in doing this with a lens of round field the centre of the picture must be thrown much out of focus, or the subject to be photographed must be arranged in a deep curve. When this is done, owing to the violence of the perspective, all but the middle of the picture will appear exaggerated in size; and this effect is to be condemned, whether in the side figures of a group, or, as it has sometimes been put forward in favour of a lens of round field, the advancing knees and hands of a sitting figure.

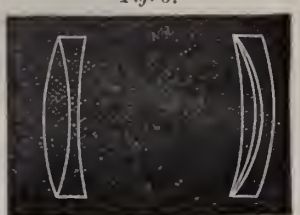
In some French portrait lenses of recent make, considerable flatness of field has been attained. The absolute definition has had to be a little sacrificed, but I think this sacrifice well worth making.

Fig. 4.



Portrait Lens—Petzval's Orignal.

Fig. 5.



Portrait Lens—Dallmeyer's Modification.

In the year 1866, the late Mr. J. H. Dallmeyer patented a variation of the Petzval lens. This variation consisted in reversing the elements of the back combination with such a modification of the curves as this change involves. The particular advantage claimed at the time for this form of lens has since been abandoned. The putting of the negative lens at the back allowed its distance from the positive element to be varied, and thus the perfection of its correction for spherical aberration to be modified. It was stated that by altering the distance of the back lens, so as to re-introduce spherical aberration, and sacrifice definition at the focus, improved definition was obtained upon the planes not in focus. This claim—"diffusion of focus" it was called—was shown to be mistaken, and is no longer made. The lens, however, when employed with the elements in the position of best definition, is a useful one, and some other well-known opticians have for some time past issued a series of lenses of this form. In this case, however, the back lenses are burnished together into their cell, and no shifting or alteration of their position is possible.

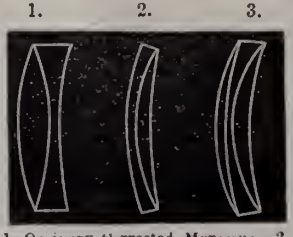
While on the subject of "diffusion" or "depth" of focus, it may be remarked that a delusion on this point is cherished by a vast number of photographers. For this the manufacturing opticians are somewhat to blame. They have been in the habit

* Continued from page 263.

of advertising lenses as having great "depth of focus," whereas that is a quality that, except as attained by the use of a small aperture or diaphragm involving slowness of action, does not exist at all. Still many photographers—careful, practical men, too, some of them—will tell you that they have, or have had, some particular portrait lens that will give the various parts of a sitter's head, the background behind him, and generally objects on different planes, with sharper definition than other lenses of similar aperture and focus, that have as fine, or finer definition on any one plane. This is a curious case of mistaken observation; but in photography, unfortunately, mistaken observations may pass current as scientific facts.

Before passing on to the consideration of other lenses, it may be observed that some discussion has taken place as to what is entitled to be called a portrait lens. It is probable that portraits have, at some time or other, been taken by all the kinds of photographic lenses in existence. I have myself had in regular use a single lens for panel portraits, and a lens of the rapid doublet, or Steinheil type, for promenades; but as the name "portrait lens" has been accepted as the distinguishing title for the Petzval instrument first described, and as the most striking characteristic of that instrument is, that it will give good definition when used with an aperture of one-fourth of its focal length, or even more, it would, perhaps, be best to retain the name portrait lens for a lens constructed on such principles that it may be made to work with that aperture.

Of single lenses there are three distinctly-marked varieties. The first is the ordinary corrected meniscus. This is the well-known single landscape lens. The two faults in it are, that a small diaphragm is necessary in order to correct its spherical aberration, and give good definition, and that it gives distortion. To correct to a certain extent the first of these evils, Mr. T. Grubb, in 1857, introduced what he called his aplanatic lens. It is not aplanatic, but the method of correction he employed—placing the negative lens at the convex side—mitigated spherical aberration to such an extent that he thought it entitled to be called "aplanatic" in comparison with the ordinary single lens. It may, therefore, be worked with a larger opening. The panel portraits now shown were, with one exception, taken with this instrument.



Single Lenses.—1. Ordinary Corrected Meniscus.—2. Grubb's "Aplanatic."—3. Dallmeyer's Single Lens.

Dallmeyer's single lens consisted, like some of Dollond's telescope objectives, of a negative lens between two positive ones; but the curves are, of course, quite different, being calculated for marginal definition and flatness of field.

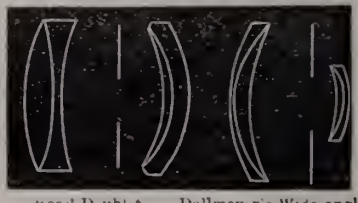
The so called "orthoscopic lens,' introduced in 1857, was constructed from calculations made by Petzval at the same time that he was engaged upon the portrait lens. The front part is identical with that of the portrait lens; but the back consists of a dispersing lens, so that the whole instrument is longer in focus than the front part alone. It was a curious misnomer to call it "orthoscopic," seeing that it necessarily gives distortion, although

Petzval's Orthoscope.

from the diaphragm being at the back, this distortion is in the contrary direction from that given by the single lens. There were some good points about the instrument, and it is quite possible that if it had been introduced since the advent of the rapid gelatino-bromide process, it would have found more favour, especially for large portraits, than it has done. I should not be at all surprised to see it, or something modelled upon it, come into use. Sufficient care was not always taken to make the correction for actinic rays perfect. In one that I possessed, it was necessary to shift the camera back nearly half-an-inch, but when this was done, a very good portrait might, in a quick light, be taken even with collodion.

Triplet lenses were introduced in two ways; one was as an instrument for obtaining architectural views without distortion, and another was an adaptation, to the portrait lens, of a concave glass in the place of the diaphragm, for the purpose of lengthening the focus and flattening the field. Slater, in 1858, I think, made instruments of this kind for sale. As an occasional expedient a similar device had long previously been employed. Derogy made many of such instruments, one of which is on the table. Triplets have now been generally superseded by doublets.

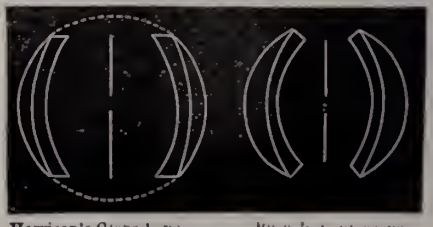
To obviate the distortion caused by the single lens many double combinations have been devised. In these, the diaphragm being placed between the lenses, the distortion caused by one lens is counteracted by distortion in the contrary direction produced by the other lens. The first of these to come into any general use was the globe lens of Harrison, brought out in 1860. This supplied such a much-felt want—that of a lens of wide angle without distortion—that it was much used; but the exact globe form was found to favour the formation of a patch of reflected light in the picture called a "flare" spot. Some five years later Ross introduced a lens which achieved great popularity, and was really so useful an instrument that it deserves some special mention. The front lens was a meniscus corrected in the usual manner, but the back lens had, like the Grubb single lens, the negative lens outwards. A description of a doublet with a back lens of this character, made by A. Ross, was published as long ago as 1846. The instrument had a wide angle of light; but this could be made even wider by setting the lenses a little closer together, as has been done in the case of the instrument now shown, and this, so far as I have been able to ascertain, without in any way injuring its definition. The great angle of light admitted, permits of the lens being used even for tall buildings by raising the camera front without tilting the back, and I think it is to be regretted that it is no longer manufactured. They appear



Ross' Doublet. Dallmeyer's Wide-angle Rectilinear.

to be well appreciated, as I notice that when any are in the hands of the dealers they are marked at good prices. Dallmeyer's wide-angle rectilinear is a doublet which, constructed on different principles, works very similarly.

Busch's pantoscope is a lens partaking of some of the characteristics of the three last mentioned lenses. It has a very wide angle



Harrison's Globe Lens. Busch's Pantoscope.

and is a very useful instrument. It differs from the globe lens in that the exterior surfaces do not form part of one sphere. I have not found "flare" when using it. A lens that I have not had the opportunity of examining is a doublet by Morrison, of New York. An excellent judge, however, Mr. Traill Taylor, gives a favourable account of it. The striking peculiarity of this instrument is that one of the elements, the backone, is single, all the correction being performed by a flint in the front combination. Some eighteen or twenty years since I constructed an experimental lens, the front of which was a single meniscus, and the back was an objective out of an opera-glass, altered by having the concave side ground deeper. This lens gave an enormously wide field, but required the use of a very small diaphragm.

Before proceeding to the consideration of the more modern

doublets, it is worth while to notice two which I believe have one out of manufacture. These are the periskop of Steinheil and the Zentmayer lens. Their particular interest consists in the fact that, being constructed of uncorrected crown lenses only, something similar to them can easily be improvised. Steinheil's

Steinheil's Periscope.

periskop consisted of two similar meniscus crown lenses placed near with a small diaphragm between them. After focussing, the camera back had to be brought nearer to the lens by $\frac{1}{40}$ of the focal distance. The field was very flat, and the angle included large. Zentmayer's lens was constructed on similar principles, but was furnished with two diaphragms, the larger of which was to be used for "convenience of light" in focussing, and the smaller one for the exposure. It was introduced as a lens not requiring correction, although made of one medium crown glass only; but this paradox was only apparent, not real.

On looking at the diagram of spherical aberration (fig. 2), it will be seen that the general approximate focus of a lens with large aperture is shorter than the focus of the same instrument when used with a small diaphragm. Zentmayer's lens had great spherical aberration, and it was, therefore, only necessary to make the focussing and exposure diaphragms of such sizes, as to alter the focus in the same proportion as the chemical focus was shorter than the optical one. I have here a lens that I had constructed some years previous to the Zentmayer being brought out, when I was desirous of photographing subjects occupying a wider angle than I could do with the lenses then to be purchased. The radii are about as six for the convex and seven for the concave surfaces, and the distance of the lenses apart as four. If the lenses are of large diameter in proportion to the focus, an enormous angle of view can be obtained.

This is the lens which within the last week your Secretary, Mr. J. J. Briginshaw, has had for the purpose of photographing a tall building in the city which he could not with an ordinary lens do, on account of there not being space to retire with the camera. He had brought the negative with him, and you will be able to judge of the occasional usefulness of such an instrument. The camera was used level, and the front much raised. From the point opposite to the lens five inches can be measured to the corner of the plate. This gives a circle of ten inches. The focus of the lens is about three and a-half inches. The back was not altered after focussing, the correction, as with Zentmayer's lens, being made by the insertion of the diaphragm.

(To be continued.)

A Dictionary of Photography.

ALDEHYDE.—Ordinary, or acetic-aldehyde, is a typical example of the aldehyde series. It forms a volatile liquid, which corresponds to the formula C_2H_4O, differing from ordinary alcohol (C_2H_6O) by containing two atoms of hydrogen less. Hence its name. Aldehyde is generally formed by the partial oxidation of alcohol, as, for example, when it is exposed to the action of spongy platinum and air, nitric acid, or chromic acid. Aldehyde is almost always present in an old nitrate bath which has been used for wet collodion work, and some commercial samples of acetic acid contain traces of it.

As aldehyde is a very powerful reducing or deoxidising agent, its accidental presence in photographic solutions may do much mischief, causing stains of reduced silver. Its odour is very characteristic, and resembles that of *sweet spirits of nitre*, of which liquid it forms a considerable proportion. Boiling, or exposure in an open dish to the heat and light of the sun, will serve to remove aldehyde from the bath, and when it is present in acetic acid, the best plan is to reject the sample, as unless the acid be neutralized with an alkali, aldehyde in acetic acid cannot be easily detected by its odour.

As aldehyde is an energetic reducer of silver salts, it may receive important applications in photography. It has been used for improving the tone of collodion transparencies, it being possible that it acts by completing the reduction of the silver. Acetic acid is formed by the oxidation of aldehyde.

ALKALIES.—Basic substances which are freely soluble in water are commonly called alkalies, as these bodies possess in a high degree the properties called alkaline. The important alkalies are potash, soda, and ammonia, while such as lithia are of little interest excepting from a scientific point of view. Some notion as to the chemical interrelation of alkalies, acids, and salts, may be gathered from a study of our article on "Acids, Bases, and Salts" (p. 460 vol. xxvii), but we may mention here that red litmus paper is a rough and ready test for alkalinity, alkaline substances changing the red colour to blue, while acid substances change the colour of blue litmus paper to red.

ALKALINE DEVELOPMENT.—*See* **Development.**

ALLOTROPISM (*ἄλλος*, another; *τρόπος*, a fashion) —It not unfrequently happens that one and the same body may exist in several distinct forms, and the rarer or unusual forms are said to be allotropic modifications of the substance. Thus carbon, which is ordinarily met with as charcoal or coke, exists in the allotropic forms of graphite and diamond. Light and heat often cause bodies to assume allotropic conditions.

ALTERNATIVE ACTION OF LIGHT.—*See* **Reversed Action of Light.**

ALUM.—The term alum is applied to a class of double salts which are analogous in chemical structure with common alum. Ordinary alum is a double sulphate of aluminium and potassium which contains $Al_2(SO_4)_3,K_2SO_4+24H_2O$, and which has been known from very ancient times. It has a specific gravity of 1·726, and is soluble in about eighteen times its weight of cold water, and in less than its own weight to hot water. It re-acts like an acid on litmus paper, and its solution slowly dissolves iron or zinc, hydrogen being evolved. If heated to about 200° C., its water of crystallization is driven off, and a spongy mass known as burnt alum remains. The so-called "patent alum" is a crude sulphate of aluminium; and ammonium alum (common alum in which ammonium takes the place of potassium) is often sold in the shops as ordinary alum. The property of alum which is of most interest to the photographer is its power of hardening gelatine and rendering it more or less insoluble, and alum consequently finds applications in many photo-mechanical processes and in gelatino-bromide work.

The subjoined table gives the composition of a few of the alums, the common or potassium alum taking the first place as the prototype:—

Potassium alum ...	$K_2Al_24SO_4.24OH_2$ or $Al_2(SO_4)_3,K_2SO_4+24H_2O$
Sodium alum ...	$Na_2Al_24SO_4.24OH_2$
Ammonium alum...	$(NH_4)_2Al_24SO_4.24OH_2$
Iron alum... ...	$...K_2Fe_24SO_4.24OH_2$
Chromium alum ...	$...K_2Cr_24SO_4.24OH_2$
Manganese alum...	$K_2Mn_24SO_4.24OH_2$

The only rarer alum which need be mentioned is chrome alum, a salt now made on a considerable scale for use by the dyer and calico printer. Its action in making gelatine insoluble is far more energetic than that of ordinary alum, and as a smaller quantity suffices, is often to be preferred. It must, however, be remembered, that chrome alum communicates a faint greenish colour to gelatine, while ordinary alum does not tint it.

AMBER.—A fossil substance, which has many of the characters of a resin, but sulphur appears to be an essential constituent of it. It is a light yellow transparent substance, of a slightly greater density than water. It has the property of becoming very electrical by friction. Amber consists of a mixture of several resinous bodies. It has been used in photography for the purpose of preparing a varnish for negatives.

Amber varnish is prepared by putting one part of finely-powdered amber, and one part of clean-washed sand, into a bottle with eight parts of chloroform; allow it to stand for some days, shaking occasionally; strain through muslin, and squeeze the liquid from the interstices of the spongy residue of the amber and the sand; then filter through bibulous paper. The best place to procure good amber is at large tobacconists, or meerschaum importers; broken mouthpieces of pipes and scraps may be procured there of any desired purity, and at a low rate.

AMBROTYPE.—A name given in America to positives on glass, or other transparent medium, in which the whites are composed of the metallic deposit, and the dark parts are obtained by placing black varnish, or other black substance, behind the picture.

Correspondence.

PRINTING PROCESS FOR INDIA.

Sir,—"Assam" may find argentic gelatino-bromide suit him. I tried the paper (imported from England) successfully in India, but did not like the tone of the prints. I believe this objection has been overcome. Biela.

PS.—The paper must be kept in a perfectly air-tight case.

EDER'S POTASH DEVELOPER.

Sir,—I have lately been trying Eder's pyro potash developer. It certainly takes longer than the ordinary pyrogallol developer; and though all the details come out, does it not require a longer exposure for the plate? Although in all cases I used about 60 minims of each solution to the 3 ounces, and then added more pyrogallol, still there was a want of the contrast and brilliancy I obtained with the usual developer.

If once the details are all out, what proportion of the pyro solution can one add without harm in order to secure density and contrast?—Yours obediently, A. G. B.

THE PROPOSED AMALGAMATION OF THE LONDON PHOTOGRAPHIC ASSOCIATIONS.

Sir,—I trust it will not be considered unseemly to reopen this question. A certain section of the photographic community is smarting beneath a sad bereavement, and are now left, so to speak, like sheep without a shepherd. I apprehend the present is an opportune moment for again referring to the subject.

It is now more than twelve months, if I mistake not, since Captain Abney first set this ball "a-rolling," but if it received a kick at all, it must have been the reverse way, for nothing of a practical nature seems to have come of it. Very few, I imagine, could be found amongst photographers who are prepared to argue against the desirability of a greater concentration of forces than now exists, for it must be admitted that at present there is a great loss of power, owing to defective organization. A proof in favour of this idea may be found in the fact that a great many of the leading photographers in this, the leading city of the world, either hold themselves entirely aloof from the societies, or, what is even worse, pay the regulation fees, and take no further interest in the matter. I am convinced that a vastly improved condition of affairs would soon be brought about if photographers, either individually, or in their collective capacity in connection with the different societies which already exist, would only band themselves together with the idea of obtaining a house of their own, which should be worthy of the associated societies, rather than be at the mercy of the proprietor of this or that hotel, wherever it may have pleased improvidence to lead them. I am not in the least degree in favour of discarding the social element from our midst, for, like the cement used in the construction of a building, it is that which keeps societies together; but I fail to see why the money which is now expended in that direction should not be employed to a much greater extent, than now, in contributing to our mental edification and social enjoyment. There are many points of detail which would have to be discussed before anything like decided action could be taken in amalgamating the London associations. —I remain, yours, &c., William Cobb.

Proceedings of Societies.

London and Provincial Photographic Association.

A meeting of this Society was held on Thursday, the 24th ult., Mr. A. Cowan in the chair.

Mr. A. Mackie enquired whether, by separating the components of a lens to improve definition, the achromatism would be affected?

Mr. W. E. Debenham said it would, to some extent.

Mr. Haddon mentioned that telescopes giving imperfect definition are sometimes much improved by separating the lenses.

Mr. J. Barker desired to know what would be the effect of increasing or decreasing the distance between the front and back lenses in any combination?

Mr. Debenham replied that the focus would be altered.

Mr. Haddon enquired whether it was possible to permanently deform a lens by keeping it tightly screwed up for some time? A friend who returned a faulty lens to the maker was informed that the lens had been spoilt in the way mentioned.

Mr. W. K. Burton said glass was too elastic to admit of this supposition. Referring to French lenses mentioned by Mr. Barker, he said it very often happened that the lenses forming the back combination were only adjusted approximately, which might or might not give the best result; many of these lenses could be vastly improved by separating them 1-16th of an inch.

The Chairman passed round a series of negatives taken with four of the eighteen combinations of Darlot's set; also a series of the same subjects taken with English lenses of similar focus and aperture. The Darlot series were not inferior to the others, whereas the same number of combinations from English lenses were very costly. Perhaps Mr. Burton would work out a table for the Darlot combinations, permitting the various foci in millimetres being compared with the universal system in inches.

Mr. Burton had just compiled a table which would answer the purpose, the diameters being in vertical lines, and the focal lengths in horizontal. It would be published in a few days.

The Chairman exhibited a book made to hold twelve plates (page 270); when closed in the two outer cases, it was under two inches in thickness. The following question from the box was then discussed:—"Will an emulsion giving 20 on the sensitometer, when mixed with another emulsion less sensitive, give a mean between the two?"

The Chairman had mixed an ammonia emulsion giving 19 on the sensitometer, with a boiled emulsion registering 8 or 9, and failed to get a mean result. The slow particles in the latter would not be acted on by light. Mixing emulsions varying only one or two degrees would not make much difference in speed.

Mr. Burton knew one commercial plate maker whose practice was to add a boiled and ammonia emulsion together to get quality and speed combined.

Mr. A. L. Henderson saw no advantage in the mixture except to prevent halation; harmony of tone could not be obtained in that way.

Mr. Moule showed an old form of bijou field camera holding fifty $1\frac{1}{4}$-inch plates, the drum in which the grooves were arranged being attached to an opera glass.

Mr. W. M. Ashman passed round several pieces of Messrs. Law and Son's new golden fabric together with green oil silk as recommended by Mr. Debenham. He exposed a plate giving 22 on the sensitometer one minute to the gaslight from a large fishtail burner passed through three thicknesses of the fabric and two of oil silk, the distance being two feet; there was no trace of fog. Four thicknesses of fabric alone gave more illumination and no fog.

Mr. Mackie had developed a rapid plate for ten minutes two feet from the light emitted from a candle covered with one thickness of the golden fabric; the illumination was excellent and the shadows were not fogged.

Mr. F. M. Hart developed plates 24 on the sensitometer with two thicknesses of orange paper illuminated by a candle, and there was no fog; he saw no advantage in any of the recent recommendations over the common orange paper.

Mr. W. H. Prestwich spoke in favour of red cherry fabric. If diffused, not direct, light were used, plates might be exposed an hour to its influence without harm, there being enough light in his own room to read in any part of it.

Mr. J. Stewart (Helensborough) used the orange paper two ply in his coating-room. The lamp was fixed in the ceiling similar to the lamps in railway carriages; the light passed through orange paper on to a white ceiling, and thus illuminated the room.

A discussion then ensued on the sensitiveness of a bromoiodide collodion film after development, opinions varying widely.

Mr. Henderson said that about 1857 he sent some transparencies to the Editor of the Photographic News, which were taken direct in the camera. In reply to queries, he said

they were partly developed, then exposed to white light (it was no consequence whether the films were washed or not), they were flooded with iodine in iodide of potasium, redeveloped with acid pyro and silver, and cleared with cyanide.

The Chairman said the members would be grieved to hear the loss photographers had sustained in the death of the President of the South London Photographic Society, the Rev. F. F. Statham.

Upon the motion of Mr. W. M. Ayres, seconded by Mr. A. L. Henderson, it was resolved to forward a letter of condolence to the family.

Liverpool Amateur Photographic Association.

The ordinary meeting of this Society was held at the Free Library, on Thursday, the 24th ultimo, Dr. Kenyon, President, in the chair.

The minutes of the March meeting were read and confirmed, and Mr. C. Hairis was elected a member.

The Chairman announced the donation of two lantern slides for the library, and eight prints of views near Settle for the album, from Mr. Watts. He (the Chairman) stated that with reference to a passage in his introductory address suggestiug the desirability of a dark slide made with the shutter to open inside the camera—in place of the usual drawn-out shutter, which was too familiar in commerce—he had received a letter from Mr. S. Sidey, of London, stating that he had constructed two such slides about three years ago, never having seen or heard of one before; he had used them ever since, and offered to send one for the Society to examine. The Chairman gladly accepted the offer, and had the pleasure of exhibiting the slide. The mechanism, it would be observed, was beautifully simple aud most ingenious. A slide of this kind would be most useful in instantaneous work, and wherever it was desirable to have the camera as inconspicuous as possible. The shutter exhibited was lighter and more compact than the ordinary form. Its use presented less leverage to the wind and less chance of admission of light during exposure. The plate was uncovered far more easily than by drawing a shutter. A rigid camera might be carried ready focussed, and with slide exposure readily effected without anyone knowing what was going on. He (the Chairman) proposed a cordial vote of thanks to Mr. Sidey for his kindness in sending this interesting exhibit.

Mr. J. Thomson exhibited and explained a new stand of his invention. The main features of this new staud consisted of stays for the purpose of steadying a large camera, and a very ingenious compass-swing arrangement for instantaneous work at sea, enabling pictures to be taken when the rolling and pitching of the vessel would otherwise render photography impossible.

Mr. H. N. Atkins recounted his last bank-holiday experience, when he found an excellent substitute for a focussiug-glass in a film of gelatine which had had some milk added to it before it had set.

The Rev. H. J. Palmer corroborated Mr. Atkins' experience, and said that five ago he had read a paper in that room recommending the gelatine-milk film as a substitute for ground glass.

Mr. Cornish exhibited a stand, each leg of which is composed of a ribbon of steel, which is rolled and extended on the principle of a paper spill-lighter. Indeed, each leg is one of the "portable walking sticks" such as may be purchased at the bazaars in Paris. In answer to numerous questions, Mr. Cornish stated that it took from five to ten minutes to put up.

The Chairman showed and described a new camera by Hare, which contained several novel features, and had been made especially for the tricycle.

Mr. J. H. Ellerbeck opened the discussion upon the subject appointed for the evening, namely, "The Best Mode of Developing Instantaneous Negatives." He thought that among the essentials for success in this department of photography were slow development and the use of less pyro than usual.

Mr. R. Crowe said that there were three classes of instantaneous subjects:—1. Open sea pictures with but little contrast. 2. Street views. 3. Lake scenes, and subjects with deep shadows. His formula for instantaneous work was one ounce of ammonia to two ounces of water, with sixty grains of bromide of potassium. For pictures in class 1 he would use a double quantity of pyro and double bromide, in order to increase the contrasts. For class 2 three grains of pyro to the ounce, and the usual proportion of bromide. For class 3 less pyro than usual, care being taken not to force development and so produce fog.

The Chairman asked Mr. Crowe the lens and aperture with which he usually worked.

Mr. Crowe replied that he used a Steinheil lens of eight and a-half inches focus, and an aperture of $\frac{f}{8}$.

Mr. W. H. Kirkby asked for further detail as to development.

Mr. Crowe said that the plate should be placed in pyro. solution first, and then the ammonia and bromide added, twenty drops at once, and as soon as discolouration took place developing should be stopped.

Mr. Ellerbeck recommended keeping bromide and ammonia solution in separate bottles. By using bromide and pyro. first, and then adding ammonia, there would be greater likelihood of clean pictures.

Mr. Kirkby preferred to begin developing with plain pyro., and then to add ammonium and bromide.

The Rev. H. J. Palmer invariably gave a preliminary soaking in very weak solution of bromide of potassium.

Mr. Watts, on the other hand, strongly advocated first soaking in water with a few drops of ammonium, and then adding pyro. and bromide.

The Hon. Secretary suggested that as the discussion was an important one, it should be deferred to the May meeting, and be opened by Mr. Watts.

Mr. Ellerbeck showed some prints from negatives recently taken at Hawarden.

The Rev. H. J. Palmer produced an excellent developing lamp made from a Chinese lantern, and rendered non-actinic by ruby varnish.

After the usual votes of thanks to the exhibitors had been accorded, the meeting was adjourned.

Edinburgh Photographic Society.

"Round the World with a Camera" formed the subject of the Society's third lantern exhibition, which took place on the 17th inst., in Queen Street Hall.

Andrew Pringle, Esq., who lately returned from a tour round the world, delivered the lecture, which was of a more than usually interestiug chuacter, as Mr. Pringle spoke from the results of his own experience.

The views exhibited were derived from negatives taken by Mr. Pringle in the various countries through which he travelled. As the transparencies were of a very high order, the views, illustrating so many lands, were put on the screen in the most efficient manner.

The frequent applause of the audience sufficieutly testified their complete satisfaction.

A vote of thanks was awarded Mr. Pringle for his lecture and admirable illustrations.

Talk in the Studio.

A Trip to the Great Sahara.—The *Echo* says:—"In these days of making minor trips of the 'Round the World in Eighty Days' type, it may interest some people to know that they may leave Charing Cross on a Monday morning and reach Africa on Wednesday night. Warm work this, aud pleasantly warm in such a season as we are having. For, according to a little work just published, 'To the Great Sahara with a Camera,' it is a very easy matter to leave our East winds and sunless shores, and reach the land of sand aud sunshine, where Arabs are clothed in white, and camels cast long shadows as they stalk. The little work is very amusing, besides being useful for the information it affords to those of tourist incliuation."

Alleged Piracy.—Summonses were yesterday applied for and obtained at Wandsworth Police Court against the Rev. John Erskine Clarke, the registered proprietor of *Church Bells*, for a piracy of the registered photograph by Mr. H. W. Taut, of Newbury Church. The case will be tried on Wednesday next week at 3 o'clock p.m.

Mr. Statham's Funeral.—On Saturday afternoon the funeral of the Rev. Francis F. Statham, B.A., F.R.G.S., F.G.S., rector of St. Peter's, Walworth, took place at Norwood Cemetery. The first portion of the service was performed at St. Peter's, to which the body of the deceased was borne from the rectory, and placed in front of the altar. At least 1,000 persons lined the approach to the church, and an immense assembly of parishioners filled every available part of the church itself. The Rev. S. P. H. Statham, army chaplain at Aldershot, assisted by the Rev. Sherrard Statham, of Birmingham, both sons of the deceased, officiated at St. Peter's and at the cemetery, a number of the local clergy and

Nonconformist ministers also being present. The funeral procession, consisting of a car and five mourning coaches, was accompanied by the 4th Volunteer Battalion of the West Surrey Regiment, 400 strong, with its three bands, the drums being muffled, and a detachment of the P Division of Police, the deceased having been chaplain to both. The coffin was covered with the union jack, and surmounted with the deceased's helmet and Bible. Signs of mourning and marks of respect were general in the immediate neighbourhood of the church, and the traffic had to be suspended for a time until the procession got away. At the cemetery the deceased was buried with military honours, the firing party, under Colonel A. W. Ray, being very large. A large number of photographers were present, and wreaths were sent by the South London Society and the Photographic Club.

Royal Cornwall Polytechnic Society.—Tuesday, the 12th of August, is the day fixed for opening the next exhibition. It will be held, as usual, in the Polytechnic Hall at Falmouth. Medals and prizes are offered for noaelties in photography, and full particulars can be obtained by application to the Secretary at the Polytechnic Hall, Falmouth, or to Mr. W. Brooks, Wray Park, Reigate.

Photographic Club.—On May 7th, the subject for discussion will be on "The Colour of Negatives as affecting the Positive Print."

To Correspondents.

*** We cannot undertake to return rejected communications.

D. H. Cussons and Co.—As we have not published "a paragraph drawing attention to some literary piracies," we can scarcely insert a letter which implies that we have done so.

W. B. C.—(Dublin).—If the washing is done with clean water they will be quite as good; but if the water should contain traces of insoluble matters in suspension, there will be rather more tendency towards surface stains than if the plates were prepared in the usual manner.

Ad. Eoois.—1. The apparatus you send is, as you say, not sufficiently well made for actual work, and as regards general design it resembles several which have been proposed, and more especially the camera which Mr. Woodbury proposed for use in conjunction with a captive balloon. 2. A small doublet would answer very well. 3. We hardly think it would answer your purpose to patent it, as it would be difficult to specify any definite point of originality; but you might register the general design.

G. A. Breithaupt.—1. It may be an advantage to use a weaker sensitizing bath, but if, as you say, the albumen has become rotten and decomposed, the paper should be rejected.

G. Pendry.—1. It is extremely probable that either you do not make your transparencies sufficiently vigorous in the first instance, or that the substitution process is not carried on far enough. Try to build up a heavier deposit of silver in the first instance. 2. We believe that it has not been published in full detail. 3. You will find drawings and descriptions of suitable furnaces on page 242 of our volume for 1882, and in the Year-Book for 1883.

John Hodda.—There is no single hand-book embodying that which you require, but you will find all the information as to recent progress in the last four volumes of the Photographic News, and a sufficient epitome of the matter will be found in the Year-Books. You may perhaps obtain these by advertising for them.

G. F. Webber.—1. We have no doubt that the firm referred to will readily examine the objective, and inform you if it is a genuine instrument. If it is a forgery, your friend should demand a return of his money from the auctioneers—that is, if the objective was catalogued and sold as being by the makers you mention. An auctioneer does not guarantee his goods, neither is he responsible for their condition; but as the firm you refer to makes a special feature of selling optical goods, the usual clause in the conditions of sale should not protect them in case of a forged lens, or a fraudulent imitation of a lens. If a lens is offered as being by ——— and Co., and it proves not to be such, it is a distinct and entirely different article. Should any difficulty arise, we shall be pleased to assist you, as we have recently taken an active part in suppressing the growing trade in spurious lenses. Under any circumstances, let us know how you get on.

Alfred Hay.—It would please us to be able to assist you or any other reader, but we do not know of any situation vacant just now. Perhaps if you were to advertise you might hear of something.

Ed. H. Rhodes.—They are, as you suppose, mounted in a bath of warm gelatinous solution; one part in twenty will answer. Your question about the black is not quite intelligible to us.

T. Sims.—Thanks for your letter. Could you leave a few of the specimens at the Office for us to see?

Poogle.—1. Use a sable brush worked to a fine point, and Prussian blue water-colour. Unless your eyesight is very keen, use a magnifying glass, and take care to only touch the pinhole with the tip of the brush. 2. It is not easy; indeed, we have never seen one which really did look like moonlight; but the usual course is to take the picture with the light coming as much from the front as the subject will bear, to retouch considerably, and to print on greenish paper. Genuine moonlight pictures have been taken by Mr. Henderson and others.

A Subscriber.—1. Write to Evison and Bridge, Law Stationers, Chancery Lane, London, for a set of forms. The cost is, we believe, 6d. A £1 stamp is required on making application for the patent, and a further payment of £3 will afford you protection for four years. 2. A trade mark does not protect a new invention in any way. The mark only is secured to the person registering; the article marked may, unless protected in another way, be manufactured by anybody.

G. Schultz.—It may be as you say, but we are inclined to think it more probable that traces of hypo have been carried on to the paper by carelessness in handling.

Sulphite.—The only spots which we notice are minute reductions of silver which correspond in position with spongy depressions on the glass. Probably some foreign matter has remained in the depressions, and this has affected those portions of the film in immediate contact.

S. F. E.—Your experience is interesting, but, at the same time, we can hardly find room for your remarks.

The Photographic Society of Ireland.—We are asked to state that the gentleman who, on the 18th inst., exhibited the Willesden paper to the members, was Mr. G. Pim.

J. E. Sutcliffe.—If you obtain an instrument from one of the well-known English makers you will be quite safe, as, should it in any way be unsuited to your requirements, you will doubtless be supplied with another.

MR. ROBINSON'S NEW BOOK.

PICTURE-MAKING BY PHOTOGRAPHY. Being No. V. of "Photographic Handy-Books" (See page 266, Photographic News.)—Price 2/6, per post, 2/8.—Piper and Carter, 5, Castle Street, Holborn, E.C.

The Photographic News Registry.

Employment Wanted.

Photo. Colourist, gen useful.—G. Manton, 49, Hurley-rd., Kennington-la.
Operator & Ret. in good house.—D. Predger, The Broadway, Ealing, W.
Operator and Retoucher, could manage.—Artist, I. Hove-st., W. Brighton.
Youth, as Assistant in dark room.—H. Eckhardt, 12, Bath st., Brighton.
Mounter & Cutter (lady).—B., 1, Great Coram-st., Russel-sq.
Recep.-Room, Printing, Colouring.—E. M., 1, Benhill-rd., Camberwell.
Improver, can Tint well.—A. H., 15, Arlington-rd., N.
Reception-Room, Spot, Mount, &c.—E. H. H., *Photo. News* Office.
Ret. & Assist. Operator.—M. G. A., 1, North-pl., Montrose-st., Glasgow.
Print., Spot., Toner, Mounter, &c.—Miss Smedley, 45, Gt. North-ter., Linc.
Photo. Colourist and Retoucher.—Photo, *Photo. News* Office.
Recep.-Room, 7 years' experience.—E. Smith, York House Cheltenham.
Spotting, Mounting, (lady) —K. B., 67, Colvestone-crescent, Dalston.
Retoucher, Recep.-Room, Spotting.—2, Marion Villas, West-st., Bromley.
Retoucher & Assist. Operator.—J. V., Folly Hall, Huddersfield.
Artist, as Op. & Retoucher in good house.—A. B. 19, *Photo. News* Office.
Artist in Oils & Mono —C. E. Sharpe, 28, Hardy-st., Gt. George's-sq., L'pool.
Op. & Ret., best houses Paris & Italy.—A. L. H. Puzzi, 420, Euston-rd.
Studio & Reception-Room, West End.—E. M., 1, Benhill- d., Camberwell.
Printer, &c., French, speaking Eng.—A. C., 6, St. Martin's-st., Leicester-sq.
Recep. Room & Colourist.—E. Smith, York House, Bath-rd., Cheltenham.
Op. & Ret. £3 3s. weekly.—W. H. H., 29, Black Lion-la., Hammersmith.
Retoucher & Colourist.—Operator, c/o Mr. Bradshaw, 52, Cheapside.
Artist, three days a week —Infelix, 3, York Villas, Brighton.
Retoucher, 25s. weekly.—Miss H., c/o Mr. Kent, 49, Newman-st., W.C.
Gen. Assist., 16s. weekly.—L., c/o. Mr. Kent, 49, Newman-st., W.C.
Mounter, Retoucher, Finisher.—E. R., 4, Offley-rd., Brixton-rd.

Employment Offered.

Lady, exp., Recep -room.—Hughes & Mullins, Regina House, Ryde, I.W.
Printer, well up in vignetting.—Winter, Midland-rd., Derby.
Oper. & Retoucher, good at lighting & pos.—Shrubsole, Davy-pl. Norwich.
Printer & Gen. Assist.—E. R. Gyde, Cheltenham House, Aberystwith.
All-round Hand (single).—Cuckney and Co., Rochester.
First-class Floater.—Tavistock Works, Tavistock-pl., Kensal-green.
Printing, Toning, &c.—Personally, 67, Pentonville Road, N.
Assistant Silver Printer —W. N. Malby, Chichester.
Operator and Retoucher.—W. H. Widwinter, 49, Park-st., Bristol.
Operator, wet and dry.—J. Bateman, St. George's-st., Canterbury.
Artist for India at once.—R. B., c/o Marion and Co., Soho-sq.
Enameller at once.—Oeffelein & Co., 51, Berner's-st., W.
Assistant Operator (must retouch).—J. Willis, Manor-rd., Gravesend.
Printer, to board in house alternate Sunday.—J. Willis.
Reception Room, Spotting, &c.—Lavis, Eastbourne.
Assist., to super. Print. & Finish.—W. H. A., 247, Brecknock-rd, Tufnell-pk.
Printer, Toner, Vignetter, &c.—H. Hallier, Stafford-st., Walsall.
Operator and Retoucher (part. of sell).—Taunt & Co., Oxford.
Retoucher (specimens).—Elliot & Fry, 55, Baker-st., W.

THE PHOTOGRAPHIC NEWS.

VOL. XXVIII. No. 1340.—*May* 9, 1884.

CONTENTS.

THE RELATION BETWEEN FOCAL LENGTH AND ANGLE OF VIEW.

THE relation which exists between the focal length of the lens, the size of plate which it covers, and the angle of view which is included, are matters continually puzzling to photographers. This was well illustrated at a recent meeting of the South Loudon Photographic Society, at which Mr. Norman Macbeth read a paper. The question was asked: "What relation should there exist between the focal length of a lens, and the size of plate used to get satisfactory perspective?"

The question called forth many remarks, and there were to be particularly noted two. Each of these came from a man well up in practical optics, and at first sight they appeared so contradictory, that some astonishment was expressed.

The first of the two remarks was to the effect that "the *form* of a lens had no influence on the perspective of a picture, which was governed by the focal length of the lens only."

The second was to the effect that the point of view being fixed, the focal length of a lens has nothing to do with the perspective of a figure, but that only the size of the image increases with increase of focal length.

The second statement appears, at first sight, to be totally wrong, for do we not all know that if we keep the position of our camera the same, and take two pictures, one with a very long focus lens, and another with a very short focus wide-angle lens, the latter will show a strained perspective as compared with the first? Certainly this is true; but then we must consider that the small portion of the second picture which formed the first one, has not its perspective altered in the least. It is only much reduced in size so as to form a small portion of the central part of the picture taken with the wide-angle. The strained perspective is, in fact, produced by the introduction into the second picture of objects which, in the case of the first, lay entirely outside the field.

To take a definite example, let us suppose we are taking a portrait in a long studio. We use a long focus lens, and have to go the extreme length of the studio away to make the whole of the figure come into the plate. Now, we substitute a very short-focus wide-angle lens—say, a quarter the focal length of the last one. "You will certainly get a picture all out of perspective," we may hear said. So we will, but the perspective of the *figure* will be precisely what it was before. It will be only a quarter the size it was in the first picture, and will be seen in the centre of the surroundings, and of the sides of the studio, the latter being visible to within a short distance of the camera, and producing a strained perspective indeed.

We may put the result of these remarks in the following words:—The size of plate and the point of view remaining the same, alteration of focal length does not alter the perspective of an object in the picture, but alters the perspective of the picture as a whole.

The first of the two statements which we quoted involves the supposition that the size of image remains the same, whilst the focal length is altered, this further involving an alteration of the point of view.

This is a view of the case particularly applicable to portraiture. We may again imagine a specific case, and take it as an illustration.

We again imagine the long studio, with a figure at one end which we wish to take full-length. This time we try the short-focus lens first, and find that to cause the figure to cover the whole plate we have to go very close. We now certainly find the perspective strained enough. We unscrew our short-focus lens and replace it with the one of long focus. We shall now find that we take in a small portion of the figure only. The perspective of this will, however, be precisely the same as the perspective of the same small part of the image produced by the wide-angle lens.

We move away the camera till we get the image small enough. Now there is a marked enough change in the perspective. It will appear that this change has been brought about by a change in the lens. It has not been so brought about in reality, but has been brought about from the change in the point of view which the change of lens has permitted to be made without dwarfing the image.

Disregarding for a few moments the point of view—or rather, perhaps, we should say, considering it fixed—we cannot be too emphatic in our statement that the perspective of a picture in no way whatever depends on the *form* of lens used. With a 12 by 10 plate, and a lens of twenty-four inches focus, we will get a picture with precisely the same perspective, whether we use a portrait lens, a universal lens, a rapid landscape lens, a symmetrical, a single, or, in fact, any kind of lens whatever. Apart from differences of definition (especially marginal) and of depth of focus, the only difference between one image and another will be, that the one produced by the single lens will show the least possible amount of distortion—certainly not perceptible with the relation of focal length to size of plate which we have mentioned. In fact, were the equivalent foci of all the lenses really precisely the same, all the negatives might be superposed; and it is probable that no point of the image of one would miss covering the corresponding point in another by more than a sixteenth of an inch.

We have very frequently of late advocated the use of single lenses; but it must be distinctly understood that they offer no advantages in the way of perspective which are not afforded by any lens of the same focal length. The advantage of the single lens is, that when we come to a case requiring a long focus, it will do for most subjects (including por-

traiture) as well as a more complicated lens; it displays one distinct superiority in having but two reflecting surfaces, and it is comparatively cheap.

THE ROYAL ACADEMY.

PORTRAITURE and figure study is always a main feature at Burlington House, but taking a general view it does not appear to us that the work of this year is so excellent as to do much credit to the British painters of the present day. That painters of the highest standing make use of photographs as guides in figure painting and portraits is well known; and indeed this practice is on the increase. It is curious to notice, however, that the bad points of the photograph, rather than excellences, are generally transferred to the canvas. We notice the stiff and ungainly attitudes of unskilful posing, and it is quite clear that painters often copy those distortions which result from a careless use of the camera and lens.

"Treasures of the Home," by J. R. Herbert, appears to represent a woman carrying two children away from the scene of a fire, but although her hair is represented as streaming behind, the attitude is one indicating stillness and inaction; and the elder child, although apparently wide awake, is held as no living child could be carried; it would, however, be possible to carry a lay figure in the way represented. "Idle Moments" (No. 15), by C. E. Perugini, is a figure study which seems quite familiar. A sentimental young lady with a high-placed belt, and head leaning a little on one side, holds a peacock feather in the usual oblique position. The left arm, however, appears to us somewhat longer, and the left hand (which projects) somewhat larger, than is usual in productions of this type. The title of "Children of Arthur Pease, M.P." (No. 36), by James Sant, R.A., might well be called "Posing for a Photograph," and although the scene is laid in a wood, the figures forcibly recall the glass room. The boy holds a basket of fruit, but he does not seem to be aware of the fact, as both he and the girl seem to be intently regarding some object which we may suppose the photographer has told them to look at, while the girl seems to be offering an apple to somebody who is in front of the canvas. A portrait of Irving, an exact ninety degree profile, by J. A. Millais (No. 372), represents Mr. Irving as completely lifeless and soulless, with his hand in his pocket; we have seen better pictures of the great actor sold for sixpence each. Next to this is Miss Mary K. Benson's "Kittens" (No. 371), a charming little study of a white pussy-cat and its little mistress; while a little higher and to the right we notice a strange picture, "Master of his Horse," by Scholderer (No. 375). It represents a little wooden boy riding on a wooden horse. One can hardly conceive of a contest between them.

We cannot say much in praise of Frank Holl's portrait of the "Prince of Wales" (No. 298), as the position is stiff, and the lighting is quite in the theatrical style. As the flood of illumination that comes from the light brightens the figure without touching the accessories, it is difficult to divest oneself of the notion that the Prince is standing before a painted scene. Perhaps the most striking example of that style of portraiture, in which the figure looks directly forward out of the canvas with a meaningless stare, while the surrounding objects are supposed to indicate the tastes of the model, is No. 131, a portrait of Mr. Fleetwood Wilson, by J. E. Millais, R.A. But we are glad to pass on to more pleasing subjects, among which we may mention Nos. 489 and 496, by Ellen Montalba.

Two child portraits, "Winifred Cooper" (No. 700), by Mary L. Waller, and "Grettie" (No. 635), by Hugh Cameron, impressed us very favourably; while Otto Scholderer's portrait of Mr. Hermann Magnus (No. 812) is a fine example of portraiture, the attitude being remarkably easy and unconventional.

Among the more elaborate compositions, "Loading at a Quarry" (No. 137), by H. T. Wells, R.A., is well worthy of careful study, especially by photographers. It is accurately drawn; the postures are easy and natural; it shows a full contrast of light and shade; while not one of the figures (five men, four horses, and one dog) seems to be aware that he forms part of a picture, and not one is looking out of the canvas. With this we may contrast No. 798, a representation of "Daniel in the Lion's Den," by Robert Thorburn. A very robust-looking angel seems to be vehemently defying the visitors to the Academy, while Daniel stands a little behind, looking a trifle uncertain as to his personal safety. The angel and the lions seem altogether unmindful of each other's presence.

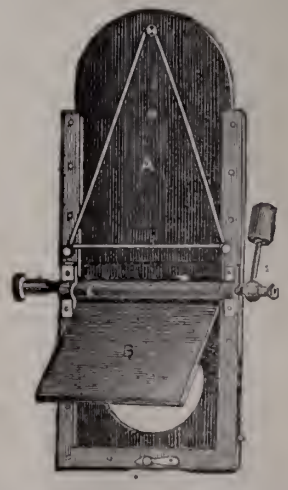
"Venetian Life," by Luke Fildes (No. 390), is a splendid study. A group of seven young women or girls, seated at the open doorway of a waterside palace, are engaged in ordinary feminine occupations; but work seems to be merely an excuse for idleness and gossip. An old crone far back in the shade, and engaged in combing the long hair of one of the girls, forms an effective foil to the other figures.

There are not many representations of those rich and verdant fields and lanes which form the chief charm of our country, but, as we observed last week, there are excellent pictures of the sea. We referred to Mr. Henry Moore's "Off the Bill" (No. 577), a bright little picture of the ever restless sea, but so badly placed as to be almost unnoticed by many visitors; and "Off the Lizard," a most characteristic example of his work. The little fleet of fishing boats carry with them the idea of motion and activity. Mr. Colin Hunter's "Herring Market at Sea" is probably the best piece of work this artist has produced, the rich blue and clear bright lights being particularly effective in their contrast.

Altogether the Academy is well worth a visit, and no photographer who is in London can well afford to lose the opportunity of profiting by the lessons (both positive and negative) which it teaches.

REYNOLDS AND BRANSON'S SHUTTER.

WE have already described the earlier form of this apparatus, and we may now call attention to some modifications which have proved to add to its usefulness. An adjustable arm with a weight shown on the right-hand side of the diagram



serves to lift the flap, this arrangement being more convenient in ordinary cases than the more complex spring with a tension adjustment. As soon as the flap B is raised, the drop A falls, its motion being accelerated by an elastic band placed as shown.

PHOTOGRAPHY OF COLOURS IN THE TRUE PROPORTION OF THEIR INTENSITY.

ADDITIONAL NOTE BY DR. H. W. VOGEL.

In the formula of the first silver bath (sensitizing bath) given in the last number of the News (page 274), I forgot to mention the alcohol—2 to 3 per cent. of pure alcohol of 96°, that is, 10 to 15 cub. cents. for the quantity of bath mentioned should be added. The alcohol is necessary for avoiding streaks, as the dyed film repels the silver solution much more than an ordinary one.

On the other hand, it is always necessary to test the acid action of the two baths with litmus paper. It must be borne in mind that eosine has an alkaline reaction, and neutralizes the bath.

[Dr. Vogel has recently made a successful application of his method to gelatine plates.—(See page 296.]

MATT PICTURES ON ORDINARY ALBUMENIZED PAPER.

An increasingly larger proportion of the public now prefer to have photographs with a matt surface, especially where large pictures are concerned, and it is a desideratum to have a simple method by which these may be produced without involving any considerable change in the routine of the printing room. It is true that pictures without gloss may be obtained by sensitizing the back of ordinary albumenized paper instead of the face; but such prints become very much weakened during the operations of toning and fixing, and the raw surface of the paper does not give a satisfactory face to the prints.

In the *Wochenblatt* we find a suggestion of Herr F. Wilde to sensitize the albumenized paper upon a special ammonia nitrate of silver bath, which so far disintegrates the albumen as to make it yield prints with a very pleasing matt surface. All other operations are conducted as in the case of ordinary printing.

To prepare the ammonia nitrate sensitizing bath, one part of nitrate of silver is dissolved in eight or ten parts of water, and sufficient liquid ammonia is added to re-dissolve the precipitate which is thrown down at first. A solution of citric acid, containing one part of the acid in ten parts of water, is then added to the ammoniacal solution until a faint turbidity which does not disappear on agitation, is produced. A volume of ether equal to one-tenth of the bulk of the silver solution is next added, and the sensitizing bath is ready for use.

At Home.

M. CHAZAL AT CONSTANTINE, ALGERIA.

Those who have seen a picture of Magdala, King Theodore's stronghold, perched upon a precipitous rock, where he kept the Abyssinian captives, may form a pretty good idea of what Constantine is like. As you approach the town by railway, the line climbing the broad valley in sinuous turns, you are suddenly surprised to see opposite you a huge table rock of red stone, its flat top covered with multitudinous roofs. For some time there has not been a habitation visible, only huge boulders, and now and then a mountain torrent, attracting the eye, in the broad inhospitable landscape. And now before you appears a packed mass of habitations, as if built by human swallows, covering the rock so densely that there is not space for another brick or tile. The railway circles round this rock, but when your train comes to a standstill, there is still a deep ravine between you and the city.

A light stone bridge takes you into the town, perhaps the largest Arab city in the world. For the Arab population here greatly outnumbers the Europeans, and, except in two or three of the broadest thoroughfares, the streets and courts are intensely native. Constantine is the capital of the province of that name, and forms part of Algeria, but it is closer to Tunis than to Algiers, and altogether is very Eastern in its character and population.

We were fortunate in possessing a few lines of introduction to M. Chazal from our esteemed correspondent, M. Léon Vidal, of Paris. A personal friend of the latter, M. Chazal was good enough to receive us very kindly, and as an intelligent experimentalist, no less than as an able photographer, he proved an exceedingly welcome acquaintance.

M. Chazal has had some interesting experiences in his time. In 1855 he photographed the progress of the Lyons railway then in course of construction; afterwards he went to Paris, and engaged in much experimental work connected with photography; then he journied to Africa, and spent some time in Tunis; and now he has settled in Constantine, where the Arab life is especially congenial to one with such roving instincts.

The recent war between France and Tunis, which upset the government of the latter, and made the Tunisian empire a sort of department of France, has not benefitted M. Chazal, for he was an intimate acquaintance of the Bey. For fifteen months, indeed, M. Chazal was an inmate of the palace at Tunis, for the Bey's brother is an accomplished photographer, thanks to our host's tuition. Very soon the Bey came to appreciate the value of photography, and, like a wise man, he cast about for a thorough master who could teach the art, root and branch. His brother, however, proved the more apt pupil, although the Bey himself was so imbued with the importance of photography, that he decided upon establishing a private studio for himself. M. Chazal was sent for and given *carte b'anche* both in respect to construction and expenditure, and the consequence was that in a few months the Bey's palace at Tunis boasted one of the most complete photographic establishments. The ruins of glorious old Carthage—or, rather, what is left of them—are very close to Tunis, as every student of the classics knows full well, and this spot afforded plenty of scope to the Royal photographers.

Naturally, M. Chazal loves to speak of his Tunisian experiences, and there are probably few French colonists who possess such a deep and thorough knowledge of the Arab character as the Constantine photographer. Nor must it be imagined that he neglects photographic progress in the study of native character. The whole series of the French *Bulletin de la Photographie* are to be found in his studio, and one of the first questions M. Chazal addressed to us bore reference to a process for producing incombustible transparent prints, that had recently come under the notice of the Paris Society.

In his studio, M. Chazal only works in the morning. Portraits are taken as early as the sitter pleases, but rarely are any sittings given in the afternoon. The light is naturally very powerful, both summer and winter, and although his atelier is situated in a dark turning out of the main street, he has to adopt many precautions in the studio itself. Thus all the side light comes through ground glass, while the top light consists of white light throughout, screens and banners being employed for still further subduing the illumination where necessary. Again, the shading of the camera is undertaken with great care, a large hood of thick black cloth enveloping the apparatus most completely, so that no stray ray of light can search out any weak points in its construction.

But if, in M. Chazal's studio, the illumination is subdued, his dark room is light enough. Indeed, we have never entered a more orderly, cleanly, spacious, and less gloomy dark room in any private establishment. M. Chazal has no less than three windows in his dark laboratory, and his idea on the subject is a very sound one. He has his windows, which are by no means small, covered with orange and ruby fabric, one of the most non-actinic of combinations; in a word, he gets the most safe light he can, and then admits plenty of it. It is in this respect that

many photographers make a mistake. They cover a tiny casement with this lugubrious combination, and then boast that they can develop a plate without the least fear of fog. They are quite right in their dictum; only if the light is not sufficient to act on the plate, neither is it sufficient to let them see it. Why have any light at all under the circumstances, since it does not permit you to see what you are doing?

M. Chazal, then, as we have said, goes in for a very sombre light, and has plenty of it. For portraiture, when you have plates you can depend upon, development is little else then a mechanical operation; but it is another matter altogether when dealing with landscapes, and when two plates are never exposed under precisely the same conditions. Before each window M. Chazal has a broad shelf, where you may rest frame or developing dish at any moment, while the laboratory is at the same time so roomy that you may retire to some distance from the windows when it is a question of changing plates or performing any operation where light is not only unnecessary, but particularly harmful. All the shelf and table room, too, we noticed, was not only scrupulously clean, but altogether unencumbered.

M. Chazal makes use of a very fine heliostat for multiplying negatives, or copying them; not that the instrument is essential to the work, as he informed us, but because, having the apparatus at his disposal, he availed himself of its valuable aid. Of course he employed gelatine plates in his work, giving a preference to those of English make, albeit those were very dear by the time they came out all the way to Africa. English cabinet work was also eulogised by M. Chazal. "We cannot get such fine workmanship among our camera makers as you have in London," said M. Chazal, and then he went back to refer to the model studio he had left at Tunis Palace, where the lenses and apparatus were by English makers, and where he had been at some pains to choose of the best. Still, M. Chazal had little to grumble at over his own apparatus, and one camera-stand especially, a tall tripod for landscape work, particularly attracted our attention for its stability and thoroughly serviceable aspect. "Yes, that is a good stand—one of my own make;" and then he added, smiling, as we landed its firmness, that it was strong enough to hang a man on.

M. Chazal experiences one drawback in living among the Arabs: you cannot get any assistance from them. A printer or studio attendant cannot be taken from among the natives unless you are willing to submit to all sorts of inconveniences. That is to say—to employ and support one man, is to support all his relations, his father and mother, sisters, cousins, and aunts. Nay, your servant's servants have to be provided for; for as Thackeray used to say of Irish gentlemen, you could never find one so poor that he had not a dependant in his train, so, seemingly, the natives here are none of them so humble that they have not a troop of female relatives and attendants. It is true, said M. Chazal, the workmen cost very little, but then they work very little; and after many experiments he has found it impossible to employ anyone but his own country-people.

THE SPECTROSCOPE AND ITS RELATION TO PHOTOGRAPHY.

BY C. RAY WOODS.

VII.—Sensitizers, and the Action of the Spectrum on Salts Used in the Printing Processes.

So far we have simply been considering the effect of the spectrum on the haloid salts of silver alone, and in the obtaining of a negative picture; but before leaving this subject, it will be well to note what effect is produced by the addition of other substances, notably dyes, a subject that is at present engaging considerable attention. The effect of sensitizers in the film—that is to say, sensitizers the only function of which is to absorb the halogen freed by the action of light—is, in most cases, simply to decrease the time of exposure by increasing the sensitiveness of the compound in the film. When used with a film containing a mixture of two or more haloid salts, they perform another function. The decrease in sensitiveness at a part of the spectrum, caused by the action of one halogen set free on the compound of another halogen with silver, is removed. This will be seen by a reference once more to fig. 8, Nos. 7 and 8, showing the effect produced when nitrate of silver is present as a sensitizer to a mixture of iodide and bromide of silver. In such a case as this, the sensitizer takes up the halogen as soon as the light sets it free. It may be remarked that gelatine is too feeble a sensitizer to produce such an effect in any marked degree, and it may therefore be noted incidentally here, that whatever be the cause or causes of the sensitiveness of modern dry plates, the function of gelatine in inducing sensitiveness would appear to be physical rather than chemical.

The addition of certain dyes to films containing sensitive compounds has the effect of increasing the sensitiveness of those compounds to certain rays; in most, if not all, cases, to those rays which the dye absorbs. It is a debated question as to how this takes place, whether the dye, by absorbing the light, causes it simply to act more energetically on the silver salt, or whether the dye itself undergoes a change. It has been pretty well ascertained that those dyes only which are not permanent, can act as "optical sensitizers"; "colour sensitizers" or "local sensitizers" would, perhaps, be a better term. The action of these colour sensitizers is greatest when a chemical sensitizer is also present; but the latter is not indispensable, as many dyes possess this property as well. To mention briefly a few dyes that give a local increase of sensitiveness, we have:—Coralline, increasing the sensitiveness to light blue near F; aurine, increasing the sensitiveness to the green; aldehyde green for both yellow and blue; methyl violet for the yellow near D; eosin, increasing the sensitiveness in the green between E and F; cyanine blue for the yellow and orange-yellow, about D and C. Of these the last two are the most important; but until lately it has been found that the sensitiveness in the parts of the spectrum where the dye absorbs is still not greater than at the natural maximum of the haloid salt.

In the preceding articles of this series, it was stated that, "since the yellow rays have the greatest effect upon the eye, the photographer would obtain results more nearly approaching to what he sees in nature by using a medium more sensitive to that part of the spectrum than to any other." It will be seen, therefore, that the influence of dyes in the film is of considerable importance. Its importance is pretty generally recognized so far as the photographing of paintings is concerned, and the use of dyes has in this direction been attended with beneficial results, in spite of the fact that the local sensitization has hitherto been far below the amount desirable. Dr. Vogel's recent claim to have produced plates twenty-five times as sensitive to the yellow of the spectrum as to the blue, if substantiated, should be productive of most important results, and the photographic world, if fully alive to the benefits attainable, will bear with some impatience the short time that must elapse before they can obtain the material with which they can try Dr. Vogel's process.

It remains now to consider the effect of the spectrum on sensitive compounds in relation to printing processes. In this we have to consider the action of light on silver chloride in the presence of nitrate of silver and organic matter; the action of light on iron salts, on which the blue process and the platinotype are based; and the action of light on bichromate of potash, on which the carbon process is based. These are the most important compounds with which we are accustomed to deal.

In the reducing action of light on the haloid salts of silver there is little difference between the result produced by printing and that by development, so far as the extent of action of the spectrum is concerned, the maximum re-

maining in both cases the same. Bromide and iodide of silver not being adapted for printing purposes, on account of the comparative feebleness of the image compared with that of the chloride, may be dismissed. The effect of the spectrum on chloride of silver on paper in the presence of nitrate of silver is shown in the accompanying diagram.

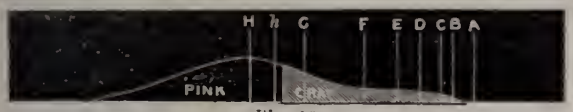


Fig. 10.

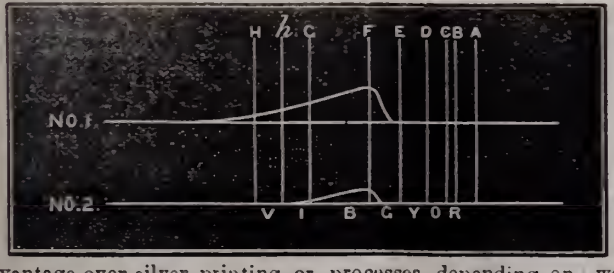
It will be seen that the more refrangible part of the spectrum, beginning from a point almost midway between H and G, a little less refrangible than *h*, darkens the paper to a somewhat pinkish or ruddy hue. Below *h* the tint produced is greyish. In the ordinary silver printing process we have other compounds of silver present, notably the albuminate. It will be found, however, that the most refrangible rays darken the paper a ruddier tone than do the less refrangible rays, whether commercial ready-sensitized paper be used, or the paper be sensitized when required. This is the general rule, though different papers will give particular differences under the action of light. The difference in colour produced by different rays will explain several phenomena with which everyone is more or less familiar. Let us, in the first place, consider the subject of printing by the electric light, as this will make what follows plainer.

Those who have tried printing by the electric light must have noticed what ruddy pictures are obtained. This is undoubtedly due to the quantity of rays of high refrangibility emitted by the arc light. Further, the same amount of contrast is not obtained that may be got when printing by diffused daylight, or even by the direct rays of the sun, and defects in the negative which hardly appear when printing by the sun, come out forcibly under the light from the electric arc. It would appear that the ruddy compound produced by rays of high refrangibility is more opaque to ultra-violet rays than the grey form, so that whilst the rays are slowly penetrating the reduced surface, they have time to penetrate through the dark parts of the negative. There is nothing to be surprised at in this when it is remembered that metallic silver in a thin film (as in the mirrors used by astronomers) is transparent to some of the ultra-violet rays.

This will explain the advantage found in printing by diffused daylight in preference to the direct solar rays, especially with weak negatives: the light reflected from the clouds having been deprived of some of its ultra-violet rays. Again, negatives developed by ferrous oxalate, print redder than negatives developed with alkaline pyro, the yellow stain of the latter cutting off some of the more refrangible rays.

The action of the spectrum on iron salts can be dismissed in a few words. The action is very similar to that of the spectrum on bromide of silver.

The carbon process possesses a very considerable advantage over silver printing or processes depending on the reduction of iron salts. The above diagram* will show that the maximum effect of the spectrum on bichromate of potash is near F, in the light blue. The carbon process can therefore be worked in a much weaker light than either silver printing or platinotype.



* From "Instruction in Photography" by Captain Abney.

Review.

Photo-Micrographs, and How to Make Them. Illustrated by 47 Photographs of Microscopic Objects, Photo-micrographs, reproduced by the Heliotype Process. By George M. Sternberg, M.D., F.R.M.S.—(*Boston: J. R. Osgood & Co.*), 1883. Price 15s.

Dr. Sternberg's name is well-known to scientific men through his researches on the Bacteria and other kindred organisms, and their connection with infectious diseases. For some years he has employed photography for making memoranda of his work; for, spite of its shortcomings, photography far excels the engraver's tool in truthfully delineating what is seen in the microscope. Microscopists generally cannot fail to be grateful to Dr. Sternberg for giving to the world, in the present volume, an account of his method of working, together with directions for preparing and photographing a large number of interesting and important objects. It is a book that can be *read*: not merely a work of reference: not bristling with technical descriptions given in the driest of scientific styles, but a book which the youngest student will devour with pleasure: a book to awaken and sustain enthusiasm. It is popular in style, yet scientifically exact, while much of the information given relating to the lowest organisms will be new to many. It has been the fault of most of the works on the microscope published in this country and America that few of them have been anything but dry compilations. This work bears the stamp of originality from beginning to end.

The book consists of two parts. Part I. Technology, treating of light, apparatus, exposures, development, selection, and preparation of objects for photography, &c. Part II. contains the plates, with an interesting and exact description of the objects photographed; in fact, as Dr. Sternberg says, this part might properly bear the title of "Elementary Lessons in Biology." Such an interesting, and at the same time scientific, course of lessons has never before been published.

In his introduction, Dr. Sternberg gives a very necessary caution respecting the use of the words photo-micrograph and micro-photograph, which many persons use as synonyms. "Photo-micrographs," says Dr. Sternberg, "are sun-pictures of microscopic objects, more or less magnified. A micro-photograph is a microscopic picture of an object which can be seen by the naked eye." Again, "micro-photographs are simply curiosities in the art of photography, and are to be viewed under the microscope."

Another very important point is insisted upon: that success in photo-micrography depends on the operator's skill as a *microscopist*, rather than on his ability as a photographer. While we agree with this, we can hardly go so far as Dr. Sternberg in saying that the microscopist can claim as his own production a photo-micrograph which he had exposed in the camera, but which had been developed and printed by another. Now, as Dr. Sternberg says, as a rule, a photographer who is unacquainted with microscopic work is not a fair judge of a photo-micrograph; thus, as he does not know what is seen in the microscope, he cannot tell what to pay special attention to in the development of the plate, nor in the production of the print. Too much, we think, cannot be said against the lazy habit of some photo-micrographers, in being content with exposing the plate, and leaving all further results to a professional photographer, who can hardly be expected to be familiar with the forms of diatoms or bacilli. Neither can we agree

with Dr. Sternberg that the photo-micrographer should hand over his negatives to be printed by any ordinary photographer, for the reason that "silver prints can be obtained more economically than the amateur can make them himself." In these days, when such good results can be got on ready-sensitized paper, which can be obtained at a low rate everywhere, we would advise the microscopist to master silver printing, if he wishes to get the best possible results; he will certainly find nothing to grumble at on the score of economy.

Dr. Sternberg does all his photographs by sunlight, using a heliostat, to give the rays of light a constant direction. Doubtless this method is infinitely preferable to any other, when it can be adopted; but in this country the uncertain nature of the sunlight, together with the mists that frequently obscure the air, compel us to fall back on artificial light for microscopic photography; yet we can confidently assert that the best work of some of the English photo-micrographers has never been excelled in any country. We do not speak of difficult *feats:* in this, the skill of Dr. Woodward, of Washington, is unrivalled.

The duration of exposures in the microscopic camera varies with each individual worker; but most photo-micrographers will be astonished to learn that at Havana, *using wet plates*, Dr. Sternberg found eight seconds to fifteen seconds ample exposure for Zeiss' $\frac{1}{18}$ inch homogeneous immersion lens! Using a Beck's $\frac{1}{4}$ inch, and an amplification of 400 diameters, the exposure was almost instantaneous! In fact, for low powers, Dr. Sternberg tells us he frequently uses a drop-shutter. For development, he prefers ferrous oxalate, a developer not much in favour here, and which in our hands seems more especially unsuitable for microscopic work. A peculiarity of Dr. Sternberg's practice is, to place the plate in the developer, and leave it there to develop itself, while he attends to the exposure of other plates. We can hardly think that the best results can be gained in this way. Captain Abney considers development an *art:* most practical men will agree with him, and condemn Dr. Sternberg's practice.

Dr. Sternberg follows Dr. Woodward in dispensing with the eye-piece in photography. He uses, however, an amplifier. More light and more rapid exposures are thus gained; but it is not correct to say that good results will not follow the use of the eye-piece. We have seen many photographs produced with the eye-piece that are certainly equal to any of Dr. Sternberg's; but for powers above $\frac{1}{4}$-inch or $\frac{1}{5}$-inch, it is best to use a long camera, and discard the eye-piece, simply for convenience sake.

On the subject of lenses, we are not at one with Dr. Sternberg, who advises the use of low-angle lenses for nearly all kinds of work. Now, wide-angle lenses have far greater resolving power than low-angle lenses, admit vastly more light, but have less penetration and a shorter working distance. Do these latter constitute any serious objection to the use of wide-angle lenses? We think not. A wide-angle lens may be made equal in penetrating power to a very low-angle lens, by the simple expedient of using a contracting diaphragm, such as the "aperture shutter" of Mr. Davis, author of "Practical Microscopy," which answers admirably. True, the working-distance is not increased, but for photography this does not matter. Our own experience has been that for *all* purposes, the *widest possible angles are best.* A lens that will resolve a diatom satisfactorily with central light is far less trouble to use than a low-angle one, of the same focal length, that requires light of absurd obliquity to do the same work. The objection to the short working-distance of wide-angles is disposed of by the fact that cover-glasses are now made of extreme thinness, and objects can be had specially mounted with such thin covers that a dry $\frac{1}{50}$-inch can be focussed upon the object without touching the cover-glass. However, Dr. Sternberg acknowledges that for special work, requiring great resolving power, wide-angles are really necessary.

In Part II., Dr. Sternberg tells us that the plates have been selected "not only for the purpose of showing what photo-micrographs are, how they are made, and what microscopic objects are best suited for photography, but also with a view to conveying, by the pictorial method, some elementary biological information." "The general truth which these photo-micrographs are intended to illustrate is, that *the lowest living beings are* UNICELLULAR ORGANISMS, *and that the tissues of higher plants and animals are made up of* CELLS.

Coming now to the plates, we wish to say that, while some are highly commended, and others criticised less favourably, they are *all good;* not one is unsatisfactory. In fact, all the plates represent in the most truthful manner the appearance of the objects as seen under the microscope. Evidently the originals have lost little by reproduction in heliotype.

We would call attention to plates 5 and 6, blood corpuscles, which are remarkably successful photographs of a difficult subject. Plate 7 has photographs of pollen, which must not be compared with photographs of flatter objects, as all spherical bodies are very difficult to exhibit satisfactorily in the microscope. The photos on plate 8 show the epidermis of plants, and exhibit the stomata, &c., in a characteristic manner. Dr. Sternberg has been exceedingly successful with plate 12, which is a marvellous production, when the difficulties to be overcome are considered. It is a photograph of the fourth square of Möller's diatom type-plate, × 50, and exhibits no less than 90 diatoms, all in sharp focus. It is a photograph that speaks well for the skill both of preparer and photographer, as well as for the splendid defining qualities of Powell and Lealand's $\frac{1}{4}$ inch.

For plates 13, 15, and 16, we have not such commendation. Good as they are, and making due allowance for the defects of the heliotype process, we think these photographs could have been done much better; and those who have seen the superb photographs of the same diatoms by Dr. Maddox will think the *coscinodisci* on plate 15, poor. The concluding plates, illustrating animal parasites, are good. Many of these creatures, owing to their natural transparency, which is much increased by mounting in balsam, are difficult subjects to photograph satisfactorily; and the brief exposure they require is such that it is often hard to bring the negatives up to printing density.

We have given but a faint idea of the attractiveness and value of the work. It is indispensable to the beginner who wishes not only to amuse himself by photographing pretty objects, but also to gain some valuable biological knowledge, and at the same time to place on record the results of his observations; while the expert will read it with interest, and also pick up many a hint for future practice. We most decidedly recommend all engaged in photo-micrography to obtain the work, which is by far the best on the subject that has yet been published.

ON LENSES.

BY W. E. DEBENHAM.*

A NEW departure was made by Steinheil in January, 1867, when he introduced the lens which he called "aplanatic." I think it only just to express my belief that photographic history will accord a place to the genius displayed in the various introductions of Steinheil only second to that of Petzval. The peculiarity of this lens consisted in the glass of which it was composed being of two kinds of flint—light and heavy—instead of crown and flint as previously. By this means it was possible to so far reduce the spherical aberration that a much larger aperture could be employed than with any previous cemented photographic combination. This lens, with a power of light unequalled in any previous combination—except, of course, the portrait lens—had its field considerably flattened, and embraced a rather wide angle. The instrument is symmetrical—that is, the back and

* Continued from page 285.

front are alike. The lens has had the sincerest flattery bestowed upon it in the manner in which it has been imitated by all the leading photographic opticians. Differences of workmanship, of

Steinheil's "Aplanatic" Lens, rapid form.

Steinheil's Wide-angle "Aplanatics."

course, influence the results produced by different makers, but it is very doubtful whether any improvement has arisen from any little variations from the original calculations that may have been adopted by any particular manufacturer. The landscape and wide-angle aplanatics by the same optician have met with similar flattering treatment by other makers, though not, perhaps, to so great an extent.

We now come to another lens of Steinheil's which is as yet scarcely known in this country. It is, or rather, they are—for there are two distinct varieties—called the "antiplanatic." One of them, called the "group antiplanatic," consists of two cemented combiuations set so closely together as only just to allow of the insertion of the diaphragm. The front lens is of shorter focus than that of the whole combination. The back lens, when looked through diagonally, diminishes very powerfully, and lengthens out the side pencils of light proportionally.

Steinheil's "Group Antiplanatic."

Steinheil's "Portrait Antiplanatic."

By this means the field is much flattened, and the spherical aberration is so far remedied that it has an angular aperture giving a rapidity about equal to what would be No. 2½ on the universal system—less than half that of an ordinary rapid portrait lens. No doubt it will work better with rather a smaller opening, but for large portraits it is seldom, if ever, desirable to use a stop giving more rapidity than No. 3; and with our modern rapid plates smaller stops than this are generally employed. For ordinary portrait use it seems to me to be a very suitable instrument. However, I should judge that it is rather a difficult and expensive instrument to construct; but, unless other makers are deterred by these considerations, I should by no means be surprised to find it largely adopted as a model.

The so-called "portrait antiplanatic" has the back elements separated like that of Petzval; but, like the group antiplanatic and the orthoscopic, the back as a whole is negative. Astigmatism has been wonderfully got rid of; but there is an amount of curvature of field which renders it unfit for working upon a large field, for which, however, it is not intended.

Lenses there are—and very good ones, too, some of them—bearing other names than those I have mentioned, and some photographer may think that I have omitted speaking of his pet instrument. If he will carefully examine that instrument, however, it is probable that he will find it included in one of the types described. Where the difference is not marked, and the particular details of construction have not been published, it could not be expected that they should be here specified.

Having now gone through these types, the question arises—"What is the best lens to use for any particular purpose?" To say that for rapid portrait work the Petzval form still holds its own, and that for landscape—when rapidity is not required—the old single view lens is hard to beat, seems to suggest that no improvement has taken place within the last forty years. It is, however, in lenses for other purposes that improvements have taken place. If it be desired to obtain the most perfect delineation of any particular subject, including near and distant objects, irrespective of size of picture, that will be best secured by a lens of short focus. If it be desired to cover a certain sized plate, and there be a latitude in the amount of subject to be included, or in the distance from which it may be photographed, choose a lens of long focus. This is particularly the case with instantaneous views, where a small stop cannot be employed, and for these reasons:—The field of a lens such as must be used is always curved. Now the longer the focus the larger the curve, and a line of any given length—the side of the plate—will line nearer to the circumference of a large circle than of a small one. The views of yachts in full sail now shown were taken with a Steinheil aplanatic of about seventeen inches focus. The length of the plate is about one-half that of the focus.

For portraiture, for the same reasons, flatness of the curve of definition, less departure from the focal plane, and the use of as long a focus lens as will take the subject of the required size, will conduce to the general sharpness of the result. An occasional objection to the use of a long focus lens for portraiture is, that in certain weather, especially in towns, the fog or illuminated smoky atmosphere between the lens and the sitter destroys the brightness of the image, and the nearer the subject can be approached, the less this is felt.

For copying flat surfaces, to avoid the curved field, the longer the focus the better, and I think that for this purpose a lens might be introduced having its normal field—that for parallel rays—convex. Astigmation and spherical aberration might abound, but stopping down would do a great deal to get rid of these evils, and for even delineation all over the picture, it is better to be *in* a rather bad focus, than to be a long way *out* from a very good one. For architectural subjects there are to choose from, the flatter curves of the modern lenses made upon the symmetrical aplanatic plan, and the rounder curves of the earlier lenses that have been described. For very wide angles the rounder curves have an advantage in transmitting more light towards the edges of the field, as it strikes the lens nearly at right angles, and so less is lost by reflection. The flatter lenses, however, have less spherical aberration, and thus permit of a larger diaphragm being used; but when a very wide angle is desired—unless in the case of an interior, or with the sides of the subject advancing considerably—a small stop is absolutely necessary for good definition.

In addition to the panel portraits taken with the single Grubb lens, I have here some of the same size taken with the Steinheil aplanatic, and some promenades with a very similar instrument—the euryscope of Voigtländer. Here are also photographs of a sitter with accessories and scenic backgrounds, taken with eight different lenses without altering the position of the camera. These were all worked with apertures No. 3 on the universal system, and it will be seen that there is little difference in the results when thus brought to the same level. The lenses are portrait lenses by two good makers—a Euryscope, a French lens on the Steinheil aplanatic pattern, an antiplanatic portrait, and an antiplanatic group, both, of course, by Steinheil. Here are also some scenes taken by Mr. Haddon with a euryscope of eight inches focus. Although the plates are nearly of the same length as the focus of the lens, the definition is remarkably good. Of course, when this angle is included, a small stop is used.

Addendum.—I have been requested by a member to state how to calculate the focus of two lenses when combined in a doublet. Make the focal length of each lens the denominator of a fraction whose numerator is unity, and add. To those unaccustomed to

arithmetical calculations, an example may make it clear. Say that two lenses, one of 12-inch and the other of 10-inch focus, are to be combined. Add $\frac{1}{12}$ to $\frac{1}{10}$ by bringing them to a common denominator; that is, $\frac{5}{60}+\frac{6}{60}=\frac{11}{60}$. Now reverse the fraction $\frac{11}{60}=5\frac{5}{11}$, and the lens is found to have a focus of $5\frac{5}{11}$, or just under $5\frac{1}{2}$ inches.

If one of the lenses be a concave, the operation is similar. Let the convex lens be of 5 inches focus, and the concave one 6 inches negative; then $\frac{1}{5}-\frac{1}{6}=\frac{6}{30}-\frac{5}{30}=\frac{1}{30}$. The compound has a focus of 30 inches. Separating the lenses will make a difference in the result, but not to an extent likely to mislead the photographer, who wishes to provide himself with a set of lenses of different length of focus.

Notes.

Mr. Norman Macbeth is not the only artist of reputation who has spoken in glowing terms as to the value of Mr. H. P. Robinson's new book. "Picture Making by Photography" is one of those works from which every photographer can learn something of real value.

A further note from Dr. Vogel regarding his process of photographing colours in their true proportion well be found on page 291, and we are pleased to be able to state that we may shortly hope for valuable information as to the application of Dr. Vogel's methods to gelatine plates. In a private letter he writes:—"After my first experiments I dare not venture to hope that I could do the same with the gelatine plates as with the wet collodion process. But now I have tried a new dye, made by myself, a derivative of aniline. This dye sensitizes gelatine emulsions in a most remarkable manner, not only for green and yellow, but also for orange and red, and whilst all dyes added to emulsions diminish the general sensitiveness for white light, this new dye improves their general sensitiveness and the intensity of the picture. The plates covered with the dye are not only valuable for reproducing oil paintings, but also for portraits, for red-haired and freckled faces, variegated costumes, &c."

New applications of photography to science are constantly being made, and such photographic observations as those of M. Henry on the position angles of various double stars will acquire increasing value as time goes on, and other records are obtained which throw light on such variations as may take place, and thus lead to the formulation of general laws.

Dr. Frölich, of Berlin, continues his researches as to the fluctuations of the solar heat, and he finds that the increase which was noticed during August last was accompanied by a notable diminution of the earth's magnetism.

The *American Druggist* tells us that a useful substitute for celluloid may be made as follows, and, moreover, the new preparation is not combustible. Dissolve 200 parts of caseine in 50 parts ammonia and 400 parts of water; then add 240 parts of quicklime, 150 of acetate of alumina, 50 of alum, 1,200 of plaster of Paris, and 100 of linseed oil. The ingredients are mixed by a rolling machine, and articles moulded of the paste are hardened by immersion in a bath composed of water 100 parts, gelatine 6 parts, and phosphoric acid 10 parts. Celluloid is an excellent material for making photographic dishes.

The English public are behind the French in appreciation of art. The Paris *Illustration* published last week a special number containing the principal pictures exhibited in the *Salon*. It is to be feared that a similar enterprize on the part of the *Graphic* or *Illustrated London News* would lack support, not only on the part of the public, but, strange to say, on the part of the artist. The whole of the pictures in the *Illustration* have been produced by photography, the paintings, of course, having been photographed before they left the studios. Over here artists, as a rule, show a singular disinclination to have their pictures photographed; but whether this arises from prejudice, or from some idea that a photograph would interfere with the engraver's province, is difficult to say. It is worthy of note, also, that the Meisenbach process, which has been used to produce the illustrations referred to, would not suit our English printing. On the highly glazed surface, never damped as is the case with our printing, and with the best quality of ink, the result is very satisfactory. These conditions appear at present to be unattainable in England. This is a pity, as photography in illustrated periodicals is in consequence heavily handicapped.

In a recent number of a German illustrated paper—the *Illustrirte Zeitung*—there is a notable instance of what the Meisenbach process is capable—a picture of the military manœuvres at Hamburg from an instantaneous photograph. In appearance, it much resembles Sprague's ink photos. The point worthy of attention is, however, that it has been printed in the ordinary way, and does not suffer by comparison with the engravings on wood in the same number.

The latest claimant to the honour of discovering photography in natural colours is an engraver at Versailles, who, according to the *Standard*, asserts that he is able to reproduce "the colours of the body or landscape photographed." The *Standard* refuses to believe this assertion, observing that "a photograph is practically a detailed shadow, and that a photograph could be taken which should preserve the green of the trees, the hue of the flowers, and the blue of the sky, together with the tints of dresses and such like matters, seems incredible." So it does; but could not the *Standard* have found a better definition of a photograph than a "detailed shadow?" Surely a picture in which only the parts actually illuminated, of course in varying degrees, is anything but a shadow.

Some time ago a correspondent of the *English Mechanic* wanted some information as to the possibility of taking instantaneous pictures from the window of a railway carriage travelling at twenty-five miles an hour. In commenting on the matter, we stated that most successful photographs of trains proceeding at a high rate of speed had been taken end on. This statement has surprised

another correspondent, who says the information is new to him. "After hearing," he remarks, "of horse-racing being photographically recorded; reading of the University boat race being thus pictured; seeing some wonderful account of a flying swallow being taken, and a shell from the 100-ton gun being so flashed off," he was little prepared "to find that such a prosaic subject as the broadside of an ordinary train had not even been decently done." We ought, perhaps, to add that M. Grassin's photograph of the "Nord" express taken near Boulogne is the best broadside picture we know; in it the steam is seen in a horizontal line above the train, distinct puffs marking the piston strokes for a distance equal to five coaches.

Mr. R. A. Proctor's statement—recently noted in these pages—that photography is of the highest value in connection with sun spots, received confirmation at the last meeting of the Liverpool Astronomical Society. A paper on "Sun Spots: their Birth and Changes," read by the Rev. S. J. Perry, F.R.S, was illustrated by ninety photographic transparencies; and, referring to the birth of sun spots, Mr. Perry expressed an opinion that sufficient attention had not been given to photographing faculæ and "rice grains," for by that means it was very probable the origin of sun spots might be traced. Mr. Perry paid a compliment to the Society when recommending it to turn its attention to solar photography, observing that if it met with the same success as it had done in stellar photography, its sun pictures would be second to none in the world.

If a portion of a gelatino-bromide plate is at a higher temperature than the rest during exposure, that part proves more sensitive than the remainder; while if a piece of ice be placed at the back of a plate so as to considerably cool a part of the film, and exposure be made, a patch of diminished density corresponding to the figure of the ice may be traced. These and other interesting observations are contributed by Captain Abney to the *Bulletin Belge*. That the characteristic properties of sensitive bromide, like those of phosphorescent compounds, should be exalted by heat up to a certain point, seems to afford some confirmation of Carey Lea's almost forgotten theory of actinism (see our vol. for 1867, p. 272). We shall probably say something more next week.

If we may judge by the opening ceremony at the Health Exhibition, less interest will be taken in this year's show than in that of 1883. The collection on view is a most miscellaneous one, most of the objects having only a remote or strained relation to the ostensible objects of the exhibiton. While the Duke of Cambridge was uttering somewhat stale platitudes about international exhibitions, the camera was at work; but as the light was not very bright, and the atmosphere inside the building was somewhat hazy, we are not sanguine as to the results.

"Blest be the art that can immortalise," said Cowper; only he spoke of painting, we believe, and not of photography. We came upon this quotation the other day in one of Dr. Holmes's works, and we came also on some other lines which are of interest in showing how we grow old in our portraits. From youth to manhood: "The artist takes a mean little brush, and draws three fine lines, diverging outwards from the eye over the temple. Five years.—The artist draws one tolerably distinct and two faint lines perpendicularly, between the eye-brows. Ten years.—The artist breaks up the contours round the mouth, so that they look a little as a hat does that has been sat upon and recovered itself, ready, as one would say, to crumple up again in the same creases on smiling." Quite a little lesson on retouching.

The *Archive* mentions an extraordinary period of darkness which, it says, affected London from Decembe 24th to January 5, and our Düsseldorf contemporary also states that during the whole of this period it was impossible to photograph by daylight, even with the most sensitive gelatine plates. We wonder that such a surprising phenomenon, extending over a period of more than a week, should have escaped our observation.

The *Daily Telegraph*, in referring to portraiture at the Academy, says:—"The modern portrait painter is on his mettle, and labours sedulously to do his best, as though he were aware that the Sun was among his sitters, taking notes, and that 'faith,' he would 'prent them.' Photography, so far from being the rival and the foe of the really good portraitist—it is true that it utterly slays the mediocre and the bad—is his counsellor and his friend. It shows him quite as many excellences to be imitated as defects to be avoided."

Mr. J. E. Taylor, of the Ipswich Museum, contributes to *Nature* an interesting account of a journey of observation he made in the track of the recent earthquake. It is much to be regretted that he did not take with him a portable camera and a stock of dry plates. The wonderful recording eye of the camera would, if it had been directed by Mr. Taylor, have placed on record an amount of detail calculated to throw much light on the subject. It appears that a few photographic illustrations of the earthquake have been secured, but no series exists having much scientific value.

A very interesting series of photographs is to be published by a firm at Pirna—the reproductions of all the portraits of the Popes in the "Chronologia Summorum Romanyium Pontificum," permission to copy which by photography has just been given by the Vatican. These portraits affect to go back to the earliest times, and if some are not genuine, there is no one to dispute their authenticity. The collection is, at all events, a valuable one.

The black cloud which recently passed over a part of Lancashire, and darkened certain neighbourhoods for about an hour, appears to have been caused by an accumulation of finely-divided carbon. The Rev. S. J. Perry,

of Stonyhurst Observatory, writes:—"At 11.30 the darkness was so great that it was found impossible to read even bold print (small pica) close by the window, and at this time a dense black cloud with a slightly yellowish tinge hung over the south-west sky; the blackness being most intense at 10° above the horizon. At 11.35 it became somewhat lighter, and at 11.40 the rain began to fall, and in forty minutes 0·114 inch of rain-water was collected in our rain-gauges, the whole being almost as black as ink, and full of fine carbon in suspension. Hail that fell a mile off to the south-west by south, and snow that fell on the hills two miles to the west, were also black.

Hydrogen is slowly liberated by the action of zinc on water, and it is consequently unsafe to store oxygen in gas-holders made of zinc. Löwe, however, states that if lime water is used in the gas-holder instead of ordinary water, no hydrogen is liberated.

Patent Intelligence.

Applications for Letters Patent.

7190. Jasper Wetter, Engineer, 67, Strand, Westminster, for "Improvements in the production of coloured engravings, photographs, and other images."—A communication to him from abroad by Lucien Forquignon, Bordeaux, France.—Dated 3rd May, 1884.

7191. Alfred Julius Boult, 323, High Holborn, Middlesex, Engineer, for "Improvements in rings for containing portraits or the like."—A communication to him from abroad by Emanuel Diamant, Budapest, Hungary.—(Complete specification.)—Dated 3rd May, 1884.

PHOTOGRAPHY IN MELBOURNE.

BY AN AMATEUR.

As a subscriber to your excellent journal, and a devoted admirer of the art and science of photography, I take the liberty of addressing a few notes to you from the Queen City of the South, and about which many people in England know and hear so little. It is the custom of many who have travelled a good deal to use the expression, "I have been round the world," who have never set foot in any of the Australian Colonies. Now, if the colonies are left out of a trip round the world, there is a great gap in the circle. But since the P. and O. Company and the Orient Company have laid on their splendid steamers and run them direct, travellers are turning their attention more to the colonies than formerly. New Zealand especially is very rich in scenery; the lake and mountain, I think, is not surpassed by any country in the world. I have no doubt you have seen examples of it, though a representative series of New Zealand views is as yet a thing of the future. There is a firm, I think, in Dunedin, who have turned out some very fair work.

Australia is not rich in mountain and lake scenery—that is, from a photographic stand-point; yet of virgin forest pictures there is an unlimited and really undeveloped field, though of such a nature that it requires judicious judgment in the selection of the point of view, and a skilful manipulation of the light, to make them meritorious as artistic productions. Some very fine studies have been turned out by one or two firms in Sydney and Melbourne Whole-plate is the general size for views in the colonies, and dry plates are almost exclusively used now; the days of collodion were numbered months ago.

There are a good many amateurs here, though nothing like in England. There is also an Amateur Photographic Association; the professional one, I believe, is defunct. Far advanced as the Colonies are, they are behindhand in photographic exhibitions, for I do not know of one ever being held in any one of them. It is to be hoped the day is not far off when they will be inaugurated, and perhaps a few English photographers will be persuaded to exhibit examples of their famous pictures, which must be really fine, judging by your excellent illustrations and glowing descriptions of them, which I read with great interest, and always regret when want of space cuts them short. By-the-way, it is a great pity that copies of these pictures do not find their way out here, for if it were not for your supplements we should have only a word description of them.

A great deal of rubbish is sent out here from England and the Continent as photographs of professional beauties, and plenty of mediocre landscape work. First-class work, such as you describe, we seldom see; and then it is only when it is in the possession of private individuals who have brought it out from home. It may be argued that it would not pay to ship good photographs of scenery out here, as there would not be a sufficient demand for it, on account of the supposed deficiency in taste of the colonials. I would like to know whether any firm at any time has tried the experiment? It comes expensive when one has to send home for copies of any particular pictures they may want; whereas, if they could be obtained here, the cost of postage, &c., would buy an extra print. In portraiture, the Colonies are not at all backward; excellent work is produced in all the principal towns, and some of the studios are fitted up very fine. Competition is very keen indeed—in fact, it could not be more so—and if a reputation is to be kept up, good work must do it. Unfortunately, the craze for the large over-retouched heads introduced by some American firms at the Sydney and Melbourne International Exhibitions has been taken up to a great extent, and has been sustained through some of the Americans establishing themselves here; but I do not think it will last. The public will fall back upon those firms who send out nothing but genuine work. It is only the vulgar in taste who are attracted by loud work, that exists at first by what eventually kills it.

THE GELATINE PROCESS.

BY WILLIAM BROOKS.

When travelling about in various parts of the country, as a rule I seldom pass a photographic studio without looking at the display of specimens exhibited in the window. I myself think that when the old wet collodion process was in full swing, the work generally was more even, but it matters not what process is used, or is the most fashionable, if I may so put it, muddles are always to be found in too great an abundance in almost every town. I allude to professional photographers. There are plenty who try to do everything they undertake to the best of their ability—and these are the ones who generally succeed in the end—and others are quite content to do things with the least possible trouble. I have at times come across many of the latter class, and sometimes I have suggested to them, when I have seen a fault, that they would get a better result if they did so and so, as the case might be, and at times I have had the reply, "Why, what's the use—people are satisfied, and why should I take any further bother about it? It pays me." And so long as this class of photographer can get an image at all, never mind if it is over or under-exposed, it is all the same.

I think since the introduction of gelatine plates, many more have been induced to go in for photography for a living than there were before.

Then there is another class of photographer who are always changing cameras and lenses, and always trying everybody's dry plates, and are satisfied with nothing, and

can never succeed, and try everything that is written almost. Their results, I need scarcely say, are anything but satisfactory.

There is another class who have the instantaneous craze; with them nothing is any good without it is instantaneous, as they call it. Their productions are generally under-exposed, and nothing done well.

Then there is the other class of photographer who are photographers in every sense of the word—who go steadily about their work, and succeed with almost any process. They will tell you, if asked, that the processes don't bother them much, and that they keep to one make of plate, and can generally get on very well. If one batch of plates does not work quite so well as the last, they only have, perhaps, to slightly alter either the developer or the exposure, as things are generally right, and on looking over the work it is generally to be found all that is needed as far as our general knowledge of photography has advanced.

Taking professional landscape photography, I think by a certain class there is far worse work done now than there was ten years since. I could not but notice, when in Oxford in the summer, the apologies for photographs that were being exhibited in some of the windows, and, say the least of them, they were abominable; intending to represent the different crews in their boats, they were simply indistinct, white patches on a black ground, and were labelled in large letters "Instantaneous." I have often wondered if such abominations ever find purchasers.

In the early days of gelatine plates, they were generally over-exposed; at the present time I may venture to say that many are spoiled by under-exposure. There has always been one weak point in the way of working gelatine plates, and that is, striving to bring them up with one development. I myself prefer to bring up the image, and not strive after density, and then intensify with pyro and silver. By my method it is a very simple matter, very easy, and without the slightest risk. After the plate has been well washed from the hypo, place it in a weak solution of alum and citric acid solution.

Stock Solution.

Saturated solution of alum	... 10 ounces
Citric acid...	... 1 ounce

For the solution above named, I dilute one part to four of water, allow the plate to remain in it about five or six minutes, in the meantime place in a developing cup about (say for a small plate) two drms. of the stock solution of alum and citric, and place in it about four grains of pyro; when dissolved, add a few drops of about a twent-grain nitrate of silver solution. Take the plate out and apply same as intensifying a wet plate; as the pyro changes colour, the colour will be imparted to the film, which is of no consequence. When sufficient density is obtained, well wash, and place in the hypo bath for a few minutes; well wash, and again place it in the alum and citric solution; dilute, to clear it. On examination, the character of sulphate will be found to have changed—it will have the appearance of an ordinary wet plate. The thinnest negative is amenable to this treatment. All this can be done in the daylight, It is best done before the negative has been allowed to dry.

RAPID *VERSUS* SLOW DEVELOPMENT.

BY E. BRIGHTMAN.*

The advocates of rapid development invariably object to slow development, first, on account of the extra time required, and secondly, on the ground that developing slowly causes a discolouration of the gelatine film. Now, as to the little extra time required, this surely should be no objection to the amateur, who works for the love of the art; a few minutes more or less spent on each picture certainly should form no objection. I readily admit that a very protracted development may cause slight discolouration, but cannot consider this as any serious drawback, because such discolouration may readily be removed by a short immersion in the alum and citric acid solution; moreover, the advantages of developing slowly are so great, that they would far outweigh the disadvantage of a slight staining of the film, even supposing such stain to be permanent and not removable.

A slow development undoubtedly gives a greater range of gradation between the high lights and deepest shadows, and as we have in nature an infinite number of gradations, it follows that a slow development will give a better and truer rendering of a subject than a rapid one.

In order to develop slowly, three courses are open to us: we may use a large proportion of bromide, or a small proportion of ammonia, or may add the ammonia gradually, adding it by successive small doses, until the desired amount of density and detail are obtained. This latter is the method I invariably adopt, and consider it gives by far the most satisfactory results, as it enables us to have entire control over the development, to avoid fog, and obtain brilliancy combined with delicacy and softness; and, most important of all, enables us to correct errors of exposure.

In the instructions issued by most manufacturers of gelatine plates, we are told to add certain quantities of pyro, bromide, and ammonia; then if the picture flashes out and shows signs of over-exposure, we are directed to apply more bromide, or, in other words, when the picture is half spoilt, we are to do what we can to prevent its total loss.

I cannot help thinking that this method of proceeding is totally wrong, as it is building up a picture on an imperfect foundation, for when once a trace of fog has made its appearance it is impossible to successfully carry the development further, without adding to the fog to a greater or less extent; but by slow development, even if a plate has been exposed five times longer than necessary, it is possible to produce a negative without the slightest trace of fog, and, moreover, without any loss of brilliancy, and in fact equal in every respect to one which has received only the normal exposure.

Now, as an ounce of practice is worth a pound of theory, I propose to expose three plates under a transparency, to one of which I will give 5 seconds' exposure, to the second 50 seconds, and to the third 100 seconds, or 10 and 20 times the correct exposure.

I can admit that for the professional photographer, working in the study with the light under control, he may so accurately time his exposures that there may be no necessity for such careful and cautious development; but with amateurs who, like myself, practise upon all classes of subjects, under all conditions of light, errors of exposure must occur; but if we observe the rule of always giving a full exposure, and developing slowly, not a single plate should be lost.

In addition to the absolute certainty of thus working, the results obtained are certainly superior to those by rapid development, having the pluck and brilliancy characteristic of a good wet plate.

Next as to formula for developer. I usually keep two stock solutions.

No. 1

Pyrogallic acid	... 1 oz.
Bromide of ammonium	... ½ oz.
Citric acid	... 80 grains
Water	... 8 ozs.

No. 2

Ammonia	... 1 oz.
Water	... 7 ozs.

To develop a half plate, take 4 ounces of water to which is added 1 dram of No. 1; immerse the plate in this solution, and allow it to soak for a moment or two. Next measure out one dram of the No. 2 solution, one fourth or quarter dram of which is poured into a measure and mixed with the pyro solution, in which the plate has been soaking; this solution is again poured upon the plate, and if sufficiently exposed, the higher lights will slowly appear, but without much density; a second quarter drachm of ammonia is next added as before; with this addition the more brilliant half tones will make their appearance, and the higher lights gain a little additional density. The third quarter drachm of ammonia is then added, when the details and faint half tones will gain in force; the remaining portion of ammonia being added, the faintest half tones will be brought out and the high lights have gained the full density; the resulting picture being,

* Read before the Bristol and West of England Photographic Association.

as far as development is concerned, all that could be desired. In the event of considerable over-exposure, the first or second addition of ammonia may be sufficient to fully develop the picture, and give full density, in which case, of course, no further addition should be made.

I do not attach any importance to the formula I have given. Any good standard formula may be used, but the one great point of importance is to commence with a small portion of the ammonia, adding it by successive small doses until the desired result is obtained.

DRYING PLATES WITH CALCIUM CHLORIDE.

BY THOMAS S. HAMILTON.

I AM ashamed of the naughty words I used formerly when engaged drying my emulsion plates, and afterwards in the development of them. Every method as published I have tried, with—I have to confess—indifferent success, for I seldom escaped without markings and spots on the films, due to a variety of causes that, I have no doubt, can be summed up in the word—"carelessness!" But humanity seeks not to be troubled with care, and a little latitude is "so delightful!"

The dried air current being my bugbear—for all those nasty things it did—I determined to do without it. To that effect I stopped up the inlet and outlet of my drying-box, making it as air-tight as possible, and distributed in six deep saucers four pounds of calcium chloride, placing one on each alternate end of the shelves, after which the plates were put in, and the box closed. The plates were dry in sometime less than forty-eight hours; and two more batches of fifteen whole-plates each were dried without touching the calcium, nor was it taken from the box until required for duty again, when it was turned out of the saucers into a drying-pan—a frying-pan—to evaporate slowly over the hot plate of the kitchen-range, and replaced in the unwashed saucers when on the point of crystallizing.

Chrome alum was used in the emulsion in the proportion recommended by Captain Abney in his "Photography with Emulsions."

This method of drying is simple—for any box that is air-tight can be used, and it is a certainty—for the plates are uniform and clean to the edges. For the past six months I have dried in this manner without a failure, and I will never again ruffle my temper in the attempt to dry air that will not dry plates half so well as act the carrier for every abomination that our too industrious "Biddy" insists on driving under the door and through the key-hole of my dark-room with that spasmodic broom of hers.

LECTURE ON THE COMPOSITION OF A PICTURE.

BY NORMAN MACBETH, R.S.A.*

HAVING occasion to be in London every year seeing the Royal Academy and other Exhibitions, I thought of paying a visit to this Society, and seeing that I had been honoured with the confidence you had reposed in me—adjudging the selected works of the year—I had the desire of having a friendly conference, and submitting for your consideration a few of the leading principles which operated in forming my judgment, and which might be deemed useful for further prosecution of such art studies. Consequently, I made the offer through your esteemed Secretary, and it was accepted.

He had, I noticed, led you to understand that I was to read a paper on the subject of "Composition of a Picture," but beyond a few introductory remarks, I prefer, from a few diagrams which formed the subject matter of some old lectures, to make a selection from them, and adapt them to our present circumstances, explaining them simply in a verbal manner. Having had some of the topics presented in the journals of photography last year, in a paper entitled "An Early Taste for Art," I have no wish that what I now give be repeated in print.

* Preparatory remarks to a discourse delivered before the South London Photographic Society (see page 301).

Before proceeding to my exposition, permit me to congratulate this Society on the very laudable effort you are now making in the direction of the art study of composition.

The pictorial is certainly an outcome of practical efforts in photography. Lately, when I was asked by the Edinburgh Photographic Club to make a design for their diploma, I represented photography in the character of a maiden as the daughter of Nature, Science, and Art. In the two former she has hitherto had great demands for her assistance, and now, by her extremely ready service in instantaneous work, she is becoming a meet help for the wants of fine art. But higher still than being an auxiliary, to her credit she is now displaying how successfully the principles and theory of art may be demonstrated. I need not refer to any higher than the composition and aerial perspective of the work which lately received the first award of this Society.

I trust that other societies will follow the example, and that conversaziones on art topics will occupy in the future as much attention as chemistry has done in the past.

In the early history of photography a transcript of any object caught up by the camera was such a marvel, one was satisfied with any production provided it was perfect in development but such has ceased to be curious, and far less to satisfy. A merely photographic transcript, however perfect in itself, does not constitute a picture. There must be a specific purpose, an object of some meaning aimed at, having a principal point constituting the main feature of the theme, and the subordinates following with their respective values.

The composition of a picture embraces, and is manifested in, form, light and shade, and colour. The latter, colour, you have nothing to do with, but by representation in tone. A putting or placing of them together in their respective values, in combination with varied treatment, constitutes the perfection of composition, and all the more when accompanied with great invention and originality. It is not to be expected that photography will ever rival the painter's manipulative skill in subordinating accessories, but it will go further in realism, if that be an object, and it is quite capable in the hands of an artist to show how a complete grasp of the spirit and theory of art may be fulfilled; but until this is clearly enunciated, it will hold but a very second place in the department of fine art.

Correspondence.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

SIR,—Will you please allow me a few lines to inform intending contributors to the "Statham Testimonial Fund" that the subscription list will be closed to-morrow (Saturday), May 10.—Yours truly, F. A. BRIDGE.

Hon. Secretary and Treasurer.

9, *Norfolk Road, Dalston Lane, London.*

THE PROPOSED AMALGAMATION OF THE LONDON PHOTOGRAPHIC ASSOCIATIONS.

SIR,—Does Mr. Cobb seriously believe it is possible for there ever to be an amalgamation of Metropolitan Societies, Associations, and Clubs? It is unwise to prophesy unless one knows, but of all the unlikely things I should suppose possible would be the amalgamation proposed in Mr. Cobb's letter. Still, it must be conceded that, as matters stand at present, there is undoubtedly a great waste of energy and needless expense in the maintenance of some three or four societies where one might serve. A glance at the YEAR-BOOK shows that in the three societies named there are no less than fifty-three officers, viz.—

The Photographic Society	25
The South London	16
The Photographic Club	12
	53

This does not include the newer London and Provincial Society, in which there are some four or five officers, and in which every member is on the Committee; nor does it include the Amateur Field Club. It is true that in the

three societies named there are gentlemen holding office in all of them, yet fifty-three individuals might be office-bearers; whereas, if amalgamated, one dozen would suffice. Probably the more serious objection is, that there are three separate rents and expenses, representing a waste of revenue quite sufficient to maintain a house all its own.

The real key-note of Mr. Cobb's letter seems to be that there are too many Metropolitan Societies; and if that is his meaning, I readily agree with him.—I remain, yours, &c.,

A Member of them All.

Proceedings of Societies.

South London Photographic Society.

The ordinary meeting of this Society was held on Thursday, the 1st inst., at the House of the Society of Arts, John Street, Adelphi, W.C., Edwin Cocking, Esq., Vice-President, in the chair.

The Chairman: It is my most painful duty to take the chair at this first meeting of the Society after the lamented death of our President, whose loss we must all so deeply deplore. For twenty-five years this Society has existed under one President, and during those long years we have not only entertained feelings of deep respect for him, but I may say love. I think it will be admitted that that feeling arose from one great characteristic of our late President, which was that of genial, warm-hearted sympathy. He was a man who was animated with the spirit of kindness which smoothed down angularities, and brought to light the latent good which was in everyone; after listening to his remarks we felt the tone of our minds elevated, and besides the brighter view of things which his words inspired, we felt grateful, and our hearts warmed towards the man who, with such unflagging interest, had presided over this Society from its first formation.

Mr. F. A. Bridge: It was thought before this meeting commenced, that a formal letter of condolence should be drawn up and sent to the family of our late President, whose loss has been such a great blow to this Society; had this been done, as a matter of strict etiquette a chairman would have been appointed, the minutes read, and the meeting adjourned. Our late President's first idea was duty; the best way we can do our duty towards him is by carrying on the work of the Society in which he took such an interest. Mr. Bridge then read an extract from the *South London Press*, which he considered a fair estimate of the general esteem in which their President was held. They all desired to be proposers of this letter of condolence, so he would ask the meeting to arise in mass, and an informal letter of condolence would be sent to the family.

The members again having taken their seats, the minutes of the previous meeting were read and confirmed.

The Treasurer said that the Society was represented at the funeral by a great many members; a wreath was also sent by the Society, which he photographed, a copy of which could be seen.

The Chairman then called upon Mr. Norman Macbeth, R.S.A., to deliver his promised lecture on "Composition" (see p. 300).

Mr. Macbeth, after alluding sympathetically to the memory of the late President, said a great portion of the matter he intended bringing before them would be of a desultory character, leaving himself open to questions which might arise in the course of his speaking, rather than simply confining himself to writing, and thus more information be contributed. Continuing, he divided his subject into seven different topics, viz.—1st, the field of view, its boundaries; 2nd, Landscape work; 3rd, Sea views; 4th, Mountainous views; 5th, Sky effects and arrangement; 6th, Figure subjects; 7th, Portraits.

In reference to field of view Mr. Macbeth said: Given any space, exercises the mind to fill it, and the artist's power to make manifest his own individuality. Every man has a distinct way of treating a subject, and makes a proper field in which to define his ideas. The thought may never have passed through one's mind why pictures are oblong, not square. The square shape was then illustrated, also the diagonal of the square of breadth of picture shown to form the most suitable measurement for the length of base-line of it. The lecturer then proceeded by saying that either longitudinal or vertical fields of such proportions and relationship must produce variety. When properly filled, square proportions would be too finely balanced. The question then arises, on what principle is it to be filled? All cameras should be made as much as possible of the oblong shape proportioned to the length, being the diagonal of the square of the breadth.

Dividing the field.—Divide an oblong into three equal divisions by three longitudinally, the points where these lines intersect constitute the principal points of choice in the picture. The principle is founded on the mathematical ratio of odd numbers; when even numbers, such as two, four, six, eight are employed, the same difficulties would be met with as in the square form—the parts would be too finely balanced, an illustration of this being shown. The lecturer, continuing, said, take care to keep the principal object as much as possible out of the centre, as it is always more forcible towards either side than it would be if it were in the middle of the picture. Divide the focussing glass of the camera into three or five, these being the simplest subdivisions. Looking at nature over these, some characteristic points will be sure to light on one of these intersections. Seven divisions may be made, but they are more confusing. Subdividing them by even numbers would constitute weak parts. Howard's "Sketcher's Manual," now out of print, is the best work Mr. Macbeth knew in which these principles were very fully enunciated.

Landscape.—The first thing when in the field is to determine the base-line of picture desired. The landscape painter begins his subject at a fixed distance from where he stands; this base-line should not be less than twelve paces or thirty-six feet from the position of drawing the scene. When the camera is raised to meet the eye, either standing or sitting, if dead level, the base-line is not likely to be too near. Many landscape photographers dip the camera to get more foreground than is desirable, thus straining those portions of the foreground out of their due proportions. Supposing the camera is placed twelve paces from a fixed point, and marked by some object such as a handkerchief, let six places be taken on each side of this; that span forms an angle of 60°, and constitutes the base-line of the picture; this prevents getting too near, and defines the extent of view. Some think that the centre of view is the centre of picture; but that is very often, and most desirably, kept to either side, with the intention of being on some strong intersected point; neither should the two sides in balance be alike, as in photographing a street view one should always preponderate over the other—*i.e.*, be more seen.

An illustration of the vanishing points was then shown, and the manner in which these ran out of a picture explained.

Overcharging the foreground was next spoken of, a diagram showing three sizes of picture taken with an instrument, and the errors seen in photographs taken with wide-angle lenses exemplified the radius of the human eye being a desirable field. Speaking on the importance of the horizontal, according to the subject, so the position of the horizontal line must be placed either towards the top or bottom. Where everything is flat, the horizontal line is placed low, affording space for clouds.

In photographing mountainous districts it is recommended to have the line near the top, thus allowing space for ravines, valleys, &c. There is not anything more important in the case of rendering hills, than keeping the principal light on either side of the picture and running diagonally.

In taking sea views, the horizontal line being low, allows space for clouds, which are often very beautiful in composition when taken on the same plate; but being made parallel with the base, should be avoided, especially where mountains are distant. Great value may be imparted by getting opposing lines of clouds in the composition. The skies may be secured on separate negatives, combination or double printing being resorted to. The sky shade of Mr. Parker (page 710 of our last volume) is invaluable for coast scenes when the horizontal line is low, the lecturer having succeeded in getting some very good results in the evening, when it was necessary to give a long exposure to the foreground, the sky all the time being shielded. The afternoon is the best period for making sky pictures.

Figure Subjects.—The best book on composition, the lecturer said, was by Burnett, the celebrated engraver of Wilkie's works. No books he had met with were so complete and reliable in giving information on the education of the eye, a proper appreciation of light, shade, and colour in its treatment, as these. The study of the Dutch pictures was recommended, particularly Teniers and Ostade were mentioned. A careful study of Mr. Robinson's new work should also receive special attention. The composition in Wilkie's works was next instanced, also Raffael's

cartoons. Speaking of "The Blind Man at the Beautiful Gate of the Temple," he said each of the pillars there formed fine intersections, and were beautifully filled by forms in the shape of a cross. In all cases it is necessary to guard against repeating in exact balance, an important point on the other side of a picture. By keeping this in mind, and the intersection by odd numbers, photographers would be sure of getting variety. In visiting the French Exhibition, these principles were well carried out in pictures there. Some of these painters may never have known these rules, but have been guided according to them through following the works of others. From exhibitions we see many artists, not knowing these methods, or ignoring such teaching, run into many errors.

Speaking of portraits, the lecturer noticed there was a tendency to place the head too near the centre of the picture. A good rule is to let the space from the hair to the top of the picture be one-quarter the length of the head for an English head size, 25 by 20; the next size, 30 by 25, let the distance be double, that is, half a head; kitcat, 28 by 36, three-quarters of the head; and 50 by 45, a full head. He should have said something about the composition of the works of Vandyke, Rembrandt, Turner, Rubens, Velasques, Reynolds, Millais, and others, but time would not permit. A man should be regulated by his own ideas and feelings, so long as these do not altogether violate such simple guides; the recognition of such principles as now laid before them would be ample; they would be able to produce immense variety in form and general interest. A large number of examples from engravings were then shown, illustrating where these rules had been observed, and where they had been disregarded.

The subject being closed, several members put questions, which Mr. Macbeth answered, in so far as they related to the subject. In reply to Mr. Downes, Mr. Macbeth stated that everything depended in carrying out the proper length at which the subject was to be viewed, and photographed, on length of focus of lens, and length of accommodation in studios; he strongly deprecated wide-angle lenses to meet limited spaces. By whatever means employed, there should never be over-straining the lens, and so producing false effects. His own studio for painting was 35 feet long, 25 broad, and 22 feet high. He could never feel the true aspect of his sitter without such accommodation. As to Mr. J. Traill Taylor's question regarding the base-line of a full-length portrait, Mr. Macbeth recommended it to be low, to guard against the tendency of overloading the field with too much furniture, and the appearance (unless you represented a very distant view of the field of picture) of making the floor and accessories on the table all tumbling or sliding down. A very distant view, and the horizontal line low, gave great dignity to the whole arrangement. The painter, in contra-distinction from the photographer, views his subjects from many levels, the latter from only one point. Hence the necessity of being far from his sitter.

The Chairman, in moving a vote of thanks to the lecturer, said he hoped societies in the future would induce artists like Mr. Macbeth to accompany them into the field, where they might get the advantage of practical illustration of the principles set forth.

The vote being accorded, Mr. Macbeth said no jealousy existed between himself and photographers; each were only studying facts, and the great object of each is, who will make the most of them. Many most excellent artists fully appreciated photography, and took advantage of any assistance a photograph could give them. He should be exceedingly glad to come again to this Society.

The Chairman announced the presence of a distinguished visitor, Mr. Pancoast, late Secretary of the Photographic Society of Philadelphia, who was accorded a warm greeting.

Mr. Pancoast said he had just returned from a tour in India, visiting the Calcutta Exhibition *en route*. At no time in the history of India had such a magnificent collection of fine arts been brought together as on this occasion. Many of the exhibits he photographed, and would send them some prints as a token of his appreciation of the Society.

The Chairman announced that the subscription list for a suitable memorial to the late president would close on May 10th. The next meeting of the Society will take place June 5th.

London and Provincial Photographic Association.

The usual weekly meeting of the members was held at Mason's Hall Tavern on Thursday, the 1st inst., Mr. W. E. Debenham in the chair.

Mr. J. Barker, in reference to the discussion of previous week on definition, showed a print from a negative taken with a common French portrait lens of 4¼-inch back focus with full aperture.

The Chairman did not consider a print was sufficient evidence in itself of a power of a lens; it should be compared under precisely similar circumstances with a well-known and tested lens.

Mr. J. Cadett, refering to diffraction, remarked that Professor Stokes had said: "If the diaphragm is placed exactly at the optical centre, no diffraction can take place, however small the aperture of the diaphragm."

Mr. F. G. Hart showed a simple way of locally removing matt varnish to increase printing power. Having coated a sheet of glass with matt varnish, and dried it, he passed it over an uncorked bottle of ether; those parts of the glass plate that had been exposed to the vapour were reudered quite transparent. This plan has the advantage of leaving perfectly soft printing edges.

Bristol and West of England Amateur Photographic Association.

The ordinary monthly meeting was held at the Association's Studio on Wednesday, 23rd inst., Colonel Playfair, Vice-President, in the chair.

After the usual preliminaries,

The Chairman called upon Mr. E. Brightman to read his paper on "Slow *versus* Quick Development" (see page 299).

The Chairman said that Mr. Brightman, having exposed two plates of similar sensitiveness, one for eight seconds, and the other for eighty seconds, and developed both with successful results, had demonstrated that, so far as these experiments were concerned, slow development possessed decided advantages. He should like to have seen compared the development of two negatives correctly exposed, one by slow, and the other by quicker, development.

Mr. Brightman said that he should very probably bring such examples at a future meeting, and he thought the results would prove the superiority of the former mode.

The Chairman asked Mr. Brightman if he followed exactly the same practice with regard to under-exposed negatives?

Mr. Brightman replied that he did exactly, always using the same quantity of pyro.

The Chairman said that that appeared to him to quite oppose the usually accepted law.

Mr. Daniel said that probably the effect produced was that of obtaining full detail at an earlier stage of the development, so that such detail was really worked up before the pyro was sufficiently acted upon by the ammonia to produce much density in the high-lights.

Mr. Tribe had generally considered that in developing an under-exposed negative, it was desirable to lessen the amount of pyro.

After some further discussion, the next and first excursion meeting of the session was fixed for Saturday, 17th May.

A cordial vote of thanks, on the motion of the Chairman, was unanimously passed to Mr. Brightman for his interesting paper.

Dundee and East of Scotland Photographic Association.

The eighth and last monthly meeting for the session was held in Lamb's Hotel on Thursday, 1st inst., Mr. J. Geddes presiding.

After the routine business had been disposed of,

Mr. Jno. Robertson read a paper on "Dark-room Illumination." Until lately he had scrupulously obeyed the injunctions accompanying dry plates, and had worked in ruby light. As the result of some experiments, however, he had entirely discarded ruby, and fitted up his dark-room windows with two thicknesses of cathedral glass with a double sheet of orange tissue between. The illumination of his dark-room was now all that could be desired, and he had never enjoyed such a perfect immunity from fog, as, since the adoption of this light, the result was so satisfactory that he was fitting up the same light in his coating-room. A hearty vote of thanks was awarded to Mr. Robertson.

One new member was admitted.

Mr. Walker kindly sent a collection of prints taken about 1856, which excited much interest, and the fact that in very few of them were signs of fading to be detected, testified to the carefulness of the manipulation.

On the motion of the Chairman a vote of thanks was passed to Mr. Walker.

Glasgow Photographic Association.

The annual business meeting of the session was held in the Religious Institution Rooms on Thursday, 24th ult., Councillor Robertson presiding.

The minutes of last meeting were read and confirmed.

The office-bearers for the ensuing session were then elected, and were as follows :—

President—Councillor Robertson.
Vice-Presidents—Messrs. Robert Dodd and John Parker.
Treasurer—Mr. G. Bell.
Interim Secretary—Mr. J. Craig Annan.
Council—Messrs. J. Craig Annan, W. Laug, Juu., Geo. Mason, James McGhie, J. Y. M. McLellan, and Mr. J. M. Skinner.

An outdoor meeting was then arranged for, and Cadzow Forest (the home of the Duke of Hamilton's famous white castle) was suggested as the place, and 6th of June as the date. The arranging of the details was left to the Council and Mr. Falconer.

Some business of a private nature followed, and at the close of the meeting

Mr. Falconer showed a number of very good magic-lantern and stereoscopic transparencies, and also a sky-shade. This was something like the upper half of a diaphragm, and was composed of slips of card, which could be pushed up or down to the approximate shape of the sky-line. This was inserted on a slip in the front of the lens during the greater part of the exposure, and removed just before replacing the cap.

The meeting closed with the customary votes of thanks.

Talk in the Studio.

Photographic Society of Great Britain.—The next ordinary meeting of this Society will take place on Tuesday next, May 13th, at eight o'clock, p.m., at 5A, Pall Mall East (the summer exhibition of the Royal Society of Painters in Water-Colours being on view), when papers will be read, on "Observations on Fading," by John Spiller, F.C.S.; "Illumination of the Dark-Room," by W. E. Debenham; and "Commercial Fabrics Suitable for Dark-Room Illumination," by J. R. Sawyer.

The Copyright Act.—Mr. Sheil heard ten summonses which had been taken out by Mr. H. W. Taunt, photographer, of Oxford, under the Copyright Act, against Canon Erskine Clarke, the registered proprietor of *Church Bells*, for publishing a colourable imitation of a photograph, his property. Mr. Dudley, of Oxford, appeared for the complainant, and Mr. Turner for Canon Clarke. It was stated by Mr. Dudley that it was a photograph of St. Nicholas Church, Newbury. Mr. Turner admitted that the illustration was taken from the photograph, but he submitted that it was not a copy, nor a colourable imitation, as provided by the Act. Canon Clarke had no desire to infringe the Copyright Act. The photograph was sent by a gentleman from Newbury, with a request to publish it. Mr. Sheil dismissed all the summonses, and granted the compiainant a case for the opinion of a superior court.

A Question of Ancient Lights.—In the case of Parker *v.* The First Avenue Hotel Company, heard in the Queen's Bench on Wednesday, the plaintiff had for many years carried on the business of a photographer at 30, High Holborn, which is at the corner of Warwick Court, and his studio is at the top of the house. The First Avenue Hotel was built on the west side of the plaintiff's premises, and there had been a good deal of litigation in reference to the obstructiou of the plaintiff's light. Mr. Justice North granted an injunction to restrain the defendants from carrying on their building operations except in a particular way; and this order was afterwards modified in the Court of Appeal. The present application was that a sequestration should issue in consequence of this injunction not having been obeyed. Mr. Finlay, Q.C., and Mr. Colt were for the plaintiff; and Mr. H. Matthews, Q.C., and Mr. Bedall for the defendants. The proceedings were for the most part of a technical and an uninteresting character. But in the end, counsel, acting upon a suggestion from the Bench, came to an arrangement by which it was said that all further litigation would be put an end to. It was mentioned that there were two actions pending, and also an appeal to the House of Lords in one of them.

The Photographic Co-operative Stores.—We understand that the business of the Photographic Artists' Co-operative Supply Association, Limited, has changed hands, and that a new Company has been formed to carry on the concern. Messrs. Arthur H. Laing, A. F. Charrington, and W. B. Whittingham are mentioned as being on the Board of Directors. Mr. H. R. Faulkner, who has been connected with the business for upwards of five years, has been appointed manager and secretary.

Death of Mr. F. A. Wenderoth, of Philadelphia.—This veteran photographer and artist died on the 15th of March, his age being sixty years. He was a native of the Hesse-Cassel, but removed to Philadelphia in 1857.

Magnesium.—At the close of the last meeting of the Berlin Physical Society, Dr. Frölich handed round a large lump of magnesium as the product of an electrolytic industry. The piece was wrought in a factory according to a patented method based essentially on the melting of chloride of magnesium, and decomposing it in the melted state by an electric current.

Lecture Experiments on the Actinic Action of Light.—By V. Meyer (*Ber.*, 16, 2998—3001).—For the purpose of showing the action of light on an explosive mixture of chlorine and hydrogen, the author fills jars 25 cm. high and 35 mm. wide with the mixture, and closes them with paper covers; one is left colourless, and others coloured violet and yellow by means of spirit varnish and aniline colours. On igniting a large quantity of magnesium-dust in a Bunsen burner, the gas in the colourless and violet jars instantly explodes, but that in the yellow jar does not, and may be fired with a burning chip. A fourth colourless jar may be kept to show photo-chemical induction, for whilst with sufficient magnesium-dust the explosion takes place instantly, on exposing the mixture to burning magnesium wire, several seconds elapse before the gases combine.—*Journal of the Chemical Society.*

Cantor Lectures on Optical Instruments.—Mr. Norman Lockyer has just delivered a short course of lectures at the Society of Arts, on "Some New Optical Instruments and Arrangements." The course commenced by a discussion of some points in connection with astronomical telescopes, while in the second lecture he laid great stress upon the want of proper arrangements for the manufacture of optical glass. The great want for instruments, such as those described in the last lecture, was a mirror of sufficient size; and if it were possible to cast a disc of glass of eight feet diameter, and of the necessary thickness (which would be for a dise of that size about one foot) there was no difficulty whatever in silvering the surface. He then proceeded to give some account of the progress which had been made in photographing celestial objects, by Mons. Janssen in photographing the sun, by Mr. Huggins in obtaining photographs of spectra of the stars, and by Mr. Common in obtaining photographs of the nebulæ themselves. He exhibited and described the instantaneous shutter arrangement used by Mons. Janssen. In the case of the long exposure, rendered necessary by the faintness of the light of the stars, the motion of the clock proved not to be sufficiently accurate to keep the image of the star always in the same position on the photographic plate, and it was necessary for the observer, by means of apparatus which Mr. Lockyer described, continually to regulate the position of the photographic plate by hand. Mr. Lockyer pointed out the importance of these photographic observations, which were not influenced by the idiosyncrasy of the observer, and which possessed the advantage of dealing with larger portions of the heavens, and more rapidly than the observer's eye. He expressed the view that it was now a waste of time to employ the eye in astronomical observations, and sketched an instrument having an aperture of eight feet, and costing only half the price of the domes now being built in Paris, by which photographic plates exposed by electro-magnets should be alone employed. By this means a complete reference library of the heavens at the present epoch could be secured for the benefit of those who come after us, giving forms of nebulæ and clusters, photometer star maps, double stars, and stellar and nebular spectra.

Gelatine.—By H. Weiske (*Bied. Centr.*, 1883, 673).—The author has prepared gelatine in various ways, and has found that the products differ in properties. Pieces of bone were treated repeatedly and for a long time with dilute hydrochloric acid to remove the inorganic matter as completely as possible; they were then washed. Gelatine made from this is not precipitated from its solutions by tannic acid unless a few drops of a solution of a salt (sodium chloride, &c.) are added simultaneously; in other respects it does not differ from ordinary gelatine. By boiling bones

free from mineral matter with repeated quantities of water, and then dissolving the residue by heating with water under pressure, two solutions are obtained which, when evaporated to dryness at 100°, yield two kinds of gelatine differing from one another, and also from the above variety in various properties.—*Journal of the Chemical Society.*

PHOTOGRAPHIC CLUB.—At the next meeting, on May 14th, the subject for discussion will be on "Developing with and without Sulphite of Soda."

To Correspondents.

*** We cannot undertake to return rejected communications.

J. H. B.—As the negatives are larger than the required slides, you must perforce copy them on a reduced scale by means of the camera. As any method by which negatives can be produced in the camera will serve for the making of lantern transparencies, it is difficult for us to give you useful advice unless we know what you can do; but if you are specially experienced in any one negative process, you had better adopt that. Very fine results—perhaps, indeed, the best of all—can be obtained by the wet collodion process when it is in the hands of a skilled manipulator. A series of articles on lantern slides was commenced on page 129 of the last volume of the NEWS.

H. SPINK.—We have not yet got the information you require, but will communicate with you by post should we be successful.

J. M.—We have every reason to believe that the markings arise from the presence of a trace of greasy matter in the gelatine, and this seems to exist mainly on the surface of the original flakes. In similar cases we have found it to be an advantage to wash the gelatine in ether before dissolving it.

A. G. B.—1. Your query appeared on page 286 last week, and we hope to have Dr. Eder's opinion on the subject. 2. We have not seen the pictures, but should like to have further particulars. 3. Ths firm is an old-established and respectable one, and has been carrying on the same business for about twenty years. We are altogether unable to account for your experience, but will write to them. 4. Each component will make an excellent single lens, but you will find that their foci are not identical, except in the case of some of the older instruments. If you use the front combination, with the stop behind, the distortion will be of the pincushion kind; but it is perhaps more convenient to use the back combination, as the tube forms a sky-shade. In any case, cover the bright brass screw with a ring of black paper. 5. We can hardly recommend its use unless circumstances render thorough washing impracticable. If any lead remains in the prints, they are liable to blacken if exposed to an impure atmosphere. 6. Probably you did not wash away the hyposulphite of soda completely, and, as the film dried, the image became partially dissolved. 7. It may be used to replace the distilled water, but we would recommend you not to use it unless circumstances render it unavoidable.

W. E. W.—We should strongly advise you not to enter into the transaction unless the person is well known to yourself, or you have the written consent of the publisher to copy the engravings. We know of a case in which a paid informer called on a photographer with a similar story, and afterwards extorted a considerable sum by threatening to prosecute for piracy.

F. W. B.—1. We cannot judge well without seeing examples, but should think it likely that the first mentioned defect arises from irregularity in the drying, perhaps caused by opening the door of the drying cupboard; and the second from pimples or defects on the glass plates. 2. No harm will result as long as the acid does not come in contact with the plates.

WILLIAM LANG.—1. We believe it has not been translated at full length, but nearly the whole is comprised in an abstracted translation, which was commenced on page 172 of our volume for 1878, and runs through this volume and that for 1879. 2. We believe that the method has been worked very successfully under the direction of M. Leon Vidal himself.

L. T. HAAKMAN.—1. You are quite right—the inlet should be the larger of the two. 2. We think it will be quite necessary to warm the upshot pipe, as otherwise you could not depend on a constant circulation of air taking place. 3. Thank you; we shall be very pleased to have particulars.

GIULIO ROSSI.—1. Traces of greasy matter in the emulsion (see answer to J. M). 2. We think they are due to a disintegration of the surface, arising from the circumstance already referred to.

QUI BONO.—You can hardly expect us to assist you in selling them, but if your work is good, you should have no difficulty in finding a market for them in the town where you reside. If you wish to work for the photographic profession, you cannot do better than to advertise.

R. T.—"*Trockenplatten*" would be the equivalent of the English "dry plates," but this expression does not in any way correspond with the French "*Clichés Photographiques*," as by cliché one understands the original from which copies are produced, whether this original be a negative or a positive. There is no precisely equivalent expression in English or German, and, as a consequence the term cliché is frequently imported into these languages.

R. S.—We believe that twenty-one years is required in ordinary cases, but you should consult a solicitor.

A CONSTANT READER.—It is a trade secret of some value, so we imagine it would be of no use for you to make an enquiry of the firm interested in the matter.

SOUTH DEVON.—Any maker of photographic apparatus will construct it from the designs which have appeared in the PHOTOGRAPHIC NEWS.

W. G. CLEMENT.—1. We do not think there are any commercial plates which can be depended on in this respect. Indeed, if you could devise a means of making such plates as you require, you would confer a benefit on the photographic fraternity. 2. You should try the combination of orange glass and ground glass recommended on page 50.

J. E. H.—1. We recommend you not to use a preparation of unknown composition for the purpose. 2. It has been done long since by Mr. Woodbury and others.

ALPHA.—1. The best series we know of consists of the "Photographic Handy Books," published by Piper and Carter. No. V., Mr. Robinson's "Picture Making by Photography," has just been issued. 2. Certainly you can if the lens is a good one.

J. H.—(Plymouth).—Write to Dr. Pick, of 38, Queen's Road, St. John's Wood.

Price 6d., by post 6½d.

A TRIP TO THE GREAT SAHARA WITH A CAMERA. BY A COCKNEY. Being an Account of a Month's Winter Holiday, with Diary of Journey and Statement of Expenses.—PIPER & CARTER, PHOTOGRAPHIC NEWS Office, 5, Castle Street, Holborn, E.C.

The Photographic News Registry.

Employment Wanted.

Photo. Colourist and Retoucher.—Photo, *Photo. News* Office.
Recep.-Room, 7 years' experience.—E. Smith, York House, Cheltenham.
Spotting, Mounting, (lady) —K. B., 67, Colvestone-crescent, Dalston.
Retoucher, Recep.-Room, Spotting.—2, Marion Villas, West-st., Bromley.
Retoucher & Assist. Operator.—J. V., Folly Hall, Huddersfield.
Artist, as Op. & Retoucher in good house.—A. B. 19., *Photo. News* Office.
Artist in Oils & Mono.—C. E. Sharpe, 28, Hardy-st., Gt. George's-sq., L'pool.
Op. & Ret., best houses Paris & Italy.—A. L. H. Puzzi, 420, Euston-rd.
Studio & Reception-Room, West End.—E. M., 1, Benhill-rd., Camberwell.
Printer, &c., French, speaking Eng.—A. C., 6, St. Martin's-st., Leicester-sq.
Recep. Room & Colourist.—E. Smith, York House, Bath-rd., Cheltenham.
Op. & Ret. £3 3s. weekly.—W. H. H., 29, Black Lion-la., Hammersmith.
Retoucher & Colourist.—Operator, c/o Mr. Bradshaw, 52, Cheapside.
Artist, three days a week.—Infelix, 3, York Villas, Brighton.
Retoucher, 25s. weekly.—Miss H., c/o Mr. Kent, 49, Newman-st., W.C.
Gen. Assist, 16s. weekly.—L., c/o. Mr. Kent, 49, Newman-st., W.C.
Mounter, Retoucher, Finisher.—E. R., 4, Offley-rd., Brixton-rd.
Reception-Room in first-class house.—Sophy, *Photo. News* Office.
Printer & Toner, first-class.—T. Cook, 20, Bromhead-st., Commercial-rd., E.
Operator, good at landscapes.—Mercury, 3½, Queen-st., Soho.
Col. & Ret. (lady).—F. W., 24, Fairview-ter., Milford Manor, Salisbury.
Italian Operator, speaks English & French.—Spagliardi, 20, Grove-la., S.E.
Retoucher (young lady).—E. F., 92, City-rd., E.C.
Reception-Room or Shop.—L. A., 77, City-rd., E.C.
Retoucher (lady), Lond. or near.—H. M. A., 45, Rye-hill-pk. Peckham.
Spot. & Mounter, Recept.-Room.—Miss Smedley, 45, Gt. North-ter., Linc.
Printer & Toner.—F. K., 40, Brooksty-st., Liverpool-rd, N.
Reception-Room, Correspondent, &c.—A. J., 6, Marlbro'-st., W.

Employment Offered.

All-round Hand (single).—Cuckney and Co., Rochester.
First-class Floater.—Tavistock Works, Tavistock-pl., Kensal-green.
Printing, Toning, &c.—Personally, 67, Pentonville Road, N.
Assistant Silver Printer.—W. N. Malby, Chichester.
Operator and Retoucher.—W. H. Widwinter, 49, Park-st., Bristol.
Operator, wet and dry.—J. Bateman, St. George's-st., Canterbury.
Artist for India at once.—R. B., c/o Marion and Co., Soho-sq.
Enameller at once.—Oeffelein & Co., 54, Berner's-st, W.
Assistant Operator (must retouch).—J. Willis, Manor-rd., Gravesend.
Printer, to board in house alternate Sunday.—J. Willis.
Reception Room, Spotting, &c.—Lavis, Eastbourne.
Assist., to super. Print. & Finish.—W. H. A., 247, Brecknock-rd, Tufnell-pk.
Printer, Toner, Vignetter, &c.—H. Hallier, Stafford-st., Walsall.
Operator and Retoucher (part. of self).—Taunt & Co., Oxford.
Retoucher (specimens).—Elliot & Fry, 55, Baker-st., W.
General Assistant, to retouch, finish, &c.—T. Price, Jersey
Printer, Toner, Vignetter, &c.—T. Moss, 199, Derby-st., Bolton.
Person to Mount and Spot Cards, &c.—Lafosse, Knolls House, Manchester.
Retoucher, and assist in Reception-Room.—Artist, *Photo. News* Office.
Operator, to take entire charge.—Cobb & Son, Woolwich.

THE PHOTOGRAPHIC NEWS.

VOL. XXVIII. No. 1311.—*May* 16, 1884.

PATENT OFFICE LIBRARY

CONTENTS.

Henry Baden Pritchard.

IT is with deep regret that we have to announce the death of Mr. Henry Baden Pritchard, whose name has been so long and intimately connected not only with the PHOTOGRAPHIC NEWS, but with the photographic world in general. He had been ill for a week or ten days with an attack of pneumonia, but was progressing very favourably, when on Sunday evening last, the 11th May, he was seized with faintness, and died almost immediately.

Mr. H. B. Pritchard was the third son of the late Mr. Andrew Pritchard, the eminent microscopist, and author of the "History of Infusoria." He was born in 1841, and in 1873 married Miss Mary Evans, whose acquaintance he had made at the house of his friend, Mr. H. P. Robinson, of Tunbridge Wells.

In 1861 he entered the Royal Arsenal, Woolwich, and for some years past conducted the Photographic Department there. Being a man of great mental activity, he got through a large amount of work in his leisure moments, and devoted much of that time to literary pursuits, contributing to scientific and other journals, and also writing interesting papers on the various places visited by him from time to time. The bright and chatty account of "A Trip to Sahara with the Camera," which has recently appeared in these columns, fittingly illustrated his powers of imparting much useful information in a cheery and humorous manner; and this power has also been recognised by the success of his "Photographic Studios of Europe," and other papers. His busy pen was also engaged at times in lighter literature; and "Daugerfield," and "George Vanbrugh's Mistake," may be quoted as perhaps the best written of his novels.

Nor was it only in literary work that his unbounded energies were spent. At the commencement of the Volunteer movement, he took it up with enthusiasm, and until a few years ago was a most active and efficient member.

In social life his presence was always welcome. With grown-up people and with children alike, his arrival was hailed with pleasure, for his bright and genial appearance seemed to bring sunshine whenever he appeared, and his power of entertaining a youthful audience was proverbial. Only the Friday before he died, he sent a most characteristic telegram to his friends at the Whitefriars Club, regretting his enforced absence, adding, in his humorous way, that he was prevented by a more pressing engagement (he was ill in bed at the time), but that "he was very jolly, nevertheless."

With all his love of fun, he had the kindest heart imaginable, and was ever ready to defend the weak cause, and to help those who were in trouble, so that his death will cause a void, which will not easily be filled, in a large circle of friends.

The interment took place at Abney Park Cemetery, at half-past four o'clock, yesterday afternoon.

A MIXED SODA AND POTASH DEVELOPER.

MR. NEWTON, at a meeting of the Society of Amateur Photographers of New York, proposed to use a mixture of carbonate of potash and carbonate of soda in the alkaline developer. He claims advantages for the mixture which neither of the alkaline salts possesses when used by itself. As chemists fully recognise the fact that certain reactions are more easily effected by a mixture of the carbonates, we are quite prepared to believe in the advantages which Mr. Newton claims for the mixture. Apart from all question as to any gain by using the two alkaline carbonates in conjunction, we may refer to the advantage of using the carbonate of potash or soda for the alkaline element of the developer, as the salts in question are easily obtainable in a pure state; and when the solutions are once made, mere exposure to the air will cause no alteration unless by the absolute evaporation of the water. We hope our readers will make up a developer in accordance with the following directions of Mr. Newton, and report to us on the result. Mr. Newton says:—

"Into a quart of water I put three and one-quarter ounces of carbonate of potash and three and one-quarter ounces of carbonate of soda; that will give you (reckoning four hundred and eighty grains to the ounce) very nearly one hundred grains to the ounce; a little short, but near enough for all practical purposes. If you buy the carbonate at the grocery stores, dry it before you use it—dry out the water. Into another quart of water I put three and one-quarter ounces of sulphite of soda. Those are the two stock bottles. Three ounces of each of those two stock solutions with six ounces of water added, will give you twelve ounces. In each ounce there will be twelve and one-half grains of each of those ingredients—potash, soda, and sulphite. That will give you twenty-five grains to the ounce of developing solution, that is, the carbonate of potash and soda. The sulphite will develop a picture, but it is not reckoned as a developer; it is used here to give color to a negative or to prevent color. The developer given will develop a picture without any restrainer, and give you a clear, beautiful negative, if the exposure is right. If the exposure has been too long, then you must add a restrainer or make it weaker.

"Now, in contrasting the soda developer or the potash, with the ammonia developer, there is this to be said in its favor: you are limited to a very small range with the ammonia developer. If you get up to six or eight drops to the ounce, you are pretty sure to get a fog any way—I do not care how much bromide you have in it—but with this developer you cannot get a fog with the strength that I have given you, twenty-five grains to the ounce for a very rapid exposure; two and one-half grains of dry pyro to the ounce, is the proper amount of pyro. If you reduce the strength, however, do not use but one grain and a half of pyro. As you increase your strength up to fifty grains, you run your pyro up to six grains to the ounce. You can go on up so that you will have to use twelve grains to the ounce, by increasing the quantity of alkali. The quantity of pyro must be in harmony with the strength of the alkali development in order to get the proper intensity.

"I have found, in my experience, that acid solutions of pyro after standing two months, lose four-fifths of their potency as a developer, so that I do not use them any more. I never was in favour of using pyro in solution anyway. Dry pyro is the best form in which pyrogallic acid can be used. Put the dry pyro into the solution that I have just given you; you can put it in half an hour before you want to use it. You can develop four or five negatives right in this same solution, one after another. I have developed four, and the last one was just as good as the first."

CAREY LEA'S THEORY OF THE LATENT IMAGE, AND ABNEY'S RECENT EXPERIMENTS.

Last week we alluded to some experiments of Captain Abney's, which prove that heat has a remarkable action in increasing the sensitiveness of the gelatino-bromide film; or, what comes to the same thing, that if two portions of the same film differ as regards temperature, the warm portion will be more sensitive to light than the cooler portion. The limits within which this holds good have not yet been determined, and this week we publish (page 315) an important communication by Captain Abney on the subject.

In order to render Captain Abney's main idea as clear as possible, we will translate a portion of his recent communication to the *Bulletin Belge*. He says:—

Your readers are aware that if a phosphorescent plate is exposed to light, and, after a certain time, the finger is pressed in contact with the back of the plate, it may be noticed that the luminosity increases temporarily; but after some time, the part which has been pressed becomes darker than the rest of the plate. If one is inclined to theorise as regards this phenomena, one will say that it is the heat which has caused the molecules of the phosphorescent tablet to shine more brightly. I concluded that if this is true, it might apply equally to the sensitive plate, and I will relate some experiments which I have made in this connection.

A phosphorescent plate was exposed to the rays of a source of light, and, after an interval, I applied a piece of heated iron to the back of the plate, the result being the production of a visible image of the piece of iron, the image being brighter than the rest of the plate. A similar experiment made with a piece of ice resulted in the production of a diminution of the phosphorescence. Afterwards I took a gelatino-bromide plate, and placed the same piece of hot iron against the back until the part was warm. I next gave a short exposure to light, and, after cooling, the plate was developed; the result being that the image of the piece of iron was visible. The sensitiveness of the plate was much increased by the application of heat.

Captain Abney next describes a perfectly similar experiment in which a morsel of ice was placed against the back of the plate, and an exposure was made while a part of the plate was still cold. A region of less sensitiveness corresponded to the outline of the ice.

The following experiments which we made with a sample of phosphorescent sulphide of calcium are strictly analogous, and serve to confirm the view of Carey Lea that the action of light on a phosphorescent body is strictly analogous to its action on a sensitive film. As far as we know, the stored-up light in sulphide of calcium can only be entirely removed by exposure to a somewhat high temperature; so in order to obtain a suitable sample free from light, we packed some of the commercial powder tightly into a crucible, and heated it to redness for half-an-hour, after which we allowed the whole to cool in a completely dark place. Working now in the feeblest ruby light possible, we used a fine saw to cut some slabs from the material, which was now agglomerated, so as to be similar in texture to bath brick, and the slabs were stored away in a perfectly light-tight box. A piece of hot iron was now held against one of the slabs so as to heat a portion, but as there was no light stored in the material, no luminosity was noticeable; but on exposing the slab to the light for a few instants, and then taking it into the dark, it was quite obvious that the warm sulphide, like the warm film, possessed increased sensitiveness to light. Local cooling produced the contrary effect, the sensitiveness to light being less where the sulphide was cooled. When the sulphide of calcium is warm it not only takes up light more readily than when cold, but also gives up or discharges the light more rapidly. Whether an exposed plate will lose its image more rapidly when subjected to heat than when kept cool remains to be seen; but if the analogy between the sensitive plate and the phosphorescent surface holds good we should expect this to be the case.

A letter from Mr. Killick, which will be found on page 315 shows that it has already been observed that a longer exposure is required on a cold day than on a hot day; but we do not find that it is at all clearly indicated that the heat actually increases the sensitiveness of the film. A person reading the article referred to (Year-Book, 1884, page 41) might conclude either that the film becomes more sensitive when heated, or that the developer becomes more active in hot weather.

As the theory of actinism propounded some seventeen years ago by Carey Lea has not received much attention in recent times, we print some extracts from our volume for 1867. Mr. Carey Lea says:—

If certain bodies, known as "phosphorescent," be exposed to a bright light, such as the direct rays of the sun, and then be removed to the dark, they will emit a very distinct light. This light continues to be emitted for a time of variable duration. With some substances it continues for days, with others it terminates in a few hours. Becquerel has enormously extended the number of substances that act in this way, by showing that the period of time during which they phosphoresce may be exceedingly short, and so escape ordinary observation. He constructed an extremely ingenious instrument by which phosphorescence could be made evident even when it continued for but a very minute fraction of a second, after the light which fell upon the substance was removed. These facts, then, embraced under the general term of phosphorescence, prove incontestably that bodies may, by light, be thrown into a state of vibratory motion, lasting for a longer or shorter, sometimes a very considerable, time after the exciting cause is removed, and that, so long as this vibratory movement continues, they will themselves emit light.

But light, such as it comes to us from the sun, is endowed with another property distinct from illumination, and which we conveniently term actinism. There is not the slightest reason to doubt that bodies may be endowed with the power of being impressed by these rays, and retaining them precisely as bodies may the illuminating rays. Herein lies the explanation of the physical or latent image. It is simply a phosphorescence of actinic rays. Once stated, the whole matter is so evident as to carry conviction with the simple statement.

Let me, then, explain the manner in which this phenomenon takes place with iodide of silver. Pure iodide of silver undergoes no decomposition by light when thoroughly isolated from all substances, organic and inorganic, which are capable of aiding in effecting reduction. But, if exposed to light, it continues for a certain time thereafter to retain the vibrations it received; and just for so long as these vibrations continue, will it be instantly decomposed if brought into contact with any substance which would have caused its decomposition had the two been subjected to the action of light together.

Iodide of silver, if exposed to light in the presence of pyrogallic acid and nitrate of silver, is reduced. If the iodide be exposed separately, it is thrown into a state precisely similar to that of a phosphorescent body, except that it continues to vibrate in unison with the actinic instead of the illuminating rays; and so long as this condition remains, if it be brought into contact with the above-mentioned substances, the effect is the same as if they had been exposed together to ordinary light.

For this property of light I propose the name of *Actinescence*, a name which, though not in every respect suitable, has the great merit of indicating the parallelism of the phenomenon to that of phosphorescence.

On what, then, does the faculty of receiving a latent developable impression depend?

On the possession by the body of two properties: first, that of being decomposed when brought into contact with certain agents in the presence of light; second, that of being able to retain the influence of the chemical rays, so that on being brought into contact with these agents after removal from the light, the same decomposition may be brought about.

The first of these properties is sensitiveness to light.

The second is actinescence.

The joint possession of the two renders a body capable of receiving a latent or physical image.

It is easy to conceive that a body may be actinescent without being sensitive to light. In fact, substances that phosphoresce with a blue light are probably actinescent also, but not being sensitive to light, they of course can form no latent image.

This new view will, I think, dispel all the mystery that has seemed to some to envelope the idea of a physical image, and

brings all the most obscure facts of photo-chemistry into parallelism with well-understood and very simple phenomena.

Phosphorescent bodies, after ceasing to shine, recover that power by another exposure to sunlight. So pure iodide of silver, isolated from all other bodies so that no chemical decomposition can take place, is capable, as I have elsewhere shown, of entirely losing one physical impression and receiving another, and doubtless an indefinite succession of such. The parallelism is perfect.

This new theory which I here bring forth, and which I shall develop more thoroughly later elsewhere, rests upon certain facts which I have long advocated and argued, and which are now, I believe, accepted very generally. They are principally:

1st. The sensibility to light of pure iodide of silver.

2nd. The spontaneous re-sensitizing of pure iodide of silver.

NOTES ON MESSRS. DARKER'S LECTURETTE.

The profusely illustrated lecturette on light, given last week by Messrs. C. and F. Darker, a resumé of which will be found in another column, was perhaps the most complete demonstration of the various phenomena rendered visible when a ray of light is studied, as falls to the lot of the ordinary photographer to witness. The subject of light is one which should engage a great deal more attention than it does.

Another portion of Messrs. Darker's discourse had reference to the production of kaleidoscopic effects by means of the lantern, which hitherto has not been done to any great extent. Not only were the usual chromatic effects obtained in the lecture referred to, but a new field is opened up for photography. Photographic films suitably arranged may be made to assume designs of the most exquisite kind when projected upon the screen, and by a careful selection of suitable subjects much amusement may be derived. Prof. Tyndall has rendered familiar many interesting phenomena met with in the study of light, and the photographer, beyond every other scientific worker, requires to familiarize himself with its intricacies.

PHOTOGRAPHY OF YELLOW, BLUE, AND OTHER COLOURS IN THE TRUE PROPORTION OF THEIR INTENSITY.

BY DR. H. W. VOGEL.*

In the paper already published I have thoroughly described the method of working with the colour collodion, and now add some observations which are the result of my more recent experiences.

1. From 2 to 3 per cent. of alcohol should be added to the silver bath, No. 1 (see page 291).

2. When the yellow glass is not used, it suffices to give double the exposure which would be required if an ordinary iodised collodion were employed.

3. When the yellow glass is used, the exposure may be estimated at about five times what would be required in the case of ordinary work on iodised collodion.

4. As eosine is alkaline, and not only neutralises the silver bath, but may occasion further mischief by its decomposition, both baths should be tested before use, as follows:—A drop of a solution of potassium permanganate containing one part of the salt to fifty of water is added to the nitrate solution, and if the rose colour disappears immediately, a second drop is added, and so on until the tint remains for the period of one minute. After this the solution is tested with litmus paper, and is, if necessary, made slightly acid; acetic acid being used for bath No. 1, and nitric acid for bath No. 2.

Baths which, in the hands of my pupils, gave comets and stains, were quickly restored to a good working condition by being treated with permanganate of potassium, as above described.

When, however, organic compounds have accumulated in the bath, it is not sufficient to treat it in the cold with permanganate of potassium, and it is necessary to heat the solution to the boiling point in a porcelain dish, and treat it gradually with permanganate solution, as already described. When the rose colour remains for half a minute, the solution is filtered and treated as before. Permanganic acid is to be preferred to the potassium salt, but its use naturally requires spirit, skill, and care.

The grain of the paper in copying.—It is a very remarkable fact that the grain of the paper shows very much less when a negative is produced by the new method, than when made by the usual process on iodised collodion, and this circumstance has been so often proved by my own experiments, and by those of my pupils, as to be beyond doubt. It may be that the shadows of the grain are mainly lighted by the yellowish reflections from the studio, and the yellowish light counts far more in the new process than in the old.

In the ordinary wet process iodide of silver possesses but little sensitiveness for the deeper shades; while bromide of silver also requires very long exposures to reproduce the deeper shades in the case of studio work; but a mixture of the two salts is, perhaps, ten times as sensitive to darker gradations. Something analogous occurs in the case of the spectrum, as, with a short exposure, iodide of silver is only impressed a little beyond the line G, that is to say, in the dark blue. Bromide is impressed under similar circumstances as far as the line F (bright blue); but a mixture of both is sensitive as far as the bluish green (lines *b*, E). In such a case, it is pretty clear that an especially sensitive silver compound is formed, which explains the peculiar action of eosine in the wet process. In the case of a dry plate this compound appears not to be formed, and the eosine merely acts as an optical sensitizer.

Thus, in the case of a wet plate, eosine acts not only as an optical sensitizer, but also as a chemical sensitizer; cyanosine, for example, is analogous to its action; but other colouring matter, as fuchsin and Magdala-red, act merely as optical sensitizers. In the wet process only such colouring agents should be used as are both chemical and optical sensitizers.

The next problem was to make the eosine silver compound available in the gelatine process, and for this purpose four cubic centimetres of eosine solution containing 1 in 400 were precipitated with 2 drops of a ten per cent. solution of silver nitrate, and the precipitate was dissolved in 2 drops of ammonia; when 4 drops of this solution were added to 10 cubic centimetres of gelatine emulsion, a notable increase in the sensitiveness for the yellow was noticed; indeed, tenfold the increase noticed when a mere addition of eosine with ammonia was made.

In conclusion, it may be remarked that the region of activity resulting from the use of eosine in photographic plates does not correspond exactly with the absorption spectrum of an alcoholic solution of the dye, but tends more towards the yellow. This fact will not surprise the experienced spectroscopist, who knows that through the action of highly refracting media a shifting towards the red occurs. Eosine, besides giving an intense absorption line in the greenish-yellow, gives also a fainter one in the bluish-yellow; but the influence of the latter is most notable when methyl eosine is used.

* Additional Remarks to a previous paper, page 273.

By-the-Bye.

AMATEURS AND PROFESSIONALS.

Now and then—at wide intervals, perhaps, but still with recurring regularity—there comes a bout at sparring between the amateur and the professional photographer. The latter generally begins it, we must say; but then, on the other hand, no doubt, there is sometimes a good deal of provocation. Photographers are not the only people who quarrel

in this way. The actor makes his perennial protest against amateur theatricals; the scribbler complains that publishers want to be paid to publish now-a-days, there are so many amateur authors; and the painter laments that people in comfortable circumstances take up with palette and easel. In fact, the photographer may consider himself the best off, in this respect, among professional men.

That there are thoroughly good amateur photographers, just as there are very capable amateur actors and singers, is a matter beyond denial; still it is just as obvious that the number, in whatever walk of life you seek them, is but few. But as regards ordinary professional work and ordinary amateur work, there is a wide difference between them. This holds good, whether it is of amateur photography, amateur acting, amateur writing, amateur carpentry, or amateur engineering, you speak. That dilettante work, for excellence and uniformity, cannot be compared to professional work, is the rule, and the existence of a few capable amateurs is the exception that proves it. This is so in photography as in everything else; when you have skimmed from the top the names of a score or two of capable men, there is left the mass of ordinary workers, who produce, by dint of much care and attention, very fair results, but who could not produce such results with the same certainty nor of the same excellence, as the every-day professional who possesses taste and skill. It would be very strange indeed if it were otherwise.

Do not let us be misunderstood, however. We are far from saying that all professionals are superior to amateurs in photography, or in acting, or in anything else. Heaven save the mark. Unfortunately, photography is a calling not unfrequently adopted by men who have tried everything else, and failed; but the broken-down tailor or frozen-out gardener, who take to blacking their fingers and messing about with developers late in life, scarcely demand serious attention. We speak of the professional photographer as someone whose taste and inclination have led him to learn and practise the art, and who, having to earn his bread, is likely to strive heart and soul to master the difficulties in his way. With the same natural abilities of the amateur, he simply progresses more because he labours more; and that practice makes perfect, is an axiom that dates back as far, at any rate, as old Solon.

We have said something about provocation on the part of amateurs. This is not very serious, but still it is annoying to find a portrait has been copied and printed in a private studio, and that the credit and emoluments attached to it are henceforth diverted. Of course, when the amateur begins to take portraits for a fee, and to print negatives at so much a dozen, he ceases to be an amateur any longer, and all opposition ceases also, for it is not too much to say that five out of every six photographers were amateurs once upon a time. In fact, in any calling in which art finds a place, there is scarcely any other way of entering the profession. The actor is sometimes engaged about the theatre in a menial capacity before he blossoms forth in a speaking part, but, as a rule, he is an amateur for years before he adopts the stage as a profession. A boy or girl who is clever with the pencil may be sent by parents to an art school, to learn perspective and study chiaroscuro; but it is not this early phenomenon that usually turns out the successful painter; he steps out from any and every rank of life, and comes to the front in vigorous strides that know no halting. *Nascitur non fit*, they say of poets, and we should like to apply the quotation here also, but for the reflection that if to be a poet you must be born one, the same holds good, too, of fools and idiots.

As the ranks of the militia are the natural recruiting ground for the regular army, so it is from among amateurs that professionals are chosen. Mr. Henri Rocher, a well-known United States photographer, recently remarked in an address that amateurs gave him no fears, and that he should not make himself uneasy "on account of the amateur photographic craze." He might have gone further and said that he looked upon the "craze" as matter for congratulation, for in this country, at any rate, where there are probably more amateurs than elsewhere, photographic progress is deeply indebted to the amateur. Recruiting the ranks of professionals is the least he has done. With us, the amateur has been the pioneer, whether in respect to the art or science of photography. Medals at exhibitions are so frequently taken by amateurs, that the matter causes not the least remark, and no committee or jury has ever dreamt of dividing the prizes into two sections, the one to be taken by amateurs, the other by professionals. There was no need. Few, comparatively speaking, as may be our first-class amateurs, they are quite capable of holding their own, while exhibitions there have been in this country repeatedly, where the amateur has outdistanced his brother altogether in the race for distinction. No better incentive could have been given to the professional photographer.

It is the same in the science of photography. Look at our Societies, and you find half their members composed of amateurs. Nay, more; in the papers and discussions that come before these societies, it is the amateur who is the more active man, and who is generally the experimentalist. In fact, with us—if it were not that we have in our Gordons, Conways, Berkeleys, Gales, Brightmans, Manfields, &c., artists in the first rank—we could almost say that the rôle of the amateur is a distinct and separate one to that of the professional, inasmuch as the latter makes perfect what the former, by dint of patient investigation and subtle research, have made possible. In any case, no professional in this country would deny the useful rôle of the amateur, nor the assistance the latter has lent, time after time, in helping the art onwards.

Again, there are certain regions over which the amateur holds undivided sway. In micro-photography there is but little inducement for the professional photographer; it is a work in which scientific investigation is intimately connected with photography, and unless taken up by the amateur, it would not be taken up at all. When it comes to spending a whole afternoon on focussing a single object, and choosing the best lens and best exposure to suit it, naturally the ordinary professional photographer must find such labour unprofitable. It is the same in other instances when photography is intimately connected with science; as, for instance, with astronomy, medicine, or mathematics. If we had no amateurs, we should have no successful results to be proud of, in all these connections, and, what is more, the professional would have less to feed upon.

In fact, we may go a step further, and say that whatever may be the influence of the amateur upon other callings, upon that of photography he has proved himself of signal benefit. If Mr. Rocher had pointed out how the professional photographer, rather than fearing the amateur, should regard him as a benefactor, he would have done some service by placing the matter before his American brethren in its true light.

THE PHOTOGRAPHIC TEACHINGS OF ART CRITICISM.

BY A. H. WALL.

I remember one of Mr. Ruskin's earlier papers on art, which set out with the assertion that for every separate class of books or pictures there should be a separate public or set of critics. He argued, for instance, that the works of Turner were "deeply toned poems intended for all who love poetry; but not for those who delight in mimicries of wine-glasses and nutshells"; that they were "deep treatises on natural phenomena, intended for all who were acquainted with such phenomena, but not for those who, like the painter Barry, are amazed at finding the realities of the Alps grander than the imaginings of Salvator, and assert that they saw the moon from Mont Cenis four times as big as usual, from

being so much nearer to it!" * He claimed for Turner's works, that they were "studied melodies of exquisite colour, intended for those who have perception of colour, not for those who imagine that all trees are Prussian green." Proceeding, he pointed out that while Newton's Principia would find few to understand or criticise it outside the Royal Society, the poems of Wordsworth could be judged by all who had hearts, and those of Moore by all who had passions. He held that Hogarth's works appealed only to those who were observant of human life and character, and said pictures by Giotto were only intended for critics inspired, as their painter was, by the fervour of deep religious feeling.

The legitimate conclusion from this line of argument was that we should accept no critics of Newton who were ignorant of mathematics, no critics of Wordsworth who were heartless, and none of Moore who were cold and passionless. "Each work," said he, "must be tested exclusively by the fiat of that particular public to whom it is addressed. We must not submit a treatise on moral philosophy to a conclave of horse jockeys, nor a work of deep artistical research to the writers for *The Art Union* (now better known as *The Art Journal*). The public, when referred to with respect to a particular work, consist only of those who have knowledge of its subject, and possessed of the faculties to which it is addressed. If it fail of touching *these* it is a bad work; but it in no degree militates against one that it is rejected by those to whom it does not appeal." It is well known that artists, in criticising a work of art—say for exhibition on the walls of the Royal Academy—are apt to value it in proportion to the technical excellences it displays. They give the mechanical difficulties overcome in its execution, and the skill displayed in the development of accepted rules and principles, precedence over qualities which constitute a more real and important claim to public notice. For this reason their judgment is often antagonistic to that of thoughtful and observant critics who are without technical knowledge, but who are quick to see in art what they have studied in nature. This lends force to Ruskin's idea. Pictures are not painted for painters.

No better illustration of what I mean is to be found than the difference between Ruskin's "Modern Painters," and those sets of lectures delivered by a succession of Royal Academicians to the students of the R. A. Schools, which are still given as prizes to successful students. From those of Sir Joshua Reynolds, downwards to those of Fuseli, each follows in the other's well-worn footsteps. Design, composition, chiaroscuro, and colouring, are the group of subjects to which they are all confined. The illustrations and examples advanced were drawn exclusively from famous paintings and the ancient Greek sculptures, and when anything was added, it invariably consisted of the backneid accounts of the progress these had made, by painting, architecture, and sculpture, in different countries and successive ages.†

Ruskin, the founder of a new school of art study and criticism, wrote very differently.

Although, being himself a practical and talented artist, he was probably as familiar with technical necessities, requirements, and scientific rules as any of the R. A.'s were, he justly considered them only as weak inferior means to great and superior ends. He constantly urged upon students the primary importance of more careful and accurate observation of nature, with the adoption of all such means of investigation and explanation as would help them to a fuller understanding of its grandeur, beauty, and mysteries. He denounced as beyond everything bad "that wicked pride which makes man think he can dignify God's glorious creation, or exalt the majesty of the Universe." He urged that honest, earnest, faithful study of nature would demonstrate most forcibly and practically the real importance of all mechanical and scientific aids, and at the same time develop feeling, imagination, ambition, loftiness of thought, and last, not least, humility.

The great landscape painter, Turner, in all I have read and heard about him, appears to have been neither literary nor learned, and the ignorance Ruskin scorned in Barry was probably very much less than that which he ignored in Turner. But Barry's ignorance was proud. He thought that in depicting the wildly grand and romantic scenes of nature, a great painter's imagination could surpass the reality: whereas, Turner appears to have known how woefully short his grandest achievements fell when contrasted with the natural effects from which they were but faint far-away echoes.

Ruskin himself once asked (the purest white of the palette being as black compared with the white of sunlight, and the purest black as white compared with the black of nature's darkest shadow) how we could hope to emulate the gradations of nature's light and shade, with only our black and white paint for its two extremes of light and dark? Obviously, not by merely painting white light with white paint, and intense darkness with black paint seen in light. Here, then, we have a practical illustration of how the study of nature leads to the study of all those aids of which the R. A.'s speak in their lectures—technical, mechanical, intellectual, or simply mechanical. An artist who, by studying nature, has become deeply impressed with the comparative insufficiency of the means he has for its representation, will certainly neglect nothing that may assist in bringing his glorious aim within the scope of a powerful realization. Whether it be his object to touch the heart, arouse the passions, recal natural phenomena, or hold up to humanity Hogarth's wonderful mirror of character and action, he will bring to the task every faculty of his intellectual and physical nature, and every practical discovery of his greatest predecessors. He will know what to look for, and where to look for it, and with such knowledge his chances of success will be enormously increased.

And all this, if rightly understood and studied, is as fairly and practically applicable to photographic art-study as it is to any other.

Technically and scientifically, photography has of late years made wonderful strides. We can hardly hope that it will attain much greater perfection in the direction of processes and tools; but there is a world of discovery and application before it in an artistic direction—a world which is as yet in the very infancy of its discovery.

Every now and then some lucky operator or artistic student is startled into wonder by the striking superiority of one particular negative. But I am afraid it is not often that he sets to work and finds out by what special or combined effects, natural—optical, artistic, or chemical—such exceptional results had been obtained. Proofs from such precious negatives are in many a painter's folio, cherished as sources of instruction and inspiration. They teach the artist because he knows how to dissect them and trace effects to causes; but they would be useless to him if he had studied neither nature nor art, but simply set up his easel and prepared his canvas and palette as some photographers set up their cameras and prepare their dry plates for exposure mechanically.

Photographers as a body should make that use of art examples which artists commonly do of famous paintings and sculpture; that is to say, they should discover the principles underlying effects of modelling, chiaroscuro, atmosphere, pose, expression, tone, sentiment, design, composition, or feeling, the technical elements by which they are applied, and their proper effects when most powerfully realized. In that way they may learn to criticise a work of art, and apply the discoveries they make to their own productions.

* Barry, of whose singular ignorance of natural phenomena Ruskin notes this striking instance, may have been unfitted for criticising such works as Turner produced, but the lectures he delivered to the students of the Royal Academy are full of original thoughts expressed in vigorous language, and based on the correct principles of drawing, design, composition, and colour; showing him to have been a careful student, and no mean critic. He was, however, essentially a figure draughtsman, and his view points were frequently too exclusively technical.

† It will be only fair to add that the field of teaching at the R. A. is now of a sounder and more extended character.

I sometimes imagine what marvels in the way of art photographs Daguerre would have achieved had he been amongst us now. His early dreams were of a much higher stage of perfection than the Daguerreotype realized, either before or after his death. His cravings were for pictures which should have all the charms of nature, including colour; and as he was himself a painter of great excellence and repute, it is not difficult to conceive how his artistic and scientific studies, blending with his untiring perseverance and industry, if backed by our advantages, would have produced pictorial results of the greatest beauty and highest pretensions.

A dear old friend of mine—now, I grieve to say, dead, who was a clever painter before he became an art-photographer—O. G. Rejlander, used to moan sadly over the rapidity with which his plates lost sensitiveness in the camera when, after thoughtful, painstaking posing, grouping, and lighting, he strove to act upon the thoughts and feelings of his models for telling some story which his fine imagination had previously conceived as a subject. The operator of to-day has the great power which he coveted so vainly; but still, it is not often that we see photographs which equal or surpass the productions of Rejlander in those qualities of imagination, sentiment, feeling, and picturesque effects, for which they were so remarkable.

It was this thought which prompted the utterance I have committed to paper.

I would fain impress upon young photographic students who are not too proud or too successful to need advice, two things: first, the desirability of their pleasing those whom it is the highest honour to please—the real critics described by Ruskin; and, secondly, the folly of uplifting means above ends, and expecting to master effects by neglecting causes.

Review.

THE A B C OF MODERN PHOTOGRAPHY. BY W. K. BURTON, C.E. Fourth Edition (*London: Piper and Carter*).

WE can say but little as to a book which has originated in our columns, but the work now before us has so far outgrown the limits of the "six lessons" as they appeared in the PHOTOGRAPHIC NEWS, as to form a compact but comprehensive manual for the beginner. It is, indeed, just the book to put in the hands of a person proposing to become an amateur photographer; while the fact that it contains a large mass of carefully compiled information, and a good index, make it a useful book of reference to those who merely wish to practise the gelatine emulsion process and the usual method of silver printing. Indeed, the proportion of amateurs who go beyond this is not at the present time a very large one; but in addition to the every-day branches of photography just mentioned, we find a mass of useful information, including the platinum printing process, the production of transparencies on gelatino-chloride plates, home portraiture, and many other topics.

FRENCH CORRESPONDENCE.

M. AUDRA'S EXPERIMENTAL MEETING—PHOTOGRAPHY IN COLOURS—SALON NUMBER OF L'ILLUSTRATION—RAPID COPIES OF ORIGINAL NEGATIVES—OPERATORS' EXAMINATIONS—POCKET PHOTOGRAPHIC APPARATUS.

M. Audra's Experimental Meeting.—Some few days ago the Photographic Society of France assisted at an experimental meeting, at which one of our most active and distinguished members, M. Audra, demonstrated before a very large audience his process of preparing gelatino-bromide of silver emulsion, and method of coating plates. This process, explained by its inventor with great clearness, does not present anything new, but it was very interesting to a great number of the members, who, being amateurs, had neither made nor seen emulsions made. It is well known that both professional and amateur photographers prefer to get their plates from some well-known maker, but it is at the same time useful to them to know how the sensitive composition is made. The example set by our sympathetic colleague is worthy of being followed; and the favour with which it was received by the audience testifies to the great interest attaching to an experimental meeting. It is to be hoped that the Society will, from time to time, encourage reunions of this kind.

A True Version of the So-called Photography in Colours.—A certain rumour has been spread abroad concerning a pretended invention of photography in colours, but it is called photography "of" colours, and one reads short paragraphs in the newspapers like the following:—"Photography of colours is now an accomplished fact. For some time past M. Charles Cros has been experimenting in this direction. It is an engraver of Versailles who has definitely found it out. A few days ago he made known his discovery to the Minister of Fine Arts, who charged him with the reproduction of a picture. Three prints were successively taken, and all succeeded admirably." On examination it is easy to see that they are in too great a hurry to cry out victory. The process does not yet arrive at the solution of the problem of reproduction in natural colours. Napoleon I. said, "*Le boulet qui me tuera n'est pas encore fondu!*" (The bullet to kill me is not yet cast.) We can also say of the process in question, that it has nothing to do with the desired solution. I am perhaps better able to speak on this subject than any one else, as the inventor submitted his results to me; I also furnished a plate and coloured object which he reproduced, and I do not hesitate to say that the results were in the least satisfactory. This gentleman confesses that he uses colours, and I am of the firm conviction that colours are employed diluted with albumen, then sensitised with nitrate of silver, and when dry exposed behind a negative. It is therefore apparent that this attempt and a reproduction of colours are as far off as possible.

The Salon Number of L'Illustration.—It has been generally noticed, as also in the last number of the PHOTOGRAPHIC NEWS, that the illustrations of this journal are phototypes by Meisenbach, of Munich. For a long time I have always declared that photographic reproductions would so ingraft themselves upon printing, that they could not possibly be neglected: and the phototypes from pictures of this year's *Salon*, reproduced in *L'Illustration*, prove that I am right. These reproductions are not perfect, perhaps, but the negatives were, as M. Chéron tells us, taken under rather unfavourable circumstances, and the coloured ink employed in the printing seems scarcely suited to the subjects. We must not forget that perfection is not to be arrived at at the first trial, but the commencement is certainly praiseworthy.

Method of Obtaining Copies of Negatives.—I should like to call the attention of our readers to a method of easily producing copies without recourse either to the camera or any printing process requiring development. Suppose one disposes of a negative by sending it to some house for engraving purposes, or gives it away, at the same time desiring to have an equivalent as perfect as the negative. Take a good print and fix in hypo without toning. It must be sufficiently printed, but not over-done. When fixed, its yellowish-brown colour renders it very non-actinic. The negative copy is obtained by exposing the print to sunlight pressed against the same kind of sensitive paper; fix with hypo, and one has, in spite of the grain of the paper, a negative image from which may be taken as many prints as desired. By waxing the negative, the paper will be more transparent, and the printing hastened, giving softer impressions. Care must be taken not to over-expose the negative when taking it

from the print, as it will be rather hard. Toned positives do not give such good results.

Operator's Examinations.—The examinations for candidates desiring certificates of capacity as photographic operators will be held towards the end of May.

Conference on Pocket Photographic Apparatus.— The *Chambre Syndicale* is about to organize a conference relating to photography with the aid of pocket apparatus. The entire work is to be shown in the presence of an audience, comprising enlargements from the tiny negatives and the projection of positives which have been taken. The bearer of the signature to this letter is charged with this conference. Pity him! LEON VIDAL.

PHOTOGRAPHERS AND SITTERS.

BY G. G. MITCHELL.*

RAPID changes in our art soon make the past grow old. The collodion age, with its capricious baths and laborious manipulations, has practically passed away, so that the present generation only know in part of the troubles and difficulties of earlier workers. Many of us know nothing of them, and the rising one will read of them as ancient history. Old faults are overcome, while with the advance of processes, new troubles rise and task our patience and carefulness.

It is the case, generally speaking, that a person who steps into a studio for the purpose of having a portrait taken, does so in what may be called a smiling frame of mind. The idea is commonly looked upon more or less as a sort of joke, or at least, something that is alluded to with a smile, and as if the proposal needed just the faintest approach to an apology. Whenever this is observed, and it will be often, it should be accepted as the key-note to what intercourse may follow. Other sitters come in serious moods. Partings and unhappy events bring business, as well as joyful occasions. Death itself at times demands our services, and thus we do not always work under the most favourable or cheerful circumstances.

If, as Pope says, "the proper study of mankind is man," perhaps in this matter of portrait taking we, who are engaged in it, see as considerable a share of the human nature about us as most people who serve the great British public. Some studios of course invite, in the very nature of things, certain classes. In some the comparatively poor man is never seen, and in others again the aristocrat is a *rara avis*, or unknown. The experience of these two extremes in many respects is very different, and both possess advantages or difficulties of treatment peculiar to themselves. The better classes, without question, are, for example, more refined in feature, and of course much better dressed. The sanctity of the æsthetic hangs about them, all of which are distinctly great advantages and aids towards successful portraiture. The educated face in any class has generally an indication or suggestion of something superior behind it. Low caste or very unintelligent features do not attract the interest of any one, save it may be as a study of physiognomy. Subjects vary immensely in the facilities they afford for good composition, and so on, and I believe it will be agreed that it actually demands from every one more tact and knowledge of effect to make a passable picture of a common-place subject than with one of a higher type. That, I think, ought to be obvious at a glance.

Perhaps I may be permitted to touch briefly on a few of the characteristics and odd points occasionally met with in sitters in our every-day practice. Popular ideas about portraiture, as about many other things, are often erroneous. Among these I would mention, for example, the notion commonly entertained that the photographer will do all that is required himself. "He knows best," and so he does, doubtless; but Giles and his sweetheart go into the studio as nearly as possible in the character of lay figures. They have an honest resolve to be docile in order to get a good likeness, but wanting in intelligent conception how to assist to this end. This sitter is probably more frequently found in the shape of the country cousin than the town one, but they come from all quarters. When the lay-figure sitter is taken to be posed, his distressing condition is most vexatious and trying; and it taxes the artist, who had better smile and bear it, to get him by any kind of artful byplay to feel at his ease and relax the rigidity of his muscles; but no one unacquainted with the actual fact in extreme cases could fairly credit how difficult is the task. The sitter is gently inclined to this side a little, or to that, and he mechanically obeys with all the elegance of a leaning chimney pot. But there is one grand feature about this man—he never asks for credit, unlike my Lord Heavymasher, who may give a world of trouble, and to whom the idea of cash payment is "bad form."

It is not sufficiently understood by many that whatever peculiarity of expression is worn during the sitting, that must be produced in the photograph, such as tight-set lips or elevated eyebrows. Nor, again, is the effect of certain little covert movements, sometimes indulged in, correctly reckoned upon. Miss Jones, for instance, stands pleasantly as placed, and all seems finally arranged for the moment of removing the cap, when she executes a little manœuvre on her own account by shifting a hand or re-arranging something which has not been to her mind exactly, which may turn out all right, but is quite as likely to be all wrong. In this same connection sitters will occasionally allow themselves to be posed with the head-rest; but having a dislike to its use, from the impression that it makes them look "stiff," quietly remove their heads from it at the moment of exposure, and by so doing generally expose their having done so.

Ladies very generally miscalculate the effect of *primming* the mouth. That feature is one over which, after a comparatively early age, they manifest a great solicitude, and it is precisely on account of this anxiety where the danger arises of a slight distortion. I need scarcely remark that it almost invariably takes the form of contraction. But the weakness is not exclusively confined to one sex. I have seen fellows with moustaches do it.

Another great blunder made is to suppose that the more unconcerned and indifferent one looks the better it will be. Under this impression we all get visitors who want to be taken with their legs and arms sprawled over the place, or they dump themselves down in a heap before the camera in defiance of every grace of form or gesture that has been known to man.

Again, we have a visitor who had once been young, and, it may be, blooming, who, after looking at various styles of work, will, in conclusion, point to some pretty girl's portrait, and, apparently oblivious of any difference in the originals, give us a commission to "take me just like that." How is it possible in these circumstances to explain the impossible, even in the most gingerly chosen terms? It is better to do your best, and leave the rest to fate, which is often very kind.

What I have said has had reference to studio work. There are other phases equally fruitful of remark.

* Abstract of a paper read before the Edinburgh Photographic Society.

Notes.

A paper which Dr. Vogel contributes to the NEWS this week gives important working details regarding his method of photographing colours in the true proportion of their intensity; and next week we shall publish some further investigations of Dr. Vogel about the action of cosine on photographic films.

English photography, apparently, holds a much higher position than it did some years ago. At one time the photographs of Austrian and German photographers were generally to be seen in our shop windows, but these have long since been superseded by the production of our own men, and in the course of a short trip lately in Belgium and Holland, we noticed that a large proportion of "portrait studies" exhibited in the principal towns were by English photographers. Had the photographs been those of celebrities, the reason for exhibition would have been obvious, but in most cases the sitters were utterly unknown, and the photographs had evidently been selected for excellence of manipulation alone.

The "Copyright (Works of Fine Art and Photographs) Bill," brought in by Mr. Hastings, Mr. Hanbury-Tracy,

Sir Gabriel Goldney, Mr. Agrew, and Mr. Gregory, is of the most comprehensive character. The mere enumeration of the headings relative to photographic copyright will at once stamp the importance of the measure. What may be termed the purely photographic clauses are as follows:—Copyright in photographs done by an assistant, servant, or workman to belong to the employer; photographic portraits taken on commission not to be sold or exhibited in shop windows without consent; copyright not to prevent the representation of the same subject (that is to say, two photographers may photograph the same scene or the same picture without infringing each other's copyright): copying a copyright work as part of a scene (an interior, for instance, containing a copyright picture) no infringement of copyright. There are also several clauses applicable to photography relative to penalties for infringements, power to search houses and seize unlawful copies, the seizure of pirated copies in the possession of hawkers, the prohibition of the importation of pirated works, &c. The Bill, which was issued on Tuesday last, is a most important one, and deserves the careful consideration of photographers.

The framing of an Act of Parliament is, however, one thing, and its construction another. A case in point was heard last week at the Wandsworth Police Court, in which Mr. W. Taunt, of Oxford, sued Canon Erskine Clark for publishing an illustration of St. Nicholas Church, Newbury, which he (Mr. Taunt) alleged was a colourable imitation of one of his photographs. It was not denied that the illustration was taken from the photograph, but counsel for defendant urged that it was neither a copy nor a colourable imitation as provided by the Act, and the magistrate, in the absence of any precedent, this being the first case of the kind, coincided. He accordingly, as we stated last week, dismissed the summons, but granted a case for a superior court.

In the new Bill, clause 14 sets forth, with much elaboration, that "no person shall make, or cause or procure to be made, for sale, hire, exhibition, or distribution, any copy, repetition, or colourable imitation of any work of fine art, or of any photograph, or of the design of any work of fine art, in which work, design, or photograph, or in the negative of which photograph, there shall be subsisting copyright, or of any part of such work, design, or photograph, by any means, in any material, or of any size, either in or by the same or any other class or kind of art, as or than that in and by which the original work was executed," and much more to the same effect. But the Bill does not, nor could it, define what is meant by colourable imitations, hence litigation on this point is by no means put an end to.

A lucky photographer at Darmstadt has secured what may prove an historical picture. He has taken a group of the Queen, her daughter, the Crown Princess, her granddaughter (Princess Charlotte of Prussia), and her great grand-daughter Princess Fedora of Saxe Meiningen, aged five—comprising four generations.

The organization recently formed by the amateurs in New York is likely to lead to very material progress as regards photographic work in the New World. Hitherto photographic societies in America have been, in the main, trade associations, and comparatively little has been done to encourage amateurs.

To illustrate this point, we may refer to a remark made by Mr. Pancoast, of Philadelphia, when he visited the Photographic Club a week or so ago. He said:—"In the States we find it difficult to get the members of our Association to talk, and if one man is disposed to say anything, he may keep possession of the meeting for the whole evening. The majority come to listen, not to speak. Here I see that each one is so anxious to say what he knows, that very often the chairman has a difficulty in determining who shall have the longest say."

In the *Philadelphia Photographer* we find a long and interesting report of a meeting of the New York Amateur Association; and so numerous were the subjects brought under discussion, that we should not be surprised if Mr. Pancoast finds a new condition of things on his return.

Several novel shutters were shown. Mr. Beach, of the *Scientific American*, gave a demonstration of enlarging on gelatino-bromide paper. Mr. Newton and others gave the results of their experience in searching for the best developer (see page 305). Mr. Hull referred in glowing terms to the comfort he had experienced in discarding ruby glass in the dark-room, for the olive green glass and two thicknesses of lemon yellow paper.

Death has indeed been busy in the ranks of scientific men of late. Adolphe Wurtz—whose "Leçons de Philosophie Chimique," published just twenty years ago, served to bring about the change of thought which resulted in the universal adoption of the new notation—died on Monday last.

From Chicago a new fortnightly, *Photography*, comes to hand. It is under the editorial management of Mr. F. H. Davis, and the first number contains a good selection of matter.

We witnessed an amusing instance the other day of photography being used to prove a self-evident proposition, as Sam Weller has it. At Carthagena, there happened to be a quack doctor, a glib-tongued young fellow with long flowing hair and pointed moustache, who harangued the people on the market place with considerable fluency. He was no new upstart, he said, but the veritable Dr. Francesco, of whom they had all heard, and of whom the pamphlets he held in his hand spoke so eloquently. But to remove all doubt as to his identity, he would hand round photographs to prove what he said. Whereupon, in the coolest manner possible, he held up to view some photographs of himself with name and title printed underneath. Could anything more conclusively demostrate that he was somebody?

There is, however, one application of photography to prove identity, which would be very useful to banks and the travelling public, if made use of. We mean in connection with the payment of letters of credit. An Englishman goes abroad, and instead of taking money with him, secures letters of credit from his bankers on various towns he may visit. The banker at home supplies these correspondents of his with his customer's signature, and mentions the maximum sum to be drawn. But, occasionally, the local agents are unused to the business, or are unduly impressed with its importance, and the consequence is, that at times a good many tedious formalities have to be gone through. If, however, a photograph of the customer were sent with the letter of advice, a simple and effective means of identification would be at hand.

"Have you any spoilt photographs to give away for my collection?" writes a painter to a photographer of our acquaintance. Neither the request nor the way it is worded will be unfamiliar to many of our readers, and they will do well to reply, "Have you any spoilt sketches that will go in *my* collection?" The painter will then probably realise the fact that it is impolitic to give away "spoilt" things, and that as he does not like to risk his reputation by parting with defective work, so possibly the photographer with a name might be equally reticent. There is the same similarity, he will find out, between a sketch and a photograph, as there is between a moat and a beam.

Some years ago we pointed out in these columns, as did Mr. Tunny shortly afterwards, that the transfer paper on which carbon photographs are laid, not unfrequently became yellow, and thus suspicion of fading was cast upon the carbon prints themselves. Some samples of unsensitized albumen paper exposed to light in a show-case for the same time as finished prints contained therein have lately come under our attention, and here, while the pictures became yellow, the untouched albumen paper had become equally so. In this case, therefore, what discoloration existed was clearly due to the paper itself, and not to any imperfect washing of the print on the part of the photographer. We suspect there are many albumenized papers, especially among the cheaper qualities, open to this suspicion.

How pleasant it would be if all sitters were as sensible and as philosophical as the lady who some time ago sat to a well-known photographer. In criticising the proofs, she remarked of one, that according to some of her friends she looked like "a simpering idiot," naively adding, "but I suppose it is like me." Subsequently, she wrote: "Yes, the 'simpering idiot' is the best"; and gave a good order from this particular negative. "Save, oh! save me from the candid friend," is a prayer which ought to be offered up by all who have their portraits taken. In this instance, common sense rose superior to captious criticism.

In Cologne, the police and a certain section of the professional photographers have been continually engaging in contests on the Sunday question. Not always as to whether portraits may be taken during service times on the first day of the week, but whether they may be exhibited. Herr Overheydt, being recently charged with carrying on his business contrary to the law, was acquitted after three appeals, because it was proved that the actual pictures on exhibition were not for sale.

Darwin was one of the first to appreciate the value of photography in recording expression. Two years ago, our readers may remember, we gave some examples in these pages of human expressions—of pain and suffering, of joy and grief, horror and disdain—the late Mr. Rejlander posing as the model in some of these studies. Although the pictures we allude to were wood-cuts, being, indeed, extracted from Mr. Darwin's book, they were faithful copies of photographs, and represented the intention of the author with considerable force.

But photographs pure and simple would be still more truthful in recording expression, whether the pictures, as in the case of Darwin, are required by the philosopher or the painter. The latter would be spared much of his trouble in securing not only suitable models, but suitable expressions (two very different things), if it were in his power to purchase and select such photographs as were requisite to his aim. Thus, if called upon to depict hunger or thirst, fatigue or pain, gladness or joy, grief or sorrow, could he but procure artistic photographs of these presentments, his work would not only be facilitated, but likely to have far more of truth in it. No doubt the photographer would find it no easy matter to discover suitable models for his studies, on his part, but to a patient, painstaking student the task would not be very difficult, and he would know that if good models are scarce, his studies would also be both scarce and valuable.

Patent Intelligence.

Applications for Provisional Protection.

7365. WILLIAM HENRY MARSHALL, 12, Westborough, Scarborough, Yorkshire, Watchmaker and Optician, for "Improvements in photographic shutters or caps."—Dated 7th May, 1884.

7552. DUNCAN MACNAUGHTAN, 44, Radner Street, Chelsea, Middlesex, Librarian, WILLIAM SPIERS SIMPSON, 47, Battersea Park Road, Surrey, Mechanician, and GEORGE SMITH, 151, Strand, London, Middlesex, Sadler, for "An improved method of obtaining or reproducing pictures, drawings, and designs, &c., &c."—Dated 10th May, 1884.

7606. DUNCAN CAMPBELL DALLAS, 12, Crane Court, Fleet Street, London, Engraver and Printer, for "Improvements in the production of raised and sunk designs on metal and other suitable surfaces for printing and decorative purposes."—Dated 12th May, 1884.

Specifications Published during the Week.

4557. E. G. BREWER, "Apparatus for touching up photographic pictures, &c."—A Communication from Messrs. J. Geesbergen and La Societe Geruzet Freres.

A description of this invention will be found on page 645 of our volume for 1883.

4705. R. BROWN, R. W. BARNES, and J. BELL, "Obtaining by photography definite photographs to be used in the production of typographic blocks and in the art of photo-lithography and like arts.

Our invention has for its object to produce definite photographs broken up into dots, lines, or grains, so that they can be used in the production of typographic blocks by the art of photo-etching and like arts, and can also be used in the art of photo-lithography and like arts. In the practice of our invention we proceed as follows:—We take what is known as a photographic transparency of the object or picture; we prefer that this transparency shall be as clear a transparency as possible when seen by transmitted light, and such a transparency can be obtained by processes well known in the art of photography. Having obtained such transparency, we place the same upon a lined or hatched background, such as a sheet of white paper having a lined or grained surface, or a stippled cross hatched, or like surface printed, or drawn thereon. Any material having such a lined or stippled surface, or effect, or variety of effect may be used as the background for the transparency. The lining, graining, or stippling of the background may also be varied to suit the picture or object, and its surroundings, so that portions of the background may be lined and portions stippled. Having so backed the transparency, when viewed by reflected light the picture of the object can be fairly seen broken up into dots, lines, or grains of the backing, showing through the half tones and clear parts of the transparent picture when viewed by reflected light. In attaching or fixing on the face of such transparent photographs the lined, grained, or stippled surfaces, or backing before described, we do not always confine ourselves to a single sheet of the said surface or backing containing one design only, but we sometimes make combinations by placing in various parts of the transparent photograph suitably cut out portions of various and differing sheets of lined, dotted, or stippled material, so as to produce a varied and harmonious variety of background suitable to the subject under manipulation. Again, in preparing a suitable backing to combine with the transparent photograph, we prepare the backing by hand, or by mechanical manipulation in an artistic manner best suited to the subject or object. Having so prepared and backed the transparency, we take from the transparency so prepared and backed a definite photograph on paper, glass, gelatine, or other sensitized material. This definite photograph has the photograph of the transparency broken up into lines, dots, or grains by the backing. The definite photograph is thus in a condition to be used in the production of typographic blocks by the art of photo-etching and the like arts, and is also suitable to be used in the art of photo-lithography and like arts. Another method of producing a definite broken up or divided photograph, having dots, lines, or grains according to our invention, consists in covering the sensitive plate in the camera with a material such as net-work, or with a photograph on glass, or other transparent medium, of lines, grains, or stipples, or cross-hatched lines, fine or coarse, according to the nature of the result required. The photograph on the sensitive plate will then be broken up into the dots, lines, or grains, which are photographed simultaneously with the object on the sensitive plate. We thus produce direct a definite photograph broken up and divided into dots, lines, or grains, and in the condition to be used in the production of typographic blocks by the art of photo-etching and the like arts, and also suitable to be used in the art of photo-lithography and like arts. When required, we complete such photograph by hand manipulation, removing, or adding, dark or light portions after the manner known in the art of photography as "retouching." By another method, according to our invention, to produce a typographic block, we proceed as follows:—We take a transparent photograph of the picture, or object, and we take a transparent photograph of grains, lines, or stipples, and we prepare a plate or block of zinc, or other suitable metal, with bitumen or other substance that will give a sensitive surface to the zinc, or other metal. We then place the photograph of the picture or object, and the photograph of the lines, dots, or stipples before spoken of, over the sensitive zinc or other metal, and print by light in the usual way, and thus we produce the picture in dots, grains, or lines upon the surface of the zinc or other metal. We then develop the picture, and subject the plate or block to the process of photo-etching in the usual way. Having now particularly described and ascertained the nature of our said invention, and in what manner the same is to be performed, what we claim is—First. The method substantially as herein set forth of producing from half-tone pictures and photographs, photographs to be used in the production of printing surfaces. Second. The method substantially as herein set forth of producing in the camera and direct from an object, photographs to be used in the production of printing surfaces. Third. The method substantially as herein set forth of producing photographs on sensitized surfaces of metal, such as zinc, to be used in the production of printing surfaces.

Patents Granted in America.

297,773. Crosby M. French, Garrettsville, Ohio, "Method of producing ornamental relief borders or foregrounds for photographs." Filed June 4, 1884. (No specimens).

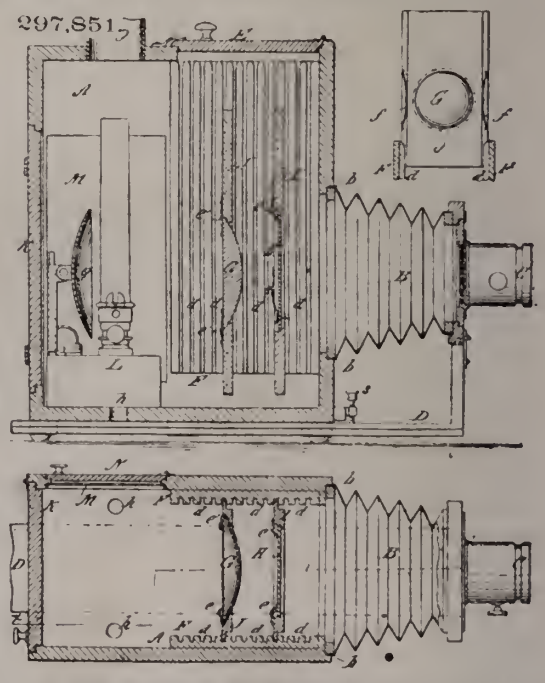
Claim.—The method of producing photograph-borders, consisting in first making a bas-relief border of any desired design, then taking a negative of such design, and finally using this negative in "printing-in," in conjunction with a portrait-negative, as a border substantially as and for the purpose set forth.

297,851. Thomas C. Roche, Brooklyn, assignor to E. and H. T. Anthony and Co., New York, N. Y., "Enlarging-camera." Filed January 30, 1884. (No model).

Claim.—1. In an enlarging-camera adapted to use an artificial light, the camera-box having a lamp and reflector chamber in its rear end, constructed with a series of interior grooves or slideways at or near its forward end, adapted for the reception and adjustment of the condensing and picture slides, and an opening to the grooves to facilitate the adjustment of the slides, said opening being closed by a cover or door, substantially as and for the purposes specified.

2. In an enlarging-camera, the combination, with the box A, having a series of interior grooves, *d d*, near its forward end, of the slide J, fitted with a condensing-lens, the negative or picture slide I, and the bellows B, with its attached lens, essentially as and for the purposes herein described.

3. The slides I J, or either of them, provided with holding-springs at their sides, in combination with the slideways or grooves *d d* in the interior of the sides of the camera-box, essentially as and for the purpose herein set forth.



4. In an enlarging-camera, the box A, having a series of interior slideways in its front end portion, a lid or door for insertion and removal of a lamp and reflector, *g*, within and from its rear portion, one or more air-feeding inlets in its bottom, and a chimney in its top, over the place occupied by the lamp, substantially as specified.

5. The combination, with the box A, having a series of interior slideways or grooves in its forward end portion, for the insertion, removal, and adjustment up or down and toward or from each other of a negative or picture carrying slide and condensing-lens slide, or diffusing-glass, of a lamp and reflector, *g*, in the rear portion of the box, and a front lens or lens-tube in close adjustable connection with the forward end of the box, essentially as described.

6. In an enlarging-camera for operation by artificial light, the camera-box provided with a non-actinic glass in one or both of its sides, at or near its rear end, and constructed to form a lamp-chamber at said end, essentially as and for the purposes specified.

MOLECULAR PHYSICS AND PHOTOGRAPHIC ACTION.

BY CAPTAIN W. DE W. ABNEY, R.E., F.R.S.

In the last issue of the NEWS, you had a reference to a publication of mine in the Belgian Photographic Association's *Bulletin*. At my lectures at the Royal Institution I gave an explanation of the subject alluded to, and I think it may be of interest for me to add a few words on the topic. It is well known that if a phosphorescent plate is excited, and then warmed—say, by a flat iron—that an image of this flat iron is shown by increased luminosity at that particular part of the plate to which it has been applied. This is probably due to the fact that the molecules of the body have an increased amplitude of vibration, caused by the externally-applied heat, and that, therefore, the atoms of the molecules of phosphorescent matter (which cause the light-giving radiations to be emitted) have greater play, and, therefore, themselves take up a larger amplitude of vibration when once set in motion, which is shown by an increase in the luminosity body. From this point I started my enquiry. What is true of one kind of matter, ought to be true for another. Take a gelatine bromide plate, and press against the back surface a hot flat iron, and examine the film by reflected daylight. It will be seen that the colour of the sensitive salt is altered, becoming deeper orange. On the plate cooling, the film resumes its normal colour. Place iodide of silver in an intense cold, such as produced by carbonic acid snow, and ether, and the iodide will be found to have a grey colour, quite different to that it has at a normal temperature. Such changes of colour mean something, and that "something" ought to show itself when exposing these sensitive compounds.

If a gelatine plate be warmed at the back by an iron, and then be exposed to light whilst still hot, an image of the iron is produced on development, shown by increased density at that part. In some plates, so brief an exposure to match-light was given that whilst the image of the iron was fully developed, the parts outside were very nearly unacted upon. This is the case, whether the plate be developed immediately, or be allowed to cool; hence has no connection with warm developing solutions. If the plate be heated and then cooled, and then exposed to light, no action is visible. This is what would be expected. The heat gives the molecules greater amplitude of vibration, and therefore the atoms are more free to swing, and can attain to that amplitude more rapidly, which is necessary for the throwing off of the bromine or iodine; *hence we have heat causing greater sensitiveness*. Now other experiments suggested themselves, viz., with collodion and paper. A collodion emulsion plate was taken and dried, and the iron pressed against its back, and on development the very reverse of what took place with a gelatine plate exhibited itself, viz., the heated part seemed less sensitive. Here was a crux. The theory seemed to fail. Another experiment settled this, however. A plate was coated and washed, and one half placed in boiling water, and whilst still warm the plate was exposed, with the result that the heated portion behaved like the gelatine plate. The cause of the difference of behaviour in the last used plates was evident. It was a matter of moisture only. Now a collodion dry plate, if thoroughly desiccated, is insensitive; it requires moisture to enable the liberated halogen to be taken up, and this is the case whether a preservative be used or not. With the first plate the hot iron had expelled the moisture, leaving that part less sensitive, owing to the absence of a halogen absorbent. In the last plate, where moisture was equally present, the effect of heat manifested itself. In a gelatine plate which is colloidal, it is almost impossible to get rid of the last traces of moisture, except by a prolonged sojourn in a dry place; the short time during which the heat acted rendered no essential difference in the amount of moisture present. The same was the case with paper.

In trying the sensitometer on a heated plate I found a marked increase in sensitiveness, such increase in sensitiveness disappearing when the exposure took place after the plate had cooled. The phosphorescent plate of the sensitometer, and also sensitive plates, were heated to the same temperature, and exposures made, with the result that the sensitive plate *seemed less sensitive* than at ordinary temperatures. For instance, in one case, a 22 plate only registered 15. This is due to the fact that the heated phosphorescent tablet after exposure loses its luminosity very rapidly, and that after a lapse of a minute, as is usual in sensitometer experiments, the increase of sensitiveness of the warmed plate does not make up for this loss. By warming a plate which read ordinary 18 on the sensitometer, I have on one occasion got a reading of 24.

A set of experiments with temperatures of melting ice have also been carried out with results corresponding to the above, viz., cold diminishes sensitiveness by causing the amplitude of vibration of the molecules to be obstructed. I hold that in the region of molecular physics, the above experiments are important and conclusive. If the matter be considered, it will be seen that the sole connection between phosphorescence and the sensitive salt is that of the increase of the molecular and atomic vibrations, and not that the sensitive salt itself is phosphorescent. Facts are against this, as can be experimentally shown, whilst by the theories in molecular physics, the phenomena are quite accounted for.

Correspondence.

NEW COATING MACHINE.

DEAR SIR,—Several weeks ago, Mr. A. L. Henderson spoke at one of the Society meetings of a new coating machine that he had invented, and which he promised shortly to give to the public; and I presume many others besides myself have been waiting anxiously for a description of it. The season of plate-making is upon us: will not Mr. Henderson come to our aid ere it is too late?—I am, yours, &c., ANXIOUS.

Troy, N.Y., U.S.A.

INFLUENCE OF TEMPERATURE ON SENSITIVENESS.

DEAR SIR,—In reference to a paragraph in your "Notes" this week, page 297, speaking about Captain Abney's contribution to the *Bulletin Belge*, I may observe that I wrote an article, which appears in the YEAR-BOOK for 1884, page 41, in which the subject is introduced. For a long time I have observed the conditions of temperature affecting the gelatine plate, and the experience I record there would be worth a Jew's eye to many a photographer who does not change his formulæ with the changing weather. While my pyro always remains the same, my ammonia and bromide are varied to suit the temperature of each succeeding day.—Yours truly, J. H. KILLICK.

MATT PICTURES ON ALBUMENIZED PAPER.—PHOTOGRAPHY IN MELBOURNE.

DEAR SIR,—Your article "Matt Pictures on Albumenized Paper," in last week's number, loses sight of the best and simplest method of producing them. The gloss is easily removed by rubbing finely-powdered pumice stone over the finished picture with a soft india-rubber pad, leaving a perfect and pleasing matt picture.

In reference also to an article on "Photography in Melbourne" in the same number, I have the pleasure to inform you that four different albums of New Zealand scenery photographs are now in actual course of preparation by the firm alluded to, viz., Messrs. Burton Brothers, of

Dunedin. The photographs of scenery are exquisite in the extreme, and these beautiful little works will certainly attract many European tourists to this, as yet, comparatively unknown "land of loveliness." These albums will be ready during the current year, and will be then announced in your advertising columns.—I am, dear sir, yours obediently,

F. Parsons.

[Is it not much easier to merely use a different sensitizing bath than to roughen the prints afterwards? Still the method mentioned by our correspondent is likely to be useful.—Ed. P.N.]

THE PROPOSED AMALGAMATION OF THE LONDON PHOTOGRAPHIC ASSOCIATIONS.

Sir,—I heartily endorse nearly all Mr. Cobb's and "A Member of Them All's" objections to the numerous so-called clubs and societies; but the most serious loss of all is time, for I do not like to lose anything, and it behoves me (if I want to keep pace with the times) to attend every meeting—that is, all that will receive me.

At the close of the Brittlebank meetings a few years ago, I offered a sum of money to start a club proper, provided a like amount was subscribed or guaranteed collectively. The amount named was reached, but no efforts were made to supplement these guarantees, or organize a proper club, beyond having a weekly meeting at an hotel.

These club meetings were not too harmonious, and the result was a kind of split, and subsequent formation of the London and Provincial Photographic Association (as much a club as the other society called by that name).

Some gentlemen, whom for the nonce I will call the upper ten, sneer and treat with contempt others who, by force of circumstances, have not been born with silver spoons in their mouths.

I confess I cannot see how (so long as cliquism prevails) the difficulty is to be overcome, unless we are to have an Upper House and a Lower House. For my part, I would rather sit on the cross-benches, or, if need be for the good of the cause, become a Bradlaugh.

Leaving joking aside, the time has now come when a permanent club might be established. The existing little circles may have their talk *in camerâ*, and those that are not ashamed of propounding their theories before the whole world, "can have their chiel amang them takin' notes." I for one, whether admitted into the upper or lower house, will not be backward in coming forward.—I remain, yours, &c.,

A. L. Henderson.

Proceedings of Societies.

Photographic Society of Great Britain.

The ordinary meeting of this Society was held on Tuesday, the 13th inst., at the Gallery, 5A, Pall Mall East, James Glaisher, Esq., F.R.A.S., in the chair.

The minutes of the previous meeting having been read and confirmed, Mr. Samuel H. Salmon was elected a member of the Society.

The Chairman: Since we last met, the death of our old friend, the Rev. F. F. Statham, has occurred. For twenty-five years he presided over the South London Photographic Society. During that long period, all who came in contact with him were familiar with his kindly manner, and the able way in which he advanced the interests of that Society. Painful as that intelligence was to me, yesterday I experienced another shock, too painful to describe in words to-night. On opening a letter, I was startled with these words: "You will grieve to learn that Mr. H. Baden Pritchard is no more." Our dear friend, who, for twenty years as member, councillor, and vice-president, has done so much work for our Society. Few men have gathered round them such a large circle of friends as he has done, and none are better acquainted with his kind and genial qualities, or will miss him more, than the members of this Society. The Council have decided to send a letter of condolence to the widow; perhaps, in addition, the members might like to add something to what has been already said.

Mr. A. Cowan said, in addition to the words expressed by the Chairman, he should move that a floral wreath be sent before the funeral takes place, as a tribute to the family of the Society's esteem for the memory of their lamented friend.

Mr. W. S. Bird, in seconding the motion, said the feelings expressed by Mr. Cowan harmonized with his own; the wreath should be sent by the whole of the members of the Society, not the Council only.

The vote being carried by acclamation, the Chairman called upon Mr. John Spiller, F.C.S., to read his paper, "Observations on Fading."

Mr. Spiller commenced by saying that a good deal had been written and said on the subject of fading at different times, and no new light appeared to be thrown on the subject by the discussions which have recently taken place. Mr. E. Dunmore recently read a paper on "Old Photographs" before the South London Photographic Society, in which there were some points which induced him to re-open the subject. Some years ago he (Mr. Spiller) made numerous experiments in this direction, the results being published at the time. From enquiries recently made he found that the principles then enunciated are tolerably well carried out now. For instance, very much more care is taken with the washing before and after fixing than was usually the case a few years ago. Toning and fixing solutions are newly made, instead of being used over and over again. Another thing, negatives are not left too thin. In short, his enquiries tended to show that the suggestions then made are well observed. Having exhausted the chemical and manipulative portion, his attention was turned to the paper makers, at whose mercy we were, in a great measure, placed. Numerous samples of mounts were collected, many of which undoubtedly contained hyposulphite of soda or one of the chlorides—generally lime. Some sixteen years ago he wrote an article in the Photographic News, which the Society did him the honour to reproduce in their own Journal, and it would be remembered by many present that the causes of fading were pretty well gone into. As the subject is again well to the front, he considered it a fit time to say something more about it, with the hope that the remaining causes of fading would be discovered, so that it would never trouble them again. Mr. Spiller then read an extract from the *Journal of Chemical Industry*, having reference to recent investigations into the behaviour of a large series of sulphites and bi-sulphites of the alkaline earths, and their reactions on the alkaline chlorides used in bleaching; some of these compounds being here shown, the magnesic bi-sulphite being especially recommended for this purpose. Attention was also called to the suitability of a paper pulp made from wood fibre, either alone or mixed. Mr. Spiller then read an extract from the specification of Ainsley Cooke, 1852, in which the hyposulphites of lime, soda, and potash were mentioned, these being included in the practice of the present day. Other extracts were quoted, one dating back as far as 1846, wherein sulphurous acid was mentioned. Mr. Spiller said if the paper makers would employ sulphite of soda instead of the hyposulphite, no danger would arise. As a proof, he had submitted two photographs cut in halves to the action of both salts. The solution of sulphite of soda had no appreciable effect on the print after forty-eight hours' immersion, while the portion in hyposulphite of soda was badly bleached or faded. A well-cleaned silver coin was placed in the sulphite solution, and no indication of silver was found on testing for that metal; but a similar coin placed in the hyposulphite solution gave strong indications of the silver being dissolved. He (Mr. Spiller) considered this experiment furnishes an answer to that portion of Mr. Dunmore's paper published on page 170 of our present volume, where he says that a twenty per cent. solution of hyposulphite of soda applied to and left in the prints has no effect whatever on their permanency. Mr. Spiller had frequently found soluble chlorides in samples of cheap mounts, but never free chlorine. In the event of sulphite being used by paper makers, the usual iodide of starch test would no longer serve, as sulphite affects it. We have a ready means of determining the presence of sulphite by means of a weak magenta solution; hyposulphites do not affect this colour, therefore it should be the paper-maker's guide. In the Journal of the Society of Chemical Industry, Messrs. Giles and Shearer have worked out this method to an absolutely reliable standard. Mr. Valentine Blanchard, in the current Year-Book (page 77) speaks of prints mounted on a lithographed tint being more permanent than on ordinary white mounts; no doubt the thin layer of a greasy

substance protects the print. An additional security is also found in the use of an eucanstic paste, thus shutting out the influence of the atmosphere in a measure. It is stated that paper makers in Germany and Scotland have given up the use of hyposulphite of soda; if it were generally adopted, photographers would hear that this fertile source of fading had been banished for ever. Mr. Spiller then placed some dilute rosaniline salt in two tubes, adding sulphite of soda to one, and hyposulphite to the other; in the former case, the colour was instantly discharged; in the latter, no alteration took place.

The Chairman enquired if there were any remarks?

Mr. Giles said there was a good deal of sulphite to be met with in the market as hyposulphite; possibly in Mr. Dunmore's case, alluded to by Mr. Spiller, he may have come across a sample of it.

Mr. E. Dunmore: If Mr. Spiller had gone a little further, and left the hypo in as he had suggested, a different result might have been obtained. He was not alone in the experience mentioned; others had done the same. If prints are kept in hypo some time, there is not the slightest doubt but they will fade.

Captain Abney remembered Mr. Spiller's earlier experiments, which had refereuce to a different form of fading, viz., a yellowing in the lights. He (Capt. Abney) thought there was more to fear from organic compounds than from hyposulphite. Mr. Spiller recommended the fixing bath being kept alkaline, and fading seemed to be worse since that time.

Mr. J. R. Sawyer made some prints from waxed paper negatives about thirty years ago; he used an eighty-grain silver bath to float his albumen paper on, and toned with hypo and gold; these are in perfect condition now.

Mr. T. Sebastian Davis found that deep printing in sunlight, and with gold toning—not sulphur toning—is satisfactory. Sulphur toniug must lead to fading sooner or later.

Mr. T. Brownrigg said the oldest prints he had, which had kept well, were taken out of the frame, placed in hypo to which silver had been added, and toned afterwards.

Col. Stuart Wortley, when in Naples some years ago, printed a large number of pictures, which received very little washing; some of these, sent home to the 1862 Exhibition, and mounted here, had faded; others were as good as when first printed.

Mr. W. England remembered the circumstance. The cause of fading was due to dampness in the new Exhibition building. Slovenly washiug has much to do with fadiug, aud bad mountiug boards also.

Mr. Spiller briefly replied to the various speakers.

The Chairman said they were certain to accord Mr. Spiller a warm vote of thanks, for the paper had proved valuable iu many ways. He hoped paper makers would avail themselves of the suggestion to use sulphite in the future. His own experience was that good washing was necessary; some prints he made thirty years ago are good now.

The vote having been accorded,

The Chairman called upon Mr. W. E. Debenham to read his paper on the "Illumination of the Dark-Room."

Mr. Debenham commenced his paper by speaking of the importance of the preservation of the sight, and quoted the opiuious of Mr. W. Acklaud and Dr. G. A. Herschell as to the injurious effect on the eyes of a red light. Whilst there might be some few persons who preferred as a matter of comfort a red to a yellow light, he believed that the great majority found the red light of the dark-room very trying and injurious to the sight, aud would prefer not to use it, if they did not suppose, from what they had been told, that yellow was not so safe for the plate. The use of red light had been introduced and insisted upon because it had been asserted that bromide was proportionately so much more sensitive to the yellow and orange—the middle of the spectrum—than iodide; that the same coloured light proper for working in, with one haloid, was not so with another haloid. In view of the different results obtained by different experimentalists when photographing the spectrum, it is better to rely upon tests made upon colours such as are likely to be used. He produced a sheet of various coloured ribbons, and photographs taken from them with three plates, one containiug bromide only, one with the addition of five per cent. of iodide, and one with ten per cent. The colours all came out in the same series on each plate. This proved, he thought, that the great effect stated to be produced on the colour sensitiveness of plates by the addition of iodide did not, in fact, exist. With reference to Captain Abney's experiments with stained red as compared with canary medium, described at the March meetiug of the Society, it was poiuted out that the glass known as stained red was a silver stained glass of the same material as the yellow, and was only red by virtue of the accumulation of yellow. This was showu by dissolving part of the staiu from a picce by means of fluoric acid, when the colour was seeu to be of a clear yellow. Captain Abney's experiments, however, could not be considered conclusive. The plates ought to have been exposed iu a similar mauner to that iu which the readiug distance was taken. That Captain Abney, moreover, should find less photographic effect through stained red thau through canary medium he could not understand, as he had always found more. Passing on to the use of supplementary screens of different colours, he said that Captain Abney had advised the use of cobalt with staiued red. He therefore showed a lautern, one side glazed with stained red and cobalt, and the other with stained red and green, the latter of which combinatious allowed more than three times as much illuminating power as the other; at the same time, that as a plate exposed and developed before the audience showed, it had far more protective influence from photographic light. This he attributed to the fact that stained red being an accumulation of yellow, allowed that coloured ray to pass, and so did green, whilst the latter assisted by cutting off both ends of the spectrum. A composite whitish light, produced by throwing green and red upon a white screen, was showu, and it was stated that this gave far less photographic effect than an ordinary white light, aud could with some precautions be safely used for developing. The couclusious that he considered established were:—That the great difference in relative sensibility to different colours, stated to exist in the two substances, bromide of silver in gelatiue, and the ordinary bromo-iodide bath plates, does not exist; that, therefore, the difference in the colour of the illuminatiug medium, said to be required, is a mistake; that yellow light gives more luminosity iu proportion to its effects upon the photographic plate, than real red light; that "staiued red" glass owes much of its character to the fact that it is a piling up of yellow; that green glass cuts off both ends of the spectrum, aud therefore, in addition to renderiug the light cooler, is a considerable protection; that green glass used as a supplement to stained red, allows more illumination to pass than cobalt so used, aud is much more strongly protective of the plate by obstructing photographic power. Mr. Debeuham hereupon exposed a plate to burniug magnesium wire transmitted through red glass; also, red with green superposed, and red with cobalt, the latter upon examination beiug far less luminous than with green superposed. This plate was developed in the presence of the meeting; when development was complete, it was shown that the portions exposed to red, also red iu combination with cobalt, had considerable photographic action, whereas, with the combination of green and red, no action took place.

A vote of thanks having been asked for and accorded to Mr. Debenham for his paper,

The Chairman anuounced that, owing to the lateness of the hour, Mr. J. R. Sawyer would defer his paper until the next ordinary meeting. His attention had been called to an Art Loan Exhibition to take place next month at Guildford. Exhibitors were confined to the residents in the county of Surrey. Photographs would be accepted. It was also decided that the discussion on Mr. Debenham's paper should be taken at the next ordinary meeting, to be opened by Mr. C. Ray Woods. It was also announced that the next intermediate meeting will take place on the 27th inst; the next ordinary meeting, June 10th.

London and Provincial Photographic Association.

A meeting of this Society was held on Thursday, the 8th inst, Mr. A. Haddon iu the chair.

Mr. A. L. Henderson, referring to old developing solutions, showed a negative developed with pyrogallol three years in solution.

Mr. A. Mackie passed round a flexible tube arranged for releasing shutters by hydraulic pressure, similar to the ordinary pneumatic tube.

The Chairman then called upon Messrs. C. and F. Darker to give their lecturette, "On the Phenomena of Light."

Mr. C. Darker, replying, said it would give them much pleasure to treat the subject as far as time would permit; they rather desired it to be a friendly chat thau the more formal lecture. He said the ancients' ideas of light was very crude: some imagined light was emitted by the objects themselves, others that it originated in the eye. Archimedes must have

known something about light and its action when he made his celebrated concave reflector. One hundred and fifty years ago, Sir Isaac Newton imagined light was caused by minute particles, which were shot out from luminous bodies; this was known as the emission theory. The famous Dutch astronomer, Huyghens, about this time propounded the undulatory theory, so that Newton likened it to a rifle bullet passing through space, and Huyghens to undulations or waves of sound. A scale of the measurement of undulations was then thrown on the screen, and the different conditions of surface necessary to reflect different colours were explained, and by means of the oxy-hydrogen lantern a beam of white light was thrown on to a sheet of paper covered with biniodide of mercury; heating this salt caused an alteration of the surface of the substance to take place; where the crystals formed, the red colour changed to bright yellow; by crushing down the crystals the red colour returned, to again disappear upon the application of heat.

The absence of colour in flowers when seen by monochromatic light was also illustrated.

With regard to the speed at which a beam of light travels, the lecturer said it was estimated, calculating by the eclipse of Jupiter's satellites, to be 192,500 miles per second; this had been somewhat modified since by Foucault, Young, Forbes, and others. It was not a matter of how long it takes to see an object, so much as the time occupied by the optic nerves to convey the fact to the brain. An illustration of this would be seen after they had burnt some magnesium ribbon; black lines would appear on a white screen, which was caused by the nerves being over-wrought. By placing a ruby glass cap over the light, and moving a black object in the red light, the shadow gradually appeared green. By revolving the same object in green light it gradually appeared purple, showing the power of the eye to assimilate itself to circumstances with the complementary colour. Moving circles, rotating dots, and a rotating spectrum were shown, first slowly, afterwards rapidly rotated. The eidoscope came next, some beautiful patterns being obtained; another illustration was the popular chromatrope.

The persistence of vision was next dealt with by means of the revolving wheel, the possibility of seeing the true pattern or different patterns by revolving a flashing shutter in front of the beam of light. The angle of reflection was then shown to be equal to that of incidence, while divergence of a ray was illustrated by means of a convex mirror, and convergence by means of a concave mirror.

The use of the Nicol prism was explained, and the use of the analyser illustrated by passing a ray of light through the prism on to a pyramid, a piece of quartz placed in front of the prism rendering the complementary colours visible. Analysing by small particles was also shown. A tube of water containing mastic in fine division was placed under the ray from the Nicol prism; when intercepted by quartz, the red and green colours were obtained. A cell containing milk and water was shown to act in a similar manner. It was mentioned that towards the close of the day during the summer, the light from the north is so far polarized that the sky may be regarded as forming a very fair polarizer. The polariscope was next dealt with. A ray of light falling on a bundle of (thirteen) glass plates fixed at an angle of abont 56° was shown to be polarised.

In conclusion, a number of objects were shown, including annealed and unannealed glass under pressure, various forms of crystallization, also designs in mica, selenite, &c.

Upon the motion of the Chairman, a hearty vote of thanks was accorded to Messrs. Darker for their interesting lecture.

It was announced that the subject of the next lecturette in June will be "Altering the Density of Negatives," by Mr. W. Coles.

Edinburgh Photographic Society.

The seventh meeting of the current Session was held in 5, St. Andrew Square, on Wednesday evening, 7th of May, Mr. Wm. Neilson presiding.

The minutes of the previous meeting having been passed, Messrs. E. Park, James Melville, Robert Gray, and J. Wilson Stewart were admitted ordinary members of the Society.

The Secretary read a revision of laws as re-arranged by the Council, which will be discussed at next meeting.

Mr. G. G. Mitchell read a paper, "Photographers and Sitters" (see page 311), for which he received a vote of thanks.

Mr. John Annan exhibited a large number of landscapes by Mr. Andrew Pringle, Mr. Hay, the late Mr. Black, and others, amateur and professional. Mr. Annan had collected several sets, each representing the same subject, but by different hands, and was thus able to show great diversity of treatment. From the same point of view and on the same sized plate, one man produced a bold massive composition, while another (perhaps through using a wider angled lens) showed a poor, flat, insignificant result. Another set showed the great diversity of results from very slight modification of point of sight; another set showed prints from the same negative, but cut in different sizes and shapes. In all these examples there was little difficulty in picking out one that stood out distinctly superior to the others, and Mr. Annan pointed out the reasons why, and showed how others had failed. The exhibition possessed high educational value.

A vote of thanks was awarded to Messrs. Annan, Hay, and Pringle, by acclamation.

Packets of hydrokinone were distributed among the members willing to experiment with it and state results at next meeting.

A set of photographs of the characters in the Passion Play at Ober Ammergau was exhibited by Mr. G. G. Mitchell, and excited considerable interest.

A vote of thanks to the President terminated the proceedings.

Bolton Photographic Society.

At the third annual soirée, held in the Baths Assembly Room, there was a large attendance of members and their friends. Round the room were ranged tables filled with specimens of the photographic art, the work of the members, the productions being highly creditable to amateur effort.

Prominent amongst the specimens exhibited were those of Mr. T. Parkinson, a hundred in number, which claimed a large share of attention. One of the finest of these was a view of the interior of Mytton Hall, the residence of Mr. John Hick, J.P., President of the Society; another was a good view, taken by electricity some few years ago, of a group of the members of the Microscopic Society, in the Town Hall; and others, again, portrait and view, were in carbon. Some exceedingly good specimens of photography were shown by Mr. C. K. Dalton, including instantaneous photographs, and one in platinotype. Mr. R. Mercer had some beautiful views, also in platinotype, chiefly of Smithills Hall, which were greatly admired. Mr. J. W. Hawksworth, the energetic secretary of the Society, displayed a few good specimens recently taken, as well as a large view of the Fever Hospital, with the Sanitary Committee in the foreground. Mr. J. R. Bridson, J.P., one of the vice-presidents, displayed some twenty views of Windermere scenery, beautiful in execution and production; and Professor Heaton displayed some pretty views of Swiss scenery. Mr. W. Banks had a few good photographs, and also displayed a quantity of apparatus, &c. Mr. W. Laithwaite had a few good views of Turton Tower, the Jumbles, &c. Mr. E. N. Ashworth had some fine photographic pictures of Scotch and Cumberland scenery, and Haddon Hall, with Dorothy Vernon's door. Mr. B. Abbatt and Mr. J. S. Jackson were also exhibitors, their specimens, though few, being good; and the Rev. J. W. Cundey, M.A., had some excellent photographs of the Italian Alps.

Among the outside specimens were three excellent sea views from the Autotype Company, and a number of splendid photographs produced by Mr. J. B. Wood, a member of the Manchester Photographic Society, who kindly officiated as descriptive lecturer. Mr. J. R. Bridson, one of the vice-presidents, acted as chairman, and congratulated the Society upon its proficiency.

Mr. Hawksworth, Secretary, read the report, which was satisfactory, showing that since last season twenty new members had joined the Society.

The Bolton Glee Party, with Mr. J. Bentley at the pianoforte, enlivened the proceedings by their united efforts.

Notts Photographic Association.

A meeting of this Association was held on Friday, May 9th, at the Morley House, Shakespeare Street, the President in the chair; there was a very good attendance.

The President dwelt on the rise and progress of photography in Nottingham, the difficulties that had been encountered, and the obstacles which had been successfully overcome. He advised the members to study nature as much as they could during the summer in their trips, as the more they studied the more she would reveal herself in her true and interesting character.

Mr. T. Bourne (President of the Nottingham Society of Art),

in moving a vote of thanks to the President for his very interesting and encouraging address, said that the subject of photography was an interesting one which could not be exhaustively dealt with in one paper, and the degree of excellence which was arrived at had not been brought about by one, two, or three men, but by a little army of workers. He might say he was the principal founder of the old Nottingham Photographic Society, which had been in existence twenty-five years ago, he believed. It had died a natural death through the removal of one and another, and he heartily wished the present Association great success. After alluding to his connection with the Fothergill process, he said that beautiful as this process was, it is now slumbering as a process of the past, having given way to its rival the gelatine bromide plates.

The motion having been carried, the members proceeded to the examination of the apparatus &c., after which the proceedings terminated.

Halifax Photographic Club.

The usual monthly meeting was held on the 7th inst., the Rev. W. E. Hancock, M.A., in the chair.

The President, Mr. Thos. Birtwhistle, gave a practical demonstration of the platinotype process, developing a large number of prints before the audience, the great simplicity of all the operations and beauty of results being highly appreciated. The majority of the Club, however, expressed themselves as not altogether pleased with the new sepia tint.

The Rev. W. E. Hancock asked Mr. Williams if he still held the same high opinion of single lenses for landscape purposes.

Mr. Williams always used such when practicable, and preferred one of the longest possible focus; he did not think any modern single lens gave as good definition, depth, and brilliancy, or as pleasing perspective, taken all in all, as that afforded by the old-fashioned and more bulky form in use twenty-five years ago; and never cared to sacrifice *utility to portability*.

The annual trip of the Society was arranged to be held on Midsummer Day next, and the field of operations, Bolton Woods, when a number of prizes will be competed for.

A hearty vote of thanks to Mr. Birtwhistle for his able and interesting demonstration brought the proceedings to a close.

Sheffield Photographic Society.

The usual monthly meeting was held at the Masonic Hall, on Tuesday evening, the 6th of May, Mr. Councillor Firth in the chair.

A very numerous attendance of members and friends assembled in anticipation of seeing the work of the first trip of the season, which took place on Thursday, April 24th, Haddon Hall being again selected for the dry-plate campaign. The day was misty and damp in the early part, and the trees were in some places covered with hoar-frost, but as the party went on their journey and the sun went on his, life and warmth increased, and with them, the zeal of some of the members. Haddon was reached about eleven o'clock. The weather for the first hour was not bright, but cloudy, and the splendid old Hall was overshadowed, so that many of the first pictures of the pile and its surroundings, taken from the meadows, were wanting in contrast, with the exception of one taken by the President, Mr. Firth, who waited and was favoured with a gleam of sunshine which made his picture a brilliant and charming representation of the subject. Mr. W. Dakin produced some charming pictures of the old place; one in particular, of the Dorothy Vernon steps, which was original in selection and well timed in exposure, considering the shady corner they stand in.

Mr. J. Taylor (the Secretary) succeeded in adding to his already valuable and choice selection of Haddon pictures, some splendid 12 by 10 views, from picturesque positions. Mr. Leaman, of Chesterfield, worked two cameras, both in and out of the Hall, with unflagging enthusiasm, taking with him a rich lot of pictures, both in selection, subject, quality, and manipulation. Mr. H. Rawson, in his usual careful manner, selected a few choice bits as stereos and half-plates. Mr. W. B. Hatfield exposed plates on such views as were absent from his collection, and succeeded in winning in the contest for the best picture, with a whole-plate representation of the banquetting hall (interior). Mr. Word showed a lot of very good 7½ by 5 pictures. Mr. Hayball also succeeded in making up a nice and varied selection by availing himself of the lady figures, which were more for studies than representations of the place. Mr. Millward also made good additions to his stock of 10 by 8 pictures. Mr. Foxon found many subjects suitable to his way of producing pictures, he having a choice for bits suitable for enlarging.

On this trip there was a good attendance of new members, all amateurs. In all there were 17 cameras at work, and 112 plates exposed of various sizes, and 56 finished prints shown at the meeting.

The next trip will be to Dovedale, on the 22nd inst.

The subject for the competition picture for next meeting was announced to be "A Rustic Bridge." Two prizes will be given.

Mr. J. Charlesworth was elected a member.

Talk in the Studio.

Royal Cornwall Polytechnic Society.—The fifty-second Annual Exhibition will open at the Polytechnic Hall, Falmouth, on Tuesday, August 12th, 1884. These are the regulations regarding the competition in photography:—In all cases state whether the work is professional or amateur, and name process of production. All works sent for competition must have been executed within eighteen months of the date of this Exhibition. Carte-de-visite portraits are excluded from exhibition, except when illustrating some special process or novelty. *Professional Photographers*—Medals are offered by the Society for meritorious productions in the following subjects:—1, Landscapes; 2, Portraits; 3, Composition Pictures; 4, Instantaneous Pictures; 5, Interiors; 6, Transparencies for Lantern or Window Decoration; 7, Pictures by improved processes; 8, Enlargements. All enlargements for competition must be the work of the exhibitor. *Amateurs*—Medals are offered for meritorious productions in this department. *Photographic Appliances*—Medals are offered for improved apparatus and appliances, including magic lantern apparatus, &c. All exhibits in this department must be accompanied by a written explanation of their specialities. Exhibits to be sent in not later than August 5th, and further information respecting the photographic department may be obtained from Mr. W. Brooks, Laurel Villa, Wray Park, Reigate.

The Society of Amateur Photographers of New York.—The President, Mr. F. C. Beach, writes:—"I am pleased to inform you that we have just organized a new Amateur Photographic Society for this city and vicinity, of which I am President. Our aim is to provide meetings in which information shall be given by practical demonstrations. We purpose to fit up a hall with suitable appliances for photographic experiments. We also desire to open correspondence with photographic societies abroad, and establish a system of exchange of pictures. We shall have a very complete photographic library."

The Surrey Art Loan Exhibition.—Arrangements are being made for holding a country Exhibition at Guildford Town and Borough Hall, in June, many Royal and titled persons being among the supporters, and it is expected that it will open on the 14th. Objects of art which are in the possession of residents in the country, or which have originated in Surrey, will form the main feature of the Exhibition; but specimens illustrative of the natural history or geology of the county will also be admitted. The only photographs which can be accepted are pictures illustrative of Surrey scenery which have been taken by residents. Mr. T. M. Brownrigg is the Secretary, and communications should be addressed to him at the Town Hall, Guildford. Exhibits must be sent in before the third of June.

A Competition for Photo-Cyclists.—Arrangements have been made for a "Cyclist" camp at the Alexandra Palace during the Whitsun Holidays (May 30 to June 3), and it is proposed that amateur photo-cyclists shall compete for two prizes, value £2 2s., one for the best view of the camp, and the other for the best instantaneous view of machines in motion. A similar competition is to be arranged for professional photographers. Rules may be obtained from Mr. L. A. Edwards, Secretary, 28, Southampton Street, Strand.

The Artificial Light of the Future.—Professor Mathieu Williams, writing in the *Gentlemen's Magazine*, says:—"My note on this subject last July was preceded by one on the researches of Professor Radziszewski. I learn now that he has actually separated

the luminous matter of the *Pelagia noctilnca*, one of the multitude of species of marine animals that appear like little lumps of jelly, and produce the phosphorescence of the sea. He evaporated to dryness 180 specimens, and from the dry residue dissolved out by means of ether a peculiar kind of fat, which, mixed with potassa, gives out, when shaken, phosphorescent flashes. This is exactly what happens to the living animal. When quiescent it is not luminous, and if shaken or rubbed it flashes. I have collected and examined a great variety of these animals at different times; the most remarkable occasion being one morning after a magnificent display of marine luminosity in the Mediterranean, a few miles off the shores of Algiers. The surface of the sea was encrusted, I might almost say, with countless millions of small jelly-like creatures, of spherical, ovoid, oblong, dumb-bell, and other shapes, varying in size from a mustard-seed to a pea; a bucketful of water taken over the ship's side appeared like sago broth. They were all internally dotted with a multitude of what I suppose to be germs, that would be liberated on the death and decay of the parent. The practical importance which I attach to the study of the luminosity of these creatures is the fact that they supply light without heat. The costliness of all our present methods of artificial illumination is due to the fact that we waste a largely disproportionate amount of energy in producing heat as well as light. This wastefulness may be illustrated by supposing that we obtain a pound of the phosphorescent fat of the noctilnea, and divide it into two equal halves, making one-half into candles to burn in the ordinary manner, and using the other half to give out its light by cold phosphorescence. I am not able to give precise figures, but believe that I am well within the truth in estimating that the candle would dissipate 95 per cent. of the potential energy of the fat in the form of heat, giving but 5 per cent. of the amount of light that the other half-pound would emit as cool phosphorescence. Let us, then, hope that Professor Radziszewski will continue his researches, and discover the whole secret of both the analysis and synthesis of this fat, and that of the glow-worms, fire-flies, &c. Now that we can supply the confectioner with the flavours of almonds, raspberries, jargonal pears, nectarines, &c., and imitate the perfumer and the richest colours of nature's sweetest and brighest flowers, all by the chemical manipulation of coal tar, we need not despair of solving the chemical problem of transforming mutton suet or palm oil or vaseline into glow-worm or noctiluca fat, to be used for illuminating purposes.

Photographic Club.—At the next meeting of this Club, on May 21, the subject for discussion will be "Relative Merits of Boiled Emulsion and Ammonia Nitrate Ones." Saturday afternoon outing—Watford to Grove Mill, finish at Essex Arms, Watford.

To Correspondents.

*** We cannot undertake to return rejected communications.

Non-Chemist.—In your case you had better put a piece of copper into the solution, and this will cause the whole of the silver to be precipitated or deposited as a greyish powder. When the copper ceases to cause the deposition of more silver, stir the powder (silver) up with hot water, then allow it to settle, and pour off the liquid. This washing should be repeated once or twice, after which a little ammonia is poured on the silver to dissolve the last traces of copper. Once more wash the silver, and then redissolve in nitric acid.

W. A. C.—1. Mischief is very likely to happen, in consequence of the concentration of the small quantity of hyposulphite solution left in the film. 2. In consequence of the different systems adopted in the manufacture, and the various views held as to the amount of profit which should result. Perhaps, as a general rule, we may conclude that the highest priced plates are the best; but of course there are exceptions. 3. Select either the first or the third. There is nothing to choose between them, and no other objective would be better adapted to your requirements.

Sam. Jutsun.—Nothing which has been published is equal, both as regards completeness and reliability, to the articles on the subject which Major Waterhouse has recently contributed to the pages of the Photographic News.

W. J. W. S.—It will doubtless answer your purpose very well, but probably will not prove quite so convenient as the much more expensive set of lenses which it is intended that it should replace.

G. W. Hall.—It is strange that you should have had such an unfortunate experience of camera makers, and as you conclude that all those who advertise are incompetent, we can only advise you to consult the London Directory with a view of finding out any others who may be in the business.

The Photographer of the Boat-Races at Oxford.—We do not think Mr. Brooks referred to your pictures; indeed, we have reason to think he did not, as if he had seen the pictures you send us, he would hardly have written as he did. Indeed, as you yourself point out, his description does not correspond with the pictures. What do you wish us to do with the pictures?

Topsail.—When we have met with a similar difficulty to that you describe, we always found it advantageous to fume the paper. It may also be advisable to add a small quantity of ammonia to the last water used to rinse away the free silver previously to toning, say a dozen drops to each pint. The smell does not, perhaps, signify much, but we should certainly prefer to use paper which does not possess an unpleasant odour.

Ruby.—Let the objective of the camera look into the instrument just as the eye looks into it; but we hardly think that you will obtain the result you require without a more expensive art rangement.

C. Banyard.—A portrait combination having an equivalent focus of about twelve inches will serve well.

Y. T.—It is by no means advisable to use zinc trays, although cases may occur in which no mischief occurs.

F. H. W.—The best book for you is Fownes' Chemistry, published by Churchill; the cost is, we think, rather under the sum you mention.

Hugo.—See an article which appeared on page 226 of the present volume.

J. Dyment.—1. We can hardly judge without seeing a specimen; but from what you say we are inclined to think the fault must be in the plates. 2. Here, again, we should require to knew more before giving a decided opinion. 3. Probably some hyposulphite remained in it.

G. M.—1. The only way is to make as perfect a copy as possible, let us suppose by contact printing on a gelatino-bromide plate. From this you can make a reproduced negative. 2. A difficult problem, but we have seen this kind of thing done very successfully by the local application of cyanide of potassium solution thickened with gum. 3. Considerably less, perhaps one-fifth.

J. Jobson.—1. We believe it costs one shilling, and it can be had on the premises. If you send the amount to the Secretary, no doubt it will be posted to you. 2. Roscoe's Elementary Chemistry would perhaps not contain as much as you require, so you might obtain Fownes', published by Churchill. 3. The *Chemical News* is a weekly publication, which would doubtless suit you.

W. Kent.—Full working details of an excellent method will be found on page 161 of our present volume. See also page 210.

The Photographic News Registry.

Employment Wanted.

Retoucher, 25s. weekly.—Miss H., c/o Mr. Kent, 49, Newman-st., W.C.
Gen. Assist, 16s. weekly.—L., c/o. Mr. Kent, 49, Newman-st., W.C.
Mounter, Retoucher, Finisher.—E. R., 4, Offley-rd., Brixton-rd.
Reception-Room in first-class house.—Sophy, *Photo. News* Office.
Printer & Toner, first-class.—T. Cook, 20, Bromhead-st., Commercial-rd., E.
Operator, good at landscapes.—Mercury, 3½, Queen-st., Soho.
Col. & Ret. (lady).—F. W., 24, Fairview-ter., Milford Manor, Salisbury.
Italian Operator, speaks English & French.—Spagliardi, 20, Grove-la., S.E.
Retoucher (young lady).—E. F., 92, City-rd., E.C.
Reception-Room or Shop.—L. A., 77, City-rd., E.C.
Retoucher (lady), Lond. or near.—H. M. A., 45, Rye-hill-pk. Peckham.
Spot. & Mounter, Recept.-Room.—Miss Smedley, 45, Gt. North-ter., Linc.
Printer & Toner.—F. K., 40, Brooksty-st., Liverpool-rd, N.
Reception-Room, Correspondent, &c.—A. J., 6, Marlbro'-st., W.
Printer, Toner, Vignetter, &c.—Carbon, *Photo. News* Office.
Printer, generally useful (age 19).—Eunieles, Eton, Bucks.
Assistant Operator, Printer, Toner, &c.—Pyro, 38, Union-st., Birmingham.
Reception-Room, Mounting, Spotting.—49, Brecknock-rd.
Operator & Retoucher, German.—L. Welter, 66, Killigrew-st., Falmouth.
Gen. Assist. (engineer).—J. W. Pateman, 60, Trent-st., Gainsboro', Linc.
Operator, wet and dry.—C. O., 25, Duke-st., Bloomsbury-sq.

Employment Offered.

General Assistant, to retouch, finish, &c.—T. Price, Jersey
Printer, Toner, Vignetter, &c.—T. Moss, 199, Derby-st., Bolton.
Person to Mount and Spot Cards, &c.—Lafosse, Knolls House, Manchester.
Retoucher, and assist in Reception-Room.—Artist, *Photo. News* Office.
Operator, to take entire charge.—Cobb & Son, Woolwich.
Printer, Vignetter, routine of print.-room.—Lafosse, Knolls House, Manch.
Operator for N. of England.—A. & G. Taylor, 70, Queen Victoria-st., E.C.
Gentleman of experience, for City warehouse.—H., *Photo. News* Office.
Printer, perm. to good man.—Benedetti, adjoining Peckham Station.
Coaters, (several).—J. D. England, 21, Charles-st., Notting-hill.
Operator, to take charge.—W. A. S., c/o Marion & Co., Soho-sq.
Lad, as General Assistant.—W. McLean, Hunstanton, Norfolk.
Apprentice in all branches.—Studio, 34, High-st., West End, Sittingbourne
Reception-Room & Retoucher.—Russell & Sons, 49, Brecknock-rd., N.W
Retoucher, to assist in reception room.—Artist, *Photo. News* Office.
Retoucher, male or female.—M., *Photo. News* Office.
Operator, experienced—63, Darlington Street, Wolverhampton.
Spotter & Finisher (Lady).—63, Darlington Street, Wolverhampton.
General Assistant.—W. S. Laroche, 43, Mostyn Street, Llandudno.
Young Man, assist in print., &c.—W. S. Laroche, 43, Mostyn-st., Llandudno.
Oper. & Retouch.; Ferro. pref.—G. Threadwell, 288, High-st. Stratford E.
Photographer for studio on the beach.—T. Sutcliffe, Dovercourt, Essex.
Operator & Retouch. (first-class).—Long & Co., Wellington-st., Woolwich.

THE PHOTOGRAPHIC NEWS.

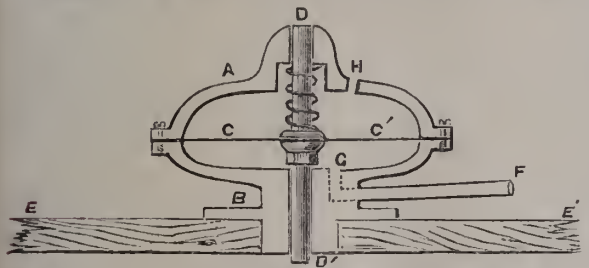
VOL. XXVIII. No. 1342.—*May* 23, 1884.

CONTENTS.

PANCOAST'S PNEUMATIC RELEASE FOR THE INSTANTANEOUS SHUTTER.

OUR readers will remember the original pneumatic shutter which was patented by Mr. Cadett, in which a flap was lifted by a small air motor, and we may here refer to an ingenious instrument of a somewhat analogous character invented by Mr. Spink—this latter being described on page 321 of our volume for 1882. Everyday experience, however, has proved that a pneumatic release is far more generally useful than a pneumatic go and return shutter, and we have seen several ingenious arrangements which have been devised, not only by Mr. Cadett, but also by others, for releasing the drop or spring shutter. In most of these, however, a small balloon or bag of india-rubber lifts a lever by its expansion, and thus withdraws the detent which holds the shutter in its position; but we have now an opportunity of describing an apparatus which seems to offer notable advantages over any pneumatic release that we have seen, insomuch as a simple disc or sheet of rubber is used as the elastic portion, and it is of course easy to replace this in any civilised part of the world; moreover, the rubber is so completely protected from the light as to be but little subject to decay on this score.

Mr. Pancoast's pneumatic release consists of two nearly hemispherical casings of brass, A and B, in the subjoined



diagram, these being bolted together by set screws as shown; but between these is clamped a disc of soft rubber, CC'. A spindle, DD', which passes axially through the whole system, and works tolerably freely in its bearings, grips this disc in its centre by means of a pair of adjustable nuts, like the setting of a circular saw; but the light spiral spring shown in the upper part of the diagram tends to hold the spindle down in the position indicated in the drawing.

To the projecting tube, F, is attached one end of a rubber tube, to the other extremity of which is fitted an ordinary elastic ball or small enema bottle. When this elastic ball is compressed, the air entering the lower compartment by the part G, lifts the diaphraghm and central spindle, and as EE is supposed to be the main board of the shutter frame, the withdrawal of the terminal, D, serves to release the drop or moving part of the shutter. The hole, H, serves to allow of the free escape of air from the upper compartment, or the escape may be provided for by channelling the upper bearing at D. As regards the lower bearing at D', it might be at first sight supposed that very high class and expensive work would be required to ensure a sufficiently accurate fit; but this is not the case, as, if ordinary straight drawn wire be taken for the spindle, it will be sufficient to merely drill out the bearing-hole with a twist-drill.

Mr. Pancoast has proved the value of the pneumatic release by the good service it has rendered him during his recent tour in India. Some details of an earlier and less complete form of Mr. Pancoast's apparatus will be found on page 396 of our volume for 1882.

MR. DEBENHAM'S PAPER ON DARK-ROOM ILLUMINATION.

IT was Mr. W. E. Debenham who recently re-opened the discussion on the subject of the best colour of light for use in the so-called "dark-room," and for this reason his paper on the subject recently read at the Parent Society was looked forward to with considerable interest. The subject of the paper was one which was thought to have been so thoroughly threshed out that no more could be said on it. Nevertheless, the interest which is taken in the matter is such that photographers on the Continent, and on the other side of the Atlantic even, have taken it up, and seem to find that there is something yet to learn.

Putting aside for the present all questions of the particular colour of light which Mr. Debenham proposes to adopt, we may say that if he has done nothing more than to point out the fallacy of the reasoning common among photographers, that, because the red of the spectrum of the sun's light gives the least photographic effect on a gelatine plate, therefore this colour is the best for illuminating the "dark-room," and will be the safest; he has done much.

As a matter of fact, the rays of the spectrum which have the least photographic effect, and the colour of light which (allowing us to see what we are doing whilst developing plates, &c) will give the least photographic effect, have not of necessity any connection whatsoever.

This may be made evident in the form of a *reductio ad absurdum* by arguing as follows.

The ultra red (dark) rays of the spectrum have the least effect of any on a gelatino-bromide film; therefore the ultra red (dark) rays will be the best with which to illuminate the dark-room—which is absurd.

As to the particular shade of yellow light (whether obtained by the use of yellow paper and green glass, or other-

wise) which Mr. Debenham recommended, he appeared to us to fail to make out a case in its favour as against light filtered through "stained red" glass, except on the ground that red colour is hurtful to the eyesight. This latter statement appears to be scarcely proved, and it appears difficult to prove it if we take into consideration how common idiosyncracy is in the matter of the effect produced by the different colours on the eyes. Thus we can say that we do know some persons to whom a red coloured light is emphatically painful, even at times intolerable, and with whom the pain increases as the light does, thus showing that it is not produced by the straining of the eyes in a feeble light. Before this fact had any weight in the matter, however, it would be necessary to show that there are not others who find other colours—for example, blue or green—painful.

Mr. Debenham pointed out a fact with regard to stained red, apparently not generally known, namely, that this colour is in reality built up of a sufficient thickness of yellow merely.

As a matter of fact, the colour which is in "stained lemon," "stained orange," and "stained red" glass is precisely the same. It is only a question of the thickness of the film. Even in the case of stained red it is shown by the spectroscope that a large amount of yellow passes, and in fact the colour is, as we mentioned some little time ago, more of the nature of an orange than of a red.

One thing of real use which Mr. Debenham proved at the meeting of the Parent Society by the actual development of a plate is, that the light got from a combination of red stained and cobalt glass is very much less safe than one got by a combination of red stained glass and green glass, equal visual amounts of light being allowed to pass in each case.

An experiment which must have been new and interesting to many, was that in which red and green lights were combined to make white light. It is well-known that by the addition to each other of lights of any two complementary colours, white light may be produced. The two complementary colours which are the nearest possible to the low refrangible end of the spectrum are a certain shade of red and a certain shade of green. Mr. Debenham had lamps fitted with chimneys possessing colours as nearly as possible to those particular shades; and by receiving the rays on the white reflectors, whence they were thrown on to a screen of white tissue paper, a nearly white light was got. To those who have never seen the experiment it is difficult to believe how like the light from an ordinary candle appears to that got by the addition of the bright green light to the bright red light.

It is very necessary, when considering this experiment, to remember that the light got by combining the two reflected colours will be very different in its action on a photographic film from that got by filtering light first through green, then through red glass, or *vice versa*. The difference is, in fact, almost precisely that which exists between addition and subtraction. In the light got by combining red and green lights, there is present all rays which are allowed to pass through either of the coloured glasses. In the light got by filtering through red glass and then green, there are present only those rays which will pass both the glasses; which, in fact, are common to both the colours. As in the case of the green there is present a considerable quantity of blue light, we could not expect to get a white light very safe for photographic purposes in the manner which we have described. Nevertheless, the difference in photographic power between such a light and one quite similar to the eye, but coming unfiltered from a candle or lamp flame, is very remarkable.

A sensitive plate exposed to the white light composed of red and green, at such a distance as would enable small print to be read, showed only the very faintest trace of fog after one minute's exposure, whilst a similar plate exposed to apparently similar light, obtained from a lamp direct, gave a dense image in the same time. Probably we should not be far wrong in stating the ratio of the photographic powers of the two lights as one to ten.

It will thus be seen that there is nothing impossible, or even difficult, if reasonable care be taken, in using white light in the dark room. The discussion on Mr. Debenham's paper which is to take place at the next meeting of the Parent Society will be looked forward to with interest.

AMMONIA: ITS COMPOSITION AND USES.

BY W. M. ASHMAN.

Probably next in importance to silver haloids among the chemicals employed by the photographer, may be classed that universally known substance ammonia, for by its aid we are enabled to increase the speed of an emulsion to an almost unlimited extent; besides which, it forms with pyrogallic acid the active agent by which the majority (in this country, at least) of the exposed sensitive salts or latent images are developed to a successful issue; for these purposes we employ ammonia either in the liquid form or a solution of the solid carbonate. It is also recommended either in one form or the other as a valuable addition to the positive printing-bath, in order to prevent the liberation of sulphurous acid, and the consequent destruction of the prints.

Owing to the extreme volatile nature of ammoniacal gas when dissolved in water, it is largely used in the arts for various purposes, the well-known liquor ammoniæ, generally having a specific gravity of near about ·880, contains the largest amount of this volatile and strongly alkaline pungent gas. It is outside the limits of these columns to treat of the numerous uses to which this gas is applied in the arts and manufactures; there is one, however, to which we might refer, since it has a direct bearing on studio furniture and picture-frame mouldings. Wood carvers and cabinet makers of the antique, when desirous of imitating old furniture with new wood, principally oak or walnut, are wont to resort to ammoniacal fuming, precisely in the same manner as photographers employ it for increasing the sensitiveness of silver paper for positive printing, with this difference in point of time: three to thirty minutes generally suffices for most samples of photographic paper freshly prepared, and an hour for those permanent sensitized papers containing a large percentage of citric acid; the fuming of wood, however, occupies a fortnight or more, to effect the desired result. In many formulas we have met with, the simple term ammonia is used, but this is not sufficiently explicit; because it may mean the carbonate, or the more highly impregnated solution of the gas referred to above, or some other compound in which ammonia plays a part, such as bromide of ammonia, the two former behaving as exciters or accelerators, the latter being employed also as a restrainer in alkaline development. As the value of ammonia to the photographer as an accelerator in either form rests principally on its properties of alkalinity, we cannot do better than place before our readers a short resumé of the mode of manufacture, together with an easy method of ascertaining the amount of alkali present in any given sample of ammonia, with more scientific accuracy than the physical method practised by the druggist of bygone days, or rather before the Pharmaceutical Society possessed the influence it now enjoys.

The then prevalent custom was to impart instruction to novices by making them acquainted with the appearance, taste, or smell, either separately or collectively, of nearly all the principal articles kept in stock; the latter sense was always a *sine quâ non* in recognizing ammonia, the writer retaining a vivid recollection of this jocular method of teaching.

It is scarcely desirable to include diagrams of the appa-

ratus employed in the manufacture of ammonia, because this would necessitate our dealing with other by-products, such as pitch, tar, and aniline dyes, substances which are of considerable use to photographers, but are capable of furnishing enough matter for a series of articles devoted to their own peculiar properties. Nearly, if not quite, all the ammonia of commerce is obtained as a by-product in the manufacture of coal gas, which latter, as our readers are aware, is subject to a certain amount of purification after leaving the retorts and before entering the gas-holder. This purification consists in passing the gas through a vessel of water, which dissolves the ammonia, carbon dioxide, and sulphuretted hydrogen; these act together to form ammonic carbonate and sulphide, and in this form is known as gas liquor; the gas liquor is neutralized in a closed leaden trough with hydrochloric or sulphuric acid, and ammonic chloride or sulphate (according to which acid is used) crystallizes out in large quantities, and is collected in baskets for further treatment, the mother liquor being partially evaporated to obtain more crystals. The ammonia salt thus obtained is mixed with an equal weight of slacked lime, and heated in a large copper or iron retort, the head of which is connected to a series of large bottles partly filled with water, which absorb the gas. One volume of water at 32° F. absorbs as much as 1050 volumes of ammonia gas, and it is found that two volumes of water when saturated have increased to three volumes, with great rise of temperature, the gravity of the solution becoming less, *i.e.*, ·880 (water=1·000).

Ammonia should always be kept in well-stoppered bottles, and never opened more than necessary, as every time the bottle is opened the solution loses ammonia-gas, and becomes weaker in alkali. It is for this reason manufacturers of dry plates recommend dilution of the strong ammonia to form stock solutions, there being much less tendency at ordinary temperatures for the gas to escape from a twenty or thirty per cent. solution, than there is from one of the full strength.

A solution of ammonia is commonly known as spirit of hartshorn or volatile alkali, and on account of its volatile nature is often used to neutralise an acid to make a neutral salt, as an excess can easily be boiled off.

Commercial ammonia is liable to contain the following impurities, which can be easily detected, and some, no doubt, may have caused spots in emulsions, which at present are but imperfectly understood.

Carbonate.—A few drops of lime water causes turbidity.

Chloride.—Cautiously add nitric acid till acid, then a few drops of nitrate of silver solution. A white turbidity or precipitate indicates the presence of a chloride.

Lime.—A few drops of oxalate of ammonia solution gives a white turbidity, or is left as a solid residue on evaporation.

Sulphate—Neutralise with nitric acid; add a few drops of barium nitrate solution, a white turbidity or precipitate.

Lead.—A brown tinge on adding sulphuretted hydrogen.

Ammonia, when taken in quantity, is fatal to life, producing inflammation of the lungs, and stricture of the throat; frequent inhalation renders susceptible persons liable to suffer periodically from cold in the head. Such persons should not inhale the fumes from the alkaline developer more than is absolutely necessary, and whenever they feel an indication of an attack, should freely inhale the fumes of glacial acetic acid.

Ammonia-gas is soluble in alcohol, just as in water, but less freely. Dry silver chloride absorbs more than one-third of its weight of ammonia-gas, which is given off again on heating. It also forms solid compounds with the oxides of gold, silver, platinum, mercury, &c., which are decomposed by heat, frequently with explosive violence.

We have hitherto been dealing with the active principle, ammonia; we will now devote a little space to its compounds.

Ammonium iodide, or ammonium in combination with, iodine, was for many years largely used for iodizing collodion is prepared by decomposing calcic iodide with a mixture of ammonia and ammonia sesquicarbonate in slight excess. The solution (filtered from the calcic carbonate produced) on evaporation yields cubical crystals of ammonium iodide. This salt cannot be directly prepared from ammonia and iodine, owing to an explosive compound called iodide of nitrogen being produced by a complex reaction.

Ammonium bromide or ammonium, in combination with bromine, has been employed for the same purpose as the iodide, but is now largely used in emulsions to form silver bromide; also in the alkaline developer, where it acts as a restrainer, as previously mentioned. It is usually prepared by adding ammonia to hydrobromic acid until neutral, and evaporating to obtain cubical crystals.

This salt should never be taken internally, except under medical advice, owing to its peculiar effect on the system.

Ammonium chloride is a compound largely used. In its pure state it is employed in the manufacture of emulsions; perhaps its greatest commercial value is to be found in its use for the Leclanché battery, and as an ingredient in freezing mixtures. It was formally imported in large quantities from Egypt as a product of the distillation of dried camel's refuse, but is now prepared almost entirely from gas liquor (as previously stated). It may also be prepared by adding ammonia or ammonic carbonate to hydrochloric acid till neutral. Photographers may have noticed bottles containing hydrochloric acid that have been left untouched for some time have an incrustation round the neck and stopper; this is ammonic chloride, the hydrochloric acid uniting with the ammonia in the atmosphere.

Ammonium sulphate is largely used as a manure, and in the preparation of ammonia alum; it is soluble in twice its weight of cold, and its own weight of boiling, water. It is prepared from gas liquor, or may be prepared by adding ammonia or the carbonate to dilute sulphuric acid till neutral, and evaporating to obtain crystals.

Ammonium nitrate is frequently used for producing a low temperature for the formation of ice. When thrown on red hot coals the salt explodes, but when gradually heated in a flask by means of a lamp it decomposes entirely into water and nitrous oxide gas; this gas is now largely used by dentists to cause insensibility to pain, and is commonly known as laughing gas. Ammonium nitrate is prepared by adding ammonia to dilute nitrate acid and evaporating to obtain crystals; it is soluble in about half its weight of cold water.

Ammonium oxalate is prepared by neutralizing oxalic acid with ammonia; it is of very little use in photography.

Ammonium acetate is obtained by saturating glacial acetic acid with dry ammonia gas. If dilute acid is used instead of glacial, this, on evaporation to obtain crystals, gives off ammonia, and the acid acetate is obtained instead of the neutral acetate.

Hitherto this salt has been used principally as a febrifuge by pathologists; recently, however, it has been recommended for emulsion work, nitrate of silver being converted into an acetate, and afterwards bromide, by double decomposition. From our own experiments with this method, we were led to consider the neutral condition of this salt an important factor in obtaining a successful result.

Free ammonia can be recognized by its smell; or if the quantity is small, on warming and holding red litmus paper over, which changes to blue, or paper dipped in a solution of turmeric root is changed to brown. These colours are restored to the original on exposure to the air for a short time. Another very delicate test is known as Nessler's. A solution is made by saturating iodide of potash with mercuric iodide, and adding caustic potash solution till

strongly alkaline; if this solution is added in excess to a liquid containing a trace of ammonia or any of its salts, it assumes a brown tinge, or furnishes a brown precipitate, according as the proportion is less or more.

Strong ammonia solution can be estimated by weighing a measured quantity. If ten cubic centimetres are taken, it is only necessary to shift the decimal point one degree, and the gravity is at once seen; by referring to tables showing the amount of ammonia at various gravities the per centage can readily be ascertained.

Ammonia is usually determined by adding from a burette a standard solution of sulphuric acid to the ammonia solution (diluted and coloured with litmus) till the solution is changed to red. The standard solution of sulphuric is made by taking 49 grammes of pure sulphuric acid, and diluting to 1,000 cubic centimetres with distilled water; every cubic centimetre of this solution is equal to ·017 grammes of ammonia (NH_3). So if one cubic centimetre of original solution was taken, and it required 10 cubic centimetres of sulphuric acid solution, then 10 multiplied by ·017 gives the amount of ammonia in one cubic centimetre(=·17); this multiplied by 100 gives the percentage.

Solid compounds of ammmonia are distilled with an excess of caustic potash or soda, and the distillate collected in standard sulphuric acid: the over-plus of acid is now neutralized by a standard ammonia solution, and it requires less of this in proportion as the original compound contained more ammonia.

MR. IVES' SECOND PATENT FOR HIS BLOCK PROCESS.

WE now give the text of the second patent of Mr. Ives, which covers some of the details recently published regarding his method. The text of the first patent will be found on page 498 of our volume for 1883:—

To all whom it may concern:

Be it known that I, FREDERICK E. IVES, a citizen of the United States, and a resident of Philadelphia, Pennsylvania, have invented certain Improvements in the Method of Producing Impressions in Line or Stipple from Photographic Negatives, of which the following is a specification.

My invention relates to certain improvements in carrying out the details of the process of producing line or stipple impressions from photographic negatives, for which I obtained Letters Patent, No. 237,664, dated February 8, 1881.

The essential characteristics of my patented invention consist in producing an impression in pure line or stipple from a photograph from nature or artists' work by first making a photographic negative of the object to be reproduced, then producing therefrom a relief-plate in which the variations of light and shade are represented by variations in the thickness of the relief, and finally producing an impression in printers' ink by impressing such relief-plate against a surface of raised lines or dots.

The object of the present improvements is to gain rapidity and economy in carrying the invention into effect. With this object in view I proceed in the following manner: I first produce a relief-plate from the usual photographic negative of the object to be reproduced, such relief having a white surface. I prefer to use a plaster cast from a swelled gelatine relief, because a suitable relief may be made more quickly and cheaply by this method than by any other.

Instead of making the surface of raised V-shaped lines or dots of paper, as described in my aforesaid patent, I employ printers' roller composition, or equivalent elastic material, the raised lines or dots being moulded or otherwise formed on the surface of such composition, in any convenient manner, of the forms shown in the exaggerated views, Figures 1 and 2 of the drawings.

One of the advantages of employing the printers' roller composition, or similar elastic material, is, that a single surface of such material may be employed in the production of a great many different line or stipple impressions. Another advantage is, that it is less likely than paper to injure the plaster relief in producing or receiving the impression.

Having thus prepared the photographic relief and the surface of raised lines or dots, the third requisite of my patented process—that is, the production of the line or stipple impression in printers' ink by impressing the relief-plate against such surface—is carried into effect by inking the lined or dotted surface with printers' ink, and then pressing this inked surface against the white photographic relief. The result is, that a line or stipple impression is produced on the white surface of the relief, the thickness of the lines or size of the stipple-dots depending on the degree to which the raised V-shaped lines or points on the elastic surface are pressed against the varying surface of the relief. From the line or stipple impression thus produced on the white relief a photo-engraving may be made by any of the usual methods.

Sometimes I employ a single elastic V-shaped line, instead of the surface of V-shaped lines, and impress each line separately.

I claim as my invention—

The mode herein described of producing an impression in pure line or stipple from a photograph from nature or artists' work, said mode consisting in first making a photographic negative of the object; second, producing therefrom a relief-plate having a white surface; and, third, impressing on such plate an inked elastic surface of raised lines or dots, all substantially as set forth.

In testimony whereof I have signed my name to this specification in the presence of two subscribing witnesses.

FRED. E. IVES.

Witnesses: { JAMES F. TOBIN, HARRY SMITH.

INVESTIGATIONS AS TO THE ACTION OF EOSINE ON PHOTOGRAPHIC FILMS.

BY DR. H. W. VOGEL.

IN my investigations with various colouring materials, I have by no means confined myself to the wet collodion process, but have made numerous experiments with dry collodion plates and gelatine plates; indeed, my earlier experiments were made exclusively with dry collodion plates. Under these circumstances, it is quite unnecessary to say that colouring matters exist which act well on dry collodion, although they act better in the case of wet collodion. Still there are a few which behave in a contrary fashion, while if the behaviour with gelatine plates is taken into account, the whole question becomes very complex. As regards this latter point (the behaviour of colouring matter with gelatine plates) comparatively little has been published; but Clayton and Tailler obtained a patent for making eosine gelatine plates in France and Austria, but the patent was not allowed in Germany. In the specification they say that they dissolve eosine in ammonia (in what proportion?) and add one part to one hundred parts of emulsion. They also recommend the immersion of gelatine plates in an ammoniacal solution of eosine; the plates being then dried. Schumann also worked with eosine, and gave quantitative particulars. He obtained results without using ammonia,* but his plates were less sensitive to the greenish yellow than the indigo, while a recently published paper contains no more information. The recent communication of Eder (PHOTOGRAPHIC NEWS, 1884, p. 259) requires some notice, as he says that prints soaked in a solution of eosine, and exposed wet, behave differently from plates exposed dry; an observation which I have also made, but not yet published.

As regards the extent to which eosine exalts the sensitiveness, there is great diversity of opinion, and my first experiments showed that the action of eosine depends very much upon the nature of the emulsion; indeed, with two samples, one made in Berlin and the other in San Francisco, I obtained no result at all. In the case of the first a long exposure to the solar spectrum showed a region of activity between D and E: the addition of ammonia did not assist.

On the contrary, a bromide emulsion of moderate sensitiveness, which I made myself, showed a very good sensitive-

* The absorption band of the eosine silver bromide, in the presence of acetic acid, is rather nearer the yellow end of the spectrum than the absorption band of eosine.

ness for the yellow (about one-third that of the blue), when it was treated with a two per cent. solution containing one of eosine in four hundred, and one per cent of ammonia. Drying reduced the sensitiveness for the yellow by about one-fifth.

Better results were obtained with some plates containing iodide, and some of Monckhoven's, by soaking them in a solution containing two per cent. of eosine and one per cent. of ammonia ; the sensitiveness for yellow being about half that of the blue. These results show that the action of colouring matter is, to a great extent, dependent on the character of the emulsion.

I may remark that the amount of eosine added to the emulsion varied from one and a-half to five per cent., and that as regards the yellow the difference was not very noticeable ; but the sensitiveness to the blue was lowered as the amount of colouring matter was increased. The sensitiveness to the bluish-green, between E and F, however, became very notably less when much eosine was used. Two per cent. of the eosine solution (1-400) gave the best results.

A small proportion of iodide makes the emulsion rather more sensitive in the bluish-green, but without affecting the yellow.

It must be noted that the immersion of the plates in a solution of the colouring matter never gives such uniform results as adding the dye to the emulsion, as when the former method is adopted, fog sometimes results, and sometimes spots may be observed when the solution has not acted. Many plates refuse to take the colour at all.

The use of eosine in collodion emulsion is, however, far more satisfactory than in the gelatine emulsion, as eight drops of eosine solution (as above) added to 10 c.c. of emulsion made it more sensitive to the yellow than to the blue.

Still, it is impossible to overlook the circumstance that the wet process is best of all. But why is this? It appears to be due to the circumstance that the silver compound of eosine is itself sensitive, and the following experiments will serve to throw light on this point.

I added five per cent. of an eosine solution (1 to 400) to plain collodion, and allowed a plate to remain in a silver bath for five minutes, after which I exposed to the spectrum for intervals of 5, 10, 15, 20, 40, 80, and 160 seconds ; the ordinary iron developer was then used, and notable action was perceptible in the green, the bluish-green, and in the position of the absorption band of eosine ; but the action was only noticeable when an exposure of 20 seconds had been given, whereas one second would have sufficed in the case of a bromo-silver-eosine plate, a sensitiveness of twenty times as much being, therefore, indicated for the latter in the case of yellowish-green rays. The eosine silver compound is not decomposed by dilute acetic acid, although dilute nitric acid attacks it. We may from this justly conclude that when an eosine plate is sensitized in the bath, the silver compound of eosine is found together with bromide of silver, and that the eosine-silver compound is individually sensitive. The result of general observation indicates to us that two sensitive compounds used in conjunction influence each other favourably.

The following, which was added to a previous paper (p. 302), must be read in connection with the present :—

In the ordinary wet process, iodide of silver possesses but little sensitiveness for the deeper shades ; while bromide of silver also requires very long exposures to reproduce the deeper shades in the case of studio work ; but a mixture of the two salts is, perhaps, ten times as sensitive to darker gradations. Something analogous occurs in the case of the spectrum, as, with a short exposure, iodide of silver is only impressed a little beyond the line G, that is to say, in the dark blue. Bromide is impressed under similar circumstances as far as the line F (bright blue) ; but a mixture of both is sensitive as far as the bluish-green (lines *b*, E). In such a case, it is pretty clear that an especially sensitive silver compound is formed, which explains the peculiar action of eosine in the wet process. In the case of a dry plate this compound appears not to be formed, and the eosine merely acts as an optical sensitizer.

Thus, in the case of a wet plate, eosine acts not only as an optical sensitizer, but also as a chemical sensitizer ; cyanosine, for example, is analogous to its action ; but other colouring matter, as fuchsin and Magdala-red, act merely as optical sensitizers. In the wet process only such colouring agents should be used as are both chemical and optical sensitizers.

The next problem was to make the eosine silver compound available in the gelatine process, and for this purpose four cubic centimetres of eosine solution containing 1 in 400 were precipitated with 2 drops of a ten per cent. solution of silver nitrate, and the precipitate was dissolved in 2 drops of ammonia ; when 4 drops of this solution were added to 10 cubic centimetres of gelatine emulsion, a notable increase in the sensitiveness for the yellow was noticed ; indeed, tenfold the increase noticed when a mere addition of eosine with ammonia was made.

In conclusion, it may be remarked that the region of activity resulting from the use of eosine in photographic plates does not correspond exactly with the absorption spectrum of an alcholic solution of the dye, but tends more towards the yellow. This fact will not surprise the experienced spectroscopist, who knows that through the action of highly refracting media a shifting towards the red occurs. Eosine, besides giving an intense absorption line in the greenish-yellow, gives also a fainter one in the bluish-yellow ; but the influence of the latter is most notable when methyl eosine is used.

By-the-Bye.

A FRAGMENT OF HISTORY.

BOUGHT AT THE SALE OF EFFECTS OF THE LATE J. J. BENNETT, F.R.S.

Lot 201.—"The first photograph fixed from nature, obtained by Niépce in 1827."

Lot 204.—"The autograph memoir of M. Nicéphore Niépce on his own invention of héliographie, dated Kew, 8th December, 1827, together with an autograph note of instruction ; also two impressions from a pewter plate, engraved by the héliographie process, and another impression of a landscape by the same process."

The above are extracts from the catalogue of sale, describing two lots that passed into our hands a few months ago. They have been examined with some care, and the results of that examination we propose to lay before our readers.

When Nicéphore Niepce came to London in the year 1827, he had already made two important discoveries. The first was in 1816, when he produced the first photograph ever taken in a camera. This photograph, and the circumstances under which it was secured, we have already described.* It was a picture of a pigeon-house taken direct in the camera upon paper sensitized with silver salts, and, as a matter of course, was a negative, the sky being black, and a pear-tree being shown in white. These pictures were not fixed in any way, and after a little while they gradually disappeared in a general discolouration of the paper. Still, it was a wonderful thing to have done, to have held fast a reflection of nature, even for the short space of a few hours. Why, some of our silver prints of to-day fade in a few years!

The next discovery was not less important, but the date of it is a little uncertain. We know that in 1820 Niepce occupied himself with researches connected with bitumen of Judea, and in 1823 we know also that he produced photographic prints by its means. But it was probably a year or so later before he actually succeeded in producing camera pictures of a permanent character by the aid of this sensitive compound. In any case, he produced a *permanent camera picture from nature* in 1827, for it is in our possession at this moment. The description of this picture in the handwriting of the late Mr. J. J. Bennett, F.R.S., is as follows :—

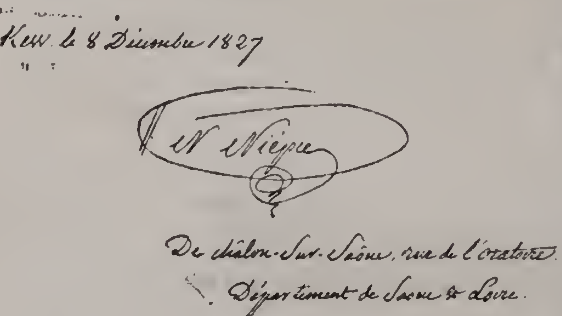
"The first photograph fixed from Nature, obtained by Niépce in the year 1827. Brought by him to London to illustrate his paper for the Royal Society, and given by him to his friend F. Bauer, of Kew."

* See "Photography and Photographers." (PIPER & CARTER.)

But just one word as to the authority of the picture before we proceed. A long time has elapsed between 1827 and the death (during the last twelvemonth) of Mr. J. J. Bennett: what was the history of the picture before it came into Mr. Bennett's hands? Fortunately, we have a clue in Mr. Bennett's own writing, for he says that Niépce gave the picture "to his friend F. Bauer."

Now who was Mr. F. Bauer? He was Secretary to the Royal Society (of which Mr. Bennett was a Fellow, it must be remembered), and it was to Mr. Bauer that Niépce came when he wished to submit his process to the Royal Society. Niépce deposited with Mr. Bauer a memoir and a picture, but as the process was not thoroughly described, the Royal Society, as we are aware, refused to consider the matter. This was at the end of the year 1827, and Niépce, returning to France in January, 1828, left both the objects in Mr. Bauer's hands.

How right Niépce was in this, is shown by the way in which Mr. Bauer afterwards championed his cause. Mr. Bauer carefully kept the picture, while the manuscript was submitted in turn to several savans. This manuscript, attested by Mr. Bauer, is also in our hands, bearing Niépce's signature, as under:—



Kew le 8 Décembre 1827
N Niépce
De Châlon-Sur-Saône, rue de l'oratoire.
Département de Saône & Loire.

The MS. is written very neatly, and, of course, in French. It describes a framed picture, as well as some prints on paper, and we have translated those portions that appear most important:—

"No doubt my framed picture, made upon tin, will be found too weak in tone. This defect is due principally to the circumstance that the high lights do not contrast sufficiently with the shadows represented by the bare metallic reflections; but it will be easy to remedy this by giving more whiteness and more brilliancy to the parts that represent the effects of the light, by receiving the impressions of this fluid (light) upon plated silver, well-polished, and browned. In this way, the contrast between white and black will be much more marked; the blacks, being rendered more intense by some chemical agent, will lose their brilliant reflection, which is disturbing to the eye, and even exerts a sort of vanishing effect.

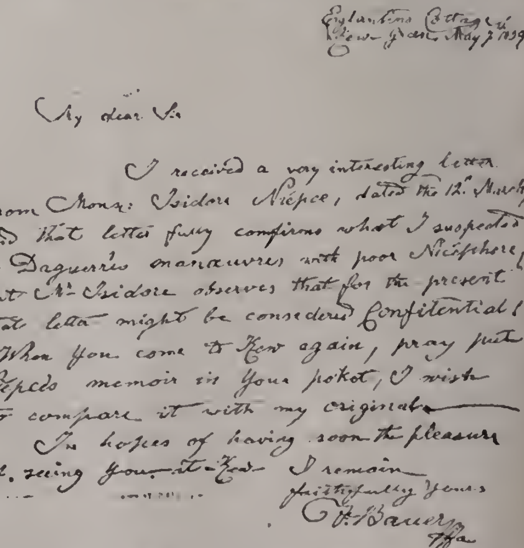
"My efforts at printing leave much to be desired, both in respect to the fineness of the lines and vigour. I only exhibit them, indeed, to show an important application of my process which may be improved upon. The difficulties I have had to surmount were less connected with the process itself than with the insufficiency of my resources in an art with which I am little familiar. It may not be unnecessary to add that the process may be adapted to copper as well as to tin. I have repeatedly produced images upon stone with success, but I believe that glass will be more preferable still. It is sufficient, after production of the image, to blacken slightly the engraved portion, and to place a sheet of white paper upon it, in order to obtain a vigorous impression. M. Daguerre, the painter of the Diorama of Paris, has advised me not to neglect this last mode of application, which, it is true, does not possess the advantage of multiplying the results, but which he *regards as eminently suitable to reproduce all the delicacy of nature.*

"Among the principal means for improving the process, those concerning optics must be put in the first rank. I was deprived of these resources in the few essays I made with the camera, although I strove to do my best by means of certain combinations. But it is with apparatus of this kind, perfected as much as possible, that a faithful image of nature may be obtained, and conveniently fixed."

Now several things will strike the reader here; as, for instance, the mention of employing a polished silver plate browned by chemical means. We know that iodine was among the chemicals he employed in the early days, and in M. Fouqué's history of the "Invention of Photography," it is said that the French philosopher also hinted at the employment of mercury. So that here there is certainly a paving of the way towards Daguerreotype. Another point is the mention of M. Daguerre himself, whom, it seems, Niepce visited in Paris, while on his way to England; while a third matter of importance is that Niepce tells us very plainly that our optical instruments must be improved before we can hope for any great success in photography.

And now to describe the "framed picture" of Niepce. It is upon a sheet of tin, and measures about 9 × 6 inches. It is doubtless a bitumen of Judea picture, but it has all the appearance of a faded Daguerreotype, and would be regarded as such by any casual spectator. There is a low roof of old-fashioned tiles occupying the centre of the picture, with buildings whose roofs only can be made out, on either side. Beyond, there is the outline of a tree or bush. That is all you can say about it. Indeed, so faded is the image, and so deceptive are the metallic reflections, that some little time is necessary to make out even these details. Fifty-seven years have elapsed, it must be remembered, since the bitumen surface was exposed and developed with animal oil of Dippel. According to experiments we have made to produce bitumen of Judea pictures in the camera, it is necessary to expose for at least a dozen hours in bright sunshine to produce anything like a successful result, and it is for this reason, no doubt, that Niépce chose for model some house-roof where there was plenty of light, and where the camera was not likely to be disturbed during the lengthy experiment. We carefully tested the metal surface for silver, but no trace of this metal could be detected.

But perhaps the most important object connected with



Eglantine Cottage
Kew Green May 7 1839

My dear Sir

I received a very interesting letter from Mons: Isidore Niépce, dated the 12. March, and that letter fully confirms what I suspected of Daguerre's manœuvres with poor Nicéphore, but Mr. Isidore observes that for the present that letter might be considered Confidential. When you come to Kew again, pray put Niépce's memoir in your pocket, I wish to compare it with my original.

In hopes of having soon the pleasure of seeing you at Kew I remain
faithfully yours
F. Bauer

our purchase of Mr. Bauer's relics is a letter from that gentleman's pen, with which we close this little essay. The secretary of the Royal Society, as we have said, warmly espoused Niépce's cause, and believed thoroughly

in his invention. Years went by, however, and in 1837 Niépce died, leaving, as we know, the secret of his discovery with two persons only—his son Isodore, and M. Daguerre, with the latter of whom he had contracted a partnership. Of late years there has been a disposition to regard Daguerreotype as due in part to Niépce, and it is of interest to know, therefore, that Mr. Bauer, who was the best independent judge living, was very much of this way of thinking. From the foregoing note it is quite clear that Mr. Bauer believed the invention to be due almost wholly to Niépce, and a more valuable testimony will never be forthcoming than these lines of the Secretary of the Royal Society. To whom they are addressed we know not, for, unfortunately, the name does not appear upon the letter; but this is of little importance. What concerns photographers at the present day, and all those who take an interest in its history, is, that the Englishman who knew most about Niépce's invention wrote this interesting epistle in May, 1839, a few weeks after Arago announced Daguerreotype to the world.

As we say, we do not know to whom this letter was addressed; but whoever it was, he came at once to visit Mr. Bauer, and brought Niépce's memoir to compare with the original. And that original MS., as well as the one alluded to in the above note, is at present, we are glad to say, safe and sound in our possession.

Review.

DIE COLLODION-VERFAHREN. Achte Auflage. Von Dr. Paul E. Liesegang. Preis M. 2·50. (*Dusseldorf: E. Liesegang's Verlag.*)

DER SILBERDRUCK. Achte Auflage. Von Dr. Paul E. Liesegang. Preis M. 2·50. (*E. Liesegang's Verlag.*)

ALTHOUGH one would certainly not be justified in now regarding the collodion process as the principal method of making negatives, there are many persons in this country who use it exclusively, and its advantages over gelatine for enlarging work, copying, and the reproduction of negatives, will not be contested by many. We are, therefore, glad to see a new edition of the thoroughly practical manual of Dr. Liesegang. Not only do we find sound working details for making negatives by the ordinary collodion method, but full instructions in the best methods of intensification and reduction, how to make reversed negatives, the production of enlargements, the collodion transfer process, ferrotypes, and collodion emulsion work. A good index completes the book.

As regards the hand-book of silver printing, we may say that it is a good every-day working manual, in which rather more than half the space is occupied with a consideration of work on albumenized paper, while chloride of silver collodion comes in for the next largest share of the space. The chapter on enlargements is, perhaps, not quite so complete as might be wished, as we find no description of the gelatino-bromide process. This process has, indeed, already taken up a position of some importance, not only in reference to enlarging, but also as a mode of direct printing.

ISOCHROMATIC GELATINE PLATES.

BY DR. O. LOHSE.

IT is probable that there are very many compounds which can influence the colour sensitiveness of gelatine plates, and among others I have recently tried an alcoholic extract of turmeric root, and I find that this, under certain circumstances, acts as favourably as eosine, especially as the red develops well. Their colour sensitiveness was approximately equal between D and H (from the yellow to the violet), but without giving that prominence of the yellow over the blue which is observable in the case of eosine. It might be well to use a mixture of eosine and turmeric extract.—*Photographisches Archiv.*

Notes.

Thirty-two shillings a week is the average salary paid to the members of the photographic staff in the Imperial Printing Office at Berlin.

It was not the fault of photography that the spurious fifty franc notes issued for the last twelve months from a manufactory in Courbevoie were discovered to be forged. The photographic manipulations were faultless, but there was a defect in the paper and an error in the watermark.

Once more postage stamp portraits are popular in the United States. The best way of making a profit by them is to do like Mr. C. H. Tondorff, of St. Louis. When he has taken a larger portrait—let us suppose a cabinet—he suggests making stamp pictures from it. He charges one and a half dollars for one hundred, or twelve dollars a thousand, all ready gummed and perforated.

Whether made direct from life, or from an existing portrait, the method of producing the stamp pictures is simple enough. A camera with several small portrait combinations is used—let us suppose four—and with eight shifts this will enable two dozen pictures to be taken on a half-plate. Immediately in front of the sitter is placed a paste-board frame or border, on which he can inscribe his signature in chalk. If the stamp pictures are made from a carte or cabinet, similar borders can be used.

Could not the *clichés* or types from which postage stamps are made be originated by photography; such a method as this, in conjunction with an engraving process, as that of Ives or Meisenbach, being used?

Speaking of the production of stamps by photography, we may mention that we have seen the collotype press used for the production of forged stamps on a considerable scale; but we do not care to say whether it was in England, Germany, France, or Belgium. They were printed in sheets of fifty, and so good was the imitation that we do not think detection at all likely. They were not produced with the intention of defrauding any national revenue, but in order to assist that harmless eccentric, the stamp collector, to complete his album of rare specimens.

Zinc dishes are not suitable for use in developing with ferrous oxalate; at any rate, this was the opinion expressed by Dr. Kayser when presiding over a recent meeting of the Berlin Association for the Advancement of Photography. Minute particles of zinc are cut off by the sharp edges of the plates, and these, settling on the film, cause spots; a proof of this being afforded by the circumstance that similar spots can be produced by dropping a little zinc dust on the film while in the developer.

The extemporisation of something that will serve as a developing dish is generally an easy matter, for a sheet of stout letter paper with the edges turned up and pinned,

answers admirably; only it must be supported on a rigid surface, such as a board, a glass plate, or a slate, and lifting threads should be used. A more permanent dish can be made by turning up the edges of a ferrotype plate or sheet of tin plate; but zinc must be avoided for the reason already stated.

Although photographers and others who have occasion to work with pyroxyline and nitro-derivatives of the same nature know the need of caution, few persons imagine any danger to exist in the free handling of the alkaline nitrates. Recent experiences, however, indicate that it is not safe to store such salts in contact with wood or other combustible materials, as the other day an explosion took place of a ton of nitrate of soda and a waggon in which it was contained. This happened at Horsemonden, in Kent.

We are about to communicate to some of our amateur friends a new and astonishing fact. It is this; that they can get their freckled portrait negatives satisfactorily retouched for a few pence. We are led to make this revelation because of late we have repeatedly seen excellent portraits that only required five minutes' skilful pencilling to render them perfect. No one more than ourselves deprecates elaborate retouching, but, as we have said before, it is grossly unfair to depict a damsel as afflicted with small-pox simply because her face shows a few freckles, and almost as bad to turn her fair brown hair into a jet black. A few pencillings done by a skilful retoucher who knows the vagaries of the camera will set these matters straight.

What we have just said is patent to all who give a casual glance at our advertising columns; but, strange to say, our friend the amateur is a bit of a conservative, and wants to keep on as he has been doing these many years past. "I have tried the pencil, but I don't like it," said a friend the other day; and when we looked at his performance we could well understand that he did not like it. As with many others, it had never occurred to him that retouching was an art, and a very delicate one, too, not to be acquired in half-an-hour. He would have been surprised to hear that some of our best retouchers are not only artists, but artists who have given years of study and practice to the particular calling they follow.

Bamboo is an excellent material, and the useful purposes to which it is put are endless. Still, there is one application made of it by photographers in the East to which it is eminently unfitted, namely, for rolling unmounted prints upon. We recently received some charming pictures from Egypt wound round a bit of bamboo, the knots of which had indelibly impressed themselves upon all the prints.

Little or no evidence of hard work is to be found in the second and final report of the Commissioners on Technical Education, which was issued on Friday; but the Commissioners have had some very nice touring in the best times of the year, and if a moderately intelligent holiday-maker, just returned from a month's ramble through Europe, were casually conversing on the technical education question, his remarks would perhaps be more to the point than those embodied in the official report.

What the Commissioners fail to say, is of much more real importance than all which we can learn from the report. They do not tell us that it is usual for the head of a scientific department in Italy, in France, in Germany, or in Belgium, to receive only a small fraction of the official pay which is given in Great Britain; neither does the report tell us that the continental *savant* may be found daily labouring among his students, while the English man of science is generally another person as soon as he gets an "appointment." It is certainly true that he delivers his lectures, but he is not always to be found in the laboratory, as he devotes most of his time to outside consulting work; frequently leaving the students in the hands of assistants, who, like the waiters at the restaurant, pay for their places. These "Articled Pupils," in looking out for the crumbs of patronage which fall from the rich man's table, cannot afford to assist the students much; indeed, it often happens that they have not the power.

Contrast this with the state of things at a continental school of technology, or, what will serve as well, the old Royal College of Chemistry in Oxford Street when it was under the direction of Dr. Hofmann—one whose love of hard work infused energy into every person in the establishment, and directly led to the establishment of gigantic chemical industries in England; but under the present system England is losing what it then gained. A thorough and candid report on scientific and technical education in England might be useful.

Talking some months ago with M. Rommelaere, whose photographic classes at the Polytechnic School in Brussels are ordinarily attended by about one hundred and fifty students, he remarked, "As the classes are free, we may hope to include almost every person in the city who has a real inclination for hard study or work, and when we find one who can make his mark, we take care of him."

This observation seems to strike the key-note of the highly successful Continental system of technical education. A wide-spread system of elementary schools and classes serves as a kind of index to the young population, and enables those in charge to find such as possess enough ability and industry to make it worth the while of the State to care for them. In England, the elementary schools are conducted as if all were equal in ability, and consequently much effort is wasted.

By using bichromate of soda instead of bichromate of potash for sensitizing gelatinous mixtures, certain advantages are realized, as the sodium salt is soluble in about its own weight of water, and a rather smaller quantity will produce a definite degree of sensitiveness.

Until recently, carbon printers could not obtain bichro-

mate of sodium as a regular article of commerce; now it is made on a large scale, and costs less than the potassium salt.

The position of the photographer on the staff of an illustrated newspaper becomes increasingly important. Mr. McSpedon, at a recent gathering of photographers in New York, said:—"Last summer I was connected with Frank Leslie's illustrated paper. Everywhere I went I would go directly to the photographer of the town, to get interesting points, and through him I gained a better and a readier means for illustrating my articles. I am convinced that very soon the travelling artist and correspondent will have very little to do. It will be the travelling photographer and correspondent.

The remarkable property of more or less completely dissolving cellulose, which is possessed by a cupro-ammonium solution, has laid the foundation of what promises to become a large industry, the manufacture of the so-called Willesden paper.

Although the manufacture of the material was commenced as long ago as 1870 (see our volume for that year, page 119), it is only recently that it has acquired much commercial importance. An interesting paper on the subject by Dr. C. Alder Wright will be found in the last number of the *Journal of the Society of Arts*.

The *Ladies Pictorial* last week issued the first of a series of competitive portraits of babies printed from photographs by some process, perhaps that of Meisenbach. The effort is a praiseworthy one, since it is an attempt to introduce the direct use of photography into illustrated periodicals. Naturally, the art of direct printing from photographs has not yet arrived at perfection, and good as these pictures are, we are afraid that the mammas will not make allowance for their shortcomings, and will be disappointed that their darlings are not flattered.

Photography has much to answer for in the case of Savanyl Joszi, who has been posing in Hungary as an imitator of Fra Diavolo. This gentleman was a sort of ideal highwayman, robbing only the rich, making presents to the poor, and equally ready to kill a man or make love to a woman. The latter propensity led to his downfall. A lady who had heard of the romantic bandit expressed a wish for his photograph, and, anxious to gratify her, Joszi ventured into civilized regions and sat for his portrait to a photographer. He paid for his temerity, as it was while he was being requested to "smile and look pleasant," that the police appeared on the scene. At least so says *Truth*.

The difficult task which the Royal Academy has every year of finding room for the pictures sent, and the probability that as the time goes on the labour will increase, has led an ingenious individual to suggest an easy method by which the problem may be solved. He calculates that two hundred excellent portraits of eminent persons can be condensed by microscopic photography into a space of the hundredth part of a superficial inch, and it would be easy, therefore, to pack ten thousand pictures or more on the walls of Burlington House. Every visitor would, of necessity, have to carry a powerful magnifying glass, and as for the drawback of the pictures being without colour, this is, as the *Globe*, in commenting on the proposition, remarks, "merely a temporary difficulty consequent upon our not having yet discovered how to make the sun paint as well as engrave." On the whole, though the plan might suit the artists who are now rejected, it is rather hard on the visitors. Why not, then, develop the idea further, give a detailed catalogue, illustrated with the ten thousand microscopic photographs, so that people may examine them quietly at home, and thus do away with the exhibition, its heat and fatigue.

Photography is rapidly assuming a very important position in relation to astronomical observations. In the course of a discussion at the last meeting of the Royal Astronomical Society on the observation of sun spots, it was remarked that owing to the rapidity with which the spots changed, no process of changing could represent them with sufficient accuracy, and what was wanted was a series of photographs on a larger scale than had hitherto been attempted. This attempt, it was elicited, is now being made at Potsdam, by Dr. Lohse, where the method adopted was to watch the sun with a high power, and wait until a moment of extremely tranquil definition arrived, and then an exposure was made by touching an electric button.

But perhaps the most emphatic endorsement on the use of photography was made by Mr. Norman Lockyer, who expressed his belief that in the future all astronomical observations will be made photographically, and he advised all astronomers to assist in obtaining a complete photographic catalogue of the whole heavens. Certainly the picture drawn by Mr. Lockyer, that in a hundred years time or so there would be a room filled with photographs giving a complete picture of every part of the heavens from the North Pole to the South, while the great telescopes would be charged with twelve photographic plates at a time, is no purely imaginary.

Patent Intelligence.

Applications for Letters Patent.

7678. Abel McDonald, Penrith, and Thomas Williamson Kendall, Cockermouth, both in Cumberland, Photographers, for "Improvements in apparatus for washing unmounted photographs and the like."—Dated 14th May, 1884.

7746. Thomas Furnell, 1, Matlock Villas, Lordship Lane, East Dulwich, London, Surrey, Civil Engineer, for "An adjustable-instantaneous shutter for photographic purposes."—(Complete Specification.)—Dated 15th May 1884.

7792. William Heath, 24, George Street, Plymouth, Optician and Mathematical Instrument Maker, for "An instantaneous shutter for use in obtaining photographic pictures."—Dated 16th May, 1884.

7853. George Brown, Photographer, 7, Broad Street, Deal, Kent, for "Retouching or re-modelling photographic negatives by aid of electricity."—Dated 17th May, 1884.

Patents Sealed.

416. George Duncan Macdougald, Chemist, of Dundee, in the county of Forfar, North Britain, for "Improvements in apparatus for storing, conveying, and applying, developing and other chemicals required or suitable for the production of photographic pictures.—Dated 2nd January, 1884.

5204. Harrison Garside, of the city of Manchester, in the county of Lancaster, Photographer for an invention of "An improved method of producing surfaces for mechanical or ink printing by means of photography."—Dated 2nd November, 1883.

Specifications Published during the Week.

4732. John Edwin Atkinson, of Greenwich, in the County of Kent, "Improvements in apparatus for use in transporting and exposing sensitized photographic plates on films."—Dated 29th March, 1884.

This specification is very long, verbose, and profusely illustrated with diagrams. The Patentee appears to claim the making of soft slides with envelope or flap closure of the back, and a draw-shutter in front. He seems, however, to prefer to put one of these into a rigid slide hinged to the camera. His claiming clauses are as follow :—

1st. An envelope for sensitized plates or films constructed of a frame closed at back by overlapping flaps, and provided with a dark shutter substantially as and for the purpose described.

2nd. The construction of the "back" for a photographic camera of a frame or receptacle adapted to receive an envelope of the kind herein specified, and having an opening at front corresponding to the opening in the envelope, and a slot at the side for drawing out the shutter of the envelope, and a door at back at which to introduce the envelope, substantially as herein shown and described.

3rd. The combined employment in the manner and for the purpose herein specified of a series of holders or envelopes for sensitized plates or films constructed substantially as herein described, and of a camera "back" constructed substantially as herein described to receive one such plate-holder or envelope at a time, and enable the plate or film to be properly exposed by drawing out the shutter of the envelope, such camera "back" working on hinges or in slides substantially as specified.

4735. Walter Bentley Woodbury, of South Norwood, in the county of Surrey, for "Improvements in methods of producing printing blocks by means of photography." Dated 5th of October, 1883.

This invention received Provisional Protection only, but we believe the essential features are embodied in a second patent.

My invention relates to surface blocks by the aid of which typographic prints may be obtained in the ordinary printing-press, and it has for its object novel methods of giving to the photographic negatives or positives the necessary qualities to produce from them such surface printing-blocks. These qualities have usually been obtained by breaking up the continuous half-tone of the negative or positive produced in the ordinary way by photography into a series of lines, simple or crossed, dots, or grain similar to that produced by a lithographic stone, or by effects similar to net-work or gauze. From negatives or positives so produced, printing-blocks have heretofore been obtained either by making reliefs in the well-known way, and pressing such reliefs into the surface of metal, or by transferring to zinc and then etching, also by exposing negatives so produced over a sheet of zinc covered with a substance having the property of becoming insoluble by the action of light, such as bitumen, or gelatine and bichromate of potash, and after removing the soluble parts, etching the parts left bare. These processes are, and have been for some time, in ordinary use, and my invention consists in new or improved methods for the production of negatives or positives suitable for the purposes above described. In order to put my invention in operation, I procure a series of negatives or positives from such objects as fine ruled lines, netting, gauze, dots, or a print from a grained stone. I use these as "resists," from which I make in the ordinary way what is well-known as a carbon transparency, and I transfer the same by the ordinary method to the negative or positive, and by then washing away the soluble portions I give them the necessary qualities. Or sometimes I make a photo-lithographic transfer, and I transfer the same to the negative or positive, and if sufficient density is not obtained, I dust bronze or other opaque powders over the image, so increasing it in force.

In another method which I sometimes adopt, by means of what is known as the dusting process, I coat a sheet of glass with a compound of gelatine or albumen, grape, sugar, and bichromate of potash, and after exposure under a negative or positive I sift over it suitable granular powders, or the material used for flocking paper, thus producing a grain negative or positive suitable for the purposes already described ; or I coat a negative or positive with the same solution, and I treat it in the same way as the plain glass. Or sometimes, by means of what is well-known as the Woodbury process, I make a relief image from the combination of the negative or positive and any of the various resists mentioned, and by rolling or other convenient pressure I make a reverse relief of the same in a sheet of enamelled or glazed cardboard ; this image I ink over carefully with an ink roller, and I transfer in the ordinary way the image so produced to zinc for etching, or to stone for lithographing. Or sometimes I take a gelatine relief developed on glass by the Woodbury process in the usual way, and having warmed the relief, I pour over it melted wax, paraffin, or similar suitable material, and on this I lay a sheet of plate-glass, previously greased and warmed, and after squeezing out the superfluous wax I allow it to cool. When set I detach the glass, leaving a smooth and even surface of wax, filling up the hollows of the relief. Over the surface so prepared I pass backward and forward a fine flexible and elastic V-shaped tool in the same way as in an ordinary planing machine, the tool cutting deeper or shallower lines according to the depth of the wax ; the same operation is then performed in a transverse direction, giving a series of cross lines varying in depth and thickness, and from this I take an electrotype, from which I take a second one, which forms the printing matrix.

1908. Henry Rafter, Artist, 1, Kingswood Place, Dacre Park, Lee, Kent, for "Improvements in obtaining relief printing surfaces." Dated 22nd January, 1884.

The principle of this invention, the prior conception of which I claim, consists in combining "process" for relief printing surfaces with "wood engraving." In the first place the surface of an ordinary wood block, metal plate, or other suitable surface, undergoes a preliminary engraving either by machinery or hand, whereby it receives certain "tints or grounds" required for a proposed drawing or work of art. After the surface of the block has been thus treated, the object of the process for relief printing surfaces is to raise up and create in these furrows and cavities, left by the preliminary engraving, certain matter, substance, or material, which, being artistically disposed, and distributed, over the block, will, in conjunction with the said "tints and grounds," represent in "proofing" the outlines, shadows, and general features of the drawing or work of art. The "lights, clearing, and cleaning," are then executed by engraving. I make use in part, of the process already patented in the two following expired Patents, as a factor in the practicability of my invention.

A.D. 1860, 21st Sept., No. 2309. An improved mode of producing relief printing surfaces.

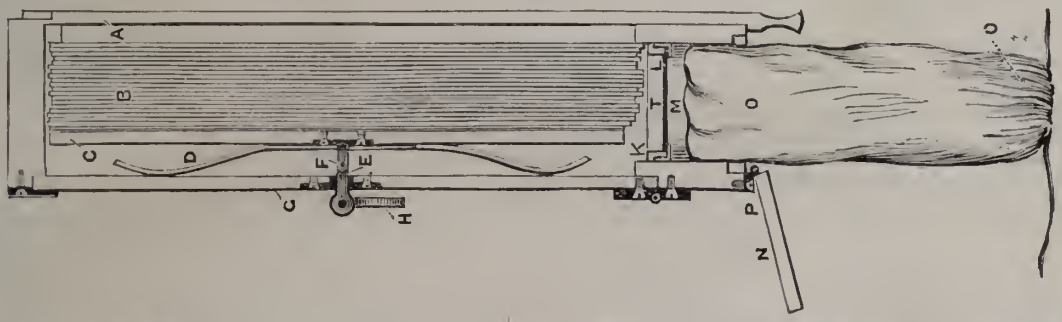
A.D. 1864, 15th Sept., No. 6041. Producing relief printing surfaces. The furrows or cavities already mentioned as being left between the ridges, or reliefs, by the preliminary engraving of the "tints and grounds" are filled, under pressure, with a material, such as pulverized chalk, oxide of zinc, &c., which is forced into an exact level with the top of these ridges or reliefs, producing a "prepared surface" apparently similar with the original surface of the block, uniform and polished. This "prepared surface" is then ready to receive the "artistic work," which will principally consist of the outlines, shadows, and general features of the drawing or work of art as distinguished from the "tints and grounds." This is either drawn direct on the prepared surface, or transferred, photographed, or otherwise projected on it ; inks, or other suitable mediums being used, which, wherever applied, will harden or protect the surface of the material pressed into the cavities. The rest of the material in the cavities, not having its surface hardened or protected, can then be brushed or wiped away. Whereupon the "tints and grounds" will appear in equal relief with the "artistic work" represented by the hardened or protected parts, the "tints and grounds" terminating, or rather merged in the "artistic work" wherever the latter crosses or covers them. A thorough hardening of the material left in the cavities can now be made, with either fluid silex, wax, varnish, or any suitable medium. If the "artistic work" is executed by "etching," intaglio engraving, photo-lithography, photo-zincography, or similar methods, it is necessary to procure an impression of the same in transfer ink on transfer paper, then coat the impression with an adhesive medium, and lay it on the

"prepared surface" under pressure until the adhesive medium has dried. Damp and remove the transfer paper, leaving the impression in transfer ink on the "prepared surface;" this ink will protect those parts that are not to be removed in the subsequent brushing or wiping. In this last operation the "material" will require damping. By means of the well-known effect of light acting on a film of gelatine sensitized by bichromate of potash, I spread a sensitized film of gelatine on the "prepared surface," and exposing it under a negative obtained from the "artistic work," I retain the parts acted on by the light, by brushing away after damping the film, and "material" unacted on, thereby leaving the "artistic" work in equal relief with the "tints and grounds."

5353. Heinrich Kayser, Doctor of Philosophy and Lecturer at the University in Berlin, of No. 16A, Neue Wilhelm Strasse, in the city of Berlin and German Empire, for "Improvements in photographic exchange boxes with sleeve for preventing the penetration of light to the plates."—Dated 24th March, 1884.—Complete specification.

My invention relates to the construction of photographic exchange boxes, the object of which is to permit the removal of the exposed plates, and to bring a fresh plate in its place in full daylight, without being compelled, as heretofore, to slide the box or case into a second case, in order to be able to effect the said manipulation; *id. est*, the exchange of a fresh plate for the exposed plate. By employing my construction of exchange boxes, I am able to exchange a series of 12 to 15 plates, when glass plates are employed, and expose them consecutively. The front or foremost plate lies just behind the slide in suitable position for exposing, and is, after being exposed, withdrawn and placed behind the other plates which have not been exposed. For this purpose, one end of the box or case is made to act as a door, so that the exchange can be readily effected by inserting the hand; as, however, the plates must be entirely withdrawn from the box or case, and it is necessary to exclude the light, I employ a sleeve of suitable material capable of excluding the light, which is slid or pushed over the arm of the operator. A suitably arranged spring or springs, presses or press against the moveable partition or false bottom of the box or case, and hold the series of plates firmly against each other when the outer or foremost plate is to be exposed, whereas a device is provided so that the pressure of the spring can be removed, and so that the plates rest loosely against each other and can be readily exchanged.

The accompanying drawings represent my improved exchange box or case in section. A is the slide for closing the box or case behind which the plates B, which are to be exposed, are arranged so that they rest against the frame of the box or case. The single plates are separated by an intermediate layer of black or other paper through which the light cannot penetrate, which said layer is loosely attached to the back of each plate. The plates B are continuously pressed against the bearing surface of the frame by means of a suitable spring acting on the moveable or false bottom, so that the front or foremost plate is kept in focus. I represents the side of the box or case which is formed to act as a door; which said door lies snugly against the two ledges or rails K and L, and is moveably connected with the box or case by means of a piece or strip of canvas, leather, or other suitable material, which is glued or otherwise attached to the box or case frame, and clamped tight by means of the ledge K or a suitable joint; hinge or hinges can be employed to the like purpose. The ledges K L serve also to hold the sleeve O of suitable fabric which will exclude the light, which said sleeve can be folded up and carried in the space M of the box or case between the door I and the outer door N to the exchange box or case, which said door is provided with suitable hinge or hinges, I. The requisite play for enabling the plates to be readily exchanged is attained by drawing back the false bottom or partition C towards the bottom of the said box or case, thereby compressing the spring or springs D, which can be effected by connecting a rod or spindle E to the false bottom C, which said rod E is provided with a suitable knuckle or other joint F, and reaches through the bottom G of the box or case. The outer end of the rod E is provided with a ring H, so that by pulling this ring outwards, the joint F is drawn to the outside of the box or case, the spring D compressed, and space or play for the exchange of the plates in the said exchange box attained, whereby the false bottom C can be retained in the position mentioned above by simply giving the outer end of the rod E a partial revolution of 45° around the knuckle or other joint, so that the said outer end of the rod E lies flush, or about flush, with the bottom or back of the box or case. As soon as the exchange of plates has been effected, the rod E is returned to its original straight position by means of the ring H, whereupon the plates are again firmly compressed by the intervention of the false bottom C and the spring D. My improved exchange box or case for photographic plates possesses, in comparison with the ordinary exchange boxes, not only the advantage of the enormous reduction in weight, but also of being able to employ plates of various sizes, for which purpose it is only necessary to insert a suitable adjustable or readily removable ledge to lessen the length or width of the said box or case, but so as to leave the space next the door, I, free. My said improved box or case can be employed for the ordinary dry plates, but is specially adapted for dry plates in which the emulsion is not attached to glass, but to a thin flexible plate of suitable material such as have already been the subject of various patents.



The photographic exchange box as shown in the accompanying drawing can contain about 50 of such said flexible plates, and when such said plates are about 18 centimetres wide and 24 centimetres long, weighs, inclusive of the plates, only about 4 lbs. The back or bottom of the case is also provided with suitable hinges to facilitate the introduction of the plates into the box.

Having now described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is—

1. The construction of a photographic exchange box or case in which the plates can be changed in full daylight by employing a suitable sleeve O of a fabric which will not permit the light to penetrate the same, thus rendering the employment of an extra case unnecessary, whereby the said box or case consists of the bottom or back G arranged to open on suitable hinges, the slide A, the moveable or false bottom or partition C, which said false bottom, and with it the plates, are pressed forward by means of a suitable spring or springs D, so that the plate to be exposed is pressed snugly against its seat in the frame, and of the door, I, formed in the one end or side of the said box or case, substantially as described and shown in the accompanying drawings.

2. The moveable false bottom C is provided with a rod E, which said rod has a knuckle or other joint F at about the centre of its length, and a ring A or its equivalent at the outer end, so that when the ring H to the said rod is pulled outwards, the rod E is drawn out through a boring in the back or bottom of the box or case, the spring or springs D is or are compressed, the false bottom drawn back, and the plates given free, so that the exchange can be made, for which purpose the rod E is turned on its knuckle or other joint F, and the false bottom held in its rear position, whereby the arm of the operator must be inserted in the said sleeve O of impenetrable material or fabric, substantially as described in foregoing specification and shown in the accompanying drawings.

3. The combination of the door N to the space at the end of the box or case to receive the said sleeve O, with the said sleeve of light-excluding fabric O and the door I to the inner space of the said box or case, substantially as described in the foregoing specification and shown in the accompanying drawings.

4. The general arrangement and construction of the parts of my improved photographic exchange box or case, substantially as and for the purpose set forth in the foregoing specification, and shown in the accompanying drawings.

CARBON PRINTING.

Lesson II.

Double Transfers upon Sawyer's Flexible Support.

For this process we shall require sensitized carbon tissue, Sawyer's patent flexible support, and waxing compound for ditto, composed of—

Yellow resin	...	...	...	6 drachms
Beeswax ...	...	...	...	2 ,,
Turpentine	...	...	...	1 pint

Also, two or three pieces of clean linen rag, a few ounces of fine gelatine, a little chrome alum, double transfer paper, in addition to the necessary negatives, printing frames, &c.

The tissue, being sensitized and dried, is cut up into the requisite sizes (remembering to have a sufficient margin outside the opening of mask upon negative, for a safe edge). Both it and negative being carefully dusted, the frames are filled and placed in the light for exposure simultaneously with the actinometer, each frame having marked upon the outside the number of tints it is judged the negative occupying it will require. Be careful that all the tints of the actinometer are equal in depth; do not let one tint be the proper depth, then the next black, and the next bronzed, else there will be no certainty of exposure, and nothing but vexation and failure can result.

The exposure being effected, the prints are withdrawn from the frames, and a piece of flexible support cut for each a trifle larger than the print, except they are carte-de-visite or cabinet size, when as many as convenient may be mounted together. This being done, each piece of flexible support must be prepared as follows:*— With a soft piece of rag moistened with the waxing compound, well saturate the glazed surface, allowing the solution to sink well in for a minute or two, then polish off with another piece of rag. Lay this piece aside, and proceed to treat the remainder of batch in the same way. Do not rub the surface too hard, but polish firmly and carefully, so as to get a highly polished surface, from which the prints will transfer to the paper with a surface very near akin to an albumenized paper print. With flexible support used for the first time, it will be as well if this operation be repeated so as to get the waxing compound well into the pores of the support; but for support that has been already used, once polishing after waxing will be sufficient.

The support being prepared, immerse a piece of support, with its attendant piece of exposed tissue, in clean cold water, slipping them in edgeways so as to avoid air-bells forming upon the surface, also examining each carefully for these, and removing them if formed.

When the tissue is first placed in the cold water it will curl a little inwards, and in a few seconds this curl will relax, and soon the tissue will lie flat, and if not removed from the water and mounted, will curl outwards, when it is spoilt; therefore, just before the soaked tissue lies flat, place the face in contact with face of flexible support, adjust in position, and remove from the water, place face upwards upon a smooth board, and, whilst the left hand is occupied in keeping the tissue in position, apply the squeegee vigorously with the right. If more than one piece of tissue is to be mounted upon a sheet of temporary support, immerse them all in the cold water at once, and after placing them *in situ* upon the flexible support (which for this purpose will be best laid upon the squeegeeing bench and well covered with water), cover the whole with a piece of American cloth, which will prevent the squeegee disturbing the prints; but when this is done, heavier pressure of the squeegee must be used than when the print is squeegeed without the intervention of the American cloth.

The tissue, being mounted upon the temporary support is allowed to rest for a few minutes, when it is immersed in water at about 100° F., and very soon the exudation of pigmented gelatine from between the backing paper and temporary support will indicate that the unaltered gelatine is yielding to the influence of the hot water, and, by inserting the finger-nail between the two papers, the backing may be stripped off and thrown away, care being taken to keep the print under the hot water during the operation of stripping off the paper backing; each print in the batch is treated in the same way, care being taken not to abrade the surface of those already stripped.

Now add a little water at about 130° F., and half-fill another dish or tank with water at 120° F., to which transfer one of the prints, and, holding it upon the surface of the water with the left hand gently lave it with hot water, when the pigmented gelatine that has not been rendered insoluble by the action of light will gradually dissolve, leaving the carbon image upon the temporary support, the development being complete as soon as the soluble pigmented gelatine ceases to flow, when the print is placed in cold water, the rest of batch being treated in the same way. As the flexible support can be used over and over again, prints that from either under-or over-exposure are useless, must not be destroyed, but with the good ones hung up to dry upon American pegs attached to a line in a position favourable to desiccation in a reasonable time; and, for the sake of economising space, instead of suspending the prints separately, they may be hung in pairs back to back.

The prints being dry, they are ready for transferring to the final support, which may be paper, opal, canvas, ivory, glass shades, vases, &c.; in fact, anything that will permit the application of a solution of gelatine and chrome alum to it without injury.

To transfer to paper, cut up some of the double transfer paper a little larger than the prints upon the temporary support, and immerse in clean cold water, taking care to see that the paper is evenly soaked. Also, in another dish of clean cold water, immerse the prints upon temporary support that it is intended to transfer.

Another dish is now filled with water at 120° F., and a piece of double transfer paper taken from the cold water and placed in it until the surface feels quite slimy; now remove the print from the cold water, and place it upon the squeegeeing bench face up. Place the slimy double transfer paper over it, slimy side in contact with the image, and apply the squeegee to the back gently but firmly, after which the print is hung up to dry; treat the rest of batch in the same way, and when all are thoroughly dry, insert the point of a paper-knife under the edges of transfer paper, when the two papers will easily separate, the image being now attached to the transfer paper, leaving the flexible support upon which it was developed quite clean, and ready after waxing for using again.

Those prints that, from errors in exposure or other causes, are valueless, are immersed in cold water, and squeegeed down upon a plate of ground glass flooded with a warm solution of gelatine 1 ounce, chrome alum 10 grains, water 10 ounces, and placed away to dry, when the flexible support may be stripped off quite clean, leaving the image upon the ground glass, which will serve as the receptacle for other failures in the same way.

If, instead of transferring the image from the temporary support to paper, it is desired to transfer to opal or canvas, the substance selected is freed from dirt and grease, and

* From Autotype Company's instructions issued with each parcel of Sawyer's Patent Flexible Support.

flooded with the above solution of gelatine and chrom alum, and after soaking the support carrying the image in cold water, place it in position, and apply the squeegee.

For transferring to ivory, before placing the print in cold water, place the ivory over it, and adjust the position, then cut the support to the size of ivory; now soak the print in cold water, then place both in the gelatine solution. Place in position, next remove from gelatine solution, and apply the squeegee, then, with a sponge, remove gelatine from back of ivory, and place between sheets of blotting-paper to dry; when dry, the support may be stripped off, leaving the image upon the ivory.

To transfer the carbon image to any object that cannot be manipulated easily—such as the panel of a door, a lady's work-box, or many other positions that may be required to decorate—this most excellent support will be found invaluable. In such a case, to the object it is desired to transfer the carbon image a solution of gelatine of double the usual strength is applied by means of a brush, and allowed to get nearly dry; the support carrying the image, previously trimmed, is soaked in tepid water, and, after placing in position, is squeegeed into contact. When dry, the support is stripped off, leaving the image behind. Any superfluous gelatine may be removed by means of a rag dipped in hot water, and if the print is in a position where it is likely to get spoiled by dust, two or three coats of a bright hard varnish will be advisable.

THE SPECTROSCOPE AND ITS RELATION TO PHOTOGRAPHY.

BY C. RAY WOODS.

VIII.—The Illumination of the Dark Room.

When we read that the feeble actinism of the red rays was noticed in the beginning of the present century, that the Daguerreotype was not introduced till 1839, and the Calotype of Fox Talbot till 1841, it is somewhat singular to find that developing by a light sifted through coloured glass does not seem to have been introduced till Claudet made it the subject of a patent in 1844. Whether early photographers performed their operations in darkness, or in a very feeble light, we are left to guess; but this much is certain, that the system that has been in vogue since the time of Claudet was delayed for some years through a disregard of facts which physicists had drawn attention to over forty years before. At that time the spectroscope in its present state was unknown; but that did not deter early experimenters in compounds sensitive to light from testing the power of different rays with the rougher apparatus at their command—the simple prism and hole in the shutter of Newton. Wollaston also tried the effect of coloured glasses, and Becquerel recommended that such coloured glasses should first be examined by the spectroscope, before the date of Claudet's patent. Since Becquerel's time the spectroscope has played an important part in the investigation of this subject, and it can readily be shown that the spectroscopic test, if properly carried out, is one that can safely be relied on, and, in its very simplicity, is superior to the somewhat haphazard methods more frequently adopted.

There are three things to be taken into consideration in the investigation of this subject:—First, the action of the spectrum on the sensitive compound used; second, the absorption of the glass and the illuminating effect of the light which passes through the absorbing medium; third, the comparative comfort—or, rather, the comparative lack of discomfort—of the light passing through the absorptive medium, this last-named consideration being mainly one of individual choice.

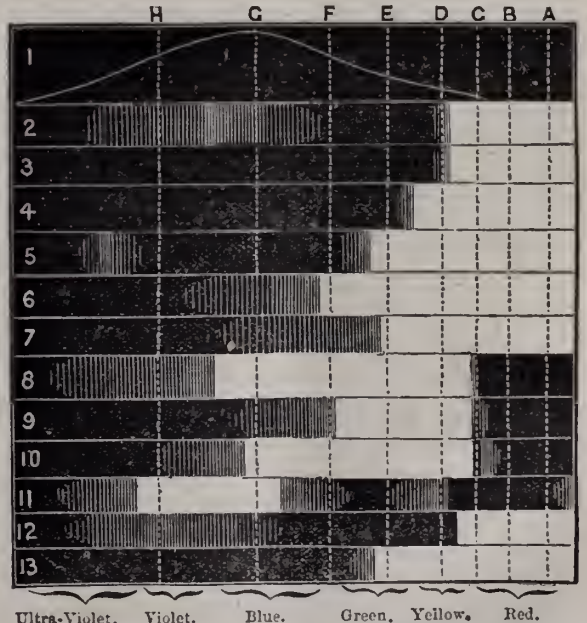
In considering the first of these, we are practically limited to one thing—the action of the spectrum on bromide of silver in its normal physical state, omitting, therefore, the state of bromide of silver when prepared in collodion by Captain Abney's process for photographing the red end. As iodide of silver, and a mixture of bromide and iodide of silver, are barely as sensitive to the visible rays of low refrangibility as pure bromide is, it follows that a light suitable for working bromide of silver in, is also suitable for the manipulation of plates containing iodide.

Bromide of silver, as has already been shown, is most sensitive in the blue rays, and it is absolutely necessary, therefore, that all rays in the blue and above the blue should be discarded for dark-room illuminating purposes. Below F, which is near the lower end of the light blue, the spectrum shows a marked decrease in its action on silver bromide. From F down to E the decrease is still more marked; and from E down to the red the action of the spectrum decreases at a regular rate. How low down in the spectrum any action is produced, depends mainly on the rapidity of the emulsion and the length of exposure.

This brings us to the second consideration. It is pretty obvious that the medium we use should not let through any rays above E; we are limited, that is to say, to that part of the spectrum from the yellow green downwards. Moreover, but for the high illuminating power of the yellow, and the fair illuminating power of the yellow-green, giving a comparatively large amount of illumination in proportion to its reducing power, our choice would lie within still narrower limits.

What medium, then, best fulfils the required conditions? In considering this, it will be well to look at the method of testing adopted by the spectroscopist, as a consideration of his *modus operandi* should silence some of the loose talk one is still apt to hear in photographic circles as to the supposed discrepancies between spectroscopic evidence and ordinary practice.

In the first place, one has recourse to an eye observation. Allowing a beam of light to pass through the instrument, the medium to be tested is placed in front of the slit, and its absorption noted. This is but the first rough test, however. The medium may let through some



1. Curve showing action of spectrum on bromide of silver. 2. Absorption of ruby glass. 3. Three thicknesses of ruby glass. 4. Stained red glass. 5. Orange glass, a lighter form of stained red. 6. Yellow glass. 7. Amber glass. 8. Signal green. 9. Yellow green. 10. Cathedral green. 11. Cobalt glass. 12. Magenta dye. 13. Aurine.

ultra-violet rays, which, being invisible, would escape detection by the eye, as in one important medium that may be instanced. It is necessary, therefore, that a photograph should be taken in the spectroscope; such a photo-

graph will not only show what portions of the spectrum the particular medium lets through, but will also give the relative reducing effect of the light which passes, showing, therefore, in addition, what rays may still be advantageously dispensed with. It is found that there is no part of the spectrum which produces absolutely no effect if the exposure be sufficiently prolonged, and the problem to be solved, therefore, may be briefly stated in the five words, "maximum light with maximum safety."

The foregoing diagram indicates roughly the absorption spectra of various transparent media.

It will be noticed that a single thickness of ruby glass cuts off the greater part of the spectrum above and including the yellow, but it also allows some blue and violet rays to pass through; in quantity this blue and violet is small, but it has a considerable effect upon the plate. There is, of course, some slight amount of general absorption in the red which cannot readily be represented in a diagram. If two thicknesses of ruby glass be taken, the amount of blue and violet light which passes is very small, and with three thicknesses it practically disappears. With each additional thickness of glass the general absorption in the red is also increased, so that three thicknesses of ruby appears considerably darker than one, but the additional safety is greater in proportion to the loss of light. Next, we have stained red, a glass recommended by Captain Abney, the particular kind he uses being stained a deep red on one side and yellow on the other. Lighter tints in stained red are also to be met with, one of the best orange glasses being of this character. When examined by the eye through a spectroscope, it appears almost as safe as the darker stained red, but a photograph shows that it lets through a small amount of ultra-violet rays at or about the same place as the rays which find their way through a thin film of silver. Yellow glass lets through blue rays in addition to green, yellow, and red; the amount of blue and green which passes varying considerably with the depth of the yellow stain. A glass that was used very frequently in wet plate days is amber, sometimes erroneously called orange. Even when deeply coloured, amber glass allows a certain amount of blue to pass, and its general absorption is very considerable, so that when sufficiently thick to ensure moderate safety, its illuminating effect is weak compared with other media. The absorption of the two most important greens, signal green—which is almost a blue—and yellow green, are shown in 8 and 9. In No. 10 we have the absorption of a slightly tinted glass, commonly used for the windows of ecclesiastical edifices, and generally known in the trade as "cathedral green." This glass varies considerably in tint, and the makers will only guarantee a particular shade when very large quantities are required; the diagram, therefore, cannot be taken as representing the absorption of all glass sold under the name. By itself it is practically useless for photographic purposes, and was introduced by Mr. Debenham for use with other media, to cut off the lower part of the red in the spectrum. In No. 11 we have the absorption of cobalt glass, the red between A and B, and most of the blue and violet, passing through with but little absorption. In 12 and 13 the absorption of magenta and aurine dyes are given. The first named allows all the red and orange and some of the blue and violet to pass, the latter giving a passage only to rays less refrangible than the blue. The two combined furnish a good medium when dissolved in varnish.

Stained red, letting through only the red, orange, yellow, and a little yellow green, approaches, if it does not actually reach, the ideal which spectroscopic experiment and ordinary practice proclaim as the most suitable medium. Careful experiments carried out in accordance with usual methods of manipulation, details of which would be out of place in these articles, show that it gives the maximum amount of illumination with maximum amount of safety. Modifications may, however, be conveniently introduced to suit the eyesight of the manipulator. Those to whose eyes yellow light is irritating may with advantage introduce a thickness of ruby, and thus work only with red and orange light. Those who dislike red light may cut off a great deal of it with a sheet of cathedral green, but at the same time they also sacrifice a small amount of the yellow as well, and weaken the illuminating power of the light in much greater proportion than they increase its safety. The illuminating effect of the light passing through good stained red bears a much greater ratio to its effect upon the plate than does a combination of stained red with either ruby or cathedral green. Those who can see well with rays of low refrangibility will find a good combination in stained red and cobalt glass, and will be using that portion of the visible spectrum which possesses the least reducing power.

So far, we have simply been considering the absorption of transparent media, but it is usually found convenient to diffuse the light by some translucent substance, such as thin tissue paper or ground glass. This will be found preferable to using the fabrics and papers which have been recommended from time to time, inasmuch as they derive a considerable amount of what safety they possess from their general absorption along the whole spectrum. This is particularly the case with canary medium. Of all the media of this character which have been proposed, the best by far is the common orange paper, frequently used for packing plates. The illuminating power of the light which passes through it is very considerable, compared with its action on a gelatino-bromide plate.

Correspondence.

NEW COATING MACHINE.

Dear Sir,—In answer to a letter from "Anxious," which appeared in your last issue, I do not know that any explanation is necessary for the non-appearance of the coating machine.

The facts are these. The engineer who has charge of the manufacture of the machine met with an accident, which incapacitated him for some time.

I have seen Mr. Oakley (the maker), who is justified in claiming a share in the honour of producing the machine.

I may say that, as far as my experience goes, the machine leaves nothing to be desired, and its appearance cannot be much longer delayed.

I am now working on a glass-cleaning machine, which I hope to bring out shortly.

I see no reason why a machine should not be constructed that will clean, coat, rack, and perhaps pack, in one operation.—I am, yours respectfully,

A. L. Henderson.

THE NETWORK METHOD OF PRODUCING GRAINED NEGATIVES.

Sir,—Can you find me room in your valuable journal for a few facts anent Messrs. Brown, Barnes, and Bell's Photo-litho Process, No. 4705, which appears in last week's "Patent Intelligence?" In their second method they claim the invention of using grained surfaces in front of the sensitive plate. Now, every observant reader of the News for the past few years must know the process—the only difficulty being in getting a proper grain. Now, I have been working the process for the last three years, and can bring forward photographers who have taken me negatives (samples of which I have sent you) repeatedly, and there is no doubt but what many more have tried the same thing.—I am, yours truly, S. C. Riley.

[The method referred to is very well known. It is remarkable that any fresh patent claims should be made respecting it. Mr. Riley's negatives are the best of the kind we have seen.—Ed. P.N.]

Proceedings of Societies.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

A MEETING of this Society was held on Thursday, the 15th inst., Mr. F. W. HART, F.C.S., in the chair.

The CHAIRMAN said there was a sad duty for him to perform, which was to announce the death of their esteemed member Mr. H. Baden Pritchard. They all knew what a great worker he was in photography, especially in the literary part of it. All felt they had lost a friend; all felt sorry to hear he passed away from them so suddenly and at such an early age. After reading an extract from a daily paper in reference to this sad loss, he concluded by moving that the Secretary be empowered to send a letter of condolence to the widow and family, expressing the Society's deepest sympathy in the loss of so genial and clever a man. Carried by acclamation.

The SECRETARY read a communication from Mr. Beach, of the *Scientific American*, in reference to the Amateur Photographic Association recently started in New York, mentioning that they would be happy to hold correspondence with this Society. After some discussion it was arranged that the Secretary should write for further particulars.

Mr. W. M. ASHMAN enquired if any one had tried the samples of golden fabric he distributed at the meeting held on the 24 ult. ?

Mr. A. COWAN said Mr. Mackie had tested it by prolonging the development with only one thickness placed round a candle, and found no injurious effect from this light.

Mr. A. L. HENDERSON passed round a metal plate-box made with double grooves to contain one dozen half-plates. He enquired if any one had used tinned iron plate for plate-boxes, and, if so, had they found them injurious ?

Mr. W. E. DEBENHAM said it was stated at another Society that spots were caused by the use of metal cases. He would suggest bent grooves instead of square, as being easier to make, and occupying less room.

Mr. A. COWAN preferred the metal folded, as soldering could be done much easier.

Mr. W. M. AYRES suggested making the grooves of zinc, and in one piece.

Mr. W. M. ASHMAN found that minute particles of metal falling from a rusty nail or stove on to a wet gelatine negative would produce a black spot; he saw no reason why the particles caused by friction in these grooves should not do the same.

Mr. HENDERSON had observed the metallic particles on the surface of plates stored in these boxes.

The CHAIRMAN thought the chances of spots from this source remote, if the plates were brushed before developing; or a better plan would be to pass them over a pad of chamois leather.

Mr. HENDERSON, speaking on spots, said he remembered a case where grey rubber tubing used for washing an emulsion caused spots; on replacing it with red rubber, the evil ceased.

The CHAIRMAN said the same thing might happen with red rubber if a cheap tubing were employed. Those samples which had particles of dust adhering to them should be abandoned.

The following question from the box was then discussed:—"Why do negatives made from boiled emulsion fix out more than those made by the ammonia process?"

Messrs. COWAN and DEBENHAM questioned if there was any difference.

Mr. HENDERSON found three degrees were lost in the case of plates recently tried, and his remarks applied to boiled emulsions generally.

Mr. W. H. PRESTWICH said if this was proved to be the case, the difference must be due to the action of the developer and the greater permeability of an ammonia emulsion film.

Mr. DEBENHAM suspected a difference in the quantities of iodide used in making these emulsions.

Mr. COWAN called attention to a plate which had been divided into halves and exposed in the sensitometer; one half receiving three exposures of thirty seconds each, the other half, one exposure only. The half which received three successive exposures was not affected more than as much again as the one receiving a single exposure.

The discussion which took place became of a desultory character, several members being of opinion that sensitometers varied a good deal.

Mr. C. Ray Woods was elected a member of the Association.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

THE Board held their monthly meeting on the 7th inst. at 181, Aldersgate Street.

The minutes of the previous meeting were read and confirmed, and Mr. G. Haupt was elected a member.

This being the first meeting of the Society since the decease of the Rev. F. F. Statham, their Vice-President, a letter of condolence was forwarded to Mrs. Statham.

The next meeting will be on June 4th, at eight o'clock p.m.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES' PHOTOGRAPHIC ASSOCIATION.

THE last ordinary meeting of the session was held in the College of Physical Science, Newcastle-on-Tyne, on Tuesday, the 13th inst., Professor BEDSON, D.Sc., occupying the chair. Messrs. W. C. Fletcher, P. Hall, and A. D. Fisher were elected members.

Professor HERSCHEL, M.A., &c., then delivered a lecture on "The History and Results of Improvements in Photographic Lenses," which was followed with close interest by a good muster of members. Professor Herschel related particulars of the first aërial telescopes of long focus, and explained the principles of correction of chromatic aberration of single lenses by which Hall and Dollond, at the middle of the last century, and Dr. Blair, produced compound objectives of two-feet focus equal in magnifying power to the single lenses of 60- to 120-feet focus made and used by Huyghens. The non-agreement of the focus of red rays with that of blue rays in a single lens was illustrated with the lime light, as well as the different positions in the same lens of the foci, towards which it collected rays passing through it respectively near its centre and near its margin. The removal of this second defect, or spherical aberration of objective lenses, is connected with the subject of increasing the angle and flatness of field, and of lessening distortion of the image in modern combinations of photographic lenses. As it embraced a much wider class of corrections than that performed by methods of achromatising, further explanations of it were reserved; and, if another opportunity for describing them should occur, it would form the subject for a future lecture.

The CHAIRMAN proposed, and Mr. J. P. GIBSON seconded, a vote of thanks to Professor Herschel, which was carried.

Six photographic prints, size 18 by 16 downwards, were then balloted for and duly handed over to the successful members. These pictures were given by Mr. Ed. Goold and Mr. P. M. Laws. The former gentleman also presented a few to the Society.

Mr. WM. RIDLEY was appointed Curator to the Society's album and portfolio, in place of Mr. Kemmish, resigned.

The Hon. SECRETARY showed an universal camera having revolving bellows and great length, the half-plate size extending to sixteen inches, and very light and portable; also, two of Guerry's pneumatic shutters (sent by Messrs. Proctor and Sons, of Newcastle). These were examined with much interest by members, and attracted general approval.

The meeting was then adjourned.

Talk in the Studio.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The next meeting of this Society will take place at the Gallery, 5A, Pall Mall East, on Tuesday next, May 27th, at eight o'clock.

CITY AND GUILDS OF LONDON INSTITUTE OF TECHNICAL EDUCATION.—The following notice has been issued to those who entered their names for the forthcoming examination in photography:—"I have to acquaint you that the examination in photography for which you have been entered as a candidate will be held on Wednesday, the 28th instant, from 7 p.m. to 10 p.m., at the City Middle Class Schools, Cowper Street, E.C., in rear of the Finsbury Technical College. You are requested to be in the Examination Room at 6.45 p.m., after which time the doors will be closed.—I am, Sir, yours obediently, PHILIP MAGNUS, Director and Secretary."

RICE PAPER.—This is made from a plant of the ivy family, known to botanists as the *Arabia papyrafera*, a native of China, a specimen of which can be seen in the horticultural collection at Kew. In China it is said to grow seven feet high, with large terminal branches of twenty feet circumference, while, drooping

like magnificent plumes in regular form over the dark palmate leaves, are some twelve or fourteen white panicles, three feet in length. The stem seldom grows to a diameter of more than four inches, generally only about two, and forms but very little wood, but is filled with the most beautiful white pith, and it is from this the celebrated rice paper is manufactured by the Chinese.—*American Druggist.*

PHOTOGRAPHIC CLUB.—At the next meeting of this Club, on May 28, the subject for discussion will be "The Preparation of Lantern Slides." This being the last lantern night of the season, members and visitors are invited to bring slides.

To Correspondents.

*** We cannot undertake to return rejected communications.

S. FLEET.—The work is quite an elementary one, and rather treats of easy methods with which success is certain, than with the more difficult phases of the subject. As regards emulsion making, you cannot do better than to follow carefully Eder's directions for making a highly sensitive emulsion, as given on page 90 of "Modern Dry Plates." The most common sources of failure are overheating, the use of impure ammonia, or the contamination of the emulsion with such remains of previous batches as may be conveyed by the use of vessels of porous earthenware or imperfectly cleaned utensils. If you should fail, let us have full particulars of your mode of working.

F. S. L.—1. Make a hinge of vellum, taking care to glue it carefully in saw-cuts made in the wood. If you look at the action of a pianoforte you will see some vellum hinges. 2. It is not desirable to leave plates in the dark slides for longer than is absolutely necessary, as most wood gives off vapours which act more or less prejudicially.

J. M. C. G.—Although we rather think, from the appearance of the spots, that the defect is one existing in the original plates, we cannot form a decided opinion without seeing some of the negatives.

F. A.—We can hardly incur the responsibility of advising you to embark in the venture you allude to unless you have special facilities for the work; neither can we recommend you to spend much in advertising. If, however, you should advertise, you cannot do better than make your wants known through the medium of the PHOTOGRAPHIC NEWS.

SOUTH DEVON.—In our volume for 1881, on pages 45 and 231. All the back volumes may be consulted at our office.

J. S.—We do not think that there is any photographic association in your town. It is, however, probable that you might very successfully form one.

T. D.—The black deposit is gold, and a very large proportion of the precious metal is always deposited when the toning solution is kept as long as the time you mention. The only way is to restore its strength a short time before you have occasion to use it. Of course you will not waste the precipitate of metallic gold.

STUDENT.—You should obtain Captain Abney's "Instruction in Photography," as it contains very full information on all the points you refer to.

J. R. WILSON.—1. It would not be a reversed negative, but a transparency. 2. One of the best materials we know of for the purpose is the vernish sold as Crystal Paper Varnish. Take care to dry the paper very thoroughly before applying it.

C. R. B. D.—1. We have never examined this maker's apparatus sufficiently carefully to give you the information, but in similar arrangements which we have used, it has been necessary to put the eye close to the small sight-hole. 2. Adjust your camera so that some prominent object occupies the centre of the focussing screen, and then shift the view-meter until the same object is seen in the middle of the field.

S. S.—You can certainly obtain excellent pictures on 4½ by 3¼ plates with the lens you mention; of course assuming that you possess the requisite skill. Pictures of such a small size taken with a long focus lens will necessarily include only a moderate angle of view; and then there are many subjects which could not be included in the field, owing to the impracticability of removing the camera to the requisite distance.

PHOTO-PICTURE.—His present address is, we believe, either Philadelphia or Chicago; we are not sure which.

R. D. B.—1. Use a substratum: soluble glass one part, white of egg five parts, water 60 parts. 2. Cyanido of potassium will remove it. 3. We fancy you may be mistaken, as the thorough wesbing of a hardened gelatine film takes a long time.

SAM. JUTSUN.—The first article of the series appeared on page 482 of our volume for 1882, and they have been continued at intervals ever since.

PIN.—In the first place the film of gelatine is not of uniform thickness—perhaps you did not level the plate exactly; and in the second place, it appears to us that the film has become generally insoluble, possibly from exposure to the products of the combustion of coal gas. Much depends on the roller; you should use a lithographic roller in first-rate condition.

A. H.—It seems as if the newspaper reporter had misunderstood the matter.

G. E. W.—1. The process does not yield vigorous images in ordinary cases, but some variation may be made by regulating the proportion of silver in the hyposulphite solution. We have used it tolerably strong with moderate success. Dissolve four ounces of hypo in half a pint of water, then measure out two ounces of this, saturate with freshly precipitated chloride of silver, and add it to the bulk. 2. Prints produced by the ordinary carbon process might answer very well; there is no difficulty in developing them on the metal.

CAMBIA.—1. The burnishing bar should be so hot as to create a decidedly unpleasant impression when brought into contact with the back of the hand, but not hot enough to scorch the picture. 2. See page 102 of the present volume. 3. A normal iron developer will serve your purpose very well. See the Formulary on page 240 of the present volume.

AMATEUR.—Your pictures are out of focus, and appear to us underexposed. As regards the nature of the deposit, we cannot form any conjecture. Perhaps you use dirty dishes, or allow the developer to come in contact with some substance which causes a decomposition to set in.

W. H.—The articles were cheap; that is to say, if you can make any use of them. The large lens is a portrait lens, but not a very good one. Altogether, we should imagine that the things cost about £30; but if they were put up for sale at Stevens' auction rooms (the usual outlet for such goods), we do not think they would fetch much more than you gave.

S. C. RILEY.—We will write to you, and also return the negatives in a few days.

The Photographic News Registry.

Employment Wanted.

Spot. & Mounter, Recept.-Room.—Miss Smedley, 45, Gt. North-ter., Linc.
Printer & Toner.—F. K., 40, Brooksby-st., Liverpool-rd, N.
Reception-Room, Correspondent, &c.—A. J., 6, Marlbro'-st., W.
Printer, Toner, Vignetter, &c.—Carbon, *Photo. News* Office.
Printer, generally useful (age 19).—Runicles, Eton, Bucks.
Assistant Operator, Printer, Toner, &c.—Pyro, 38, Union-st., Birmingham.
Reception-Room, Mounting, Spotting.—49, Brecknock-rd.
Operator & Retoucher, German.—L. Welter, 66, Kilgrew-st., Falmouth.
Gen. Assist. (engineer).—J. W. Pateman, 60, Trent-st., Gainsboro', Linc.
Operator, wet and dry.—C. O., 25, Duke-st., Bloomsbury-sq.
General Assistant (young man, age 25).—M. D., *Photo. News* Office.
Printer and Toner.—L. Knight, 40, Brook by-st., Liverpool-rd., N.
Printer and Assistant Operator.—W. F. Dew, Jesson-st., Coventry.
Printer and Toner.—W. A., 18, St. Saviour's-ter., Bury-St.-Edmund's.
Retoucher, first-class.—H. Edwards, 11, Sharsted st., S.E.
Assistant Operator & Retoucher.—C. W., Susan's-rd., Eastbourne.
Retoucher & Reception Room.—A. D., 147, Victoria-pk.-rd., S. Hackney.
Colourist and Retoucher (lady).—F. W., 24, Fairview-ter., Salisbury.
Operator of experience.—Lux, 30, Mornington-rd., New Cross.
Assistant, to learn.—A. S., Rupert House, The Green, Tottenham.
Operator, wet or dry.—J. Ransdell, 12, George-st., Euston-rd.
Operator, Retoucher, Copyist.—F. M., *Photo. News* Office.
Reception Room, &c.—Z., 18, Cardigan-rd., Bow.
Retoucher, Spotter (lady).—Y. Z., 72, Aznhy-sq., Peckham.
General Assistant.—G. H. Barthorpe, 50, Victoria-st., Bradford.
Reception Room, &c.—Miss Ayre, 21, Dorchester-pl, Blandford-sq.
Copyist, Landscape, wet and dry.—X. Y. Z., *Photo. News* Office.
Operator, carbon and silver.—A. Hey, 71, Park-st., Aberdeen.

Employment Offered.

Gentleman of experience, for City warehouse.—H., *Photo. News* Office.
Printer, perm. to good man.—Benedetti, adjoining Peckham Station.
Coaters, (several).—J. D. England, 21, Charles-st., Notting-hill.
Operator, to take charge.—W. A. S., c/o Marion & Co., Soho-sq.
Lad, as General Assistant.—W. McLean, Hunstanton, Norfolk.
Apprentice in all branches.—Studio, 34, High-st., West End, Sittingbourne
Reception-Room & Retoucher.—Russell & Sons, 49, Brecknock-rd., N.W
Retoucher, to assist in reception room.—Artist, *Photo. News* Office.
Retoucher, male or female.—M., *Photo. News* Office.
Operator, experienced.—63, Darlington Street, Wolverhampton.
Spotter & Finisher (Lady).—63, Darlington Street, Wolverhampton.
General Assistant.—W. S. Laroche, 43, Mostyn Street, Llandudno.
Young Man, assist in print., &c.—W. S. Laroche, 43, Mostyn-st., Llandudno.
Oper. & Retouch.; Ferro. prof.—G. Threadwell, 288, Highest Stratford E.
Photographer for studio on the beach.—T. Sutcliffe, Dovercourt, Essex.
Operator & Retouch. (first-class).—Long & Co., Wellington-st., Woolwich
Reception Room, and Retouch (lady).—Artist, *Photo News* Office.
Negative Retoucher.—Williams, Talbot-pl., Darlington-st., Wolverhampton.
Tint, Spot, &c. (lady).—Williams, Talbot-pl., Darlington-st., Wolverhampton,
Operator, Retoucher, Lighting, Posing.—J. Moffat, 125, Princes-st., Edin.
Carbon Printer.—Personally at 11a, Wellington-st., Camden-town.
Operator, first-class.—F. V., 110, Southwark-pk.-rd., S.E.
Apprentice, out-door.—Mr. Dixon, 112, Albany-st., Regent's-pk.
Photo-mechanical Photography for America.—J. O., *Photo. News* Office,
Reception Room, good writer.—Turner, Barnsbury-park, N.
All-round hand, 30s.—Relph, Steam Circus, Hampstead Heath.

THE PHOTOGRAPHIC NEWS.

VOL. XXVIII. No. 1343.—*May* 30, 1884.

CONTENTS.

DIFFICULTIES ARISING FROM IMPURITIES IN COMMERCIAL BROMIDES.

AT the meeting of the Photographic Society of Great Britain held on Tuesday evening last, a conversation took place which may lead to the thorough elucidation of a matter of so much importance, that we cannot help feeling surprised that it has not been seriously considered before.

Mr. Sebastian Davis having remarked that in one case great importance had been attached to the obtaining of bromide of potassium from one particular dealer, conversation became general upon the subject of variation in the bromide, and some half-dozen persons spoke strongly in favour of what they seemed to regard as special qualities of the article. It was then suggested that the commercial bromide may—and, indeed, often does—contain traces of iodide and chloride, to say nothing of possible contamination with a small quantity of carbonate of potassium, or even bromate of potassium. Although these impurities are not likely in any way to interfere with the ordinary commercial or medicinal uses of the salt, they may, and undoubtedly do, very seriously embarrass the maker of emulsions. Indeed, one can readily understand that the use of impure bromides reduces the making of emulsion about to the level of a game of chance; but we hope that a valuable suggestion made at the time by Captain Abney may be so thoroughly carried out as to effectually clear one difficulty for the path of the emulsion maker. Captain Abney, in commenting upon the subject, suggested that a committee of the Society might be formed to deal with and report upon the question, and expressed a hope that this might be brought before the next meeting of the Council. If this is done, and Captain Abney can be induced to take an active part in the laborious investigation which will become necessary, much good must of necessity follow.

It may, at first sight, be supposed that the whole question is an easy one, and can be dealt with without much labour; but this is not by any means the case, as only those who have had most to do with the estimation of the halogens in the presence of each other—or even their detection when in small quantities—can properly understand the difficulties of the position.

It is, however, as was pointed out at the meeting, a very easy matter indeed to prepare bromide of potassium which shall be perfectly free from all traces of either chlorine or iodine; easier, indeed, than to ascertain the absolute freedom of a given sample from traces of these haloids; but either operation requires the skill of an experienced chemist. To prepare the pure bromide, the principle of fractional decomposition must be adopted, as suggested at the meeting, and we will briefly indicate how the operation may be conducted on a small scale. A known quantity of bromide of potassium or sodium is placed in a retort along with sufficient water to more or less completely dissolve it, and a reagent capable of liberating bromine is added in sufficient quantity to liberate a certain fraction of the bromine—say one-fifth.

Heat is now applied so as to cause the whole of the liberated halogen to distil over, and when this is the case the receiver is changed, suitable precautions being taken to prevent any lodging of impurity about the neck of the retort. Another portion of the reagent for liberating the haloid is now added—let us suppose enough to liberate four-fifths of the remainder, and the distillation into the fresh receiver is proceeded with; certain precautions to prevent the carrying over of solid matter from the body of the retort being of course necessary. The fraction now in the receiver will consist of bromine free from either iodine or chlorine, the former having passed over with the first distillate, while the latter will remain in the retort. From this bromine the potassium salt can be prepared by well-known methods. As regards the reagent for liberating the halogens, chlorine gas itself may be used if careful precautions are taken, as this substance sets either iodine or bromine free instantly; but in most cases a mixture of a bichromate and sulphuric acid, or of manganese peroxide, and sulphuric acid would be preferred, these being, as is well known, capable of liberating all the haloids.

It must be remembered that in nature the three halogens are invariably, or almost invariably, associated; hence it happens that notwithstanding the commercial process for separating them is virtually the method of fractional decomposition described above, it very often happens that owing to careless manipulation traces of all these haloids are present in bromides as usually sold. Some years ago we received and used large quantities of German bromine in the original packages, and we generally found traces of iodine, and nearly always a small proportion of chlorine; but we never found a large proportion of either one or the other. At the meeting of the Photographic Society mention was made of a sample of commercial bromide containing as much as a third or a fourth of its weight of chloride; but, as Captain Abney very justly observed, this must have been due to an intentional adulteration.

At the meeting referred to, Captain Abney called attention to the separation of traces of iodine from a soluble bromide by fractional precipitation with a silver salt, and this method may be of great value to the experimentalist. The bromide is dissolved in water, and a weak solution of nitrate of silver is added, a few drops at a time, and with constant agitation. The iodine is carried down with the silver; and in any ordinary case one may be certain of having thoroughly removed all traces of iodine if enough silver had been added to precipitate one-twentieth of the haloid.

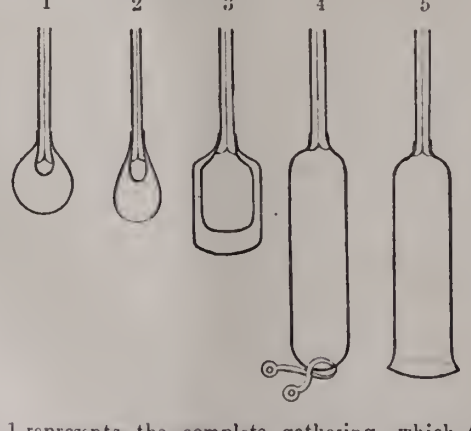
We sincerely hope that the council of the Photographic Society will appoint a committee to investigate and report upon the whole question of impure haloid salts.

GLASS.

(Eighth Article).

Very few manufacturing operations excite more curiosity than the art of glass-blowing. It is surprising with what attention spectators will follow the various manipulations of the blower and his assistants, for after listening to all the dry details of pots and furnaces, and so on, the young and the old brighten up when they are about to be shown the operation of fashioniug the crude material. Probably no article is capable of being fashioned or created from the raw into the finished article in less time than glass, and it is this fact that doubtless gives the process a touch, as it were, of the magical, and not unfrequently draws from spectators an involuntary expression of wonder and surprise.

If the reader will turn to page 226 of the last volume, he will there find a sketch of a glass furnace. Imagine the "gatherer" ascending the steps, and with his blowing-pipe he places himself about the position indicated by the iron door; then dipping the previously heated end of the pipe in the molten glass, by a twisting movement he gathers glass on the end of the pipe, much in the same manner as a cook would accumulate a mass of thick treacle about the bowl of a spoon. The "metal" is usually too thin to permit of the full quantity being gathered at one operation, therefore the workman withdraws the pipe when he has gathered a quantity equal to the size of an orange, and cools this first gathering by simple contact with the air, cooling also the pipe by pouring cold water on it. He then gathers again and again, three times generally, between each gathering cooling his pipe, and exercising care to keep the air-way open, otherwise, if the metal got into the pipe, the gathering could not be blown. In gathering for sheet-glass, almost invariably a large ring of fire clay is set to float on the top of the "metal" in each pot, and the gathering takes place from the space within the rings. The object of the rings is to prevent scum covering the surface of the pots, as it is found that as impurities rise they attach themselves to the rings and sides of the pot, leaving the centre clear and clean. It would occupy too much space to describe every detail of the operation of gathering and blowing, which would only be in place in a technical treatise, which this is not; but some notion of what takes place may be derived from a glance at the accompanying rough sketches.



No. 1 represents the complete gathering, which for a sheet of ordinary window-glass should be about the size of one of those round red Dutch cheeses we see in the shop-windows. At this stage the gatherer hands over the pipe to the blower, who forthwith proceeds to heat up the gathering—in Belgium, by holding it over the heated pot; in England, by placing it in the flame issuing from the blowing-hole of a separate furnace. The blower rests the pipe on an iron bracket, and keeping it continually turning, he stoops frequently to force his breath into the pipe, so as to elongate the gathering and enlarge the internal space, thereby getting the whole into the pear-shaped form represented by figure 2. When the gathering has been got thoroughly hot and workable, the blower leaves the furnace and proceeds to form the shoulder, shown in figure 3, getting the stuff thin near the neck, where it cools and sets, whilst the piece retains the most of the heat towards the bottom, the thicker end. By dexterously swinging the whole affair, sometimes clean over his head, sometimes holding the piece upwards over his head, and at other times swaying it to and fro, pendulum-fashion, just whether he wants it to run out quickly and take the form of figure 4, or to keep it back dumpy like figure 3, being guided always by the heat remaining in the piece, so that the ultimate form shown in figure 4 is reached. When this occurs, a boy approaches, and, with a pair of shears, he stabs a hole in the round end of the piece, and then cuts out the end or crown; the blower then re-heats, and quickly standing over the blowing-pit, holding the piece downwards, he communicates to his pipe a rotary motion whilst it is held perpendicularly, and this causes the cut-out crown to spread open and assume the form shown in figure 5. With thin glass, and especially in the Belgian works, the crown ends are burst open in the furnace by the blower stopping up the mouth end of his pipe with his hand, and holding the piece in the heat; the softened end then bursts open by the expansion of the air contained within the cylinder.

When figure 5 is reached, the blower runs down the steps and places the piece on the "cheval" or "chevalet," a wooden rest made to hold several pieces. He touches the pipe end near the shoulder with a rod of cold iron, which causes the neck to crack off and thereby release the pipe, which is then taken by a boy who knocks off the remains of the last operation, and prepares the pipe for the next gathering.

The dotted lines near the shoulder of figures 4 and 5 indicate where the neck and shoulder are removed. This operation is generally left until blowing ceases, when the blowers take a little hot metal on the end of a light iron rod in the left hand, and with a pair of tongs in the right hand they draw out a string of glass and encircle the shoulder at the dotted lines; then touching the place with a cold iron, the glass will crack, following the position of the hot string of glass, and the cap or shoulder comes off generally quite clean and neat, leaving a perfect cylinder open at both ends. This last operation accords with and is tantamount to the old experiment of encircling a bottle with a hot wire, or a string saturated with spirits, and setting fire thereto; local heat is rapidly communicated to the badly conducting material of the bottle, which, when cold water or iron is applied thereto, will usually crack in the position where the local heat had been in this manner applied.

The manner of blowing and general treatment here described is that most commonly followed; it varies in different countries and even in neighbouring works, but the general principle is the same, the minor details only varying.

The blower's duties end when he has stacked all his cylinders on end ready for the *splitter*. The journey is thus complete for that day, the blowers and gatherers collect the pipes and tools, and the furnace is again handed over to the founders and teazers, who charge the pots and fettle the furnace ready for another "found."

CARBON PRINTING.

Lesson III.

Double Transfer from Collodionized Glass.

Up to and including the exposure of the sensitive tissue, the operations are the same as for double transfer from Sawyer's

flexible support, but the temporary support upon which the print is developed is glass coated with a film of collodion.

The materials specially required are glass plates, 16 by 13, quite free from scratches; French chalk, which may be conveniently kept either in a penny pepper-box, or tied up in a piece of fine muslin; three or four clean cloths, or chamois leathers; a piece of macintosh cloth about 18 by 15; and some plain collodion made of

Methylated alcohol	1 pint
Methylated ether ·725...	1 ,,
Gun-cotton (Hopkins and Williams) ..	½ ounce

Dissolve, and allow a week to settle, then decant, or, if required at once, filter.

Preparation of the temporary support.—The edges of the 16 by 13 plates are first of all ground to prevent them cutting the fingers of the operator; they are then thoroughly cleaned with rouge and methylated spirit, and then finally dusted over with French chalk, and well polished with a clean silk duster or a clean leather. Dust the plate back and front with a broad camel-hair brush, attach a pneumatic holder, and coat with plain collodion. As soon as the film has set, immerse the plate (film uppermost) in clean cold water, where it must remain until the greasiness disappears.

Mounting the exposed tissue.—Upon a 16 by 13 plate, either twelve cartes, six cabinets, or eight promenades may be mounted at once; therefore the requisite number should be immersed in the cold water at the same time. Directly after immersion they must be examined for air-bubbles and thumb-marks, which must be at once removed by gentle friction. Now remove the collodionized plate from the water, and place as level as possible; then place the prints in position upon the plate, keeping each print from its neighbour, taking care not to disturb the collodion film, and also to get the prints in position as rapidly as possible, else some of them may absorb too much water, and refuse to lie flat.

All the prints being in position, lay the piece of macintosh cloth carefully over all (cloth side down), dip the squeegee in water, and apply vigorously to the macintosh.

The development is commenced by immersing in water at 100° F., and after the backing paper is skinned off, instead of trying to force the development by laying the water upon the prints, it is best to allow the development to proceed spontaneously, finishing off by pouring, from a small watering-can, a little hot water, so as to remove any grit, &c., that may settle upon the image; the development is complete as soon as the flow of soluble pigment ceases; then the plate must be rinsed with cold water, and placed away to dry.

When the prints are dry, carefully examine them for spots and other defects which must be removed at this stage, this being done by means of oil colours laid on with a fine sable brush.

The prints are now ready for the final transfer, for which double transfer paper is cut up into suitable sized sheets and soaked in cold water, then transferred to hot water at 120° F., until the surface is quite soft and slimy; now flood the plate containing the spotted prints with cold water, and place face up upon the bench, remove the transfer paper from the hot water, and place the surface in contact with the prints upon the glass; now apply the squeegee vigorously to the back so as to get absolute contact between the prints and the transfer paper; again place away to dry.

If the pictures were stripped off the glass directly they are dry, and afterwards mounted, they would lose most of the high glaze imparted by the collodionised surface; therefore, if it is wished to preserve this, the prints must be mounted previously to stripping from the glass. The best mountant for this purpose is made as follows:—Soak ½ pound of best glue in cold water until thoroughly soft, then dissolve in as little water as possible; when dissolved, pour into the jar of a Kent's egg-beater, and by means of beater keep the glue in a state of violent agitation while pouring into 10 ounces of methylated spirits of wine.

The transfer paper being dry, give a coat of the above glue; then cover with a piece of cartridge paper, and rub down well in contact all over; then give the back of cartridge paper a coat of glue, and allow to dry, which, in this case, must be very thorough, else the enamel glaze is sure to suffer. The whole being dry, run the point of an ivory paper-cutter round the edges of the prints, when the whole will readily come away from the glass. Now carefully trim the prints with the aid of a glass cutting shape and a sharp knife, care being taken not to abrade the enamel surface; then run a line of the glue (not too warm) round the edges of the print, and place in position upon the mount, and place under a weight to dry. The plates from which the prints are stripped merely require dusting over with French chalk and well polishing, when they will be again ready for use.

By-the-Bye.

SELF-CONSCIOUSNESS.

Self-consciousness mars nine portraits out of ten. That is to say, the fact of the model being conscious of the portrait being taken is observable in nearly every photograph, and as a result, the picture is more or less spoilt. Some people, of course, betray their consciousness more than others, and it is only the model himself who knows the full extent to which the cloven foot peeps forth. This matter of self-consciousness in photographs has, time after time, been put forth as an argument against camera portraits; and on behalf of the painter, it is urged that he never falls into the error of reproducing it. He is supposed to sit opposite the model hour after hour, and reproduce all the more winning characteristics of the face, while ignoring all such as are due to the unpleasant incidents of the sitting. Why he should not in these circumstances reflect a little boredom occasionally, as well as a bit of self-consciousness on the part of *his* model, we do not know; but we are told that his work is confined altogether to gathering all the beauty and espirit of his model, and transferring it to canvas. No doubt this is his function; unfortunately there is a wide difference between trying and succeeding, and, to judge from the portraits seen year after year on the Academy walls, it would seem that in most cases you must take the will for the deed.

In fact, it is here precisely where the public show a predilection for photographic portraits. If pictures could be painted according to the charming theory we have just expounded, which is advanced again and again by artists to prove that the photographer can never compete with the painter in producing satisfactory portraits, there would not be another word to say on behalf of the camera. Who can gainsay the painter in his wonderful professions? He seizes the smile as it hovers about the lips, the deep thought that marks the brow, the soft pensive expression straying over the eyes. All that his keen watchfulness sees, his subtle brush arrests, he would have you know; while on the other hand, the glassy eye of the camera, that stares on glowing warmth and icy coldness with equal indifference, simply reproduces the hard outlines before it. What can be more convincing than this argument, with which painters are ever ready to pulverise and utterly annihilate the poor photographer?

But where are these wonderful portraits of our painters? Granted, if you please, that there are six portrait painters at this moment in Great Britain who can do all this—though the Academy walls deny the fact year after year—what influence can these six men have? They require their hundreds, nay thousands of guineas for a portrait, and even if they only asked as many pence, the portraits they could paint would be but a very insignificant number. How are other people to fare who want their portraits? They must surely choose between the photographer and the second-class painter. So that with ninety-nine persons

out of every hundred it is not a matter at all whether a fine painting is not better than a fine photograph; this is beside the question; it is whether an ordinary photographic portrait is not better than an ordinary painted portrait—nay, if you like, whether a bad photograph is not better than a bad painting, in portraiture.

This is why people, despite the grand arguments of the painter, are content with a photograph. But then there is that grave fault—self-consciousness—to which we have alluded. No doubt; only if this is observable, as we say, in nine photographs out of ten, it is painfully apparent in every second-class painting. The vacant look, more or less rigid, and the pose, at once stiff and unnatural, are to be seen in the great majority of portraits accepted by the Royal Academy. In fact, if you took in your hand the same number of photographs issued by first-class studios, as there are portraits in an Academy exhibition, and were to pass all of them in review, we make bold to say there would be twice as many instances of "having your portrait taken" among the paintings as among the photographs.

Self-consciousness in portraiture is therefore not confined to photography; it is a fault still more common in paintings, despite the grand theorising of the painter. So that the public have come to make comparison not between the finest photograph and the finest painting, but rather between a defective photograph and a defective painting. We say defective, not in any inferior sense, but simply because both classes of portraits lack perfection. Since it is absolutely impossible for most people to get this absolute perfection in their portraits, they wisely choose the lesser of two evils, and take photography. A second-class photographic portrait may show the model in a bad light, but at any rate it is the person himself with all his individuality and identity, while the second-class painting is considered sufficiently good if it contain a "something" recognisable in the original.

While pleading guilty to the presence of self-consciousness in most photographic portraits—a defect that painters, at any rate, should be silent about, if we judge from their results rather than their professions—it must not be forgotten that the days of slow-acting films have long since past, yet the old criticisms passed on Daguerreotypes still cling to photography, albeit no model is asked now-a-days to remain quiet before the lens for two or three minutes. People still think—and some photographers among them, we are sorry to say—that it is absolutely necessary to adopt a fixed look during the pose, notwithstanding the circumstance that the duration of this is reduced to a very few seconds. Now there is just this difference between the photographer pure and simple, and the photographer who is an artist. Not content with occupying his mind with the pose, lighting, and drapery, of his model, the latter takes endless pains to get a happy—not necessarily a smiling—phase of the model's face, while the former's chief concern is all confined to the steadiness and immobility of the sitter. If the model has not moved, if he has kept his mouth steady and his eyes fixed, nothing can be more successful, thinks the matter-of-fact photographer, and hence came the old popular cry that all camera portraits were alike; they all possessed the same sort of expression. It could not well be otherwise in the days of Daguerreotypes, and even collodion in the hands of an artist failed very often to do what was wanted. But every day not only brings more artists into the ranks of photographers, but increases the power in their hands; and we trust that the time is not far distant when the artistic picture will be the rule, and the self-conscious portrait the exception.

Gelatine plates should do much to advance art-photography in portraiture. By their means the true artist has twice as many chances of success, for his tools are now so much sharper in their action. His efforts at successful lighting and posing will not be so frequently marred at the last moment by a defective expression; he is able to watch the features before him, and to choose the expression that pleases him most, whether this comes during a phase of animation, or during repose.

The main object, however, is, after all, to get rid of the look of self-consciousness. In presence of this, the most delicate and transient phases of expression—generally the most beautiful—are irretrievably lost. The photographer can do this properly in only one way, by not permitting the model to know the moment of exposure. But then the exposure must be of the briefest. With some nervous persons, even in these circumstances, it is necessary to pretend to expose once or twice before the flurry and excitement under which they labour is appeased; still, how he brings about the end is a matter that the photographer must settle for himself. We ourselves, a short time ago, sat for a portrait, without being aware of the moment when it was taken. The artist had finished lighting and posing us, and we were about to begin to feel nervous at the close proximity of the eventful moment, when we were told the expression would not do at all. And while we were in good faith trying to do something better, the artist looking on and criticising the while, we were quietly told it was all over, and that there was no necessity for nerving ourselves for the ordeal. The top of the spine had omitted its function of Rhumkorff coil in shaking the head-rest, and our expression had been seized before there was time to utter that phrase of "papa, potato, poultry, prunes, and prisms," which we have the authority of Charles Dickens for saying affords a proper setting for the mouth.

The photographic picture, if not yet perfect, is nevertheless a portrait, the value of which is so intrinsic that it will always be set before any other portrait, except, perhaps, a painting of the very first order. But it behoves photographers to strive their utmost to improve it, and this can only be done by first acknowledging its shortcomings. A rapid exposure is certainly one of the best means of encompassing the worst of these, self-consciousness, and our readers will do well in striving to minimise this defect to the utmost of their power.

FRENCH CORRESPONDENCE.

The late Mr. H. Baden Pritchard—Disputed Question of a Picture said to be Copied from a Photograph—Conference of Artists and Scientific Men on Photographic Matters — Operators' Examination — Balagny's Paper used in the Studio of the Museum of Decorative Arts.

The late Mr. H. Baden Pritchard.—I cannot take up my pen to commence this letter without expressing the deep sorrow the sudden and premature death of Mr. H. Baden Pritchard inspired. Among us in France he had many friends, who desire to convey some tribute of sympathy. He has left his example as a rich legacy behind to us, for he had the rare qualities of being both a learned and kind-hearted and amiable man, and a scientific and literary writer. On reading his works, one is struck by the diversity of his talents, as well as the facility with which he passed from one order of production to another. Those who, like myself, have personally been able to appreciate his character, and place him among the foremost of our friends, have suffered a great loss.

Picture said to be Copied from a Photograph.—A singular incident has occurred with regard to Dantan's picture in this year's *Salon*, "A Modelling Studio." The art-critic of the *Siècle*, M. Havard, on seeing the picture, was struck with its resemblance to a photograph in his possession. From that to accuse M. Dantan of having copied the said photograph was but the work of a few words in writing. "Mark well," says M. Havard, "that M. Dantan does not limit himself, like many of his colleagues, to make use of information directly acquired to assist in the working out of scanty notes. No, he borrows the whole thing at once, principal and accessories, figures, furniture, marble and

plaster groups, everything, including the effects of lighting and values; I would say also including colour. It is impossible for anyone to be a more sincere, respectful, or faithful copyist. In this respect, his *Atelier de moulage* is a prodigy. By illuminating the original photograph with skill, a more happy effect could not be obtained." The accusation thus set forth ironically is none the less grave. Indeed other journals have referred to it, and *La France* was particularly loud in exclamations of regret at this canvas being included in the purchases made by the State from the *Salon*. The Photographic Copyright Commission have found here a decisive argument in favour of their claim, and the president, M. Davanne, instantly wrote a letter, published in the *Siècle*, in which he pointed attention to the anomaly existing between the term "work of art" applied to a picture copied from a photograph, and the refusal of the term to the original photograph. He takes this pretext for drawing public attention to the necessity for the cessation of a misunderstanding in the terms of the law regulating the artistic copyright. It is there formally stated that photographic productions are excluded from participating in this law. Photographs often form the original ideas for works of art, and it is inconceivable why legally they are put aside and are victims of a law of exceptions. M. Dantan thought it well to reply without delay to M. Havard's accusation, by proving, in the presence of a jury of honour, that he had composed and executed his picture in one of M. Aviland's studios, in a manner, it is true, similar to the photograph M. Havard had had taken of the studio. It is, therefore, understood that M. Dantan executed his picture from nature. "All's well that ends well"; but it must be kept in view that an artist wishing to gain rapidity of execution may well think out his composition, group his figures and accessories, and then take a photograph which can be afterwards used for the picture. There is no crime in such a proceeding, and, from our point of view, a direct homage rendered to progress. It would be curious to say whether it was more meritorious to travel from one place to another by *diligence*, or take advantage of the rapid transit afforded by the railway. Admitting, for one moment, that M. Dantan had really used a photograph for his picture, would it have been judged as not coming under the name of work of art, and, therefore, not admissible as such to the *Salon*, or to be bought for the State collections? It only matters whether the work is beautiful. It is, if it be worthy of admiration.

Photographic Conference for Artists and Men of Science.—I said last time that the Syndicale Chambre had organized a conference on the intervention of photography in scientific and artistic work, to which scientific men and artists are to be invited. It will be a favourable occasion for defending the point which the Dantan incident gives rise to. At the conference, after indicating all round the advantages to be drawn from photography by men of science and art, the speaker will show the means of having always about one apparatus for photographic reproductions. A demonstration of experiments relating to the enlarging of negatives and projection of positives on the screen will also form part of the proceedings. The aim is to render the simplest photographic processes as popular as possible.

Operators' Examination.—The second session of operators' examination takes place on May 29th. The oral examiners are MM. Bardy, Davanne, and Léon Vidal.

Balagny Paper used at the Decorative Arts Museum Laboratory.—Since the formation of this photographic laboratory, Balagny's gelatino-bromide reversible pellicle paper has been exclusively used. I am pleased to state that it has given the best possible results, lending itself admirably to all kinds of reproduction, such as engravings, etching pictures, statuary, crystals, drapery materials, views, and monuments. The emulsion forming the sensitive film spread on the paper is very thin, giving full force of intensity without destroying the softness of the half-tints. An advantage consists in the capability of printing off from either side. It is best to mount the film on thin sheets of gelatine to give greater solidity. I do not hesitate to recommend this preparation above any other of the kind when using pocket photographic apparatus.

LEON VIDAL.

AMONG THE PHOTOGRAPHIC ARTISTS.

BY A WANDERER.

IT is questionable if there be any unfamiliar with the obtrusive designation, a "Photographic Artist." Clearly, in that part of his conformation which did duty for mind, the originator of this phraseological inspiration opined that a "photographic artist" was a species of its own, not an artist, else he would have said so, and not a photographer, or he would have spared himself the labour of writing two words when one would suffice. This is a restriction which, to be appreciated, required to be exercised; but this species of its own, this hybrid form selected without derivation or the authority of custom, once hit upon, a certain class take pride in proclaiming their absurd cognomen to the world.

There is one body of men who are *par excellence* "photographic artists," the peripatetic gentry who trudge our highways propelling a nondescript conveyance, half perambulator, half baker's barrow, and the tell-tale tripod duly strapped alongside. A certain intercourse with this genus may be desirable to discover how much, if any, of the photographer they can lay claim to, and how much of the artist in their half-and-half nomenclature appertains to them. Now professional pride may beget a repugnance to this experience, but this is a very wrong state of feeling.

But an animal is best studied in his haunts. The "photographic artist" is, according to the naturalists, an animal like the rest of us, but not so highly developed, and if he have one haunt preferable to another, it is that of the sands at Yarmouth. There are at home plenty of congenial fellowship and numerous brother workers all branded with the same trade mark, "photographic artist."

'Tis a fine beach these broad Yarmouth sands, so clean and firm to the foot, and as at high water it is never covered by the sea, the black-fingered gentry can exercise their lawful calling throughout the day, only regulated by a police order to keep all stalls in one line above high tide mark, and to pay a hebdominal two shillings in advance to the town authorities for privilege of standing.

Now underneath the pier is erected a wooden shanty, a drinking "cabin," where "photographic artists" and their attendant "touts," gipsies and shell fishmen, shrimp girls and comic singers, niggers and phrenological lecturers, chairmen, boatmen, fruit girls, and mendicants of all description, herd together in one strongly perspiring mass of struggling humanity, beer the aim of each, and elbowing, jostling, crowding, and crushing to indulge in their life's one luxury. There is little ventilation, and, what with the low roof, the seething mob of people now reinforced by a strong contingent of 'Arry's out for a 'oliday, the dense heat from the sultry July sun, the dirty faces, the still dirtier garments, the fruit, the fish, the cakes and the sweets, the combined odour is, to say the least, peculiar. Presently a few wailing discordant notes from a dulcimer out of condition break the never-ceasing monotonous hubbub of sound, while a cracked apology for a voice requests us to "Hold the fort, for He is coming." Surely that nasal twang proceeds from an old acquaintance! Was not this the individual, attired in the suit of seedy rusty black, the person who, the preceding night, was making the solitude of the sad sea waves most alarming, by aid of the wreck of a harmonium and a series of deep-throated appeals to be "saved?" Suddenly a stir is created among the "artistic" fraternity by a cry of "Joe, look to your joints!" and Joe, quickly putting himself outside the dregs of his half pint, sallies forth to a

select party of buxom girls and their swains, who are lost in admiration over a dirty frame of faded photographic specimens. Joe is a character. He might be a descendant of a wandering Hebrew with a dash of the man of the world thrown in; middle height, thin, wiry, florid in the extreme, and active to excess; endowed with a rolling eye, rather deeply set and piercing, and somewhat bloodshot; while a hirsute appendage conceals his sunken cheeks and his sensual mouth. He ambles through the crowd, and by a succession of leaps and bounds, is soon "on the track" for business. "Yes, dear ladies, you will make a charming picture, and if any man can do you justice, I can, with the quickest and the largest lens on the beach; so quick, ladies; I can scarcely open and shut her fast enough, and I am the only one who can take a *Metallika* picture by the new instantaneous process. None of the portraits here, ladies, which fade before you leave the barrow, but all taken by the last patent, which never fades. Thank you, dear ladies; this way, under the shadow of the boat, and all the whole lot for a shilling!"

Passing a variety of sweet stalls, cake stalls, try-your-weight stalls, nut stalls, fish stalls, "photographic artist" stalls, each with flag all flying, behold the gentleman who tells your bumps, sagaciously dilating on the phrenological development of Mr. Jenkins of London, Mr. J. perched aloft in a chair on a raised platform in full view of the jeering crowd, while Mrs. J., who is listening in rapt attention to this unfolding of the hidden life of her lord, is jocularly advised she has nothing to fear, for the gentleman might be trusted anywhere, so differently constituted to the last case that *he* could not go astray. Mr. Jenkins looks somewhat abashed at this proclamation of his marital fidelity, but Mrs. Jenkins regards with triumph the face of Mrs. Tomkins, wife of aforesaid last case, who was pronounced so emphatically a ladies' man. The crowd thickens, interest increases in the possibility of scandal, and the "touts" from the various "photographic artists" ply their vocation with redoubled energy.

Onwards past the happy family of cats, rats, birds, beasts, and fishes, on past the monkeys—"and you will be careful not to play with them to-day, ladies, for they are very savage"—and the centre of interest for cockneydom out for enjoyment is reached, a circular arrangement of chairs surrounding a platform on which disport themselves the comic singers. Here, in full blast of choral strains from husky throats that Clara is to come out to-night and keep her appointment on account of the brightness of the firmament, firstly attiring herself in hat and jacket, and lulling maternal solicitude by the platitude she will not be long. It is amidst the din of a noise such as this the "Professor" drives a roaring trade when not too far advanced in intoxication to hinder the performance of his work. Of course, he is a "photographic artist"; he wears a full beard, he would be too lazy to shave; he is unwashed, that is to say, his facial hue is of the same dusky tint as his fringed and rumpled collar, and what is left of the cuffs of his—possibly once white—shirt; he is a short, thick-set man, with hair of the popular ginger hue; and equally, of course, his hands look as though they had never been cleansed since a very early period of his existence. Surely, never was seen such a heterogeneous collection of broken-down cameras, mounted on diminutive and rickety tripods, as here assembled, and the visitors seem to enjoy being plagued by having these machines pointed at them, especially in the thick of the crowd. The light from the heavens is brilliant to excess, and the light reflected from the sea equally so. It is hot everywhere—dreadfully hot. It is, then, small wonder that with no shade, except that procurable from boats on the beach, the "photographic artists" turn out some rather ferocious expressions when anything like a face is visible on the plate, and when there is not a face to be seen, it is always the effect of *passing cloud*—but it will *dry* all right, believe me! The more ferocious the glance, the more the people seem to enjoy it; and the more readily the professor pockets his shillings—now from a donkey group, now from a spoony couple who fancy they are unobserved, here from a family party of a dozen of all ages, with a portly and pompous *pater* posing as the author and being of it all, and there from a group of bare-legged boys and girls engaged in the happiest of all childish occupations—that of making dirt pies in the sand.

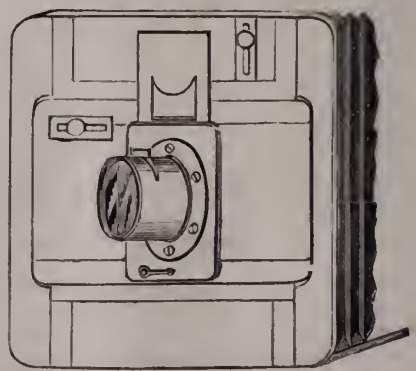
Yonder is a more pretentious arrangement, which has had the distinguished honour of being engraved among the *Graphic Sketches of Yarmouth* as a "beach studio," a sort of private omnibus converted into a dark-room for collodion work; but age and use have played havoc with it, and it seems to stand as a memento of fallen greatness, and indifferent to the rollicking life which teems around it.

Of a different class is the Australian, a short, swarthy specimen of the Colonial artist, and more than a match for his English *confrères*, with his never-ceasing chatter and quick *repartee*. "Oh yes, sir, quite ready for you; this way. Now we're busy; now we're doing the trade! You make a charming photograph, you do, sir! Half a moment, ladies—always make a beautful picture for the ladies—so clear, we can see what you've had for dinner! Here you are, sir, been waiting for you all the afternoon—beautiful light now, sir. Oh no, sir, I wouldn't tell a lie for the world—I wouldn't do it. If you've been imposed upon, perhaps it's my brother, who is just like me, and the biggest liar in all creation. Now, you little children, go home, and wash your dirty faces, and we shall give away the bread and butter at eleven o'clock to-morrow morning. This way, ladies, this way; all the work done here is for the benefit of the poor, and I'm the poorest man in the parish. This way; now we're busy. What, sir, not like you—not good-looking enough? Well, you'll never grow any prettier, believe me. Never mind, I'll nail it up on the barrow; it will do to frighten the birds away when I'm eating my dinner. Good day, sir, good-day!"

"THE SIMPLEX;" A CHEAP AND EFFECTIVE DROP SHUTTER FOR "BEHIND THE LENS."

BY W. CLEMENT WILLIAMS.

Who has not designed an instantaneous shutter? I venture to think there are few amateurs of even a slightly mechanical turn who have not done so. I have many, and confess to having wasted many an hour in seeking after a means of regulating the exposure to decimal parts of a

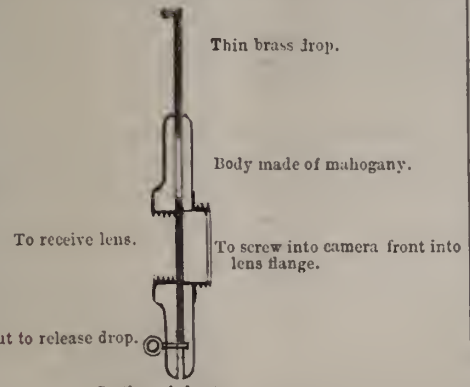


Shew's shutter screwed on to lens flange of any camera.

second, and other fine shaves; and it is astonishing what a fascinating power this hair-splitting mania has—in more matters than instantaneous shutters, however. One day, as I sat brooding over the problem, a little voice seemed to say—"It is no good whatever to regulate shutters thus finely, for no two horses can be yoked to the same cart unless they trot at the same speed, for it won't work.

First regulate the speed of the emulsion that covers the plate to a nicety, and not till then need you trouble about fine shaves in the trap that is to catch the sun-beam." And so as far as I am concerned the bubble burst.

The shutter I now rely on I have named the "Simplex," for in it I have eschewed the use of all complications; in fact, it is a simple drop-shutter, the novelty being that it works behind the lens, the advantages of which are now fully recognised. It screws into the ordinary lens flange



Section of shutter.

attached to any camera, thus obviating the necessity of alteration, and the system of adapting rings will enable its being used with any lens less than the shutter aperture. I thus use my shutter from 8½ by 6½ to 12 by 10 on different cameras, and with different lenses, the shutter being for 12 by 10. After the shutter is screwed to the camera, the lens is screwed into the shutter.

This shutter does away with the necessity of a lens cap altogether, for it is only needful to turn the shutter from the vertical to a horizontal position, to allow of any length of exposure being given, by simply sliding the drop of the shutter by hand, to open or shut, timing by the watch to suit, the cap thus being always dispensed with.

A little loose pin attached to a piece of string, piercing and crossing the slot under the drop, will hold the drop up till the moment of exposure arrives. Another hole, piercing the shutter over the lens, allows of the pin being inserted through the drop-shutter aperture when it is necessary to lower the drop for focussing, the pin thus holding it in its half-way place.

The drop is made of hardened sheet brass, so as to allow of the slot in which it slides being as thin as possible, the weight of such a drop giving ample speed for taking breaking waves and passing vessels in the foreground. There is another advantage, while on this topic, in consequence of the shutter working behind the lens. In addition to the full power of the lens being thus ensured, the drop, contrary to when working in front of the lens, uncovers the foreground or picture portion of the plate first, and so the moving object is caught and disposed of the instant the drop is released.

I have proved it to be light-tight, and a safe contrivance to have fixed permanently to the camera for all purposes, having worked it at the seaside for many days during the past summer, with the lens in the sun's eye, and the plate unprotected for long periods while waiting for a good shot. For those who would make it a permanent part of camera, no extra flanges are needful; the camera front would form the back of slot for drop to work in, and the whole projection need then only be three-eighths of an inch from camera. I had almost forgotten to say of this drop-shutter, that, coming as it does against the front of camera, wind has no effect upon it; wind is a great drawback to the use of shutters when placed in front of lens.

My shutter only cost a few shillings.

Review.

Light. By P. G. Tait, M.A. (*Edinburgh: Adam and Charles Black.*)

We have here a sound working text or class book, no attempt being made to unduly popularize the subject, and at the same time we find but little which need offer any difficulty to a person of average education.

The introductory or historical chapter interests us. After having drawn a parallel between light and sound, the author traces up the birth of the science of optics since the time when Aristotle seriously asked, "What is darkness?" The publication of Ptolemy's great work on Optics in the second century marks the first era in the exact study of the subject, and includes measurements of angles of incidence and refraction: although the trigonometrical relations between these were not discovered until a millennium and a-half had passed. Alhazen or El Hasan, who wrote his text-book in Arabic during the twelfth century, was almost the sole optical authority during a dark period of five hundred years. Alhazen founded his work on that of Ptolemy, but added a treatise on the eye. He showed how it is we see but one image with the two eyes, and pointed out how it is that we see, even the smallest object, by a pencil or bundle of diverging rays, and not, as had been supposed, by a single ray. Many points relating to astronomical optics were also elucidated by Alhazen.

The author does not treat much on points bearing very directly upon photography, but refers rather vaguely to the actinic rays as being merely vibrations too rapid to affect the eyes; and in speaking of the application of photography to the realisation of the idea of motion, through the agency of the wheel of life, refers to the photographs of the trotting horses; but does not mention the name of Mr. Muybridge, who, by his indefatigable labour, realised a substantial advance in photography as applied to science. We sought in vain for photography, photograph, or any similar word in the index.

All About Derbyshire. By Edward Bradbury. With twelve Platinotype Illustrations by Richard Keene. (*London: Simpkin, Marshall, & Co.; Derby: Keene.*)

The enterprise of Mr. Keene has given us a charming book treating of one of the most delightful districts in Great Britain. Indeed, we have already had a word or two to say regarding the work, and are pleased to now find that a fresh issue is required. The application of Platinotype printing to book illustration may be looked on as a happy one, for the soft character and cold tone of these pictures render them eminently suited for the purpose. Let us hope that we shall see no more new books illustrated with silver prints, as who can look on a faded book illustration without regretting that such an enduring reproach against photography should be stored up in so many libraries? It is, indeed, difficult to suppose that any photo-engraving or collotype method could so perfectly render the splendid effects of hazy distance in Mr. Keene's attractive picture of "Misty Morning in Ashwood Dale." "Goyt's Bridge" is a study which must be seen to be duly appreciated, the effect of the broken water streaming over the rocky bed being delightful. The "Runic Cross in Eyam Churchyard" forms a striking contrast with a wood-cut of a similar subject placed opposite to it, and suggests the hope that, in a future edition, Mr. Keene may see his way to replacing the whole of the wood-cuts by permanent photographs.

We need not discuss the literary merits of the book, although it has many; but we find that it opens with the usual lament of the English guide-book writer—that home beauties are neglected for Switzerland. This is certainly true, and will be so as long as economy is on the side of Switzerland. We have distinct recollections of the relative cost of a fortnight's holiday in Switzerland, and that of a similar time in the holiday resorts of Derbyshire.

Notes.

There are fewer actual manufacturers of gelatine plates than is ordinarily supposed, as most of those who profess and call themselves makers are merely dealers. Indeed, we could mention one provincial dry plate works which supplies no less than six professed makers. Or, to put the matter more concisely, the weaker are being ousted by the stronger; and only those who can successfully battle with unforeseen difficulties may hope to survive.

Still, we hear of a new plate works being established at Vienna, in which Plener's method is to be adopted. Herr Löwe takes the business control, while Dr. Eder acts as scientific adviser; and Mr. Plener is technical director for a time.

Is it necessary to remind our readers that Mr. Plener's method consists in separating the sensitive constituent of an emulsion by means of a centrifugal machine, and mixing it with fresh gelatine?

"Take a larger piece of bamboo and roll up the prints inside," says a correspondent who read our note of last week. "I have received prints from China which were packed in this way, and they were quite uninjured." Bad as bamboo may be when used as a roller for prints, it evidently makes an admirable protective casing.

There are, apparently, some photographers who pass their time in inspecting studios to let. A friend who has had the letting of a studio some four times in five years, has had one applicant call upon him on each occasion. The odd part is that the applicant never can remember he has seen the studio before. Four separate times has he inspected the place, and four times has he said it would not quite suit. Our friend firmly believes that if he were to advertise the same studio to-morrow, the first answer would be from this individual "on the look out," to use his own words, "for a studio."

Few spectroscopists would now think of relying on the eye for recording and mapping out lines, the work being done so much better and more rapidly by the camera.

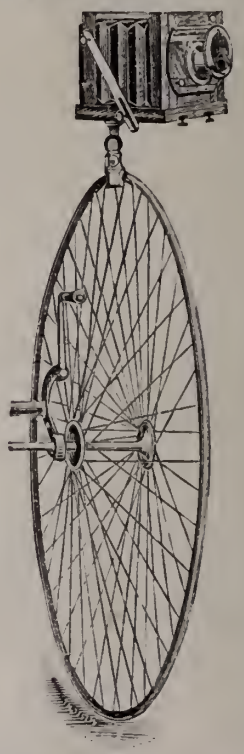
The recent researches of Liveing and Dewar illustrate the value of this application of the camera. When an explosive mixture of oxygen and hydrogen is fired in a close vessel, the flash usually gives a spectrum corresponding to the material of the vessel used, and in the case of an iron vessel with a quartz window, no less than sixty iron lines were recorded on the sensitive plate.

The photographer who makes his own chloride of gold will no longer dissolve half sovereigns if the proposed nine shilling token take the place of the coin; but a more serious fraud on the revenue would be the manufacture of the nine shilling token, a branch of industry which might be carried on in any photo-experimentalist's laboratory.

A small Fletcher's gas furnace, a pair of jeweller's rolls, apparatus for electrotyping in iron or nickel, and the smallest size hydraulic press, would comprise all the plant required for making both the dies and tokens.

It is remarkable that the "precious" metals, gold, silver, and platinum, should be so essential to the photographer, and it is interesting to note that a rich mine of the latter metal has been discovered in the Thames gold district of New Zealand. The metal is exceptionally pure, and crystallized in octahedra.

One may look upon the tripod stand as the most unmanageable article with which the photo-tricyclist is encumbered, but no tripod need be taken if a suitable clip is used to attach the camera to one of the large wheels. Messrs. Lancaster and Son, of Birmingham, send us the subjoined sketch, and we can readily believe that such a clamp



as is represented, may be very useful to others besides photo-cyclists, as the clips may be fixed to a fence, chair, or even the window-frame of a carriage. Indeed, it may be used under many circumstances when a tripod would be out of the question.

The idea of establishing a scientific society requiring a capital expenditure of £10,000, and an income of not less than £1,500 per annum, is an original one; but the curious part about the prospectus of the "Marine Biological Association of the United Kingdom" is the lavish manner in which the honours of the Society are to be conferred upon those who subscribe liberally. A donor of £500 or upwards is to be a governor and permanent member of the Council, while one giving £100 becomes a founder or member for

life. To give £1 1s. per annum merely constitutes one an "Annual Subscrib r." Mr. Frank Crisp is treasurer, and the office is at Burlington House.

The idea of organizing a naturalist's exchange post, now under discussion in Canada, is worthy of serious consideration, and it is suggested that the scheme might even extend to the whole of the postal union.

Careless packing of negatives having led to a regulation forbidding the sending of glass by letter or book-post, it will doubtless be found that the authorities hesitate to encourage the sending of parcels which may contain noxious insects, snakes, or bottles with pond-life specimens.

Notwithstanding the regulations, many negatives are sent to us by post. When merely placed between mill-boards or thin slabs of wood, they are almost invariably broken; but when a negative is sent in a box about an inch deep, and is well packed with bran or saw-dust, an accident is rare.

A regenerative burner for gas, which gives about four times as much light as when the gas is burned in the usual way, has been invented by Mr. Wenham. The advantage on the score of economy is obvious, but as less gas is burned, the total heating effect is proportionally diminished.

A firm in Chicago announces their intention of conducting their business in a different way from that of most other galleries. They intend to furnish finished proofs, and not ask any payment until the sitter is first satisfied with the proofs. The *Chicago Eye* considers this will "cause them lots of trouble and loss of money." Highly probable.

The magnesium light for portraiture may be regarded as one of the best artificial lights to use, as the apparatus required is of the cheapest description. No difficulty is likely to occur in working by the method described on page 347, except from a possible accumulation of fumes in the apartment. Of course the burning of the magnesium should be performed as near the fire-place as practicable, and a good fire materially assists by creating a strong draught.

The high price of magnesium shows no sign of reduction, as the price of the wire has been twelve shillings an ounce for over fifteen years; but the dust can be had for seven shillings. Chemists have often promised us cheap magnesium and cheap aluminium, but the promises have come to nothing.

The secretary of the Illinois Photographic Association has a pleasant way of putting matters. According to an American journal he "informs Mr. Ferguson, and *all fools like him*, that no notice of his communication or others of same tenor will be noticed or read to the Society." Neat, if not complimentary.

How best to manipulate the pyro, is a question often asked. This is what Mr. England says:—"Dissolve one ounce in four ounces of *absolute* alcohol, and measure the solution out with a dropping tube. Many fail with alcoholic solution because they use ordinary spirit; but if the alcohol is absolute, the preparation will keep well."

When half-plates are ordered, glasses $6\frac{1}{2}$ by $4\frac{3}{4}$ are generally meant; but it not unfrequently happens that the old or legitimate half-plate ($6\frac{1}{2}$ by $4\frac{1}{4}$) is required. Much trouble and difficulty might be obviated by calling the smaller size simply "half-plate" rather than "double quarter" or "semi-whole," and the designation, "extra half-plate," would clearly indicate the $6\frac{1}{2}$ by $4\frac{3}{4}$ plate.

Let us give an instance of the desirability of a uniform rule. A. orders a gross of half-plates, and the extra half plate is sent as being the size more ordinarily asked for; but as A. required the legitimate half-plate, he proceeded to cut down the plates, and in doing so fogged them. He, however, was unaware of this, and made a claim on account of bad plates, but as part of the outline of the cutting-guide was impressed on each, it became evident that A. was at fault. He therefore lost his plates, and had to pay the expense of an arbitration.

The other day Mr. Cobb showed us the camera-stand he used for his celebrated pictures of London taken from the top of an omnibus. It consists of a kind of table-top, one edge of which is strapped to the edge of the omnibus rail, while a single leg, adjustable as to length, serves to steady it. The table-top consists of three thicknesses of wood, so as to allow of a rotary movement on a central pin, and a hinge action of the upper board.

Enlargements upon canvas to serve as a basis for portrait-painting are sometimes objected to by the artist, because of the dark outlines printed by photography. A painter is used to black outlines, it is true, but these are made by charcoal, which are easily removed where unnecessary. But the lines printed by photography cannot thus be removed, at any rate without difficulty, and sometimes they are not easy to cover up by pigments. In these circumstances, it is not strange to find that in Paris there are painters who prefer to sketch the photographic outline themselves in charcoal, throwing a lantern enlargement from a small cliché upon their canvas.

The plan has the two-fold advantage that you do not sketch in any photographic trait that the artist thinks is best left out, while, again, the canvas has not undergone any process, and its surface is that which the painter prefers. A good paraffin lantern gives plenty of light for the purpose, and the painter has simply to darken his studio whenever he desires to study his photograph. The plan

may be in use by our English portrait painters, but we have not heard of the fact.

The demand for glass transparencies for the stereoscope is not so great as it was. The charming productions of Breese and of Ferrier et Soulier, costly as they were, found many purchasers. But they are seldom seen now, like the beautiful albumen printing process by which they were produced. Soulier was a noted painter, as well as photographer—nay, successful as he was, he never had his whole heart in photography—and he parted with his interest in the beautiful glass slides, as our readers know, to M. Léon Levy. Unfortunately, a large number of the negatives were destroyed by fire at the time of the Commune, and were to a large extent irreplaceable.

Patent Intelligence.

Application for Letters Patent.

7974. Herbert John Haddan, of the firm of Herbert and Company, Patent Agents, 67, Strand, Westminster, Civil Engineer, for "Improvements in the production of printing plates or blocks by photographic means."—A communication to him from abroad by Heinrich Riffrath, Gladbach, Germany.—Dated 20th May, 1884.

Notices of Amendment.

In the matter of Letters Patent granted to Richard Brown, Robert William Barnes, and Joseph Bell, on the 15th March, 1883, No. 1380.

Notice is hereby given, that leave has been granted to the said Richard Brown, Robert William Barnes, and Joseph Bell to amend the Specification filed in pursuance of the said Letters Patent in the manner set forth in the Official Journals of the Patent Office, published on the 1st and 4th April, 1884, pages 1062 and 1092 respectively; and that the said specification has been amended accordingly.—Dated this 22nd May, 1884.

In the matter of the application for Letters Patent made by George Duncan Macdougald, No. 416, Dated 2nd January, 1884.

Notice is hereby given, that leave has been granted to the said George Duncan Macdougald to amend the specification accompanying the said application in the manner set forth in the Official Journal of the Patent Office of the 11th April, 1884, page 1159, and that the said specification has been amended accordingly.—Dated this 22nd May, 1884.

Specification Published during the Week.

1898. Charles Sands and John James Hunter, both of 20, Cranbourn Street, Leicester Square, in the county of Middlesex, Photographic Apparatus Manufacturers, for "Improvements in the construction of photographic cameras." *Provisional specification.*

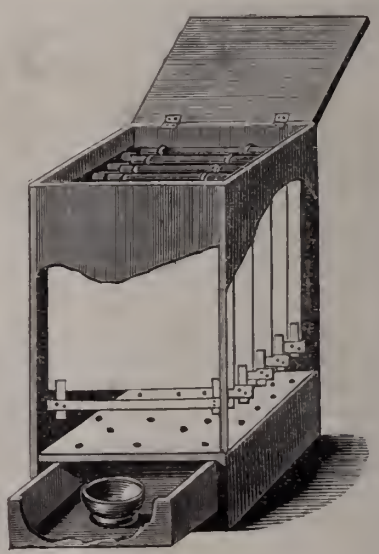
The object of this invention is to render cameras adjustable in a superior manner, and to afford increased facilities for working the same. In carrying out our invention, we so mount the cradle that it can be placed at any part of the base-board and at any angle thereto that may be required. The camera can be fixed upon the cradle either horizontally or vertically. We use either a rigid base-board or one extending and folding either at the front or back by means of screw, rack or clamp: upon this base-board is placed the cradle or double-action swing. The cradle can be made of either one or more pieces of wood working on a centre or otherwise; the top piece of wood being slightly rounded underneath and working on a pivot, ball, or ball-and-socket. To facilitate the rocking and swinging of the cradle we use a double action rack-and-pinion movement, one pinion working through the head of the other; this is arranged in the following manner, viz.:—there is fixed on each side of the bottom board of the cradle a piece of brass with a slot or elongated hole therein, through which is passed the double pinion; working in suitable racks attached to the cradle which can thus be adjusted by simply moving either of the pinion heads; the racks are fixed to the cradle, one on each side. The cradle can also be worked by means of a screw, pin, or clamp, and can also be fixed by clamp or other fastening. The camera can be fixed on this cradle either horizontally or vertically by means of a spring screw, nut, bolt, or any other convenient means, and can thus be made to swing in any direction. The front of the camera can also either be fixed or made removable to any part of the base-board, and the bellows also is so arranged that it will revolve on the front, or can be taken out and turned in any direction. The swing cradle can be adapted to any ordinary camera.

The final specification indicates in detail the method of constructing the double swing back, and is accompanied by ten drawings.

FUMING THE SILVERED PAPER WITH AMMONIA.

BY DR. PAUL E. LIESEGANG.

This operation is not exactly essential—indeed, it is generally dispensed with—but by adopting it the following advantages are realised. The printing is more rapid and more brilliant, while the pictures tone more readily. He who will profit by the advantages must not mind the small labour involved in toning, and should take a wooden box of the required size, and must provide it with a properly-hinged and well-fitting cover. About six inches from the bottom is to be fitted a perforated board, as shown in the drawing, only it is well to make more holes in it than are indicated by the sketch, excepting in the central portion. Under this false bottom a drawer is placed, a portion of the front of the box being cut away



for the purpose, and in this is placed a saucer containing strong ammonia. The paper must be quite dry, but as in this condition it tends to roll up, it is as well to attach a wood slat to the lower edge of each sheet, by means of two American clips. In the upper portion of the box a number of cross-bars, upon which the sheets can be clipped or pinned, are provided. These may be about three inches apart.

The sheets may remain between ten and fifteen minutes in the fuming box; but a longer time is required if it has been sensitized upon an acid bath than upon a neutral one, and in winter a longer time is required than in summer. It is also well to fume longer in bright weather than in dull, and also when weak negatives are to be printed; and as the ammonia tends to make the paper a little damp, it

is necessary in wet weather to re-dry the paper before placing it in the copying frame; but in dry weather the slight amount of moisture taken up from the ammonia is advantageous.

It should be noted that it is advisable to print a little deeper on fumed paper than on unfumed; and as the fumed paper becomes yellow very soon, it should be used as soon as practicable. At the same time, it is often desirable to allow the paper to remain exposed to the air for ten or fifteen minutes, in order that the excess of ammonia may evaporate, as otherwise the varnish might be softened.—*Liesegang's "Silber-druck."*

TAKING A PHOTOGRAPH BY THE MAGNESIUM LIGHT.

Taking portraits at night by the electric light is now a matter of every-day occurrence, and has many advantages, but as an experiment it is too expensive for the amateur photographer to undertake.

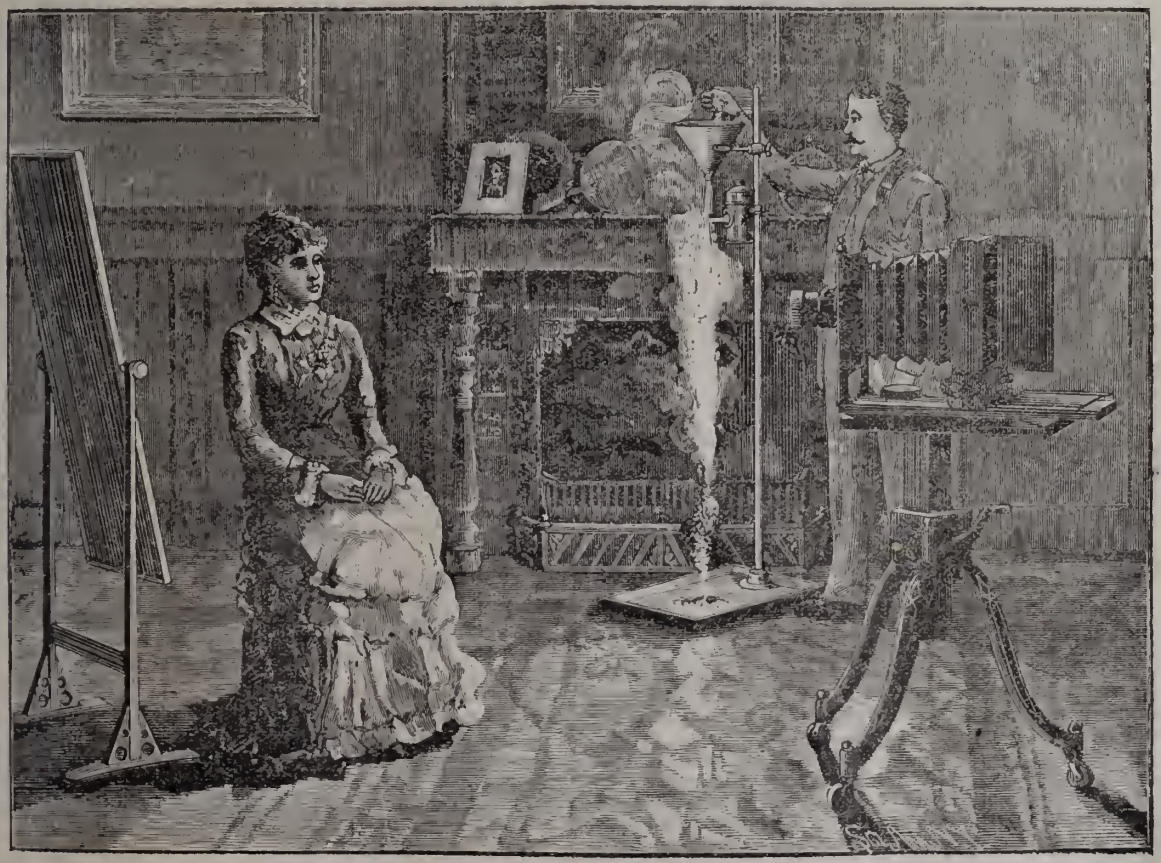
Our engraving illustrates a novel and easy method of photographing by the aid of the magnesium light. If a magnesium ribbon of a certain length be used, the ash will sometimes drop, and suddenly extinguish the light.

This difficulty may be overcome by the use of magnesium powder mixed with fine sand. Upon a metal or wooden rod six or eight feet long is clamped an alcohol soldering lamp capable of giving a large horizontal flame, and above it a funnel of tin or brass with a short mouth about three-quarters of an inch in diameter. The lamp should be quite close to the funnel; the rod may be secured at the bottom to any suitable base of wood or metal, and may rest upon a table instead of the floor. A pan or dish set upon the base will catch any falling particles.

The proper focus may be obtained by focussing upon the flame of a candle placed where the person is to sit. The shadows are softened by reflecting the light with a white muslin screen secured to a frame, which may be tilted at any angle, as shown. No cap is used on the lens.

One thimbleful of magnesium powder is mixed with two of fine sand, with a spoon or piece of wood, upon a white sheet of paper.

To make the exposure, the operator, after fixing the sitter in position, and drawing the slide of the plate-holder, simply steps up to the funnel, and quickly dumps the magnesium mixture into it The alcohol lamp sets fire to the magnesium, as it, in falling, comes in contact with the flame, and a long, brilliant, dazzling sheet of light, lasting for a second or two, is the result. Such a brief exposure is gene-



rally sufficient. The duration of the flame can be regulated by the addition or subtraction of the magnesium or sand.

Should a picture be over-exposed, the duration of exposure can be shortened by the addition of a little sand and a corresponding diminution of magnesium powder. If a larger amount of magnesium is used in proportion to the sand than that stated, the light will be more brilliant and of short duration. By varying the proportions of the two, it is possible to produce a flame of light from six to seven feet in length.

The large area of the light tends to diffuse the same, softens the shadows, and gives the picture a brilliant effect.

By varying the position of the light, very artistic effects of light and shade may be produced. The sitter should be placed so as to look away from the point where the light is to appear, in order that the dazzling effect of its intense glow may be avoided. Once the proper proportion of magnesium powder has been ascertained, several exposures may be made one after the other, with the certainty of obtaining good pictures each time.

As an experiment, nothing can be more attractive and entertaining than taking a photograph at night.—*Scientific American.*

THE EFFECT OF SHEARING STRESS ON A SENSITIVE SALT.

BY CAPT. W. DE W. ABNEY F.R.S.

AT the last meeting of the last session of the Photographic Society I gave a paper on the above subject, which, at the time, was commented upon, both in the PHOTOGRAPHIC NEWS and in the *British Journal*. In the latter journal the effect was laid to an abrasion of the film, and not to stress on the particles of silver bromide. Since that time I have carried on a few experiments on the subject, the results of which seem to point to a different conclusion. When writing paper was placed between the film and the writing point, though an image of the markings developed with apparently no abrasion, yet it might be due to two causes: one to organic matter from the paper pressed into the film, or to the fact that an abrasion might have taken place imperceptible to the eye. In order to test what effect abrasion really had, a gelatine plate was marked with a point, and a small amount of abrasion could be seen; it was then placed in water and soaked for a few minutes, after which it was placed near a hot water bath till the surface of the gelatine had melted, and no trace of any rupture in the gelatine could be traced. It was next allowed to set and dry, and then developed. The phenomena I have described in my last paper presented themselves as before; but a remarkable thing occurred, viz., that the developed writing was as sharp as if the surface had remained unaltered by melting. This pointed to the fact that the real effect was produced below the abrasion. To test this, a plate was written on as before, and the gelatine melted to the very surface of the plate, and a gentle rocking given to it to displace the sensitive salt next the glass. The gelatine was allowed to set again, and then developed. In this experiment the writing was thickened and distorted, showing that the seat of the phenomenon had been reached. I may remark that in the first described experiments, the plate was also rocked when the surface gelatine had melted, and this gave me an idea in what direction further search ought to be made. The destruction of the writing took place, as in my before described experiments, by the application of bichromate of potash to the plate. We have here, then, a further step in tracking this curious phenomenon to its source, and is in support of shearing stress excreised on the sensitive salt of the film, as against mere abrasion, since the altered sensitive salt was below the abrasion.—*Photographic Journal.*

CITY AND GUILDS OF LONDON INSTITUTE FOR THE ADVANCEMENT OF TECHNICAL EDUCATION.

THE Technological Examination for 1884, in Photography, took place on Wednesday evening, the 28th inst., at the various centres appointed.

The number of candidates who were examined last year was larger than either of the previous examinations; about forty certificates, besides several medals and money prizes, being awarded in the "Honours" and "Pass" grades. We have good reason for saying that these figures will be considerably augmented this year; nearly fifty students taking photographic question papers in one centre alone. The results will be made known in August next.

The examination consists of two grades, Ordinary and Honours, Certificates (first and second class) being awarded in each grade.

Prizes.—Honours.—1st prize, £5 and a silver medal; 2nd prize, £2 and a bronze medal. Ordinary.—1st prize, £3 and a silver medal; 2nd, £3 and a bronze medal; 3rd, £2 and a bronze medal; 4th, £1 and a bronze medal; 5th, a bronze medal.

The following are the instructions and questions given by the examiner, Captain Abney, F.R.S.

Instructions.

The Candidate must confine himself to one grade only, the Ordinary, or Honours, and must state at the top of his paper of answers which grade he has selected. He must *not* answer questions in more than one grade.

If he has already passed in this subject in the first class of the Ordinary Grade, he must select his questions from those of the Honours Grade.

The number of the question must be placed before the answer in the worked paper.

Three hours allowed for this paper

Ordinary Grade.

1. In wet-plate photography the solution of silver nitrate is left on the sensitive film. What is its action (1) during the exposure of the plate, (2) during development?

2. Silver prints on albumenized paper sometimes appear dead and sunken in. To what causes may this be due?

3. Give an outline of the method of producing prints by the Woodburytype or the stannotype process.

4. Wishing to test the strength of the silver nitrate bath, I take half-an-ounce of the liquid and add dilute hydrochloric acid to it till no further precipitate is formed. After carefully washing the precipitate and drying it, the silver chloride is weighed, and found to be 47½ grains. What was the strength of the silver nitrate solution?

Ag = 108
N = 14
O = 16
Cl = 35·5

5. Gelatine is rendered insoluble in warm water (1) by the action of light on bichromate of potash when mixed with it and dried, and (2) by the addition of chrome alum. Is there any difference in the properties of the gelatine thus rendered insoluble?

6. Describe the method you would adopt to practically ascertain the comparative rapidities of two plates.

7. Explain as fully as you can the use of stops in a lens.

8. Bromide, iodide, and chloride of silver are given a lengthened exposure to sunlight; (1) in the presence of silver nitrate solution; (2) in the presence of a solution of sulphite of soda; (3) dry, after being thoroughly washed. Describe the appearance of each silver compound before and after the exposure in each of the three experiments.

9. Describe briefly the theory of the development of the photographic image when an alkaline developer is used.

10. Describe the production of a photographic transfer for lithography.

Honours Grade.

1. State what you know regarding the cause, and the cure for green fog in a gelatine emulsion.

2. After very carefully focussing a fine engraving on the focussing screen of the camera, a negative is taken and found to be wanting in sharpness. To what causes may this be due, and how should you ascertain the cause? Can the defect be practically eliminated, and if so, how?

3. Describe the method you would adopt for ascertaining the range of graduation of a gelatine plate.

4. Plates prepared with collodio-bromide emulsion are briefly exposed in the presence of tannin, beer, silver nitrate, mercuric chloride, bichromate of potash, and potassium nitrate respectively. What would be the results on development?

5. Describe Fox-Talbot's process for producing a positive instead of a negative in the camera, and state the theory on which it depends.

6. Describe the process you would employ for producing gelatine chloride plates, and the method you would adopt for developing them.

7. What are the theoretical and practical disadvantages of using a pin-hole stop in a lens.?

8. In the collodio-chloride process, what part does the citric acid play?

9. How should you practically test the suitability of different coloured media as screens with which to cover the window of the dark room?

10. Is the light transmitted and reflected from coloured paper the same? Give in detail the reasons for your answer.

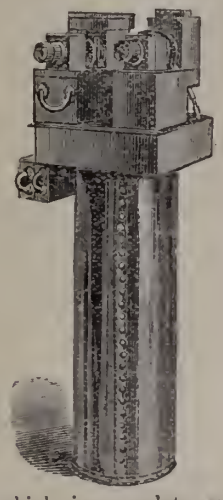
Correspondence.

THE IVES ETHOXYGEN APPARTUS.

SIR,—My oxyhydrogen jets have no "safety" contrivances about them, but work perfectly with the patent ether saturator, and the flame never "snaps" in dissolving. The ether light can best be produced with a jet having small tubes, small mixing chamber, and not very

large aperture tips. The jets in the market here all have too large mixing chambers, and most of them too large supply tubes; and the manufacturers would rather condemn the use of ether, than to make their jets right to work with it.

I send you a small photograph of my own dissolv-



ing view outfit, which is complete and powerful, but remarkably compact. The steel oxy-cylinder is 40 inches high, and holds 80 feet of gas at a pressure of 220 lbs. to the square inch. It serves me also as a stand for my lanterns, which are my own make, and can be folded up in thirty seconds, so that each forms its own "carrying case," and measures only 5½ × 6 × 8½ inches. The condensers are 4½ inches diameter, and the objectives about 4 inches back focus, with rack-and-pinion. The table-top attachment to the cylinder, together with both lanterns, the ether saturator, two boxes of slides (100), and an extra pair of objectives, all pack into a small trunk.

I have never seen any other outfit equally powerful which could be packed in *twice* the space.—Respectfully yours. FRED. E. IVES.

Philadelphia.

THE ILLUMINATION OF THE DARK-ROOM.

DEAR SIR,—As the discussion upon my paper on illumination of the dark-room, read before the Photographic Society of Great Britain, stands adjourned until the next meeting of the Society, I should have preferred to keep silent till that occasion, but that an article in which my name is mentioned, contained in your last impression, by Mr. C. Ray Woods, who has expressed his intention of joining in the discussion and of criticising my paper, appears to me to call for reply in the same medium as that in which it appears.

In the article referred to, "Illumination of the Dark-room," page 333, Mr. Woods says that "it can readily be shown that the spectroscopic test is one that can safely be relied upon, and is superior to the somewhat haphazard methods more frequently adopted." It is rather difficult to see why the method which I adopted and exhibited at one of the technical meetings of the Society last autumn, and which consisted of a direct comparison of the luminous effect of colours with their protective power upon the photographic plate, should be called a haphazard one. By this method the three elements to be considered—illuminating power, protective power, and irritating or comfortable character of the lights to be considered—can be directly compared without the complications which ensue when using a purely spectroscopic method. The powerful effect, for instance, of any of the ultra-violet rays which may pass through any given medium will be at once shown by the direct experiment method, whilst to the eye of the spectroscopic observer they are unperceived. And even if spectrum photography be called in aid, the comparison with photographic illuminating power is by no means so easy and precise as with the direct method. If, as Mr. Woods states, it can be so readily shown that the spectroscopic test is really superior, he certainly has not shown it.

For the argument from the spectrum to be sufficient of itself, it would be necessary, in the first place, that the facts of spectrum photography should be established and beyond dispute. The differences, however, that exist between the results of different observers show that this has not been done. To take only the diagram with which Mr. Woods illustrates his article, he makes the action of the spectrum upon bromide of silver entirely cease near line C, about the middle of the red, whereas it is generally conceded that at least the whole of the visible spectrum has its photographic effect. If this diagram were correct, the question of safety would indeed be settled, as any amount of red about the region of B might be used with perfect impunity.

Another difficulty which occurs when using the spectroscopic test, is that of determining the relative illuminating value of the different rays. This difference of illuminating powers has indeed commonly been ignored when using the argument from the spectrum, but as you have, in your article on page 321, so powerfully pointed out the absurdity of this omission, it is not necessary to say more on that head.

Mr. Woods complains of "loose talk" about "supposed discrepancies between spectroscopic evidence and ordinary practice." I have never spoken disparagingly of the "evidences" of the spectroscope. If what is called the argument from the spectroscope is not in accordance with observed facts, the presumption is not against the instrument, but that either the assumed facts of spectrum photography have not been correctly ascertained, or that the deductions from the facts have not been properly made. Speaking of "loose talk," however, what is to be said for Mr. Woods' persistence in speaking of certain glass that I employed as cathedral green? Cathedral is the name of a "make" of glass, and, as I have repeatedly mentioned, I selected it merely because it happened that I could not get at the time the colour I wanted, a yellow-green, in any other make. Cathedral glass may be had in a great variety of colours; in the greens there are light-greens and dark-greens, blue-greens and yellow-greens. I have given many patterns of the colour I used, light and dark, to any photographers who have wished for them, and I should have been happy to furnish Mr. Woods with a sample also. It would seem, however, from the fact that in his diagram, fig. 10, of what he calls "cathedral green" shows a spectrum nearly like No. 8, which he speaks of as green "almost a blue," and very unlike No. 9, a yellow green, that he has happened upon a piece of bluish rather than yellowish-green glass.

In speaking of "stained red" glass, Mr. Woods says that that used by Captain Abney is stained red on one side and yellow on the other. It would be interesting to know what is the recognized name of glass thus prepared. The several samples that I have obtained bearing Chance's printed label "stained red," have been very much alike, and are heavily stained on one side with silver. This may be tested by dissolving a portion of the surface away with fluoric acid, when the yellow colour of a thinner film is evident.

In a former article on page 214, April 4th, Mr. Woods gives a diagram representing the sensitiveness of green bromide of silver as greater to the red ray of the spectrum, than to the yellow. The sensitive compound that photographers use in gelatine plates has been described as the green bromide, and if this diagram is to be relied on, therefore, spectroscopic evidence would be powerfully in favour of yellow as the illuminant of the laboratory. If (of which there is no indication in the article) there is any special preparation of green bromide necessary in order to produce this result, will Mr. Woods furnish the precise formula. The value of a statement on a scientific subject depends

upon its being accompanied by the details necessary for its examination and verification.

In spite of the demonstration that I gave of the fact that green glass is a more powerfully protective supplement to stained red than cobalt is, Mr. Woods states that those who work with the latter in combination, "will be using that portion of the spectrum which possesses the least reducing power"; whilst of the green he states that those who use it weaken the illuminating power of the light in much greater proportion than they increase its safety. Mr. Woods has, by his own statement and that of Captain Abney, an extraordinary facility for seeing with red light. The observers whom I have had the opportunity of testing, Mr. W. K. Burton, Mr. J. Cadett, Mr. A. Haddon, and Mr. J. Traill Taylor, all found that to them the combination of green and stained red, that gave so much more protection to the plate than the stained red and cobalt, gave from three to four times as much illuminating power, and was of more agreeable character. It is not probable that all these gentlemen were exceptionally averse to red, but would more probably represent the average or normal state of vision.

On the Editor's article on my paper, I would only make one comment. It is said that "Mr. Debenham appeared to fail to make out a case in favour of yellow light as against that filtered through 'stained red' glass, except that red colour is hurtful to the eyesight." I did not endeavour to make out a case against that medium upon any other ground; and for the reason I pointed out—namely, that stained red is only a pile of yellow, I stated that it was not surprising that it shows as of about the same safety as another yellow. When a real red, such as the copper-stained ruby, which, when in thin layers, shows still as red, and not as yellow, is tried in comparison with a yellow light, the superiority of the latter is seen; and in the battle of yellow light *versus* red, it is certainly a point in favour of the former, if for the representative red medium, one has to be selected which only appears to be red from the fact of its being in a very thick layer, and which is brilliant yellow in a thinner layer.—I remain, yours, &c., W. E. Debenham.

Proceedings of Societies.

Photographic Society of Great Britain.

A meeting was held in the Room attached to the Gallery, 5A, Pall Mall, East, on Tuesday last, the 27th instant, Captain W. de W. Abney, F.R.S., in the chair.

Mr. Sebastian Davis referred to the fact that there had been a notable tendency towards a falling off as regards the brilliancy or vigour obtainable on gelatine plates, and he could not deny the fact that, notwithstanding much endeavour, he had not been able to satisfy himself as to the reason of this falling off. That "sparkle," to use the expression of Mr. Payne Jennings, which results from a full series of gradations ranging from bare glass to a sufficient maximum of density, constitutes the principal charm of a photograph; and every effort must be made to acquire the knowledge requisite to ensure this. At first Mr. Davis thought that the tendency towards weakness might result from an imperfect removal of the nitrate salts by washing, but this was found not to be the case, as little or no advantage resulted from prolonging the washing beyond the usual amount. Details were then given as to the method he adopted in preparing his emulsion. The proportion of gelatine with which he emulsified was usually eight grains to the ounce, and he was in the habit of adding twenty-two grains afterwards; ordinarily he used Heinrich's "hard," although he had frequently made use of other sorts.

The Chairman here remarked that he had found the proportion of gelatine present during emulsification to very materially influence the sensitiveness; the emulsion being made quicker by increasing the quantity of gelatine added in the first instance. He then enquired of Mr. Davis as to the colour of his usual emulsion.

Mr. Davis said it was ordinarily a greenish-violet; but as small a quantity of iodide as one grain to the ounce seemed to communicate a yellow tint. In order to try to obtain more density, he had used gallic acid, having found this reagent very valuable for a similar purpose in the case of the collodio-albumen process; but no advantage resulted. He had used the gallic acid by making up the volume of the emulsion with a saturated solution—say 2 ounces of the solution to the batch of 10 ounces of emulsion; but no advantage resulted.

Mr. Warnerke spoke of the value of isinglass for emulsion making, and said that it could be distinguished from ordinary gelatine by the fact that it (isinglass) became opalescent when soaked in water, the opalescence being generally accompanied by a greenish appearance. A cheap article is made in Russia by boiling up all the more solid parts of the fish; while the genuine isinglass is well known to be made only of the sound or air-bladder.

The Chairman had met with instances in which ordinary gelatine became opalescent when soaked in water.

Mr. Warnerke stated that the quality of the gelatine had considerable influence on the sensitiveness of an emulsion, and great difficulty arose from the impossibility of getting two samples alike, the ordinary practice being to order large batches, and to thoroughly experiment with them before venturing to use them.

Mr. Davis enquired whether the bromide of potassium was to be preferred to the ammonium salt?—and

The Chairman said that the difference was not great, but perhaps the use of potassium salt was conducive to density.

Mr. Davis remarked that Mr. Wilson, in his directions, had insisted on the importance of using a special bromide, which was only to be obtained at a certain shop.

A general conversation here ensued as to the special advantages to be realised by obtaining special brands of bromide; but it was subsequently pointed out that potassium bromide may be regarded as a constant, if only reasonable precautions are taken to obtain it in a pure state, and it was stated that by adoptiug the well-knowu principle of fractional decomposition, bromine perfectly free from other haloids could readily be obtained.

Mr. Warnerke remarked on the fact that German bromine is often contaminated with iodine and chlorine.

The Chairman referred to a very ready way in which iodine might be removed from bromides—viz., by fractional precipitation with silver nitrate, the iodine being, of course, thrown down first. As regards chlorides, they were, perhaps, of less immediate importance; although he might mention, as quite an exceptional case, that he had known a sample of bromide of potassium to contain one-third or one-fourth of its weight of chloride. This was, however, clearly a case of adulteration. He considered that the subject of the purity of haloid salts was of vital importance, and he would be glad to see a committee of the Society formed to deal with the question.

The importance of considering and duly studying the condition under which fine deposits were obtained was next referred to by the Chairman, and he said that he had found, when dense images were obtained, that the grain was fine and tolerably regular. A thin-image plate shows, on the other hand, a coarse and irregular grain. It is a matter of importance to secure a fine grain when accurate measurements are to be made; and it must be remembered that he had carried some of his measurements so far as to recognize the 200,000th of an inch. With a quarter-inch objective, it is possible to obtain readings to the 100,000th of an inch; while much good work may be done with a one-inch power, but in this case it is difficult to read beyond a 10,000th.

Mr. Warnerke enquired if any members had tried the effect of dissolving magnesium wire in the oxalate developer according to a suggestion made by Captain Abney. He had found a remarkable increase of activity to result, and denser pictures were obtained than when the ordinary developer was used. The speaker then referred to the circumstance that Mr. Levitzki, of St. Petersburgh, adds tartaric acid to his old oxalate developer, and runs it in tall clear bottles. It is thus obtained in fine condition for copying work, and gives negatives of great intensity. Mr. Warnerke then referred to the use of the collapsible metal tubes, ordinarily used for artist's colours, as vessels for storing small doses of developer, and indeed many other photographic chemicals or preparations, more especially printing inks for the collotype process. He also spoke of a new accelerator sold by Carrette. It is a colourless liquid, smelling of acetic acid, and if poured over a plate before development it appears to have the same effect as would have resulted from a more prolonged exposure.

A general conversation regarding the use of the potash developer then followed, and Mr. England said that he finds that pyrogallic acid keeps very much better if dissolved in absolute alcohol than in spirit of the usual strength.

London and Provincial Photographic Association.

A meeting of this Society was held on Thursday, the 22nd inst., Mr. J. H. Hare in the chair.

A communication from the Balloon Society was read, inviting the members of this Society to attend with their cameras, to photograph the balloons in the Crystal Palace grounds on the 31st inst.

Mr. A. Cowan showed a photograph of an ordinary four-wheeled cab he had used as camera-stand, dark-room, and changing-box combined. By lining the inside as well as covering the outside, it was rendered perfectly light-tight, one dozen 12 by 10 rapid plates being changed within in safety.

Mr. W. E. Debenham said he intended showing the effect of a composite white light, but was prevented through breaking one of the glasses, so would defer it until the next meeting. He said one of the difficulties met with when photographing interiors, was hitting the proper exposure; the advantage of being able to develop a trial plate on the spot was very great. He then showed a convenient tent for changing or developing plates. This consisted of a shallow tin dish, thirteen by eight inches, as a base, a frame of stout wire, the same dimensions with two folding supports, eight by eight inches, the whole being covered with black fabric, in which two sleeves were placed. Mr. Debenham demonstrated the safety of this tent by changing and developing a plate; he said that it was important to pass a soft brush freely over the plate during development, to prevent irregular action, through the inability to watch the progress of development. The tent was large enough for changing or developing half plates.

Mr. A. L. Henderson considered the graphogenic camera designed by Mr. Edwards would answer well for testing plates, especially if ferrous oxalate development were employed.

Mr. A. Cowan said Mr. Harrison's idea was a good one; he made a small camera for exposing and developing inch plates as a guide, making the allowance for lenses of larger dimensions in calculating the correct exposure.

Mr. Henderson passed round two plates of the same batch, exposed under the sensitometer for ten minutes, eight inches from his new lamp, the illumination being the same.

The general opinion was, that one plate was six times more affected than the other.

Mr. Henderson said he used a small paraffine lamp, the light being passed through a disc of plain glass containing four surfaces, and two plates of aurine in the case of the most affected plate; whereas, in the least affected, a diffraction gratiug was substituted for the plain glass. The diffraction grating was made for him by Messrs. C. and F. Darker, who would answer any queries respecting it.

Mr. A. Haddon enquired how many lines Messrs. Darker employed per inch?

Mr. C. Darker replied that there was three thousand in the one shown.

Mr. W. M. Ashman enquired what would be the size of the largest disc and diffraction grating capable of employment with a larger flame?

Mr. Darker said about two inches, which would be very expensive.

Mr. Henderson remarked that a firm in Philadelphia advertised diffraction grating as large as five inches.

Mr. C. Ray Woods said there were some Roland gratings at South Kensington six inches long by two inches broad; these came from America.

The Chairman exhibited a rapid shutter for attaching outside the lens; by means of a small lever, the metal disc is raised and released by a rubber band being thrown off, the disc descending with a speed which is regulated by the tension of an adjustable spring.

Talk in the Studio.

Removing Hyposulphite from Gelatine Films.—A trace of hyposulphite remaining in the gelatino-bromide film has caused the destruction of many a good negative; and the means of removing this deleterious agent, referred to by M. Felisch at a recent meeting of the Russian Technical Society, may be worth consideration. He makes a bath with about equal parts of iodide of potassium and iodine dissolved in water, so as to make a solution having about the tint of port wine, and the washed plate is allowed to remain in this for a few minutes, a final rinse in water being all that is then required.

Pigment Tissue for Enamel Pictures by Pavloffski's Method.—It is said that Herr Romain Talbot, of Berlin, has introduced into commerce a pigment tissue for making photo-enamel pictures according to the method of Pavloffski (page 193). Lieutenant Pavloffski has now adopted the simpler method of spreading the mixture of gum and enamel colour on paper rather than a plate of metal, and he prefers to sensitize afterwards instead of mixing the bichromate with the gum in the first instance. A mixture of gum and pigment is made precisely as described (page 193), only the bichromate is omitted and less water is used. This gum mixture is spread evenly on stout paper, dried, and it is sensitized just like ordinary carbon tissue, but it is necessary to use a bath containing alcohol in order to prevent the dissolving of the gum. The following is the formula:—Potassium bichromate, 2 parts; water, 50 parts; 90 per cent. alcohol, 50 parts. The remaining operations are similar to those in the ordinary Swan's carbon process, only alcohol must be used when required to prevent the solution of the gum. For coating the paper, a gumming machine may be used, and one constructed by M. E. Ravasse, in Paris, is recommended.

Reducing the Intensity of Negatives.—Mr. Belitzki makes use of the greenish crystals which are deposited from old oxalate baths. He dissolves 3 parts of these in 100 parts of the usual hyposulphite fixing bath, and he finds that if a recently-fixed negative is immersed in this solution, and meanwhile exposed to a full light, a gradual and very satisfactory reduction of the density takes place. The reducing bath keeps well in the dark.

The "Daily Telegraph on Photography.—In an article on the Derby day the *Daily Telegraph* says:—"Who can fail to experience regret that some such recourse to instantaneous photography as was adopted last Sunday, and on many previous occasions, at Chantilly and other French racecourses, was not within the reach of our forefathers? It is reported from Paris that the late starter, who was formerly employed as an official by the French Jockey Club, has reveuged himself for his dismissal by taking a series of instantaneous photographs of his quondam masters, and of the scenes which are witnessed at the starting-post on the eve of a great race. Occasionally a jockey is revealed in earnest confabulation with some trusted commissioner, who receives his latest inspiration from 'the man in silk,' while, in the words of a contemporary, 'several of the photographs have been printed, and others suppressed as telling too many tales. Were it possible for the lens and camera of the photographer to reproduce all the unpublished histories of which Epsom racecourse has been the scene within the last century and a half, we doubt if there would be enough collodion in the world for the purpose." What a pity these writers do not read up a little before venturing into technicalities! Collodion would not do it, and the sooner the *Daily Telegraph* writer knows it the better. His idea is good and perhaps some day, Derby pictures will be produced equal in conception to Frith's celebrated painting.

Photographic Club.—At the next meeting on June 4th, the subject for discussion will be on "The consideration of the best means of obtaining Density in Gelatine Plates without resorting to intensification." An out-door meeting will be held on Whit Monday at Welwyn; train leaves Kings Cross at 10.32.

To Correspondents.

*** We cannot undertake to return rejected communications.

W. Evans.—We are sorry to have to admit that you are right. It is painful to find such a condition of things existing.

J. W. P.—We gather from your letter that your assistant has used you badly, and that you suspect him of having taken photographs from your establishment; but you are unreasonable in expecting us to publish his name and description, especially as you wish to cover your own identity under a *nom de plume*.

J. H. N.—You can perhaps understand that to do so would be a little painful just now, but the matter shall be considered, and we thank you for the kind expressions in your letter. At any rate, we will endeavour to obtain one for you.

Charles Cranch.—1. The manufacturers are Messrs. Chance and Co., of Birmingham. 2. We have found it excellent, but should recommend you to use two thicknesses.

G. F. Webber.—1. A formula suitable for citro-chloride emulsion will he found on page 161; the same, in fact, that we recommended for pictures on opal. 2. We quite agree with you, but can hardly make the suggestion to the firm you mention; hut you might write as one interested in seeing such an article introduced into the market. 3. As regards the lens, we are inclined to think that your friend will now have to make the best of his bargain. Whether it will be worth whilo to have a new front glass constructed by the original makers is a matter upon which they only can advise.

J. G.—If we were to do as you suggest, it would he solely in the interest of our readers. We will enquire into the matter, and shall he glad to have any particulars you may he disposed to send.

W. Field.—In order to fairly deal with the question from your point of view, you require the judgment and experience of one who has not only made a special study of the matter, but who is also acquainted with the conditions under which you intend to work. No one process can be simply designated as "best," hut we are inclined to think that if you intend to make blocks yourself, you had hetter adopt either the Asser process (p. 259 of our volume for 1883), or the Ives' method. Concerning the latter, much information will be found in the News during the past eighteen months. Several of the best methods are covered by patent rights, or are not made public. We could, perhaps, help you more if we knew what experience you have had hearing on the matter; but under any circumstances, you would do well to obtain Husnik's "Heliographie," published by Hartleben, of Leipzig. The cost is only a few shillings, and it can be had through any foreign bookseller.

C. R. B. D.—We fancy the plate must have been under-exposed, hut if good, it should have withstood the forcing treatment, unless you fogged it by light during development. When a plate is to bo treated with an energetic developer, it becomes necessary to take especial precautions as regards the dark-room light. 2. Sometimes it will keep good for months, but it is hetter to use it freshly made. 3. Thank you for the note. It is strange how such an obvious improvement should escape observation.

S. Rousseau.—The suggestion is likely to be a useful one. We will write to you.

Pin.—1. Both the numbers are in print, and our publishers will forward them if you send the price with an additional stamp for postage. 2. We are afraid that no use can be made of it except for cleaning plates.

A. G. B.—1. Excellent work can be done with them, but they form no exception to the general rule, that a tool or appliance made to serve many purposes, is not equal to a set of tools in which each instrument is specially adapted for its own work. We cannot answer the second part of your question, as we have not the instruments at hand; but we will endeavour to ascertain. 2. You perhaps hardly grasp the point of view from which it was written; but we agree with you that it is strange that the English makers have not adopted the convenient plan to which you allude. 3. The following you must regard altogether as a personal opinion: S. F. D. H. 4. It is a dark slide in which the draw shutter is replaced by a kind of roller blind, made by gluing strips of wood on a flexible basis; the general arrangement being somewhat analagous to the revolving shutters which are used for shop windows.

M. Colton.—Captain Abney's "Instruction" is the best hook for you to obtain; but we are afraid you will have to wait a few weeks, as it is just now being reprinted.

The Photographic News Registry.

Employment Wanted.

Reception Room, &c.—Z., 18, Cardigan-rd., Bow.
Retoucher, Spotter (lady)—Y. Z., 72, Azenby-sq., Peckham.
General Assistant.—G. H. Barthorpe, 50, Victoria-st., Bradford.
Reception Room, &c.—Miss Ayre, 21, Dorchester-pl., Blandford-sq.
Copyist, Landscape, wet and dry.—X. Y. Z., *Photo. News* Office.
Operator, carbon and silver.—A. Hey, 7, Park-st., Aberdeen.
Assistant Operator, wet or dry, can copy—B., *Photo. News* Office.
Vignette Printer and Toner.—W., St. Mary's-sq., Kennington-rd.
Reception-Room & Retouching.—M. D., 46, Friern-rd., East Dulwich.
Assist. Op., Ret., Enlarger—Mr. Cubberley, c/o Messrs. Turner, Barnsbury.
Operator & R toucher, or Manager Branch.—H. Betts, 94, High-st., Merthyr.
Op. for 6 mos. at sea-side, at £3 3s.—B. B., 13 King Henry's-walk, W.
Op., Printer, Toner, Retoucher—Bromide, 133, Union-rd., Newington, S.E.
Manager & Operator.—M., Mr. Nicholls, High-st., Shanklin, I.W.
Ret., Artist in Oil, Water, Monochrome.—F. G., 3, Kenyon-ter., Clapham.

Employment Offered.

Lady Retoucher, with references.—Norman May, Malvern.
Reception-Room & Retoucher.—Artist, *Photo. News* Office.
Reception-Room Lady, good writer—Messrs. Turner, Barnsbury.
Printer & Retoucher.—Chancellor's Studio, 55, Lower Sackville-st., Dublin.
Assist. Op., dry.—Weston & Son, 23, Sandgate-rd., Folkestone.
Lad as Assistant Printer.—Boning & Small, 22, Baker-st., W.
Operator & Retoucher.—W. H. Midwinter, 49, Park-st., Bristol.
Operator, about June 10.—Marwick & Co., White Rock Library, Hastings.
Spotters & Mounters, first-class—Fradelle, Regent-st.
Enameller, at once.—Oelfelein and Co., 54, Berner's Street, London, W.

THE EVERY-DAY FORMULARY.

The Gelatino-Bromide Process.

Emulsion.—A—Nit. silver 100 grains, dist. water 2 oz. B—Bromide potassium 85 grains, Nelson's No. 1 gelatine 20 grains, dist. water 1½ oz., a one per cent. mixture of hydrochloric acid and water 50 minims. C—Iodide potassium 8 grains, dist. water ½ oz. D—Hard gelatine 120 grains, water several oz. When the gelatine is thoroughly soaked, let all porsible water be poured off D. A and B are now heated to about 120° Fahr., after which B is gradually added to A with constant agitation; C is then added. Heat in water bath for half an hour, and stir in D. After washing add ½ oz. alcohol.

Pyro. Developer.—No. 1—Strong liq. ammonia 1½ oz., bromide potassium 240 grains, water 80 oz. No. 2—Pyro. 30 grains, water 10 oz. In case of an ordinary exposure mix equal vol.

Iron Developer.—Potassium oxalate sol. (1 and 4) 80 parts. ferrous sulphate sol. (1 and 4) 20 parts, dist. water 20 parts. To each 4 oz. of the mixed developer add from 5 to 30 drops ten per cent. sol. potassium bromide, and 30 drops sol. sodium hyposulphite (1 and 200).

Substratum or Preliminary Preparation.—Soluble silicate of soda 1 part, white of egg 5 parts. water 60 parts. Beat to froth and filter.

Fixing.—Sat. sol. of sod. hypo. 1 pint, sat. sol. of alum 2 pints, mixed.

Cowell's Clearing Solution.—Alum 1 part, citric acid 2 parts, water 10 parts. Edwards makes this sherry coloured with perchloride iron.

Eder's Method of Intensification.—The negative is whitened by soaking in sat. sol. of mercuric chloride, and after thorough rinsing immersed in potass. cyan. 10 parts, potass. iod. 5 parts, mercuric chloride 5 parts, water 2,000 parts. As film becomes dark brown, the actinic opacity is increased; but prolonged action causes brown tint to become lighter, until at last the negative is no denser than at first.

Fol's Backing Sheets.—A chromographic paste is prepared with gelatine 1 part, water 2 parts, glycerine 1 part, and a very small addition of Indian ink. Strong paper or shirting is coated, and the sheets are laid, face downward, on waxed glass to set. Press to back of glass plate.

The Wet Collodion Process.

The Nitrate Bath.—Water 14 oz., nit. silver 1 oz., nitric acid 1 drop. Before using coat a small plate, and immerse it for 20 minutes.

Cleaning Preparation for New Plates.—Alcohol 4 oz., Jeweller's rouge ½-oz., liquid ammonia ½-oz.

Film-removing Pickle for Old Plates.—Water 1 pint, sulphuric acid 4 fluid oz., bichromate potassium 4 oz.

Substratum.—Whites of 2 eggs well beaten, 6 pints of water, and 1 dr. liq. ammon.

Negative Collodion for Iron Development.—Alcohol 1 pint, pyroxyline of suitable quality 250 grains, shake well and add ether 2 pints, *Iodize this by mixing with* one-third of its volume of alcohol ½ pint, iod. ammon. 80 grains, iod. cadm. 80 grains, brom. ammon. 40 grains.

Normal Iron Developer.—Water 10 oz., proto-sulphate iron ½ oz., glacial acetic acid ½ oz., alcohol ½ oz. The amount of proto-sulphate iron may be diminished to ¼ oz. when full contrasts are desired, or increased to 1 oz. when contrasts are unduly marked. With new bath quantity of alcohol may be reduced to ¼ oz; but when bath is old more is wanted.

Intensifying Solution.—Water 6 oz., citric acid 75 grains, pyro. 30 grains. When used, add a few drops of the silver bath to each ounce.

Lead Intensification.—After neg washing, immerse in dist. water 100 parts, red pruss. potash 6 parts, and nit. lead 4 parts. When it is yellowish white wash and immerse in liquid sulphide ammon. 1 part, water 4 parts.

Fixing Solution.—1. Potass. cyanide 200 grains, water 10 oz. 2. Sat. sol. of sod. hypo.

Varnish.—Shellac 2 oz., sandarac 2 oz., Canada balsam 1 dr., oil of avender 1 oz., alcohol 16 oz.

Printing Processes.

Albumen Mixture for Paper.—White of egg 18 oz., 500 grs. ammon. chlor. in 2 oz. of water. Beat to a froth, stand, and filter.

Sensitizing Solution.—Nit. silver 50 grs., water 1 oz., sod. carb ½ gr.

Acetate Toning Bath.—Chl. gold 1 gr., acet. soda 20 grs., water 8 oz.

Lime do.—Chl. gold 1 gr., whiting 30 grs., boiling water 8 oz., sat. sol. chl. lime 1 drop. Filter cold.

Bicarbonate do.—Chl. gold 1 gr., hicarb. soda 3 grs., water 8 oz.

Fixing Bath.—Sodium hypo. 4 oz., water 1 pint, liq. ammon. 30 drops.

Reducer for Deep Prints.—Cyan. potass. 5 grs., liq. ammon. 5 drops. water 1 pint.

Sensitizing Bath for Carbon Tissue.—Bichromate potash 1½ oz., water 30 oz., ammonia 1 dr., methylated spirit 4 oz.

Enamel Collodion.—Tough pyroxyline 120 grs., methylated alcohol 10 oz., ether 10 oz., castor oil 20 drops.

Mountant.—1. Fresh solution of best white gum. 2. Fresh starch.

Collotypic Substratum.—Soluble glass 3 parts, white of egg 7 parts, water 10 parts.

Collotypic Sensitive Coating.—Bichromate potash ½ oz., gelatine 2½ oz., water 22 oz.

Collotypic Etching Fluid.—Glycerine 150 parts, ammonia 50 parts, saltpetre 5 parts, water 25 parts.

Printing on Fabric.—Remove all dressing from fabric by boiling in water containing a little potash, dry, and albumenize with ammonium chloride 2 grammes, water 250 cubic cents., and the white of 2 eggs, all being well beaten together. A 70-grain silver bath is used, and the remaining operations are as for paper.

Cyanotype Printing.—Water 1 oz., red prussiate of potash (ferricyanide 1 dr., ammonio citrate of iron 1 dr. Prepare and preserve in the dark. Float the paper and dry. Fixation by mere soaking in water.

Various.

Luckardt's Retouching Varnish.—Alcohol 300 parts, sandarac 50 parts. camphor 5 parts, castor oil 10 parts, Venice turpentine 5 parts.

Matt Varnish.—Sandarac 18 parts, mastic 4 parts, ether 200 parts, benzole 80 to 100 parts.

Encaustic Paste.—Best white wax, in shreds, 1 oz., turpentine 5 oz. dissolve in gentle heat, and apply cold with piece of flannel.

Ferrotypes.

Collodion.—Ammonium iodide 35 grains, cadmium iodide 25 grains cadmium bromide 20 grains, pyroxyline 70 grains, alcohol 5 oz., ether 5 oz.

Bath. Silver nitrate 1 oz., water 10 oz., nitric acid 1 drop.

Developer.—Ferrous sulphate 1 oz., glac. acetic acid 1 oz., water 16 oz.

Fixing and Varnish.—Same as wet collodion process.

THE PHOTOGRAPHIC NEWS.

VOL. XXVIII. No. 1344.—*June* 6, 1884.

CONTENTS.

IODIDE OF NITROGEN AS A PHOTOMETRIC AGENT.

SOME very interesting and valuable observations have recently been made by M. Guyard on the sensitiveness of iodide of nitrogen to light, and a translation of his recent communication to the *Annales de Chimie et de Physique* will be found in another column (p. 357).

M. Guyard's first observations as to the sensitiveness of iodide of nitrogen were brought about in a very curious way. He was watching what has long been believed to be the spontaneous decomposition of the iodide, the material being suspended in water contained in a glass vessel placed in a somewhat dark part of the laboratory, and, on lifting up the vessel to the level of the eye, he noticed an immediate formation of bubbles of nitrogen; but, on replacing the glass upon the table, the decomposition almost ceased. On now exposing the beaker to a bright ray of light which penetrated into another part of the laboratory, he at once perceived such an increase in the rate of decomposition as to convince him that light was the active agent.

Iodide of nitrogen is one of the most remarkable bodies with which the chemist is familiar, as it belongs to that small class of binary compounds which decompose into their elementary constituents with explosive violence when subjected to slight disturbing influences. When finely powdered iodine is stirred into ordinary liquid ammonia (say, 60 or 70 grains of iodine in an ounce or so of the liquid), a portion only of the iodine dissolves, and the remainder of the iodine is, in the course of five or ten minutes, converted more or less completely into iodide of nitrogen, this new body forming a black powder which may be separated by collection on a filter. When dry, the black powder is so prone to decomposition that a touch with a feather, or the shock caused by allowing it to fall from a height of a couple of feet upon the surface of water, will cause it to detonate. For this reason, only small quantities should be prepared at a time, and if it is intended to dry the substance, it should be separated out into small batches of a few grains, each of these being placed upon a separate piece of blotting-paper.

Chemically, iodide of nitrogen may be regarded as ammonia in which the whole of the hydrogen is replaced by an equivalent proportion of iodine; the formula of ammonia being NH_3, and that of iodide of nitrogen being NI_3. When, however, it is prepared by the comparatively crude process above indicated, it not unfrequently happens that the replacement of the hydrogen of the ammonia is incomplete, the compound NHI_2 being formed; but as regards general character this is very similar to the true iodide. Indeed, it appears to be convertible into the true iodide by mere washing with water; a splitting up into the true iodide and ammonia taking place in accordance with the following reaction:—

$$3NHI_2 = NH_3 + 2NI_3$$

In order to prepare the iodide of nitrogen in a pure state, a cold saturated solution of iodine in absolute alcohol is mixed with twice its bulk of ordinary liquid ammonia, and the black precipitate which is thrown down is well washed with water.

The experiments of M. Guyard are of especial interest, as opening up a method by which we may hope some day to arrive at an accurate determination of the dynamic equivalent of light; but before venturing to speak confidently regarding this matter, we should like to have a more satisfactory proof than M. Guyard gives, that radiant heat takes no part in the decomposition of the iodide of nitrogen. In fact, we cannot regard M. Guyard's experiment, on which he bases his assumption that heat is not concerned in the re-action, as possessing any value whatever, as it is merely based on an observation that the decomposition under the action of light can take place rapidly without sensible rise of temperature. Now, the fact of the matter is, that this experiment, if it indicates anything whatever, tends to prove just the contrary, as, if the radiant heat decomposes the iodide, it naturally ceases to exist as heat, and takes mainly the form of potential energy which has been exerted in lifting the atmosphere by the elastic force of the gaseous nitrogen liberated, or, what amounts to nearly the same thing, the heat is, to use an old-fashioned expression, rendered latent in converting solid nitrogen into the gaseous state. In addition to this, the kinetic relations of iodine and nitrogen towards each other must be taken into account. Certainly, from a physical point of view, one would consider the possibility of the decomposition taking place without a rise of temperature rather an evidence that heat is an essential factor in this re-action, than that it takes no share.

M. Guyard's contention also appears untenable from another point of view, as the researches of Captain Abney and others conclusively prove heat and light to be absolutely inter-continuous, and no line of demarkation can be drawn between them. The practical distinction is not alike for all, as the extent to which the visible spectrum extends towards the least refrangible end cannot be measured, but must be expressed by a personal constant for each observer.

It is interesting and curious to find that when the decomposition of the iodide of nitrogen has reached a certain point, sudden decomposition or explosion takes place, this decomposition being preceded by a rise of temperature.

We cannot for a moment accept the kinetic equation by which M. Guyard represents the physical aspect of the decomposition (page 357), as many collateral circumstances are not considered at all; but one must not expect too

much, as at the present time chemistry does not possess a notation by which dynamic changes can be represented in the same exact fashion that the gravimetric interchanges of elements can be set forth.

Guyard finds that the maximum of decomposing action on the iodide is possessed by the yellow rays; but his experiments are not so exact as to justify us in concluding more than that the less refrangible rays tend to be more active in the case of the iodide than the more highly refrangible rays.

In conclusion, we may remark that the whole question of the action of light on the iodide of nitrogen affords a most promising field for work to those who have leisure and inclination to labour towards the elucidation of the fundamental doctrines of actinic action.

ON THE RAPID DRYING OF GELATINE NEGATIVES.

WHEN first the use of gelatine plates became general, the difference between them and collodion plates in the matter of the time taken for drying after fixing, &c., was found to be a considerable inconvenience, and one of a somewhat irritating nature.

The photographer had been accustomed, when using a wet plate, to have it, if he so desired, dry, varnished, and in the printing frame within a few minutes of the time when it was developed. The difference was very great when we came to use gelatine plates, and found instructions given that artificial heat was on no account to be used in drying the negatives, and this the more so as a gelatine film dries without heat much more slowly than does a collodion one even under the same conditions.

There have been from time to time introduced methods of assisting the process of drying, and although one or other of these is probably known to every photographer, a resumé of those which have come under our observation, with a few remarks on each, may not be out of place.

The one which will probably occur first to the mind of each of our readers is that in which alcohol is flowed over the plate. This is a simple method, and, if there be no very great haste, probably the best and most practical of any. A word or two concerning it may therefore possibly be useful. It is evident, from remarks that we have heard, that the function of the alcohol (generally not pure alcohol, but methylated spirit) is not by all correctly understood. It is supposed that the alcohol has some mysterious power of absorbing the water in the film. This is, it need scarcely be said, a mistake. What happens when a quantity of alcohol is flowed over a plate is as follows. On account of the "affinity" which water and alcohol have for each other, the two, when brought together, incline to mix in such a manner that any small proportion of the mixture will contain the same relative quantities of alcohol and water as any other. As a consequence, it comes about that some of the alcohol over the films penetrates the latter, whilst some of the water in the film is withdrawn to mix with the flowing alcohol. This is one effect, and it will be seen that were this all, there would remain in the film a more easily evaporated liquid than there was before, and that therefore the film would be more readily dried. There is another action, however: the mixture of alcohol and water has a certain physical effect on the gelatine film. It tends to harden it, and to cause it to shrink up, so that it squeezes out some of the fluid, much as sponge does when compressed.

When the flowing process is repeated, the action is similar, but more powerful, as the mixture of alcohol and water contains a larger proportion of the former liquid than before. When the process is repeated several times, the result is, that the film contains in it only alcohol, practically as strong as that which was poured over it, and that the thickness of the film is materially decreased. There is, therefore, now nothing requiring drying ou except a small quantity of alcohol, and this will, of course, evaporate very much more quickly than would the water which was originally in the film. Still, some little time is necessary in ordinary circumstances, perhaps from a quarter of an hour to half-an-hour. This is if no artificial heat is used, but the objection to artificial heat, which holds when there is water in the films, does not hold to the same extent when there is alcohol. Indeed, if we use absolute alcohol, and flow so frequently that the water in the films is entirely extracted, we may use artificial heat as freely as with a wet plate, because gelatine is quite insoluble in absolute alcohol. Even when ordinary methylated spirit is used, and there are only two or three flowings given to a plate, we may carefully warm it afterwards.

We may here say that when a number of negatives are to be dried with alcohol, the best course to pursue is to use a flat dish, into which there is poured enough of this liquid to completely cover a plate. The plates are left in this dish for a few minutes. The first of these are immediately placed on one side to dry. After three or four have been dried thus, and some appreciable quantity of water has been so added to the spirit, it is advisable to flow each plate, after removal from the bath, with a little fresh spirit.

A method of still further increasing the rapidity of drying was first communicated to our columns by a correspondent now about three years ago. It consists in flowing the plate with ether (which may be methylated) after the operation with spirit has been completed. The ether and alcohol diffuse into each other, so that a liquid even more readily evaporable than alcohol is left in the film. A negative flowed first with alcohol, then with ether, will dry by being placed in a cool draught of air for, perhaps, a couple of minutes. Heat may, however, in this case, be used in moderation without danger.

We must on no account pass over a method of rapid drying which was shown to us by an assistant in a photographic portrait establishment some little time ago.

"How do you dry your negatives?" asked our friend.

"Let them dry of their own accord if there be no hurry. If there be, use methylated spirit"

"Ah, but there is a much better way than that; don't you know it?"

We mentioned ether.

"No, better still; we dry our negatives with a towel."

We naturally thought this was a joke, and asked for a demonstration. Our request was at once granted. A negative from the washing vessel was taken, and was flowed with methylated spirit several times, and immediately afterwards, to our no small astonishment, a towel was taken, and the film was rubbed with this (apparently in no very tender manner) till it was quite dry.

We looked at it expecting to see at least marks and scratches, but there were none such.

We will not venture to say that any brand of plates could be so treated, nor can we be sure that some particular skill or knack, not noticeable to the casual observer, may not be a necessity on the part of the manipulator. We have ourselves never summoned up courage to make the attempt with one of our own negatives.

Whilst on the subject of the drying of negatives, we must not forget to mention the considerable effect which alum has on a film in squeezing the water out of it, and thus making it dry more readily. After a film has been thoroughly treated with alum, a little artificial heat may be applied in drying, even if no alcohol be used. It must be very little, however, because although a film treated with alum becomes, after it has once dried, insoluble in even boiling water, it is by no means so before it has dried. It is quite possible to dissolve gelatine in a warm saturated solution of alum.

If chrome alum (a saturated solution) be used instead of common alum, the effect is much more marked.

THE *SALON* PICTURE SAID TO BE COPIED FROM A PHOTOGRAPH.

In reference to the affair of M. Dantan, alluded to by M. Leon Vidal in our last issue, Mr. A. Davanne writes to the *Siècle* as follows:—"In the present case, the photograph, an original work, is a complete composition, and not a reproduction; yet this initial composition will not have, according to the future law, any of the rights accorded to artistic property; whilst the copy, executed by M. D——— or any other person, confers upon its author rights which are refused to the original production. You will doubtless be struck, Mr. Editor, with this strange anomaly, thanks to which an application of colours, used with more or less art, transforms a composition already existing, and tranfers the legal artistic property to a person who has not originally conceived it." After much newspaper correspondence and discussion in relation to M. Havard's criticism of Dantan's picture, this latter gentleman at last freely acknowledged that he made use of a photograph in the composition of a photograph. No one can reasonably regard this use of the pencil of light as a fault, for why should not artists take advantage of every facility afforded them by science? Still, M. Dantan must be blamed for not freely and at once acknowledging the aid he received from the camera. M. Dantan lays great stress on the fact that he can prove that he worked on the picture for two months, and he further adds: "Loyalty compels me to acknowledge that I have had in my hands a photograph representing the same subject as my picture, and that this document was used by me for the arranging and the composition of my painting, *L'Atelier de Moulage*."

In reply to this, Mr. Havard, who origiually called attention to the matter in the pages of the *Siècle*, writes:—"We never assumed that the author of *L'Atelier de Moulage* did not work at his picture, but we simply insisted that the photograph played an excessive part iu the composition of this remarkable painting. This M. Dantan confesses in part, and may his loyal acknowledgment of the fact serves as a warning to other artists who may be tempted to borrow too freely."

THE SPECTROSCOPE AND ITS RELATION TO PHOTOGRAPHY.

BY C. RAY WOODS.

IX.—Fluorescence and Phosphorescence.

These two analogous, if not identical, phenomena demand our attention, inasmuch as one of them, at least, is familiar to the photographer, by reason of the important part it plays in the measurement of the brilliancy of light, and more particularly in the determination of the rapidity of gelatine plates.

Fluorescence was first investigated by Stokes, about thirty years ago, he having proposed the name on account of this peculiar property being possessed by fluor spar (fluoride of calcium), iu connection with which it was first noticed in a high degree. Fluoride of calcium is met with in nature of various colours, green being one of the most common; but, if placed in a light rich in ultra-violet rays, it glows in a manner more readily noticed than described. A solution of quinine, which is itself colourless, fluoresces with a bright blue colour; cosine dye, in itself of a crimson red, fluoresces with a bright green colour. Canary glass, which is coloured with uranium, derives its value for ornamental purposes from its fluorescent nature.

If we place a piece of white paper or cardboard coated with a solution of quinine in the spectrum, it will be noticed that the rays beyond the violet become visible, appearing in colour a bright lavender blue. The same thing may be equally well shown by using common lubricating oil, as recently pointed out by Captain Abney. Eye-pieces containing a fluorescent substance have been made for the spectroscope to facilitate observation in the ultra-violet portion of the spectrum. They are not extensively used, however, inasmuch as photography furnishes the readiest means of investigating the more refrangible portion of the spectrum.

Phosphorescence is most familiar to as in connection with luminous paint and the luminous tablets used with our sensitometers. Here we have an absorption of light by exposure to some brilliant source of illumination, and a subsequent and comparatively slow emission of it. Becquerel, who has made this subject a study, found that nearly all bodies are phosphorescent; but, in most cases, the phosphorescence is so small, and the light is emitted so soon after exposure, that it requires a special piece of apparatus (which he devised) to show it. As in the case of fluorescence, phosphorescence is caused by absorption of the *ultra-violet rays*, and the emission of rays of lower refrangibility.

That substances should absorb light, and be capable of storing it up for some little time, so that it may be afterwards utilized, is a phenomenon which is apt to cause some surprise, and at first sight appears difficult of explanation. Phosphorescence, however, is strictly analogous to another phenomenon that everyone meets with in his every-day experience, and which, moreover, he usually thoroughly understands—namely, the conversion of light into heat. When light falls upon a body capable of absorbing it, the temperature of that body is raised, and it radiates heat, or sends out *dark rays* to other bodies surrounding it. We have an indirect conversion of rays of high refrangibility into rays of lower refrangibility. So with phosphoresence: rays of very high refrangibility and short wave-leugths, the invisible rays beyond the violet, are absorbed, and rays of lower refrangibility, but still of sufficiently short wave-lengths to excite the retina, are emitted. Considering the resemblance of phosphorescence to the conversion of light into heat, it is little wonder, therefore, that the phenomenon is almost universal.

Among the substances that most readily exhibit phosphorescence are the sulphides of the alkaline earths, the sulphide of calcium being that which is used for making lumiuous tablets for photographers. If a tablet has been kept for a long time in the dark, so that it has lost all its luminosity, and be then exposed to the spectrum, it will be found that luminosity is excited strongly where the ultra-violet rays have fallen, the luminosity decreases where the violet rays have fallen, and stops short in the dark blue or indigo near G. If the tablet be rendered luminous, and then examined by means of the spectroscope, it will be found that the light it emits is mainly confined to a small portion of the spectrum just below G. A small amount of yellow-green, yellow, and red, is also emitted, but it is too weak to impress itself upon a sensitive plate.

For all photographic purposes, the light from the tablet may be practically regarded as monochromatic, and its position in the spectrum almost coincides with that which produces the maximum effect upon bromide of silver. Its value, therefore, in measuring the rapidity of a gelatino-bromide plate is considerable. When we take into consideration, however, other salts of silver, the maxima of which differ very much from that of the bromide, it is pretty plain that the sensitometer cauuot give us a comparative test of their various rapidities. It has been estimated by Captain Abney that if a wet plate be exposed beneath a sensitometer depending on a luminous tablet for its light, the number given would really represent only about one-fourth of its real rapidity. The number given on a chloride plate would represent only about one-third of the true value. When iodide is present in a plate, there must necessarily be some difference between the rapidity of such a plate, and one containing pure bromide only, giving the same number in the sensitometer; but the percentage of iodide that is put into an emulsion is usually so small that the slight difference may be dis-

regarded. In such a case, however, the plate containing the iodide has the advantage of whatever difference exists.

Actinometers depending on the action of light on a phosphorescent tablet have not the same great value that the sensitometer has. In this case, we have to consider what rays have the greatest effect upon a tablet. These are undoubtedly the ultra-violet rays, which do not have as much effect upon a gelatino-bromide plate as the dark-blue portion of the spectrum.

An important application of the phosphorescence of substances was made many years ago in the examination of the infra-red portion of the spectrum. It is well-known that the luminosity of the phosphorescent tablets is increased by the application of heat, but the luminosity lasts for a much shorter time. The application of a cold body, on the other hand, decreases the luminosity, but such luminosity extends over a longer period. Hence may be mentioned, by the way, the importance of allowing an interval of time to elapse between exciting the sensitometer tablet and exposing the plate, thus averaging the luminosity of the tablet which forms the standard light. The red and infra-red (or dark rays, as they are sometimes called) produce the same effect as the more direct application of heat. When a phosphorescent substance that has been rendered luminous is placed in the spectrum, the rays of low refrangibility cause it to become more luminous for a time, but, as the increase in luminosity is but temporary, the lower portion of the spectrum soon appears dark on a bright background.

As far back as 1866, Edmund Becquerel was thus able to show some of the solar lines in the infra-red. More recently, Henri Becquerel has been making further experiments in this direction.

This way of investigating the less refrangible portion of the spectrum is not so good as the photographic method, the lines not appearing as sharp, and the action not extending so low down in the spectrum. The results are evanescent, but by placing the phosphorescent surface in contact with a gelatine plate (as suggested a short time back in the Editorial Notes), a permanent record may be obtained.

By-the-Bye.

THE CAMERA AND THE TRICYCLE.

THE old-fashioned wooden velocipede, with its loud rattle over the stones, its ungainly-looking cranks, and creaking connecting rods, is now a thing of the past. How completely it has been crowded out in the struggle for existence by the spider-like and rubber-shod steel tricycle of the present day!

Who cares much about the history of the velocipede? Still, as photographers, we should remember the share that Nicéphore Niepce and his brother Claude had in the invention. Claude first came to England in order to push his Pyreolophore, an ingenious velocipede in which both hands and feet were used in driving; and while Claude was in this country he died; but Nicéphore, being busy with his photographic researches, altogether neglected the invention.

Respecting the two-wheeled velocipede or bicycle as a vehicle for an outing with the camera, need we say more than that it may answer in the case of a few adventuresome spirits who do not mind risking their own limbs and their own apparatus; but the main point for our readers now to consider is how far labour can be saved by taking out one's photographic kit on the far more comfortable three-wheeler or tricycle, and in this matter, as in many others, there is no alternative but to rely upon the experience of others. "But surely it is easy to borrow a tricycle and gain experience for oneself?" may be said. There are, however, more difficulties than one; indeed, in the first place, it is by no means easy to borrow a tricycle—at any rate, such a one as can give a just idea of the labour involved in 'cycling; and even if a first-rate tricycle were borrowed, several weeks' practice would be necessary before the full advantages of 'cycling as a means of locomotion could be thoroughly brought home to the rider. One who has a first-rate tricycle would be considered indiscreet if he were to lend it, even to an experienced rider; but very, very few would be rash enough to place such a machine in the hands of a learner; indeed, it is almost considered an axiom among tricyclists, "Never lend your machine to a friend unless you wish to make an enemy of him." Still, it may be urged, there are many persons who let machines out on hire, and what can be easier than to have one of these for a few weeks? In actual practice, however, difficulties will arise here, as it will be found that, although the dealer may be quite ready to lend out his best machines to experienced riders, the non-rider can get nothing but such a machine as is likely to make him forswear tricycling for ever; and if the patched-up wreck should give way at any point, he will, perhaps, be called upon to pay more than its value for repairs.

As before stated, several weeks' practice is required in order to enable one to judge of the real advantages of tricycle-riding over walking; and not only must one find the best position for the seat, and the most suitable height for the handles, but a more important point still: there are certain muscles which must be broken in to the work, muscles which are scarcely exercised in walking. Hence it is that the first half-hour's ride on a tricycle often serves to tire you out, and effectually prevent further trials.

For the above reasons, it is well to so far trust to the experiences of others as to boldly spend the £20 or so which a first-rate tricycle will cost, instead of tampering with half measures, as the latter are almost of necessity misleading.

A second-hand machine is not, as a rule, a very satisfactory purchase; but if you are not only a mechanic, but have also studied the details of tricycle construction, you may often obtain a really good second-hand machine at a little more than half the price of a new one; but one always runs some risk.

Although there are nearly four hundred kinds of tricycle in the market, we may class these under the heads of the front-steerer, the back-steerer (hayfork or bicycle action), and the "Rudge" or "Coventry" tricycle; in the latter, a large driving wheel is at the left-hand side of the rider, and two smaller wheels are at his right, both of these being simultaneously acted on by the tiller. We are inclined to put the front-steerer out of the competition, and to only consider the back-steerer or the hayfork type and the "Coventry." In the case of the former, the leather case containing the apparatus should be suspended beneath the fork of the backbone by straps passing fairly underneath the package, and the stand (a folding one) should be firmly attached to the top of the backbone, the end, perhaps, projecting, tail fashion, over the rear wheel, this arrangement being made to so place the load as to tend to neutralize the main disadvantage of the back-steerer. Instead of a stand, the Lancaster clip (p. 344) may be used. Should the "Coventry" form be adopted, the case containing the luggage is best supported on a light frame fixed immediately behind the seat, while the long bar on the right-hand side takes the tripod. Indeed, our first photographic experiences with a tricycle were gained on a "Coventry," not, indeed, as the machine is now made, but in its original form, with long foot levers and connecting rods instead of the gear wheel and chain now used. With this machine we found no difficulty, easily taking out a whole-plate kit for wet collodion work to a distance of twenty miles; but on our present machine, a modern one of the same type, we could do much more than this without over-fatigue.

One word about the relation between speed and power

When the road is level and the load light, the gearing of the machine may be such that a complete revolution of the treadle crank shall propel the machine as much as 15ft., but with a machine so geared it is impracticable to do hill work or to take much of a load, consequently it is far better to select a slower gearing; let us suppose one which gives us a progression of a little over ten feet for each revolution of the treadle shaft, this corresponding to what is technically known as a "40-inch" gearing. An efficient brake is of great importance, and great care must be taken not to let the loaded tricycle get the better of the rider in running down hill.

What kind of ground can be covered, and how much luggage may be taken, is a natural question? It should suffice to say that the Furca Pass has been "doue," and that the carrier tricycle used by the proprietors of the *Evening Standard*, in London, and *Le Matin*, in Paris, takes loads of as much as a hundred pounds, and makes as good speed as the average Hanson cab. Mr. John Browning, writing in the last YEAR-BOOK, speaks of a load of sixty to eighty pounds and a twenty mile ride. Indeed, the tricycle has now a commercial importance which does not seem at all likely to diminish, but rather promises to increase.

Readers who may wish to study out the subject of 'cycling as adapted to the wants of the photographer, may find severl articles in our back volumes, and also in the YEAR-BOOKS, and our advice to those in doubt as to whether to adopt the tricycle, is emphatically, "do so, by all means."

A CHEMICAL PHOTOMETER OR RADIOMETER BASED UPON THE DECOMPOSITION OF IODIDE OF NITROGEN.

BY M. ANTHONY GUYARD.*

IODIDE of nitrogen which is moist, or better still, suspended in pure water, decomposes with effervescence when exposed to diffused light or other luminous radiations, and the decomposition of this body by light is a phenomenon of such exquisite sensitiveness that the iodide of nitrogen constitutes a true chemical radiometer; but there is this difference: in cases when the radiometer of Crookes remains unmoved, the iodide of nitrogen is decomposed with a notable degree of activity.

Let us, for example, allow some iodide of nitrogen to lie at the bottom of a vessel full of water, and it will be found that it remains unchanged as long as it is kept in absolute obscurity; but one can scarcely expose it to a dull diffused light without finding that bubbles of gas are evolved; and in full daylight the number of the air-bubbles increases, and these are formed with a certain rapidity and much regularity.

Even in diffused light it is easy to perceive that the decomposition is determined by the surrounding light. If the sun shines, the decomposition becomes rapid; but should a cloud pass, it diminishes immediately, while a further diminution in the evolution of gas takes place if the sky becomes generally overcast.

Supposing that a bundle of luminous rays is allowed to impinge upon the iodide, the decomposition takes place with considerable energy, and the effervescence is as distinct as that which takes place when sulphuric acid acts upon chalk, the effervescence lasting as long as the action of light is maintained, and ceasing immediately the iodide is brought into darkness. Those portions of the iodide of nitrogen which remain round about the portion illuminated by the intense pencil of rays only evolve a few bubbles, as the iodide appears to be a bad conductor of the molecular disturbance which is produced locally by the direct action of the pencil of rays.

Nothing can be more strikingly beautiful than this experiment, in which the bundle of rays, whatever its form, is converted into a collection of bubbles having the same configuration. Immediately the luminous rays are shut off the active effervescence ceases, but to continue in a modified intensity proportional to that of the surrounding diffused light, or to totally stop, if the iodide is placed in absolute darkness. Once more, the active decomposition may be called into existence by exposure to the full intensity of the luminous pencil, and so on as long as any iodide remains undecomposed.

The decomposition of the iodide of nitrogen is powerfully affected by the various coloured radiations, but under the action of violet rays, as obtained by transmitting light through a solution of permanganate of potassium, it diminishes; but under the influence of the blue rays (sulphate of copper) it augments slightly. Orange-red rays, obtained by transmission through a solution of bichromate of potassium, have approximately the same effect as white light, while yellow rays produce a maximum of decomposition far exceeding that due to white light.

The use of the iodide of nitrogen photometer should, one might expect, be very easy, and it may perhaps render it practicable to determine the chemical and mechanical equivalents of light.

One may, for the present, define the chemical equivalent of light as the quantity necessary to decompose one equivalent of ammonia with the liberation of one equivalent of nitrogen; and the mechanical equivalent of light, as the elastic force, or the work produced by the passage of the equivalent of nitrogen into the gaseous state. It is probable that in an actual experiment the light is transformed into heat, and then accompanies the gas. It remains to be proved that it requires exactly as much light to cause a decomposition as to determine a combination—or, in other words, it will require as much light in the iodide of nitrogen radiometer to cause the separation of the constituents of one equivalent of ammonia as to determine the combination of their equivalent of chlorine, and of hydrogen in the photometer of Bunsen and Roscoe. By representing by ϕ the chemical equivalent of the decomposition of the light, and by ϕ' the chemical equivalent of combination of light, we can arrive at the following dynamic equation:—

$$\underbrace{\phi + NH_3 - I_3}_{\text{Decomposition}} = \underbrace{\phi' + Cl_3 + H_3}_{\text{Combination}}$$

The estimation of the force occasioning combination as exemplified by the photometer of Bunsen and Roscoe, in which the maximum of action situated in the violet, and of its decomposing action, as exerted upon iodide of nitrogen, with a maximum in the yellow, should be of great interest, and opens up new fields for the optician.

It must be called to mind that the maximum of decomposition has already been proved to be in the yellow, as the result of the excellent researches of Caillelet, Cloëz, and Gratiolet on the decomposition of carbonic anhydride and chlorophyl in the leaves of plants. Still these observations, bearing upon highly complex phenomena, cannot render photo-chemistry the same kind of service as may be expected to result in the case of bodies so well known as ammonia, iodine, and water. All these can be readily obtained of an identical degree of purity, and the reactions, which can be carried out in apparatus of the simplest construction, are well under control. The reaction of light on iodide of nitrogen is calculated to give to chemistry, physics, physiology, and industry much valuable information.

The reaction of iodide of nitrogen is to light what the voltameter is to electricity, and it may be called the *chemical radiometer*. The equivalent of iodine or that of nitrogen may be destined to become the unit by which sources of light are to be measured, whether the light be that by the humble night-lamp, or that of the orb of day.

The decomposition of iodide of nitrogen under the influence of light is so strongly defined that the eye can dis-

* A communication to the *Annales de Chemie et de Physique.*

tinguish the least variation, so that the iodide of nitrogen will become the most valuable quantitative reagent used in optics; indeed, with a few centigrammes of iodide of nitrogen one may obtain six or seven cubic centimetres of nitrogen in fifteen or twenty minutes, under the action of the yellow rays.

An important point is the circumstance that the physical conditions which may contribute to the decomposition of the iodide of silver are at least as simple as the chemical conditions which obtain; indeed, one cannot well attribute the effect to calorific radiations accompanying the light, as the luminous rays alone influence the decomposition of the iodide of nitrogen.

This may be proved readily enough by placing a small iodide of nitrogen apparatus in a vessel of glass, through which a current of water at a constant temperature circulates rapidly, and a small thermometer placed in contact with the iodide of nitrogen shows no variation, however intense the light which causes the decomposition may be.

When iodide of nitrogen is suspended in water and decomposed under the influence of light, a period arrives (perhaps corresponding with some determinate constitution of the substance) when a violent explosion takes place, which serves to break the glass vessel into thousands of fragments, and what is remarkable is that such explosions are far more violent than when the iodide is exploded by other means.

When vessels of thick glass are used, a period is arrived at when partial explosions take place at intervals of five or six minutes; but generally a total explosion ultimately occurs, the glass vessel being then broken.

In a vessel of thin glass, on the contrary, there are rarely more than one or two partial explosions, the explosions being generally total. In many cases, a sudden elevation of temperature has been observed to precede the explosion, and this elevation has often served as a useful warning.

The author will continue his experiments.

A VISIT TO THE "STANDARD OF WHITE LIGHT."

BY YOUR STROLLER.

BEING in Paris a short time ago whilst the Electrical Congress was sitting, I happened to stumble against one of the English delegates, who seemed full of the new standard of white light, of which, up to that time, I had learnt nothing. Being of a turn of mind which naturally resents anything like an acknowledgment of ignorance, "I knew all about it, you know," and by degrees managed to pick up from answers to casual, but, at the same time, rather leading questions, that the new standard of white light was the light given out by melting platinum, and that there was to be an exhibition of this interesting curiosity. I was dragged by the arm by my friend across the river, and whilst he energetically explained the peculiarity of this new standard—sometimes, it must be confessed, in rather a depreciative manner—eventually we found ourselves in the *Rue d'Ulm*, and outside the *Ecôle Normale Superieur*. A ring at the bell, and an explanation in execrable French by *mon ami*, caused us to traverse a narrow open passage, and to enter into *la troisieme porte à droite*, as the *concierge* told us. Here we were ushered into Monsieur Débray's laboratory, the man, of all others, who is fitted to deal with that most refractory metal, platinum, since it is here where his classical experiments on its purification and properties have been carried on. "*Descendez, Messieurs, je vous prie*," says M. Débray, after our introduction to that famous chemist, and we did descend to the cellars below; and here, in a vault painted pitch black, which might have been well left to ghouls and other such-like folk, we saw the standard of white light. Monsieur Violle, the energetic proposer and carrier out of this standard, greeted us cordially, and took us round from the deep gloom to a hissing and spluttering crucible, in which was some glowing liquid of some kind being *warmed* by an enormous jet of oxygen and hydrogen, which played on and round the surface of this liquid. A square opening in the cover of the crucible, we were informed, was a square centimetre, and the glowing liquid was melted platinum. The surface was not uniformly bright, but ever and anon little particles and scum of something or another would cloud it. "Not very satisfactory," said I, to my friend; "not uniform enough." Wait a minute, however. "Now," said M. Violle, "look at it at the moment it solidifies." And we did. The blow-pipe was stopped and in five or six seconds the surface of the liquid assumed a perfect uniformity. The platinum had begun to solidify. I nudged my friend, who did not, somehow or another, seem half pleased. There, then, was the new standard—*molten platinum at the moment of solidification*. Above the orifice of the crucible was a mirror, at an angle of forty-five degrees, reflecting the light emitted on to a photometer, with which the comparisons were made, the other source of light being a Carcel lamp of the ordinary moderator type. "How much platinum have you in the crucible?" I asked of Monsieur, who was conducting the melting operations. "About 30 kilogrammes," he replied.

I should like to have turned that 30 kilos into money, though I did not say so. I ventured to remark that the oxygen used must be pretty considerable, and so it was, for we again descended, and came upon what would ordinarily be considered a fair sized gasometer for ordinary house gas, and in it, we were told, was stored oxygen under a pressure of some atmospheres. Orchard, of Knightsbridge, would have made a fortune by selling it by the foot, but they don't seem to think much of that lot in Paris. They measure it by the ton, I should fancy.

This cellar is not unknown to other scenes of science, for here it was that Mascart made his celebrated experiments in spectroscopy, and determined wave lengths, and what not, in a manner which those who understand these kind of things say will remain as a record for all time. "I lived down here for some months," said Monsieur Mascart, who was present. I can't say I envied him. The Bastille was a joke to this, I should say, and yet Monsieur did not have that loathing for the place which I should have had under ordinary circumstances.

But the standard of white light is my subject, and I must confess that if the standard has to be used with such apparatus as I saw, and with such precautions, I should guess that Paris will have the unique honour of being the permanent home of the standard. Fancy 30 kilos of pure platinum, and crucibles that are incapable of giving up impurity to the metal. Fancy, too, the chlorate of potash and manganese that must be used to prepare the enormous quantity of oxygen required; and then fancy the anxiety of catching the light from the molten metal at the moment of solidification; and then you have further to fancy that when the Carcel lamp has been standardized, the quality of oil and of wick may vitiate days of experiments. As a practical unit this fails entirely, and I should say that it will be long before it is adopted in any way except theoretically. As regards photographic purposes, it is useless. But I have not told what is the standard. Here it is in French:—

"L'unité de lumière simple est la quantité de lumière de même espèce emise en direction normale par un centimetre carré de surface de platine fondu à la temperature de solidification. L'unité practique de lumière blanche est la quantité totale de lumière emise par la même source."

In English it is thus:—"The unit of simple (monochromatic) light is the quantity of light of the same kind emitted in the normal direction by a square centimetre of melted platinum at the temperature of solidification. The practical unit of white light is the total quantity of light emitted by the same source."

Well, it may be *practical*, but it is not *practicable*. What we photographers want is something more simple. This, perhaps, may be given us at the promised Photographic Congress at Brussels.

CARBON PRINTING.

Lesson IV.

Making Transparencies for Enlargements.

For transparencies a special tissue is made, the colouring matter being indian ink in an extremely fine state of division, the quantity of pigment used being more than double that present in ordinary tissues. The sensitising, drying, and printing of transparency tissue is the same as for the ordinary, except that the exposure to light is from twice to thrice as long.

The development of transparencies is effected upon glass plates covered with a thin film of gelatine composed of—

Gelatine	1 ounce
Bichromate potash	30 grains

Dissolve by the aid of heat; then—

Water	20 ounces

Filter before use.

The plates may either be polished, and then coated, or they may be cleaned in acid and water, and then, after a thorough rinsing, be coated with the gelatine solution whilst wet.

When coated with gelatine, place the plates upon a rack to dry, and when dry, put them into sun or daylight so as to render the gelatinous coating insoluble, for which purpose the bichromate is used. When the exposed tissue (which should have an opaque safe edge of at least half-an-inch all round the opening in mask) is taken from the frame, turn up the edges about an eighth of an inch all round so as to form a shallow tray, and pin upon a light board; then coat with plain collodion, and when set, hang up to dry in the dark-room; then, with a pair of scissors, trim off the turned-up edges and immerse in cold water. As soon as sufficient water has been absorbed, insert a prepared plate underneath (the plate being a little larger than the piece of tissue), and place the tissue in position upon it; then lift from the water and proceed to squeegee.

Develop the image in water at 120° F., and when development is complete rinse in cold water and place away to dry.

If a transparency is to be made from a negative that is flat and weak, instead of developing upon a gelatinized plate, polish a plate and coat with plain collodion, next immerse in cold water until greasiness disappears, then (omitting the coat of collodion) immerse the tissue in cold water, and, before squeegeeing, cover the plate and tissue with Mackintosh cloth, so as to avoid disturbing the collodion between the edges of the tissue and glass plate. Develop as usual, and, when dry, intensify with a strong solution of permanganate of potash, when the transparency will, instead of being weak and flat like the original, be strong and vigorous, and capable of yielding an enlargement much superior to the original negative.

In making transparencies for enlargements, care must be taken that all detail in the light lights is present, else the result cannot be satisfactory.

From the transparency an enlarged negative is made in the camera, either by the wet process or upon a gelatine plate, the film of transparency being towards the lens; the negative, when dry, is retouched, and edged with black varnish, all round, for a safe edge. A print is then made upon carbon tissue, and when the exposure is completed, a piece of *single* transfer paper, a little larger than the tissue, is cut from the band, the two are immersed in cold water, examined for air-bubbles, and, when the tissue has absorbed sufficient water, they are removed, with the faces in contact, laid upon a smooth bench (tissue being uppermost), and the squeegee applied to the back.

Development is effected by immersion in hot water, which will soon loosen the backing paper, which is stripped off; gently laving with hot water will complete the development, when the print is transferred to cold water, and from thence to a strong solution of alum, which will remove any traces of bichromate that may linger in the paper. After remaining in the alum for ten or fifteen minutes, again place in cold water, and give three or four changes, after which the print is hung up to dry, when the print is ready for mounting, and requires no second transfer, having been made from a reversed negative—this being the single transfer process of carbon printing.

Notes.

A Photographic Society has been formed in Derby, and Mr. Fred W. Simpson has taken the office of Honorary Secretary.

A fire, which broke out in Swan's Electric Light Works at Lille, on Friday last, did much damage to property, and four persons were injured.

That yellow light should exercise an actinic effect greater than that of white light, is not quite what one might expect from every-day experience with silver salts; yet M. Guyard says that iodide of nitrogen is decomposed more rapidly when exposed to yellow radiation than to white light.

An instance of a photograph of a natural history specimen being preferred to the actual thing is interesting; but we find that, at a recent meeting of the Massachusett's Institute of Technology, Mr. Praz preferred to exhibit a photograph of a remarkable cotton stalk in a fresh state rather than the dried specimen itself.

In the course of his interesting paper on the cotton plant, he called attention to the value of photo-micrography as a means of building up such a history as may be expected to ultimately lead to solid information in relation to cotton culture.

A microscopic examination at once reveals the quality of the cotton, as the better it is, the more perfect its spirality, and the more regular, sharp, and positive are the oily deposits. But to merely observe is a very different thing from obtaining permanent records, as these must ultimately throw light on the influence of meteorological and other conditions. India and the United States might do well to exchange series of such photographs.

A correspondent writes:—"Having a large stock of glasses which had become so stained and corroded as to be apparently valueless, I tried Mr. Plener's plan of using hydrofluoric acid. Six ounces of the commercial acid and a quart of water were mixed together in a gutta-percha dish, and each plate was immersed for about ten seconds, when it was rinsed with water. Nothing could have been more satisfactory."

In dealing with hydrofluoric acid some precautions are necessary, as it must not be allowed to come in contact with the skin, and it should not he used in the same apartment where there are lenses or other optical instruments. A trace of *the vapour* takes the polish off glass very rapidly.

The legal statement of the case in the action brought by Mr. Sarony, of New York, against a Lithographic Company for an infringement of copyright in a photograph of Mr. Oscar Wilde, and referred to in the NEWS some time ago, is funny reading. The document, with much circumstantiality, sets forth that the photograph in question "is a useful, new, harmonious, characteristic, and graceful picture, and that said plaintiff made the same at his place of business in said city of New York, and within the United States, entirely from his own original mental conception, to which he gave visible form by posing the said Oscar Wilde in front of the camera, selecting and arranging the costume, draperies, and other various accessories in said photograph, arranging the subject so as to present graceful outlines, arranging and disposing the light and shade, suggesting and evoking the desired expression, and much more to the same effect. If all this is necessary to explain what sitting for one's portrait is, one would rather take a photograph than describe it.

Are the best phototypic blocks which can be made by such processes as those of Ives or Meisenbach equal as works of art to the best wood engravings? This is a question very often asked, and, like many other questions, it cannot be answered by a simple yes or a direct no.

The photographic block picture is undoubtedly the more truthful to nature, provided that all the conditions conducive to technical excellence have been fulfilled, as every gradation of light and shade is represented at its proper value; but still, those who have been accustomed to wood engravings complain of a flatness, and say that the outlines are not well defined, or rather that they lack boldness and decision.

These charges have a certain amount of truth, for the photographic engraving has all these faults in comparison with the wood engraving; unless, indeed, we may say that the wood engraving has the contrary faults when compared with the photographic engraving.

The fact is, that almost all wood engravers put in false and exaggerated outlines in order to lead the eye to the main objects in the picture. Let us suppose the case of a cubical box lighted from all sides and placed before a background of nearly the same tint: the draughtsman begins by drawing lines to represent the edges of the cube, and when these are done, he tries to introduce such shading as may be suitable; but the camera only reproduces the shading. These artificial outlines, which the wood engraver may regard as the main feature of a reproduction, are often in reality a mere index or pointer to the true picture. As long as the public prefer to have the index and the true picture combined, so long will they prefer the wood engraving to the phototype block.

It would be interesting to know who were the experts consulted in the framing of the new Copyright (Works of Fine Art and Photographs) Bill. From internal evidence it would seem as though the photographic publisher, and not the photographer, had had his hand in the matter.

On one point some photographers will be of the same mind as the publisher. This is Clause 20, relating to penalties on production and sale of fraudulent works. Unscrupulous men have been known to exhibit in their specimen cases as their own work photographs which they have purchased. We know an instance of a photographer of celebrity in connection with children's portraits being intensely gratified at seeing in the window of a provincial man, and put forth as the productions of the latter, several pictures of his own taking. Clause 20, we fancy, is capable of being construed so as to impose a penalty upon anyone exhibiting another man's work as his own.

The history of the first dozen plates tried by an amateur friend new to dry plate work is instructive. No. 1 fogged—light discovered entering dark-slide through an ill-fitting shutter. Dark-slide repaired before trying No. 2. Nos. 2 and 3 fogged—light between flange of lens and camera; remedy applied. Nos. 4 and 5 fogged—minute defect discovered in bellows body. No. 6 fogged—light entering camera through old screw-hole unplugged. Nos. 7 and 8 fogged—light of dark-room not sufficiently non-actinic. No. 9 fogged—door of ditto not light-tight. Nos. 10, 11, and 12 fogged—lid of plate box accidentally left open. He thinks by this time he knows a little about the causes of fog.

It is odd to read that in order to prevent crowding, a small fee will be charged for admission to Mr. Francis Galton's "Anthropometrical Laboratory" at the Health Exhibition. The long and mysterious title may perhaps stimulate curiosity, but if all the attraction when one gets inside is the filling up of a formidable schedule with personal particulars, the place will scarcely be crowded. The average person can scarcely be expected to furnish information such as Mr. Galton demands. Who knows his or her "height sitting and standing, strength of squeeze and pull, swiftness of direct blow, acuteness of vision as measured by a test type," &c.? Of course, if you are enabled to be enlightened on these points at the laboratory, it may be worth a visit; but the thing would be more popular and satisfactory if Mr. Galton photographed every visitor, keeping a copy himself, and giving one to the sitter.

When Dr. Vogel was in America last year, his attention was directed to albumenized paper, and he told us that paper which answered well in Europe was very often unsatisfactory in the United States. He ascribed the failure to lack of moisture, and was of opinion that the atmosphere of the States was, as a rule, too dry for paper of European

manufacture. In Algeria, however, it seems, photographers are very content with the ready-sensitized paper they receive from Europe in round tin cases, and in some instances the material, we are assured, keeps six months without discolouration. On a recent occasion we certainly saw some samples prepared in Paris which were as white as home-sensitized paper.

Between the Health Exhibition and its title a wide gulf exists, unless, indeed, one may act on the undoubtedly correct idea that everything mundane bears on health and should be included. But why include whole streets which consist of the shops of lollipop makers, grocers, cheesemongers, confectioners, feeding-bottle makers, florists, bird stuffers, electro-plate manufacturers, and coffee-mill makers, and give no prominence to the technology of the healing art as exemplified by pharmaceutical products or processes, and the wonderfully perfect mechanical appliances used by the surgeon; to say nothing of such exhibits as might be calculated to instruct the public in those numerous and laborious researches which have almost raised medicine to the rank of a science?

As it is, we have little more than a number of stalls of the "Aquarium" type, added to a large fag-end remaining over from the Fisheries Exhibition.

As an example of the extensive use to which photographs are put by the exhibitors for advertising purposes, we may mention the case of a seedsman surrounding his stall with large, but not very good, photographs of his products and premises.

"Do you make any charge to the dramatic profession for photographs? I require some for professional use only, and have heard you very highly spoken of, and should be glad if you would drop me a line."

So writes the manager of a travelling company to a provincial photographer of good standing; but the reply was eminently unsatisfactory, as merely indicating the usual charges, and expressing a desire on the part of the writer to know if the manager kept his house always open to the members of the photographic profession.

There is a sharp competition going on just now among American makers of dry plates. Two firms are offering 600 dollars, and one firm 500 dollars, for the best work produced on their dry plates, the prizes to be awarded at the forthcoming Cincinnati Convention.

A modest photographer in the provinces, who is diffident about asking his sitters for payment beforehand, gets over the difficulty this way. He has in the studio a neat tablet, having on it the inscription, "Previous payment is in all cases requested." This is hung just about the spot where the sitter should look, and it is the easist matter in the world to say, "Kindly turn your eyes in this direction," and indicate an imaginary spot just below the tablet. As he truly remarks, those who have already paid won't mind, and those who havn't, may take the hint.

A French amateur told us a home truth the other day, which landscape photographers will do well to note. His complaint was, that in taking pictures for sale, the photographer frequently destroys the *point de vue*; that is to say, that if there is a fine view from this bridge or that pass, he is not content to set his camera on a level with the eye, but must needs employ a very high stand—sometimes a pair of steps fifteen feet high—whereon to set his camera. The consequence is, that although he may possibly see a waterfall to better advantage, or get a finer view of a palace, the photograph is not so familiar as it would otherwise be. The visitor or tourist does not recognize the picture at once—there is something unsatisfactory about it that he cannot explain—and hence he sometimes objects to purchase.

For tourists, as a rule, like to buy what is familiar to them. No doubt many who visit Rome, or Naples, or Paris, as the case may be, select a few pictures of public buildings to take back with them, without much question as to *point de vue*. But others again, there are, who do not buy a photograph unless it shows them a scene exactly as they have seen it. This class does not run after photographs, but seeing a picture that will be a perfect souvenir to them, they buy without hesitation. Our French correspondent gave it as one reason why he carried a camera, that he could not always purchase photographs taken from a standpoint with which he was familiar.

It is surprising how little use is made in the studio of the silver birch. It is a wood that is practically valueless to the carpenter, and may therefore be purchased at a nominal price. Yet the picturesque markings on the bark, which are eminently photographic, render it very suitable for studio accessories when rustic surroundings are desirable. Still, as its effect is somewhat florid, it behoves one to study its use a little.

Thus, a fair-haired girl, habited in a straw hat and summer attire, would accord well with the thin, elegant stem, and silvery markings on its bark, whether the birch wood was employed in the form of a tree-trunk to hold or lean against, or in the shape of fence, stile, or rustic bridge. On the other hand, a dark beauty, with more sombre costume, might be better harmonized for an outdoor picture with a pine trunk, such as Mendelssohn employs with excellent effect in many of his pictures.

It is impossible, of course, to make very much headway in a science without a thorough grounding in its theories; still, there can be little doubt that one of the best ways to impart knowledge is to connect in the student's mind some practical application of it. Sometimes this is difficult, if not out of one's power altogether; but still, where feasible, it is the best way of giving instruction. A student, if he once gets interested in the application of a science, will then follow it of his own accord, and require no further incentive. This is exemplified in the lecture-room every day; if there is nothing visible but the green baize lecture table and a glass of water, the young student fails in interest from the commencement; if, however, there are plans and diagrams

or apparatus and models visible, to supplement the lecturer's words, then scholars are all attention from the commencement. Photography, to take an instance, is a wonderful incentive to the chemical student, just as telegraphy is to the student of physics; every one who takes to a branch of applied science of this character ceases at once to be a passive student, and becomes an active one.

Specifications Published during the Week.

3026. J. and A. G. HOPKINS, "New apparatus for the exposing of photographic sensitive plates in cameras."

Our invention as above, to be designated hereafter as the Simplex Slide, and Reversible Camera Back, consists of a perfectly light-tight box or slide, made so as to receive the sensitive plate in a carrier, which said carrier is made to run in grooves in slide, and which cannot get displaced when putting in or taking out plates; this said slide is made perfectly impervious to light by means of a simple lid affixed to the plate-carrier, in such a manner that when the said carrier containing sensitive plate is pushed home into the slide, and by means of a simple turn of screw let in on top of slide, into a screwed plate on plate-carrier to keep it fixed, it becomes perfectly proof against light. The camera-back is so made, with an opening on top the exact size of the plate slide, which, when exposure is to be made, it is fixed thereto by means of two levers each side of back inserted in small grooves made in plate slide, which by this means makes the whole perfectly rigid. The exposure of plate is made by simply removing the small screw on top of slide, and inserting a rod with screw at end, so as to screw into plate-carrier, by which means the plate is let down or drawn up at will of operator; the said rod to be just the length of slide, so that by simply pushing the plate-carrier down in grooves into the said back, the sensitive plate is kept in position by means of a spring which is attached to back of plate-carrier; the plate is then ready for exposing. The camera-back is made with a door, so that the focussing-screen can be inserted or taken out without interfering whatever with plate-slide when attached to camera-back, so that the focussing of a subject and exposure of plate on same becomes a most simple and very easy method, and very quickly done. Having now particularly described and ascertained the nature of our said invention, and in what manner the same is to be performed, we declare that what we claim is:—

1. The plate-carrier, with spring back, and light-tight lid affixed.

2. The slide or box to receive plate-carrier.

3. The arrangement of rod with screw end passing through top of slide into a screw-plate on carrier for bringing into position the sensitive plate into camera-back for exposure, and then also into slide after.

4. The arrangement of the screw passing through top of slide into screw-plate of carrier, for keeping slide impervious to light when closed.

5. Reversible camera-back, made with an opening to receive plate-slide.

6. Levers on camera-back, for making slide quite rigid when brought into grooves of slide.

7. Method of inserting focussing-screen into camera-back without interfering with slide while attached to the back.

8. The camera-back can be made to fit any camera, and any number of slides can be used with same.

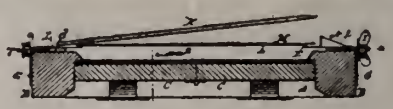
5045. ALFRED JULIUS BOULT, of 323, High Holborn, in the County of Middlesex, Engineer, "Improvements in rings for containing portraits, or the like." A communication from Emmanuel Diamant, of Budapest, in the Kingdom of Hungary. —Dated October 23, 1883.

This invention relates to an improved construction of a ring, so made as to contain or enclose two or more miniature portraits, or the like. In making a ring for four portraits, the bezel carrying the stone, or a plain or ornamental plate, is hinged to the ring, and on the underside of this bezel or plate a frame of a suitable kind, preferably one that can be removed at will, is affixed to receive one picture. Another frame is placed upon the body of the ring just below the hinged plate or bezel, so that these two are, when the hinged part is closed down, hidden or covered by the stone or other ornament. The hinged part may have any convenient kind of fastening to keep it closed. At each side of the hinged top there may be another hinged plate covering a frame to contain a picture, and these two side plates may either be kept down by the plate under the stone, or have separate fastenings. All the places may be so fitted that they will fly open (simultaneously if suitably arranged) upon their fastenings being released. If two portraits only are required to be inserted, the two side plates and the frames underneath the same are omitted.—*Provisional Protection only.*

Patent Granted in America.

298,901. OLIVES PERRY SCOTT, Quincy, Ill. "Printing and Vignetting Frame. Filed, April 28, 1883. (No model.)

Claim.—1. The combination, with a printing frame, of a housing or vignetting attachment fitting over said frame, and adapted to be vertically adjusted thereon, having the central opening and the skeleton frame, the said wire frame being



attached to the housing, and operating to hold the paper, substantially as described.

2. In combination with a printing frame, a vignetting attachment consisting of a housing fitting over said frame, and provided with a central opening, slotted sides, and thumb-screws for the adjustment of the attachment, the skeleton frame for holding the paper in place, and the spring or springs beneath the said vignetting attachment, to force it upward from the frame, substantially as described.

THE SILBER LAMP.

BY C. L. FIELD.

I WILL content myself with giving a brief description of the Silber lamp. At first sight the burner appears to be a simple aggregation of concentric tubes—and this, in fact, it is. The use of these, especially the innermost, bell-mouthed pipes, becomes very apparent in the lighted lamp. From the right hand one of these two lamps, both burning petroleum, with equal wicks and similar chimneys, I remove the interior tube—immediately the flame lengthens and darkens, wavers and smokes. The current of air which is, by this internal conduit, directed into the interior flame surface, is the essential principle of Mr. Silber's invention. The wick is contained in this metal case, surrounded by an air-jacket, which passes down the entire length of the lamp, leaving a small aperture at the base, through which the oil flows from the outer reservoir to the wick chamber. Thus, by the interposition of an atmospheric medium, the bulk of the oil is maintained throughout at a low temperature. Two concentric bell-mouthed tubes pass down the interior of the wick case, and communicate with the air at the base of the lamp, which, you see, is perforated for the purpose. Two cones, perforated, the inner and smaller throughout, the largest only at the base, surround the wick, and heat the air in its passage through the holes to the flame. The effect of these appliances is, firstly, by the insulation of the outer reservoir, to avoid all danger of vapourisation of the oil, till actually in contact with the wick. As it is drawn nearer and nearer the seat of combustion, the hot metal wick-holder heats, and ultimately vapourises the luminant, so that at the opening of the wick tube concentrically with the air conduits—all of which are exceedingly hot—a perfect mixture of vapour and hot air is

formed, and this it is that is burnt. An all important feature is the shape and position of the chimney, which, Mr. Silber asserts, influences the flame to the extent of quadrupling its brilliancy if properly adjusted. The numerical results obtained by the photometry of these lamps, as to brilliancy and price, are truly gratifying. I refrain from quoting disjointed values and beg to refer you to two tables given in Mr. Silber's paper.

I cannot enter into all the beautiful applications of this principle, with which the Silber Light Company have so kindly and bountifully supplied me. But upon this marine lamp, as it involves certain important modifications, a few moments may be spent with advantage. Its purpose is to maintain an even and steady light, during a violent tempest, with, it may be, waves dashing over it. Fig. 1 shows you this lamp, with the top

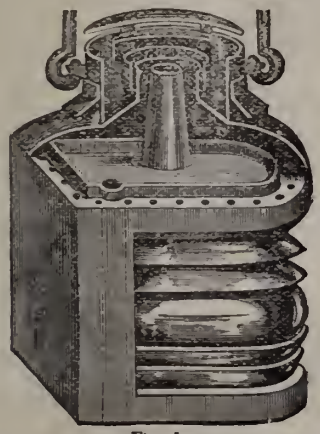


Fig. 1.

ssected. It is provided with a cut dioptric lens, and a powerful reflector, and the light, which is equal to that of fifty candles, can be seen on a clear night for more than five miles. Fig 2 shows

Fig. 2.

the interior of the lamp, in a glass model made for the purpose. The air enters a chamber, by means of two tubes, about one-third of the height of the chamber itself, perforated. This checks aud dissipates the most violent current. After entering, the air expands with the heat, loses much of its velocity, and, being still cooler than the air inside, above the flame, descends to the chamber below the burner (Figs. 3, 4). As the heated products ascend, the fresh air is drawn up to the flame to supply their place. The smoke from this paper will best show the direction of the currents. You observe the rapidity with which the smoke rushes into the air-pipe, and enters the chamber, which velocity gradually diminishes in ascending, till it falls over, and descends to the lower chamber, whence it is drawn up and consumed in the flame. I direct a stream of air from this powerful bellows against the inlet, and the flame you see as steady as ever. The products of combustion pass up a conical chimney, and strikes against the apex of an inverted cone, which divides the current, and allows the products to pass out on every side. Above the cone is a horizontal plate, projecting on all sides beyond the cylinder it covers, and somewhat convex. This serves to divert any water that might pour upon it innocuously away. This cover has a space between it and the base of the

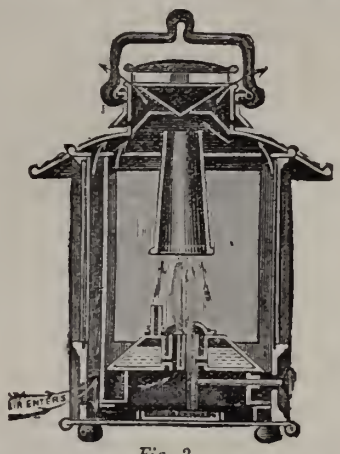

Fig. 3.

cone, so that any horizontal air-current striking against the top of the lantern passes through this aperture, meeting less resistance than if it chose the downward direction. As this

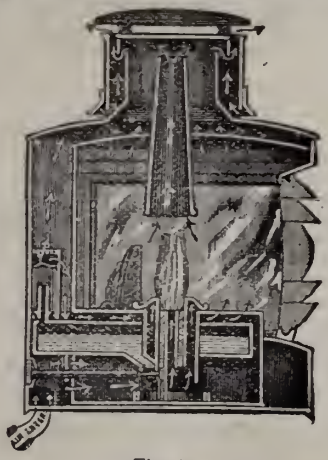

Fig. 4.

sweeps away the products of combustion from the top, a gust of wind tends rather to increase the brilliancy of the flame than otherwise.

These lamps have been tested in ships, high towers, express trains, and in every case successfully. As the carefully-adjusted metal funnel renders a glass chimney dispensable with, there is no part which is liable to damage. The one great point to be observed is keeping the whole case air-tight, except at the legitimate outlets; for, you perceive, when I open the door at the back, be it ever so little, the perfect equilibrium of supply and combustion hitherto obtaining, is disturbed, and the flame wavers and smokes.

ON THE DEVELOPMENT OF INSTANTANEOUS PICTURES.

BY W. A. WATTS.*

Mr. R. CROWE, in his interesting remarks upon the subject last month, divided instantaneous negatives (by which I presume are meant those taken by the aid of a quick-acting shutter) into three classes. Now, I accept his principle, so far as believing that all instantaneous negatives are by no means to be treated alike; but would prefer to make *two* divisions only, namely, fully-exposed and under-exposed negatives. There is one class of instantaneous negatives which, requiring only a very brief ex-

* A communication to the Liverpool Amateur Photographic Association.

posure, have by means of the shutter received quite as much as they need. Such are sea-views, which I look upon as instantaneous pictures merely in name—that is to say, they are as fully exposed by action of the light lasting only a fraction of a second, as the average of plates where there is nothing to limit the amount of exposure but the photographer's own judgment.

In Mr. W. K. Burton's table of exposures I note that, for a view containing open sea and sky in good light, the correct exposure with a lens of f_8 (about the aperture of the No. 1 stop of a symmetrical) is given as $\frac{1}{40}$ second; whilst, when the lens is stopped down to f_{16} (about the No. 4 stop), the exposure ought still to be as little as $\frac{1}{10}$ second. It may easily happen, therefore, that even with a quick shutter such a picture may be rather *over*- than *under*-exposed, and, consequently, may demand the treatment suitable to the former rather than to the latter class. For such negatives the treatment Mr. Crowe lays down for his first class is no doubt exceedingly well suited, although I must confess that my own experience leads me to believe that there is no advantage (and probably no disadvantage) in the preliminary soaking in pyrogallol over plain water, and that the essential point of his developer is rather in the relative proportions of pyro., bromide, and ammonia being especially well suited to the peculiarities of the subject.

I would take, however, as my second class of instantaneous negatives, those where, had it been convenient, a longer exposure would have preferably been given; and, where only the exigencies of the subject have necessitated an exposure of so limited a duration, that objects in motion may not seriously spoil the picture or may even be taken with good definition, such as street views or a train in motion, the latter being a subject which most amateurs have, at some time or other, been tempted to attack. Such negatives, I think, need a different treatment, and the method I advocate is to soak them before developing in dilute ammonia.

Probably the most convenient method of employing this mode of development—at all events, of those who use the more scientific method of separate ten-per-cent. solutions— is to add the correct amount of ammonia to the full quantity of water to be employed, and to leave the plate soaking in that whilst measuring out the pyro. and bromide solutions (which may of course be in the relative proportions that experience suggests as suitable to the class of subject and make of plate); then return the ammonia solution to the developing cup, and flood the plate with the mixture. Thus if developing a quarter-plate, and using three grains of pyro., two minims of ammonia, and one grain of bromide—which, I believe, is an average formula—I should take twenty minims of ammonia to one ounce of water in which to soak the plate, and while soaking place in the developing cup thirty minims of pyro. solution and ten minims of bromide solution, return the ammonia to the cup, and finish development in the usual way. In my own practice, however, as I use Edwards's method of developing, in which the ammonia and bromide are mixed in one bottle under the name of "accelerator," I soak the plate in water containing a few drops of ammonia whilst mixing the usual developer, throwing away the dilute solution of ammonia, or keeping it for the next plate, and developing with the mixture in the ordinary way.

In case any of our members should not have employed the sulpho-pyrogallol solution, I may perhaps, in passing, advert to the great convenience of that mode of employing pyrogallol, particularly for an under-exposed plate, where a good deal of forcing may be required. The sulpho-pyrogallol solution permits the addition of a good deal of extra ammonia when necessary, and of a very prolonged development without any staining of the plate. I took an opportunity, whilst at New Brighton of exposing three plates with a drop shutter working in about one-twentieth of a second on the same subject in rapid succession, so that the light might be presumed unaltered. One of these plates then received a preliminary soak in ammonia and one in pyro., the two being afterwards developed together in the same dish with the same solution. The third plate was developed without soaking in either pyro. or ammonia, but with the same proportions as the other two; only one half of that plate was soaked in water and the other half remaining dry, in order to test the question whether soaking in water was to be taken as an advantage or a disadvantage.

On developing, the negative soaked in ammonia began to come up in ten seconds, and was finished, as I judged, in nine and a-half minutes from the time of commencing, when it was removed from the developing dish, leaving the other one still developing. The one soaked in pyro. showed no signs of development until eighty-five seconds had elapsed, and was not finished until it had been in the dish for twelve and a-half minutes. The third plate, half soaked in water, began to show signs of action on the unsoaked side in ninety seconds, and on the soaked side not till the expiration of 150 seconds. As it was inconvenient to remove the one-half from the dish before the other, both were pronounced finished at the same time, namely, in sixteen minutes.

The result is that the soaked side is perhaps a shade less dense than the unsoaked one, but is, I think, somewhat clearer. A print is before you, and I will leave you to judge which side shows the advantage, if any. In developing these three plates I used Fry's plates and employed Fry's ordinary developer, taking care that each plate was subjected as nearly as possible to the same treatment. I did not, therefore, vary the solutions, and arrested each when it had attained the same degree of density as the first. It might, perhaps, have been in some respects a fairer test had they all been developed for the same period of time. I, however, exposed another plate to an exactly similar subject at the same time of day, but a somewhat different point of view, and that plate I developed according to the best of my judgment, first soaking in ammonia and, when partly finished, adding a double portion of accelerator. This began to come up in ten seconds, was finished in nine minutes, and I think is undoubtedly the best of the four.

Probably the exposure was not very insufficient, as the view was brightly lighted, and I gave about $\frac{1}{20}$th second with an aperture of f_8. With less illumination or more rapid exposure the difference between the two methods would probably have been more marked. The fact, however, that one negative attained a certain density in nine and a-half minutes, whereas with the same developer the other took twelve and a-half minutes to attain the same point, seems to me to show considerable gain in sensitiveness due to the preliminary soaking in ammonia.

In confirmation of these views as to increased sensitiveness under difficult circumstances of light, I may perhaps venture to call your attention to a print of a plate exposed during our recent visit to Rufford. The light on that occasion was so unusually dull as to cause us almost to despair of getting ordinary pictures, and when inclined to try a drop-shutter picture on a magnificent bull, the mere idea of getting any result seemed almost an act of lunacy. I ventured, however, upon the trial, and, although I certainly cannot say I obtained a picture, yet there is something to show, which would probably be considerably improved by intensifying the negative. So bad was the light that I should scarcely (but for knowing the effects of soaking in ammonia) have been surprised had the plate shown no result whatever, but been capable of being used over again. As Mr. Ellerbeck with a much quicker lens and, I believe, quicker plates (I use Fry's 20 times) took the same subject, perhaps if he would kindly show his result and explain his method of development it would be interesting.

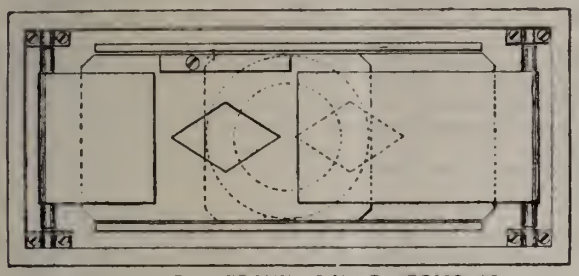
Another experiment bearing upon the same point is as follows:—At Easter of last year I took a very peculiar subject—a deep pot-hole in the limestone district at Settle. Some portions of the hollow were in deep shade. In another portion a stream of water falling over had frozen into a mass of stalactites with a hill of ice underneath, into a basin on the top of which the water fell; this portion and the masses of snow were in sunlight. On this subject I exposed two plates (Edwards's). One with a stop of f_{16} received four seconds' exposure; the second, with f_8, was taken with the drop shutter. The first was developed by Edwards's ordinary formula, whilst the second was soaked in ammonia. After finishing, the two plates were so much alike that it was difficult to distinguish which was which except by the numbers attached.

AN INSTANTANEOUS SHUTTER.

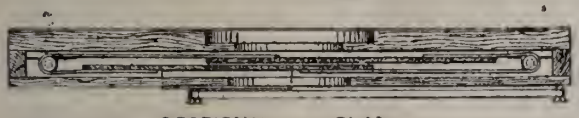
BY P. B. GREENE.

THE construction of my shutter is so well indicated by the drawings that little description is necessary. It consists of two flat plates of metal, hard rubber, or heavy cardboard, each with a diamond-shaped opening in the centre, and connected together at both ends by a flexible band passing around rollers which revolve in brass bearings attached by screws to the corners of outside case.

A strip of wood attached to the front slide by glue, or screws, or both, according to the material of which the slide is made, projects through a slot about twice its own length in the front cover, and has a rubber band or bands attached to it in the manner shown. It will be evident



VIEW WITH FRONT COVER REMOVED



SECTIONAL PLAN

that the full opening of the diamond is presented only at the instant when the two openings are exactly opposite, and that the aperture gradually increases from a point, and decreases to a point again. By varying the number or size of the rubber bands, considerable variation in speed can be attained, or it may be operated by hand, removing the rubber entirely. A coiled brass spring could be substituted if preferred. A slight modification in trigger would enable it to be released by a straight pull from behind camera, as in Mr. Burnham's shutter. By making the entire shutter of brass it could be made much thinner and some smaller every way, and, of course, somewhat more durable. But my aim has been to show how such a contrivance may be cheaply made, and by the photographer himself if he is at all handy at such work; old cigar boxes will furnish the necessary lumber, and a very heavy press-board will answer admirably for the slides; for the flexible bands thin leather will be the best—in fact, the bands and slides could all be made of one piece of leather of suitable thickness, and I not sure but this would be the best arrangement. The rollers can be made of heavy brass or iron wire, if nothing more convenient is at hand.

Correspondence.

THE ILLUMINATION OF THE DARK-ROOM.

Dear Sir,—As my recent article on the above subject stands apart from the adjourned discussion on Mr. Debenham's paper, and refers moreover to matters which, with one trifling exception, have been before the photographic world for some time, I need have little hesitation in replying to the remarks of Mr. Debenham in your last issue.

The main points in my article which Mr. Debenham has criticised can be replied to in a few words.

The spectroscopic test is not a complicated one, for by one simple operation, that of taking a photograph in the spectrum, it shows:—1. The rays which pass through a particular medium. 2. Their relative effect on the plate. 3. What rays should further be dispensed with, and with this, what sort of medium must be added to effect the desired object. Add to the spectro-photographic test an eye observation, and the relative illuminating powers of the rays which pass through are shown. If I did not make this sufficiently clear, I take this opportunity of stating the case plainly and briefly.

In my article I explained that the extent to which the spectrum could be impressed on a gelatine plate depends on the rapidity of the plate and the length of exposure. I also referred to this in No. VI. As I have already stated, there is no absolute limit, but the lower the refrangibility of the rays, the longer the exposure required. Mr. Debenham's correction, therefore, is superfluous. My diagram represents an average exposure, too long for the blue, and too short for the infra-red; besides, it must not be taken without the accompanying explanation.

The cathedral green I used (I have good authority for using the expression) was a yellow-green. To a large extent it *does* show a spectrum resembling the blue-green, but since it lets through less blue light than signal green, its tint is easily accounted for. It resembles the common yellow-green of my diagram, but is lighter in colour.

The recognized name of the stained red glass which Captain Abney uses is "stained red." I procured it under that name from Messrs. Willmore Bros., of Brompton Road.

The sensitive compound which photographers use in gelatine plates is not green bromide. Whoever has described it as such, did so in error. The difference between it and the bromide of silver in gelatine I have already laid stress on (see Article No. VI). In the series of articles I have been writing on the spectroscope, it would have been out of place to give details of known and recognized processes. Mr. Debenham will find full details in the Photographic News for November 10th, 1882, the formula having been given a few years before at the Royal Society. It forms the subject of the Bakerian Lecture for 1880, and Mr. Debenham will find that Captain Abney there states that a yellow light *would* be preferable for that particular sensitive film.

Whether Mr. Debenham has, or has not, demonstrated that green glass is a more powerfully protective supplement to stained red than cobalt glass, is a question which belongs to the adjourned discussion, and I therefore pass it over here.

I will beg to conclude with a protest against the idea, which seems to run through Mr. Debenham's letter, that my article was intended as an attack upon him.

With apologies for taking up so much of your valuable space, I am, dear sir, yours respectfully,

C. Ray Woods.

Dear Sir,—Now that dark-room illumination has become a matter for serious attention, I would like to say a few words in favour of cherry fabric used in conjunction with green cathedral glass.

Some time ago Mr. W. E. Debenham was good enough to send me samples of his green glass and orange paper, which I tried and used with some success; but afterwards, getting a batch of very rapid plates, I was induced to try cherry fabric in place of the orange paper, and I must say that the result has been most satisfactory. I have noticed that cherry fabric is very much more luminous than paper.

I should tell you, that as my window now stands, the cherry fabric is outside, and at a distance of about three inches from the green glass. Trusting that this may be of some use to someone or other, I am, yours, &c.,

Cherry and Green.

PAVLOFFSKI'S PHOTO-TRANSFER AND ENAMEL METHOD.

Dear Sir,—My invention has been described in your journal with such details that there is scarcely anything more to be added. I beg only to observe that the whole operation as described in your journal is generally performed on glass plates, but it can certainly be as well done on paper. The paper in such case is coated with sensitive solution in the same manner as with the ordinary carbon printing (tissue). It is self-evident that the sensitive paper can-

not be preserved longer than two or three days, as in consequence of the influence of the bichromate salts it becomes no longer soluble. In consequence thereof, I have lately made some new experiments (which proved very successful) by preparing paper covered with a mixture of colours, gum and honey, which can at any moment be made sensitive by merely immersing the same in a chromate bath (like gelatine paper). In making the mixiure one can use glucose, glycerine, and ordinary sugar, instead of honey.

I am thinking of occupying myself with the preparation of such paper for common sale. I intend making it of two kinds:—1. For transfers on wood, oilcloth, and the like surfaces, to be made with ordinary colours; and 2, for enamel photographs on porcelain, crockery, and other ceramic surfaces, to be made with porcelain colours. By this means the transfers of photographs on such surfaces as up to now offered great difficulty, will be extremely simplified, and besides such transfers will become accessible for everybody.

I would have liked to establish this enterprise on a large scale, as the demand for such paper is sure to be considerable, and it is to be hoped that the photographic art will then become a powerful assistance for decorative art.

It may in general be observed that up to now photo-ceramics is in a neglected state. There are some firms who prepare enamel photographs, but the means by which they procure them is kept the strictest secret. My communication, the authenticity and validity of which I guarantee, will break the fetters, and give to everyone the power of making these indestructible pictures, particularly when photo-ceramic paper appears for sale.—Yours faithfully.

St. Petersburg. V. PAVLOFFSKI.

RETOUCHING.

"Wanted, a Dark Room Assistant. Will be required to assist generally, and *do the retouching*."

"Wanted, an Assistant Operator, to attend to the printing; must be a *good retoucher*."

"Wanted, by a Young Man, a Situation as printer. Could take an occasional negative. Is a *first-rate retoucher*."

DEAR SIR,—The above are typical of advertisements we often see in the PHOTOGRAPHIC NEWS. In fact, it seems now that everyone connected with the studio must, and can, "retouch," as a matter of course; so retouching, and cleaning the studio windows, seem to be looked upon as kindred duties; and the question seems simply, "Of course, you can retouch?" and the reply, "Oh, of course I can."

If "retouching" means simply blocking a few freckles on the one hand, or by a mass of blacklead obliterating every trace of character or likeness on the other, then "retouching" is simple enough, and but little skill required to do it. But, to retouch well, to do just sufficient, and that with judgment; to correct the shortcomings of photography, where colour is concerned, as in the case of freckles and slight irregularities or spots of colour, deep lines of age, and many minor natural effects which photography magnifies, and, in many cases, misrepresents; and still to retain, unaltered, the character, expression, and correct likeness of the original, require the eye and hand of the artist. In fact, it is easier to paint a decent picture than to retouch a negative properly; and I venture to say that not one in five hundred (and that is a low percentage) who profess to retouch can do more than just spot out a freckle or pimple, or, doing more, spoil the portrait altogether. A good retoucher should have much artistic talent. The camera in judicious hands does a great deal, but it does a great deal *badly*; and it is to the *artistic* retoucher we must look for that character that renders portraiture at once striking and attractive. This being so, how very few "retouchers" are to be found, and yet how numerous they are supposed to be.

PLUMBAGO.

Proceedings of Societies.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

A MEETING of this Society was held on Thursday, the 29th ult., Mr. A. L. HENDERSON in the chair.

Mr. A. COWAN initiated a discussion on the effect of chrome alum in a finished emulsion, especially to find if it made any difference in development. He found that five grains added to forty ounces of emulsion before coating, not only permitted plates being washed with warm water without frilling, but in no way retarded development. Plates with and without the addition, which otherwise received the same treatment, were passed round; no difference could be traced either in detail or density.

Mr. W. COBB understood pyrogallol was employed by some dry plate manufacturers for a similar purpose.

The CHAIRMAN said the addition of chrome alum to certain gelatines was beneficial. No doubt those Americans who wash their plates in boiling water, use a substance of this kind. He preferred gelatine as soft as possible, short of frilling, and obtained the finest quality in those plates which were on the verge of frilling. Perhaps Mr. Cowan would experiment further, developing with warm pyro and a minimum of ammonia. He would also suggest, as another experiment, mixing chrome alum with meta-gelatine.

Mr. COWAN intimated that he would make further experiments.

The CHAIRMAN mentioned that the unfixed plates shown by him on the last occasion had been placed in the box wet and left there; upon opening the box that day he found the images had entirely disappeared. They had been developed with ferrous oxalate, slightly washed, then floated with very dilute nitric acid, and again slightly washed. He could not account for this extraordinary result.

Mr. W. E. DEBENHAM, in showing his lamp for working with composite white light, said he did not propose to show a light which was absolutely safe, but with suitable precautions it would be useful. By means of two lamps, emitting red and green light respectively, on a sheet of white cardboard, the reflected rays from this surface, after filtering through white tissue paper, were shown to be white composite light. A yellow reflecting surface was seen to make the light a little more yellow. Mr. Debenham then exposed portions of the same plate for one minute at a readable distance (*i.e.*, twenty-eight inches from the tissue screen) with each reflector; also with the lamps turned low enough to obtain the same luminosity, without the intervention of the coloured screens. Upon development it was noticed that an impression was obtained in the latter case, but not in either of the others.

Mr. H. S. STARNES found that light thrown on raw sienna and reflected back through yellowish-green media is safer than red glass or anything else he had met with.

The CHAIRMAN passed round a clamp with ball-and-socket joint, for attaching a camera to the rail of an omnibus or any position where a tripod is undesirable; a similar arrangement is also described on page 344 of this volume. A very pretty experiment was also shown by the Chairman, in which red and white light impinging on an opaque substance rendered complementary colours visible on a screen placed at a suitable distance beyond; by altering the distances, overlapping was obtained, and shadow produced. The Chairman also showed a plate of the "Start for the Derby."

It was announced that the "lecturette," "Altering the Density of Negatives," by Mr. W. Coles, would be given on the 12th inst.

BOLTON PHOTOGRAPHIC SOCIETY.

THE first out-door meeting of the season was held on Saturday, the 24th ult., at Adlington, near Chorley. The weather was beautifully fine and clear, and caused a good muster of members to assemble. About twenty (including some friends) left Trinity Street Station for Chorley, and thence walked on to Yarrow. As most of the members were fully armed for the photographic warfare, their appearance caused no little surprise to the natives. The woods behind Yarrow Hotel proved fertile in "bits," and the members soon began operations. Proceeding through the woods, the party emerged on the banks of the canal above Adlington. Not "striking oil," a start was made for the Bostonian's Elysium, Rivington. Plates were exposed on

the house and beautiful grounds of the late Mr. Martin, and it was getting late in the evening when a réunion was made at the "Black Lad" for tea, after which, and a stroll around the lakes, a start was made for Horwick Station, and Bolton was reached about nine o'clock.

The next meeting will be at New Brighton.

Derby Photographic Society.

At a meeting held at Rodney Chambers, Corn Market, Derby, on Wednesday, May 28th, Mr. Arthur J. Cox in the chair, the Derby Photographic Society was formed. About twenty members were enrolled, and the Society shows every prospect of being a most successful undertaking.

Among those elected were Messrs. Charles Abney, Richard Keene, Arthur J. Cox, H. Arnold Bemrose, J. E. Kaye, J. W. Price, and T. Scotton.

Mr. Fred. W. Simpson, Hamilton Villas, Mill Hill, Derby, was elected Hon. Sec.

The first meeting will be held this month, when a paper will be read on some photographic subject by a member of the Society, and will be followed by a discussion.

Photographic Society of Ireland.

The closing meeting of the session 1883-4 was held in the Royal College of Science, Dublin, on Wednesday, 28th ult., Thos. A. Bewley, Esq., in the chair.

Mr. Howard Grubb, F.R.S., delivered a most interesting and instructive discourse on photographic lenses, in the course of which he described by means of figures on a black board the nature of lenses in general, and their action in refracting the rays of light passing through them. He next referred to the various errors arising from spherical and chromatic aberration, astigmatism, &c., and the various means adopted to eliminate such errors in the different forms of lenses used in photography.

In the discussion which followed, the Chairman, Messrs. J. T. Robinson, H. Bewley, E. P. Johnson, G. Pim, and others took part.

M. Richard C. Walker exhibited a very light and compact single "back" which he had made entirely, except the skeleton, of Willesden paper, and which was much approved of.

The meeting then adjourned to October.

Liverpool Amateur Photographic Association.

The monthly meeting of this Society was held at the Free Library, on Thursday, the 29th ult., Dr. Kenyon, President, in the chair.

The minutes of the May meeting having been read and confirmed, Messrs. Cross, Heape, and Stott were elected members of the Association.

Mr. A. Beer exhibited and explained a new and very ingenious changing-box.

Mr. E. Roberts showed a fine negative developed by himself with—

Washing soda	1 ounce
Bromide of potassium	3 grains
Water	10 ounces
Pyro	10 grains

This formula had been given in the present year's Almanac, and Mr. Roberts said he found it a capital developer, giving clean negatives of good printing colour and density.

Mr. J. H. Day remarked that an artist friend of his had used the soda developer exclusively for some time with the very best results; but he (Mr. Day) would like information as to rapidity of action.

Mr. Roberts said that he had only used this formula with some Swan's plates which he had kept by him for some two years, and with these plates he certainly found it slow; but possibly it would not differ from other developers in this respect when fresh plates were used. There was perfect freedom from fog.

Mr. Rogers and the Chairman exhibited specimens of Mr. George Smith's sciopticon camera. This little camera measures when folded $2\frac{3}{4} \times 5\frac{3}{8} \times 4\frac{5}{8}$, and weighs under $1\frac{1}{4}$ pound; yet it carries a $3\frac{1}{4}$-inch square plate, and has a range of focus of from $2\frac{1}{2}$ to 12 inches. The double dark slides are correspondingly light, and the whole work in the most simple and yet rigid manner; there is a rising front and a swing back. The great novelty is the manner in which the extra range of focus is provided for without detriment to the field of short-focus lenses, and in this respect the pattern is the very model of perfection.

The Chairman called attention to some good prints of portraits and groups taken by Mr. H. N. Atkins with one of Smith's cheap single lenses.

Mr. Watts read a paper "On the Development of Instantaneous Pictures" (see page 363), and passed round a number of prints in illustration of his remarks.

The Chairman, in proposing a cordial vote of thanks to Mr. Watts for his careful and useful paper, remarked that he (the Chairman) had little doubt but that the principle enunciated was the correct one, and would in practice be found of substantial benefit. This was testified to by the relative times occupied by the development of the negatives exhibited, and to some extent by the relative densities of the negatives; but as to detail, it was noteworthy that the difference between the negatives exhibited in this respect was scarcely appreciable. This corresponded with the recorded experience as to different proportions of bromide in the developer, viz., that a large proportion of bromide, although it lengthened the period of development, produced no real loss of detail.

Mr. H. N. Atkins had, since the last meeting, been experimenting in the direction pointed out by Mr. Crowe in his valuable remarks at the April meeting, and found his formulæ work admirably.

Mr. Watts said that he thought it important to use sulphite of soda in fresh solution of pyro., and alluded to the tendency of sulphite to change to sulphate if the solutions were kept too long.

Mr. Crowe exhibited some specimens of his instantaneous work, taken in the streets of Liverpool on the Queen's birthday.

The Chairman explained a new apparatus by Lancaster, of Birmingham, for affixing a camera to a bicycle.

The meeting, which was numerously attended, was then adjourned to the last Thursday in June.

Talk in the Studio.

Photographic Society of Great Britain.—The last ordinary meeting of this Society for the present session will take place on Tuesday next, June 10th, at 8 p.m., at 5A, Pall Mall East, in the Gallery of the Royal Society of Painters in Water Colours, when the discussion on Mr. W. E. Debenham's paper, read at the last meeting, will be taken, and papers will be read on "Commercial Fabrics Suitable for Dark-Room Illumination," by Mr. J. R. Sawyer, and on "Silver Prints," by Mr. E. Dunmore.

Two Balloon Ascents.—Mr. Cecil V. Shadbolt writes:—"We launched our new little balloon of about 26,000 feet capacity from the Crystal Palace on Saturday. It is only just finished, and this was its first ascent. A splendid little beauty she looked, too, when inflated—alternate gores of red and yellow, and carried three of us easily with good supply of ballast. We have not named it yet, and the name reported in the *Daily News* is, therefore, incorrect. It is a very light little machine, a good deal lighter than the 'Sunbeam.' We let go at about 5.20, and rose steadily into the air. There were in the car General Brine, Mr. Dale, and myself; but the weather being unfavourable for photographic work, I left my apparatus on *terra firma*, and contented myself with flying two pigeons from 2,000 and 1,500 feet respectively over Croydon. These birds went down without any apparent fear, the first reaching its home at Chislehurst in about two hours; but the second one did not get back till after dark. We had a thoroughly enjoyable voyage, and very nice descent at Woodcote Grove, Wallington, in Surrey, where we were hospitably entertained by Mr. Puckle and his son, in whose grounds we alighted. These gentlemen not only sent one of their own carts for the balloon, but, after taking us to their residence and giving us refreshment, turned out their new waggonette to send us to the station—all honour to them!" It is reported that on the same day an ascent was made at Lille. The car, when about 40 metres from the ground, became detached from the balloon and fell to the earth. Twenty persons were in the car, of whom three were killed on the spot, and several others injured. The accident was due to over-loading, the car being only constructed to hold eight or ten persons.

Lime-light Explosion at Drury-Lane Theatre.—An explosion occurred during the morning performance at Drury Lane on Wednesday, which, although slight in itself, nearly

caused a serious panic. The lime-light apparatus in a room under the stage in some way got out of order, and the oxygen is supposed to have escaped into the hydrogen bag, so that an explosion ensued. The noise was not startling, as heard in the auditorium, but the clouds of dust, looking like smoke, which permeated the theatre, would undoubtedly have led to an alarm of fire had not Messrs. Emerson and Sweatman, two of the end men of Haverley's Minstrels, who were in the midst of their "business," interpolated a wheeze, which led the audience to suppose that the explosion was part of the performance. Emerson said, "Did you bear my trunk fall then?" Sweatman answered, "No; that's too heavy for your trunk." The two men in charge of the limelights were injured, and at once removed to Charing Cross Hospital.

PHOTOGRAPHY AND PERSIAN CALIGRAPHY. — Dr. G. W. Leitnee, in a recent communication to the *Society of Arts*, said: "Here is a *Hitopadesa*, which, in print, costs 7s. 6d., and which may be brought out by means of photography for a shilling. It is beautifully done. Here, again, is a Koran produced by a similar process. Surely those in India who practise caligrapby—and it is an art taught by absolute rules as to the distance of the dots between the curves of letters, &c.—are not wrong when they pay so much attention to it; and the lithographs of India, which spread education so cheaply, would be worse than they are—and some of them are very beautiful—if that art were not cultivated. Here is a Persian book, brought out by a relative of the Shah, correcting the pictures that are drawn in it of ancient rulers by corresponding coins. The Shia Mahommedans, it may be incidentally stated, allow pictures of living objects, the Sunni Mahommedans do not; at the same time the latter cultivate the design of inanimate objects. When it is alleged that pupils in Government schools do not object to pictures, it is evidently forgotten that the first thing a Mahommedan boy does in a Government school is to drive his pen or a bit of wood through the eye of a picture of a human being, in order to reduce it from the condition of an animate being to that of an inanimate object."

A STORY FROM ST. LOUIS.—*Walzl's Monthly* is responsible for the following:—"A man who was unable to read or write was in St. Louis, where he was a complete stranger, and wished to draw money from a bank in Texas where he had an account. He could not identify himself in any of the ordinary ways, and he was asked to have his photograph taken. When this was done it was attached to a check upon which he made his mark and was forwarded. A telegram was sent back to pay the check, and the man got his money by means of his photograph."

STAINING WOOD.—A wash of one part nitric acid in ten parts of water will impart a stain resembling mahogany to pine wood that does not contain much resin. When the wood is thoroughly dry, shellac varnish will impart a fine polish to the surface. A glaze of carmine or lake will produce a rosewood finish. A turpentine extract of alkanet root produces a beautiful stain which admits of French polishing. Asphaltum thinned with turpentine makes an excellent mahogany colour on new wood.

PHOTOGRAPHIC CLUB.—At the next meeting on June 11th, the subject for discussion will be "On the best Methods of Preserving Sensitized Paper." Saturday afternoon, meeting on Hampstead Heath, North End, and West Heath; meet afterwards at the "Bull and Bush," at 6.30.

To Correspondents.

*** We cannot undertake to return rejected communications.

LEICESTER.—1. Sulphite of soda, about 120 grains; carbonate of potash, about 250 grains; and washing soda, about 150 grains. 2. Your second question is not quite clear. Do you wish to know the relative quantities of the two salts which will decompose each other?

H. DE RUSELL.—It is very good of you to call our attention to the matter, but you will find a word or two regarding the subject on page 344.

W. FIELD.—1. The Asser process is not covered by any patent, and if you have had moderate experience in general photographic work you should succeed very well. 2. We quite think that the process adopted in the case of the lion should serve your purpose, but certainly do not think the specimens which you send very good.

J. GEORGE.—Thank you for the catalogue and particulars. We are sorry that dissatisfaction has been expressed, but such a condition of affairs is by no means exceptional.

CAMAS.—Directions will be found in Pritchard's "Studios of Europe," and you can obtain this from our Publishers.

PYRO.—So many circumstances may occasion a want of brilliancy, so that we can do no more than to suggest that it may arise from over-exposure, diffused light in the enlarging room, a disordered bath, or the presence of ammoniacal fumes in the locality where the development is performed.

W. T. W.—1. The firm has a place of business at Leeds, and it will be quite sufficient for you to address your letters to them at this town. 2. As far as we know, it has not yet been made commercially.

AD. EGGIS.—We would do so with pleasure, if we knew where to lay our hands on it, but we fear it has been thrown on one side, and lost sight of.

R. D. B.—1. All details will be found in Eder's "Modern Dry Plates," and Abney's "Photography with Emulsions." 2. Try very much diluted hydrofluoric acid, if you think it is worth the trouble.

NOVICE.—Under the circumstances, you must either use another sample of paper, or else the usual sensitizing bath, as the colouring matter appears to be one which will not withstand the action of the nitric acid.

A. C. ELWES.—For such a large window it may be necessary to have further protection in bright weather, say one thickness of the "Golden Fabric," in addition to your present covering. This material might be nailed on a light frame so arranged as to be readily placed in position when required.

TECHNIKER KRAUS.—You should state more definitely what you require.

SAMUEL KIRK.—You will see how far we have been able to make use of the information. Thanks.

J. H. C.—The pictures are very fairly good, and if they represent your average work you should have no difficulty in getting such a situation as you wish for.

DR. C. SCHLEUSSNER.—The address of Mr. A. L. Henderson is King William Street, London Bridge.

ENGRAVER.—In all ordinary cases, the bleaching of the engravings may be satisfactorily effected by a solution of the so-called chloride of lime, to which a little nitric acid has been added in order to set free the hypochlorous acid. Stir an ounce of the chloride of lime in a pint and a half of cold water, and strain through fine calico, after which add a drachm of nitric acid. Immerse the engravings one at a time in this fluid, and, as soon as the yellow spots have disappeared, rinse them thoroughly in several changes of cold water. Any trace of chlorine or hypochlorous acid remaining will cause the paper to become rotten, and it is therefore well to give the rinsed prints a dip in a 10 per cent. solution of hyposulphite of soda, after which they should be rinsed once more. It is seldom that a satisfactory negative can be obtained from an old and discoloured engraving, unless a bleaching process is resorted to.

S. C. RILEY.—We shall look forward to another opportunity.

E. G. M.—1. Although the earlier experimentalists arrived at widely differing conclusions, we think that the discrepancies have been sufficiently cleared up by the more recent investigations of Captain Abney regarding this point. 2. Under the circumstances, you might venture to write to him, and you can send a letter, under cover, to our office. 3. It was described in the NEWS about three months ago, but it is in reality founded on an old process invented by Mr. Robert Hunt many years ago.

NITRATE.—It is not sufficiently soluble in alcohol for the purpose.

The Photographic News Registry.

Employment Wanted.

Op., Printer, Toner, Retoucher.—Bromide, 133, Union-rd, Newington, S.E.
Manager & Operator.—M., Mr. Nicholls, 11 gh-st., Shanklin, I.W.
Ret., Artist in Oil, Water, Monochr me.—F. G., 3, Kenyon-ter., Clapham.
Reception Room, Spotter, Mounter.—L. S., 45, Gt. North-ter., Line.
Retoucher (gentleman), first-class.—A. B. C., *Photo. News* Office.
Printer, Toner, Retoucher.—H. H., 64, Drayton-gar., S. Kensington.
Reception Room.—R., 19, Torrens-rd., Hayter-rd., Brixton.
Tinting, Spotting, &c. (lady).—A. G., 5, Heaton-vil, Heaton-rd., S.E.
Operator and Retoucher.—E. Wilkinson, 5, Fair-st., Cambridge.
General Assistant.—W. W., c/o Mr. Wood, Folly Hall, Huddersfield.
Operator, £3, for permanency.—Lux, 30, Mornington-rd., New Cross.
Retoucher, Finisher (lady).—L. F., 30, Swanmore-rd., Ryde, I.W.
Reception Room and Retoucher.—A. B., 72, Azenby-sq., Peckham.
Operator or Gen. Assist.—F. W. Dodge, 12, Langland's-st., Kilmarnock.
Operator, dry-plate, studio and field.—H. S. L., 203, Mayall-rd., S.E.
Assistant Operator, good all-round.—Pyro, 45, Ladbroke-rd., W.

Employment Offered.

Spotters & Mounters, first-class.—Fradelle, Regent-st.
Enameller, at once.—Oeffelein and Co., 54, Berner's Street, London, W.
Retoucher, lady preferred.—Russell and Sons, Wimbledon.
Operator, Retoucher, Manager.—F. Benham, 7, Arcade, Landport.
Printer and Toner.—Messrs. Taylor, Manningham-lane, Bradford.
Assistant Operator at 25/-.—W. Mountain, 211, Clapham-rd., S.W.
Printer and Toner, good references.—Stiles, 8, Kensington-High-st., W.
Operator, Assistant, and Pupil.—B. K., *Photo. News* Office.

THE PHOTOGRAPHIC NEWS.

VOL. XXVIII. No. 1315.—*June* 13, 1884.

CONTENTS.

DR. LOHSE'S ISOCHROMATIC PLATES PREPARED WITH TURMERIC EXTRACT.

As much interest now centres around the various methods of obtaining justly gradated negatives from highly-coloured originals, such as paintings, we are pleased to be able to lay before our readers the working details of Professor Lohse's method of treating gelatine plates with turmeric extract (see p. 327).

Dr. Lohse writes:—"The method of treating gelatine plates with turmeric extract, in order to make them sensitive to the yellow and the green, is as follows: Bruised turmeric root is extracted with alcohol, and of the strong alcoholic extract ten cubic centimetres are added to one hundred cubic centimetres of water containing ten per cent. of strong ammonia. In this fluid the gelatine plates are immersed for two minutes, and dried. Such plates when exposed to the solar spectrum do not give such a notable maximum in the yellow as is the case with eosine plates, but notwithstanding this, the sensitiveness for green and yellow is so far exalted that you are in a position to satisfactorily reproduce the whole spectrum from the yellow to the ultra violet."

In the above directions, Professor Lohse does not exactly specify the strength of the alcoholic extract which should be used, but we have found that a satisfactory preparation may be made in the following manner. Four ounces of turmeric root are thoroughly bruised so as to isolate all the larger fibres of the roots from one another, and the material is carefully packed into the funnel of the simple filtering or

percolating arrangement referred to by Captain Abney in his "Instruction;" but instead of using a cone of platinum foil, as one would when employing the apparatus for an ordinary filtration through a paper filter, a piece of fine platinum gauze was rolled up into a cone, and placed in the funnel as shown, in order to prevent the turmeric falling through into the receiving flask. Four fluid ounces of alcohol were now poured on the surface of the turmeric root, and after this had percolated through into the flask, another quantity of four ounces was similarly poured on, a third batch of four ounces being used in order to displace what alcoholic extract was retained by the porous root. When all had drained through that would come, the alcoholic extract in the receiver was found to measure almost exactly eight ounces; and if the packing of the turmeric root in the funnel is carefully performed, one may depend on the extraction of the bulk of the colouring matter; so the extract may be considered as representing about half its quantity of turmeric root. It was not found necessary to create a partial vacuum in the flask by connecting the outlet tube with an exhausting syringe; indeed, it would probably have been disadvantageous to have done this, as then sufficient time might not have been allowed for the thorough extraction of the colouring matter. It is, perhaps, scarcely necessary to say, that during the percolation of the alcohol the top of the funnel should be covered by a glass plate, as if this be not done, not only may a considerable amount of the alcohol be lost by evaporation, but the remainder is likely to be weakened by absorbtion of moisture from the atmosphere.

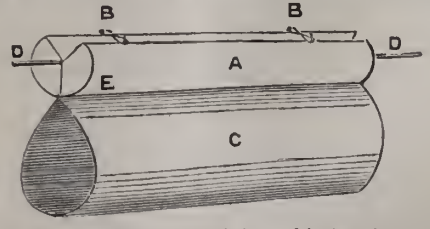
Anyone can try Dr. Lohse's method, and we shall be glad to be informed as to the result of such trials as our readers may make.

TO DRY ALBUMEN PAPER OR CARBON TISSUE WITHOUT CURLING.

MR. F. JAY HAYNES communicates to our contemporary, the *New York Photographic Times*, an account of an excellent idea which has struck him in connection with the drying of paper, his plan being to so clamp two edges of the sheet together that a kind of tube shall be formed with the coated surface outwards.

Mr. Haynes describes his clip arrangement in the following words:—

"A A, sectors cut out of a round piece of wood, working on a hinge-rod at its centre, as shown; B B, two



springs forcing the jaw, E, tight; this jaw holds the two edges of the paper as shown; C, albumen paper in process of drying; D D, rods for supporting the whole."

Excellent and useful as this arrangement may be for albumenized paper, it is the carbon printer and the user of Woodburytype tissue who will most highly appreciate the

importance of a simple apparatus for keeping the sensitive material in good condition while drying.

Although it is difficult to conceive a more easily constructed and more satisfactory clip apparatus than that figured above, it may be worth mentioning that something which will answer the same end may be extemporised by means of a couple of strips of printer's "reglet" and two or three American clips; but this would prove less satisfactory than Mr. Haynes' gripper, owing to the want of rigidity on the part of the jaws, and the inconvenience of having to loosen or remove several clips.

We would suggest that Mr. Haynes' apparatus might be improved by driving two studs or longish nails into the upper part of the sectors (near A, and at a corresponding part on the other side), as such studs or nails would be of assistance in opening the jaws.

THE AIR BRUSH—A PNEUMATIC RETOUCHING APPARATUS.

To Dr. Liesegang, of Düsseldorf, we are indebted for an opportunity of placing before our readers drawings of the latest form of retouching apparatus for producing stippled or crayon effects. The new apparatus is, in reality, an arrangement for breaking up any kind of liquid colour into a fine spray, and it is in principle quite analogous to the well known "perfume distributor," in which a stream of air is directed across the mouth of a tube delivering the liquid.

The air-brush apparatus, as manufactured by the Air-Brush Company, of Rockford, Illinois, U.S.A., consists of a kind of table with an adjustable desk, and near the

ground is fixed a bellows, which is actuated by the foot of the manipulator. The air passes from the bellows into a metallic drum, shown on the right-hand side of the apparatus, and from this drum it is led by an elastic tube into the spray-producing portion, or air-brush proper. Here it passes with considerable force through the blow-pipe shown at the lower and left-hand part of the small drawing, and in impinging against the tip of the pen-like ink ductor, it blows the liquid colour into the finest spray. The long lever, which is shown as projecting downwards, serves to regulate to a nicety the rate at which the ink spray is produced.

Any kind of liquid colour may be used with the air-brush, but Indian ink is the most convenient as a basis. If a photographic tone is desired, it can be made by

grinding alizarine lake and indigo water colours with the Indian ink.

That the air-brush will prove of great value for working up enlargements there can be but little doubt; but so perfect is the air adjustment that even small pictures can be retouched with advantage.

Not only can the shading and retouching of existing pictures be performed, but the air-brush may be used as a drawing apparatus for the direct production of pictures, either with or without the camera image as a guide. Let us suppose, for example, that the camera is used to project an enlarged image on a sheet of cardboard, and instead of making the enlargement by photographic agency, it is made in the dark-room by following over the image with the air-brush. Of course, an ordinary crayon can be used for making the sharp outline, if desired.

BLUE-INTENSIFICATION FOR GELATINE PLATES.

ANDERS, of Dresden, describes an intensification method which yields negatives having a blue or violet colour.

According to him, the fixed and well washed negative is treated with *his intensifying fluid*, and the image gradually becomes blue and vigorous, while the lights remain white; the half-tones come out well graduated, and, according to the length of time the plate is treated, one obtains any required degree of intensification. The method is available for under-exposed plates, as details previously invisible are brought out with distinctness.

If one wishes to transform the blue image into one having a deep violet tint, the plate is immersed in very weak ammonia (1 and 100 of water), and allowed to remain for some minutes.

The above *method*—if, indeed, one may apply the term to it—has been made the subject of a German patent; no further details having been published.

We can, however, see in this the essence of a mode of working which was described by Dr. Eder about eight years ago,* and it is interesting now to give some account of Dr. Eder's method. At the time referred to Dr. Eder wrote:—"A mixture of ferri-cyanide of potassium and a ferric salt acts in an analogous manner to the lead or uranium salts. If, however, one wishes to ensure the greatest regularity in action, the ferric sulphate should be used; and in this case the reaction takes place readily, and is quite similar to the lead intensification. The silver of the negative reacts so as to give rise to the precipitation of a deposit of Prussian blue, in consequence of which the negative becomes intensely blue. The following equation represents one phase of the reaction:—

$$\underset{\text{Ferricyanide of Potassium}}{2K_6Fe_2Cy_{12}} + \underset{\text{Silver}}{2Ag_2} =$$

$$\underset{\text{Ferrocyanide of Potassium}}{3K_4FeCy_6} + \underset{\text{Ferrocyanide of Silver}}{Ag_4FeCy_6}$$

The ferrocyanide of potassium, however, re-acts at the moment of its formation with the ferric salt, and gives rise to Prussian blue.

To make the blue intensifying liquid, Dr. Eder recom-

* *Photographischen Correspondenz*, 1876, p. 27.

mends that 6 parts of ferricyanide of potassium and 4 parts iron alum be dissolved in water; but it must be remembered that the fluid is very sensitive to light, and it is therefore necessary to keep it in the dark. A solution made up with ferric chloride instead of iron alum decomposes with tolerable rapidity even in the dark. If the negatives are imperfectly washed, they gradually become blue all over during the process of printing; and the intensified portions themselves become darker. The blue intensification is more delicate than mercury intensification, as the deep blue colour allows sufficient light to pass, to obviate the objectionable tendency to over-hardness.

By-the-Bye.

SMILES AND SMILING.

A REALLY beautiful smile, natural and without the taint of artifice, is one of the rarest as well as the most delightful inventions of nature. To smile is a joy reserved for mankind alone, for the hyæna does *not* laugh, whatever unscientific natural historians may say to the contrary. Not that we should like to assert too positively that all animals have not some equivalent method for displaying their emotions, for surely many of them show rudimentary attempts at expression in their faces.

Some dogs, for instance, can convey an easily interpreted expression of their feelings by their looks. The other morning we asked a friendly terrier, belonging to a neighbour, to go for a walk. There was a most distinct look of pleasure on that dog's face as he frisked around us when he accepted the invitation, and we fancied we could detect an upward curl of the mouth; there was certainly a twinkle in the eye. It happened that after we had walked a mile from home, we went into a shop, leaving the dog to wait outside. We stayed longer than we intended, and left by a different door to the one by which we entered, forgetting our canine friend. Since that time we have never been able to induce that dog to take any notice of us, except to put on a dejected, disgusted visage whenever we approach. His feelings were hurt, and he did not care to conceal it.

That rudimentary expressions are to be traced in animals goes to prove that the smile is the result of evolution, and that the perfected smile is a product of civilization.

The smile, then, being a product of civilization, is capable of being overdone and of becoming unnatural, as, indeed, is the tendency of all cultivated things; and it is this false smile that gives the conscientious photographer more trouble than any other phase of expression. The unconscious smile, that perfect expression of happiness, seems to be dying out. It is rarely present even in children, especially when they are in the hands of the photographer, however sympathetic he may be. Who amongst us does not constantly observe that painful nervous contraction of the lips and elongation of mouth seen in many children when they are being photographed? Parents and nurses are a good deal to blame for this. They impress on the young people, before they take them to the studio, that they must be still, and, above all, look pleasant. Now what is the effect of telling a child to be good? If it is of a kindly disposition, it will become prim; if the demon that seems to possess some children's souls has possession of it, it will become sullen. Then, being dressed specially for the occasion has its effect. It is impossible for a child used to the enjoyment, in easy fitting clothes, of the rollicking pleasures of the nursery, to appear at its ease in its "Sunday best," yet its natural guardians not only overdress the child, but will sometimes go even further, and try on unaccustomed garments and new ways of doing the hair. Now to dress a child in stiff clothes different from its ordinary wear, to alter the style of hair, and to solemnly impress upon the poor little mite that it must be good and smile, is to kill that child as a subject for the photographer. It is sometimes possible for a clever individual to make a modern young person forget all the world, and become "even as a little child" again, but the exertion is more than some photographers are equal to. So the natural smile is dying out, killed through the folly of mothers and nurses when they prepare their children for being photographed. We are glad we have been able to trace this growing defect of nature in its origin!

Mothers and nurses know so little of children! They are incredulous when told that infants never smile, but that it comes to them as they grow. The art of smiling has to be learnt by experience, and, perhaps, at that early age, infants have no happy thoughts to smile at. Mr. Darwin, who has gathered up so many facts in nature, describes his observations on this point in a characteristic passage:—"It is well known to those who have the charge of young infants, that it is difficult to feel sure when certain movements about their mouths are really expressive; that is, when they really smile. Hence I carefully watched my own infants. One of them, at the age of forty-five days, and being at the time in a happy frame of mind, smiled; that is, the corners of the mouth were retracted, and simultaneously the eyes became decidedly bright. I observed the same thing on the following day; but on the third day the child was not quite well, and there was no trace of a smile, and this renders it probable that the previous smiles were real. Eight days subsequently, and during the next succeeding week, it was remarkable how his eyes brightened whenever he smiled, and his nose became at the same time transversely wrinkled. This was now accompanied by a little bleating noise, which perhaps represented a laugh. At the age of 113 days these little noises, which were always made during expiration, assumed a slightly different character, and were more broken or interrupted, as in sobbing; and this was certainly incipient laughter."

In a second infant the first real smile was seen at about the same age, and in a third somewhat earlier. In this gradual acquirement, by infants, of the habit of laughing, we have a case analogous to other uses of the human frame. As practice is requisite with the ordinary movements of the body, such as walking, so it seems to be with laughing; it must grow, and if in its growth it is twisted out of form, it will never be a graceful and pleasant expression of joyous feeling.

The natural smile in children of a larger growth is interfered with by another cause. Young ladies seem to think that the glory of a woman does not lie, as of old time, in her long hair, so much as in her mouth. Modern ideas of beauty insist that the mouth must be small, therefore the owners of them must make them as small as possible. The facial efforts made to effect this purpose are prodigious. The lips are drawn in, and useless attempts are made to contract the lateral extension; while the desire to look cheerful, which naturally lengthens the mouth, fights with the antagonistic determination to keep within limits, and the result is an hysterical grin.

One of the most difficult features a photographer has to contend with is that form of mouth which has permanently-parted lips, leaving the teeth full in view. This is a defect that seems to be becoming more prevalent in this country. An inspection of a large collection of old photographic portraits will perhaps show that it did not exist to such an extent even twenty years ago. The effect is usually not disagreeable in nature. Momentary changes of expression seem to qualify the defect, if defect it can be called; but in a photograph, when the form is permanent, and has not the aid of varied movement, it is not agreeable, indeed, it gives the photographer much trouble, and taxes his ingenuity to hide it. This is a case in which any attempt at smiling is best avoided, as it only tends to make matters worse.

AN ELECTRIC RELEASE, APPLIED TO THE CENTRAL DROP-SHUTTER.

BY M. MAUDIT.*

THE object of this paper is to resolve the second part of the problem which I set myself when I had the honour to present an account of my pneumatic release; and to indicate in a practical manner how to render it possible to give the worker a free choice between an electric release on the one hand, and a pneumatic release on the other hand.

The arrangement (fig. 1.) is enclosed in a small cylinder

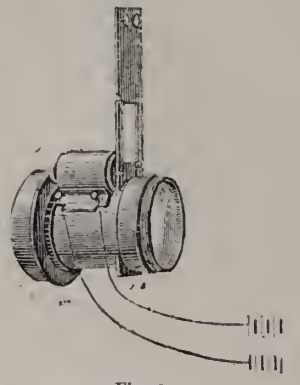


Fig. 1.

of soft iron, nickel-plated, and fixed upon the objective just in the same way as the piston actuated by air pressure. The cylinder, C, as may be gathered from an examination of the section shown by fig. 2, is merely an electro-magnet

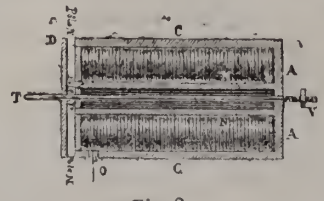

Fig. 2.

with concentric poles, exactly similar to that made use of by Mr. d'Arsonval in his ingenious telephone. One pole is in the middle of the helix, while the other occupies the whole of the circumference. The end plate, A A, is of course neutral. One terminal of the coil is soldered to the metal work at a point (between B and A), while the other extremity is attached to an insulated binding-screw, O. When a current is passed, the iron becomes magnetized, the central cone becoming north, and the extremity of the outer tube becoming south, or *vice versa*, according to the direction of the winding, and the angle at which the current enters.

The advantage of this electric magnet is the circumstance that it unites in a small volume the greatest of power, as the whole of the surface of the soft iron is subject to the maximum of magnetic influence.

Through the central rod or core of the electro-magnet there passes a stem of brass marked T on the diagram, care being taken that this rod can move quite freely. Near one extremity of this is attached a disc of soft iron, D, while the other end is furnished with a regulating-screw, which renders it easy to adjust the distance of the moveable disc from the magnetic poles.

When the magnetization of the iron takes place, a consequence of the passing of an electric current through the wire, the projecting end of the brass rod (which should previously have been so placed as to support the steel drop) is withdrawn, and the exposure takes place.

As a generater of electricity, I prefer to make use of the small sulphate of mercury battery which M. Ed. Loiseau makes for actuating his electrical ornaments. Its electromotive force is a volt and a half, while the circumstance that it remains in action for several days renders it suitable for photographic use.

* *Bulletin de la Societe Francaise de Photographie.*

IMPURITIES PRESENT IN PYROXYLINE.

BY DR. J. M. EDER.

PYROXYLINE invariably contains bye-products which vary much according to the raw materials from which it is made.

When pyroxyline is made from perfectly pure cotton-wool with the view of collodion making, it contains 1·3 to 5·6 per cent. of hygroscopic moisture, and about 0·1 per cent. of ash. In addition may be mentioned traces of nitric acid, sulphuric acid, and potassium salts (these latter if nitre has been used in the preparation) are present in recognizable quantities.

As regards the photographic relations of pyroxyline, however, the organic bye-products are of importance. The presence of such substances has been supposed by Hunt,* and to such he has erroneously attributed the rapidity of the wet collodion process.

Hardwich was the first who clearly enunciated the view that the sensitiveness and other peculiarities of wet collodion do not depend on the presence of organic bye-products, although these foreign bodies undoubtedly influence the photographic behaviour of the collodion. In 1859 he announced that the filtrate drawn off after pyroxyline has been precipitated with water contains a bitter substance which is always to be found in collodion pyroxyline. In the case of linen pyroxyline this body was present to a much larger extent than in the case of cotton pyroxyline; but when the linen pyroxyline had been allowed to remain in the acid mixture for a long time, or was prepared at a high temperature, the amount was considerable. The circumstance that pyroxyline undergoes rapid alteration when in negative collodion (as evidenced by the reddening of iodised collodion), and the great intensity and dark colour of the negatives, led him to suppose that such appearances depended on the presence of a greater or less proportion of the organic product. Hardwich considered this substance to be nitro-glucose, and he recommended its separate preparation and addition to the collodion in order to obtain increased intensity.

Mouckhoven accepted this view of Hardwich,† and it has been adopted in all the text-books.

The addition of nitro-glucose to bromide of silver emulsion has been tried, and indeed recommended by Gough, three or four drops of grape sugar syrup being added to the acid mixture used for nitrating 100 grammes of cotton-wool; by this means a pyroxyline either containing nitro-glucose or its decomposition products was obtained. De Pitteurs preferred to add nitro-glucose directly to the collodion which he used in making the emulsion. Notwithstanding this, the advantage of the addition is questionable.

The gum-like bye-product that is contained in pyroxyline, and which passes over into the collodion, appears, according to my experiments, not to be nitro-glucose. If collodion is precipitated with much water, and after boiling the liquid is filtered off, evaporated to a small volume, again filtered, and once more evaporated, a transparent yellowish-brown amorphous mass separates. This substance has a feebly acid reaction, also a slightly bitter taste, and I propose to call it "pyroxyline gum."

Pyroxyline gum yields a trace of pyroxyline to a mixture of alcohol and ether, but it is itself not very soluble in this fluid: it, however, communicates a yellow colour to the liquid. It does not re-dissolve perfectly in water, an indication that a portion has become decomposed during

* *Horn's Photographic Journal*, 1856, vol. vi., page 57.
† *Photo. Arch.*, 1862, vol. cxvi., p. 190.

the evaporation; and it is noteworthy that the aqueous extract, if evaporated again, yields a material which is not perfectly soluble in water. Dried at 100° C., pyroxyline gum becomes brittle and feels quite dry, but when exposed to the atmosphere for twelve hours it absorbs water and becomes pasty.

Pyroxyline-gum is, before its decomposition, soluble in a mixture of alcohol and ether, also in water; but not in benzole or chloroform. After being heated to 100° C., it loses solubility in the first-mentioned liquid.

Pyroxyline-gum consists of carbon, hydrogen, oxygen, and nitrogen (the latter being recognized by Dumas' method). The amount of nitrogen present amounts to 1·2 per cent.

As bye-products there are traces of nitric acid (recognizable by means of brucine) and sulphuric acid; and also traces of potassium salts when nitre is used in the preparation of the pyroxyline. The aqueous solution of pyroxyline-gum becomes gradually brown when exposed to sunlight, while ammonia dissolves it when heat is applied, forming a brown fluid, which reduces an ammoniacal solution of silver slowly in the cold, but rapidly if heat is applied. In a hot and concentrated solution of caustic potash it dissolves rapidly and completely to a yellow fluid, and from this hydrochloric acid throws down a very small quantity of a white flocculent precipitate which contains no nitrogen, while the acid solution contains nitric acid and nitrous acid. Warm nitric acid or concentrated sulphuric acid dissolves it; the latter solution showing the reaction of nitric acid when tested with sulphate of iron in the usual way.

Pyroxyline-gum also reduces Fehling's copper solution, and it has the property of liberating iodine from iodide of potassium; but it does not appreciably affect bromide of potassium.

The amount of pyroxyline-gum in pyroxyline varies according to the method of nitration and the purity of the cellulose; but, as a rule, it may be mentioned that my analysis leads me to conclude that from 1·25 to 1·83 per cent. remains in solution when the ether-alcoholic solution of the pyroxyline is precipitated by water. Of this about 0·91 or 1·60 becomes insoluble in water and a mixture of alcohol and ether during the evaporation, leaving about 0·21 or 0·35 as the amount of gummy residue.

If the cellulose is not pure, the proportion of gummy impurity becomes greater; and if, for example, a small proportion of gelatine is present, the yield of pyroxyline-gum is as high as 3·9 per cent.

OBSERVATIONS UPON FADING.

BY JOHN SPILLER, F.C.S.*

So much has been said and written upon this subject, that it might be thought almost superfluous to attempt to throw new light upon such a worn-out topic; but the supreme importance of the matter, coupled with the fact that discussion has been reopened by the reading of a paper on "Old Photographs," by Mr. E. Dunmore, at the March meeting of the South London Society, must be my justification for once more returning to the subject.

The conditions of permanence are tolerably well understood by photographers, and, so far as regards silver prints, much more care is taken at every stage of their production than was formerly the case. By the liberal use of fresh hyposulphite, and subsequent removal of the excess of fixing salt by very thorough washing in water; the employment of alkaline, or at least well neutralized gold toning baths; silver sensitizing bath, not too weak; negatives not too thin; all are points to which attention must be paid, and, so far as my inquiries lead, are now generally observed.

The photographer having done his best, is now unhappily at the mercy of the paper-maker, for he must needs mount his pictures in some sort of presentable form, and these perchance will find their way into portfolios or albums. What now, if after all the operator's care and trouble in the exclusion of every trace of hyposulphite from his finished print, he proceeds to mount it upon a cardboard impregnated with this very substance? Or if, careful himself about the card mount, his client thrusts it through the grooves of a mass of paper stuff in the shape of a common album, or puts it behind a heavy "cut mount" of doubtful constitution, with a view to its better preservation?

Sixteen years ago, I pointed attention to the "Occurence of Hyposulphite in Mounting Cards," in an article written for the PHOTOGRAPHIC NEWS, which this Society did me the honour to reproduce in the *Photographic Journal* for May, 1868 (Vol. XIII., p. 54). It was there shown that cardboard was seldom or never free from hyposulphite, and a mild appeal was made to paper manufacturers to abstain from using this salt as "antichlor." Now that the subject of fading is again to the front, it seems to me desirable to re-open this old question, and I have been testing cards and mounts, and making a heap of inquiries of the paper makers. My Report, briefly stated, is as follows:—Hyposulphite still to be found in cards of recent make, and the practice of using this salt as antichlor generally admitted by the English paper-makers.

Without mentioning names, I may say that the testimony is most conclusive as to its continued use; but I am not without hope that experiments now being tried on the large scale, on improved methods of manufacturing paper-pulp from wood, &c., by the bisulphite of magnesia process, will result in the introduction of a new system likely to be of considerable benefit to our craft. If this should succeed—and I hear favourable reports from several quarters—a revolution of manufacture will be brought about, and henceforth no antichlor necessary. At the recent Soirée of the Chemical Society (April 24th), Messrs. Cross and Bevan exhibited some samples of Ekmann's new paper-stuff, made by the disintegration of wood under great pressure, and boiling with the bisulphite solution; and these specimens certainly looked like the right article. On the same occasion, Messrs. A. Boake and Co., of Stratford, exhibited a large series of sulphites and bisulphites, as used by paper manufacturers. I am told that Ekmann's pulp can be mixed with an equal quantity of white rag pulp to make the finest paper, and that there is no necessity to employ hyposulphite. If this experience is confirmed, we are out of our difficulties. On the other hand, we know there has been of late a demand for extra thick mounting boards, which could only be supplied at a low or moderate cost by the use of very inferior materials, faced and backed with a better quality of paper. This, of course, offers no guarantee of permanence to the photographer, and the black or highly coloured tablets are often the worst of all.

Tracing the history of this "Antichlor" proceeding, I find, on reference to the English patents, that in the year 1852 (Nov. 26) Thomas Ainsley Cook filed a petition for "Improvements in Bleaching," described as follows:—"In all bleaching operations where chlorine is employed it becomes necessary to take up or neutralize any chlorine that may be in excess. Now, my invention consists in the use of any of the following salts:—Hyposulphite of lime, of soda, of ammonia, of potash, of magnesia, or of alumina, which I apply to the goods, after being treated with chlorine, when the hyposulphite used will neutralize any excess of chlorine that may remain in the material bleached."

Eighteen months later (A.D. 1854, May 9) Eben Norton Horsford took out a patent, No. 1,038, for "The Removal of Chlorine from Substances and Fabrics." This invention "consists in neutralizing chlorine by means of the substance called 'antichloride of lime,' which may be prepared by passing the fumes of burning sulphur into milk of lime, contained in a suitable vessel, provided with agitators. The antichloride of lime, being collected on filters, may be dried and preserved for use. It may be applied by adding a small quantity directly to the pulp engine; or fabrics out of the 'chemic' may be passed through water slightly acidulated, containing in suspension a little of the antichloride."

Here, then, it will be seen that sulphurous acid was proposed to be used instead of the hyposulphite. On tracing back, however, to the earliest mention of the use of sulphites in paper-making, I find a prior claim in favour of John Donkin (A.D. 1846, Oct. 15, No. 11,417); and, as I shall presently show, it is a true misfortune for us that at this early date the manufacture of bisulphite of soda was not sufficiently perfected to allow of its general use as an antichlor, or we should have been spared many of our troubles during the last thirty years. The specification runs thus:—"Improvements in the Manufacture of Paper, or in the machinary employed therein, and in the process of bleaching paper, linen, and other manufactures in which chloride of lime

* Read before the Photographic Society of Great Britain.

is employed." By disclaimer (dated 1847, March 22) the title of this patent is altered to "Improvements in the Manufacture of Paper, and in the process of bleaching linen and other manufactures in which chloride of lime is employed." This invention consists in "the application of bisulphite of soda in solution to paper, pulp, linen, and other articles or materials which have been bleached by means of chloride of lime, so as to decompose and get rid of the chloride of lime which may be remaining mixed therewith or attached thereto." In practice the patentee has found that "about a pound of the saturated solution of bisulpite of soda is sufficient for decomposing the chloride of lime in the pulp obtained from a hundredweight of rags, when the pulp has been well drained or pressed."

By all means, let the paper-stuff be well washed from the bleaching lime and other salts subsequently applied as antichlor, but in order to determine by actual experiment the relative effects of sodium sulphite and hyposulphite, if left inadvertently by the paper-maker, I took two photographs (silver prints), cut them in halves, and submitted them for equal periods of time to the action of these two solutions. The results (exhibited) show that sulphite of soda has no appreciable effect in 48 hours, whilst the other portions of the prints immersed in the hyposulphite are considerably bleached, or, as we should say, badly faded.

These striking differences are borne out again by another experiment which I then made. Clean a few sixpences or small silver coins, and put them into sulphite of soda solution, weak or strong, hot or cold, and leave them there for an hour. Pour off the top liquid, and test for silver by adding a drop of sulphide of ammonium. No trace will be found dissolved. Now try a similar experiment with the hyposulphite, using the same coins, and we shall soon find very distinct evidence of silver in the solution, showing that the metal has been attacked and dissolved by the combined action of air and hyposulphite, forming the well-known double salt of sweet taste.

With these facts before us, the fading of a silver photograph becomes perfectly intelligible, and the necessity for thorough washing, and careful exclusion of hyposulphite from the finished print, become at once apparent. I have described these results somewhat at length, because they furnish an answer to Mr. Dunmore's extraordinary statement, "fresh hyposulphite, even as strong as a 20 per cent. solution, applied to and left in the prints, and dried in the usual way, has no effect whatever on their permanence."*

Forced to indicate the cause of fading, the last-named author attributes the deleterious effects, wherever it arises from the mounts, to the presence of chlorine (excess of bleach) rather than to the hyposulphite. I have looked into this question also, and certainly find soluble chlorides in the cheaper sorts of cardboard, with plenty of sulphates and all kinds of mineral rubbish, but never met with *free chlorine* in the finished mounts. It would most likely be absorbed by the sizing, if traces only were left in the pulp.

Now, in the event of the paper-makers accepting the suggestion to use sulphite instead of hyposulphite, how would this affect the iodide of starch test, upon which we have been accustomed to rely for the detection of the last-named ingredient? It is known that sulphite of soda will also quickly discharge the blue colour of the starch compound. Thus far no difference. But we have a ready method of distinguishing between them, for the sulphite instantly discharges the colour of weak magenta, whilst the hyposulphite has no such action. This, then, ought to be the paper-maker's guide as to the quantity he should add to the bleached pulp— so much as will neutralize the chlorine, and yet not discharge the colour of highly-diluted magenta. Messrs. Giles and Shearer have gone fully into the testing of sulphites in a recent communication to the Society of Chemical Industry, which was printed in their last month's *Journal*. They worked upon some very pure samples of crystallized sulphite of soda made by Messrs. A. Boake and Co., on a large manufacturing scale, which tested over 99 per cent. This proves that high qualities are now procurable, which was not the case when Donkin took out his patent.

Mr. Valentine Blanchard, in speaking of "The Finished Photograph,"† says :—"In a conversation with Mr. England some little time ago on this subject [fading], we confirmed each other's experience that prints mounted on a lithographic tint were more permanent than prints on the ordinary board—the reason for this is not difficult to find. The thin layer of greasy ink keeps the photograph from contact with any deleterious matter in the board, and that such matter exists in a great many samples of pasteboards is only too well known to most of us."

The selection of tinted mounts in preference to pure white is always to be recommended, for then the paper-stuff need not be so highly bleached, and a further precaution is the final application to the photograph of an encaustic paste, which, by diminishing the hygroscopic qualities, helps to shut out the influence of moisture, always so detrimental to the permanence of a photograph exposed in our variable climate.

I have only to add that Dr. Hugo Müller informs me that in South Germany the makers have entirely given up the use of hyposulphite, and he says the same of North Britain. From another source, I learn that the paper-makers of Angoulême tried to do without it a few years ago, but have gone back to the old practice. Perhaps now the reduced cost will again offer encouragement to the use of sulphites ; if so, the photographic community will be well content to hear that a fertile cause of fading has been banished for ever.

† YEAR-BOOK OF PHOTOGRAPHY, 1884, page 77.

ILLUMINATION OF THE DARK-ROOM.

BY W. E. DEBENHAM.*

THE preservation of one of our most cherished faculties, that of sight, is of so much importance to our comfort and well-being, that it is proper to give full consideration to the question of how it may be affected by the light in which we work.

Mr. W. Ackland remarks that since the introduction of red light into photographic dark-rooms, he has observed a remarkable increase among photographers, more than others, of failing sight. On this ground he deprecates the use of red light, and recommends the employment of one of a cooler character.

Dr. G. A. Herschel writes :—"Unfortunately for the dark-room operator, red light of all colours is a great deal the most injurious." By those who advocate the use of red light in the dark-room, other reasons have been sought for to account for the photographer's special liability to failing sight. To some extent these reasons may co-exist with the evil influence of the red light.

There have even not been wanting those who say that they prefer a red to a yellow, or greenish light, as a matter of personal comfort ; but I am sure that the great majority feel the fatigue and irritation to the sight of working in red light, and would gladly change it for light of a cooler colour, if they were aware that the necessity for using a red light, which has been so insisted upon, is a mistake, and that yellow light, of the same degree of illuminating power, has no more effect upon the photographic plate, if as much, as the long vaunted ruby.

The question naturally arises,—How is it that, if there were no necessity for red light, it came with the introduction of gelatine bromide plates to be insisted upon, and almost universally adopted ? It was because it was said that bromide of silver was, compared with the wet plate collodion, the sensitive compound of which consisted mainly of iodide, much more sensitive to the yellow light in particular, and that red light must therefore be used for bromide, whereas yellow was proper for iodide manipulations.

It has often been stated that bromide of silver, whether in the form of collodion or of gelatine emulsion, is more sensitive to the colours of the middle and lower part of the spectrum, and will represent these as lighter, compared with blue and violet, than the old collodion bath plate, which ordinarily consisted of iodide of silver and a small proportion of bromide. So strong a hold had this idea upon the minds of photographers, that when collodion bromide emulsion came into use, although it was less sensitive as a whole than bath plates, it was said that it was so sensitive to yellow and orange light in particular, that it was necessary to use red light for the purpose of the dark-room, and plates were stated to be fogged in a laboratory, the light of which did not injure the bromo-iodide bath plate. This probably arose from the much longer time that bromide emulsion plates were exposed to whatever light was used, during their preparation and lengthened development, than was necessary with bath plates.

When rapid gelatine plates first came into common studio use it was during a winter season, and it was asserted that their

* Read before the Photographic Society of Great Britain.

rapidity was due to their greater sensitiveness to the yellow light of winter; and it was predicted that when the spring and summer came round, it would be found that they would be no more sensitive than the accustomed collodion. This was found to be a mistake, and the most careful experimenters could find no difference in the relative sensitiveness of the two processes in the winter and summer seasons.

Captain Abney, when recommending the use of a small portion of iodide of silver in bromide emulsion, stated that this addition so changed the range of sensitiveness of the compound, by lowering the sensitiveness to orange light, that plates containing a small quantity of iodide might be safely developed in such light, whilst those containing pure bromide only, and of equal general sensitiveness, were so sensitive to orange, that a red light only must be employed in the dark-room. Dr. Eder states recently, *Photographische Correspondenz*, April 1884, page 95, that the addition of iodide renders the plates more sensitive to the yellow and green. Considering that yellow and orange are so close together in the spectrum, and that the bulk of photographic action is at the other end in the blue and violet and beyond it these statements are almost exactly opposed to each other.

I have here a sheet of coloured ribbons, made up of violet, blue, green, yellow, orange, scarlet, and crimson; the colours, of course, are not as pure as those of the spectrum, but they are much purer and brighter, and should produce more difference of photographic effect than the colours of natural objects with which the photographer ordinarily has to deal, and in the delineation of which spectrum photography professes to direct him.

For photographing these, I have prepared three emulsions: No. 1 containing bromide only, No. 2 containing five per cent. of iodide, and No. 3 ten per cent. The emulsions were prepared in other respects in a similar manner, and were made by the boiling process.

Here are photographs produced by these emulsions, and I think you will not be able to find any difference between the results sufficient to be positively affirmed. In each case the violet has come out the strongest, and then the blue. From the green downwards, the colours have all come out in each plate of nearly equal depth, but it will be noticed that the yellow and orange have had less effect upon the plates than the reds. Probably some white may accompany the reds, although they were the purest colours I could obtain in ribbons; still the main point is that with each plates the result is about the same. From this we gather two things: first, that the addition of iodide does not make that difference in the range of sensibility to the colours presented to the camera that has been stated; and, secondly, that if we were to work in our dark-rooms by light reflected from these surfaces, we should choose the yellow and the orange, as having less effect upon the plate than the reds, and giving at the same time far more luminosity.

About a year ago, Mr. J. A. Sawyer showed a somewhat similar sheet of coloured ribbons and photographs from them, in which it was remarked that each colour came out lighter or darker than another in precisely the same series, whether the negative had been taken on an ordinary bath plate, consisting of iodide and a small quantity of bromide, or of a gelatino plate containing bromide and a small quantity of iodide. There was not, however, among Mr. Sawyer's experiments one with a plate containing bromide only; and it is to compare this with plates also containing iodide, and to examine the alleged effects of this addition, that these experiments are made.

At one of the Technical Meetings of this Society I brought forward a lantern, the four sides of which were glazed with different materials, the two most contrasted of which were two thicknesses of ruby glass in the one case, and in the other a yellow produced by two thicknesses of yellow paper and one of a yellowish-green glass. The latter combination was considered by all those present to give a much better, as well as a more agreeable, light to work by than the rubies, and at the same time it had been found to produce at a given distance much less upon a sensitive plate.

Captain Abney, at the March Ordinary Meeting of the Society, followed with a paper, in which he spoke of the questions, which he had considered settled, as having been re-opened, and without referring specifically to the particular light that I had compared, maintained that red was better than yellow for the purpose of dark-room illumination, selecting, as the types for comparisons, a glass known as stained red, and a yellow paper known as canary medium. Now the stained red glass has this peculiarity, that it appears a red, but is really formed by the piling up of yellow. It is a curious fact that, if a clear, transparent yellow is taken, and fresh thicknesses of the same added, the transmitted colour becomes orange, and, finally, to the eye, red, although, when examined with the spectroscope, it will be seen that the yellow still passes, and this adds to the luminous effect to the eye, although the existence of the colour is unperceived. Everyone who has used bichromate of potash solution must have noticed that a thin layer appears pure yellow, but a thick one orange; and, if very thick, red. Stained red is a silver stained glass, in which the quantity of silver is sufficient to give an orange-red appearance instead of the yellow which a thinner layer shows. I have here a wedge made up of increasing thicknesses of stained yellow, where it is seen the colour passes from a pale yellow to a reddish-orange. More thicknesses would show a colour identical with that of the stained red, except for the fact that the natural greenish tint of so much ordinary glass would have its effect. If a piece of stained red be broken, it will sometimes happen that it will chip a little so as to divide the layer of stain, when, as in this piece, it will be seen to be yellow. Immersion for a short time in hydrofluoric acid will, by dissolving away part of the layer, allow the characteristic yellow to be seen, as in the piece now handed round.

In the experiment described by Captain Abney in the March paper, there appears to have been an unaccountable oversight, which, when pointed out, will, I think, be admitted. The trial of illuminating power was made by light passing through rather small holes in the sides of a lantern. Now to find a reading distance with a clear medium like stained glass the opening in the lantern may be reduced until no larger than the flame, without affecting the result. With a diffusing substance like canary medium, the smaller the opening the more the light is cut off, and the nearer the observer has to come to it to see with equal distinctness. The trials for protective power should have therefore been made in a similar manner, at definite distances from the screens of the lantern. Instead of this, the glass and paper were laid upon a plate, and this exposed to the light of a candle flame; the conditions were therefore not comparative. It is, of course, obvious that when using a clear medium—the stained red—enlarging the area of the sides of the lantern would not have increased the illumination at any given spot—the book read from—but would have made a great difference to the diffusing medium—the yellow canary. Another, to me, unaccountable circumstance is, that Captain Abney should have found so much more protective power with the stained red glass than with the canary medium. I have examined several samples of the stained red, which, however, differed but very slightly, and find in each case that more photographic action passes than through canary medium. I have here a sort of negative, composed of three media side by side—a piece of stained red glass, a piece of canary medium, and one of ruby glass. Exposed either to lamp-light or daylight, the canary medium shows less image than the stained red, and the latter less than the ruby.

In addition to condemning the use of a yellow light, Captain Abney stated that the use of a green glass only stopped those rays that were comparatively harmless; and in an article, about the same time, in the *Bulletin Belge*, said that he thought the recommendation to use it proceeded from a confusion of ideas. Now, if a piece of green glass, such as I have here, be examined in the spectroscope, it will be seen that both ends of the spectrum are cut off, the blue is darkened, and the violet almost entirely cut off; the red rays are very much stopped, but the yellow passes pretty freely. When, therefore, such an accumulation of yellow medium is employed as to present a red appearance to the eye, the use of a green supplementary medium, by cutting off the red rays, restores the yellow character which, to most people certainly, is more agreeable and less irritating than red or orange, at the same time that it assists in more completely cutting rays off of some actinic power. In the lectures last delivered by Captain Abney before the Society of Arts, it was recommended, when additional safety was required, to supplement stained red glass by a sheet of cobalt. I have here a double lantern, in one compartment of which I will use a stained red and a cobalt, and in the other a stained red and a green. It will be seen that much more light passes through the stained red and green glasses than through the red and cobalt.

(To be continued.)

Notes.

Light for the dark-room still offers abundant matter for discussion, and Mr. J. R. Sawyer's suggestion that the source of light itself should be thoroughly screened from the eyes is an excellent one. Two years ago, in recommending the Swan electric lamp for dark-room use, we suggested suspending the lamp over the work, and using a piece of tinfoil so as to shade the eyes.

Certainly yellow light is now finding more favour than red light for use in developing gelatine plates, and as far back as 1880, Captain Abney (Bakerian Lecture) pointed out the conditions under which yellow light might be of especial service.

Martius' yellow, one of the nitro-derivatives of naphthol, appears to be one of the best yellow colours for protecting dark-room windows, and years ago we used it for collodion work. It is said to be the colouring matter used for tinting the so-called "golden fabric" that has recently been introduced into commerce, and of which Mr. Debenham spoke so highly at the meeting of the Photographic Society on Tuesday last.

Cloth or fabric possesses especial advantages of its own over paper or glass, as it is not likely to be fractured on one hand, or torn on the other. Moreover, by taking a piece of cloth and a few pins with you on a journey, there is but little difficulty in extemporising a dark room in almost any situation.

"But no experiments have been made with a view of proving it," was depreciatingly said on Tuesday by Mr. Peck, in reference to the supposed injury to the eyesight resulting from dark-room work. Long ago Mr. Woodbury told our readers how he had suffered; but the idea of experimentally investigating the matter is original. Who is to be the martyr to science?

Last week a hope was expressed that the Council of the Photographic Society would appoint a committee to deal with the whole question of impure haloid salts, and we understand that some steps have already been taken. No better guarantee for good work can be offered than the co-operation of such men as Abney, Davis, Donkin, Spiller, and Warnerke.

An incident which we noticed during a performance of Gounod's *Redemption* at the Trocadero one day last week illustrates the carelessness with which optical instruments are often handled.

A lady, whose face was covered with one of the spotted red veils so much worn in Paris just now, evidently derived but little or no advantage from the use of her opera glass, one by Arthur Chevalier, and it was almost painful to see her repeated attempts to remove imaginary dirt by probing at the lenses with the butt-end of her fan.

Not that photographers use their objectives after that fashion, but very few obtain on the sensitive plate the maximum of dividing power of which the instrument is capable. Unsteady stands, glasses screwed up too tightly, tarnished or corroded surfaces, and slides out of register are ordinarily of far more moment than the optical imperfection of the lens.

A good proof of the occasional phosphorescence of the diamond was afforded by a trial recently made by M. Picard, with an exceptionally clear and fine stone of 92 carats. It shone in the dark for more than twenty minutes after having been exposed to sunlight.

A photographic portrait is said to have enabled the Prussian Police to arrest Degaieff, who, it will be remembered, assasinated Colonel Sudeikin.

Photographing colours is a main question of the day, and in the *Bulletin Belge*, Captain Abney once more calls attention to the fact that the addition of Prussian blue to gelatine emulsion makes it more sensitive to the yellow than the blue; or, to put the matter more clearly, the sensitiveness to the blue is diminished below the yellow. Abney has found but little or no advantage in using isochromatic plates for landscape work, and he attributes this to the fact that almost all coloured bodies reflect very much white light.

Mr. David Gill, F.R.S., astronomer at the Cape of Good Hope, in a recent lecture at the Royal Institution, held out hopes that Mr. Norman Lockyer's idea of a complete photographic map of the heavens would shortly be attempted in a practical form. Dr. Elkin, an American astronomer, had expressed his willingness to do it in the Northern hemisphere, and Mr. Gill wished to do it in the Northern hemisphere if the Lords of the Admiralty would supply the necessary apparatus. There is much virtue in an "if," and it would not, perhaps, be well to say much about this map until the Admiralty authorities have acceded to Mr. Gill's wishes. It is estimated that it would take ten years to make a complete photographic map of the heavens—not so long when we consider the length of time the ordnance map of England alone has occupied.

The competitions held every year in Paris and London by *coiffeurs*, in which the competitors manipulate the hair in view of the members, suggests a new form of photographic contest. Why should there not be competitions in the posing and lighting of the sitter—a prize to be given for the most artistic picture? Practical demonstrations of this kind—not, however, as competitions, but by artificial light—have already been instituted by the Photographic Association of America.

A good many daring things were done at the Shakespearian show at the Albert Hall, but the boldest individual, perhaps, was a gentleman who actually offered for sale, photographs of himself in his fancy costume!

When photographers change the specimens in their cases it is as well to see that no inscription remains referring to former exhibits. Through neglect of this precaution, a Clifton photographer has been exhibiting a case of cabinet portraits, described as "Bristol Clergy and Ministers," all of which, with one exception, are portraits of young ladies!

It now appears that the Artistic Copyright Bill is the outcome of the deliberations of the Law Amendment Society, assisted by the advice and co-operation of "authors, artists, publishers, and others," invited to their meetings to discuss it clause by clause. Photographers appear to have been left out in the cold, unless they are included among the "others." The Printsellers' Association subscribed £50 towards the expenses, as also did the Royal Academy, and subscriptions of smaller amounts were received from the lesser artistic societies. "The Bill," observes "a print seller" in a letter to the *Pall Mall Gazette*, "may be said to go before Parliament with the unanimous and hearty approval of all the art bodies in the three kingdoms." It is very consoling to know this. The title, however, might, in the interests of truth, be improved. It should be called a "Bill for the protection of artists, engravers, and publishers, and to prevent the dissemination of art at low prices by means of photography."

Those who are interested in knowing how the photographic portion of the Bill has grown to its present proportions will find that the story has been fully related in our pages. It all arose out of an action brought by the Stereoscopic Company against a photographer in the north of England. The Company photographed the Australian Cricketing Team of 1882, and the defendant copied the photograph. Hence the action. The contention of the defendant was that, although the Stereoscopic Company had their name on the photographs, they had not complied with the Act, as they had not registered the name of the author (that is, the operator) and his place of abode. Mr. Justice Field held that the defendant was right, and this decision was upheld by the Master of the Rolls. It became necessary to meet this objection, and the Bill, which stands for the second reading next Wednesday, has consequently been strictly and elaborately framed.

Direct copying processes, in which the original writing or drawing is used as a cliché, are largely used by engineers for multiplying plans and drawings; but the somewhat slow iron or cyanotype methods are generally used. Gelatino-bromide paper may be advantageously employed instead; as, at a recent meeting of the Amateur Society of New York, Mr. Beach made a copy of a drawing on thick card, and another of a letter by Captain Abney. The exposure was one of a few minutes to the light of an oil lamp.

For legal purposes one would think that direct copies of documents impressed on gelatino-bromide paper would prove of great value, especially as one "photographic clerk" could easily make fifty or sixty reproductions by gaslight in the course of an evening.

Seaweed certainly should have more than a passing interest to the photographer, as not only is it the main commercial source of iodine, but our readers will remember how successfully Mr. Paymaster Mitchel used seaweed (*agar-agar*) as a basis for a gelatine emulsion (1882, p. 67).

Mr. Edward Stanford, whose name is so intimately connected with the development of the seaweed industry, has communicated to the Society of Arts an important memoir on seaweed products. As regards photographic uses he recommends for trial the British species *gelideum corneum*; and of gelose, the product of this, he says:—"Gelose has eight times the gelatinizing power of isinglass, and the jelly keeps well, the others soon get mouldy. Gelose may be valuable in the arts as a substitute for gelatine, which it so much exceeds in gelatinizing power. I would specially suggest its use as a substitute for gelatine in the production of instantaneous photographs."

From the wording of Mr. Stanford's remark, we cannot help fancying that his views as to the way of making instantaneous photographs are vague; but we gather interesting information, further on, regarding seaweed paper, a product which is made in France from the *Zostera marina*. Seaweed jelly, like ordinary gelatine, becomes insoluble by the joint action of light and bichromates.

The lime-light explosion, which we recorded last week, has terminated fatally, one of the injured men having died. This is the second lime-light explosion which has been fatal within the past few months.

A photograph on the season-ticket as a mode of proving identity deserves to be more used than it is; but we can recall to mind cases in which the railway season ticket has done service for us as a passport. An innocent deception of similar character was practised by a contributor, who, after much effort, obtained authority to be present at the opening ceremony of the Turin Exhibition; but on presenting himself he found that only wearers of orders could enter. He calmly pinned the badge of the 'Cyclist Touring Club to the breast of his coat, and was immediately admitted to the presence of the King of Italy and his Queen.

By the resignation of Mr. Alderman Hadley, Mr. Alderman Nottage is next in succession to the Mayoralty—that is to say, if the Municipal Bill does not step in meanwhile.

The latest absurdity in fashion with the New York "dudes" is to have the portrait of some leading beauty delicately outlined on the forehead between the eyes. We are not told whether this picture is effected by means of photography. Any way, it suggests that a fashionable Strephon might, if he chose, have the portrait of his Delia transferred to his own skin, and so be able to boast literally that he wears the picture of his lady love next his heart!

Patent Intelligence.

Applications for Letters Patent.

8538. JEAN JOSEPH DESIRE HUTINET, Paris, France, Manufacturer, for "An improved preparation or compound for photographic purposes." Dated 3rd June, 1884.

8566. GEORGE WILSON MORGAN, Photographer, 5, Crimon Place, Aberdeen, Scotland, for "Mechanically shifting photographic scenery, called Multiplex Background Screen."—Dated 4th June, 1884.

8643. BENJAMIN JOSEPH EDWARDS, 6, the Grove, Hackney, Middlesex, Photographer, for "Improvements in coating photographic plates or paper with gelatine emulsion." (Complete Specification.)—Dated 5th June, 1884.

8721. WILLIAM SAMUEL ATWOOD, 1, Lime Tree Villas, Chase Side, Southgate, Middlesex, Photographer, and SAMUEL BENJAMIN GOSLIN, 27, Jewin Crescent, Cripplegate, London, Engineer, for "Improvements in photographic cameras."—Dated 7th June, 1884.

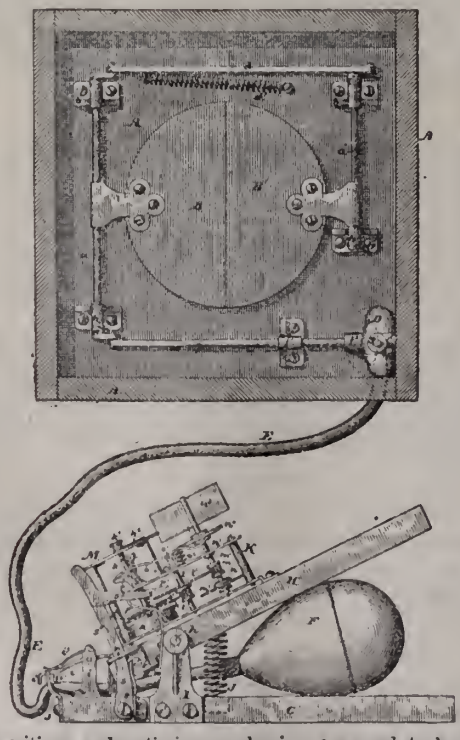
Patent Sealed.

5681. WILLIAM ROBERT LAKE, of the firm of Haseltine, Lake, and Co., Patent Agents, Southampton Buildings, London, for an invention of "Improvements in and relating to colour-printing, also partly applicable for producing coloured photographs and for similar purposes."—A communication to him from abroad by Auguste Bisson, of Paris, France, Heliographic Engraver.—Dated 8th December, 1883.

Patents Granted in America.

299,289. CHARLES W. STIFF, Foxborough, and NATHANIEL C. BOUSLEY, Salem, Mass. "Photographic camera." Filed Aug. 27, 1883. (No model.)

Claim.—1. In combination with a photographic camera, a mechanism to be worked by the operator, and arranged and adapted to open the lids or shutters of the lens-tube, a device for automatically locking and retaining said lids or shutters in their



open positions, and a timing mechanism arranged to be set in motion by the operation of the shutter-opening mechanism, and to release said locking device and permit the closing of said lids or shutters at the end of any predetermined interval of exposure.

2. A pneumatic device adapted to open the lids or shutters of a photographic camera, and at the same time set in motion a timing mechanism which will automatically close the same at the end of any predetermined interval of exposure.

3. A presser adapted to open the shutters of a photographic camera by forcing air into an expanding-chamber, to keep said shutters open by preventing the return of the air by any suitable mechanism, and at the same time to set in motion a mechanism that will automatically release the air from said chamber at the end of any predetermined interval of exposure, thus allowing the lids to close.

4. The combination of the lever H, pivoted to the frams G in any suitable way, the bracket r', with its slotted horizontal projection r, the spring-actuated lever s, provided with the notch s^2, the bulb F, the tube E, and the bulb D, in conjunction with a suitable mechanism for operating the lids or shutters of a photographic camera, substantially as and for the purposes specified.

5. The combination of the spring-actuated nipper-lever i', the forked bracket j, the spring-actuated hook j', all attached to the frame G, and the projection u, and plate x, secured to the shorter arm of the lever H, all adapted to operate substantially as and for the purposes described.

6. The combination of the presser G H, spring J, the projection r, the lever s, provided with the notch s^2, and bent arm s^3, and the arm w, attached securely to the shaft k of the clockwork, all adapted to operate substantially as and for the purposes described.

7. The combination of the dial M, the pointer k^6, the ratchet-wheel k^3, the pawl k^4, the gear k^5, and the spring k' all adapted to operate substantially as and for the purposes described.

8. The combination of the friction-disk n^2, mounted upon the shaft n' of the clock-work, the spring-actuated lever o, the bent lever p, and the bent stationary arm p', all adapted to operate substantially as and for the purposes described.

9. The combination of friction-disc n^2, mounted upon the shaft n' of the clock-work, the spring-actuated brake-lever o, the bent lever p, the spring-actuated dog q, the arm v, securely fastened to the shaft k, and means for operating the lever p, substantially as and for the purposes specified.

10. The combination of the lids or shutters B B', adapted to close the inner end of the lens-tube of a photographic camera, the shafts a a', the rocker-arms c c', the connecting-rod d, and means for operating the same, substantially as and for the purposes specified.

11. The combination of the lids or shutters B B', adapted to close the inner end of the lens-tube of a photographic camera, the shafts a a', the rocker-arms c c', the connecting-rod d, and the spring d', all substantially as and for the purposes described.

299,361. THADDEUS B. EIKER, Baltimore, Md. "Head-rest." Filed Sept. 19, 1883. (No model.)

Claim.—1. The combination, with a frame whose sides each consist of upper and lower folding sections, of arms for securing the device to the top edge of a seat, stops for supporting the upper sections of the sides, a transverse brace securing the sides together, and flexible covers, substantially as set forth.

2. The combination, with a folding frame whose sides each consist of sections pivoted together and formed with extensions and stops, substantially as described, of a transverse brace pivotally secured to the side sections, and transverse flexible strips or covering connecting said sections, substantially as set forth.

3. The combination of the sides of the folding frame each consisting of a lower section formed with a rearward extension and a stop, substantially as described, and a top section pivoted to the lower section, a transverse brace pivotally secured to the pivot of the side sections, and transverse flexible strips or coverings connecting the said top and lower sections, substantially as set forth.

4. The combination of the lower side sections, each formed with a rearward extension and a forwardly-projecting stop at its

top, the top sections pivotally secured to the lower sections below said stops and engaging the same, as set forth, the transverse brace, a transverse flexible removable strip or covering connecting the top sections, and a corresponding removable strip or covering connecting the lower sections, substantially as set forth.

FRENCH CORRESPONDENCE.

REPRODUCTION OF COLOURS—PHOTO-TRACING PROCESS—BALAGNY PELLICLE PAPER—M. MOLTENI'S IMPROVED LANTERN—PANORAMIC LENS COMPETITION—BALAGNY'S RED TONING FORMULA—GELATINO-CHLORIDE OF SILVER PLATES—CHAMBRE SYNDICALE.

Researches on the Reproduction of Colours.—It is very satisfactory to note the experiments just now being carried on in the reproduction of colours in their relative tones. Since MM. Tailfer and Clayton established in Paris a factory for isochromatic plates, a new impulse has been given in that direction. Ammoniacal eosine stands first among the substances added to the emulsion susceptible of diminishing the action of the blue and violet rays, and intensifying the yellow, green, and red. These experiments are interesting, as applications of photography to the correct reproduction of nature or works of art, and it is to be hoped that shortly we shall be able to take all colours in their respective values.

Photo-tracing Process.—At the last meeting of the Photographic Society of France, M. Davanne described a photo-tracing process as indicated by M. Cheysson, director of the map and plan department in the published works office. It is very simple in idea. A silver print on salted or albumenized paper printed from a negative, positive, or original design traced on paper, is taken, and the outline is gone over with a pencil, and the print submitted to a chloride bath for the purpose of transferring the image into chloride of silver. A bath of bichloride of copper answers the purpose satisfactorily; the photographic print disappears when immersed, the paper becoming white, while the outline traced remains visible. It is fixed in hypo or cyanide of potassium, and washed. The process is also applicable to tracings to be transferred to stone or zinc, only it is of no use to suppress the photographic image, and lithographic ink should be employed in the outline. I have always worked in this way myself with photographs to be printed in colours. From the tracing on the first stone as many prints are taken off as are wanted, so as to have copies on paper to be again brought on to stone or zinc in the process of chromo-lithography or chromo-typography. By destroying the image with bichloride of mercury, it can be made to reappear by using ammouia, or simply immersing in hyposulphite of soda, this being the process followed in the so-called "magic" photographs.

Balagny Pellicle Paper.—I have already pointed out some of the merits of this paper, used so successfully at the laboratory of the Museum of Decorative Arts, and I have conducted further experiments on outline subjects with it, and from its sharpness of definition find it suitable for making negatives for tracings on bitumen in zincography. It can be coated with wet collodion for impressions on bitumen. It shows no tendency to fog, and is sufficiently rich in bromide of silver, in spite of its thin substance, to give very opaque blacks in the shadows. These advantages combine to render it excellent both for objects with delicate gradations of shadow, and outline subjects, giving images in sharp black lines on a white ground.

M. Molteni's Improved Lantern.—M. Molteni, in presenting his new form of lantern for projecting and enlarging, has improved on his old model, so as to fulfil more fully the wants of photographers, and particularly the execution of enlargements from the small pictures taken by pocket apparatus. Among the characteristics of M. Molteni's lantern may be noted:—1st. The petroleum lamp, with a single flame, giving a steady light; 2nd. The reflecting mirror, placed at the back of the lamp, so that the rays converge on to the condenser placed in front of the light; 3rd. The lantern does not allow any diffused light to escape, so that it can be used without a conical guard. Of course, the same lantern serves equally well in projecting pictures on the screen, and, in such a case, a lens with full aperture should be used; while, for enlarging, it is best to use the same lens used for the original picture.

Report on the Panoramic Lens Competition.—The Photographic Society of France reported in December last on the competition for panoramic lenses. A prize of 2,000 francs was offered by the Minister of Public Instruction to the inventor of a lens fulfilling certain conditions. Unfortunately, but one competitor presented himself, without fulfilling all the requirements.

Balagny's Red Toning Formula.—The following is the formula employed successfully by M. Balagny for the red toning so much in vogue at present. Dissolve 1 gramme of chloride of gold in a litre of distilled water, then add 200 c.c. of a filtered solution, made at boiling point, of 30 grammes of borax and a litre of water. The toning bath is brought up to the temperature of 70° or 80° Centigrade, and then the prints are plunged into it for thirty or forty seconds only. They are afterwards fixed in hypo containing 1 to 2 per cent. of ammonia.

Gelatino-Chloride of Silver Plates.— Gelatino-chloride plates are now on sale by M. Hutinet for dia-positives. It is to be desired that this preparation should be more universally used for transparencies.

Conference organised by the Chambre Syndicale.—This conference is to bear on the all-important question, "The part taken by photography in the creation of works of art." Such is its title, and it is particularly directed to the attention of artists. It will take place on June 16th, and interesting communications will be made on the actual state of jusisprudence in the matter of photography.

LEON VIDAL.

Correspondence.

POTASH SODA SULPHITE DEVELOPER.

DEAR SIR,—In No. 1341 you gave us particulars of Mr. Newton's "Potash Soda Sulphite Developer," asking experimenters to advise you as to the result.

I find it to compare very favourably with "Alkaline Pyro" of the old form, giving a denser negative with more of the old wet plate characteristics, and takes a somewhat less exposure, but very much aggravates "blister and frill." I have tried it on four makes of plates, and consider it the best for amateur work, if judiciously used with the alum bath.—Yours truly, RICHARD PARR.

A PRINTING PROCESS FOR INDIA.

SIR,—I would strongly recommend your correspondent "Assam" (PHOTOGRAPHIC NEWS of 25th April) to stick to the silver printing process when travelling about in camp. The climate of Assam is warm and damp, and this will make both the carbon and platinotype processes very troublesome to manage. The collodio-chloride process might answer "Assam's" requirements, but the prepared paper would have to be procured from Europe, and it is doubtful whether it would keep. A printing process, simple, certain, and permanent, has yet to be discovered. —Yours faithfully, W. L. NOVERRE, Lt.-Col.

CHLORIDE OF CALCIUM FOR DRYING.—A CHEAP ARGENTOMETER.

DEAR SIR,—A few weeks since a letter appeared in your paper stating that the writer used chloride of calcium to dry photographic dry plates. I have made a number of drying boxes, but with indifferent success, dust, &c., being

a great enemy and a nuisance. I was going to try calcic chloride, but cannot obtain it here. A chemist told me that powdered quicklime would answer the same purpose, as they always used it for drying, &c. Will you be kind enough to say whether you think it would answer the purpose in an air-tight box? I am only an amateur, so that is my excuse for troubling you.

I have made an argentometer for the bath with one of those little bottles which are sold at the confectioners all ready filled with sweets. I removed the sweets, and loaded with a drop or two of mercury, after which I gummed inside a paper scale. Cost of it one-halfpenny. —Yours, GEO. W. PHILLIPS.

[Either chloride of calcium or quicklime may be used for drying, and although, as we have already pointed out, the latter may possess special advantages in some cases, chloride of calcium is to be preferred for gelatino-bromide plate work. An excellent plan is to obtain sheet iron baking dishes, and after having broken the chloride in fragments about the size of a marble, to well cover the bottom of each dish. These dishes being placed in the central part of any tolerably air-tight box or case, the plates are arranged on racks or otherwise round about the dishes. When the chloride of calcium has attracted much moisture, it can be restored to its original condition of usefulness by being baked till once more dry. Although the actual market value of chloride of calcium is trifling, it does not pay a retailer to sell it under about one shilling per pound unless there is a considerable demand. Doubtless our correspondent will find the local chemist willing to obtain some with the next consignment of goods he has from his wholesale druggist. If this should not be the case, it would be well to send a few shillings to a London dealer in photographic chemicals, and ask him to forward chloride of calcium to value.—ED. P.N.]

EXTREMELY SMALL DIAPHRAGMS.

SIR,—A question I have not seen touched upon in my reading is, What are the disadvantages and advantages of a very small diaphragm—smaller than one that is ordinarily used—say with portable symmetrical lens $\frac{f}{64}$? Supposing it were $\frac{f}{120}$, would its advantages in possible depth of focus compensate for the extra length of exposure on any subject?—Yours obediently, A. G. BROPHY.

[The point touched upon by our correspondent is one of considerable importance, and, as Captain Abney has had especial experience regarding this matter, and has also studied it theoretically, we hope he will say a few words on the subject in our issue of next week.—ED. P.N.]

THE PERMANENCY OF AURINE.

DEAR SIR,—In the paper read by me last Tuesday before the Photographic Society upon "Commercial Fabrics for Dark-room Illumination," and of which a report will doubtless appear in this journal, I recommended the use of aurine dissolved in varnish to give a very non-actinic colour to paper and fabric for use in lanterns and dark-room illumination generally. In the short discussion that ensued, Mr. Warnerke stated that he had found the aurine very fugitive in daylight.

I have had but little experience with it in daylight, and when it was introduced some years ago by Mr. Spiller, it was believed to be permanent under all conditions. Upon enquiry, I find that it is a permanent colour when used upon certain fabrics—silks and woollens, I believe—but not upon cotton goods; and, according to Mr. Warnerke, it is not a permanent colour upon paper. Be this as it may, it is perfectly stable, and very useful for all artificial light work; and as I employed my aurine locked up in the gums of a varnish, I am not disposed, without further trial, to abandon it for daylight work. I shall expose one of my aurine paper screens to the full daylight and sunlight for the next two months, partially shielded, and with your permission report progress in the pages of your journal.

I may mention that on receipt of a stamped and directed envelope, I will send a small sample of the yellow fabric and yellow paper that I recommend, and which in my hands form a perfect and safe screen for making or developing the most sensitive plates. The paper is treated with a drying varnish to give it transparency. J. R. SAWYER.

WELLINGTON AMATEUR PHOTOGRAPHIC SOCIETY.

SIR,—In your issue of the 1st February, I notice that you state that New Zealand has beaten Australia in forming the first photographic society at the Antipodes; and as you mention that the Auckland Society held its first meeting on November 2nd, 1883, this would lead to the impression that Auckland held first honours.

The Wellington Amateur Photographic Society was formed here in August, 1882, and I was under the impression that our late Hon. Sec. had informed you of the fact. Perhaps a few facts regarding our condition may not be uninteresting to you.

We at present number about twenty working members. A monthly meeting is held at the residence of our President, Dr. Hutchinson, of this city, at which work is compared and the usual photographic gossip indulged in. The photographic journals are also circulated amongst the members. Field excursions are held occasionally: our last one extended over three days, being held in the hilly district, about twenty miles from the town. Some of our members are continually making trips in various parts of the Colony. One of the members and myself have just returned from a six weeks' trip by sea to Auckland, returning overland, when we obtained about one hundred and eighty negatives.

From these remarks you may gather that amateur photography in Wellington is in a by no means unsatisfactory condition; and as we increase our numbers we hope for even better things in the future.—Yours faithfully,

W. WILLIAMS, Hon. Sec.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

THE last ordinary meeting of this Society for the present session was held on Tuesday, the 10th inst., at the Gallery, 5A, Pall Mall East, JAMES GLAISHER, Esq., F.R.S., President, in the chair.

The minutes of the previous meeting were read and confirmed, after which the following gentlemen were duly elected members of the Society:—Messrs. W. Von-Sommer, and S. G. B. Wollaston.

The CHAIRMAN said that on the last occasion the papers occupied a longer time than they were used to, so that Mr. Sawyer's paper, as also the discussion on Mr. Debenham's paper, was adjourned until the present meeting. It was proposed to take Mr. Sawyer's paper first, and the discussion on the two afterwards. He then called on Mr. Sawyer to read his paper on "Commercial Fabrics Suitable for Dark-Room Illumination."

Mr. J. R. SAWYER alluded to his friend Mr. W. S. Bird's remark at the March meeting, that "The great discrepancy between the scientific evidence, and the experience of skilled observers, indicates that something is wrong somewhere. May it not happen that our knowledge of the chemical effects of the spectrum is not so exact as it might be? When some observers are convinced that a light modified with yellow paper and a green glass will give the maximum of luminosity and the minimum of chemical action, it is bewildering to be assured that spectrum analysis demonstrates to the contrary. Futher enquiry is necessary to clear up the subject under discussion." "Yes," said Mr. Sawyer, "that is so, and for that reason I have been at some pains to bring the matter before you in a practical manner." He hoped to put the subject before them in such a way that they could give a verdict in favour of one kind or another; he intended steering clear of the spectrum, stained red, cathedral green, and canary medium. It had been said with great stress that red light was injurious to the sight—as much as

to imply that those people who are engaged in making, and those engaged in using, plates are always staring at the red light, instead of the work they have to do. In well arranged works this is not the case. When persons are reading they do not stare at the light, but at their book, and there is no reason why the same should not apply to the manipulations of dry plates. The strain put on the muscular fibres composing the ciliary muscles when the eye is quickly transferred from bright sunlight to semi-darkness was referred to, but with care to avoid overstraining the eye would accommodate itself to the changed conditions. Mr. Sawyer continued by saying that more than a year ago he read a paper before them on "Photographic Relation of Colour to the Eyes," and exhibited a series of bands of coloured ribbons, also photographs of the same; these he would again bring before their notice. No. 5, it will be remembered, was a more luminous colour than No. 7, yet it had a less actinic—that is, photographic—action on a bromo-iodide gelatine plate than the red. This fact indicated to him the direction for experiment. Taking the luminous values of red and yellow to be about the same, red is more trying to the eyes than yellow. The most suitable material he could find was book-binders' cloth, a substance obtainable anywhere; specimens of which, together with yellow paper, were handed round. By means of a suitable lamp, Mr. Sawyer showed the luminosity of the following media, also the amount of action on plates of known speed:—Ruby fabric, orange fabric, yellow fabric, ruby-orange, and yellow fabric; orange and yellow fabric, ruby and yellow, ruby and orange fabric; yellow fabric treated with aurine varnish; white paper treated with aurine varnish; the last two together also repeated with two thicknesses of aurine paper. The plates were of the same batch—*i.e.*, 24 on the Warnerke sensitometer. They were exposed, in all cases, the same time—five minutes at a distance of fifteen inches from the screen. Developing occupied four minutes with alkaline pyro, the maximum quantity of alkali being used; and to get the greatest possible fairness of results, they were all developed at the same time in the same dish. Mr. Sawyer then passed the results before the lamp, each plate being initialled with the particular kind of media employed. The results of the three first showed much action, the illumination being very good. The ruby-orange fabric showed a marked diminution in illumination, and likewise veiling. Orange and yellow fabric gave about the same amount of effect; but the illumination was better. Mr. Sawyer considered it proved, from those experiments, that a yellow medium had the advantage of diffusing more light than red with less effect, and less pain to the eyes. He could see that aurine, a substance which Mr. Spiller recommended some time ago, would prove better than any other substance for staining paper or fabric than he could procure. He therefore prepared both paper and fabric which gave him a colour somewhat approaching orange. Here is a single thickness of aurine paper, and it will be noticed that there is far less effect with it than any other of the mediums tried. It is dissolved in negative varnish, the proportions being 1 drachm of aurine in 1 ounce of varnish. It is soluble in water and alcohol. We next come to one thickness of paper and one of fabric, each treated with aurine. Beyond the plate being fogged, from forcing the development, there is no trace of decomposition—that is to say, there is no image. With two thicknesses of aurine paper and one of fabric, the light would be absolutely safe. Before quitting this part of the subject, he would recommend the mediums to be hinged. Two thicknesses of aurine paper and fabric should be sufficient for daylight if the major portion were covered with a black roller-blind until details appeared. His experience with greens was singular. He found ordinary light passed through dark green glass impressed a plate a good deal in five minutes; the same light passed through light green glass had no more effect, although the luminosity was much greater. He had tried several combinations of green and yellow, but would not bring them forward to night. They would agree that the experiments he had performed were fair and perfectly practical. With proper ventilation, and sufficient light from the proper direction, there is no reason why they should have any cause to attribute evil effects to dark-room work.

The CHAIRMAN: Before asking for a discussion, Mr Debenham has made an important improvement in his lamp which he will explain.

Mr. W. E. DEBENHAM: Since the last meeting I have made an improvement in the composite white light, making it, I believe, the safest light known, without intending to lead away from the conclusion that a general safe light is obtained with yellow medium. I have here three lamps; this one in which the light is turned down is merely used to give diffused light, of about the same relative power as the others used for the composite white light. One of these is glazed with green glass, the other fitted with deep silver stained glass (stained red) covered with pale green; light from this appears orange. Light from these lamps received on yellow paper is reflected through the front of the lantern covered with white tissue paper. Rapid (fifty times) plates exposed at reading distance (names in a directory were taken) for a quarter of an hour behind a transparency gave no image, but showed a slight mark where part of the transparency had been scraped away, leaving bare glass. Comparing this light with that produced by turning down the lamp low, reflecting from white cardboard, and transmitting through tissue, the second lamp appears more white than the first. The first is a little yellow looking. The lamp turned to such a height that reading distance was the same gave an image through a transparency in one minute. [The results were shown.] If in place of tissue in front of the double lantern, two thicknesses of Messrs. Law and Son's Golden Fabric be employed, the light appears yellowish; moreover one hour's exposure at a reading distance gives scarcely a perceptible trace where the transparency was scraped away. The same experiment has been tried with other very rapid commercial plates with a similar result. The sample of golden fabric was sent me, and I must say that it is the safest thing for the same degree of luminosity that has ever come under my notice.

Mr. C. RAY WOODS: At the last meeting I brought the results of some experiments, but owing to the lateness of the hour I was unable to show them; I will pass them round now. The plates were exposed through a negative made of one thickness of ruby and two of orange paper, something like Mr. Sawyer's; also through canary medium, orange and red glass, and dense ruby. Three thicknesses of canary medium transmit about as much light as two thicknesses of orange paper. The weak point in all fabrics is that so much of their safety is due to general absorption. From a piece of stained red glass a portion of the colour was removed, leaving the centre untouched; that central portion, when tested, had no effect on the plate. The stained red employed was a portion cut from a large sheet obtained at a glass merchant's in Kensington, and he (Mr. Woods) thought Mr. Debenham should have obtained the same kind of glass as Captain Abney had recommended before he (Mr. Debenham) made his experiments. Captain Abney had explained the difference between a stained red and a flashed ruby. Had Mr. Debenham used the same glass as that recommended by Captain Abney, he (Mr. Debenham) would have obtained similar results to Captain Abney. He (Mr. Woods) used a lamp for his experiments. Magnesium wire gave a different result; moreover, it is a light photographers are not used to. He never yet met a green which, when examined spectroscopically, would not permit the blue to pass. He considered he was justified in using the term cathedral green, as he found there was such a term used in the trade. In reference to Mr. Sawyer's paper, had he tried his media spectroscopically, it would have been better; the two results might be found to agree very well together.

Mr. J. CADETT had carried out some experiments with canary medium and stained red. He found the power of different observers to read in the two coloured lights varied. Of three observers, the difference in power of stained red was as 1·4 and 1·6. He considered bright red light had greater efficiency than yellow; when dealing with light of low power, then the yellow would be superior. It is surprising how much blue can be seen through canary medium by the spectroscope, only red and a little green being seen through the stained red glass. Yellow light would do for a packing room; but, for examining plates, the light should be stained red.

Mr. DEBENHAM said glass known as stained red is sold of two kinds, and they may resemble each other so closely as to deceive an experienced observer. Some red glasses are stained red on one side, yellow on the other, some red and orange flashed. Referring to the report of the last meeting in the *Photographic Journal*, he thought Mr. Cowan must have misunderstood him. The bundle of yellow plates passed round was not those used by him, they were merely to show that red is a compilation of yellow. In Mr. Sawyer's opening remarks, he referred to the scientific accuracy of the question. The best way is to get the distance by a scientific method, and try the photographic effect afterwards. In Mr. Sawyer's first experiments he showed very clearly the advantage of yellow over orange; the yellow was stated to give less effect. The distance should have been increased to get the

same luminosity or reading distance, then it would have been perfect. Aurine was not proved to be a better colour than yellow-green. Hinging the dark-room window was good; but he preferred the sliding form, as less in the way of bottles, &c. He did not think green alone had been suggested by anyone; the dark green shown was a blue-green; it should have been a yellowish-green. Mr. Woods is right in speaking of cathedral green as such, because it is possible to get cathedral in several colours; to speak of cathedral green as any particular colour is at least misleading.

Mr. L. WARNERKE found the best substitute for canary medium was chromate of lead, made by floating paper on a solution of nitrate of lead, then on bichromate of potash. Aurine and most of the dyes bleach considerably, so what might be good at first, soon becomes dangerous. Chromate of lead did not bleach like aurine.

Mr. SAWYER, replying, said everyone must define in his own mind what scientific evidence meant; but he did not mean his to be a scientific paper, only a practicable method of testing suitable screens in suitable lamps. Our dark-rooms are in a fixed position—windows, sinks, shelves, &c., remain in the same position. If we can have a yellow light fixed at two feet from the position of working, it must be preferable to a ruby light and working close to it. Although he did not trouble them with his experiments with the greens, he hoped Mr. Debenham did not think he had not gone into that part of the subject. Green takes from the illumination without any corresponding advantage. He was sorry Mr. Warnerke found aurine fugitive; if it was really fugitive, then lead chromate might be easily applied.

The CHAIRMAN, in asking for a vote of thanks to Messrs. Debenham and Sawyer, also to those who had taken part in the discussion, said that in all philosophical research the object is to increase our knowledge. With respect to glasses, no two pieces of glass are of the same intensity; it is a most difficult thing to obtain it when both are made at the same time. He felt thankful for the spectroscope, which proved so valuable; also thankful to Mr. Debenham, and to Mr. Sawyer. It would be a boon to have as much light in the dark-room as in the collodion days.

The vote having been accorded, the CHAIRMAN called on Mr. E. Dunmore to read his paper on "Silver Prints."

Mr. DUNMORE commenced by saying that the paramount importance of silver prints induced him to put a few notes together in the form of a paper. Permanency as applied to prints was a very elastic term, but with suitable precautions silver prints are to all intents and purposes permanent. Many of those produced in early days are as good as when first done. This being the case, there must be a reason for it. It is an axiom, that anything once done well, must have been owing to certain rules. Many years ago, Mr. Spiller introduced carbonate of ammonia in the fixing bath, and he at once adopted it, but he found it produced a white deposit on the prints. The question arises, What do silver prints consist of? First, we have the paper or foundation, which comes principally from a foreign market, and is the only portion which is beyond the control of the photographer. Coating this paper with albumen comes next. This is seldom done by the photographer, so is in a measure out of his control, but it essentially consists of coating the paper with a mixture of albumen, chloride of ammonia, and acetic acid. Stale albumen is well known to give a high gloss, and prints on paper albumenized in this way have been found to keep as well as on fresh albumen. Next comes the silver. His opinion was that the prints from a strong sensitizing bath are more permanent than those weak in silver. The action of light was next dealt with, and the change of silver chloride into silver sub-chloride pointed out, also the red substance which forms so important a part in the process of printing alluded to. The preservative effects of carbonated paper and their action during printing were pointed out. Weak light was said to produce an organic image; strong light a metallic image—the organic image being the one which fades. It matters little how carefully the prints may be prepared, they will be short-lived; but, on the other hand, if the metallic and organic images are properly combined, permanency would result. Toning was next dealt with. Here again a weak print consisted of too little silver to receive a good coating of gold before bleaching occurs. It is not necessary to carry toning so far to get permanency that bleaching should take place; it is better to stop the action before the reduction of the organic image occurs. Fixing should be freshly made, and the duration varies with the thickness of the coating of albumen. The functions of the fixing bath being performed, nothing remains but to well wash and dry the prints.

The CHAIRMAN thanked Mr. Dunmore for the capital manner in which he had put his thoughts together. Hitherto the organic and inorganic images have been too much mixed up: dull days and fine days give a very different looking coloured image. Regarding stale albumen, he (the Chairman) had a print hanging in the light for the last nine years which had been prepared on paper smelling very badly.

A vote of thanks having been accorded,

It was announced that the opening soirée will take place on Saturday, October 4th. All pictures for exhibition must be sent in by Thursday, Sept. 25th; no pictures can be received after that date. The judges will consist entirely of photographers, viz., the President, Messrs. Bedford, Donkin, England, Mayall, Mayland, and Pringle.

The next meeting will take place June 24th.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE last ordinary meeting of this Society for the present session was held on Thursday, the 5th inst., at the House of the Society of Arts, John Street, Adelphi, W.C., Mr. F. YORK, Vice-President, in the chair.

The minutes of the May meeting were read and confirmed.

The CHAIRMAN said the first duty he had to perform was one of a most melancholy nature; it was to announce that their old friend and highly-esteemed member, Mr. H. Baden Pritchard, had passed away from among them. He felt sure that it was the unanimous wish of all the members that a letter of sympathy be sent from the Society to the bereaved family.

A resolution to that effect was carried unanimously.

The date of the out-door meeting was next discussed, the CHAIRMAN remarking that as it was the desire of the Committee that their out-door gathering should be as popular as possible, they were open to discuss any suggestion from the members present. He believed Mr. Thorneycroft (who is an accomplished amateur) would place one of his steam yachts at their disposal, if a suitable time could be arranged; they might thus get an enjoyable day up the river.

The TREASURER mentioned that the date usually fixed was the last Saturday in July. It had been suggested in committee that they should ask the Photographic Club to join them. If they acted upon the Chairman's suggestion to have a steam launch, they could land when they pleased.

Mr. W. E. FOXLEE said the meeting at Hampstead last year was most successful, and he saw no reason why they should not go there again on the last Saturday in July.

After some further discussion, it was decided to communicate with Mr. Thorneycroft, the date of meeting to be subsequently announced.

The TREASURER read a letter from the son of the late President, the Rev. F. F. Statham, expressing, on behalf of the widow and family, their sincere thanks for the kind and compassionate letters they had received from members of this Society. They also felt deeply the kindly tribute paid to the deceased's memory by those members who were present at the funeral.

The CHAIRMAN, referring to the presentation prints, enquired if the subject should be selected by ballot from among the prints sent in for competition during the past year?

Mr. A. L. HENDERSON: If there is a good negative of the late President, I would suggest it be used for that purpose.

The TREASURER pointed out that they had already issued a presentation print of their late President, and still had several copies by them.

After some further discussion, a sub-committee, consisting of Messrs. F. York, W. K. Burton, and W. M. Ashman, was appointed to decide on a suitable subject, and report at the October meeting. It was also announced that the committee had decided to make the October meeting "special," for the purpose of considering the state of the Society, and making such alterations as may prove beneficial. A paper is promised for that meeting on "A New Lens," by Mr. Aekland.

The TREASURER hoped if any one had hints to give, or ideas stored up, they would please divulge them at the October meeting.

The following question from the question-box was read:—"What is the best developer for gelatine plates when copying for line work?"

Messrs. HENDERSON and BRIDGE spoke in favour of wet collodion for copying of any kind; but if an emulsion must be used, they would give preference to a very slow one.

Mr. A. COWAN advocated ferrous oxalate development, and said that with a suitable emulsion there should be no perceptible fogging or frilliug up of the fine lines.

Mr. W. K. BURTON recommended the questiouer to give plenty of exposure, then develop with plenty of pyro aud bromide, and use very little ammonia.

Mr. E. COCKING was able to bear out Mr. Burton's remarks. Reeently he had copied a good deal of line work, engravings, &c., and obtained good results by adopting the precautions just mentioned.

The CHAIRMAN said the great difficulty in developing with ammonia was the discolouration of the film, which it is not always possible to remove with alum and acid. With soda and potash he could develop for au hour for density, and get no discolouration which could not be easily removed.

Mr. FOXLEE thought the questioner meant which developer would give clear lines for photo-lithography, this being of more importance than density.

The CHAIRMAN had some difficulty in keeping down the density with the carbonate of soda developer. Replying to a member's question, he said he used twelve and a-half grains each of carbonate of soda, sulphide of soda, aud carbouate of potash, in each ounce of developer. It is necessary to put the plates in alum before fixing, which latter operation occupies a long time.

Mr. W. BROOKS found no difficulty in copying engravings with gelatine plates; he used ferrous oxalate developer, followed by inteusification with mercury, and afterwards ammonia.

Some silver prints seut by Messrs. Morgan aud Kidd were passed round; they were printed from paper negatives, made by exposing gelatiuo-bromide paper in the camera, and developing with alkaline pyro. The peculiar feature in these prints (some of which were of large size) was the abseuce of grain. The paper was not rendered translucent as in Calotype.

A vote of thanks to the Chairman having been passed, the meeting adjourned.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

THE usual weekly meeting was held on Thursday, the 5th inst., Mr. MACKIE occupying the chair.

Mr. H. STARNES exhibited his dark slide referred to at the previous meeting. It was of the usual shape, but made wholly of tin, the exhibitor claiming economy of space, less weight, and much less cost, in comparison with those made of wood. An extra piece of tin, with turned edges of same shape and length as the sides, but a trifle narrower in width, was soldered down the inside of each side, the space between the turned edges of the inner and outer sides allowing the two slides to be drawn out and closed freely. The plates were inserted into the slide with a sheet of thick black paper between them, through an opening in the top, and the opening being closed by a piece of wood covered with velvet fitting the aperture, an alternate portion of the projecting top of each slide being bent over this piece of wood, it was secured by either one of the slides while the other was pulled out.

Mr. DEBENHAM, referring to a paragraph read from a magazine on the washing of prints, remarked that prolonged washing weakened prints. He had noticed this with his Monday's prints that had been in water since the previous Saturday; the less time the prints were in the water (providing they were thoroughly washed), the more permanent they were likely to be.

The CHAIRMAN passed round a plate coated in 1875, by way of comparison with the plates of the present time (it was very thinly coated): also another plate coated from the same batch; this plate had been exposed and developed, receiving five seconds' exposure—the plate showed good density. The Chairman also drew attention to an *impromptu* dark-room lamp, made from a piece of "Golden fabric," simply rolled into acyliuder and pinned, the top being uncovered. A plate that had been developed at twelve inches from the lamp, a candle being used, was passed round; it was quite clear, without any trace of fog.

A question from the box was read, "Why does a very rapid plate take longer to develop when exposed with a drop-shutter in the open air, than the same plate given its relative exposure in the studio?"

Mr. HENDERSON said this was quite in accordance with his experience.

Mr. COWAN had found that plates exposed out of doors required different treatment to the same plates exposed in the studio.

Mr. W. E. DEBENHAM remarked that from the greater illumination of the shadows the contrast of an out-door picture was much less than one taken in the studio; apart from this, other causes, such as stroug reflections, a hazy atmosphere, &c., combine to influence, although not uecessarily, a plate exposed out of doors.

Some prints were sent by Messrs. Morgan and Kidd from paper negatives taken on their ordiuary gelatino-bromide paper. The negatives were not waxed, aud no grain was perceptible; this was attributable to the fact that waxing renders some portion of the paper more transparent than others.

Mr. COLE asked the relative exposure compared with glass negatives.

A member replied, about four times.

Mr. HENDERSON brought down his diffraction gratiug lamp, referred to at a previous meeting, for demonstration, Mr. A. COWAN supplying the plates for this purpose. The lamp consisted of a box with hinged lid, with the front taken out and the sides grooved, a trapped hole through the lid allowing the products of combustion to escape; the lid was raised to admit the lamp being placed iuside, or the re-arrangement of the media in the grooves. A portion of a plate was exposed under a sensitometer for teu minutes to the light passing through a diffraction gratiug and two sheets of auriue; and the other portion of the plate, exposed the same time and distauce to the same light, passed through for surfaces of plain glass made to appear of the same opalescence by rubbing with putty, and the same through two sheets of auriue. Upon development no deposit was found upon either portion of the plate. The lateness of the hour preventing a repetition of the experiment, it was understood that Mr. Heuderson would make a further demonstratiou at a future meeting.

Talk in the Studio.

PICTURE-MAKING BY PHOTOGRAPHY.—The following is extracted from a long and appreciative review of Mr. Robinson's recently published book, in the *New York Photographic Times*:—"When we received this, a new work by H. P. Robinson, we were at first strongly inclined to pen a few words of what we think would have been justly merited censure upon this well-known artist and art teacher, for having allowed his pen to remaiu for so many years in a state of apparent quiescence. But we recollected that if he has not been of late teaching or preaching, by precept, art as applied to photography, he has certainly been doing so by example, a fact of which the readers of the *Photographic Times* have been duly made aware. The reason why we attach importance to the teachings of Robinson is, because he possesses a trinity of qualifications: he is a good technical, practical photographer, and, in virtue of this, he takes technically perfect photographs; he is an artist, and therefore his photographs are works of art—by which we mean fine art, in contradistinction to technical art; lastly, he is not only well conversant with the canons of art, but he is a facile writer, and a master of the art of conveying his ideas to others in a manner capable of being understood."

MAKING "OLD MASTERS."—A well-known Paris picture dealer has published an interesting and useful pamphlet on "Sham Old Masters." He says that the commonest mode of counterfeiting an old picture is to cover a new one—painted, of course, for the purpose—with a certain transparent paste, which, when exposed to slight artificial heat, cracks and becomes brown. If a sufficiently venerable tint has not been produced, the canvas is washed with a mixture of lampblack and licorice juice. The picture is next exposed for some hours to the smoke of a wood fire, and the loose soot having been brushed away, is rubbed here and there with a rag which has been dipped in very dilute sulphuric acid. This operation gives a mouldy appearance to those parts which have been touched. The work is finely sprinkled by means of a tooth-brush aud a hair-pin with minute spots of a solution of sepia or gum-water, to imitate fly-specks, and it is then ready for the market. Signatures are imitated by experts who are known as monogrammists, and who devote their exclusive attention to such matters; and one of these men, who died recently and was known to the author of the pamphlet, confessed to the forgery of no fewer than 11,000 signatures of the Italian masters alone, and said that he had for years made a large income by the exercise of his art.

CHATTERTON.—A photographic likeness of Mr. Wilson Barrett, as the young Bristol poet who perished miserably in his poor

London lodging, has been taken by Mr. H. R. Barraud. The dawn stealing through the garret-window falls on the upper side of the face, leaving the lower part in shade.

THE SEASON FOR OUTDOOR WORK.—Members who go in for landscape work hardly need reminding that about now is the time for those delicate greens in foliage which are so difficult to pourtray by photography, yet are so pleasing when they are done. To a lover of nature, few sights are more pleasant than the blending of these delicate colours of early spring, and a few days spent in the country now go a long way towards counteracting the continual nervous strain produced by the noise of the increasing traffic of London streets.—*Journal of the Photographic Society.*

EXHIBITION OF INVENTIONS, 1885.—The first division of the Exhibition of Inventions, to be held at South Kensington in 1885, will comprise apparatus, appliances, processes, and products, invented or brought into use since 1862, and the second division will be devoted to musical instruments produced since 1860. His Royal Highness the Prince of Wales, the president, has nominated the following gentlemen to form the Executive Council:—Sir Frederick Bramwell, F.R.S., chairman; the Marquis of Hamilton, vice-chairman; Sir Frederick Abel, Mr. I. Lowthian Bell, Mr. Edward Birkbeck, M.P. (hon. treasurer), Sir Francis Bolton, Sir Philip Cunliffe-Owen (secretary) Professor Dewar, Mr. Joseph Dickenson, Sir B. T. Brandeth Gibbs, Sir George Grove, Mr. Edward W. Hamilton, Mr. Harry Jones, Mr. W. H. Preece, Sir Edward James Reed, M.P., Prof. W. Chandler Roberts, Mr. John Robinson, Mr. John Stainer, and Mr. Webster. Photographic appliances and processes will in all probability be well represented.

PHOTOGRAPHIC CLUB.—At the meeting on June 18th, the subject for discussion will be on "Printing-in Skies." Saturday afternoon outing will be held at Waddon. Train from London Bridge at 2.35, finish at Carshalton.

To Correspondents.

*** We cannot undertake to return rejected communications.

F. W. B.—1. A very wide margin is allowable, and an addition of an amount of bichromate equal to anything between one-twentieth of its weight and one-tenth will answer well. We should recommend you to dissolve the bichromate in the smallest quantity of water, and mix this solution with the melted size. Use the mixture before it sets. 2. A sheet iron dish (see page 379).

STUDENT.—You will find all you require in Robinson's "Picture Making by Photography," and also some valuable chapters on light, shade, and composition.

F. S. LYDDON.—You will doubtless find a list of them in the Post Office Directory, and you may also learn of some through the medium of our advertising columns.

R. PARR.—There are two forms, one for portraits and one for landscapes; but both are figured on page 295 of the present volume; still the advantages over the form you mention are very questionable indeed.

R. D. D.—1. All the information is to be found in Pritchard's "Studios of Europe;" both this and the work you mention being published at our office. The price of the former is 2s., and the latter 3s.

C. GILLMAN.—There is no silver whatever in the developing solutions, but a considerable proportion in the old fixing baths. Obtain some of the impure sulphide of potassium, known as liver of sulphur, and dissolve this in about five or six times it weight of water, after which add it to the old solutions until no further precipitation takes place. The precipitate is sulphide of silver, and it may be collected and sent to a refiner; or it may be reduced as directed on page 134.

HILLY.—1. Half a grain to the quantity mentioned will be quite enough, but the solution will work quite satisfactorily if you do not add any. 2. Quite strong enough unless in exceptional cases; also add twenty-five minims of glacial acetic acid, and thirty of alcohol. 3. It is very desirable to do so, but we have known cases in which excellent results have been obtained with the cheaper materials.

J. DUNCAN.—The weather is now very favourable, and you should select a locality where there is a long unobstructed view of the horizon.

RECRAM.—"Silver Printing, by Robinson and Abney," will answer your purpose.

M. J. H.—The sample of paper which you send is evidently made in the main from wood pulp, and moreover it contains a considerable proportion of hyposulphite of soda.

ENQUIRER.—It seems to us that one engaged as "assistant" should be prepared to do his best either as the former or the latter; but in ordinary cases the operator makes the negative, and the printer confines himself to his own branch of the work.

THOS. STOKOE.—We think your best plan would be to register each design as a "Photograph to be used for a border." Each must of course be specified separately, as, for example, "photograph of apple blossoms." You cannot take a patent for the process of bordering photographs as you propose; and, as far as we know, it is not possible to register the mere names as trade marks. It is impossible to in any way protect the mere idea, as it is not original.

G. BELL.—1. It is merely another form of the same substance, but when sold under the former name it is more likely to be of indifferent quality. 2. Carbonate of potassium is almost invariably present as an impurity in the product sold for pharmaceutical purposes. 3. What you require will be found in the present number. 4. A plain background is to be preferred in such a case, as you do not require a picture, but a mere diagram or exact representation. 5. You are mistaken: make enquiries of the last named person.

AMATEUR.—A solution of gelatine, if long kept in a heated condition, entirely loses its power of gelatinizing or setting when cooled, and it is converted into a substance known as metagelatine.

DOUBTFUL.—You will find that excellent results can be obtained on wet collodion, and as you are acquainted with this method, you had better make use of it for producing the first series, at any rate.

PYRO.—1. There is no advantage whatever in using fused nitrate of silver, as the sample you enclose is quite free from any excess of acid. 2. We have forwarded your letter as requested.

B. L. T.—It is well to blacken it inside, as otherwise any stray light might be reflected on the plates; black velvet makes an excellent lining.

T. T. OSBORNE.—Your picture is a good one, but you have mounted it so badly as to spoil it.

DELTA.—It merely consists of sulphide of calcium, but some physical condition, which is not understood, determines the properties to which you refer.

DILEMMA.—The print has not been allowed to remain in the hypo bath for a sufficient time to remove the whole of the chloride of silver. Do not forget that if the fixing solution is very cold, its solvent action is comparatively small, and that a notable degree of cold is produced when the salt is dissolved in water.

B. HUGHES.—You have certainly given ten times the necessary exposure, but probably much more than this—perhaps twenty.

W. A. F.—The addition of thirty drops of alcohol to each ounce will doubtless suffice to make it flow freely.

The Photographic News Registry.

Employment Wanted.

Reception Room and Retoucher.—A. B., 72, Azenby-sq., Peckham.
Operator or Gen. Assist.—F. W. Dodge, 12, Langlard's-st., Kilmarnock.
Operator, dry-plate, studio and field.—H. S. L., 203, Mayall-rd., S.E.
Assistant Operator, good all-round.—Pyro, 45, Ladbroke-rd., W.
Operator, Retoucher &c.—E. P. W. Tayler, 47, Ferndale-rd., Clapham.
Operator and Manager.—J. F., 1, Chapel-rd., Notting Hill
Assistant Operator, Printer, &c.—Pyro, 38, Union-st., Birmingham.
Reception-Room, Retouch, Tint.—Miss Collier, 20, Howson-rd., Brockley.
Reception-Room, &c.—Miss Maunder, 6, Marlboro'-st., Paddington,
Printer or Dark-rm. Assist.—H. Barthorpe, 84, Manningham-la., Bradford.
Reception-Room, Mount, Spot.—R. E., *Photo. News* Office.
Printer or Assistant.—W. J. Stearn, 72, Bridge-st., Cambridge.
Assistant Operator, good all round.—Pyro, 45, Ladbroke-rd., W.
Recep-Room, Spot, Mount, &c.—Mr. Spencer, Kingsthorpe, Northampton.
General Assistant.—Pyro, 17, Cobbold-st., Ipswich.

Employment Offered.

Operator for Dry Plates.—9, Widdicomb-ter., Barking-rd.
Assist. for Studio (£1 weekly).—Searle Bros., 191, Brompton-rd., S.W.
Lady to Spot, Burnish, Mount.—Taylor, 84, Manningham-la., Bradford.
Lady Learner for Reception Room.—T. C. Turner, 10, Barnsbury-pk., N.
Printer, for first-class work.—T. P., 328, Upper Brook-st., Manchester.
Assistant as Improver.—A. A., c/o Adams and Stilliard, Southampton.

THE PHOTOGRAPHIC NEWS.

VOL. XXVIII. No. 1346.—*June* 20, 1884.

CONTENTS.

EXTREMELY SMALL DIAPHRAGMS.

On another page of our issue we have an answer to the query of Mr. Brophy regarding the advisability of using a stop still smaller than the smallest which is usually supplied with an ordinary lens. The matter has been treated by Captain Abney in a theoretical manner, but it seems to us that the main issue is whether there would be any real practical gain in diminishing an aperture to as small an amount as $\frac{f}{120}$. Our correspondent has scarcely settled this point, for though he has shown that such a diminution of aperture is admissible, he has not stated that it is requisite. He has, however, pointed out that, in addition to depth of focus and flatness of field, a flatness of image would also probably arise. In the days of wet-plate photography it was a well-known fact that a small aperture to the lens was inducive of diminished pluck in the resulting negative, and hence most photographers essayed to use as large a stop as possible consistent with fair definition. The same, no doubt, applies to the present gelatine plates, though perhaps not in so marked a manner, since a gelatine negative is, as a general rule, with any stop, more delicate and much less vigorous than one produced by a wet plate. It would be well that a set of careful experiments should be undertaken to determine whether an increased exposure, when a small diaphragm is used, really means a diminution in the intensity of the image. Such experiments would give an answer in one respect to Mr. Brophy's query.

The diffraction phenomena which a small diaghragm $\frac{f}{120}$ would entail have seemingly no effect on the sharpness of image; though we would point that in the case of a negative taken with a view to enlarging, such a diminution might be hurtful. Supposing, for instance, that a negative were sharply focussed with a lens of 12-inch focus and an aperture $\frac{f}{40}$, the disc of confusion of the image of a point would be perhaps only $\frac{1}{400}$ of an inch. Were this the case the use of a diaphragm $\frac{f}{120}$ would be absolutely hurtful, as the disc of confusion would be, according to Captain Abney, about $\frac{1}{800}$ of an inch. This means that with the former a sharp enlargement could be made to four times linear that of the original, whilst with the latter the degree of enlargement with equal sharpness would only be about twice. It is evident that with every lens there is some smallness of aperture beyond which it is not desirable to go, the diffraction undoing, as it were, the sharpness of the focus which would be attained were this phenomenon non-existent. We trust that before long we may be in a position definitely to give this information.

We well recollect that the late Mr. Dallmeyer was horrified at the idea of making any stop smaller than $\frac{f}{50}$ or $\frac{f}{60}$, but we gathered that it was more an objection to the curves to which such a lens must have been ground that should require such a small stop, than to the fact that diffraction stepped in. There is no doubt that in a good lens the stops usually supplied are sufficient to give good definition under ordinary circumstances; with inferior lenses they certainly may not be. In such a case the use of a smaller diaphragm should be tried. The great drawback to its use is the increased exposure required; for instance, the smallest stop of one well-known lens of 12-inch focus has the smallest stop, in which the aperture is about $\frac{1}{3}$ of an inch, or $\frac{f}{36}$; by diminishing the aperture to $\frac{f}{120}$ the exposure would have to be increased about 11 times more than that required by the optician's smallest stop.

With a lens of 12-inch focal length $\frac{f}{120}$ means a hole of only $\frac{1}{10}$ of an inch in diameter, and we can scarcely imagine that under any circumstances would a lens require a stop smaller than this; and from the calculations to which we have referred, it seems that anything much smaller than this would really defeat the very object for which the diminished aperture was employed.

RED OR YELLOW LIGHT FOR THE DARK-ROOM

The battle of the red and yellow lights still rages, as is evident by the manner in which the discussion on the paper of Mr. W. E. Debenham, and that of Mr. Sawyer, was conducted at the last meeting of the Parent Society.

The principal subject has certainly been worn pretty threadbare; but, as is often the case when matters of the kind are discussed, there were brought forward some side issues, which are of no small interest.

Mr. Cadett called attention to a matter which may do much to account for the extraordinary discrepancies which have existed in the results got by different experimenters. Mr. Cadett's statement amounts to this—that the relation which exists between actinic power and illuminating power in coloured light is not the same for a strong light as for a weak light. To take the definite example which was given, it is, according to Mr. Cadett, the fact that, whereas if we are using a strong light, red will be safer than yellow; luminous powers being the same; if we are using a weak light, the yellow will be the better of the two. We have not ourselves put this matter to a practical test, but we can at least conceive the possibility of its being correct, and, as we have said, it would account for much that is otherwise somewhat inexplicable.

It will be seen that it follows, as a deduction from the statement just made, that yellow light is better for the *general* illumination of a room than is red, the less brightly-lighted parts of the room being in the yellow light quite visible; whilst with the red they are not. We think that most of our readers will agree with us that this is correct, and that, therefore, Mr. Cadett is right when he points out that yellow light is the better for certain operations in

connection with emulsion and plate-making matters; whilst red light is better for others. He took, as two typical examples, the packing room and the place where plates are singly examined for defects.

In the former case, a general and well-diffused light is most desirable, as the work will be spread somewhat over the room; in the latter case, all that is done is to hold each plate for a moment pretty near a comparatively strong light, no diffusion being necessary, or, indeed, even desirable. In the examination of plates with a view to the discovery of thinly-coated parts, it is almost necessary that the shape of a flame of some kind be visible. It is very difficult to judge either whether a plate is coated sufficiently thickly, or is coated evenly, by looking through it at a merely transiucent screen of any colour. When, however, on the other hand, we look through the plate at, for example, a gas flame with transparent glass intervening between the two, we can, by moving the plate about for a moment, tell at once whether it is properly coated; the outline of the flame visible through any portion being an indication of an insufficiently thick coating.

Mr. Cadett stigmatized a great portion of the talk which there has recently been about the use of the spectroscope as "silly," and we think he did this not without cause. It is absurd to say that because it is impossible to tell in all cases by the use of the spectrum alone, which of two colours may be the best for practical dark-room illumination, therefore the spectroscope is useless as an assistance in coming to a conclusion. A very good case in point was given. Canary medium, it appears, when examiued by the aid of the spectroscope, shows a considerable band of blue. Now this fact indicates to us the direction in which we should work to get a light much safer than that got by the use of canary medium. We have to search for some medium which will absorb this blue. Here the spectroscope has been of undoubted use; but it cannot be too emphatically understood that judgment of colours for illuminating the dark-room cannot be made by the spectroscope alone; it could, were there any portion of the visible spectrum which had absolutely no action on a gelatino-bromide film. Were this the case, we might follow the oft-repeated advice: "Get a safe coloured light, and use plenty of it."

Mr. Sawyer's experiments were very interesting, and would have been useful had any account been taken of the illuminating properties of the different coloured lights shown. As no such account was taken, we can hardly see that the demonstration will do much good. Various media were placed in front of a lamp, and the effect which the light filtered through them had on a gelatino-bromide plate was shown, the exposures being of the same duration, and made at the same distance from the light, in each case. A certain yellow paper which allowed a very large amount of illuminating rays to pass, gave a comparatively slight effect on the plate. A certain combination of, if we recollect rightly, orange paper and aurine varnished paper, gave no effect at all; and Mr. Sawyer concludes from this result that the latter is the safer medium. This we consider to be by no means proved by the experiment. Had the lamp been lowered in the case of the yellow paper so as to give as little illumination as is got when the aurine and orange papers were used, we believe there would have been made no developable impression. In fact, the matter was put rather neatly by a friend of ours, who remarked that by adopting Mr. Sawyer's line of reasoning, it would be easy to prove that a boiler plate made the best material for a dark-room window.

Mr. Debenham's "composite white light" has been much improved, and we should be by no means vastly surprised if it turned out to be a most useful light for practical purposes. It will be remembered that in its first form it consisted of two lights filtered, one through a red glass globe, the other through a green glass one, both being afterwards reflected from a white reflector on to a tissue paper diffuser. White light was the result, and this white light, although to all appearance the same as that got by reflecting the light of a candle from a white reflector, was found to be comparatively safe.

Mr. Debenham has now substituted for the white reflector of his composite lamp a light yellow one, and in front (or behind) the tissue paper diffuser has placed a sheet of "golden fabric" which is of a very light yellow colour.

It is curious that even when the light has been so treated, reflected from a yellow surface on to a yellow medium it looks as white as that got by reflecting the light from a lamp turned low, from a white reflector on to a white diffuser. It must, however, be borne in mind that the light got from a lamp turned low is in reality somewhat yellow.

It will be curious if, after all that has been written about the necessity for using the deepest ruby-coloured light, we eventually come to work gelatine plates by white light.

A METHOD OF REDUCING AND UTILIZING BROMIDE OF SILVER RESIDUES.

M. SCOLA communicates to the *Bulletin* of the French Photographic Society an easy method of reducing waste bromide of silver to the metallic state, and not only obtaining the bromine in a useful form, but also generating an electric current at the same time.

To separate the bromide of silver from the waste emulsion, M. Scola recommends that two or three per cent. of sulphuric acid should be added, and the mixture should be boiled for some minutes, after which the bromide settles rapidly to the bottom of the vessel. It is now washed and dried, when it is ready to be cast into sticks for use in the battery about to be described.

The battery in which the reduction is effected is constructed on precisely the same principles as the chloride of silver battery of Warren de la Rue, and one form of this, as is well known, consists of a rod of amalgamated zinc immersed in acidulated water, and opposed to a similar rod of fused chloride of silver, a platinum wire being embedded in this latter to serve as a conducting terminal. When the plates of the battery are connected by a conducting circuit, the chloride of silver becomes reduced to the condition of metallic silver, while the chlorine unites with some of the zinc to form chloride of zinc.

If the negative plate of the battery is made of fused bromide of silver, reduction takes place quite readily when the terminals are united, and when the battery is exhausted it is merely necessary to fuse the resulting spongy silver in order to obtain it in a convenient condition for use in making a fresh supply of nitrate, while the whole of the bromine takes the form of bromide of zinc, and remains in solution.

GLASS.*

NINTH ARTICLE.

Flattening.—The cylinders of glass as left by the blowers may be carried by boys (and in Belgium by very young girls) into the shed or house wherein is built the flattening kilns. Before being taken in hand by the flattener, the cylinders must first be split, which operation is performed by a man whose special duty it is to examine the cylinders, and by means of a diamond on the end of a long handle to cut each one inside lengthways. The split or cut does not open appreciably until the cylinder becomes hot in the flattening furnace. Before being introduced into this furnace, each cylinder is cleaned by the assistant to the flattener, who carefully deposits a cylinder into a short

* Reference to previous articles, vol. xxvi., pages 675 and 737; vol. xxvii., pages 3, 93, 226, 419, and 757; vol. xxviii., page 338.

passage leading into the furnace, where it becomes warmed. When ready, the flattener introduces a long iron rod into the cylinder, and dexterously lifts it into the hottest part of his furnace, wherein is a large slab of stone covered with a sheet of glass; on this the flattener deposits the cylinder. Soon the heat begins to tell upon the form of the cyliuder, which begins to lose its shape, and would threaten to collapse but that the flattener has his eye on it, and (the split being upwards) he, by neat touches with his iron rod, causes it to open out U-shaped, and then the heat soon brings the sides down flat. The flattener then takes another iron rod with a block of wood on the end, about the size of two columns of the PHOTOGRAPHIC NEWS; this is called the "polissoir," and with it he rubs down all the cockles and waves, and renders each sheet thus fairly flat. The stone is mounted on wheels, whereby it can be pushed away from the hot part of the furnace, when the sheet of glass is slid off the flattening stone on to the cooling stone, and then on to the small iron trucks which traverse the annealing kiln. And so the process goes on until each truck has received about a dozen sheets, when it is pushed ou, and an empty truck takes its place. Thus the truck first filled can be pushed out to the taking-off end of the annealing kiln in a very few hours. The glass is then still pretty warm, but for all practical purposes it is found that this annealing is sufficient. The glass as taken off the trucks is ready to be carried to the warehouse for cutting up or packing.

It would occupy too much space to figure and describe here minutely, flattening kilns. There are several styles in vogue, some heated by gas, others by coal or coke. Sufficient will doubtless be gathered from the foregoing description to convey to the mind of the reader that the manufacture of sheet glass is by no means a perfect process theoretically considered. Being blown in cylinders, the internal diameter must of necessity be less than its external diameter; there are no means applicable to obtain perfect parallelism of the sides of the cylinder, nor yet of uniformity of substance throughout the material. Notwithstanding, a fair approach to theoretical perfection is attained up to the point where blowing ceases; it is where the "spreading" or "flattening" commences that the really unscientific comes in as a sort of makeshift process. In the now almost obsolete article termed "crown glass," which was made in discs as large as an ordinary cart-wheel, the surface was not touched unless it was desired to be afterwards flattened, when it became "flatted crown," and therefore the original surface was much more perfect than glass blown into cylinders, which are finally spread out into planes. "Crown glass," however, unless "flatted," is always curved, every square, in fact, having the appearance of being part of a huge sphere or circle; this curvature is fatal to its use in photography, and unless it be "flatted"—when it becomes much enhanced in price—it is commonly superseded by sheet glass. Sheet glass, with its admitted defects—cockles, waves, strings, knots, sand-holes, dust, scratches, and burnt and sulphured surfaces—is so very cheap that it is difficult to see how any other article can be produced to compete with it. A theoretically perfect glass is at present only attainable at a high price, which in these days of cheapness must restrict its use.

In the flattening process through which sheet glass has to go, there is no doubt that its theoretical perfection is diminished by half; however well the cylinder may be blown, the flattened sheet has almost invariably some blemish or defect cast upon it by the flattening. This is regretable, but at present appears to be unavoidable. Whenever a theoretically perfect flattening process is invented, then we may look for a degree of excellence approached now only by the article known as patent plate.

The method of flattening described in the foregoing is that adopted in principle in all works; it may vary in details of form of the furnace, and arrangements for taking off the glass when it is flat, and in some works the annealing takes place in a kiln in which the sheets are "piled" or stacked on edge, not laid flat on moving iron trucks. Yet, whatever be the practice, the principle is to unfold a cylinder and spread it out flat, in the very doing of which it must be evident that the innermost surface of the cylinder must be *extended*, while the outer surface becomes *compressed*; in other words, a partial re-arrangement of the atoms must take place, which the softening heat of the flattening furnace is supposed to permit, and the subsequent gradual cooling—technically called *letting back*—of the annealing kiln is expected to adjust.

Since the introduction of the gelatino-bromide process there has been a considerable increase in the consumption of sheet-glass for making dry plates. Gelatine plates are now exported to every country on the face of the globe, but it is to be regretted that so much bad glass is used for the purpose, such inferior qualities as would not have been tolerated during the collodion era. Who is there that is not unhappily familiar with plates coated on wavy or wedgy glass supporting films presenting the most exasperating variations of density in the finished negative?

On dit, of late the complaints have been so numerous that already some of the makers have seriously considered the advisability of issuing their plates upon better glass, and we think it by no means improbable that very shortly photographers will awake to the advantages to be derived from the use of the very best descriptions of glass, even patent plate, especially so wherever the size of their plates is such as to make it self-evident that the loss of a valuable negative due to bad glass may entail a money loss equal to the difference in price between that of a gross of plates on bad glass and the same on patent plate.

By-the-Bye.

THE STRONGER WILL.

A YOUNG LADY in faultless attire, of graceful figure, rich in beauty, full of animation and affable withal,—how is the picture to be taken?

Turn her to the right, then to the left, to a demi-semi-three-quarter, as you were, and again an arrangement of one arm, followed by a cautious but bewildering anxiety for the whereabout of the other one, a turn of a hand, a turn back again, a twist of a finger——Ah! what is this? A sudden and overpowering sense of responsibility consequent on the dawn of recollection that in life she possesses two hands—and very pretty ones—and only one is visible. Just the slightest inclination of the head towards the instrument. Now look to the lens—no, no, the wall—and 'tis done. Not quite! 'Tis all gone!

The poor girl has simply been worried; her flow of spirits, the interest she felt in the coming picture, even her desire to be photographed, have fled, and in place of a volatile little damsel, full of effect in the hands of an artist, nothing remains but a languid, listless, tired-out subject. No more use this day, try as you will; only one more unfortunate to swell the ranks of those who "hate being photographed—it is such a bother!"

Take the case of another young lady, rather more matured this time. We have often met her; middle—well, say middle age, short of stature, rosy in complexion, rather asthmatical, and always carries an elaborate pocket handkerchief in her well-jewelled hand; a pillar pattern chain adorns her neck, which is set off by a genuine point-lace collar; and her brooch is an elaborate harmony in amethyst and gold. Of course her dress is black silk—she never has worn anything else since she was quite a child, and equally she will not, at her time of life, change her attire to suit anyone's notions. Well, she enters the atelier absolutely bursting with importance, and full to over-flowing with directions, which she rapidly proceeds to discharge point-blank in the photographer's face almost before he has had

time to realise the arrival of a new sitter. And you will be very careful to notice that one of her eyes is not the same size as the other, and that it has what ill-natured folks say is a cast; and you will notice one side of her face is fuller than the other—she is such a martyr to neuralgia; her mouth is a little askew, and her nose a little more so. She does not wish to sit down because she is—well, some people are so fond of saying she is inclined to be stout, and she does not wish to stand, because her figure—you see she is not quite so young as she used to be, and could she be taken leaning? She would prefer not holding a book, because it makes the hands look large; and she would rather not have a basket of flowers, because everybody else has a basket of flowers; and she decidedly and positively refuses to have anything to do with a fan, because she utterly objects to fans in any shape.

Now this is a fair sample of what may be termed "difficult sitters"—the best sitters of all when skilfully treated, and the class most enjoyable to the true artist. All these complaints are only so much human nature, nothing more. All these people require, is guidance. They must feel, and at once, they are in the presence of a stronger will, a stronger intelligence, and a superior brain power to their own, and they immediately become among the most docile, the most easily pleased of the photographer's *clientèle*.

Here we have the irrepressible baby, only six months old, and such a wonderfully forward child for his age; he nearly talks; he is the first increase in the family, and, as a consequence, is duly accompanied by an imposing processional of his father, proudly conscious of his own nothingness, and bearing a gorgeous Jack-in-the-box, wherewith to attract his attention at the auspicious moment; his mother, radiant in smiles, preparing the way for nurse, slow, but sure of foot, who follows with the darling, clad in vesture of dazzling whiteness. An aunt comes next, and her duty is simply to see that all doors and windows are shut, and that the little treasure does not sit in a draught; and a cousin, carrying toys and a powder-puff, brings up the rear. "You see, we could not trust a strange powder-puff, in case of anything, you know. And mamma would prefer baby taken alone in the largest of arm-chairs, so that he should not knock his dear little head, and the lowest of seats, for fear he should fall and break his divine little neck; and she would prefer it when she is holding out her arms to him, and papa lets go the Jack-in-the-box, and calls 'Ba-bee!' in that funny tone of voice of his, while nurse shows his bottle, and Sissy runs along the room to him crying out 'Bo peep!'" A marvellous arrangement, certainly; but as babies are, photographically speaking, exceptional, the *stronger will* must dispense with aids, and rely on its own powers.

Take the case of the gentleman of clerical mien, who insists on a position in the act of addressing a multitude—the arm is extended from habit. This gentleman, from his position, is accustomed to be obeyed, and at first he seems unable to realize it is *he* who has to render obedience to a man, but to a man the possessor of a master-mind to his own. In the studio all men are *not* equal; all men are inferior, for the time, to the artist; but, unless he would awe, he must conceal this power by tact and affability. Extempore speakers on any subject are readily found, men and women of fashion abound, but it is a work of time and much difficulty to alight on men who can stamp an individuality on every portrait taken. It is this individuality which is the result of genius, which brings to view an inception of the brain; and it is this individuality which must be the aim and the ambition of the photographer. Let him never rest content till of him it be remarked—not by accessory, not by background, not by stereotyped pose, but by *intellect* in the resulting picture—"That is a work by So-and-So."

Granted that pose is of paramount importance, the primary object is to hide this importance as much as possible; to convey the idea to the sitter that nothing unusual is about to take place; that the whole affair is a most ordinary transaction, not in the least differing from a customary drawing-room attitude, and the thing is done. But, to be effectual, a pre-conceived idea, which must be quickly acted upon, is essential; and the moment minute details are elaborated, altered, or emphasized, from that moment all is over. If the power to compose quickly and correctly do not exist, cultivate that power by study, cultivate it by reading, by drawing from, by reflection on, the works of the masters. And, let it be remembered, our sitters, in the majority of cases, take our measure as rapidly as we take theirs. The true artist works in a quietly assured way which begets immediate confidence; one feels safe in his hands, for the eye is calm, and there is no striving for effect. He evidently has a purpose, and that purpose is just carried through, and there is an end of the matter.

ALTERING THE DENSITY OF GELATINE NEGATIVES.

BY W. COLES.*

OUR subject this evening is "Altering the Density of Gelatine Negatives." Some there are who say they scarcely ever require to do this, but it may, I think, be taken for granted that, notwithstanding improvement in the quality of plates, and better illumination of the dark-room than formerly, it is still advisable frequently to slightly modify the density of the image after fixing if the best results are wished for.

What constitutes *proper printing density*, I shall not attempt to define. No two photographers taken at random would be certain to agree on that point, and I shall content myself with alluding to the means whereby we may secure the end without taking upon myself to set up a standard for you.

Inasmuch, however, as *lowering* rather than *increasing* the opacity is the easier (if colour and permanence are to be taken account of), it is preferable to make sure of sufficient density to start with, and reduce if necessary, than to stop development too soon and have to intensify.

Reduction of density may be obtained in several ways, and the following remarks will apply pretty equally to negatives or positives (with perhaps the omission of lantern slides), and, excepting the action of acid, to results obtained by pyro or oxalate development.

Negatives may be uniformly too dense, or have the high lights too thick and the half-tones thin; or there may be excess of detail with, at the same time, too great general opacity. The treatment of the negative must depend, therefore, on the existing gradation.

We will consider first the case in which a thin layer of the deposit may be removed from the whole film without injuriously affecting the gradation. On most pyro-developed negatives, acid will produce a change of colour dependent on the amount of yellowness present, and the strength of acid or time of immersion in it.

This may be usefully taken advantage of, where only a slight reduction is required, by employing a weak acid (5 per cent. will do), and removing and washing the plate as soon as the action has gone far enough.

Owing to the tendency of acid alone to produce frilling, it is customary to dilute it with a strong alum solution instead of water.

The weakening effect of acid not being always sufficient, it is desirable to be able to have recourse to other means. These may be: attacking the image only, or removing a thin layer from the film itself. Hypochlorite of calcium (chloride of lime), hypochlorites of the other alkalies, or of zinc, and ozone bleach, have a solvent action on the gelatine, and will remove a thin skin from the negative, carrying with it, of course, the silver contained in that portion of the film so dissolved. I have used this method both successfully and otherwise, but do not recommend it. It was very well till we knew of a better. Gelatines are not equally acted on, the softer kinds yielding too freely. The harder sorts are more tractable, but if hardened still more by alum, the softening of the gelatine is likely to proceed but slowly, and then all at once the film commences to come away rapidly, so that great care is necessary to ensure a uniform and certain result. If a heavy stream of water is allowed to fall upon the plate when

* Read before the London and Provincial Photographic Association.

it is desired to arrest the action by washing off the bleach, the film sometimes gets carried away more in one part than another, and even in holding up the negative to watch the progress of the operation, there is a liability to have the film drip off in little rivulets, giving streaky marks. A fine spray from a rose should be used for washing. Ozone bleach may be diluted with about 6 or 8 parts of water. A saturated solution of chloride of lime should he diluted with 12 parts of water.

The methods of acting on the silver alone are many. The metal itself may he dissolved away by cyanide of potassium, or a portion may be converted into chloride (or bromide), and dissolved out hy hypo or cyanide. For this purpose ozone bleach with chrome alum has been recommended and employed, but it possesses no advantages over other chemicals more agreeable to use.

Some metals, such as copper, iron, aud gold, form two kinds of chlorides (and hromides), one containing more chlorine than the other; and when the one with the larger quantity of haloid (that is, the cupric, ferric, or auric chloride) is brought into contact with silver, it gives up a portion of its chloriue to the silver, being itself converted into cuprous, ferrous, or aurous chloride. According to the extent to which this proceeds, the image becomes changed into chloride, and therefore soluble when placed in the fixing solution. An alteration in colour is produced without dissolving out the chloride of silver, hut this would probably darken if left in the film, so should he removed. It is desirable to wash thoroughly hefore commencing to reduce, in order to prevent stains.

Chloride of copper or cupric chloride is, of the three, perhaps the hest to use. Gold is expensive. Iron is, I fancy, more likely to give a yellow colour to the negative than copper. Five grains of ferric chloride to one ounce of water is a good strength. A few drops of hydrochloric acid in addition has been recommended. It may, if preferred, he mixed with the alum solution. If any pyro stain exists, it should first be removed with acid. The solution can be used until it gets weak, and then strengthened or thrown away. Ferric oxalate, as you are aware, is also used. Its action is similar to that of the chloride. Captain Abney drew attention some two or three years ago to the fact that its presence in old oxalate developer was a cause of thin images, the metallic silver being attacked as soon as formed.

Cupric chloride is a very nice reducer, easy and clean to use. I have employed it for some time, and find a suitable strength to be: copper sulphate 4 grains, sodium chloride 6 grains, water 1 ounce. The stock solution may, if preferred, be made more concentrated and diluted for use. If a good quantity is kept in the dilute state it can be used over and over again for some time without getting weak. When it is thought that the silver has been sufficiently acted on, the negative is washed and flowed over with, or placed in, clean hypo. If not reduced enough, after washing the operation should be repeated. The cuprous chloride formed is not readily soluble in water, but is easily washed out if the plate is dipped into weak acid and alum after the hypo has been removed. As the cuprous salt while in the film has a slight brownish tinge, its removal lowers the density a trifle more, and a little allowance should be made for this. With practice there is no difficulty in obtainiug any required reduction. Should the solution by any chance be used too strong, or, from unequal wetting of the plate with it, the negative be more affected in one part than another, the plate should be left in till the image is hleached right through, and then, after treating with acid and washing, he re-developed, again washed, and the reducing begun again. If washing between each operation is not pretty thorough, stains will probably make their appearance.

I now call your attention to an exceedingly easy, clean, and practical method, to which publicity was given by Mr. Howard Farmer in the Year-Book for 1884.

The reducing agent is ferridcyanide of potassium, and as this can be mixed with hypo, and will remain clear for some time, we have the very decided advantage of only requiring one solution instead of two. The slight uncertainty which always exists where reducing consists of two operations, is here removed. I had been experimenting a little in this direction last year, but on the appearance of Mr. Farmer's article found some one else had forestalled me.

Mr. Spiller's modification of the chloride of copper process, published in the Year-Book at the same time, was an attempt to do away with the use of hypo by employing a saturated solution of common salt along with the chloride of copper. In my hands the strength of cupric chloride recommended by him is too great for the operation to be well under control, and the action of the sodium chloride does not seem to keep up with the copper, so that the image gets couverted into chloride of silver faster than the sodium chloride will dissolve it out. Possibly an alteration of the proportions might give satisfactory results. The ferricyanide of potassium I prefer to use rather stronger than suggested by Mr. Farmer, viz., about 3 grains to 1 ounce of a 5 per cent. solution of hypo; it must be used fresh. The negative is allowed to remain in this till sufficiently reduced, then well washed. As there is then a slight yellowish tinge imparted to the film, the plate may he dipped in acid and alum after previously washing it. The ease and certainty of this process will commend it to all who try it.

The douhle oxalate of iron and potassium found in old oxalate developer has been recommended when dissolved in water with hypo. This, it is said, will keep. As it does not appear to possess any advantages over the process just named, and as those who do not use oxalate developer fiud it easier to obtain the ferridcyanide (red prussiate of potash) than this double salt, I have not thought it necessary to do more than allude to it.

Cyanide of potassium alone will act on the silver, hut not quickly, and I think on the finer details most. I am speaking now of a solution applied to the plate. Mr. Henderson has told us that it may he hetter employed hy exposing the plate face downwards to the fumes arising from a strong solution. One of the conditions of success is tbat the film must bc thoroughly wet right through, so as to be soft and easily permeated hy the fumes; and that the surface of the negative should be wiped free from drops of water, otherwise the reduction will not take place uniformly.

If the details are attended to, any amount of reduction can be obtained, as the negative passed round shows. The strength of the cyanide was about one in six; distance of the plate from the liquid perhaps $\frac{3}{4}$ to $\frac{1}{2}$ inch. At the end of fifteen minutes no change observable; in three-quarters of an hour, some reduction; in one and a quarter hour, a considerable lowering of density had resulted. Still it does not come up to the ferridcyanide of potassium and hypo method. The time required is too long for auyone to stand hy and watch it, and if the dish is placed on one side there is always the possihility of forgetting it till the action has gone just a little too far, whereas Mr. Farmer's process is quick or slow according to the strength of the solutions, and quite under control. It is therefore equally applicable to large or small plates. In using the plain cyanide it is advisable to lift the plate up frequently, as, if the air charged with cyanide fumes remains stationary for loug, irregular markings might be produced.

Local Reduction of Density.—When the dense part is of a fair size, a good way is to flow over first with a weak solution of the chemical employed, and then to pour on and off a stronger solution, letting the liquid impinge on the place where most reduction is needed. When, however, the too intense portion is of small dimensions, as in the case of a hand or finger, it is better to partially dry the negative, so that the liquid shall not readily spread, and apply with a brush, keeping the outline sharp. A better way still is to paint carefully with a tough varnish round the part to be reduced, and when it has hardened, to brush over with the reducing agent. Unfortunately, ordinary spirit varnish has a tendency to split up when wetted with water, so that there is danger of the chemical finding its way through the cracks, and producing markings where not wanted. For this reason I think a thin asphalt or turpentine varnish is the most suitahle to use. After the plate has been washed and dried, the surface should be cleaned hy ruhbing with spirit or turpentine, and varnished in the ordinary way.

Selective Reduction.—Thinning the shadows more than the high lights, or *vice versa*. The building up of the image in development commences at the surface, and proceeds gradually down through the film; the silver forming the detail in the half-tones and shadows therefore lies pretty much on the surface. As in most reducing processes an even layer of silver is attacked, it follows that the shadows lose proportionately more than their share, so that there is rarely any occasion to act specially on them. It may happen, however, in case of a much over-exposed and over-developed negative, that it would he improved by a little thinning down in chiefly the shadows; such a negative would, perhaps, he best treated hy reducing it altogether, which would of course leave the shadows barer, and then intensifying what was left of the image.

At a meeting of this Society some time last autumn, at

which I was not present, I saw by the report that a discussion took place on abrading the film with hard powder rubbed on with the finger or a stump. If any present have tried this method, perhaps they will give us the benefit of their experience. Cigar ash appears to me best suited for the purpose. I have tried it on waste negatives, but without sufficient success to warrant me in using it on a negative of any value.

Intensification of Negatives.—On this subject I have less to say than on the preceding one. When it can be seen while developing that the image is showing on the back of the plate before the details are out, a more brilliant print will be obtained if the developer is washed off as soon as sufficient detail appears, and intensification resorted to, than if it is attempted to get printing density by allowing the plate to soak till it has acquired enough pyro stain to make it dense. Granted that a negative is to be strengthened, the question arises what shall be used. There are in the market some preparations, the composition of which has not been made public; these I shall say nothing about. If a very little additional density is needed it will suffice, after fixing, to dip the plate in fresh hypo solution containing about five or ten per cent. of ferrous sulphate; this is rather of the nature of a stain than a deposit on the silver already forming the image, so does not impart much brilliancy, but is, nevertheless, useful at times when the negative is merely thin, but not over-exposed. Where more than a slight increase of intensity is required we must resort to other methods, of which we have several to choose from. The principal qualities desired are permanence, a suitable colour for retouching, and ease of application. Unfortunately these do not always go together. The first—that is, permanence—is nearly always wanted for any kind of work; the second is immaterial for general landscape and architectural purposes, copying, &c., but for portraiture a good colour is very important.

Silver Intensification has always been recommended. The chief condition necessary to success is, that all hypo should be thoroughly removed from the film. It does not, however, follow that all makes of plates are equally amenable to this treatment. Those which have a matt surface take the silver best, and some gelatines are much less liable to stain than others. If the negative is not filled up much in the shadows, and possesses proper gradation, silver intensification is certainly to be recommended. It must be borne in mind, though, that, since the silver is deposited on the surface, there is a tendency to flatten the image, as the half-tones receive nearly as much fresh silver as the high-lights. For this reason, it is less suitable for over-exposed, flat negatives, than some other methods.

Bleaching the negative with an iron or copper salt, and re-developing, has been recommended. I do not find that, after clearing with acid, to remove discolouration of the film which is produced, there is much increase in opacity. Negatives intensified with uranium salts are, I believe, found to get denser by keeping. The colour, also, is objectionable for portraiture. Two processes, which give very similar results, are Monckhoven's, and mercuric chloride, followed, after washing, with ammonia, the negative being then placed in water containing a few drops of a solution of sulphuretted hydrogen in dilute glycerine. The colour with either of these is a nice brownish black. I have here a series of little negatives intensified about eighteen months ago by various intensifiers, and, as far as I can judge, there has been no deterioration in those treated by the two methods just named.

These, however, will not always impart sufficient density to very thin, over-exposed negatives. For these there is, I think, nothing so useful as bichloride or iodide of mercury, followed, after a thorough washing, by Schlippe's salt. I do not recommend this for portraiture where it can be avoided, because of the reddish-yellow colour, which renders the retouching of such negatives a matter of difficulty. As far as preserving gradation and being under control go, it answers every purpose. I was somewhat surprised to see, some little time back, in the "Answers to Correspondents" given by a photographic journal, the statement that this intensifier was only suitable for line work, on account of the great density produced. Since density is easily regulated with a little care and practice, it seems to me that for exceedingly thin portrait negatives (which, of course, are only obtained now and again through accident) and for general out-door work (on which retouching is not usually required), and especially for large plates on which it is somewhat difficult to use silver or mercury, Schlippe's salt may form a serviceable and permanent intensifier.

LESSONS IN OPTICS FOR PHOTOGRAPHERS.

BY CAPTAIN W. DE W. ABNEY, R.E., F.R.S.

LESSON XI.

IN the last lesson we gave an account of the brightness of an image without regard to any loss by the reflections from the surfaces. This loss is small, but still appreciable, it being about two per cent. for each surface when the light falls on it perpendicularly, and increasing rapidly as the angle is increased. The method of finding the approximate radius of curvature of the surface has already been given in one of the earlier lessons, in which it was shown that the reflected image of a point of light could be obtained and focussed from each surface of the lens. Now where there is reflection there must of necessity be loss of the light transmitted through glass.

If a simple lens be held opposite a candle, and the light examined by an eye-piece or focussing glass, the faint images of the flame given by reflection can readily be focussed. A reflection of a candle-flame from the surface is the example of what takes place from any bright object, and we shall consequently get a flare, as shown in the last lesson. It has usually been assumed that the halation seen in the photographs of strongly-lighted windows is simply due to reflection from the back of the glass plate, and that, if the plate is backed, so that no photographically effective rays are reflected, such halation will disappear. This is partly right and partly wrong. There will still be halation, but of a much diminished intensity. A good experiment to try is, to wet a ferrotype plate with collodion, and try what effect is obtained when photographing a well-illuminated window from the inside of a room. If the exposure be prolonged, halation will be there, but not nearly so markedly as where a glass plate is used. The halation that is found is due to the reflections from the surfaces of the lens, and may be called flare.

Cementing Lenses.—In previous lessons we showed how it was necessary to get rid of spherical and chromatic aberrations, and that this could be effected by the use of two lenses (or more) combined together. To avoid loss of light, for one reason, the curvatures in most single and doublet landscape lenses are so adjusted that the concave surface of one lens is the same as the convex surface of another. Thus two such lenses may be placed together so as to have no air space between them. If two lenses were not placed in optical contact there would be four reflecting surfaces, and there would be a loss of light amounting to nearly 8 per cent. of the whole incident light. If, however, the lenses are cemented together with a substance of fair specific gravity (for the amount of reflection from a surface depends on the difference in densities of the glass and the medium with which it is in contact), the reflection from the two interior surfaces of the glass will be perfectly negligible. The ordinary cement used is Canada balsam, which is colourless and tenacious, and dries hard. We may here state that, if a lens is required to be taken to pieces after being extracted from its cell,* it may be placed in cold water and gradually warmed, when the Canada balsam will melt, and the lenses can be slipped off from one another. The balsam may be removed with turpentine, and a final wash of dilute ammonia. For our own part, following a suggestion of a scientific friend, in some lenses we have replaced the Canada balsam by castor oil, which is equally effective as an optical agent, and allows the lenses to be separated at pleasure. Most photographic lenses are mounted so that unless a brass rim be lifted they cannot be removed, whilst others are only held in position by a screw.

Testing Lenses.—The glass of which a lens is formed should be homogeneous and not show striæ, and if possible it should, when examined by the polariscope, show no signs—or, at all events, very little signs—of polarization. Polarization means diminution of light, and is often produced in lenses by the mount pressing unequally on the

* The term applied to the brass mount holding the lens.

lens. Glass, when compressed, always exhibits this phenomenon in a greater or lesser degree. Small bubbles, slight surface scratches, in the glass are not detrimental, except that they cause a slight loss of light, those parts in which they occur being inoperative in forming the image. The glass should also be as colourless as possible; a greenish tint is almost worse than a violet one; a pure colourless glass is the best to aim at. The colour of a lens may be seen by placing it on white paper, and comparing the tint seen through the lens with that outside it. To test it for its spherical aberration, the plan recommended in Lesson VI. can be followed for a single lens, and for a double lens the diaphragm may be so cut in card that the margin of the lens is used in one case and the centre in the other, and then focussing with each.

To Test a Chromatic Aberration.—A newspaper or printed matter pasted on a card may be employed. This should be placed at a distance of some five to ten times the focal length of the lens, and at an angle with the axis. One portion of the printed matter should be focussed sharply visually on the ground glass. A plate should be substituted for the ground glass, and a photograph taken. If the photograph on examination shows the same portion of the printed matter to be sharp as those focussed by the eye, the visual and photographic foci may be considered coincident. Now photographic plates vary in composition, and it might well be that some slight discrepancy will show itself according as the iodide or the bromide of silver or a combination of both are used, but it will be so small as to be practically negligible if the optician has made the deviation of the indigo (G) of the spectrum to coincide with that of the yellow or green (between D and E). The reader should beware, however, if a want of coincidence be found, that he does not blame his lens wrongfully; if the ground glass of the focussing screen and the surface of the plate when exposed do not occupy the same position, the fault will be with the camera-maker, and not with the optician. If a piece of ground glass be placed in the slide (ground surface towards the lens) after the image has been sharply focussed on the focussing screen, and the image be still found sharp, then the camera is not in fault.

The Uses of the Swing-Back to the Camera.—The use of a swing-front to a camera, and also of the swing-back, have been much controverted at times, and even now, in France, the use of neither one or the other has been recognized by most camera-makers. For our purpose, we shall suppose that a lens may be represented by a pinhole, and that therefore it is non-distorting.

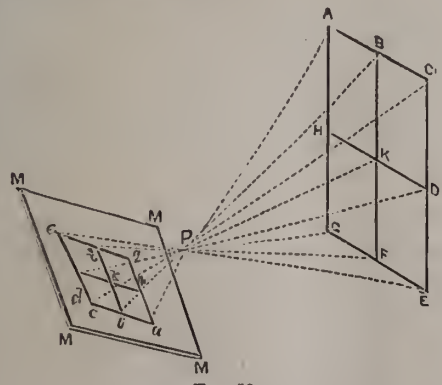

Fig. 53.

Let A B C D E F G H be a window-frame, B F and H D sash-bars, and let P, the pinhole which stands for the lens, be about the same level as the bottom of the window. Let M M be the focussing-screen, *k* the centre of it. Then, in order to get the whole of the window in the screen, the axis, P *k*, of the lens must be tilted, and be in the same line as K, the centre of the window. The focussing-glass, M M, will therefore be tilted, supposing no swing-back be used. If lines be drawn through P from all the corners of the window on to the screen, we get a figure *a b c d e f g h*. Now it will be evident on inspection that A C is further away from P than is G E, and that therefore *a c* will be smaller than *g e*, and the image of the window will therefore not be rectangular, but the top of the panes will be narrower in the image than the bottom of the frame. This is what would actually appear to the eye if it were always directed towards K; but as the eye, on the whole, sees objects in a vertical plane, the perspective appears false. In order to remedy this apparent falsity, if the focussing-screen be tilted till it is in a vertical plane, the image of the window will appear rectangular, and not distorted, for then the distance of A C from P will be to the distance of *a c* from P in the same proportion that the distance E G from P is to the distance *e g* from P, and therefore they will be equal. This was only one particular example of the use of the swing-back, but any other case equally applies. It should therefore be recollected that in order to prevent distortion of a picture with a non-distorting lens, the swing-back of the camera should always be vertical.

Should the swing-back be tilted, a reference to previous figures will show that a smaller diaphragm must be employed than if the focussing screen remains perpendicular to the axis of the lens. Again, that part of the picture nearest to the camera requires a longer focus than the part furthest away from it; now, if the lens be pointed upwards, as is usually the case when any tilt has to be given, the part of the focussing screen nearest to the lens is that on which the foreground is depicted. In most cameras there is usually a rising-front, and by raising it, the whole image is raised bodily; but this can only be employed when the lens contains a field of view larger than the plate. If the camera can be kept level—*i.e.*, the axis of the lens pointing horizontally—and the whole of the image included by using the rising-front, then the swing-back must not be tilted, and there will be no distortion. For focussing an architectural subject, our advice is to use the rising-front as far as the lens will cover the plate, and then to tilt the camera and use the swing-back. The student should consult the figures given in a previous lesson on the illumination of the field, to see what effect the foreshortening of the diaphragm will have on the illumination on the tilted screen.

INTENSIFICATION.

BY W. N. JAY.

After laying an under-exposed plate in the usual bichloride of mercury solution until its surface attained the density of city milk, I washed it thoroughly.

Soda takes the place of ammonia in the pyro developer—why should'nt it do so here? thought I, so I tried the effect of a weak soda bath on the mercury-coated plate, and after leaving it in the solution for a few minutes, a rich, brown-toned negative was the result. A number of experiments led me to think a strong solution of sulph*ite* of soda works best, producing clear black tones of good printing quality. I hunted up a number of my "first attempts," and by the above method saved a good many of them. This may be old news to some of your numerous readers, though quite new and highly satisfactory to the writer, who thinks it is worth a trial, anyhow.—*Philadelphia Photographer.*

PROCESS FOR PHOTOGRAPHIC PRINTING IN COLOURS.

BY J. SHERLOCK.*

In this process it is necessary to use *coloured negatives*—that is, ordinary negatives which have been hand-painted in their proper tints with transparent colours.

1st. Take a piece of ordinary sensitized paper and wash it to remove any free silver nitrate.

2nd. Place the washed paper in a solution of proto-chloride of tin, and expose to weak light until the silver chloride is reduced to sub-chloride, and the paper assumes a uniform grey colour.

* Read to the Photographic Section of St. Helen's Association for the Pursuit of Science, Literature, and Art.

3rd. Float the paper in a mixed solution of chromate of potash and sulphate of copper, and dry in the dark.

The paper is now sensitive to all the colours of the spectrum, and by printing on it with a coloured negative the colours of the negative will be reproduced. After printing, wash with cold water, and dry.

[We wish we could hope to see passable reproductions of colour produced by such a method.—ED. P. N.]

Notes.

Rather more than four months are available for those who may intend sending pictures to the Pall Mall Exhibition: the 25th of September has been fixed as the final day for receiving exhibits.

It has been suggested that in view of the abolition of their office, the whole of the Court of Aldermen and Common Council should be photographed, so as to form a sort of "In Memoriam" picture, which will find a suitable resting place in the Guildhall Library. We would add that this work should be entrusted to Mr. Alderman Nottage, were it not that under the circumstances the task would probably be too sad for the worthy alderman to undertake.

To test a sample of varnish, according to Herr Grundner, one should varnish a negative, and then leave it in water.

Mr. Gill's ideas as to the importance of mapping out the heavens by photography were alluded to last week, and he makes the following observation regarding Mr. Common's photograph of the nebula of Orion, which picture was issued with the NEWS in December of last year. "If now we were to suppose one hundred years to elapse, and no further observation of the nebula of Orion to be made in the interval; if in some extraordinary way all previous observations were lost, but that astronomers were offered the choice of recovering this photograph of Mr. Common's, or of losing it and preserving all the previous observations of the nebula recorded in Professor Holden's book—how would the choice lie? I venture to say the decision would be—Give us Mr. Common's photograph."

The most beautiful and rare *objets d'art* in the Fountaine Collection were photographed, and included in the half-guinea edition of the catalogue issued by Messrs. Christie and Manson. A photographically-illustrated catalogue of the Leigh Court Gallery is also to be published in connection with a picture sale, and the sale will be emphatically *the* picture sale of the season.

Mr. C. Ray Wood shortly proceeds to Switzerland to carry out some experiments on solar physics; the expedition being under the auspices of a committee of the Royal Society.

The main object is to secure photographs of the corona, and it is hoped that by working on the lines already laid down by Dr. Huggins it will become possible to secure a comprehensive series of coronal pictures, and the value of a regular series of photographs over such occasional ones as have been obtained during an eclipse will be apparent to all.

Dr. Huggin's method may be briefly described as one depending on a selective filtration of the light, such media as solution of potassium permanganate and blue glass being used to cut off the intense glare of the direct solar rays. The clear atmosphere of a high station in Switzerland will materially conduce to the production of useful photographs.

The production of drawing room portraits is not unlikely to become an important branch of work with the fashionable photographer, and in Paris we understand that Pierre Petit, who introduced this class of portrait some months since, has as many engagements as he can fill.

As an excellent excuse for not seeing visitors, the *Photographie à Domicile* has its advantages; for what excuse can be more satisfactory than that a picture is being taken?

When home portraiture in the drawing-room is undertaken, it is highly important to be provided with abundance of white screens or reflectors, and for convenience and portability nothing can surpass the plain white paper in rolls as sold for the use of paper-hangers.

Circumstances may render it necessary not only to lay this white paper over the greater part of the floor of the apartment, but to cover much of the furniture, and attach it to the walls with drawing-pins.

Old newspapers, however, make a fair substitute for the plain paper, as the proportion actually covered with printing ink is really very small. Many photographers would be surprised to see the improvement as regards lighting which may occasionally be realized by laying a few newspapers on the floor between the camera and the model.

Some weeks since we alluded to the "Baby Competition," initiated by a reckless contemporary, which undertook to adjudicate on the relative charms of the photographs of the infants of its subscribers. A New York paper has just carried the competition coupon notion to yet lower depths, and prizes are offered for the most beautifully ugly pug-dog. The canine photographs, or "dog-cartes" as the editor calls them, are pouring in.

The mucilagenous seeds of the *Psyllium* yield, according to Dr. Liesegang (p. 395), a sizing material which is of especial value in treating collodio-chloride prints. The mucilage of the seeds in question is largely used in France and Germany as a stiffening material for muslin and other fabrics; and, indeed, this use of the seed is not new, as we believe that Dioscorides refers to something of the kind.

Mr. John R. Jackson, of the Kew Museum, is good enough to give us the following information bearing on Dr. Liesegang's suggestion to use the mucilage of the *Psyllium* seeds. He says:—"Their mucilaginous property is common to many species of the *Plantago*, notably

the Indian one, *Plantago Ispaghula*, a few seeds of which I enclose. You will see by putting them into water that they produce a large quantity of mucilage. They are used medicinally, and if such a sizing material for paper is really a desideratum, it might be worth while to employ these spogel seeds, as they are called, in the water."

A photographic portrait is often used to give an air of truth to a story, and the sham detective who recently obtained goods from the Dover tradesmen by showing a carte-de-visite, and saying it was the portrait of a dynamiter for whom he was looking, may well think highly of the camera as an exponent of truth.

The total receipts of the Brussels Exhibition, held in August last, were 8,137 francs. This sum includes a subsidy of 500 francs from the city authorities, and half as much from the Ministry of the Interior. So evenly were expenses balanced against receipts, that only 121 francs remain over to go in the general fund.

The *Atheneum* asks, *apropos* of a paper by a young lady "On the Blastophore of the Newt," read at a recent meeting of the Royal Society, "Is it a sign of the times?" If so, it may not be long before we shall have ladies rising at our societies, and gravely discussing the merits of ruby *versus* green glass, or laying down the law on the vexed question of the fading of silver prints. It is doubtful whether masculine photographers do or do not derive comfort from the fact that at present lady photographers are few and far between. There is an average of about three at the monthly meetings of the Photographic Society. But there is no reason why they should not increase. The manipulation of gelatine plates is not so "messy" as collodion, and, this great objection removed, we may expect to see ladies invading the photographic profession as they have invaded almost every other.

A correspondent wants to know what he is to do with his spoilt gelatine plates, of which a large stock—from various sources of failure, many of sitters, bad expression, over- and under-exposure &c.—has accumulated. As he does not make his own emulsion he cannot utilise them as in the collodion days; what is to be done? Will the makers buy them back at a reduction?

Few photographers care to treat an unpromising sitter as Rejlander treated a lady of title who visited his studio. "I will not take her, oh! she is ugly;" exclaimed the artist, as he left the studio, trusting to others to explain matters.

When Rejlander was down with his last illness, a messenger arrived from a photographic stock house, with a note to say that unless payment of an account was made by a certain time, legal proceedings would be taken.

"Bring the camera!" said Rejlander; and a wonderful picture was taken of him as he sat up in bed with bared breast, disordered hair, and the mark of the hand of death upon him. Shortly before his last hour the picture was sent with the message, "Take your pound of flesh from that!"

Not many have seen that picture, but those who have seen it are not likely to forget it. Indeed, we only know of one copy in existence, and time has told upon that.

The statues and bas-reliefs of Dinatillo on the high altar of the Church of the Santo at Padua, have always been the despair of photographers. Apart from the difficulties presented by the colour of the bronzes, some are situated so high as to be practicably unattainable, while others are so low that it is necessary to sit on the ground so as to view them in their true perspective. Dr. Wilhelm Bode, with the aid of the Berlin Museum, has, with much trouble and at a great expense, overcome the obstacles by taking mouldings of the compositions in plaster of Paris and photographing the casts. Twenty-five photo-gravures have now been issued, and are spoken of as leaving nothing to be desired.

The Prefect of the St. Petersburg Police has come to the conclusion that to do a thing too much, may be worse than not doing it at all. And this is his reason: some time since, a certain Nihilist being "wanted," the Prefect sent round to every police bureau in the Empire not one photograph merely of the desiderated man, but six *cartes*, each showing him in a different position, and eagerly awaited the result. He was not long kept in suspense. In the course of a week or two he received a communication from the superintendent of a distant station far away in the wilds of Trans-Caucasia:—"Your Excellency," it ran, "I have the honour to report that I have already caused to be arrested four of the atrocious criminals whose portraits you recently sent, and from information received, confidently hope to capture the other two very shortly.—I have the honour to subscribe myself," &c., &c.

In this country there is a well-known proverb that deprecates the placing of a cart before a horse. The St. Petersburg Prefect of Police, though, has reason to wish he had not placed his *cartes*—at least six of them—before a donkey.

"The lime-light operations at Drury Lane Theatre were carried on by incompetent men, and in an unfit place under the stage." Such is the appendix to the jury's verdict on the recent fatal accident. As fearful consequences might follow an explosion in a crowded theatre, the arrangements might well be under the supervision of a qualified and responsible person.

The problem of directly separating oxygen from the a may perhaps be solved by taking advantage of one of t physical peculiarities of red hot silver; that of allowi oxygen to steadily filter through it. Those who ha worked with silver in the furnace know what beautiful fe like growths are sometimes thrown up as the me solidifies, and a part of the dissolved oxygen sudde escapes from the half fluid metal.

Photographers have been so often reproached for distorting the hands and feet of their sitters, especially when the picture is of a size larger than a whole-plate, and with obliterating the eyes or giving them a washed-out look, that it is quite refreshing to find the *Athenæum* last week saying that "one of our magnificently-paid portrait painters vouchsafes to produce faces with only one eye fairly drawn, and with legs not drawn at all." After this, photographers have a right to ask painters who are criticising camera pictures to look at home.

A curious instance of an artist-painter working at a weekly salary was brought to light at the Nottingham County Court this week. Mr. John Holland, who is known as a rising artist, received a contract sum of about £5 per week for all the pictures he painted, the employer being a publican in the town. One can see the possibility of a curious copyright dispute arising out of such an agreement. Just as in the case of Nottage *v.* Jackson, a question might arise as to who was the author of the pictures—master or servant?

The camera and camera-legs on the river terrace of the Houses of Parliament, which have so often puzzled the passengers on the penny steamers, would appear to be kept in readiness for the purpose of photographing distinguished visitors. King Tewhaio, we are told, was the latest sitter. But what becomes of the photographs, and who pays the photographer? Is he an officer of the House?

A West of England photographer, with a specialité for baby portraiture, guarantees, not a speaking likeness, but a "crying" one!

Patent Intelligence.

Applications for Letters Patent.

8771. HENRY JOSEPH SHAWCROSS, Office for Patents, 6, Lord Street, Liverpool, Lancashire, Bachelor of Engineering, for "Improvements in the manufacture and subsequent treatment of sensitive paper for copying drawings, documents written on one side, and the like, by photography."—Dated 10th June, 1884.

8852. FREDERICK WOODWARD BRANSON, Leeds, Yorkshire, Pharmaceutical Chemist, for "Improvements in the means for uncapping and capping the lenses of photographic apparatus."—Dated 11th June, 1884.

9026. HENRY GARDNER, 166, Fleet Street, London, Patent Agent, for "Improvements for producing from photographic negatives, blocks or plates suitable for typographic surface printing."—A communication to him from abroad by George Sutherland, Adelaide, South Australia, Journalist.—Dated 16th June, 1884.

Specifications Published during the Week.

5154. JOSEPH BROWN, of 43, Halsey Street, Cadogan Square, Chelsea, Gentleman, "Improvements in the method of obtaining incised or raised designs or patterns on the flat or other surfaces of steel, iron, copper, brass, zinc, bronze, or the more precious metals, for printing, stamping, engraving, and for ornamental purposes."—*Provisional Protection only.*

In carrying out my invention the improved process is as follows:—I take a hand drawing, print, or engraving from which I obtain an engraved plate in one or more sizes, by any of the well-known or ordinary methods either by photography, lithography, or copper plate; from this plate or printing surface I obtain an impression in a bituminous, asphaltum, or resinous varnish or material sufficiently strong to be acid resisting; I then take this print in bituminous or other varnish and transfer it by slight pressure, on to the surface on which I intend the drawing to be reproduced; the paper being removed leaves me the impression in the bituminous ink or varnish perfectly intact on the plate; I then proceed to protect those parts not forming the design with a wax or other protective varnish, and the print thus transferred to the plate is then gently sprinkled with bituminous powder, should the case require it. The plate or metal surface in its thin condition is submitted to the action of acids, or an electric battery, or any well-known mordant until such parts unprotected by the bituminous varnish are acted upon until the required depth is obtained. This process particularly applies to the production of plates for pottery printing purposes, calico or other textile printing, the production of cloisonné or mosaic work in enamels, for the preparation of dies for metal and paper printing and stamping, for leather stamping, and for obtaining designs on any other metal above referred to. Also for obtaining designs on cylindrical rollers either for repeated patterns or otherwise, as well as for producing raised type printing blocks. In cases where the pattern repeats itself I build up, as it were, or repeat it by multiplication to any extent required.

5324. JOSEPH JULIUS SAOHS, of Union Court, Old Broad Street, in the city of London, for "Improvements in or connected with the production of surfaces for printing, embossing, or ornamental purposes."

My invention has for one of its objects to produce reproductions from photographs, drawings, paintings or the like, in which reproductions are obtained of the half-tones, full tones, and lights and shades, so as to give a faithful representation of the original. In order to effect this it is necessary to print from the original, or a transparent reproduction of the same, upon a sensitive ground—such as one of chrome gelatine—with the interposition of a transparent medium, upon which is made a number of fine dots, or a grain. This grained or dotted medium it has been proposed to obtain by means of prints from surfaces which have been lined or "cross hatched" by hand and in other ways, but hitherto it has been impossible to obtain satisfactory results by these means. According to my invention, I obtain a dotted or transparent medium as follows:—

I take a metal roller or other surface of metal or hard material, and I submit it to the action of the impact or hard particles such as is obtained by the projection of sand propelled by a blast against the said surface. I thus obtain a grained surface of a degree of fineness in accordance with the fineness of the hard particles employed. I then roll over the surface thus obtained, or cover it with ink or an opaque substance, and I take an impression therefrom upon a transparent medium—such, for example, as upon paper or the like, prepared as described in the specification of my Letters Patent, No. 3948, dated 14th August, 1883. I take the transparent medium thus covered with an opaque grain, and I cover it over or place it upon the photograph, drawing, painting, or original to be copied, and then place these together over a sensitized layer, such as chrome gelatine, which will become hardened on exposure to light, and I thus obtain by the light passing through the grained surface and the photograph, drawing, painting, or the like, a reproduction of the same upon the sensitive layer which, when it is upon or has been transferred to a roller or other surface, and this is treated and etched according to any suitable process (such, for example, as is explained in the specification of my prior patent, No. 266, dated the 21st January, 1881), will give a printing or embossing surface from which impressions can be taken resembling the original. For the purpose of the transfer to the roller or other surface, the sensitive layer may before exposure be covered with a film of asphaltum or other suitable resist. The grained print or reproduction from the surface treated by the sand blast may be obtained by direct printing upon a transparent medium, or by any suitable direct or indirect process of transfer, or it may be printed directly upon the photograph, drawing, painting, or the like, without the intervention of a special transparent medium. In order to give a colour-holding surface to the design eventually produced upon the roller or other surface, I may treat the same (after it has been etched in the etching bath) with the sand blast so as to give a roughened surface to the sunk parts, the raised parts being protected by the original, or a special resist or covering.

A further object of my invention is to obtain ornamental effects upon metal surfaces to resemble inlaid work. According to this

part of my invention, I take a metal surface, and I roughen it by submission to the sand blast or the impact of hard particles, and I then cover it with a sensitive layer, which I expose to the action of light beneath the negative or design to be reproduced, whereby the parts exposed to the action of light are hardened. I then roll over or cover the sensitive film thus treated, with a resist or ink, which adheres to the hardened parts of the sensitive layer, but not to the unhardened parts, which latter may be then removed by washing or in any suitable way, leaving the metal at these parts exposed. A metal preferably of another colour or kind may then be deposited by electro-deposition upon the exposed parts, and then, on removing the resist and hardened gelatine from the other parts, the metal surface will have the appearance of inlaid work. Instead of the process of electro-deposition, I may bite into or through the metal at the exposed parts, whereby I obtain perforated ornamental metal work resembling lace patterns or other designs, which give very beautiful effects when used for decorative purposes. In the process wherein electro-deposition is used, the metal at the exposed parts may, before undergoing the process of electro-deposition, be again submitted to the sand blast to give different grains for the design and the ground. What I consider to be novel and original, and therefore claim as the invention secured to me by the hereinbefore in part recited Letters Patent, is :—

First. In the production of rollers or surfaces for printing or embossing purposes, obtaining by means of the sand blast, or the impact of hard particles, a surface from which a dotted or grained medium is produced, which is placed, together with a photograph, drawing, painting, or the like, upon a sensitive layer or material, which is upon, or is afterwards transferred to, the roller or surface to be etched, and afterwards treating and etching the said roller or surface all substantially as and for the purpose hereinbefore described.

Second. In the production of rollers or surfaces for printing purposes, obtaining a colour-holding surface by submitting the said rollers or surfaces to the action of the sand-blast or the impact of hard particles after the design has been etched or produced on the said rollers or surfaces, and whilst the parts which are not to hold colour are protected by a material or substance capable of resisting the action of the said sand-blast or impact substantially as hereinbefore described.

Third. Obtaining ornamental work by first roughening or graining a metallic surface by the sand blast or the impact of hard particles, then covering it with a sensitive layer and exposing it to the action of light beneath the negative or design to be reproduced, then rolling over or covering the same with a resist or ink, and then removing the soluble parts of the sensitive layer, and afterwards submitting the exposed parts to a process of electro-deposition, or of etching or biting through, or, as an alternative, submitting the said exposed parts again to the action of the sand blast, or the impact of hard particles, and afterwards to a process of electro deposition, all substantially as and hereinbefore described.

PROTECTING THE SURFACE OF COLLODIO-CHLORIDE PRINTS WITH EXTRACT OF THE SEEDS OF THE *PSYLLIUM*.

BY DR. LIESEGANG.

IN a former communication I recommended my readers to soak the washed collodio-chloride prints in an ammoniacal solution of bleached lac, which imparts to them a very hard surface, like that of albumen prints. As, however, this solution is not easy to prepare, and as it changes through the evaporation of ammonia, I have tried to find out another medium, and I think the best of all I experimented with is an extract of the seeds of the *Plantago Psyllium*. A convenient quantity of the seeds is covered with ten or twelve times its volume of cold water, and after macerating for a day, with occasional stirring, the liquid extract is filtered, a small quantity of methylated spirits being now added. Those who prefer to mount the prints when dry, may add a little glycerine. After washing, the prints are soaked in this fluid for a few minutes, and dried.

Even prints made on paper prepared with soluble gelatine may, after this bath, be treated like ordinary albumen prints without the collodion film cracking.

If it is desired to give the prints a coating of varnish, I find a solution of one pound of copal in two pounds of linseed oil gives a splendid and most resisting covering if applied by a pad of cotton or a brush.

Prints treated in this way may be regarded as permanent—neither light, nor air, nor humidity having the least influence upon them.

ILLUMINATION OF THE DARK-ROOM.

BY W. E. DEBENHAM.*

TAKING the average of three observers, it was found that the distance at which printing could be read with light passing through green supplement was within a trifle of half that required when the cobalt was used. This indicates a superior power of illumination of between three and four. I have here a printing-frame, containing strips of the same green and cobalt glasses, each in union with the same stained red. I will now expose a plate behind these to the light, and develop together. It will be seen that the red and blue yield a powerful image, whilst the red and green give only a trace. As a supplement to stained red glass, therefore, the green allows three or four times as much working light to pass, and gives much more protection to the plate than the cobalt. The cobalt, in fact, acts by cutting off the useful yellow illuminating power, and renders the red deeper than before; whilst the green, by allowing the yellow rays to pass (and remember that the so-called stained red is really an accumulation of a yellow transmitting medium), acts by cutting off some of the red, and restoring a yellow character to the light. How much of the additional protection afforded by the green glass is due to the removal of the red, and how much to the cutting off of the other end of the spectrum, it is not necessary now to decide. I should think, however, that in addition to the greater safety and the more luminosity, almost everyone would prefer, as less disagreeable to work by, the yellowish light with the green supplement, to the crimson with the cobalt.

As a method of working independent of coloured screens, it has been recommended as a good working method to employ the comparatively white light of a candle or lamp, taking care to allow no rays to fall direct upon the plate, but to use only the light reflected from the ceiling and walls of the apartment. Those to whom any coloured light is offensive or objectionable, may be glad to know of a method by which they can use a light of the same apparent character as the bare candlelight, but of much greater safety. Here is a lantern containing two paraffin lamps, one furnished with stained red, and the other with a green glass. By allowing the light from these to fall upon a sheet of white cardboard, and stretching a sheet of white paper in front, a light is produced which is quite as white as that given by one of the lamps when used with no coloured glass, and illuminating the card in the same manner, and turned to such a height as to give equal illumination at a given distance from the screen. Mr. W. K. Burton, who kindly assisted me in making this experiment by taking the reading distance, and exposing the plate at that same distance, considered, indeed, that the composite white light was in this case decidedly the whiter, less yellowish of the two.

I will show you both, and I think you will agree with him. On developing the plate we found much less image on the plate exposed to the composite white light than on the other, and this, indeed, was to be expected, as both glasses used cut off the violet and ultra-violet rays, the most powerful photographic portion of the spectrum. I do not recommend this light for absolute saftey, but upon a sensitive plate an exposure full square to the light for a minute at a distance at which small print could be read, gave the merest trace of a mark, such as would not be recognized as fogging if there were no sharp edge to mark. Now, there is never any necessity for giving a plate so much exposure to the developing light as this is equivalent to, those who are particularly sensitive to coloured light may, using obvious precations, safely work with a light of this description.

From the experiment described with the ruby, the stained and the canary medium, the latter shows the most powerful power; but, at the same time, it transmits less lumi-

Continued from page 375.

When these conditions are equalised, the comparative results show the least safety for the ruby; with the other two they are about equal.

With ruby glass, as stated a week or two back by Mr. A. Pringle, in describing the work of a sort of committee of investigation of well-known photographers in the North, the result was that canary medium showed less actinic effect than ruby glass in proportion to its luminosity. That stained red, and a yellow material, like canary medium, should be about equal, is only what might be expected from the consideration that stained red is, as has been pointed out, an accumulation of yellow, and yellow light passes largely through it. To compare red light with yellow light, a medium of true red colour should be used, and then the experiment comes out in favour of the yellow medium. There is another consideration which also tells in favour of the yellow. The plates we use, and to see which we require the illumination of our dark-rooms, are of a greenish-yellow, and the reading tests, to be accurate for the work, should have been on paper of a colour similar to that of the plate. These tests were, however, made on ordinary printed matter, and when—with the only observers with whom I had an opportunity of trying, Mr. J. Cadett, and Mr. J. J. Briginshaw—a gelatine plate with writing upon it was substituted for the ordinary printed paper, it was found that it had to be brought relatively nearer to the red than to the yellow light, before the writing could be deciphered.

If the balance of photographic and luminous effect of yellow and red light were equal, we should choose the former, on account of its cooler, less irritating character, and the comparative absence of feeling of strain or fatigue, which most people, at all events, feel when compelled to pass any length of time in one as compared with the other. When we add to this fact the consideration that it is probable that some are now permanently and hopelessly injuring their eyesight in the employment of dry-plate manufacturers, and of busy photographers, I think great responsibility rests upon those who would strive to perpetuate the present state of things.

The following propositions may now, I believe, be considered as established:—That the great difference in relative sensibility to different colours stated to exist in the two substances, bromide of silver in gelatine, and the ordinary bromo-iodide bath plates, does not so exist; and that therefore the difference in the colour of the illuminatiug medium said to be required is a mistake. That yellow light gives more luminosity in proportion to its effect upon the photographic plate than real red light. That "stained red" glass owes much of its luminosity to the fact that it is an accumulation of yellow medium. That green glass cuts off both ends of the spectrum, and, therefore, in addition to rendering the light cooler, is a considerable protection. That green glass used as a supplement to "stained red" allows more illumination to pass than cobalt so used, and is much more strongly protective of the plate by obstructing photographic power.

ELECTRIC LIGHT PORTRAITURE.

BY G. H. SHERMAN.*

THE subject before us to-night might well have been assigned to better hands; but I will do as well as I can to entertain you, and give you my method of using the electric light in photographic portraiture. I have had electric light on the brain, as it were, for a year or more, and having seen it established as a general illuminator in our little city of Elgin, I thought I would try it on negative making. I had talked with several who had used the light to some extent, and all thought it would do; but it was quite expensive, some parties having expended several thousand dollars in the experiment.

After witnessing the demonstration at Milwaukee last August, and having seen some of the work from other sources, I felt a little discouraged, but still I was bound to see what I could do with one light. I got no expensive plant—merely one light from circuit of thirty lamps used in our stores. The lamp is of 00 candle power, of the Van Depoele system, for which I pay 12 50 per month. So you see that I hazarded very little in the ial. I have as yet attempted nothing but bust and half-form, my arrangement of the light is more adapted to these styles. will now give you a description of my mode of operating. vill begin with the light, which, as I said before, is one of the Van Depoele lamps, suspended near the centre of my reception room. It is arranged with cord and pulley, so as to be raised and lowered to any elevation. I use a large, ground-glass globe. I wish to say in this connection that, as far as my experience and observation go, I think the Van Depoele light is the best for photographic uses. We next have a circular concave reflecting screeu of fine white muslin. This is also fixed to a standard, and made adjustable to any height and angle. This I place within a foot of my lamp. I also have a mirror about 16 by 24, made adjustable. Next are my screens, &c. On the side next my lamp I have a screen of white muslin, 7 by 8 feet. In the centre and near the top is an open space, 2 by 3 feet, which I fill with one or two thicknesses of blue gauze. This softens and diffuses the light. In the centre of this gauze I place an oval piece of white tissue paper, sometimes two thicknesses, which I arrange so as to come directly between the sitter and the bright spark of the lamp. This also has a tendency to soften and diffuse the light. From the top of this side screen I have a projecting screen of the same material coming out over the sitter, adjustable to any angle. This, when used properly, serves to give the combined top and side light effect. Next I have a large screen, or reflector, which I place on the opposite side of the sitter. This is also adjustable. I also have a hand screeu or white muslin reflector which I use to throw the light in any direction, aud soften shadows. I use the ordinary background, or sometimes unbleached muslin. I light the whole or any part of the sitter or background with my mirror reflector.

This is my simple *modus operandi*, and if it will do anybody good he is welcome. I make no issue with Van der Weyde, Kurtz, or any of the "high-lights" in photography. I do not say that my way is best, or that it cannot be improved upon; but I do say that it is simple, cheap, and, with me, successful. I have received numerous letters from parties asking information, &c., all of which I have answered as best I could. I will say to any and all, get a lamp and try for yourselves.

I have used the light for printing, with good results; also for copying.

* Read before the Chicago Photographic Association.

Correspondence.

EXTREMELY SMALL DIAPHRAGMS.

SIR,—The question which has been put by Mr. A. G. Brophy, and on which you were good enough to ask my opinion, is an extremely pertinent one, and certainly requires very great consideration. The effect of diminishing the aperture to a lens naturally divides itself into two parts:—1st, On the increase in the sharpness of image; and 2nd, brilliancy of image. As regards the first, with ordinary stops as supplied with lenses, we may take it that increased depth of focus would be attained by using the small stops, as I endeavoured to show in my "Lessons in Optics." An object to be in focus must have the image of every point of it, whether close or far from the lens, represented by a disc of confusion not greater than $\frac{1}{100}$th of an inch. By diminishing the aperture an increased depth of focus is, of course attained.

Suppose we have rays coming from a distant point, and also from another point near the lens, falling on a lens corrected for spherical aberration, the former will have their true focus nearer the lens than the latter (see

Fig. 1.

fig. 1). It is manifest that any plane, *a b*, which moves between the two foci, will never show sharp images, because the discs of confusion will always be greater than $\frac{1}{100}$ of

an inch in diameter. If the image of the distant point be sharp, the image of the near point will be represented by a disc having a breadth *a b*. How, then, can this be corrected? Let us place a small stop in front of the lens (fig. 2), and immediately the angle of the outside rays

Fig. 2.

forming the images are narrowed, and between the two true foci there will be a plane on which the discs of confusion of the images of the two points will not be more than $\frac{1}{100}$ inch diameter. Hence, depth of focus is attained absolutely by using a small diaphragm. There is no inherent quality in the form of any lens which will give depth of focus; diminishing the ratio of the aperture to the focal length alone will affect it. The real question is, however, whether or not the opticians have supplied us with stops which are just on the boundary where diffraction phenomena are negligible. Now, when a bright point, such as a star, is observed through a telescope, corrected, we will suppose, for chromatic and spherical aberrations, the image seen through the eye-piece is not a point, but a disc of measurable size, surrounded by bright rings, of which three may be recognizable.

The whole question of these rings has been treated by Fresnel, and subsequently by Airy, and the following formula was theoretically deduced.

If r is aperture of the lens in inches, and S the angular semi-diameter or radius of a ring in seconds, as viewed from the centre of the object glass, and if a mean wave-length of the yellow be taken as ·000022 inches, then

$$S = \frac{n}{1{\cdot}3846 \times r}$$

n having the value 5·12, 8·43, or 11·63 for the light rings, and 3·83, 7·14, or 10·17 for the dark rings. From this we can calculate approximately what would be the diameter of the disc of confusion for any stop.

Suppose the focal length of the lens to be twelve inches, and the aperture $\frac{f}{120}$, this being the aperture suggested by Mr. Brophy. Then the edge of the disc forming the image of a distant point will be given by calculating from the above formula, using $n = 3\,83$, which the value to be employed for the first dark ring which surrounds this disc.

This gives S = ·27 seconds of arc.

As it is viewed at a distance of twelve inches, the radius of the disc of confusion is $\frac{1}{425}$ of an inch, or the diameter of the disc of confusion, about $\frac{1}{300}$ of an inch, which is well within the limit laid down. This is not the final value, however, for theory has shown that the intensities of the three bright rings outside the disc are, $\frac{1}{57}$th, $\frac{1}{24}\frac{1}{0}$th, and $\frac{1}{85}\frac{1}{0}$th of that of the disc, and evidently the first one will have to be taken into account. The radius of this we may arrive at by taking n=5·12 for the light beyond to the edge of the second dark ring, will be neglibible. Treating this in the same way, we find that S=37 seconds of arc, and the semi-diameter = $\frac{1}{400}$ of an inch, or the diameter = $\frac{1}{292}$ of an inch, which is still within the proper limits of the disc of confusion. Hence a stop of $\frac{f}{120}$ is safe as far as diffraction goes with a lens of twelve inch focal length. With twice this focal length it is evident that the limit would be reached, since the total diameter of the disc and ring, light forming the image of any point of an object, would be nearly $\frac{1}{100}$ of an inch. It would thus appear, so far as optical conditions are concerned, that a stop of $\frac{f}{120}$ is quite admissible where lenses of ordinary focal length are employed. The next question is as to the brilliancy of the image.

This really depends on the answer to the question as to whether intensity of light and time of exposure are interchangeable. That is, supposing with an intensity of light 1, and exposure 1, do you get the same density of developed image with intensity of light $\frac{1}{100}$ and exposure 100? This is, perhaps, a debatable point, but my own answer to such a question is, that such would not be the case. The increased exposure would not make up for the diminished intensity. Again, you have only two intensities of light to deal with, which are as 100 to 1. If you take one aperture to the lens, you will get a different contrast in density to that which would be obtained by using only (say) $\frac{1}{40}$ part of such an aperture, though the exposure was proportionally prolonged. I have already touched on this point at the Royal Institution, and shall probably have more to say on the subject at an early date.—Yours faithfully,

W. de W. Abney.

PHOSPHORESCENCE DURING DEVELOPMENT.

Sir,—I have just developed several of Vérel's gelatine plates, and have had occasion to push the development of some plates, and on immersing two of them in the alum bath, dropping them on the top and letting them sink, I observed, just as the solution flowed over the surface, a distinct phosphorescent appearance, a cloud of light green rose from the surface, and instantly vanished; the development was with a strong dose of potas. carb. and pyro, no bromide. The light, though distinct, was faint and momentary, and appeared to rise in a soft cloud. It being about 10 p.m., and my eyes recovered from the effect of daylight, the lamp used being not very strong, and the alum almost in the dark, were all in favour of seeing well. But no doubt if my eyes had lately been exposed to a strong light, I should not have seen the apparent phosphorescence.

Having read your remarks on Carey Lea's theory in a late number of the News, I thought this might interest you.—Yours truly,

E. Williams.

THE DRYING OF GELATINOUS TISSUE.

Sir,—With reference to a note on the drying of gelatine tissue in your issue of the 13th inst., I would remark that in the course of some experiments on dryiug carbon and gelatino-bromide tissues, I once attempted to prevent the curling up of the tissue ou drying after the plan suggested by Mr. Haynes. In my hands the plan failed entirely, the cause, I think, being evident enough. A thiu gelatine film wetted, and left to dry unattached to a support, will contract about the eighth of its length; if dry paper be coated with a gelatinous preparation, and allowed to dry, the gelatine contracts, and as the dry paper undergoes no contraction, curling will necessarily result. The use of wet paper would meet the difficulty if it possessed the same contractile power as the gelatine; but this is not the case. By drying gelatinized paper after the method under notice, the layer of gelatine is, to some extent, prevented from contracting; but the amount is almost inappreciable, and quite insufficient to prevent subsequent curling when the tissue is put by in a dry place.—Yours faithfully,

W. Noverre, Lt.-Col.

Proceedings of Societies.

London and Provincial Photographic Association.

A meeting of this Society was held on Thursday, the 12th inst., Mr. A. Cowan in the chair.

Mr. A. L. Henderson, in speaking on the disappearance of an image from a plate shown by him on the 29th ult., showed two more plates which, after exposure to gaslight during the previous

meeting, were marked by several of the members present. They were placed in a solution of bromide of potassium and dilute nitric acid; after washing, one plate was exposed in the camera and developed without obtaining any image; the other, which received a much longer exposure (one minute), resulted in a fairly exposed negative. In reply to a question from Mr. Burton, he considered both the acid and bromide contributed to the result.

Mr. J. BARKER attributed the phenomenon to the nascent condition of the exposed silver bromide, and instanced the old method of treating Daguerreotype plates with free bromine to destroy the effect of light.

Mr. W. K. BURTON held that free bromine would destroy an image, whether the same were developed or not.

The CHAIRMAN then called upon Mr. W. Coles to deliver his lecturette on "Altering the Density of Gelatine Negatives" (see page 388).

Mr. COLES hereupon treated the subject in an exhaustive manner. Each stage in the processes dealt with was practically illustrated; many negatives being considerably altered by the treatment. At the conclusion it was decided, owing to the lateness of the hour, to defer discussion on intensification until the next meeting.

A discussion on reducing the density of negatives followed.

Mr. W. E. DEBENHAM preferred ozone bleach to common chloride of lime, a saturated solution of the latter not always being definite, there being also a tendency to deposit lime in the film; ozone bleach would not do this. Its composition was not precisely known, but it contains more chlorine than bleaching powder. It is also very useful in removing the last traces of hypo in order to intensify.

The CHAIRMAN preferred the reducer the lecturer gave preference to.

Mr. A. MACKIE enquired if perchloride of iron and hypo had been tried; did negatives so treated alter in the light? Also what action takes place between protosulphate of iron and hypo? He found if the latter is in excess, no reducing action takes place. With iron in excess and the addition of an acid, reduction is considerable.

Mr. DEBENHAM found that negatives altered with permanganate of potash were liable to change in the light; he could not say whether a persalt of iron would prove more stable.

Mr. HENDERSON admitted that any acid would remove pyro stain, but the same would reappear after prolonged washing; he succeeded very well with ozone bleach. When it became necessary to reduce a negative, he much preferred his method with cyanide of potassium; this he could recommend as a powerful reducer, also as a means of obtaining clear shadows when it was desired to intensify, there being no risk of frilling as in the case of all acids and ozone bleach.

The CHAIRMAN remarked that all gelatines will bear the application of ozone bleach; he saw Mr. Cobb reduce an exceedingly dense negative by means of it.

Mr. W. COBB was surprised to hear of frilling with ozone bleach after a negative had been dried. If the gelatine was of a soft nature, the addition of alum would stop frilling.

Mr. BURTON had met with some gelatines so hard that they will not frill when strong hydrochloric acid is poured over them.

Mr. W. M. ASHMAN, in reply to the lecturer's query *re* reducing by abrasion, said he frequently reduced gelatine negatives locally with cuttle fish bone and finely pulverized resin.

The CHAIRMAN then called on the Lecturer to reply.

Mr. COLES, in reply to Mr. Debenham, said it was true ozone bleach was a purer compound than chloride of lime usually met with; but sufficient chlorine is obtained in the latter to act on gelatine films. Some gelatines are harder than others, and the proportions given may require regulating; if anyone finds the solution is not strong enough, they can make it stronger next time. With regard to Mr. Mackie's question, he would not hazard an opinion on the compound which might be formed. He had noticed a darkening action on the film after the plate had been reduced with perchloride of iron; also a similar action after the use of chloride of copper and hypo. He found Mr. Farmer's method much better than either of the others. Speaking on the action of acid and iron referred to by Mr. Mackie, he had a great objection to putting hypo on a plate containing acid, or an acid when hypo is present, because sulphur is deposited in the film. This was instanced by the experiment of mixing alum, acid, and hyposulphite of soda together in a test-tube. Replying to Mr. Henderson, he said, if much lime were present in the water, the colour may return. Soaking in distilled water would be found to answer. He had tried the cyanide method, and with great care, it answered very well; it was free from frilling. So, also, is the ferridcyanide of potassium method, which acts slower, and is more under control. Replying to Mr. Burton's experience of gelatine resisting strong acid, he said the difference in gelatine was very great; he found some gelatines would not stand any acid, ten per cent. hydrochloric converting an image into chloride, which could be removed in the fixing bath: the same remarks also applying to ferrous oxalate developed negatives.

The CHAIRMAN, in moving a vote of thanks to Mr. Coles, said that the strict attention which had been paid to his remarks was the best evidence he could have that his efforts were fully appreciated.

A hearty vote of thanks having been accorded,

The nomination of officers for the ensuing year then took place.

The election and annual meeting will be held on the 26th inst

HALIFAX PHOTOGRAPHIC CLUB.

THE usual monthly meeting of the Club was held on the 10th inst., Mr. T. BIRTWHISTLE in the chair.

Mr. Councillor JOHN SMITH gave a practical demonstration of the Stannotype process of Messrs. Woodbury, Treadway, and Co. The great simplicity of all its working details, and the beauty of results, at once commanded the admiration of all present, the unanimous verdict being that a great future lay before it.

A vote of thanks was passed to Mr. Smith for his very exhaustive lecture and elaborate preparations.

The thanks of the Society were heartily accorded to the patentees for the kind manner in which they had responded to Mr. Smith's invitation to send samples illustrating the mode of working their process.

THE POSTAL PHOTOGRAPHIC SOCIETY.

THE annual general meeting of this Society was held on the 16th inst., at 3, Plowden Buildings, Temple.

Dr. HORACE DAY having been voted into the chair, and the minutes of the previous meeting read and confirmed,

The HON. TREASURER reported as to the progress and position of the Society, and handed in a statement showing a balance of £16, which, however, is forestalled for prizes of competitions now in circulation.

The question of appointment of an hon. secretary was then brought forward, and it was unanimously resolved that Mr. W. M. Baylis be elected Hon. Secretary and Treasurer, and that a sum of 3s. a week be paid by the Society for assistance in the secretarial work, and for pasting the prints into the albums, &c.

The vacancies in the committee, caused by the resignation of Messrs. Pocock, Senier, and Cowley, were filled up by the following gentlemen being elected in their stead:—Messrs. Harris Heal, J. C. Cohen, and Dr. H. A. Roome.

After some discussion upon the present system of competitions, it was unanimously resolved that in future one album per month (at least) should be issued; that there should be two prizes, one of 10s., and one of 5s., awarded to the two best pictures in each album; and entrance fees for the competitions should be abolished.

In order to stimulate the production of various classes of photography, Mr. Bankart's suggestion was adopted—that every alternate album should be composed of pictures of some one particular class, such as land and water subjects, portraits, interiors, architecture, &c., and the dates and subjects of these special albums were decided upon for the ensuing year.

On the motion of Dr. Day, the Hon. Secretary was requested to convey the thanks of the members to Mr. Pocock for his services connected with the initiation of the Society, and also their great regret that his connection with it was about to terminate.

After some general conversation the meeting dissolved.

SHEFFIELD PHOTOGRAPHIC SOCIETY.

THE usual monthly meeting was held on Tuesday, June 10th, at the Masonic Hall, Mr. Councillor FIRTH in the chair.

A large number of members were present, there being a very attractive programme for the evening—viz., the pictures and talk on the trip to Dove Dale, and the pictures in competition for the subject composition of "A Rustic Bridge," two prizes having been offered by the committee: one for the best in half-

plates and under, and one for whole-plates and over. Many members took part in the competition, and a very beautiful variety of bridges were pourtrayed, yielding a pleasant and interesting exhibition for the non-competitors as well as for those who were competing, the collection embracing most of the picturesque bridges in the surrounding country.

The prize for whole plate and over was won by the president, Mr. Firth, with a very brilliant picture of the rustic bridge at the entrance to Dove Dale.

Mr. Thos. Hibbert took the prize for half-plate and under with a very carefully selected and interesting representation of the wooden foot bridge near Rivilan Paper Mill.

Many of the views were beautiful and highly creditable, and in one or two instances ran very near the winners in the ballot-box.

Mr. H. RAWSON showed a stereo picture of fine manipulation and poetic subject.

Mr. B. WOOD exhibited an enlargement (not for competition) by the Autotype Company from a negative of a rustic bridge in Padley Wood, which called forth great praise.

Mr. T. S. YEOMANS showed a beautiful cabinet vignette of rustic bridge, foliage, and rippling brook, carefully selected and rich in tone.

Mr. W. DAKIN drew the attention of members to the high qualities of a developer he had mixed and tried (which was some time ago published in the NEWS), and worked with great success on both in- and out-door pictures, but which he said was invaluable for out-door work and amateurs, as a protracted development did not stain the film, there being no ammonia in it. The formula runs thus :—

Carbonate of soda	125 grs.
Carbonate of potash	125 ,,
Sulphite of soda	125 ,,
Water	10 ozs.

Use pyro as usual to the respective sizes of plates, with enough of the above solution to flood with.

Mr. H. RAWSON brought a few dishes made by the Patent Pulp Company, which were white, and seemed very likely to be of great use in the art, having the requisite chemical resisting properties, along with durability and cheapness.

The subject of the next trip was then brought on, and Millers Dale was selected.

Mr. Drummond was elected a member.

The subject of Dove Dale and the views got there was then talked over, the trip having taken place on the 22nd of May. There were 13 cameras, and 112 plates of various sizes were exposed. Plate after plate in quick succession received its charming imprint, and many were the expressions of hope that all would come out right. We must say that many have been gratified.

Mr. Thos. Firth, who worked the whole length of the Dale with a whole-plate camera, is well paid for his trouble with some excellent pictures. Mr. Taylor also succeeded in getting some choice views. Mr. H. Rawson, armed with a new stereo fit out, picked out some charming bits of river, rocks, and trees. Mr. W. B. Hatfield worked a long range lens on whole-plates, and was very successful. Mr. Dakin and Mr. Milward left the party with the object of varying the collection of pictures, and Mr. Dakin got five 10 by 8 negatives from choice positions, and with such success that leaves nothing more to be desired. Through some accident with Mr. Milward changing his box, his work was spoilt. Messrs. Turner, Wood, Pilley, Mittersham, and Pearse, all brought home some lovely things, and, taking one thing with another, the day was one of the best we have ever had.

ST. HELEN'S ASSOCIATION FOR THE PURSUIT OF SCIENCE, LITERATURE, AND ART.

Photographic Section.

A MEETING of this Section was held on May 28th, Mr. HEATHER in the chair.

The Association held its first field-day at Knowsley Park on May 11th. The photographers, favoured by splendid weather, were busy all the afternoon taking views of the hall, grounds, &c., with cameras ranging in size from 7½ by 5 up to 12 by 10. A large number of prints and negatives of these views were shown at the meeting, and much admired.

Mr. BROOK exhibited a number of mounted prints of woodland scenery at Upholland, taken with his 12 by 10 camera, but each had a light spot about two inches diameter in the centre, which somewhat marred the picture.

Mr. TAYLOR exhibited a transparency 7½ by 5 of an exceedingly pretty rose-coloured tone which he attributed to a finely-divided deposit of silver, which view was shared by most members present. He intended trying to get the same tone again, and, if possible, to reduce it to a method of working, as it would be a very effective tone for autumn scenery lantern slides.

Mr. BROOK asked for information as to the best method of packing plates for safe carriage after exposing, as he intended taking a trip to Canada and the United States, America, this summer, and did not intend developing till he arrived home. A number of plans were brought forward, but all appeared to have some defect, taking up too much room, rubbing, &c. [Will any reader kindly oblige by giving a few hints on a plan he has tried ?]

A communication from Mr. Sherlock, entitled "Printing in Colours," was read (see page 391).

A discussion then took place on the process, but was adjourned until the members had tried it.

The meeting shortly afterwards closed.

Talk in the Studio.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The next meeting of this Society will be held on Tuesday next, June 24th, at eight p.m., in the Gallery, 5A, Pall Mall East.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—We are requested by Mr. F. A. Bridge, Hon. Secretary and Treasurer of the above Society, to announce that, in future, all communications should be sent to his new address, East Lodge, Dalston Lane, London, E.

THE PHOTOGRAPHIC SOCIETY OF IRELAND has made arrangements for the holding of an exhibition—the first of the kind, it is stated, in Ireland. The exhibition will be held in November next in the Royal Hiberuian Academy. Medals will be awarded for artistic and scientific excellence, but the judging will be conducted on a different plan from that adopted by the Photographic Society, as the adjudication will be placed in the hands of the members generally, after the method adopted at the Edinburgh Exhibition.

PHOTOGRAPHY AS A MEANS OF OBTAINING PATHOLOGICAL RECORDS.—From the other side of the Atlantic we receive the following of the pen of Dr. A. L. Cory :—"As to the use of photographic outfits in medicine, I would say I find mine a great benefit. I have used it in cases of skin diseases, small-pox, spina befida, &c., and can see now where I should have kept photos of many cases if I had possessed it before. While in charge of Lake health department I took frequent copies of small-pox cases. It is so little trouble to keep the plate-holder filled and the camera in one corner of the consultation room. A photo of any case can be had at a minute's notice, the plate to be developed when convenient. I frequently take mine in the buggy when called to a case I think may be interesting, and use it if opportunity offers. Nothing that I know of offers us so easy and accurate a method of recording interesting cases."

A NEW CORK.—The accompanying drawing shows one of Mr. Kingzett's new patent corks. It is described, we believe, as the "reversible distributor cork." The one half is grooved, so that

when this portion is placed in a bottle or flask containing any liquid, and the bottle or flask inverted, the liquid escapes down one or more of the grooves. The cork is both a stopper and a sprinkle. It is so simple, cheap, and effective that it will have a large sale, and we commend the novelty to chemists and perfumers.—*Burgoyne's Magazine.*

PHOTOGRAPHIC CLUB.—At the meeting on June 25th, the adjourned discussion on "Printing-in Skies" will take place. The Saturday afternoon outing at North End and West Heath, Hampstead. Meeting afterwards at 6.30, at the "Bull and Bush."

To Correspondents.

*** We cannot undertake to return rejected communications.

W. J. B.—1. An excellent plan is to soak the recently-fixed negative in Cowell's clearing solution—alum 1 part, citric acid 2 parts, and water 10 parts. 2. The ordinary camera is not long enough, so you must arrange some kind of lengthening attachment. 3. Unless you tell us how you prepare it, we can hardly suggest a probable cause. It sometimes happens that hard water is used, this occasioning the formation of a white precipitate.

G. F. W.—The address will be found on page 365.

E. RICHARDSON.—You should endeavour to break up the lighting a trifle by screening a portion of the skylight towards the two ends. Still, your pictures are good ones, and will compare favourably with much of the work sent from the fashionable glass rooms into the retouching department. The large head would make an especially good picture if skilfully retouched.

DOUBTFUL.—Nothing is better than good gum. Select a sample which consists entirely of clear and whitish molecules, which are full of minute cracks, and make a mucilage of about the consistency of castor oil, taking care to free this from suspended matter by squeezing it through very closely-woven muslin. It is well to add a little carbolic acid, say about three drops to each ounce. The brownish and transparent pieces which are often found in cheap qualities of gum, frequently swell up and gelatinize without completely dissolving.

PETER ROMMER.—1. Nitric acid will dissolve out the reduced silver, and the unaltered haloids left in the film will form a positive picture, which of course may be rendered very intense by any one of the reducing agents commonly used in developing. 2. We are inclined to think that you will waste money by having it repaired, and that to buy a new one of modern construction will be the wiser course. 3. There is not much chance of obtaining Daguerreotype plates now-a-days, but you can easily obtain such copper plates as are prepared for the use of the engraver, and it is easy to get these electro-silvered. If you take a walk along Wilderness Row, Clerkenwell, you will be able to find a place where electro-plating is done for the trade. 4. It is not sufficiently strong; try equal parts of the acid and water.

BEGINNER.—You have evidently bought one of the cheapest cameras in the market—in fact, little more than a toy. We do not like to adviso you to cast it on one side, and to buy a more expensive instrument; but such advice would be good. First see that the position of the plate exactly corresponds with the plane of the ground glass, and for this purpose you can easily make a guage to rest across the outside of the slide and focussing frame respectively. Next test your lens to see if it works to focus, using a number of cards set up one behind the other like the "risers" of a staircase, for the purpose. You should focus the middle one, and if this comes out sharpest in the picture, the correction of the lens is perfect; if not, one of two courses is open to you: either alter the position of the ground glass in its frame, so that the card which was actually the sharpest in the picture shows with most distinctness on the focussing screen, or determine the error of the lens and make a correction each time you take a picture. For this purpose, you must notice how much the sliding tube of the lens mount must be moved in order to bring that card which was sharpest in the picture, to the best definition on the ground glass, and after having focussed a picture, you must shift the lens to this extent, but in the contrary direction. Neither of these methods is theoretically perfect for all distances, but either is good enough in actual practice. Always write if you think we can help you.

F. A. G.—1. We prefer the pyrogallic developer in such a case. 2. An article on the subject will be found on page 226. 3. You will find the information on our last page.

PRINTER.—It seems to us as if the albumen surface has been corroded or partially dissolved, and this may arise from the use of a solution containing too much alkali. 2. Try an acetate or lime bath.

CAMERIST.—Galvanized iron is not by any means a desirable material to use, and we should prefer to use zinc, although this latter is open to objection. The lead or "compo" pipe is not likely to do any harm.

CHLORIDE.—The exact proportion is not a matter of very much importance, but we have used three parts of hydrochloric and one of nitric. Take care not to overheat the mixture while the gold is being dissolved, or you will lose the greater part of the chlorine.

B. HARRISON.—We cannot judge without knowing more; it is only natural that you should take such a view.

J. D.—1. The varying hardness of the gelatine is the principa reason, but something depends on the conditions under which the bromide has been formed. 2. Not as far as our own experience goes. 3. Certainly, if you wish to do the work in the same time; otherwise you can use the weak bath in the latter case. 4. Yes. 5. We think not, unless very great pressure was put upon them to induce them to adopt the uniform system.

AMATEUR.—(Preston).—1. If you guard against moisture in films your trouble will cease. 2. We have never known a cure, and look on the matter with much doubt. 3. Full information will be found in the present number. 4. Write to the office for particulars. 5. In ordinary cases it may be made up to a volume of five fluid ounces, but rather under than over. 6. It is very much better to use fresh albumen.

H. FOLKHARD.—From your description we suppose it must be the panoramic apparatus of Sutton, but we do not think it possesses any commercial value at the present day.

J. J.—1. Either your bath is too weak, or there is too much iodide in the collodion. To add silver to the former or plain collodion to the latter is your course. Perhaps it may be well to do both. 2. All light acts on a gelatino-bromide film more or less; indeed, there is no such thing as a "safe light."

W. G.—Such a course of action would be despicable, whatever the legal aspect may be.

DOUBT.—You are by no means the first who has been troubled in the same kind of way, and we think the best course would be to tender the unopened package to the manufacturer, and ask him to give you others for them. If he refuses, obtain what you require elsewhere, and send him the bill. After having found a portion defective, you are not bound to risk your work by using the remainder.

LEX.—The film on the paper is collodion, as it readily dissolves in a mixture of alcohol and ether. Doubtless it is a collodio-chloride print.

ONE IN A FIX.—Unseasoned wood has doubtless been used, and the instrument is likely to give much trouble. Scraping and the application of black-lead may somewhat improve matters, but do not use the scraper too freely.

ENGLISHMAN.—We quite understand your feelings, but we simply record the facts.

P. S. F.—There has evidently been a scum on your printing bath, and before sensitizing you should carefully skim the solution with a piece of folded blotting-paper.

Employment Wanted.

Lady Retoucher, &c.—N. M., 83, Corranee-rd., Acre-lane, Brixton.
Operator & Retoucher (late Manager).—L. J. M. Upton, Bitton, nr. Bristol.
Lady Tinter, Spotter, &c.,—A. G., 5, Heaton Villas, Heaton-rd., S.E.
Lady in Recep. Room &c.—Alpha, 43, Appleford-rd., Upper Westbourne-pk.
Retoucher and Operator, first-class.—E. Wilkinson, 5, Fair-st., Cambridge.
Operator, Retoucher, &c., at 25 - weekly—A. H., *Photo. News* Office.
Operator, &c., indoor & out.—M. Ruffam, 11, Victoria Grove, Kensington.
Operator & Manager at £2 weekly.—F. R. H., 36, Lansdowne-rd., Dalston.
Negative Touching (piece-work).—E. B., 32, Store-st., Bedford-square.
Head Printer, 12 years' exp.—Printer, 8, Small-st., Trafford-rd., Salford.
Manager or Poser.—W. H. O., c/o Messrs. Rouch, 180, Strand.
Operator, experienced Copyist.—Alpha, *Photo. News* Office.
Youth as General Assistant.—H. Eckhardt, 12, Bath-street, Brighton.
Lady Spotter and Mounter.—X. A., 37, Gipsy-hill, Upper Norwood.
Assist., Operator, or General Assist.—Pyro, 45 Ladbroke Grove, W.
Operator and Retoucher.—Masonic, 11, Overton-rd., Brixton.
Reception Room and Fine Art Studio.—C. H., 12, South-cres., Bedford-sq.

Employment Offered.

Operator & Retoucher, entire responsibility.—A. B. C., *Photo. News* Office.
Clever Retoucher (piece).—A. W. Wilson, 13r, Dalston-lane.
Operator and Retoucher, at 30/- weekly.—C. Keeping, Exe Bridge, Exeter.
Operator at moderate salary.—31, Park-st., Bristol.
Operator for Indoor Work.—Hills and Saunders, Cambridge.
All-round hand, of good character.—L. C., *Photo. News* Office.
Assistant Printer, used to Vignettes.—G. Goodman, 6, Fort Hill, Margate.
Dry-plate Maker.—X., 6, Cranbourne-st., Brighton.

THE PHOTOGRAPHIC NEWS.

VOL. XXVIII. No. 1317.—*June* 27, 1884.

CONTENTS.

THE REMOVAL OF FATTY MATTER FROM GELATINE.

THIS question, which a few years ago had but little interest except for the few who were engaged in working bichromated gelatine processes, has now a direct bearing on every-day photographic work.

In the last number of the *Bulletin* of the French Photographic Society, we find some notes by M. Scola, which are of considerable interest, as throwing light on one of the most troublesome defects to be met with in gelatino-bromide plates.

M. Scola says:—In examining layers of dissolved gelatine, evenly spread over glass plates, I have noted that such solid bodies as dust, filaments, hairs, particles of bromide of silver or insoluble salts, can alone be fairly retained in the mass of the gelatine during desiccation; but soluble bodies, such as crystalline salts, tend to be eliminated from the mass, and to crystallize on the surface of the dry film. At any rate, this condition of things holds good unless the saline substance enters into combination with the gelatine, as alum and a few other salts are known to do. It struck me that oil or fat ought to be expelled from the surface of films of gelatine on drying, just as other substances are expelled which do not form a true combination with the gelatine; and experiment confirmed this view. Indeed, I found many sheets of gelatine are greasy to the touch, and even so much so as to grease blotting-paper, with which they are wiped. Such sheets of gelatine were washed with bisulphide of carbon, and on evaporating the liquid, an appreciable residue of oily fat was obtained. The practical outcome of these experiments is the observation that gelatine may be conveniently freed from fatty matters by immersing the sheets or flakes in benzole of good quality for a few minutes; then shake out the adherent liquid, and finally rinse them in spirit. Any ordinary solvent of fatty matters, such as ether, bisulphide of carbon, or benzoline, may be used in a similar way for the removal of grease from gelatine.

The method of clearing flakes of gelatine from fatty matter here recommended by M. Scola is an excellent one, and we have recommended something of the same character to our readers. Instead of benzole, it is both convenient and economical to employ benzoline of good quality instead of the expensive benzole, and it is scarcely necessary to say that the so-called methylated spirit should be used for the final rinse, and not pure alcohol. It is well, however, to bear in mind that the liquid sold as "methylated finish" contains a certain proportion of resinous matter in the solution, and for this reason ought not to be used. It may be noticed that methylated spirit cannot be purchased in larger quantities than a gallon at a time without a permit from the Excise authorities, while the methylated finish can be obtained without restriction at almost any oil shop.

The presence of greasy matter in gelatine not only prevents the adhesion of the film to the glass, but also gives rise to the production of surface markings and irregularities of various kinds. It is easy to understand how the presence of grease can break up the surface of the film, as when a portion of fatty matter is eliminated upon the surface as indicated by M. Scola, the cohesion of the gelatine is destroyed in this particular place, and the retractive force of the film generally serves to draw some of the still elastic gelatine away from the weakened parts of the film. Anyone who carefully watches the formation of pits and map-like markings on the surface of gelatine as it sets, cannot have a doubt that such markings arise from the lowering of the cohesive strength of the gelatine in certain parts.

It is to be feared that ordinary commercial gelatine will always contain traces of greasy matter, at any rate, unless the whole system of manufacture is changed; hence the above mode of purification becomes of importance.

LANTERN SLIDES.

FIFTH ARTICLE.*

OUR fourth article explained the formula and method of making a collodio-bromide emulsion; we will now treat upon a collodio-chloro-bromide emulsion, which has given the utmost satisfaction in our hands. The introduction of a *chloride* into emulsions is by no means a novelty; but it is not generally practised, even among *gelatino*-bromide workers. Those who have successfully introduced chlorides into gelatine emulsions have rarely discontinued the addition, as there are several marked advantages accruing from the presence of a chloride in conjunction with a bromide; and it is this very circumstance that tempted us to work out a formula for a collodion emulsion which should include chloride as well as bromide of silver.

In collodion emulsion making, unfortunately, the number of haloids available is somewhat restricted, much more so than in gelatine emulsion work, owing to the insolubility of many of the haloid salts in either alcohol or ether. Some are quite insoluble, whilst others are only soluble in the presence of so large a percentage of water in the alcohol and ether employed as to make these solvents almost useless for collodion emulsion purposes.

It is, above all things, necessary to keep down the quantity of water that must, perforce, find its way even into a collodion emulsion; and especially does this apply when it is intended to employ that emulsion by using it up at once as an *unwashed* emulsion, because an undue pre-

* Reference to previous articles, vol. xxvii., pages 129, 291, 482, and 818.

ponderance of water in the emulsion will give rise to crapy lines or structure in the films. Hence we urge what ought to have been mentioned in the last article—viz., the use of solvents of low specific gravity, and of haloids soluble in alcohol and ether, and also the *minimum* of water in making the alcoholic solution of nitrate of silver.

In *zinc bromide* and *cobalt chloride* we have two salts soluble in alcohol, although both are also deliquescent at ordinary temperatures, and these are the haloids we use in making our

Collodio-Chloro-Bromide Emulsion with Free Bromide.

Quantities.

Pyroxyline (Hopkins)	48 grains
Absolute alcohol	4 ounces
Ether, methylated (·725)... ...	4 ,,
Zinc bromide (dried at 212° F.)...	100 grains
Cobalt chloride ,, ...	5 ,,
Nitrate of silver	150 ,,

Employment.

Into a suitable 10-ounce, wide-mouthed, clean, dry bottle (with a nice soft cork), place the 48 grains of cotton, and pour thereon the 4 ounces of ether, but only 2 ounces of alcohol. When the cotton dissolves, weigh out the zinc bromide and cobalt choride, and shoot them into the bottle, and shake until dissolved. If the solvents are pure, the cobalt chloride will dissolve in blue streaks. Make the alcoholic solution of the 150 grains of silver, as directed in the last article—*i.e.*, by putting the said 150 grains into a small boiling flask with about 20 or 30 drops of distilled water, boiling it over a spirit lamp until solution takes place, and then cleverly getting 1 ounce of alcohol in without causing the silver to separate in flocculent crystals.

At the risk of repetition, we place some stress upon this operation. It is really a very nice little bit of chemical manipulation which the learner in photographic chemistry would do well to practise in order to acquire the knack of producing an alcoholic hot solution of nitrate of silver. Let the silver solution boil before adding it, drachm by drachm, to the collodion; each addition will make the surface ether in the bottle boil, but that is of no consequence. Shake between each addition of silver vigorously, and get the whole of the ounce of alcoholic solution of silver in within two or three minutes, corking between each addition, and making each addition at the boiling point of alcohol. A splendid, rich, and creamy emulsion will be the result. The whole now lacks one ounce of a solvent—alcohol—to bring it up to the orthodox thing for eight ounces of emulsion. If the formation of the emulsion goes right, and there is no indication of precipitation, this final ounce of alcohol may be added as soon as the silver has been safely got in. The method of employment here set forth has for its object to leave the emulsion minus this ounce; in fact, if the bottle be graduated it will be found to be about an ounce and a-half short—the half ounce is evaporated ether, caused by additions of boiling alcohol—so that the experimenter would do the right thing to see that if the eight ounces are to be made up scrupulously, there should be ether added as well as alcohol. The formula is framed so that six grains of cotton shall be present in the complete ounce of emulsion—there are actually eight grains per ounce present when the silver is about to be added—this is all intentional. It is more facile to form the emulsion in a strong collodion; a weak collodion will not hold up the chloride; a strong collodion permits of being afterwards brought down to any degree of creamy or milky condition of the emulsion desirable; whereas a weak collodion which is just on the verge of precipitating its "load" of silver haloid cannot be "stiffened" up so readily as the converse operation. Emulsions made with zinc bromide have a very awkward trick of precipitating the silver bromide, for reasons not exactly known.

Further, it is probable—yea, very likely—that the experimenter will elect to leave it at seven ounces, by merely adding half an ounce of ether when the emulsion is cool. We have timed ourselves from the moment of sitting down before the scales to compound this emulsion, and from the moment that we commenced until the said emulsion was complete, barely half an hour had elapsed before we had got a quarter-plate glass, and had coated it and immersed it in our washing tray (to free the film from the salts of decomposition), and after a few minutes' washing we have exposed the plate in the camera and developed it: and this was done whilst the emulsion was actually *warm* from the act of adding the hot solution of silver! We have more than once regulated the condition of emulsions made as just described by adding thereto *plain* collodion made from other cottons. Some proved old and rotten, a year in solution, and of two or three grains of such cottons per ounce of solvents. It will thus be seen that the employment at first of a strong collodion has many advantages.

The resulting emulsion is of grand quality: it gives good rich, creamy films, tough withal, partaking not of the skim-milk, sky-blue quality, we have seen so often.

This emulsion, containing chloride of silver, is quite four times more rapid than one made without the chloride; that the chloride is actually present in the films can be abundantly proved if it were necessary. It ripens quickly, develops easily, gives very clean, robust images when developed with—

Pyro	1 grain
Bromide	¼ ,,
Ammonia...	1 minim
Water	1 ounce

and, despite quick gelatine plates, we firmly believe that there is much to be done with collodion yet, in the way of making it rival gelatine in rapidity; not that rapidity is essential for films for lantern slides, but rather as proving the theory that the first impact of light can produce an effect upon a sensitive surface, which is thence entitled to be called rapid or slow accordingly as to whether that image can be developed easily or the opposite. At any rate, a given film, which will receive a readily developable image of robust quality, with a minimum of light, must surely be entitled to be called good.

A PHOTOGRAPH FOR THE PRINTING-PRESS.

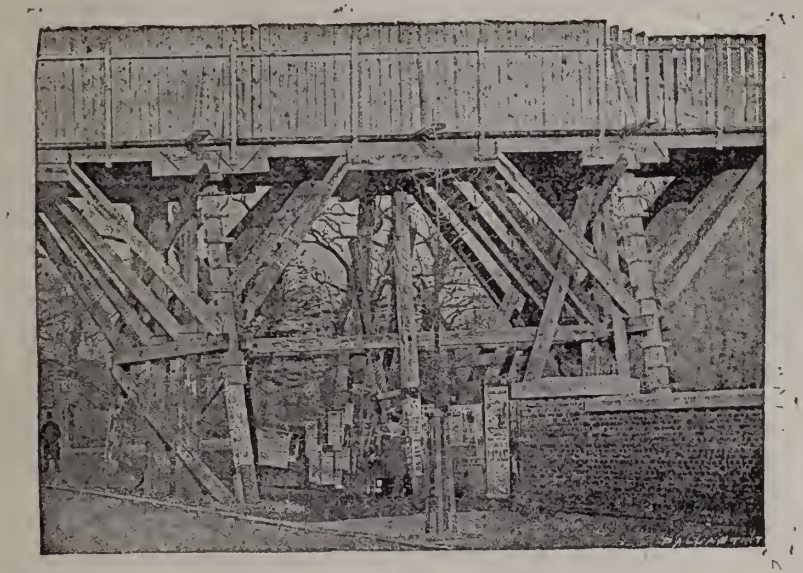
"This photograph will show you the exact condition of the clumsy structure," says a correspondent, who has long felt himself aggrieved at the presence of a delapidated wooden bridge which was allowed to remain, year after year, close to his residence in the Finchley Road, but which has been removed during the past few weeks. A glance at the photograph sent shows one that it is not of the usual kind, for it is on a metal plate, and this metal plate is mounted upon a piece of wood, so as to bring up the total thickness to near about an inch. Every detail of the subject can be clearly distinguished on the surface of the metal; but to get a good view you must hold it in a particular position with regard to the light, just as is the case with a Daguerreotype; indeed, at first sight, it does not look very much unlike one of Daguerre's pictures, only it is less vigorous, the clear, smooth parts being hardly so bright and mirror-like; while the dull and clouded portions are certainly not so white.

It is easy to see that those parts corresponding to the black shades of the original stand out a very little in relief, certainly not much more than the thickness of the paper upon which the PHOTOGRAPHIC NEWS is printed; but still the relief is clearly perceptible, especially as the high parts are smooth and unbroken; while those portions of the picture corresponding to the lighter shades of the original subject lie somewhat below the general level, and are broken up into a number of little points or grains. These granulations of the surface give the whitish appearance

which characterises the high-lights; but between the two extremes of smooth metal standing a trifle in relief, and the numerous clearly-outlined, but minute ridges and vales which form the whitish stipple, we can trace portions where the grain or stipple becomes shallow and indistinct, and, indeed, all intermediate grades between the rough and smooth.

All is clear now: our correspondent has sent us the kind of photograph of which we can best make use. It is a typographic block, which may be printed from in the ordinary letter-press; indeed, we should have known this earlier if we had read our friend's letter to the end, as he tells us that the block was made in a couple of days by Mr. Dallas, the original negative having been sent. Let us borrow an inking roller from the printer, and ink the face of the block; we find that the smooth and very slightly-projecting parts take the ink freely enough; while very little adheres to the deeply-stippled portions, or only to the tips of the granulations where the metal comes in contact with the printing roller.

"How may such a block be made?" the reader will ask. But we must reply that, as far as Mr. Dallas' method is concerned, we do not know, for this gentleman works his method as a secret process. The results, however, do not very much resemble those obtained by such recently-introduced methods as those of Ives, Meisenbach, or Zuccato, but correspond more nearly in appearance to work obtained by the Pretsch method, of which we gave an example on page 386 of our last volume; and as an excellent account of the process was published by Mr. T.



PATENT OFFICE LIBRARY

Ryley in 1858 (Journal of the Photographic Society, page 161), we cannot do better than to reprint this, with the remark that the nitrate of silver need not be added, and by "fine glue," must be understood such a gelatine as that of Coignet. Mr. Ryley says:—

1. I dissolve 1 ounce of fine glue in 3 ounces of distilled water, and to 1 ounce of this solution I add 30 grains of nitrate of silver, previously dissolved in ½ ounce of distilled water; to the other 2 ounces of glue solution I add 2 ounces of a saturated solution of bichromate of potass, and while warm I add to it the nitrate of silver and mix well.

2. I level a glass plate and pour over it as much of the above solution as will, when quite dry, form a film about the thickness of thin writing paper.

3. I now expose the plate to sunlight under a glass positive for about three hours, or until all the details of the picture appear when viewed by transmitted light.

4. I then wash it under water until those parts of the picture which are the least acted on by light become granulated, which is caused by a peculiar contraction of the film; the superfluous moisture must then be removed by blotting-paper.

5. You may use a negative instead of a positive, but your exposure must not be more than half the time, and you will still have a positive result, and the grains of your film will be much finer. And now let me remark that in this granulation lies the whole secret of the process; and yet, strange to say, not one word can you find respecting it in the specification, and therefore I contend that all patent right is justly forfeited.

6. A mould in gutta-percha is then taken from the film and rendered conductive by plumbago or other means, and put into the electrotype apparatus until you have a deposit of copper of sufficient thickness to form a matrix, from which you can deposit a thick copper plate strong enough to print from.

The progress and condition of engineering works have often been recorded by the camera; indeed, we may mention that twenty-nine years ago, the great railway bridge across the Dnieper, at Kiew, was being constructed by Mr. C. Vignoles. Each day a photograph was taken and forwarded to the Czar.

Our correspondent has, however, struck out a new path in photography; and although we quite sympathise with him as regards his years of fear lest the bridge should have tumbled about the ears of himself or family, we see no particular advantage in placing the condition of the once-existing bridge on record in our paper, except as an instructive illustration of a field of usefulness for photography.

His idea of writing a letter of complaint to a newspaper, and sending a typographic photograph or printing block illustrating his views, is an excellent one, and it seems to us that the police authorities might well take the hint. What, indeed, could more effectually assist in the discovery of criminals who are "wanted" than a publication of phototypic portraits in the *Police Gazette*? Col. Dillon, the successor of Mr. Howard Vincent, will doubtless consider the matter.

By-the-Bye.

BAD PHOTOGRAPHS.

The Greek cynic who has the credit of being the first to clearly promulgate the doctrine that "the majority are bad," may possibly have taken a very high standard of virtue by which to judge the general mass of mankind, or more probably, he wilfully shut his eyes to the good points of human nature, and brooded so much over the bad

characteristics of mankind as to acquire an altogether abnormal power of referring each action to some mean and evil motive.

That it should be possible to apply this doctrine, that of the badness of the majority, to the productions of the camera, is a supposition altogether repulsive to our feelings, and indeed we would like to view the existence of a bad photograph as being an impossibility; but if we were to shut our eyes to all defects, and to regard the work of the Sun's pencil as the British workman regarded malt liquor when he exclaimed, "There aint no bad beer; some beer is better than other beer, but there aint no bad beer," we might perhaps lay ourselves open to a charge of prejudice in the other direction.

Is it not worth while just for this once, to try to put ourselves into the most cynical frame of mind, and to try our best to say all the unpleasant things we can?—for by so doing we shall clear off all the spleen which may be lurking around, and put ourselves into a frame of mind to take a more kindly view for the future.

Where, then, are the bad photographs to be seen? Everywhere. In the shop-windows, in the show-cases, in our friends' albums, among the cherished collections of amateurs, and even at the Pall Mall Exhibitions. About the time when gelatino-bromide plates first came into general use, we well remember an occasion when some dozen persons were gazing at a frame containing pictures of a boat-race, and nearly all were loud in their expressions of admiration and wonder at the perfect outlining of the curly vapour of the steam-boats, and the wonderful delineation of the ripple on the water, when an amateur, who had never been to the Exhibition before, and who knew no one in the room, suddenly turned to a high dignitary of the Photographic Society, and in a half-whisper said, "But are they not vile photographs after all?" "They are," was the answer, "but you are the first who has said it." The pictures were really bad photographs; flat, without depth, absolutely lacking detail in the shadows, and bare in the lights.

Bad instantaneous photographs of races and processions are offered freely for sale in the shops, but the public do not buy them; to the photographer they are of very great interest, and he accordingly judges them leniently; but the public at once estimate them at their just value—as bad photographs. There have been good pictures taken of boat races, horse races, and street processions, but they are few and far between:—"The majority are bad."

Perhaps the very worst photographs to be seen in London are some of those used by auctioneers and house agents to set off their announcements of desirable villas or eligible residences—such faults as distortion owing to the tilting of the camera; painted-in clouds roughly corresponding in form to the outlines of trees or buildings; roofs and streets white as if after a snow-storm; or an extreme flatness and weakness, leaving the subject hardly distinguishable at a distance of a few yards, being common enough. To criticise work of this kind too severely would be ungenerous, as it is generally done at the lowest possible prices, and by men who not only can ill afford to devote sufficient time to the work to obtain good results, but who have often to make shift with extremely defective apparatus. The same sentiment prompts us to say but little about the bad ferrotypes and glass pictures which are made by our humbler brethren at places of public resort; and although the doctrine that the "majority are bad" certainly does apply with full force to this class of work, really good and artistic pictures may now and then be found among the collections of the travelling portraitist; and, indeed, it may be said, to the credit of more than one of our best workers with the camera, that he has raised himself to his present position from a beginning made on the sands at a seaside resort.

The amateur very often makes bad photographs, and, what is more, it not unfrequently happens that he is extremely proud of them. "All these were taken at the outdoor meeting on Saturday last," is not an uncommon remark to hear at a photographic gathering, while a series of bad slides is being passed through the lantern. Trees which might have been cut out in black paper with a scissors, and large patches of shade where one looks in vain for the shrubs and rich foliage which one knows to have existed in the locality, are common. "And this is the gem of the series," loudly shouted an exhibitor of bad photographs as one of the least objectionable examples of the previous Saturday's work was revealed to a not very delighted assembly. And yet this exhibitor would have been the very first to detect and denounce a bad picture, bad anyone else shown it.

This leads us to make a distinction between such as make bad pictures almost by necessity, as in the case of the photographer who makes prints at a painfully low figure for house agents, or the humble craftsman who takes ferrotypes in the street, and the amateur who should have no inducement to allow anything but good work to go beyond the confines of his work place.

Francis Bacon discourses of ignorance, and he indicates two kinds. When a person is ignorant, and he knows it, the ignorance is "simple," and some improvement may be hoped for; but when the ignorant person is not aware of his condition, the ignorance is described by Lord Verulam as "compound," and a cure cannot be hoped for until the ignorance has been reduced to the "simple" condition; or until, to use other words, the ignorant person ceases to regard himself as learned.

Just so in the case of photographs; any notable improvement being improbable until this producer of bad photographs shall learn to recognise them as bad.

The very highest art photographers, men whose names immediately recal the idea of something near perfection in photographic work, produce abundance of bad photographs, but they recognise them as bad, and destroy them immediately; and this is how it comes about that they maintain their reputation. The work of an artist-painter can be laboured upon and altered to an unlimited extent; a bad painting may be made a good one; but this is not so with the photograph—the only remedy is destruction. As soon as the exposure is made and the development has been fairly commenced, it becomes possible to judge whether the picture is good or bad—whether it should be preserved or destroyed. The most skilful opticians make many bad lenses, but those instruments which cannot be made good by a re-grinding of the curves are ruthlessly destroyed by those who value their reputation; and the more rigidly photographers follow in the same path, so much the less will be the probability of our again endeavouring to force ourselves to take a cynical view, and to preach from such a text as "The majority are bad."

NOTES FROM NEW YORK.

PROGRESS OF THE NEW AMATEUR PHOTOGRAPHIC SOCIETY—NEW MODIFICATION OF THE PYRO DEVELOPER.

THE widespread interest in photography upon this side of the Atlantic among amateurs continues unabated. The ranks are swelling to large proportions, and it will not be long before the young man, the man of pleasure, and a large portion of the fair sex, will be found carrying a small camera whenever they go upon a vacation.

Manufacturers are studying to secure lightness and strength in cameras or other apparatus, to encourage the increasing demand, and it will be difficult to tell where they will end. Americans, as a general rule, prefer anything which is light and strong.

The membership of our new young amateur society, "The Society of Amateur Photographers," has increased one-third within two months, so eager are the amateurs to learn and compare results; its success is secured, and its future is bound to be bright. The opening of the new permanent quarters of the Society, 1262, Broadway, on June 4th, was celebrated by a lantern exhibition of slides made by

amateurs. The exhibition was a success in point of interest and in the work displayed, and the lantern was well managed by Mr. G. W. H. Johnson, of Bridgeport, Conn., an amateur of some note. Several of the slides were made by him upon collodio-bromide, and also wet plates. Mr. Brush furnished some of the finest slides shown, these being made upon albumen gelatino plates, developed with oxalate and iron. To many old amateurs these were a great surprise, on account of their remarkable brilliancy and clearness, and will no doubt encourage many to make them.

The Society has fitted up a special dark-room with sinks, lockers, and other conveniences for the use of members and for experimental purposes; it also has a library filled with all the modern works and current literature on photography. Each member is entitled to the use of these at their leisure at any time. It is expected this feature of the Society will become quite popular, as many members residing in the city are obliged to put up with very poor substitutes for a dark-room. The room is 18 feet by 7, and is arranged with double doors, has a peculiar system of ventilation devised by the President, and will afford facilities for half-a-dozen members to work at a time. By a vote of the Society, all members of amateur societies in other cities, whether here or abroad, will have the privilege of using the society's dark-room free of charge for a brief period, when in this city.

The last regular monthly meeting of the Society was held on June 10th at their hall in Broadway. Mr. Beach, the chairman, congratulated the Society upon securing such a well-located hall, and hoped that his efforts to found and start the Society would be seconded by others in giving to members the results of their valuable experience. Several interesting communications were read, including letters from the Editor of the PHOTOGRAPHIC NEWS, and Mr. S. Fry, the Kingston dry-plate maker; and resolutions were passed, thanking the Scovil Manufacturing Company, Messrs. Anthony and Co., and others, for favours shown.

The interesting feature of the evening was a new formula given by Mr. H. J. Newton, for preserving pyro in solution, the advantages being that the acid of itself acted as a developer, and not as a restrainer, this being of much importance in the development of instantaneously exposed plates.

His formula is as follows:—

No. 1.

Water	32 ounces
Granulated carbonate soda ...	3 „
Carbonate potash...	3 „
Sulphite soda	3 „

No. 2.

Water	12 ounces
Concentrated formic acid ...	12 minims
Pyrogallol...	48 grains

To develop an instantaneously-exposed 5 by 8 plate he takes ¾ of an ounce of water and adds a ½ ounce of No. 1, and 1 ounce of No. 2, which makes a bulk of 2 ounces. The developer thus made contains approximately 25 grains of potash and soda combined, and 4 grains of pyro. For a longer exposure, he reduces the potash and soda one-half or more according to the requirements. So far as his present experiments have been carried, he finds 1 drop or minim of formic acid will preserve 4 grains of pyro.

He stated that he had kept the solution a long time, and believed the developing power of the pyro would not deteriorate as in other preserving agents.

Mr. Pearsall, of Brooklyn, had a gentleman to explain his new compact camera for amateurs. The model shown had a movable front with focussing screw as in many English cameras; the back was adjustable to any angle like a swing back, and had a bellows hood attached for focussing to avoid the necessity of taking one's hat off or using a cloth. In place of the ground glass was a screen of silk, which in an instant could be wound up out of the way on a spring roller. Very thin single plate-holders are used, made of a light wood frame covered by paper. Upon one side of each slide was printed the word "Exposed." When the plate is put in, the blank side of the draw-shutter is out, but after the exposure is made, and the slide is pushed home, the printed side is out; in this way mistakes of double exposure are prevented.

The meeting closed with a brief exhibition of lantern slides, and proved quite interesting to all present.

During the summer several field club excursions will be made to take landscape views for the benefit of the Society and members. The first trip has been planned to embrace the fine scenery on the Hudson in the neighbourhood of West Point. A steam yacht is to be hired, which will land at various points and afford the party excellent facilities for displaying their artistic talents.

Experiments are soon to be inaugurated towards a careful test by experienced men of all American gelatine plates; it is expected some months time will be required, and when published the results will probably be of much value.

THE AMATEUR PHOTOGRAPHER.

New York, June, 13th, 1884.

THE SPECTROSCOPE AND ITS RELATION TO PHOTOGRAPHY.

BY C. RAY WOODS.

X.—PHOTOGRAPHY IN NATURAL COLOURS.

IN a series of articles on the spectroscope, to make no mention of the subject of photography in natural colours would be a grave omission, for spectroscopy has played an important part in the investigation of what little has been done in this direction. The writer does not profess to add anything new in this direction, but it may not be amiss to re-state, in as clear and simple a manner as the subject will allow, what has already been said and done.

There are several ways in which this question is regarded in the photographic world generally, extreme opinions being adopted, as on most debateable subjects. One view is that taken by the optimist, who hopes that the time will come when he can get a photograph in the colours of nature with all the ease with which he manipulates a dry plate and takes a silver print. Another view, quite an antagonistic one, is that the idea is altogether the dream of a visionary, and that its realization is out of the question. Most photographers, perhaps, take a view midway between these two, and while regarding the discovery of what may be called "the philosopher's stone" of photography as by no means unlikely in the very distant future, do not expect that the "transmutation of the baser metals into gold"—as the transition of black and white to natural colours may be likened to—is to be obtained without some trouble on their part. Such a view is a perfectly reasonable one. Separating the true from the false, the genuine work of the patient experimenter from the quackery of the mountebanks who bring the subject into disrepute, enough has already been done to forbid us to entertain the notion that the seeker after photography in the colours of nature is pursuing an *ignens fatuus*. On the other hand, what little success has already been achieved, and the pains with which that little success has been obtained, only serve to make clearer the immensity of the task.

Experiments have been made in two distinct directions: 1st. In obtaining a picture by a direct process; 2nd. By taking into consideration the three-coloured pigment theory of the artist.

In connection with the first of these methods the names of Edmond Becquerel and Niépce de St. Victor are most prominent. Both these investigators, and others who have worked in the same direction, have taken as their basis the sub-haloid salts of silver, the subchloride producing the best results. The method preferred by Becquerel, of producing the subchloride of silver, was to take a silver plate and immerse it, facing a similar plate of platinum in a bath,

of hydrochloric acid. By attaching the silver plate to the negative pole of a battery, and the platinum plate to the positive pole, a film of sub-chloride of silver was formed on the silver plate. By placing this plate in the camera of the spectroscope and allowing a brilliant spectrum to fall upon it, the colours of the spectrum were impressed. Niepcé de St. Victor photographed some dolls dressed in coloured cloths, by this method, using, of course, a very bright light and giving a very long exposure.

Various other methods have been used to obtain the sub-chloride of silver, amongst others being the plan of immersing a silver plate in a solution of chloride of iron, copper, or calcium. If silver chloride be formed on paper, or films be prepared of chloride of silver emulsified in collodion or gelatine, and these films be then exposed to white light till they become lavender grey in colour by the production of the sub-chloride, they will receive the colours of the spectrum upon them.

Two explanations have been put forward to account for the colours of such images: 1st. That they are due to different stages of oxidation of the silver salt; 2nd. That they are due to interference of light, as in the beautiful display of colour from soap bubbles, the thickness of particles forming the film determining the colour. Probably both explanations are correct, the second being the outcome of the first. Unhappily, all attempts to fix these photographs have failed. They may be kept for a long time in the dark, and may be examined from time to time in a weak light, but exposure to a strong light blackens the film and obliterates the image.

So far as actual results are concerned, the method about to be described has, so far, turned out most successful. Three investigators thought out the process simultaneously, but only one of them—Ducos du Hauron—had put his thoughts into practical shape. The method depends, as already stated, on the painter's three-colour pigment theory and practice. Three monochromes—red, yellow, and blue—printed on carbon tissue, are superposed. Husnik suggested an improvement on the process by substituting mechanical printing for carbon printing, thus rendering the necessary registration easier of accomplishment, in addition to simplifying the operations. This was carried out successfully by Albert, of Munich. The negatives were obtained by taking three photographs through green, blue, and red glass respectively; but it must not be imagined that this has any relation to the three-colour sensation theory of Young, Helmholtz, and Maxwell. When an ordinary photograph is taken, a negative is first obtained, from which the print is got. In obtaining a negative for printing in colour, not only must it be a negative so far as light and shade are concerned, but it must be a negative in colour also. For instance, if a negative were obtained through glass that only let through red rays, objects of a red colour would appear black, and objects reflecting no red light would come out white. If this negative were used for obtaining a print on red carbon tissue, those parts of the print which were beneath the black portions of the negative would come out white, instead of red, exactly the reverse of what was required. To obtain a negative for printing the red monochrome, glass of the complementary must be in front of the lens or the plate.

In Ducos du Hauron's process, therefore, the negative for printing the red monochrome was obtained through green glass, the yellow through violet glass, and the blue through orange glass. In fact, as we do not meet either with pigments or transparent media that reflect or transmit light of one wave-length only, to obtain a perfect result, the transparent medium used for making a negative should transmit all rays except those reflected from the pigment in which that particular negative is to print. The whites of the view or painting photographed would appear black in each negative, and would consequently appear white in each monochrome, and therefore in the three monochromes superposed.

It is many years now since this method was described and put in practice. The most serious difficulties encountered were in photographing through red and green glass. So many improvements have been made since then, the methods of photographing any part of the spectrum by means of dyed films, and the greater facility in photographing the red, either by collodion or gelatine emulsion, that it is about time we heard something more of this process than we do. It is a most ingenious method of obtaining colour-photographs, and might be largely applied.

So far as obtaining photographs in natural colours by a direct method is concerned, we are at present far from its accomplishment, but it is in this direction, most probably, that we must look. It opens up a large question. When an image, capable of fixation, is obtained in natural colours by a comparatively short exposure, our difficulties, perhaps, will only have begun. The proper representation of light and shade, detail in the shadows, &c., are matters that at the present time require constant attention on the part of the photographer. Who knows but what, when colour-photography seems within our grasp, strictly analogous questions will come to the fore with fiftyfold complications that the representation of colour must inevitably bring?

OUT AND ABOUT WITH THE TRICYCLE.

BY J. B. B. WELLINGTON (TEMPLE BICYCLE CLUB).

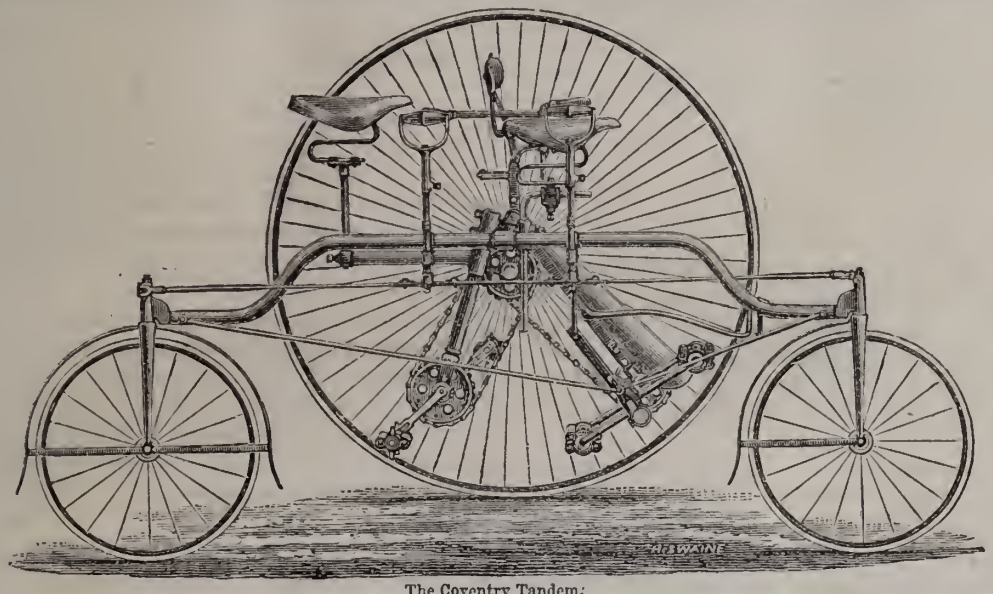
Now that you have opened your pages to tricycling in connection with photography, I think if everyone who combines photography with tricycling were to give their views and experience on what they consider the best tricycle for the purpose, that the would-be photo-tricyclist would be greatly benefited, as what is more perplexing than scanning through the advertisement pages of a cycling paper to decide—out of the hundred and more

The Coventry Rotary.

machines—"which one shall I go in for?" But after reading the experiences of others I think he ought then to be in a good position to decide on what "mount" to purchase.

I, for my own part, strongly advocate a "Coventry Rotary," made by D. Rudge and Co. I have now ridden one for over two years, and would not change for any other. In the first place, it is a very light machine,

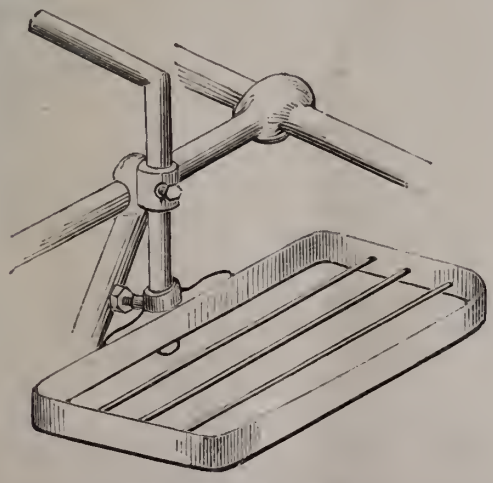
weighing 70 lbs., and is very compact, the width being only 30 inches, so that it will pass through any ordinary doorway; moreover, it will save one a good deal of discomfort if at any time you should want to take it by train. I remember, during last summer, I was riding with a friend who had a double-driver front-steerer, and it coming on to rain we thought it better policy to take train to our destination than getting wet. We forthwith found the station, took tickets both for ourselves and the machines, and the train having arrived in due time, I managed, without any difficulty, to get my "Coventry Rotary" into the guard's van; but my friend, on trying to do the same, found it quite another matter, the machine being too wide to enter. One of the wheels was then taken off, and another attempt made, but again proved fruitless; the axle caught in the hinge of the door, and now refused to go either in or out. In this state the train started, my friend hanging on outside, and the guard, inside, trying to pull it in. The bad language that was used over this I should not like to repeat. The station-master, observing what was up, stopped the train, and whilst taking off the other wheel, wished to know if we were going to keep the train all night. We then got the tricycle in, and proceeded on our journey. I do not wish you to think that all guards' vans are of such small dimensions. This is not the case; but you may drop across one as above when least wanted, as it is not always convenient or safe to have the machine sent on by another train.



The Coventry Tandem.

I also use the "tandem" tricycle, made by the same firm, the machine taking either two riders.

I will just give a brief outline how to carry the camera and stand, and this latter need not of necessity be a folding one. I find that one of George Smith's Brattice stands is very convenient for carrying on the machine,



Luggage-carrier attached to tricycle.

and is certainly both strong and light; it should be strapped to the long bar which connects the two steering wheels, and is then quite out of the way. When going on a tour, a fishing-rod will not be found to be of any appreciable weight, and certainly it is not in the way, as it can be strapped alongside the stand. Of course this applies to those photographers who take an interest in the "gentle art." Now for the heavier part of the kit. I have a carrier made of a light iron framework, and which can be purchased from Messrs. Starley and Co., manufacturers of the "Salvo" Tricycle. I think the price is 3s. 6d. This should be fixed as shown on the lower part of the ⅂ pin, which supports the saddle, as it is then easily taken off when not required. Below the carrier I strap on a basket containing a change of clothes, as well as a supply of plates; and on top the camera is placed and fastened by two large straps, which go round the basket below, also round the cross-piece of the framework, thus preventing the liability of the carrier giving way. On account of the "give" in this carrier, the vibration communicated to the camera and plates is reduced to a minimum, thereby preventing dust from shaking off the interior of the dark slide, and settling on the sensitive film.

I usually carry one dozen half-plates besides the four double dark-slides ready charged, for a two or three days' tour; but if on a tour of a week or fortnight's duration, the best way is to send a parcel of plates on by train to a place which you intend reaching in two days' time, as enough will be taken "on board," as suggested above, to last during the time the rest are in transit, so that no anxiety need be felt about their getting to their destination in time. They certainly should be labelled "Photographic Plates—not to be opened;" otherwise the vigilant railway authorities—just at present, at least—may, from their heavy nature, take them to be dynamite.

The tricycle lamp is the rider's guiding star by night, and indeed everyone ought to carry one both for his own and others' safety; certainly no photographer should omit to take it, as without any trouble it can be turned into a

most effective dark-room lamp for changing plates at night, by simply wrapping round it a piece of golden fabric, this being kept in place by an elastic band. A better developing lamp certainly could not be had.

About the 'Cyclists' Touring Club and its benefits I will leave someone else to treat more fully; suffice it to say that the subscription is but 2s. 6d. per annum; the chief advantage being, that on entering a town, you look through your hand-book and see at a glance which is the C. T. C. hotel, this being then at once made for, knowing at the same time you will not be "rushed," as a fixed tariff has been drawn up for the C. T. C.

After all, what is more exhilarating to both body and mind than to enjoy the fresh country air, to be spinning noiselessly along, no anxiety in hurrying off to catch a train, no travelling expenses, no horse to keep, and always ready at a moment's notice, and to get at the most out-of-the-way places, bringing home views which will never be forgotten, at the same time developing your muscles, which require no hypo to fix?

Notes.

It is worthy of note that the judges of the Photographic Exhibition of 1884 will, as last year, be composed wholly of photographers. This decision would seem to confirm the opinion already held, that some of the awards conferred where the judges were selected from painters as well as photographers, were not wholly satisfactory.

It is still considered quite *de rigueur* in convict prison circles that all prisoners should leave their cartes-de-visite with the Governor at the expiration of their stay. There is an exchange of "pasteboard," in fact, the convict leaving his carte, and the Governor presenting him with a "ticket of leave" in exchange. That this custom may be duly kept up, the House of Commons will be asked to vote, during this session, the sum of £850, which it is estimated will defray the cost of photographing the inmates in the prisons of England, Ireland, and Scotland.

Some months since we referred to the case of an American convict who, at the supreme moment, seized the sitter's chair and smashed the camera actually in use. Led, perhaps, by the force of this example, a recalcitrant inmate of Dartmoor, watching his opportunity whilst being taken the other day, suddenly "went for" the operator with a spade, which had been foolishly left within his reach; but luckily the prison authorities had supplied themselves with a second camera, which a warder quietly manipulated whilst a colleague was ostensibly focussing the convict with the apparatus hitherto in use. As it turned out, the ruffian, who was pounced upon just in time to prevent him doing the intended mischief, was photographed in the very act of raising the spade, and the resulting portrait was indisputable, though not exactly legal, evidence of his contemplated assault. The carte is, however, carefully preserved, and will probably always be pointed out as the most "striking" likeness the prison cameras have produced.

The sum of £850 already mentioned is not the only amount directly voted by Parliament for photographic purposes. A sum of £760 is also put down in the Army Estimates for photographic chemicals, apparatus, and working expenses; whilst the vote for Science and Art Department includes an item of £1,000 to be devoted to the photographing of art objects, &c., for loan to local museums and exhibitions. Thus altogether upwards of £2,700 of the tax-payers' money is devoted to what may be fairly called "negative" results.

The reduction of the price of magnesium has oftentimes been promised, so we do not look with absolute confidence on the statement that the Schering Chemical Company in Berlin will soon supply it at about 3s. 6d. an ounce.

Photography has always been a stumbling-block to the criminal, and Dr. Belfield, of Chicago, tells us how a murderer was convicted mainly upon photo-micrographs of blood stains; while in another case, the chain of evidence was completed by making enlarged photographs of the machine marks on two hair pins.

A "Society Journal," which, seemingly hard up for subjects for its weekly puzzle, offered a prize for the best novel suggestions, has, from one contributor, received the proposal that it should give the prize for the most original pose for photographic "sitters." Should a prize be really offered, the resulting pages of "Specimen" answers ought to furnish some useful hints. We shall look out for them.

Photographic work is fairly provided for in the new Observatory on Ben Nevis. The building, although in use, is not quite complete, and the dark room is a kind of cellar at the bottom of the tower.

Not a few clergymen gather in funds for charitable purposes by selling their own photographic productions at prices which are generally over the market value of the pictures; and as long as there is neither a serious neglect of the legitimate work of the church, nor much competition with trade interests, few are likely to complain. At any rate, it seems much better that the clergyman who longs to outstep the confines of his calling should become a quasi-amateur photographer, than that he should—like a well-known clergyman of Kensington—parade the streets as a kind of unprofessional barrel-organist.

Might not paper manufacturers turn their attention to the wants of photographers a little more than they do? Mr. Spiller, at the May meeting of the Photographic Society, drew attention to their shortcomings in the production of photographic cards as regards the presence of hyposulphite. The manufacturers of albumenized paper, it is well known, find a great difficulty in procuring suitable material in the English market, but foreign makers are ahead in this respect, and, having no competition, practically have a monopoly in their hands. This is not as it should be.

Two fatal accidents from the careless handling of chemicals took place on Monday. Mr. Reid, of Manchester, died from inhaling the fumes of nitric acid; and Mr. Griggs, a pyrotechnist of Wisbeach, was killed by an explosion which took place in his laboratory. Those who make pyroxyline, or use Bunsen batteries, should remember that many fatalities have resulted from the inhaling of nitrous fumes.

How to obtain vigorous images on gelatine plates is a question of the day, although few people candidly admit their difficulties in this respect.

Mr. Sebastian Davis has studied the subject, and he finds that the main point is to increase the proportion of bromide in the developer, and to allow more than the usual time for development.

There is nothing whatever novel in such a suggestion, but this takes nothing from its practical value. Two grains of bromide of potassium to one drop of ammonia is not too much in many cases, and the use of such a developer does not make the plate slow, if a reasonable time be allowed for development.

"The development of plates is a science, but I can teach any one to make them," remarked Colonel Stuart Wortley at the meeting of the Photographic Society on Tuesday. There is much truth in this idea, and it will doubtless give comfort to those photographers who use commercial plates, and have to bear the sarcastic remarks of others who are fortunate enough to have leisure and convenience for habitually preparing their own.

General "Chinese" Gordon is, we have heard, a practical amateur photographer, and as there was certainly one photographic apparatus, with all due appliances, in Khartoum at the time of its investment, it may be assumed that he has had it removed to "the Palace," and finds in it an invaluable aid for passing the time. To "take" the rebels' camp and the heads of the enemy every day, even in a photographic sense, must be a great deal better than nothing.

The photographing of the series of portraits of Popes in the Vatican Gallery having been completed, it is said in a Roman paper that permission has been given by Leo. XIII. for the reproduction and publication of the valuable historical paintings contained in the same vast storehouse of Art. The reproduction, too, by photo-zincography of its more interesting and historical paper and parchments is to be commenced forthwith.

At the last meeting of the Royal Astronomical Society, Mr. Ranyard read a paper on "The cause of the blurred patches in instantaneous photographs of the sun." These patches are attributed by M. Janssen to solar clouds above the photosphere: these, he supposes, change very rapidly. Mr. Ranyard, however, believes that the patches are caused by currents of heated gas, and supported his views by experimenting with a piece of hot iron suspended within the telescope. The photographs of the patches so produced were exhibited, and elicited from Mr. Common an enquiry as to the width of slit used, as too narrow a slit gave rise to diffraction fringes. On its being stated that the width was $\frac{1}{8}$th of an inch, Mr. Common observed that he thought the slit must have been narrower. "No doubt," he went on to say, "with perseverance very bad photographs can be got, but the important question is how to get good ones." The learned society of astronomers laughed at this remark, but there is much truth in it. Some experimenters never get beyond the bad photograph stage.

The *Court Journal* says of the new so-called *repoussé* work—the metalization of plants—that it has one drawback which in the eyes of many of the fair sex will be fatal to the prosecution of this new industry—it soils the hands, the chemicals used for metalising having much the same effect on the fingers as photographing has. The *Court Journal* is behind the times; we have long since passed the age of blackened fingers.

Chicago photographers just now are terribly exercised in their minds over the competition which is cutting down prices everywhere and ruining the profession. The State of Illinois Photographic Association lately discussed the matter solemnly, and it was decided that each member should hand in a card on which should be stated what the writer would do if the Society as a whole decided upon raising the prices. But if it be true, as one member stated, that the people were getting disgusted with cheap photography, and that those men were busiest who were getting the highest prices for their work, there would seem to be little need of discussion, since the matter had practically settled itself.

Incidentally, it was mentioned that a Mr. Decker, of Cleveland, had raised his prices to twelve dollars per dozen for cabinets, and, in consequence, his trade had improved. In spite of this we fear few English photographers who find their business decreasing will have the courage to try the experiment of asking £2 8s. for a dozen cabinet pictures.

We are glad to be able to assure our readers that in the arrangement for next year's Exhibition, photography has not been overlooked, and we may state that in the official classification, which is now almost completed, photography will have a group to itself.

Opportunity will be afforded for exhibiting apparatus of every sort, illustrations of processes, and examples of the application of photography to all the various purposes for which it is now used. As the show is to be confined to "apparatus, appliances, processes, and products, invented or brought into use since 1862," it will be understood that pictures will not be admissible, except as illustrations of processes; but since almost the whole science of modern photography has grown up since 1862, it is evident that the limits of the Exhibition will not press hardly upon us.

We hope that the executive will recognise at once the interest and the importance of the art, and that sufficient space will be afforded for complete illustration of its present condition. We also trust that manufacturers, inventors, and amateurs will all avail themselves of the opportunity. Next week we expect to be in a position to publish the details of the classification, and some other particulars likely to interest our readers.

The Chemical Society now possesses a nearly complete set of portraits of the past presidents—these pictures having been printed in carbon—and they are hung in the council room. Dr. Russell, who has done most of the work of making the collection, wisely insisted on admitting no silver prints.

Although silver prints often last as long as need be in a family album, a society or club collection of portraits in silver may be regarded as well-nigh valueless.

The Secretary of the 'Cyclist's Touring Club has, we are told, an album with more than seven hundred portraits of the members, and fresh contributions are coming in at the rate of about twenty per week. How many of these—if, indeed, any—are permanent photographs?

It is perhaps not generally known that when a faded silver print is copied by means of the camera, it is often possible to obtain an impression of much detail which has become invisible to the eye; and if a print is copied when the first evidence of fading becomes noticeable, a really good negative can generally be secured.

Alcohol, so long regarded as capable of remaining fluid at the lowest temperature, may, it appears, be frozen at about —130° Centigrade. Boiling ethylene was used as the cooling agent in this case, and a temperature of —136° may be reached. Still lower depths in the scale of coldness may be attained by the use of boiling oxygen; the point of ebullition of oxygen being estimated by Cailletet and Pictet at —186°. When this temperature is reached, nitrogen can be readily liquefied under pressure, and by allowing the liquefied nitrogen to boil off rapidly, a portion solidifies in beautiful snow white crystals. A degree of cold is thus reached at which the main gaseous constituent of the atmosphere actually becomes solid.

Mr. Woodall, M.P., at a recent meeting of the Polytechnic Institute, spoke very highly of the system of teaching as carried on in the class-rooms at Regent Street. He said:—"I have not seen such a practical system anywhere on the Continent." Mr. Woodall may well speak with authority on this matter, and our readers will remember that the photographic class is under the direction of Mr. E. Howard Farmer. Out of six first-class prizes awarded by the City and Guilds Institute, no less than five were taken by Polytechnic students.

Specification Published during the Week.

5204. HARRISON GARSIDE, of the City of Manchester, in the County of Lancaster, Photographer, "An improved method of producing surfaces for mechanical or ink printing by means of photography."—Dated 2nd November, 1883.

This invention consists of an improved method of producing surfaces for mechanical printing by means of photography, and the object of my invention is the production, by mechanical and chemical means, of surfaces for mechanical or ink printing, and it is applicable to typographic, lithographic, and plate printing, and to the printing of fabrics by means of rollers. Its leading feature is the breaking up of natural tints, or photographic reproductions of the same, into dots or lines of varying magnitude. This I effect in such a way that the so-called lights of the object to be represented are translated into minute dots or lines, and the shadows into dots or lines of such magnitude, and at such a distance apart, as almost to represent actual blackness. One of the ways in which my invention can be carried out is as follows:—I produce a grained plate or mould by cutting or punching, in a flat metal or other plate, a series of shallow recesses of conical form, and having their edges in close contact. From this mould I produce, by the method known as Woodbury-type printing, a transparency on glass, or thin paper, using such a mixture of fluid gelatine and pigment as will give absolute opacity at the extreme depth of the mould. I now copy this transpareney in the camera on a suitable scale, to give the grain desired in the printing block or plate. This grain may be conveniently varied to suit the different classes of work and printing. This copy, which consists of dots of absolute transparency shading into absolute or nearly absolute opacity, may now be duplicated in any of the usual ways, and, for convenience, in the form of films. If one of these grained films, or screens, be now applied to the face of an ordinary photographic negative, it will be found, on examination by transmitted light, that the more opaque portions of the negative are now absolutely impervious to light, except in the form of minute spots, while the more transparent portions or shadows are veiled by a tracery of lines which, by suitable printing, may be nearly obliterated in the further operations; while, between these extremes, the varying tints of the negative are seen as spots of varying dimensions. From the negative so adapted a photo-lithographic transfer may be made and transferred to stone, or to a zinc, or other plate, if an etched surface for block printing be desired. If a surface for plate or *intaglio* printing be required, the operations are the same, using, in this case, a photographic positive and reverse mask. For certain subjects, such as portraits, and in cases in which it is desirable to make improvements by hand, either mechanical or artistic, after the translation to grain has been made, it is convenient to make an enlarged picture from the photographic negative and the grained film combined. From this enlargement, after the needed improvements have been made, a grained negative may be produced on the scale required. I do not confine myself to the use of shaded dots in working my invention. For some subjects, such as the representations of machinery, statuary, and coins, shaded lines may be conveniently substituted, or a combination of two or more screens composed of shaded lines may be used as a substitute for the shaded dots. The grained plate or mould may also be produced in various ways. For instance, a less mechanical translation may be made as follows:—An exposed collographic plate is to be inked up with a tint approaching blackness, and a grained resist transferred to a metal plate, or a similar transfer may be made by means of the grained paper which is in use by lithographic artists, or in other ways. The plate may now have the conical grain produced by repeated etchings as practised in typographic block work. In some cases it is convenient to produce the grain on the photographic negative, in the first instance, by placing in front of the sensitive plate while exposed in the camera a grained screen, or by exposing the sensitive plate before or after exposure in the camera to the action of light under a grained screen, and in this case the exposure in the camera may be somewhat reduced.

My invention may also be carried out in the following way. I expose a piece of sensitive carbon tissue under a negative, and, after development, I support it on a surface of soluble gelatine, and, while still slightly soft, I lay it upon a hard metal plate having the V-shaped grain, and subject them to sufficient

pressure to force the gelatine into the recesses of the plate, and I so proportion the thickness of the gelatine relief that the grain of the plate is entirely filled by the thickest portion of the relief when dry. I now dissolve the soluble support, and produce a printing plate by electro deposition, or in any other convenient way. Or a piece of ordinary carbon tissue may be exposed and developed in the usual way, and transferred to a white surface thickly coated with colourless gelatine, or other slightly ductile material. While still in a softened condition it is to be placed in contact with the hard grained plate, which may be waxed to facilitate removal, and subjected to the necessary pressure. After drying, the picture is to be removed, and it will be found that the tints are broken up into dots of varying dimensions in proportion to the varying thickness of the relief picture. From this picture a negative in black-and-white may be made, and a block, or other printing surface, produced by the usual means. Instead of using a mask or screen consisting of shaded dots or lines, a mask composed of transparent dots or lines on an opaque ground may be used in the following way. The mask is to be placed at an appreciable distance from the face of the negative which may be in contact with the surface to be impressed, and such a combination of direct and diffused light is to be thrown upon the mask as will cause the rays to disperse to an extent equal to very nearly the pitch of the dots or lines before reaching the sensitive surface.

Having thus described the nature and object of my said invention, I declare that what I claim and desire to be secured to me is :—

1. The method of breaking up the tints of a photograph into positive dots or lines of varying dimensions by means of masks or screens consisting of shaded dots or lines substantially as described.

2. The method of filling up the grain of a plate by means of a gelatine relief for use as described.

3. The method of breaking up the tints of a gelatino-carbon or other relief picture by pressure in contact with a plate having a V-shaped grain.

4. The use and application of the above methods to the production of surfaces for ink and colour printing in all their branches substantially as described.

FRENCH CORRESPONDENCE.

Conference Organised by the Syndical Chamber—The "En-cas" Pocket Photographic Apparatus.

On June 16th the Conference was held at the *Hotel des Chambres Syndicales*, at which the actual state of jurisprudence in relation to photographic copyright was indicated, the numerous services photography renders to all branches of decorative art, whether engraving, sculpture, painting, or drawing, being also considered. Attention was drawn by me to the great use artists might make of the camera, and I recommended a study of photography not for the purpose of turning artists into photographers, but that they may have faithful records of any subjects or accessories they may require for their works. The recent misadventure of M. Dantan, previously narrated in the Photographic News, shows the necessity for artists having direct recourse to photography, instead of turning to account pictures taken by other people. I had in my possession the original photograph used by M. Dantan, and one of his pictures in the Salon, but had both been shown together on the screen they might have caused an unfriendly feeling. The vexatious part of it is, that a picture absolutely copied from a photograph is a work of art, while the ruling law refuses to consider the original photograph as such. At the end of the conference, in which more than 500 persons took part, the methods for simple and easy employment of photographic apparatus at the disposal of artists were shown. I exhibited and described successively, Germeuil Bonnaud's photographic opera-glass, Enjalbert's photo-revolver, Stebbings' automatic camera, the academy camera, of which two were sent by Marion and Co., and the photographic En-cas of my own invention, of which a full description will follow, as it is now offered for sale by M. Francais, optician, Paris. Next, lanterns by Molteni and Laverne were shown, for enlarging the small negatives, or for projecting on a screen with the view of better judging of their effect. Lanterns with petroleum lanterns with petroleum lamps are preferable to artists and amateurs, as they are easy to manage, and give excellent results when enlargements are required not exceeding 18 by 24 or 21 by 27 from negatives of 6 by 6 centimetres in size. If too much enlarged, all the imperfections not noticed in the original—such as want of sharpness, specks of dust, &c.—will come out, giving a result deficient in the qualities of a direct print.

The annexed diagram gives a complete idea of the *en-cas*

pocket photographic apparatus as now manufactured. The bellows camera, when closed, measures only 9 by 10 by 3·7 centimetres, and weighs 280 grammes. In front, on a slide running in grooves, F, is placed the rectilinear lens set in action by its instantaneous shutter. It is a circular shutter in the same place as the diaphragms, and set in motion pneumatically at D without causing vibration, The slide bearing the lens may be moved backwards and forwards by a rack. The back of the camera opens for the insertion of the dark-slide, shown in diagram at C, with the inner part removed. The dark-slide holds two plates, kept apart by the partition with spring. Pellicles and sensitive paper may also be used, placing them behind a clean glass so as to keep them in a state of tension. Each dark-slide, containing two plates, weighs 48 grammes; six, therefore, when filled would be from 288 to 300 grammes in weight with the case. The dimensions of each dark-box are 10 by 7 by 0·6 centimetres. The slide is drawn out underneath at C, so as to avoid the introduction of light. The stand is made of three tubes of brass, one fitting into the other. Three sockets connected by chains to a central ring permit of the stand being placed so as to give tension to the legs. The whole is enclosed in a cane, like a stout walking stick, the top, P, unscrewing to admit the three branches. At *m m'* is a brass rule fixed on a pivot *m*, taking a horizontal position, having a projecting knob at each extremity, serving as points of sight by which the objects may be centred on the plate without using ground glass. A little handle replaces the stand for rapid

exposures in the hand, as with a pistol. In such cases, the apparatus is held in one hand, the eye adjusts the picture in the centre by the two sights, and the other hand works the shutter by pressing the pneumatic pear, P. To sum it all up, three little parcels are put into one's pocket; the first is the camera, next the collection of six double dark-boxes, and the third is the lens with shutter and diaphragms complete. This last in its case weighs on 235 grammes. With the walking-stick in the hand is completed the photographic outfit, sufficiently reduced in volume and weight so as to be easily carried in the overcoat or coat pockets. Compared with all other apparatus of the kind, I think this is the most complete in point of portability, as well as the dimensions of results obtained—namely, 6½ by 6 centimetres. The question of solidity has not been overlooked, and the thickness of the wood and stoutness of finish render it not a mere toy, but a really accurate instrument. The lens is a double rectilinear, 10 centimetres focal distance giving sharp definition instantaneously of images 6 by 6 without any diaphragm, although having an opening of 12 millimetres. The shutter is a double palette, turning on a central pivot, M, where a steel spring bends it more or less. When the little crank, M, is vertical, the lens is exposed; when horizontal on the side opposite to that shown in the diagram, the lens is covered and ready to act. The exposure is as long as possible, as the one palette describes a semi-circle before that masking the lens exposes it to the light. This is equivalent to a circular shutter, the disc of which would have an opening equal to half the circumference. If pellicles were employed without glass, the weight of the dark boxes would be considerably reduced; but it is not worth while to give up this advantage for the sake of the trouble which would be otherwise caused by the difficulty of keeping the films at equal tension. It is desirable to make use of pellicles or paper, because a reserve stock can be carried about with very little additional weight. With the aid of a lantern with ruby glass, the pellicles can easily be changed at night. This seems a long talk on a small subject, but I beg you will excuse me by remembering that the smaller a photographic apparatus, the more it is necessary to study its mechanism to render it as good as possible.

LEON VIDAL.

THE VELVET ROLLER AND COLLOTYPE FOR AMATEURS.

BY SAMUEL C. RILEY.

IN using the velvet roller no particular precautions are needed, but the roller should carry enough ink of moderate thickness, consisting of pure olive oil and litho. transfer ink thoroughly incorporated. The greatest advantages accrue from first rolling the collotype plate with the velvet roller, covering the whole plate with a thin uniform coating, and immediately rolling the plate with a leather roller sparingly covered with the same ink as used on the velvet roller. Any amount of brilliancy can thus be obtained (providing the negative is perfect), always remembering that a little sharp rolling clears the whites effectively. I have repeatedly seen collotype plates that could not be inked up with the leather roller by itself (owing to the plates being dried badly), which gave perfect impressions after having been inked lightly all over with the velvet roller, the plate being cleared with a few gentle rolls with the leather roller.

To make a collotype plate that will give perfect impressions, proceed as follows:—

First, the substratum for the plate.—Take 1 ounce of ordinary dinner ale, 6 or 8 drops of silicate of soda, and well shake into a froth in a bottle, stand it by for twenty minutes, then filter. Take a clean glass plate (patent plate is best), and with a camels' hair brush go over one side of the plate; set on end to dry. When dry, go over the plate again, letting it dry this time the other way up. When again dry, let a gentle stream run on it for thirty seconds; then again dry on end. When again dry, you may coat with the following solution:—44 grains Nelson's ordinary gelatine soaked for quarter of an hour in cold water, then heated in the oven till all is melted. Then pour into it the following hot solution—

Water	½ ounce
Bichromate of ammonium ...	6 grains

Well mix and filter. On no account let the solution get to boiling point. Take an 8 by 5 plate with the dried substratum on it, and flow over it ½ an ounce of the hot gelatine solution; place at once on the levelled glass in the drying box. It should dry in two hours, and is ready for instant use. Expose under an ordinary negative for an hour, then wash in cold water for 1½ hours, and dry in the open air, which takes from 4 to 6 hours, according to the weather. When dry, damp with very weak glycerine and water, allow the moisture to slightly evaporate, roll as above mentioned, and take impression off at once.

The drying box is as under:—20 inches high, 12 inches square, the levelling glass about 6 inches from the top of the box, three sheets of loose blotting-paper lying on it for the plate to rest on, a piece of iron (say) 6 by 4 by 3 heated in the fire, and placed 6 inches under the levelling glass. There should be at least three or four holes at the bottom sides of the box, and three at the top, to promote a good draught. The heat in the box should be about 120° F.

Rebiew.

A B C DE LA PHOTOGRAPHIE MODERNE. Par W. K. Burton. Traduit par G. Huberson. (*Paris, Gauthier-Villars.*)

WE here recognise an old friend in a new guise. Mr. Burton's A B C has been so thoroughly appreciated in this country and in America, that we have no doubt the French edition will have a large sale. The translation is very well done, but here and there one finds such slips as the translation of "methylated spirit" by "alcool méthylique." M. Huberson showed his discretion in not attempting to translate Mr. Burton's allusion to methylated "finish;" he simply leaves it out. An author should always run through a book intended for translation, and annotate such points as may offer special difficulty.

Correspondence.

EXTREMELY SMALL DIAPHRAGMS.

SIR,—I am very glad to see that the question of very small stops is likely to be thoroughly ventilated. It is now more than two years since, in your issue of May 5, 1882, I pointed out the error of the then prevalent view that the physical effect of diffraction is injurious to definition, even with stops no smaller than any usually supplied. I deduced my results briefly and roughly, from observation rather than theory, and am now much interested to see how closely they agree with those of Captain Abney, who, making S=27″ with $\frac{1}{10}$ inch aperture, would make the disc of confusion subtend an angle of 54″. My estimate was 50″, which, if we are to take into consideration the three bright rings outside the disc, would appear decidedly too small. But, basing my calculation rather on observation than on theory, I feel inclined still to hold to my opinion then expressed, that, "as with points of intense light seen on a black ground this error is at its maximum, so in circumstances more resembling an ordinary photographic image, it is much less sensibly injurious." This seems to agree best with such experience as I have had in astronomical observation, in which it was often desirable to work with a smaller aperture on planets than on stars. I remember the astronomers in charge of Lord Rosse's telescope some twenty-

five years' since telling me that when observing the moon they frequently—nay, commonly—reduced the working aperture from six feet to twelve inches only, finding even then that the longer focus of the great telescope gave them an advantage over the smaller one of half its dimensions.

My estimate of accurate definition at $\frac{1}{200}$ inch, as compared with Captain Abney's at $\frac{1}{100}$, will not certainly be considered large. Much depends on whether we are thinking of the central or the marginal definitions, and on whether a swing-back has to be used to any great extent. Copying I look on as a separate question, concerning which I hope shortly to offer some remarks. But some ambiguity appears when Captain Abney refers to the case of a lens of twice the focal length first mentioned. I venture to think that when he says, "With twice this focal length it is evident that the limit (of safety) would be reached, since the total diameter of the disc and ring of light forming the image of any point of an object would be nearly $\frac{1}{100}$ inch," he is considering the stop as still $\frac{1}{50}$ inch, which would be $\frac{f}{200}$. It is well known that the error of diffraction is a function of the aperture without regard to focal length, and the expression for the value of S shows this. It does not, however, follow that the practical error diminishes when a stop giving the same intensity is used with a longer focus lens, though the absolute diameter of the aperture being greater, the absolute value of the error diminishes in the same proportion. For though this would apply to a telescope where absolute defining power is looked for, it does not apply to a photographic image, which is expected to be equally sharp on the enlarged scale of a long focus lens, as with a shorter one. And the rule is therefore demonstrable, that whatever be the focal length of the lens, a stop of *given intensity* will be accompanied by a *given error of diffraction.*

In my own practice I have frequently had occasion to use even smaller intensities than $\frac{f}{120}$, but I consider them as useful only with very large plates, or when an excessive use of the swing-back is required with an extreme wide angle. I do not consider them advisable for obtaining mere depth of focus, or to be ever called for with plates so small as 12 by 10. But in recalling instances where I have used stops as small as $\frac{f}{150}$ to $\frac{f}{160}$, and obtained results quite sufficiently brilliant, I think I am justified in repeating what I said two years ago, that, "If we can keep out stray light from the camera, secure it from tremor, and have time for adequate exposure, we need not fear diffraction, even with far smaller stops than those commonly supplied." If a copy can be printed in time, I will send you one of a statue out of a large negative which I took with a lens having the extraordinary focal length of over nine feet. The stop was about $\frac{3}{4}$, giving an intensity of about $\frac{f}{133}$. You will see that the image is quite sharp, though, being somewhat over-exposed in a flat light, it is delicate rather than vigorous. But few will require to use lenses of over nine feet focus. The reason in this case was the inaccessible position of the statue.

I think that perhaps, on the whole, the result of my experience agrees with Captain Abney's view, that intensity of light and time of exposure are not quite interchangeable; but, as he expects probably to have some more to say on the point at an early date, I shall look with interest for his further remarks. It must not be forgotten that this question has an artistic as well as a scientific side.—I am, sir, yours truly,

W. H. WHEELER.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

A MEETING was held in the Council Room attached to the Gallery, 5A, Pall Mall East, on Tuesday last, the 24th inst., Col. STUART WORTLEY in the chair.

The first point brought under discussion was the cracking of the surface of highly albumenized paper, and it was suggested that it had been noticed more especially during the time when the wind was in the east; but the general opinion seemed to be that it was merely a result of abnormal dryness of the atmosphere.

A note was now taken from the question-box, in which it was asked whether some connection might not be traceable between the period during which vision is persistent on the retina, and the best time for exposure in taking an ordinary picture of moving objects; and it was suggested that one-eighth of a second might perhaps represent the time in an average case. It also appeared that the writer of the note supposed that a similar fraction of a second represented an approximation to the time required for the impulse of sense to pass from the eye along the optic nerve to the brain.

Mr. WARNERKE pointed out how very much persons differ as regards the time required for the impression on the retina to vanish; and

Mr. W. H. HARRISON said that the determination of personal equations was a very necessary feature of the observing work at Greenwich Observatory, but that for the same individual the variation proved to be trifling, except in the case of illness.

Mr. F. COBB referred to the extreme rapidity of reflex action in some cases, the touch of a fragment of splintered glass against the eyelashes being often sufficient to determine the closing of the lid before the flying glass could reach the eye. In this case, not only must the primary impulse reach the brain, but the return impulse must also be sent in a time almost inconceivably brief.

Professor DONKIN said that it appeared to him that no connection whatever could be traced between the period of persistency of vision on the one hand, and the rate of transmission on the other hand, with the best time for so-called instantaneous exposures. The data upon which the time of exposure should be based are special, and depend on the nature of the subject.

Mr. GEORGE SMITH and Mr. SEBASTIAN DAVIS remarked upon the motionless appearance of moving objects when lighted up for an extremely short time, as by an electric discharge, the phenomenon being well illustrated during a thunderstorm at night, or when a rapidly-revolving wheel is illuminated by the discharge of a Leyden jar.

Mr. PECK called attention to the more or less generally-recognised fact that it is often possible to obtain more artistic results by a comparatively long exposure, than by an extremely short one; and

Mr. ADDENBROOKE spoke in a similar strain, and as an illustration, referred to a case in which Captain Abney had treated the same subject in two ways: first, with a "cap" exposure, and secondly, with an extremely short "shutter" exposure; the picture produced in the former case proved to possess artistic qualities which were wanting in the latter.

The CHAIRMAN said that a main point arising out of the discussion was whether the camera could be expected to depict a moving scene with a finer definition and greater distinctness than the eye sees it.

The general opinion seemed to be that under favourable circumstances the camera is a far better and more exact observer than the eye.

The question-box being again looked into, an enquiry as to the cause of green fog was found, and the Chairman invited remarks.

Mr. BOLAS said that Mr. Plener and others had demonstrated that in ordinary cases it was due to a deposit of metallic silver; and in some cases, this deposit could be dissolved off by mercury (see account of Mr. Plener's experiments on page 235 of the PHOTOGRAPHIC NEWS for 1882).

Mr. WARNERKE said that on one occasion he put a developed and washed plate away with another glass resting against it and partially covering it. After about eighteen months, the uncovered part became somewhat iridescent, and its condition was such as to suggest that something like green fog had arisen. Another instance of a similar character was also spoken of. A film picture (collodion) had been partially varnished, and the dense silver deposit had become greenish and iridescent where the varnish had covered it. Mr. Warnerke appeared to think that the gelatine plays an important part in the production of green fog, and the action of the atmosphere has considerable influence. He referred to the well-known action of the atmosphere on the edges of packed plates, and he recommended that in packing, the plates should be placed as closely together as possible.

Mr C. RAY WOODS spoke of his own experiments regarding green fog, and pointed out that it could be artificially produced by adding pyrogallic acid to an ammoniacal solution of silver bromide.

The CHAIRMAN said that whatever might be the cause, or, indeed, he could perhaps say causes, of green fog, one might generally regard a short exposure and an undue forcing of the development as an immediate cause. He then remarked that someone present had suggested that there were two kinds of green fog, but he would emphatically say that there are more than two.

Mr. COWAN remarked that green-fogged plates often developed with brightness in the transparent parts; and if a plate has only a slight tendency to green fog, the matter is brought tolerably well under control by variations in the development.

Mr. WARNERKE now observed that green fog is practically unknown in Russia, even in the case of imported plates.

The CHAIRMAN said that he could partly understand this, as plates which were newly made would sometimes give green fog, but after complete desiccation the fault became eliminated; and in a dry climate one would not expect to hear so much of green fog as in a damp country.

Mr. COWAN said that many persons must have noticed that green fog often occurs where a trial plate is exposed and developed before being dried, although the bulk of the batch may be good.

Mr. SEBASTIAN DAVIS now remarked upon the "thin image" difficulty, and referred to the advantage to be gained by using a large proportion of bromide, and lengthening the time of development.

Mr. WOODS confirmed the importance of this point, and suggested that in many cases it becomes advisable to use as much bromide as two grains to each drop of ammonia.

Mr. DEBENHAM also approved of the principle of increasing the bromide and allowing a long time for development; he had used equal quantities of bromide and ammonia.

The CHAIRMAN now referred to the development of plates as a science which could never be learned without careful study. The preparation of the plates he regarded as merely mechanical, as any intelligent and careful person could be taught plate-making. Many persons increase the proportion of ammonia without also adding enough pyro to effect a reduction. It must not be forgotten that the pyro is the true developing or reducing agent.

Mr. COWAN now referred to the discussion on extremely small stops, which has recently taken place in the PHOTOGARPHIC NEWS, and he showed two pictures taken from the same subject, one taken with an aperture of $\frac{f}{32}$ and an exposure of two minutes, the other having been taken with an aperture of $\frac{f}{256}$ and an exposure of sixty-four minutes. Little difference could be detected, the definition being as nearly equal as possible; but the latter was, if anything, a little less vigorous than the former.

The CHAIRMAN, in connection with this subject, referred to his large pictures of Carnarvon Castle, these having been done with a pin-hole stop—perhaps $\frac{f}{500}$.

Mr. SEBASTIAN DAVIS now handed round a sensitometer-frame which was constructed of a sufficient size to admit any plate up to 8½ by 6½ being tested; by its use the inconvenience of cutting plates in the dark-room may often be avoided.

Mr. GEORGE SMITH next exhibited his new "Manx" stand. It is constructed of light pine wood, and although 5 feet high, its weight is only one and a-half pounds, and it closes to 2 ft. 8 in. The general principle is that of the Kennett sliding stand, but in order to prevent the side sway of the lower half of the leg, a kind of taper fish plate or web is fastened in front. The pin-holes at top of the legs are provided with brass bushing tubes, these being attached to the side plates. The light web plate on the lower half of the leg certainly gives the stand a remarkable rigidity, and also adds to it elegance, as the outline of the leg follows a regular sweep from top to bottom. In the triangular head is a tapped hole (¼-inch Whitworth) for safely storing the camera screw when not in use.

Mr. WARNERKE said that a friend of his who was present, the Baron de Koussoff, had met with exceptional success in treating some very sensitive plates which had been much over-exposed; his method being to immerse them in a ten per cent. solution of potassium bromide before development; but he did not wash off such bromide as might be adherent to the plates. As an illustration of the success of the method in question, some extremely fine pictures of the ancient Palace of the Czars at Moscow, where Peter the Great was born, were shown. The interiors were exceptionally fine.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

A MEETING of this Society was held on Thursday, the 19th inst. Mr. W. H. PRESTWICH in the chair.

In the discussion on that portion of Mr. Coles' lecturette relating to intensification, Mr. W. E. Debenham said that the mercury and Schlippe's salt method need not be in the least objectionable as regards colour, for if a small portion of iodide be used with the mercury, an olive-brown colour would be obtained.

Mr. W. COLES found by using Edwards' formula of mercury with iodide, the negatives were not so red; but they became red afterwards.

Mr. COWAN spoke in favour of Monckhoven's method—mercuric chloride, followed with cyanide of silver.

Mr. A. L. HENDERSON was in favour of lime water, instead of ammonia, after the mercury treatment; acid pyro and silver intensification he found very uncertain.

Mr. W. M. ASHMAN passed round several negatives which were intensified in 1881 and 1882 by various means, including mercury followed by ammonia, lime water, cyanide of silver, and sulphide of ammonium, also acid pyro and silver; after printing, these negatives had been stored with others in packages in a dry place. Those treated with ammonium sulphide had not changed; all the others had deteriorated.

The CHAIRMAN thought the damage was caused by insufficient washing before and after intensification.

Mr. COWAN showed a negative developed with the soda developer recommended by Mr. G. H. Monroe, in the April number of the *New York Photographic Times*. He found it excellent for obtaining density, and well worthy of experiment. The following is the formulæ:—

Formula 1.

Sulphite soda (cryst.)	4 ounces
Hot water	11 „

When cool, acidify with from three to four ounces of sulphurous acid. Add dry pyro 1 ounce. Filter.

Formula 2.

Sal. soda	3½ ounces
Sulphite soda	¾ ounce
Water	64 ounces

To develop, use one drachm of No. 1 to each ounce of No. 2. By using more or less of No. 1, any change in density may be secured.

Mr. ASHMAN called attention to a sample of vulcanized fibre sent him by Mr. T. Norris, as being suited for many purposes in photography, it being a substitute for leather, vulcanite ebonite, &c. It is made both flexible and hard, and in thickness varying from $\frac{1}{50}$th to 2 inches, the price being about two shillings per pound. It was stated that alcohol, acids, or alkalies, would not affect it.

A communication was read from Mr. T. Norris in reference to a question asked by Mr. Mackie at the previous meeting. He found by experiment that when ferric chloride is added to hypo in small quantities, there is a precipitate, which, on analysis, was found to be an oxide, or hydrated oxide of iron (ferric), and no sulphur is thrown down when the solutions are neutral, if the solutions are made corresponding to $Fe_2Cl_6 + Na_2S_2O_35(H_2O)$. These, when mixed in equal quantities, give no precipitate, and there is a certain quantity of ferric chloride left; but if three parts of ferric chloride be added to four of hypo, there is a precipitate, the iron being completely converted into the ferrous condition. There is no sulphate formed. Further experiments are in progress.

Mr. W. K. BURTON asked what excess of bromide will give the best results in an emulsion, as he had lately seen it recommended to use a large excess?

Mr. W. B. WELLINGTON showed an example where the quantity of bromide of potassium used was of the same weight as the silver employed; the plate registered 16 on the sensitometer, and was very dense.

Mr. COWAN thought an excess would be favourable to density.

Mr. HENDERSON had gone so far as to use an ounce and a half of potassium bromide to an ounce of silver.

A Member said the addition of bromide of potassium to the finished emulsion had been frequently recommended for obtaining density: could as much density be gained by the subject under discussion?

Mr. HENDERSON contended that anything tending to slow an emulsion favoured density.

Mr. DEBENHAM desired to know how Mr. Henderson would obtain density in a very rapid emulsion?

Mr. Henderson: By the use of soft gelatine and the addition of meta-gelatine to the finished emulsion. He was engaged on some experiments with glycerine, sugar, and other substances for that purpose.

Mr. Burton could speak on the value of meta-gelatine as a valuable addition for making an emulsion more rapid.

Some experiments with the diffraction grating in Mr. Henderson's lamp terminated the proceedings.

Derby Photographic Society.

A meeting was held at the "London Restaurant," Derby, on Wednesday, the 18th of June, Mr. Richard Keene, Vice-President, in the chair.

The minutes of the previous meeting were read, and the following gentlemen were declared duly elected:—As honorary members, Messrs. R. J. Billinton, Henry Bolden, George Rice, and W. W. Winter; as members, Messrs. F. Campion, J. Crossland, E. A. G. Jewitt, J. Merry, and R. L. Warham.

The Chairman then read the proposed rules, and after a discussion, during which several alterations were made, the amended copy of the rules was unanimously adopted.

The first technical meeting of the Society was fixed for July 2nd, when a paper will be read by Mr. R. Keene.

After the usual vote of thanks to the Chairman the proceedings terminated.

The following are the officers of the Society:—

President—Captain W. de W. Abney, R.E., F.R.S.

Vice-Presidents—Charles Edward Abney, B.A., H. Arnold Bemrose, M.A., and Richard Keene.

Committee—Arthur J. Cox, James E. Kaye, and Thomas Scotton.

Honorary Secretary and Treasurer—Fred. W. Simpson.

Talk in the Studio.

Messrs. Johnson and Son, of Gough Square, have forwarded us two samples of their substantially-bound albums, the leaves being plain cardboard, so that photographs may be permanently mounted thereon. This system possesses, for amateur photographers, the advantage of preventing frequent losses of the picture, owing to unreasonable requests from admiring friends.

Estimation of Chlorine, Bromine, and Iodine in the Presence of one another. By F. Maxwell Lyte.—It has been shown that bromine decomposes silver chloride, and that iodine decomposes silver bromide. The author now communicates a convenient method of applying these reactions for quantitative purposes. The silver precipitate, containing all the halogens, is dried, weighed, and then dissolved in 30 to 40 times its weight of water, by adding the smallest possible quantity of potassium cyanide. A quantity of potassium bromide equal in weight to the precipitate is now added, and the cyanide decomposed by excess of dilute sulphuric acid. The precipitate, which contains bromide and iodide (any chloride being now bromide), is dried, weighed, and then redissolved as before. One and a quarter times the weight of the original precipitate of potassium iodide is now added, the cyanide decomposed as above, and the precipitate dried and weighed. The quantity of chlorine, bromine, and iodine present is easily calculated from the differences in the weights of the three weighings.—*Journal of the Chemical Society.*

The Vertical Camera for Photographing Natural History Specimens.—Mr. G. Brown Goode, writing in *Science*, recommends the vertical fixing of the camera for obtaining reproductions of natural history specimens, and long ago we pointed out the advantages of this arrangement for copying purposes. Mr. Goode says:—As a matter of fact, the vertical camera, now used for photographing natural history specimens, &c., is the outcome of a suggestion made in December, 1869, by Professor Baird to Mr. T. W. Smillie, the photographer in the U.S. National Museum, Washington, D.C., that the instrument be placed on an incline; the former having observed the difficulty experienced in photographing with the horizontal camera such objects as stone implements, fish, &c. This suggestion was acted upon; and in the following year (1870) Mr. Smillie invented the vertical camera, and with it introduced the use of a side-light which produced the same effect as the skylight with the horizontal camera. Mr. Smillie also attached to the side of the apparatus an endless screw, whereby the distance could be readily regulated between the lens and the object to be photographed. In 1871, and again in 1875, a camera of this kind was constructed specially for photographing the marine animals taken by the U.S. Fish-Commission at Wood's Holl, Mass. Its advantages were readily seen by Professor Agassiz, who asked and obtained Professor Baird's permission to construct for his own work a camera on a similar principle. Not less than six thousand negatives have been taken with the vertical camera by Mr. Smillie.

Photographic Club.—At the next meeting, on July 2nd, the subject for discussion will be "On the best method of making stereo transpareneics." Out-door meeting on Saturday afternoon next at Teddington, meeting afterwards at "Clarence Hotel," near the railway station.

To Correspondents.

*** We cannot undertake to return rejected communications.

H. de S.—You can obtain all the information required by writing to the Secretary of the Photographic Society of Great Britain. The address is "Water Colour Gallery, 5A, Pall Mall East."

F. Gascoigne.—Your letter has been forwarded.

A. G. Brophy.—1. It is quite clear that you have reason for complaint as regards such delays, but we hardly think that things are worse than in other lines of business. 2. Your suggestion shall be attended to.

Ad. Eggis.—We also hope so, but fear that the chance of finding it is small.

A. A. A.—Add a handful of salt in addition to the acid.

Photo.—1. What you suggest will answer very well indeed. 2. We do not know the address of the gentleman you mention, but we are sure that you can obtain the *papier maché* dishes from the firm you allude to.

Vindex.—We recommend you to obtain either No. 1 or No. 2; there is little or nothing to choose between them.

A B C of Photography.—The publishers desire us to call the attention of possessors of this valuable little book to a serious error in line 24, page 71:—"One ounce of ammonia ·880 *and* two ounces," &c., should read, "One ounce of ammonia ·880 *or* two ounces," &c.

J. L.—No, a whole-plate would be nearer the mark; but if you think out the question, you will find that the original statement is true within wider limits.

G. F. Webber, Junr.—1. It describes an arc the chord of which corresponds to a portion of the line joining the lens and the centre of the picture. 2. We rather think that the arrangement proposed by your friend is more convenient, and if you tell him so, you might ask him to send us half-a-dozen lines on the subject, and a sketch.

Leicester.—It is difficult to make it clear to you, unless you are acquainted with the ordinary chemical notation; but if we mention that in the following equation the mere writing of symbols side by side signifies that the weights represented are in combination, and that a small figure immediately after a symbol only multiplies the value of that symbol, we think you will be able to so far understand the matter as to reduce it to a simple rule-of-three sum. We will give further particulars if you require them.

Ag = 108
N = 14
O = 16

Therefore, $AgNO_3$ will be 170.

K = 39
Br = 80

Therefore, K Br will be 119.

The above quantities react together as follows:—

$$AgNO_3 + KBr = AgBr + KNO_3$$

The products are:—

$$AgBr = 188$$

and—

$$KNO_3 = 101$$

Fred W. Bellamey.—1. You may perhaps gain a little by raising the strength of the bath to 35 grains, but certainly not very much advantage will result. 2. If you like to leave the lens at our office, we will look at it with pleasure. 3. Why not adopt the gelatino-bromide process if you wish to do rapid work?

Chas. Horner.—Full working details will be found on page 378 of our volume for 1875, and also in other places. You can consult all the back volumes at our office.

Thos. Stokoe.—1. We have had the labels attached. 2. Thank you for allowing us to use it, but we will take care to do as you suggest.

A. H.—The specimen of work is very good, and if it is a fair example of your every-day productions, we have no doubt that you will be able to obtain the kind of position you wish for.

T. E. B.—Common carbonate of soda—that is to say, washing soda. —weighed after drying. Dry it in the kitchen oven or on the hob

E. CORDER.—There is certainly some fault as regards the sizing of the paper, but perhaps if you soak it in boiling water for ten minutes or so, you will remove sufficient of the sizing material. 2. It is always yellowish, and, as far as we know, there is no means of bleaching it. 3. Once a year only.

DR. REDPATH.—It should never be acid, as in such a case the deposition of sulphur is almost a certainty; but it ought not to be extremely alkaline. The right degree of alkalinity may be ensured by first making it neutral, and then adding five grains of carbonate of soda to each pint.

JOHN FILLITSON.—It may be necessary in very hot weather; but such a course is never desirable if it be possible to avoid it.

DOUBT.—Certainly not more than five shillings, but we think that half the sum would be nearer the mark.

MARK TEMPLEMAN.—1. White of egg is the best material to use, but it should be diluted with four times its volume of water and well beaten. 2. Considering that full information appeared in the last number, we may fairly decline to give you the details in this column.

REVERSED NEGATIVE.—A reflecting prism in front of the lens is perhaps the best arrangement, but many prefer to use a glass mirror silvered on the face.

H. PAULSON.—The case is quite clear to us, as you have not sufficiently washed out the hyposulphite. Several hours' soaking with frequent changes is not too much.

CHESTER.—Why not try the experiment, as one would think it easier to do so than to write? 2. Float the *back* of the sheet on the citric acid solution. 3. A temperature of 80° Centigrade is far too high, but 80° Fah. would be near the mark.

GEORGE.—Soak the prints in a saturated solution of biehloride of mercury, and they will disappear. Revival at any time is easy, mere immersion in a solution ef hyposulphite of soda being required.

LUX.—Coal gas always contains sulphur, and this is converted into sulphuric acid during combustion.

DIFFICULTY.—It is easy to obtain a good print from a broken negative, if you lay your printing-frame on a table suspended from an ordinary roasting-jack.

JOHN S.—Although the conditions are certainly rather hard, you should not complain, as you entered into the arrangement with your eyes fully open.

W. H. W.—Rub the glass with ox-gall, and allow it to dry before coating.

The Every-day Formulary.

THE GELATINO-BROMIDE PROCESS.

Emulsion.—A—Nit. silver 100 grains, dist. water 2 oz. B—Bromide potassium 85 grains, Nelson's No. 1 gelatine 20 grains, dist. water 1½ oz., a one per cent. mixture of hydrochloric acid and water 50 minims. C—Iodide potassium 8 grains, dist. water ½ oz. D—Hard gelatine 120 grains, water several oz. When the gelatine is thoroughly soaked, let all possible water be poured off D. A and B are now heated to about 120° Fahr., after which B is gradually added to A with constant agitation; C is then added. Heat in water bath for half an hour, and stir in D. After washing add ½ oz. alcohol.

Pyro. Developer.—No. 1—Strong liq. ammonia 1½ oz., bromide potassium 240 grains, water 80 oz. No. 2—Pyro. 30 grains, water 10 oz. In case of an ordinary exposure mix equal vol.

Iron Developer.—Potassium oxalate sol. (1 and 4) 80 parts, ferrous sulphate sol. (1 and 4) 20 parts, dist. water 20 parts. To each 4 oz. of the mixed developer add from 5 to 30 drops ten per cent. sol. potassium bromide, and 30 drops sol. sodium hyposulphite (1 and 200).

Substratum or Preliminary Preparation.—Soluble silicate of soda 1 part, white of egg 5 parts. water 60 parts. Beat to froth and filter.

Fixing.—Sat. sol. of sod. hypo. 1 pint, sat. sol. of alum 2 pints, mixed.

Cowell's Clearing Solution.—Alum 1 part, citric acid 2 parts, water 10 parts. Edwards makes this sherry coloured with perchloride iron.

Eder's Method of Intensification.—The negative is whitened by soaking in sat. sol. of mercuric chloride, and after thorough rinsing immersed in potass. cyan. 10 parts, potass. iod. 5 parts, mercuric chloride 5 parts, water 2,000 parts. As film becomes dark brown, the actinic opacity is increased; but prolonged action causes brown tint to become lighter, until at last the negative is no denser than at first.

Fol's Backing Sheets.—A chromographic paste is prepared with gelatine 1 part, water 2 parts, glycerine 1 part, and a very small addition of Indian ink. Strong paper or shirting is coated, and the sheets are laid, face downward, on waxed glass to set. Press to back of glass plate.

THE WET COLLODION PROCESS.

The Nitrate Bath.—Water 14 oz., nit. silver 1 oz., nitric acid 1 drop. Before using coat a small plate, and immerse it for 20 minutes.

Cleaning Preparation for New Plates.—Alcohol 4 oz., Jeweller's rouge ½-oz., liquid ammonia ½-oz.

Film-removing Pickle for Old Plates.—Water 1 pint, sulphuric acid 4 fluid oz., biehromate potassium 4 oz.

Negative Collodion for Iron Development.—Alcohol 1 pint, pyroxyline of suitable quality 250 grains, shake well and add ether 2 pints, *Iodize this by mixing with* one-third of its volume of alcohol ½ pint, iod. ammon. 80 grains, iod. cadm. 80 grains, brom. ammon. 40 grains.

Normal Iron Developer.—Water 10 oz., proto-sulphate iron ½ oz., glacial acetic acid ½ oz., alcohol ½ oz. The amount of proto-sulphate iron may be diminished to ¼ oz. when full contrasts are desired, or increased to 1 oz. when contrasts are unduly marked. With new bath quantity of alcohol may be reduced to ¼ oz.; but when bath is old more is wanted.

Substratum.—Whites of 2 eggs well beaten, 6 pints of water, and 1 dr. liq. ammon.

Intensifying Solution.—Water 6 oz., citric acid 75 grains, pyro. 30 grains. When used, add a few drops of the silver bath to each ounce.

Lead Intensification.—After neg. washing, immerse in dist. water 100 parts, red pruss. potash 6 parts, and nit. lead 4 parts. When it is yellowish white wash and immerse in liquid sulphide ammon. 1 part, water 4 parts.

Fixing Solution.—1. Potass. cyanide 200 grains, water 10 oz. 2. Sat. sol. of sod. hypo.

Varnish.—Shellac 2 oz., sandarac 2 oz., Canada balsam 1 dr., oil of avender 1 oz., alcohol 16 oz.

PAINTING PROCESSES.

Albumen Mixture for Paper.—White of egg 18 oz., 500 grs. ammon. chlor. in 2 oz. of water. Beat to a froth, stand, and filter.

Sensitizing Solution.—Nit. silver 50 grs., water 1 oz., sod. carb. ½ gr.

Acetate Toning Bath.—Chl. gold 1 gr., acet. soda 20 grs., water 8 oz.

Lime do.—Chl. gold 1 gr., whiting 30 grs., boiling water 8 oz., sat. sol. cbl. lime 1 drop. Filter cold.

Bicarbonate do.—Chl. gold 1 gr., bicarb. soda 3 grs., water 8 oz.

Fixing Bath.—Sodium hypo. 4 oz., water 1 pint, liq. ammon. 30 drops,

Reducer for Deep Prints.—Cyan. potass. 5 grs., liq. ammon. 5 drops. water 1 pint.

Sensitizing Bath for Carbon Tissue.—Bichromate potash 1½ oz., water 30 oz., ammonia 1 dr., methylated spirit 4 oz.

Enamel Collodion.—Tough pyroxyline 120 grs., methylated alcohol 10 oz., ether 10 oz., castor oil 20 drops.

Mountant.—1. Fresh solution of best white gum. 2. Fresh starch.

Collotypic Substratum.—Soluble glass 3 parts, white of egg 7 parts, water 10 parts.

Collotypic Sensitive Coating.—Bichromate potash ½ oz., gelatine 2½ oz., water 22 oz.

Collotypic Etching Fluid.—Glycerine 150 parts, ammonia 50 parts, saltpetre 5 parts, water 25 parts.

Printing on Fabric.—Remove all dressing from fabric by boiling in water containing a little potash, dry, and albumenize with ammonium chloride 2 grammes, water 250 cubic cents., and the white of 2 eggs, all being well beaten together. A 70-grain silver bath is used, and the remaining operations are as for paper.

Cyanotype Printing.—Water 1 oz., red prussiate of potash (ferricyanide) 1 dr., ammonio citrate of iron 1 dr. Prepare and preserve in the dark. Float the paper and dry. Fixation by mere soaking in water.

VARIOUS.

Luckardt's Retouching Varnish.—Alcohol 300 parts, sandarac 50 parts. camphor 5 parts, castor oil 10 parts, Venice turpentine 5 parts.

Matt Varnish.—Sandarac 18 parts, mastic 4 parts, ether 200 parts, benzole 80 to 100 parts.

Encaustic Paste.—Best white wax, in shreds, 1 oz., turpentine 5 oz. dissolve in gentle heat, and apply cold with piece of flannel.

FERROTYPES.

Collodion.—Ammonium iodide 35 grains, cadmium iodide 25 grains cadmium bromide 20 grains, pyroxyline 70 grains, alcohol 5 oz., ether 5 oz.

Bath.—Silver nitrate 1 oz., water 10 oz., nitric acid 1 drop.

Developer.—Ferrous sulphate 1 oz., glac. acetic acid 1 oz., water 16 oz.

Fixing and Varnish.—Same as wet collodion process.

Employment Wanted.

Assistant Operator, first-class Retoucher.—S. G., 15, St. Peter's-st., N.
Assistant Operator at 30/-.—E. Hopkins, 51, Cossack-st., Southampton.
Lady, to Work-up, Ret., & Recep.-Room.—A. B., 72, Azenby-sq., Peckham.
Tinter, Spotter, &c. (lady).—5, Heaton-villas, Heaton-rd, S.E.
Operator, used to electric light.—W. S., 1, Chapel-rd., Notting-hill, W.
Assist. Operator, Printer, Toner.—F. M., 15, Stony-st., Caledonian-rd., N.
General Assistant, age 16.—B. R., *Photo. News* Office.
Operator and Retoucher in good house.—A. H., *Photo. News* Office.
Assistant Printer, age 19.—C. M., 8, St. Mary's-pl., South Ealing.
Printer and Toner, experienced.—T. N., 15, West Parade, Weymouth.

Employment Offered.

Lady Ret. & Recep.-Room.—F. W. Broadhead, 65, Welford-rd., Leicester.
Operator, good all-round.—T. Wright, Barking-rd., E.
Operator, at photo-litho, large plates.—J. S., 58, Farringdon-st., E.C.
Operator for field-work.—Mr. Gandy, 5, Bishopsgate Without, E.C.
Op. well up in posing & retouching.—W. Clayton, 6, London-rd., Leicester.
Op., all-round, for small studio.—H. T. Timperley, Darwin, Lancashire.
Printer & Toner, and also a Retoucher.—West, Eagle House, Gosport.
Negative Retoucher, good and quick.—G. Goodman, 6, Fort-hill, Margate.
Oper. & Retoucher, 50s.—N. Y. Photo. Co., 17, Bennet's Hill, Birmingham.

VOL. XXVIII. No. 1318.—*July* 4, 1884.

PATENT OFFICE LIBRARY

CONTENTS.

READY-SENSITIZED PAPER.

We have recently heard favourable mention made of preparing ready-sensitized paper in accordance with a plan which, we believe, we have to ascribe to Captain Abney. In his "Instruction in Photography," we find that he states that if paper be thoroughly washed after sensitizing, and then be immersed in a solution of potassium nitrite, it will keep well, and that the resulting prints will be as vigorous as with unwashed paper, or as with washed but ammonia-fumed paper. He further stated that the principle which underlies the process is the application of a chlorine absorbent to the silver chloride. There is no doubt but that the usual plans of making ready-sensitized involve the use of citric acid in some shape or another, either in combination with silver, or else as free acid. We have tried the plan with potassium nitrite, and have but one objection to it—namely, its hygroscopic tendency, and its consequent passage into potassium nitrate, a salt which is absolutely harmless, but not possessing the chlorine absorbing properties that are necessary. We may say, however, if the paper be once thoroughly dried, and then one sheet kept face to face with another, that atmospheric moisture hardly affects it, as the paper remains nearly colourless, and the nitrite seems not to be affected in the albumen itself, presumably because the albumen surface is more or less impervious to moisture. We have toned prints taken on this paper four months after preparation, using the borax bath and the acetate bath with good results. These prints we have before us now, are vigorous, and of a good dark sepia tone. We have tried other preservatives besides nitrite, and with fair success—for instance, the sulphite of soda gives excellent results, and is not of the same hygroscopic nature as the nitrite. We have found that the acid sulphite is, perhaps, a better preservative than the neutral sulphite, for reasons which it is not far to seek. The toning of the prints taken on this paper is fairly satisfactory, and we would recommend that it be tried.

The theory of toning, as usually accepted, tells us, however, that only certain toning baths can be used. For instance, the lime bath, with which an excess of silver is requisite, is evidently unsuitable for paper so prepared; whilst the acetate bath or the carbonate of soda bath, or, better still, the borax bath, should all be available.

Regarding all ready-sensitized papers, we have one thing to remember, viz., that so far we have no absolute knowledge whether a neutral or acid condition of the paper is the better. Carbonate of soda applied to blotting-paper, and then placed in contact with the back of the sensitized paper, we know preserves it unchanged for a considerable time; the organic salt of silver or the albumenate, which is always the delinquent, remaining unchanged. This would point to the fact that a neutral condition is a good one, but it seems more probable that the real preservation consists in the exclusion of moisture from the surface, moisture being the prime cause of decomposition. It is for this very reason that we have our doubts about the nitrite of potash, as the organic salt ought to discolour spontaneously in the presence of the moisture which the former will naturally absorb; on the other hand, for brilliant prints and rapid printing, the presence of a little moisture is absolutely necessary. A good experiment to show this is to wash a piece of sensitized paper thoroughly, then dry in a water oven, and moisten a small piece of it with water. Another portion should be damped with a dilute solution of the nitrite, and the three pieces be then exposed to light. It will be found that the blackening takes place much the more rapidly with the last, less with the simply water moistened piece, and very slowly with the thoroughly dry paper.

This experiment will show the necessity of moisture as well as of a chlorine absorbent for attaining the maximum sensitiveness.

In preparing the paper already alluded to, we have found that it is better to float the albumen surface on a 20-grain solution of the salt to be used. This involves, almost of necessity, two dryings of the paper, but for experimental purposes it is not of any great moment. Should the plan be adopted commercially, the extra time necessary would undoubtedly be a drawback.

THE EOSINE COMPOUND OF SILVER, AND ISO-CHROMATIC PLATES.

In a recent communication Dr. Vogel referred to the eosine compound of silver as being itself a sensitive agent (p. 324), and he describes some experiments in support of his view. Herr V. Schumann has recently experimented in the same direction, and having introduced the eosine silver compound into a gelatine emulsion, coated a plate, washed it, and an exposure was made in a spectrograph provided with a quartz prism. The action began near D, and, if one excepts the recognised minimum at F, the action was approximately equal all through the visible spectrum. The sensitiveness for the yellowish green and that for the indigo may be regarded as about equal, according to Schumann, and he found that the minimum at F was not so extended as in some of his earlier experiments with eosine-bromide plates. The circumstance that the plates were reddish-brown, and that they did not lose this colour either in the fixing-bath or the washing, is likely to be a practical objection to the process. Even treatment with ammonia did not remove the stain.

When, instead of coating plates with an unwashed emulsion containing the silver compound of eosine and washing

the plates, the emulsion was converted into threads in the vermicelli machine and washed, the result was different. The sensitiveness to the yellow was found to be diminished, and the minimum at F proved to have extended; while the red colouration was far less than previously.

In order to arrive at a conclusion as to the reason of this peculiar effect of a thorough washing, Herr Schumann prepared some eosine-silver by adding an excess of nitrate of silver to a solution of eosine, and after having collected the precipitate on a filter he proceeded to wash it with water, and he found that as soon as all the accompanying nitrate of silver had been removed, the eosine-silver compound itself began to dissolve. From this it would appear that although the eosine-silver is insoluble in water containing a trace of silver nitrate, and perhaps also insoluble in water containing certain other saline bodies, it dissolves in pure water.

THE INTERNATIONAL EXHIBITION OF 1885.

LAST week we stated that photography, at any rate as regards its technical aspects, would have a good place in the Exhibition of next year, and we are now enabled to give particulars with respect to the classification as far as photography is concerned: the following being the particulars as given in the official circular, under section xxix.:—

1. *Photographic Processes and their Results.*—Methods of gelatino-bromide plate making, apparatus for making emulsion, apparatus for separating the sensitive constituent, coating, drying, and packing machines; emulsion and other processes; printing processes, silver, carbon, Woodburytype, platinotype, gelatino-bromide, collodio-chloride of silver, &c.; apparatus for washing, &c.; prints and negatives; methods for making photographic lantern slides.

2. *Apparatus (excluding lenses).*—Cameras, shutters, changing-boxes, slides, tents, lamps; apparatus for making enlargements, and for micro-photography.

3. *Application of Photography to various purposes, Typography, Ceramics, Relief-moulds, &c.*—Method of producing printing surfaces; photographic enamels, photographic printing on pottery; photographic reliefs. Use of photography in self-recording apparatus, in scientific observations, &c.

Photography also steps in under the heading of military equipment, optical instruments, and printing: while in addition it may be also represented in class viii. aëronautics.

The arrangments for the Exhibition are progressing very satisfactorily, and we need do no more than to give a list of the names of the executive council to make it appear that every effort will be made to render the collection as representative as possible. Sir F. J. Bramwell is Chairman, the Marquis of Hamilton Vice-Chairman, and the following gentlemen compose the Council: Sir Frederick Abel, Mr. Isaac Lowthian Bell. Mr. Edward Birkbeck, Colonel Sir Francis Bolton, Sir Philip Cunliffe Owen, Professor Dewar, F.R.S., Mr. Joseph Dickenson, Sir George Grove, Mr. E. W. Hamilton, Mr. Henry Jones, Mr. W. H. Preece, Sir Edward James Reed, K.C.B., F.R.S., Professor Chandler Roberts, Mr. John Robinson, F.R.S., Dr. John Stainer. Secretary, Mr. Edward Cunliffe-Owen, B.A.

The Exhibition, as already stated, will be devoted to illustrations of apparatus, appliances, processes, and products, invented or brought into use since 1862; and it will be opened in May, 1885, to remain open for a period of about five months.

No charge will be made for space, but exhibitors will have to pay every expense of transit, delivery, fixing and removing their exhibits, and erection of counters when required; and they must, either personally or by their agents, superintend the dispatch, transmission, reception, unpacking and installation, and at the close of the exhibition the removal of their goods; in default thereof the Executive Council reserves to itself the right of doing whatever may be considered necessary, and at the expense of the exhibitor. Should any goods be deposited in the exhibition premises during the absence of the exhibitor or his agent, the Executive Council will not be responsible for any loss or damage, from whatsoever cause arising.

Applications to exhibit must be made on printed forms, which will be supplied on application to the Secretary, International Inventions Exhibition, South Kensington, S.W.; these must be filled up and returned on or before the 15th September 1884. After this date no application will be received.

Except under exceptional circumstances, no applications will be entertained for space for objects which have been shown in the Smoke Abatement Exhibition, 1881; the Fisheries' Exhibition. 1883; or the Exhibition of Health and Education, 1884. The space allotted to agricultural exhibits will be strictly limited.

Exhibitors are requested to mark the selling price of the articles exhibited, so as to facilitate the judgment of the juries, as well as for the information of visitors.

No article exhibited may be photographed, drawn, copied, or reproduced, in any manner whatsoever, without the special sanction of the exhibitor and of the Executive Council.

It may be interesting to give the following particulars as to the classification of philosophical instruments (section xxviii.)—

1. *Optical.*—Lenses, prisms, telescopes, microscopes and accessories, spectroscopes, polariscopes, stereoscopes, photographic lenses, spectacles, eye-glasses, optical glass.

2. *Astronomical.*—Telescopes, transit instruments, equatorials, mural circles, driving clocks, siderostats, heliostats, altazimuths, methods of fitting observatories and mounting instruments.

3. *Physical.*—Acoustic apparatus, tuning forks, sirens, phonautographs, phonographs; apparatus connected with molecular physics, air-pumps, manometers, radiometers; apparatus for measuring, &c., heat, thermometers, pyrometers, calorimeters; photometers; kinematic, static and dynamical apparatus, mechanics.

4. *Electrical.*—Friction and induction machines, batteries and other sources of electricity, Leyden jars, condensers, electroscopes, electrometers, galvanometers, voltameters, dynamometers, magnetometers, rheostats, resistances, electrical units, induction coils, thermopiles, vacuum tubes.

5. *Chemical.*—Thermometers, hydrometers, pyrometers, furnaces, blowpipe apparatus, assaying apparatus, apparatus for organic and inorganic analysis, for gas analysis, and for volumetric analysis, laboratory fittings and apparatus generally, balances, re-agents.

6. *Mathematical.*—Calculating machines, indicating and registering apparatus, pedometers, counting machines, slide rules, planimeters, drawing instruments, ellipsographs, scales, straight-edges, gauges, surface planes, dividing engines, pantographs, cidographs.

7. *Meteorological.*—Barometers, thermometers, rain gauges, hygrometers, aneroids, anemometers, ozonometers, storm signalling apparatus.

8. *Geographical.*—Surveying apparatus, theodolites, chains, levels; underground surveying apparatus; apparatus for hydrographic surveying, and for marine investigations and observations; hypsometrical instruments, tide gauges; seismographical apparatus; projections, maps, charts, models, and globes.

9. *Nautical.*—Sextants, quadrants, sounding apparatus, logs, compasses.

10. *Weighing and Measuring.*—Weights, scales, balances; measures of length, graduated scales, verniers, steel tapes; measures of capacity; instruments for angular measurement, clinometers, goniometers.

11. *Biological.*—Apparatus for anatomical research; physiological apparatus; apparatus for collecting and preserving natural history specimens.

At Home.

THE STANNOTYPE WORKS.

SAFFRON HILL. It must be at least five or six years since we were here—perhaps double as many—and on that occasion we took a camera in the hope of securing a few studies of the picturesque squalor of the neighbourhood; but to obtain anything characteristic was out of the ques-

tion, as half-attired children and ragged women came trooping out to see what the strange party was doing, and even the swarthy Italian, who would invariably loll about his doorway until evening brought back his customers and the barrel-organs they had hired, moved himself. How much Saffron Hill has changed! We even miss the approach to it from Holborn, and find ourselves half-way towards the other end before we quite recognise our whereabouts. It is true that all evidences of the old Italian character of the street are not gone: one may still see little shops with boxes of maccaroni and various mystic condiments in the window. The barometer and thermometer maker holds his ground, and the looking-glass maker may be seen at work: but along a great part of the street the modern London factory has replaced dirty and crowded tenements, while large gaps in the line of buildings indicate further progress in the same direction.

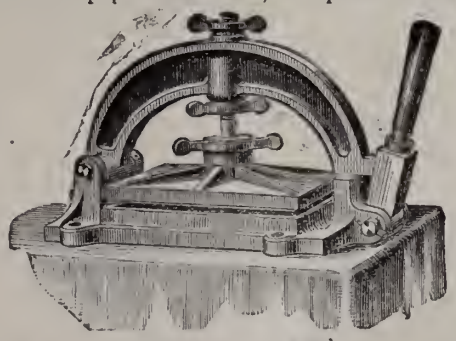
The type of factory to which we allude is a massively-constructed building with a very large proportion of window-space wherever light can be had, and but few, if any, partition or cross walls; the extensive floors being supported by iron columns and girders. The floors are usually let out to separate tenants, and sometimes a floor is divided by wooden partitions into a large number of separate holdings; indeed, so far is this system of subletting carried out, that one occasionally finds a space of about three feet square partitioned off, and let as a developing room. In many cases, perhaps in most, steam power is provided, the right to use it being included in the rent. When this is the case, the factory in flats is known as a "steam mill."

We begin to think that we may have gone too far up the main staircase of the building, but no; the row of stannotype presses, which we see through the open door on our left, shows us that we are on the right road. "This is the top floor but one," says Mr. Woodbury, who suddenly appears on the scene. "And we have the top floor also, a matter of some importance, as it gives us control over the roof, so that we can put up a glass house. Do we wish to come and see the place?" Mr. Woodbury is already half way up the last flight of steps, and we must follow; but we look the other way when he points to the step ladder leading to the roof. A part of the top floor is partitioned off as a drying room, and a light yellow curtain hangs in front of the window. A gas stove provides the necessary heat; but, as Mr. Woodbury points out to us, it is one of the "Calorigen" type, in which none of the products of combustion escape into the room. This is essential, Mr. Woodbury remarks, as burnt coal-gas contains products which make bichromated gelatine insoluble. The tissue from which the reliefs are made consists of a thick layer of gelatine spread on stout paper, and several sheets, which have just been sensitized, are clipped by one edge to a lath running across the room over the gas stove, and to the lower edge of each sheet a strip of wood is attached by a couple of American clips, in order to keep the tissue flat as it dries. This will not be dry for some hours, so a sheet of sensitive tissue is taken from a drawer and put in the printing-frame. But the exposure is not made under a negative. We have here a transparency, or, rather, four cabinet transparencies, on one glass. They are carbon transparencies made direct from the original negative, we are told, and as it is scarcely more trouble to make four on the glass plate than to make one, it is better to make four; especially as it is easy to print four pictures at once in the stannotype press. There is no occasion to wait until the exposure is complete, as here is a frame which has been out the required time. Mr. Woodbury removes the exposed tissue and immerses it in water, after which he lays it face downwards on a sheet of glass which is well flooded with water, removes the excess of water by means of a squegee; and then places it under gentle pressure for a few minutes. The glass to which the tissue now adheres is next placed in warm water, and very soon it becomes easy to strip off the paper backing, the greater part of the gelatine being left on the plate. The warm water soon acts on this, and dissolves away all those portions that have not been made insoluble by the action of light, leaving the gelatine standing up in high relief wherever the light has passed freely through the original transparency.

Before the gelatine relief can be used as a printing-mould it must be dried; and in order to expedite the drying, the glass bearing the relief is immersed in methylated spirit for an hour or so. The spirit absorbs nearly all the water from the gelatine, and the final drying is now a very quick affair.

The dry relief is next flowed over with a thin solution of india-rubber in benzole, just in the same way in which a plate is collodionized, and as soon as the excess of solvent has evaporated a sheet of tinfoil is laid on the somewhat sticky surface. The plate is now placed between the india-rubber rollers of a machine which very nearly resembles the ordinary wringing arrangement used by laundresses, and when the rollers cut fairly across the middle of the plate, they are brought together so as to grip very firmly, and the handle of the machine is moved backwards and forwards several times, the extent of the motion being increased each time until the extreme edges of the plate have been reached.

All is now ready for the printing. Mr. Woodbury takes a mould which has just been coated with tinfoil, and lays it upon the bed of a small press and adjusts the pressure by means of a screw. The mould is now slightly oiled by friction with a piece of greasy flannel, some gelatinous solution containing colouring matter is suspension is poured on, a sheet of paper is laid over, and pressure is applied.



THE STANNOTYPE PRESS.

The deep shades of the picture are represented by hollows in the printing mould, and the depth of these hollows corresponds to the intensity of the shades, so that a cast from the mould forms a positive picture with all the gradations of a silver print. Sufficient time having been allowed for the gelatine to set, Mr. Woodbury opens the press and strips the paper from the mould. The cast in coloured gelatine which adheres to its surface is a stannotype print of four cabinet portraits on one sheet of paper.

We see a row of about a dozen presses placed all along one side of a long table, and an assistant fills the moulds in succession with the coloured gelatine, lays on the paper, and applies the pressure. By the time he has charged the last, the and gelatine is set in the first of the series, he can remove the print, so that he may easily turn out fifty or sixty printed sheets per hour—say four cabinets on each sheet. Before sending out the prints, it is well to give a dip in an alum bath, and a rinse in water, the alum serving to render the gelatine insoluble.

Messrs. Woodbury, Treadaway, and Co. not only work the stannotype process, but also grant licences to those who may wish to make stannotype prints for themselves or for their customers; and among those who have adopted it may be mentioned Messrs. Sarony and Co., of Scarborough, and Wilson, of Aberdeen. That firms of such standing should endeavour to introduce permanent photo-

graphs in place of silver prints is much to their credit, and although in the case of a very small order—say a dozen cabinets—there might be a loss in adopting the stannotype process, there is an undoubted economy in the case of long numbers.

PHOTOGRAPHING *PULEX IRRITANS* AND HIS FAMILY.

BY J. H. JENNINGS.

PULEX IRRITANS, *alias* "F sharp," or common flea, is a familiar insect even to the most zealous worshipper of fresh air, soap, and water. If the spider does not scruple to hang her nets and pursue her murderous trade in kings' palaces, our lively acquaintance will at times invade the royal bed with equally bloodthirsty intent. Yet, unlike the spider, he takes no life; he is merely a robber, who would fain live at the expense of his victims, cruelly regardless of the terror and pain he inflicts.

Most persons know *P. irritans* merely through the qualities denoted by his specific name. His shape is so unfamiliar that many, on first seeing the photograph of a flea, are ignorant what insect it represents. This is partly due to the fact that the figures given, even in good works on natural history, are, for the most part, mere caricatures of the real insect; in fact, in a certain optician's window, known to the writer, there is a hideous monstrosity in water colour exhibited, with the inscription, "This is how a flea looks under one of A. B.'s 7s. 6d. microscopes!" If it be a fact that the flea *does* so look under one of the aforesaid microscopes, nothing much stronger could be said respecting their marvellous powers of distortion! *P. irritans*, instead of being a hideous looking monster, can really boast a neat, if not elegant figure.

The fleas belong to the order *Aphaniptera*, or "invisible wings," for although at present they fortunately have no wings, it was probably the fashion among the genus in former times to wear these appendages, which they have

THE MALE FLEA.

now parted with, like the folk who advertise grand pianos at a sacrifice, through "having no further use for them."

The photographs of the "human flea"—for each species of beast and bird possesses a special flea reserved for its own private use—reproduced in this week's NEWS, by the photographic process of Herr Meisenbach, show the male, female, and larva. The female is larger and stouter than the male, and, like most female insects, is endowed with a more potent weapon of attack. These lancets form part of the mouth-apparatus, and require a good quarter-inch to show them properly. When not in use, they are carefully enclosed in a sheath.

As a "sitter," the flea is very unsatisfactory. The most obstreperous baby can't hold a candle to him, and the most rapid drop shutter isn't fast enough: so all we can do is to photograph his corpse. Even here we meet with difficulties; instead of the "pallor of death," his dead body assumes, when embalmed in balsam, a strong amber colour, through which the actinic rays vainly strive to penetrate, unless aided by a powerful lamp and condenser.

The subjects of the illustration are from a slide by E. Wheeler, with male and female mounted under the same cover-glass. Both are very perfect specimens, but, as is the case with all these insects, the legs are far more transparent than the body, which renders it impossible to give a suitable exposure to all parts: consequently, in the negative, when the body is fully exposed, the legs come out too dense. This defect has to be remedied in the printing, by the simple expedient of covering the body, when fully printed, with cotton-wool, and giving a longer exposure to the legs. The specimens from which the photographs were taken had an exposure of seven minutes with a rapid plate, one and a-half inch lens, and small paraffin

lamp. With a larger lamp, the exposure would probably have been reduced to two minutes.

If papa and mamma flea give trouble through their non-actinic colour, baby flea is troublesome in just the contrary way. His body—or, rather, the thin integument that forms his mortal remains—is so transparent that taking a decent photograph of it is a feat on which the photo-micrographer may congratulate himself. The best way of doing it is probably to put on a strong light, and give an almost "instantaneous" exposure, by rapidly uncapping and capping the lens. Few persons would recognize a flea in the infant or larval stage; it is, in fact, a mere caterpillar, as genuine a grub as any, but minus legs. The metamorphoses of the flea are briefly thus: The eggs

THE FEMALE FLEA

THE BABY FLEA

—about twelve in number—are laid in blankets, carpets, rugs, old clothes, &c.; after a time they hatch, and become grubs, which feed on—well, no one knows exactly what! These grubs, or larvæ, become pupæ, which have the same form as the parent insect, but are enclosed in cases. After a proper period of, doubtless, meditative quiescence, the pupæ change into the perfect insect, ready to disturb the repose of all, from king to peasant.

The pictures given are enlarged about fifty diameters.

Review.

Workshop Receipts. Third Series. By C. G. Warnford Lock. (*London: F. and F. N. Spon*, 16, *Charing Cross.*)

The first series of the "Workshop Receipts," followed quickly as it was by the second, and now by the third, together form almost a reference library for the amateur mechanic and the unprofessional engineer. In fact, the

title "handy" does justiee to the comprehensive volumes which the enterprise of Messrs. Spon has given us, and there are few subjects of a scientific or technical nature about which one cannot find useful information.

A large proportion of the volume now under notice (about 150 pages) stands under the heading "Electric," and it consists of a full and comprehensive account of the various forms of battery now in use, practical and intelligible descriptions of electric alarums, bells, induction coils, measuring apparatus, microphones, photophones, storage cells, telephones, dynamos, &c. In fact, we find just such a practical description of electrical apparatus as will be acceptable to the man who rather wishes to make and use them, than to one who merely wants to pass an examination upon them. In a very well written article on alloys will be found all the information likely to be required in the workshop, and other metallurgical subjects are treated at more or less length; the latest details being given as to such metals as aluminium and magnesium. Under the headings of enamel and glass much useful information will be found, and we do not hesitate to say that the three series of workshop receipts should find a place in the laboratory of every experimental photographer.

ON THE WAXED PAPER OR CALOTYPE PROCESS, WITH ILLUSTRATIONS.

BY DR. HUNTER.*

THERE are few photographers of the present day who are probably aware of the fact, that one of the earliest processes for taking pictures is superior to many of the more elaborate and expensive processes that are now in use. (Views, and details of architecture, foliage, powerful effects of light and shade, or delicate traceries in marble, and carvings in wood, can be taken easily, delicately, and cheaply by this process.) I hope to be able this evening to show to you some of the results of the labours of our own countrymen, and of English, French, East Indian, Hindoo, Armenian, Rajpoot, and Polish photographers. I have been associated with persons of all these nationalities, and will leave you to judge for yourselves whether this process, from its simplicity and its relative cheapness, does not hold out to artists advantages which modern processes do not possess.

There are two other recommendations which ought not to be forgotten in matters of this kind, and these are, the large size of the pictures which can be taken on paper, their portability, and lightness in comparison with negatives on glass. There are, however, on the other hand, two difficulties which have to be contended with, and which prevent the process from being so satisfactorily applied to portraiture, or the representation of figures or animals, as the processes by wet collodion, or by the gelatino-bromide process. The first of these difficulties arises from the length of exposure requisite to obtain a clear, delicate, and satisfactory picture, and the other from the impossibility to get any living or moving creature to keep perfectly still for more than a minute or two, unless in profound sleep.

Compare the accompanying calotype of the corner of Roslin Chapel, taken more than twenty-six years ago by Messrs. Ross and Thompson, and some of their fine photographs of weeds done by this process, with pictures of the present day, and you will see how delicate they are in the shadows, and now well they have stood. Some of the views of Edinburgh from the Calton Hill, and the Dean Bridge, and St. Bernard's Well, taken by Colonel (now General) James Mayne in 1858, are also good and clear. But I have to bring to your notice subjects of great interest which appear to be particularly well suited for this branch of photography. These are views of temples, wooden-carved buildings, and pagodas in Rangoon, Ava, and Burmah, taken by Capt. Linnæus (now General) Tripe, and a Hindoo photographer named Iyahsawmy, from our Madras School of Arts nearly thirty years ago. In these days photography was in its infancy in India, but we were encouraged to commence a Photographic Society about the year 1852, in Madras, on account of the richness and grandeur of some of the architectural antiquities, and the picturesque nature of much of the scenery in the East. Our first school of industrial arts had been started in my own house in Madras in May of 1850, and it had met with such encouragement from all classes of the community, that the Photographic Society did us the honour of inviting our co-operation. This soon proved of benefit to all who were connected with both institutions, for we had the good fortune to enlist much of the artistic and photographic talent of Southern India. Many civilians, officers in the army, medical men, amateur and professional photographers, joined the Society, and the pupils in our school, who numbered 600 in daily attendance, soon found occupations of a congenial nature, as we were applied to for the manufacture of a variety of articles, both simple and complex in their construction, as camera slides, stands, stools, easels, and afterwards of cameras. Many of the chemicals for photography we had also to prepare, as the nitrate of silver, chloride of gold, salts of iron and soda, citric acid, and salts of potass. The hyposulphite of soda and several other chemicals we purchased, as they were cheap. I was surprised to find that the Hindoos had a practical knowledge of chemistry and of agricultural chemistry, and of the nature of soils, decaying rocks, and of tank, river, and running or stagnant waters, for which we did not give them credit.

* Extracts from a communication to the Edinburgh Photographic Society.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

REPORT OF THE CURATOR.

THE subjects dealt with in the lectures cover almost the whole of photography, in a general way. Mr. Darker showed us a series of beautiful experiments on light, mainly polarised, so as to give us an idea of the force with which we are constantly dealing, and a thorough acquaintance with which would, he considers, the better enable photographers to cope with the many difficulties they have every day to encounter.

Mr. Debenham told us what the lens attached to an ordinary camera-obscura was when Daguerre first began to use it for photographic purposes, and how, step by step, it has been improved. The lens as used by Porta could only cover a plate with a stop $\frac{f}{40}$ or $\frac{f}{30}$; by using a converging meniscus instead of a plano-convex, a much greater area could be covered, other things being equal. He showed us a series of lenses from the very early attempts down to the most recent, and those, as most of you know, will now effect with $\frac{f}{10}$ almost as much as the origiual lens would with $\frac{f}{20}$ or $\frac{f}{30}$. In the course of the lecture it was remarked that opticians of the present day aim too much at microscopic definitions at the centre, and neglect more than they ought to, the marginal definition. When they turn their minds to the improvements of this quality of the lens we may hope to see a great advance in the performance of the photographic lens.

Mr. J. Traill Taylor gave us a very interesting lecture on the manufacture of lenses, showing us what kind of tools are necessary for the production of the different curves on the surfaces of the glass, the rough glass as received from the glass manufacturer; also the different grades of emery and putty powder used in the grinding and polishing of the glass to the curves determined upon by the mathematician. Mr. Taylor has done us a good turn by illustrating his lecture in the manner he did. Some four or five of the members of the Association are now learning from a practical man the *modus operandi* from beginning to end as regards the production of lenses. What I should be glad to see would be the publication of a series of curves, by means of which, with two lenses as a nucleus, one could lengthen or shorten the focus of such a combination either by the addition of another lens, or by the substitution of a lens of different focus for one of the two already in the mount, and, in addition, that all, or at least most, of the positive lenses could be used singly for landscape purposes. Mr. Taylor has partly promised to give us the necessary curves for doing what I have here pointed out.

Mr. W. K. Burton gave us two formulæ for the production of emulsion.—one by the boiling method, and the other for very rapid plates produced by means of ammonia. The Ag Br produced by either of these methods can be allowed to subside, and then the supernatant liquid containing the altered gelatine and the salts resulting from the double decomposition poured off, so that perfectly-pure Ag Br is left behind. By "pure" I mean the sensitive salt freed from gelatine and foreign salts. Mr. Burton seems lately to have modified his formula very considerably as regards the quantity of gelatine associated with the Ag Br during boiling, and also the acidity of the liquid, in presence of which the ripening action goes on.

Mr. W. M. Ashman told us of the different methods that are and have been adopted in order to prepare paper suitable for photographic purposes. He exhibited specimens of prints produced on paper sensitized on baths of different strengths, and showed also the great advantage gained in some cases by using ammonia gas before printing. Here, again, a link is wanting. This is a lecture "On Toning and Fixing"; but this, I think and hope, will be supplied by Mr. Ashman during the next season.

Mr. A. L. Henderson showed the method he adopts in order to produce his beautiful enamels, which are always so rich and full of detail, and, above all, as far as our present experience goes, permanent. This subject is so important that if photographers of the present day wish their work to be handed down to posterity, they should take it up a little more seriously than it has been.

Mr. T. Bolas gave us a most instructive and interesting lecture on the production of photographic pictures in fatty ink. He showed us how a Woodburytype relief could be used in order to produce a picture on ruled paper, so that the image could be transferred to zinc and stone, and then how the former could be used in order to produce prints at the same rate as letter-press.

Mr. W. Coles, during the last lecturette, showed us results, and demonstrated on the spot how it is possible to alter the density of negatives, which, from force of circumstances, have been produced either too dense or too weak. From what he told us, I gathered that photographers ought always to try to get as much silver reduced as possible, and then, if necessary, to reduce the density by after treatment. When metallic silver only is left in the film, there is less chance of after changes than when the silver is converted into some other form, the stability of which we know very little. When intensification is absolutely necessary, bichloride of mercury followed by Schlippe's salt seems to give a more permaneut result than any other in the experience of the lecturer. Local reduction is most valuable, and in the hands of some can undoubtedly be made to improve negatives very much. For this purpose Mr. Coles prefers Mr. E. H. Farmer's reducer—ferricyanide of potassium and hypo—in consequence of one solution only being required, so that as soon as the reduction is nearly completed, the action can be arrested by washing.

The last chapter in this short history is in connection with Mr. F. W. Hart's lecture, wherein he gave us the exact dimension of furnace to be built, the proportions of carbonates and sand to be used with the haloid salt of silver to be reduced, and even the kind of fuel to be used in the furnace. The best precipitant for the silver from washings of prints, Mr. Hart finds to be dilute H Cl, and from the hypo. ordinary sulphide of potassium; but in neither case should they be used in too large an excess, as the resulting compound of silver is slightly soluble in them, and, in addition, in the case of the sulphide, the smell to many is anything but pleasant. Mr. Hart told us that within his own experience he is able to recover about ninety per cent. of the metal employed, so that if photographers would only take heed of what he said, they would be able in a very short time to diminish considerably the expenses in the printing department. A large amount of silver in many establishments, I am sure, goes down the sink, because the heads do not think it worth the trouble to save the hypo for treatment. All photographers would not, most probably, care about reducing their own residues; but, fortunately, refiners are glad to do it for them at a small charge.

THE ROYAL CORNWALL POLYTECHNIC ASSOCIATION: EXHIBITION OF 1883.

PHOTOGRAPHY: PROFESSIONAL AND AMATEUR.

Judges:—Messrs. Robert Fox (Chairman), W. Brooks, W. Naylor Carne, and G. Lanyon.

The judges have great pleasure in congratulating the Society on the success of the display in the Photographic Department this year. The number of exhibits is unusually large, and there is also a very marked improvement in the quality and general excellence of the pictures submitted. The judges wish specially to note the entire absence of anything approaching to careless or slovenly manipulation, which was very prevalent some few years since. In professional portraiture the exhibits are far below the average as regards numbers, but professional landscapes are exceedingly well represented; there are also a large number of instantaneous works, some of a very high degree of merit. The amateur work is likewise good. In the photographic appliance section there are some clever inventions and improvements, well worthy of notice; including several exhibits of lantern appliances, some of which are very ingenious.

Professional Photography.— The Woodbury Permanent Printing Company, of London, exhibit some important works of a very high order, notably No. 703—Madame Modjeska. They also exhibit two charming examples of enlargements on opal, very fine indeed. Mr. H. P. Robinson, of Tunbridge Wells, is very strong, and the judges are pleased to note the marked improvement in his exhibits over last year. To his "Merry Tale," a second silver medal has been awarded. Mr. R. Slingsby, Lincoln, sends a similar class of works, several very clear. There are two exhibitors of lantern slides, Mr. P. H. Fincham, and Mr. G. W. Gwyre, whose productions show clean and careful manipulation. They are mostly examples of wet collodion, which gives rather too cold a tone. Mr. Adam Distin sends three examples of his well-known style, the best of which is "Gloaming." Messrs. G. West and Son have a frame of studies of yachts, elaborately retouched. Mr. G. Higginson has two pleasing pictures, the "Lych Gate" and "An Old Watermill." Mr. F. M. Sutcliffe sends some of his charming little studies of shipping, &c., similar to those of last year. Messrs. Cobb and Son, of Woolwich, exhibit some extraordinary examples of instantaneous work, views of the streets of London, many of them taken from the top of an omnibus; a second silver medal has been awarded. An old exhibitor, Mr. J. Milman Brown, has a first bronze medal for his picture "A Misty Morning." It shows great artistic taste, is full of atmosphere, and generally effective. Mr. R. Walter has a few careful little bits of Epping Forest. Mr. H. Chubb sends some effective productions in portraiture. Messrs. John Chaffin and Son's exhibits this year are somewhat heavy; they would have been better had they received double the exposure. Mr. F. W. Broadhead is represented by two examples of portraiture, and a frame of views in Bradgate Park. The chief award in landscape is taken by Mr. N. McLeish, who has a first silver medal for his charming and effective production, "A Misty Morning." Mr. Norman May is represented by several examples of very careful work. Mr. G. Renwick sends eight frames, all of snow scenes, and somewhat monotonous. The best of Mr. J. Jackson's examples is "An Old Norman Doorway." Mr. James S. Catford has some very pretty views, which show careful study. Mr. W. J. Payne has a second silver medal for his excellent frame of panel portraits. The judges would like to see a larger style of portraiture from him. Mr. Luke Berry sends a few illustrations of careful work; and Mr. E. S. Ellery, some creditable examples in portraiture. Messrs. Day and Son contribute specimens of vignette portraiture, very soft and delicate. Messrs. Johnson Brothers, Henley-on-Thames, exhibit some perfect specimens of instantaneous photography, "Henley Regatta." A first bronze medal has been awarded to No. 809 as the best. They have also some exceedingly good pictures of harvest fields, and the whole of their work is soft and delicate. Mr. F. Argall, Truro, contributes a capital enlargement, "Boathouse on the Fal." He also sends a good enlargement of Dr. Benson, Archbishop of Canterbury. Mr. W. M. Harrison, Falmouth, has some very pleasing specimens of fancy portraiture. Mr. W. W. Winter contributes a frame of cabinet portraits, which are in the opinion of the judges spoilt by the mounting being too gaudy. Mr. Lyd. Sawyer has some pleasing out-door studies—"The Rivals" is the best. Mr. G. T. Whaite sends several frames of his well-known studies, which are well worthy of attention.

Amateur Photography.—Some very interesting pictures of life and scenery in the wilds of Labrador and Ungava, by Mr. J. R. Holmes, receive the first bronze medal. The manipulation is very good, considering the difficulties under which they must have been taken. Mr. J. G. Horsey sends several photographs, some of large size; but they are a little too black and cold, and in many instances the subject is too low in the plate, which dwarfs the hills. The judges are of opinion Mr. Horsey can do better work, and hope he will profit by these remarks. Mr. T. M. Brownrigg has a goodly number of examples, soft and delicate, of Italian and English scenery. Mr. C. V. Shadbolt sends some careful work. Mr. A. G. Tagliaferro contributes some very good instantaneous examples. Mr. W. R. Ridgway's frame of views in North Wales is fairly good. Mr. C. A. Fernley, of Reigate, is not so well represented as in former years. Mr. G. Brightman again sends some of his careful work, and has been awarded a first bronze medal for frame 872. Mr. P. H. Emerson sends a fairly good selection of views. The Rev. A. Malan has

a second bronze medal for some very good instantaneous pictures of express trains. This class of picture does not, however, give the idea of motion.

Photographic Appliances.—Mr. G. Hare, London, carries off the first silver medal for his New Patent Camera, which appears perfect in every way. It has great range of focus and every conceivable action, and is fitted with swing back and swing front, leaving nothing to be desired. Mr. W. G. Tweedy exhibits an instantaneous shutter, similar to Mr. S. P. Jackson's, only with four openings instead of two, passing one another. Messrs. T. F. Shew and Co., of London, also send a shutter similar to that of Mr. Jackson, with a screw to regulate the exposure. Their camera and other exhibits are of ordinary make, possessing no special feature. Messrs. W. H. Oakley and Co., London, are rather strongly represented in lantern appliances. Their portable lantern screen is a capital arrangement, and the Judges recommend it to the special attention of lanternists. They also send a portable and ingenious reading lamp, which seems very perfect, and a specimen of their interchangeable or blow-through jet, extremely well made. The notable feature is that it is fitted with a double regulating cock, whereby, when the gases are once adjusted, they can be shut off and turned on instantly without any readjustment, which is a very novel feature. A second bronze medal has been awarded to this invention. Mr. Cheney has several exhibits, including a changing bag for dry plates, tripod stand, and lantern-screen elevator. This last does not seem very substantial, and appears far too complicated to come into general use.

Notes.

Professor Eisenlohr will give a course of lectures on photography at Heidelburg University this summer, and we understand that an unexpected number of entries have been made.

Japanese paper handkerchiefs can now be purchased readily enough in London, and they are very useful in the laboratory. The strength of cloth is united with the absorbent quality of blotting-paper, while the price is such that one may well afford a new one whenever it may be required.

The exhibition of Mr. Dumaurier's drawings should have some interest for photographers, since without photography they would never have been seen in the pages of *Punch*, and possibly never attempted. Some years ago Mr. Dumaurier found his sight failing him, and he was warned that if he continued drawing in the minute style peculiar to him he would probably become blind. While in this difficulty a friend suggested that he should make his drawings about ten times larger than he wanted them for illustration, and have them reduced by photography. This plan the artist adopted, and so obtains a delicacy equal if not superior to that of his earlier days. He obtains also another advantage. The originals, being of a considerable size for pen and ink work, fetch a much higher price than if they were the same size as the cuts in *Punch*.

The phototype blocks which illustrate Mr. Jennings' paper this week are among the first made by the Meisenbach Company in this country. Their new establishment in Farringdon Street is now in active work.

A sign of the times. Baths, collodion filters, collodion pourers, pneumatic holders, glass cleaning-frames, and dusting brushes, may now be had second-hand for next to nothing.

There is little doubt the hygiene of the dark-room is too much neglected. A photographer the other day was complaining of continual head-ache and nausea. It was suggested he should look to his dark-room, but he ridiculed the idea that his dark-room could be the cause of it, as it was cool, large, well-illuminated, and ventilated by a patent method of his own. However, after some persuasion, he consented to make an examination, and discovered that the waste pipe of the sink led directly into a drain without the interposition of a trap. As his practice was to place the developing tray or stand in the sink, he got the full benefit of the poisonous emanations whenever he bent his head down to watch the development. Hence the head-ache and nausea. It is a good plan to stop up the waste pipe with a cork, which can be easily removed when it is necessary to empty the sink.

The heat in photographic studios has been very trying during the last few days. The best way of reducing the temperature is to have two or three light wooden frames stretched with calico, and kept saturated with water. One of these placed in a current of air, say in front of an open window, has a marvellous effect.

A fixing bath to which oxalate developer has been added is known to be a very energetic reducer; and Herr Martini finds that if a dense negative is left for half a day in a mixture of two parts of the usual hypo solution, and one part of fresh oxalate developer, every trace of the image disappears.

The luggage of the photographer is especially liable to excite the suspicions of the special "dynamite" police; but those who have felt their dignity hurt by having to explain matters, should read the Home Secretary's account of his own difficulties at Southampton. A square box of the "detective camera" type, with nothing projecting but the pneumatic tube and ball, can hardly be taken into a London railway terminus without bringing a plain-clothes officer down upon the bearer. We have tried the experiment.

The Republican candidate for the Vice-Presidency of the United States has declared himself to be a member of the Episcopal Methodist Church, and this declaration has impelled a well-known Methodist preacher to retort that if Senator Logan be indeed an Episcopal Methodist, "he must have joined the Church by telegraph, and have been baptised by photograph." We must confess we do not see sufficient "photographic point" in the "well-known preacher's" remark to justify the extensive circulation which has been given to it. If, now, the Senator had belonged to the sect of "Camer(a)onians," the photographic allusion would have had at least a nominal significance.

The metric system bids fair to ultimately become uni-

versal, and at the present time it is the only recognized legal standard in twenty-two countries; these having a total population of two hundred and forty-two millions.

A London firm which had been a successful exhibitor at the recent Calcutta Exhibition, has just received from the Superintendent of the Juries a photograph of the gold medal awarded to it, with an intimation that on receipt of £10 10s. (the price of the said medal), it will be forwarded. Or if the firm does not care to pay for a gold medal, it can have a silver one at a very much lower figure. To thus let exhibitors at international exhibitions pay their money and take their choice in the matter of awards is a decidedly novel proceeding, and it is not surprising that the firm in question declines to pay for the gold medal "awarded" to them, and mean to make the photographic reproduction do. They will be content, in fact, with the "look of the thing."

Dr. Vogel's proposal to use coloured glasses in conjunction with eosine plates for the reproduction of such coloured objects as paintings, is one capable of extensive application. Major Waterhouse, however, suggests that it may be better to illuminate the subject with coloured light. He says:—"Coloured glasses seem fatal to sharpness. A better plan would be, I expect, to throw a beam of *coloured light* on to the picture with a lime light or electric lamp. Some years ago I tried throwing a blue light on to a yellow object, and got a very good image of it. In this case the blue light was obtained by allowing the sunlight to pass through a piece of blue glass arranged so as to throw a blue tint on the object."

Many persons have, to themselves, satisfactorily explained the why and the wherefore of the special excellence which characterises Mr. H. P. Robinson's pictorial work with the camera; and they talk of expensive lenses, convenience for manipulation, well-trained models, and so forth. The real secret, however, lies deeper, and is to be found in the fact that holiday and work mean the same in Mr. Robinson's vocabulary. He has recently been labouring and recreating in North Wales; and we may hope that some of the results will form an attractive part of the next exhibition in Pall Mall.

A well-known caricaturist has just completed two companion portraits of the same individual, with the significant subscriptions in either case: "Before my visit to the Healtherics," and "After my Visit." The two subjects would make a good photographic study, for there is no doubt that only the most robust visitors to the new South Kensington show can taste with impunity all those samples of cake, custard, curds, candy, coffee, cocoa, and confectionery, which are so energetically pressed upon him by the various stall-keepers. "C-sickness," as it might reasonably be called, is well nigh sure to follow.

The term "optical sensitizers," as applied to colouring matters added to the films, can hardly be considered a very happy one, and Captain Abney protests against it; we fancy, however, that he will hardly object to "optical de-sensitizers."

Contrary as the two names may appear, they amount to about the same thing in actual practice; and the photographer who merely wishes to obtain a good negative from a painting, will not care much whether he exalts the sensitiveness of the plate for the yellow rays, or makes it less impressionable by the blue. The whole question is one of importance, as there is a demand for phototype blocks made directly from the work of the artist-painter.

The idea of adding such a physical sensitizer as the phosphorescent sulphide of calcium to an emulsion, is due to Mr. A. L. Henderson; and notwithstanding the chemical difficulties of the case, we have obtained results which indicate that physical sensitizers will some day become of practical importance.

It must not be said that the Government does not assist photographic research—occasionally. Mr. Gill, the Cape astronomer, was able to announce at the last meeting of the Astronomical Society that the Admiralty had promised him the necessary assistance to enable him to carry out his project of a photographic map of the heavens as regards the southern hemisphere.

Miss Mary Anderson has the satisfaction of knowing that a recent portrait taken of her is one of the largest of the stock sizes. It is called the "Heroic" size, and we shall soon no doubt get to "colossal," and have to be taken in instalments. The members of the Photographic Club of the future may, in fact, have to take in their portraits in parts, whilst the modest album of the past will have to be replaced by a photographic gallery.

But it is to be hoped that "cabinets" and other portable sizes will not generally go out in favour of the "heroic" and "colossals." Should popular taste, generally, follow the lead of "La Belle Americaine," giving away one's photograph will become a most elaborate process, demanding the intervention of a furniture van at the very least. And to receive one of these "photographs of the future" will be as awkward to most people as the receipt of a white elephant or a full-sized billiard table is now found to be. Few, in fact, will care to undertake the responsibility of receiving a friend's likeness, when its receipt involves running up a special wall on which to place it.

The sun acts as a clock-winder in Brussels. A shaft exposed to the solar rays causes an up-draught, and this draught sets a fan in motion; the fan of course winds up the weight of the clock, but when the weight is near the top, it puts a brake on the fan. The clock has now run for nearly twelve months.

According to an American paper, the latest phase of the business in the States is the photographing of cats. Babies have to a great extent gone out, and kittens are "in."

The tariff for "Pussy's" portraits is just double that charged for "human's," the reason being probably because a "cat-astrophe" of some kind is twice as likely when felines are focussed.

5373. HERBERT JOHN HADDAN, of the Firm of Herbert and Company, Solicitors of Patents, of 67, Strand, in the City of Westminster, Civil Engineer, "A new or improved method of and apparatus for controlling an engraving, cutting, or impression tool or instrument, according to the varying conditions of a given pattern or picture."—A communication to me from abroad by The Bain Electric Company, of Chicago, Illinois, United States of America.

This invention consists in controlling an engraving, cutting, or impression tool or instrument, by means of light or heat rays so that the operations of said tool correspond to the varying conditions of a pattern from which said rays are passed, and all parts of which are successively subjected to said rays. In carrying the invention into practical effect, I use a pattern (a photographic negative or positive, or any polished or transparent or translucent plate or sheet having upon it a pattern formed by lines or shades) which will, to a greater or less extent, obstruct the transmission or reflection of rays of light or heat from a flame, or heated or luminous body. In passing the rays to or through said pattern plate, I prefer to use a lens that will focus said rays upon the plate, and to then pass the latter back and forth or otherwise move it so that every portion will in succession be subjected to the rays. It will be obvious that if the rays passed thus from a pattern plate of varying opacity are thrown upon a substance or device which will respond to the varying intensities of the rays, the latter may be made the means of effecting the adjustment of a cutting tool traversing the surface of, or traversed by, the object to be cut, in unison with the movement of the pattern plate. Different appliances, depending upon the character of the work to be performed, are used in carrying out this mode of operation. In producing *intaglio* or relief, a burr or drill, or milling tool may be used—for engraving, a gouge, chisel, or cutting tool is employed; in any case, the tool traverses the object to be cut, or the latter moves beneath the tool, in harmony with the movement of the pattern plate, and the position of the tool, determining the depth or character of the cut, is regulated by the intensity or quantity or radiant energy of heat or light rays passing from the traversing pattern. In the drawing is illustrated an apparatus for automatic engraving in which a case, closed except at one point, where an opening permits the passage of rays of light or heat emanating from a source focussed upon a pattern plate (in this case a photographic negative or positive) by means of a lens. The rays passing through the pattern plate are received upon a block of selenium or a selenium cell, which forms part of an electric circuit, the resistance of which will, therefore, be proportioned to the amount of light or heat to which the cell is subjected. When a pattern plate is used adapted to reflect more or less light according to the design upon the plate, the radiant energy may emanate from any source, and be transmitted to the face of the plate, and reflected therefrom to the selinium or other circuit controlling medium, as indicated by dotted line. The circuit includes a battery and electro-magnet, the armature of the latter being pivoted and extended to form a lever, geared or connected with an arm carrying a graver. A spring capable of having its tension nicely regulated is arranged to lift the armature from the magnet. The plate to be engraved moves beneath the graver in unison with the pattern plate. As shown, both are upon a slide, which is reciprocated longitudinally, and moved laterally step by step, so that gradually all parts of the pattern plate are traversed by the rays, and all parts of the plate are carried beneath the graver. The slide may be caused to partake of any of the movements common to engraving machine slides or plate-holders, the means of providing such movements being too well known by those skilled in the art to need particular description. In the drawing for an example, however, I have illustrated one of the most primitive, the longitudinal reciprocation being produced by a crank or slotted rotating disk, and the lateral step by step motion by a screw rod having a ratchet, on one end connected to the slide, and engaging with a spring pawl on the bed or frame of the machine. As the strength of the current increases and decreases with the intensity of the rays received upon the selenium cell, there is a corresponding variation in the power of the electro-magnet, and the armature thereof is subjected to a varying force tending to draw it to the magnet against the power of the spring, so that the graver is withdrawn from, and carried towards, the plate according as the heat or light rays are less or more obstructed in their passage through the pattern plate. The depth of the cut is thus regulated and caused to correspond with the varying influence of the radiant energy, inasmuch as in proportion as the passage of the rays is interfered with by the varying character of the pattern, the strength of the current will be varied and will produce a corresponding variation in the adjustment of the tool. An equivalent of the selenium cell in some cases would be a thermo device, as a thermo pile generating its own current of greater or less intensity, or quantity, under the varying character of the rays, and controlling the operating magnet directly or indirectly as before described. Any desired means may be employed to secure a coincidence of movement of the pattern and the object to be operated on. These means will differ with the difference in the character of the work to be done. In some instances, the object operated on will be curved or cylindrical, and will revolve as the pattern slides; in other cases, while there is a unison and coincidence of motion, the degree of motion will differ, the duplicate in such case being proportionately larger or smaller than the pattern.

5464. ALBERT KEPLER, of Peckham, in the county of Surrey, ACHILLE MORIN DE PREMION, and ALFRED PIGEAU, of Lombard Street, in the City of London, "Improvements in the manner, method, or mode of preparing and producing coloured photographs, and in the arrangements and apparatus employed therefor."—*This invention received Provisional Protection only.*

In carrying our invention into practical use or effect, we take one or more ordinary photographic positive or positives, and place the same in the preparer, which may be a metallic box, chamber, or receptacle so arranged as to admit of being adjusted to, and maintained at, a uniform temperature without any great variation or loss of the heat, in which preparer we have previously placed a suitable quantity of the solution or compound hereinafter described; this solution or compound is kept at a uniform temperature of 90° Centigrade (say, 195° Fahr.), which is maintained for three hours, during which time it is allowed to act on the positive or positives, and at the expiration of this time it is allowed to cool and coagulate, and remain in that state for twelve hours. At the end of this time, the preparer is again heated in order to allow of the withdrawal of the said positive or positives. The solution, compound, or bath, hereinbefore spoken of, is composed of equal parts of clarified resin and essence or spirits of turpentine in about equal proportions, which are melted together and maintained at or in a liquid state, or that due to a temperature of 85° to 90° Centigrade—say 194° Fah; and this must be kept up whilst the positive or positives are in the bath for about twelve hours. On removing them from the preparer they will be found to have a thick layer or coating of the solution or compound adhering to them, from which it is necessary they should be freed. For this purpose we employ a dryer, consisting of a metallic trough or receptacle arranged with a jacket or casing into which steam, hot air, hot water, or other suitable and convenient means for heating, being adjusted to, and maintaining the required temperature, is or are allowed to pass, so as to maintain the same temperature as that in the preparer, namely, 90° Centigrade—say 195° Fahr. The positives are placed at the bottom of the dryer, which is, or may be, provided with a false bottom and a ready and convenient means for removing the positives, and the heat causes the solu

tion or compound to melt and run off from them to the bottom of the dryer, and when the solution or compound is fully liquid, and has passed off, the positives may be lifted out and suffered to drain for a few minutes without cooling, when the remaining solution or compound may be easily removed from the positive by the aid of a wash consisting of benzine applied by the aid of a sponge or wad, or in any other convenient or suitable manner. The positives are then laid on a perfectly clean surface for a period of a few minutes till dry, varying according to the dryness and temperature, when they will be found ready to be painted at the back with the desired artists' oil colours, each of which is laid on uniformly over the surface it is intended to occupy, without any regard to light or shade on such part, and in consequence of the materials used, and the manner of employing the same, the paper on which the positive has been printed permits the colours to penetrate into and amalgamate with it in such a manner as to render them indelible whilst retaining the brilliancy and durability of oil paintings, and they may be then cemented or mounted on a suitable surface or surfaces, and subjected to a strong pressure to render the adhesion complete. By preference we employ the best artists' oil colours, which may be either those contained in tubes, or we may take the dry colours and mix them as required.

Patents Granted in America.

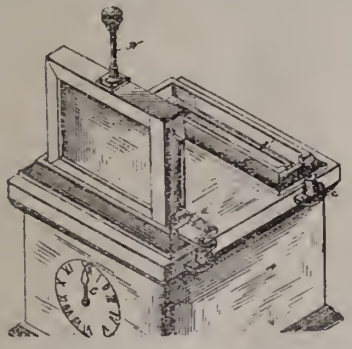
300,438. EDWIN L. BERGSTRESSER, Hublersburg, Pa., "Dry-plate holder."—Filed March 28, 1884. (No model.)

Claim.—1. A cabinet for containing plates, provided with mechanism which automatically registers each plate upon a dial as it is placed therein after exposure, substantially as set forth.

2. In a cabinet for holding plates, the combination, with mechanism for automatically registering each plate as it is inserted, of a pusher for moving the plates forward, substantially as set forth.

3. In a cabinet for holding plates, the combination, with a suitable dial having figures marked thereon, of a shaft carrying a ratchet-wheel, and an indicator, and a lever provided with means for operating said ratchet-wheel, as set forth.

4. In a cabinet for holding plates, the combination, with a suitable dial having figures marked thereon, of a shaft carrying an indicator, and ratchet-wheel, a spring-pressed pawl engaging



said ratchet-wheel, and a lever provided at its forward end with an arm to engage said ratchet-wheel, substantially as set forth.

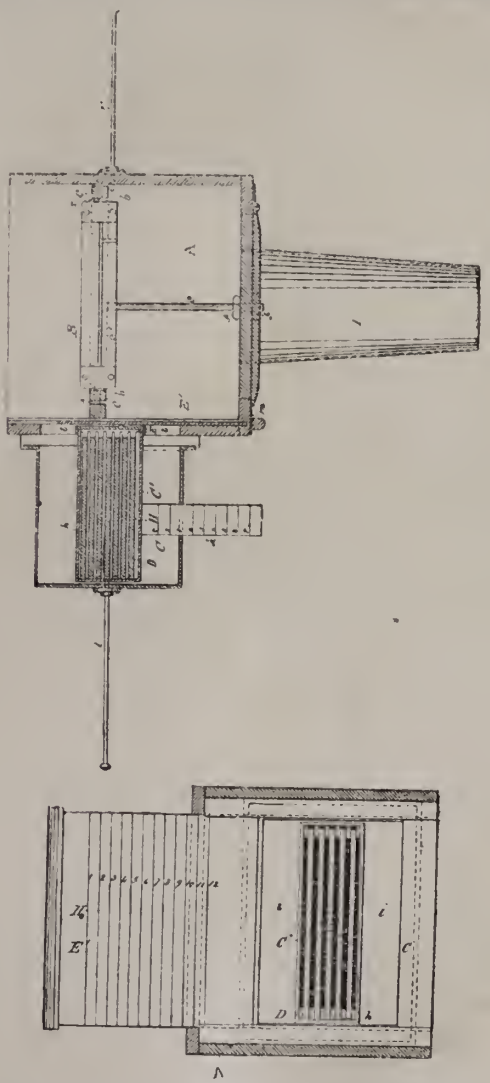
5. In a cabinet for holding plates, the combination, with a dial having figures marked thereon, of a shaft carrying a ratchet-wheel and indicator, and having bearing at its rear end in a bracket secured to a strip enclosing said ratchet-wheel, a spring-pressed pawl adapted to engage said ratchet-wheel, and a lever provided with an arm for actuating the same, substantially as set forth.

6. In a cabinet for holding plates, the combination, with a dial having figures marked thereon, of a shaft carrying a ratchet-wheel and indicator, a spring-pressed pawl adapted to engage said ratchet-wheel, a lever provided with an arm at its forward end for actuating said ratchet-wheel, a spring for retaining the same in position, said lever being provided at its forward end with an upwardly-projecting extension, and a coil-spring, located between the end of said lever and the floor, substantially as set forth.

300,477. HENRY G. JONES, Philadelphia, Pa., assignor of one-half to Henry S. Keller, same place, for "Photographic Camera." Filed April 1, 1884. (No model).

Claim.—1. The sliding plate E', having a scale, H, in combination with the camera-box A and sliding case C', provided with a handle, *k*, having a scale H', for regulating the adjustment of the case C', substantially as described.

2. The plate-rest B, having pivots *x*, and adjusting screw-rod *e*, provided with nuts *ff*, in combination with the camera-box A for regulating the position of said rest, substantially as described,



3. The combination of the adjustable strips *a* and *a'*, provided with arms *b*, with the side strips *c c*, of the plate-rest B, by means of pivots *b'* and pins *d*, for expanding or contracting said strips to receive plates D of different sizes, substantially as described.

300,478. HEINRICH KAYSER, Berlin, Germany. "Photographic Exchange-box." Filed April 9, 1884. (No model).

This invention has already been described and figured in the PHOTOGRAPHIC NEWS, present volume, page 331.

PHOTOGRAPHY AND THE NEWSPAPERS.

BY S. H. MORGAN.*

I THINK it was Charles Dickens who said of the newspaper-man, "He photographed everything, epitomized everything, was dead headed in this world, and expected to be in the next." This saying, though made twenty years ago, may be looked at in the light of propheey, for it has become literally true that in the illustrated newspaper photography, enters so largely that we can safely say that without photography the illustrated newspaper of to-day would be impossible. And this change has taken place within the past decade.

* A paper read before the Photographic Section of the American Institute at their last meeting.

It is told of the last of the Harper Bros., that when he was dying, he called his son to give him some advice in reference to the management of the business which was about to fall to his charge. Said he: "Above all things, take care of the *Weekly* (referring to the illustrated paper which bears their name); do not be tempted by new processes to deviate from the old and well-tried methods of engraving. If a rival does undertake to give the events of oue day in an illustrated form on the next, and you should come along like the old lumbering stage-coach one week later, remember that you put it on record,—you put it on record." The idea of recording current history carefully and accurately is the true duty of journalism. But I regret to say that the press, instead of educating the public up to a healthy standard, seek to pander more and more to the increasing demand for sensational and untruthful rubbish,—the result being our people's memories are ruined by over-much reading, aud when a paper publishes an illustration of an event a week after its occurrence, the public look upon it as a page of ancient history, and the same paper that would not allow a plate produced by photography to be used in its pages during the life of its founder, now uses them very largely.

To give you an idea of the varied uses of photography on a newspaper, we will classify the different kinds of illustrations. There are, first, portraits; second, landscapes—views of all kinds; third, news events; fourth, cartoons and the various ideal pictures; fifth, maps and mechanical drawiugs.

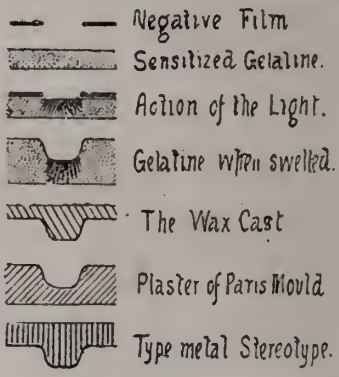
All portraits published are from photographs. The only exceptions I remember were those of the late A. T. Stewart and George Elliot. In all landscapes, where accuracy is required—as, for instance, where architecture is the prominent feature—photographic views are utilized; without photographic portraits, our moderu cartoon would be impossible. Then for news events, instead of sending an artist to sketch an event as formerly, the local photographer is telegraphed to attend to it. Here is the first aid of photography to bring the picture into the publication office. It is a messenger that brings the facts without coloring or exaggeration. Well would it be for the typographical side of the paper did they have such truthful reporters. But, then, though the photograph brings to the editor facts, the naked truth, as it were, they need some modification before publication; for instance, in the case of a man's portrait, if not a recent one, it must be altered to show his increased age. But it would be a dangerous proceeding on the part of any illustrated paper to take the same liberty with a female face, particularly if the possessor is a live woman. In the case of a picture with business in, as it is called, the particular object to be advertised must be brought out most prominent. The camera, as we all understand, does not show the partiality that the advertiser wishes; for instance, his two-story story must become a five-story one, with throngs of customers passing in and out, and loaded trucks at the curbstone; or, if it is a factory, it must extend a block or two further down the street, all the neighbouring buildings sinking into insignificance in comparison with it. I am afraid I am giving away too many trade secrets. I only mention these things in order that when you see "from a photograph," under a distorted illustration, you will understand that it is not due to any idiosyncracy on the part of the photographer. And here let me state something that may not be considered by those who expect the day is not far distant when we will publish all illustrations direct from the camera without the intervention of an artist or engraver, as many papers are now doing; and, by-the-bye, if there is any glory attached to the matter, I claim here that your worthy President, Mr. Newtou, made the first negative, and I attended to the remainder of the process of producing the first illustration direct from nature in a daily newspaper without the intervention of artist or engraver.

I have many examples of such a process as is now used in the illustrated press of to-day, and the difficulty to its more general adoption will be found in the fact that very rarely will a subject be photographed with the composition, arrangement, light and shade, of a quality possessing sufficient "spirit" for publication in *facsimile*.

At present, all photographs are altered to a greater or less extent before presentation in the newspaper. This is done after the subject is photographed the second time. We have seen how photography brings the matter to the editor's hands. Now we come to the second use of photography. The photograph is now either photographed on wood, or an untoned photographic print is made on plain paper. On this latter an artist traces the design with a pen and india ink, and here the alterations are made; if a view, the artist introduces figures, alters the light and shade, and sometimes changes the composition. When he has obtained all the assistance he requires from the photograph, he bleaches it away by pouring over the photographic print, on which is his india-ink drawing, a solution of bichloride of mercury in alcohol. This leaves his drawing on perfectly white paper.

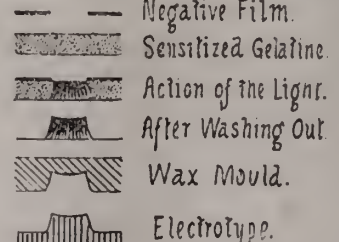
Now, in case of the photograph on the wood, the addition of figures and the other changes I have spoken of are made over the photograph-covered wood block before it passes to the engravers, where it is changed still more. In the case of a wood engraving photography is used but twice, ending with the placing of the subject on the wood; so we will dismiss it. But with the india-ink drawing on paper, photography must again be used to produce a printing block. The various processes for accomplishing this are innumerable, but they can be classed under three heads—First, what is called the etching method; second, the photo-relief plate method; third, the photo-electrotype. Of the three, each has its advantages. The first, or the "etching method," gives a plate of zinc usually, in which the whitest or hollow portions of the plate have been dissolved by an acid; the second or photo-relief plate method produces a printing plate in stereotype metal; and the third yields an electrotype. All three depend on the rendering insoluble of gelatine or albumen when in combination with a bichromate either of potash or ammonia when it is exposed to light. The peculiarities of the resulting plate I will state briefly. The zinc etching method produces the most artistic result, but it is not sufficiently mechanical in its manufacture to ever be much used here. It necessitates the personal attention of a man with artistic judgment throughout the whole process of the etching. In Europe, where artistic labour is poorly paid, they can afford to work this process successfully.

I will illustrate the differeuce between the three processes for newspaper work by diagrams on the blackboard, showing a



sectiou of a line, and the steps taken in each process towards its production.

The above shows the several stages in the photo-relief method. First the negative film is brought in contact with the sensitized gelatine, when the latter is exposed to light, after which the gelatine, which has been so exposed, is placed in a tray of water;



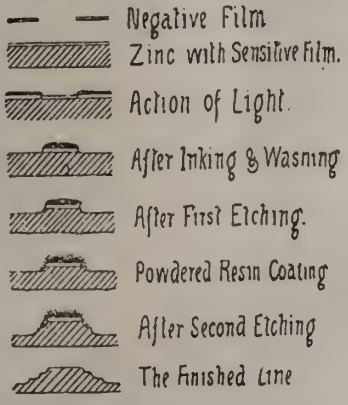
The portions unhardened swell, then a cast is taken in a waxy composition, from which is made a plaster of Paris mould in which to cast the type-metal stereotype, the peculiarity of the resulting line being that the corners of the line are slightly rounded. For book and magazine printing, where the press cylinder turns perfectly true, and time can be given to the process of overlaying, in the hands of an artistic printer this line with the rounded face can be taken advantage of to produce

a light or heavy line according to the pressure of the paper on it during the operation of printing.

With the photo-electrotype line which is produced by the action of light on a sheet of sensitized gelatine, as in the photo-relief process, the unhardened gelatine is washed out with a soft brush and a tepid solution, leaving the portions acted on by light in relief. From this an electrotype is made in the usual way.

The face of the line produced by this process is the reverse of the photo-relief line—that is, it is concave where the other is convex, the corners being sharp and highest where the wear is greatest. This makes the most serviceable plate for newspaper work, giving a square honest line at each impression.

The above diagrams illustrate the various steps of the zinc-etching process. A plate of zinc is coated with a film of albumen sensitized with bichromate of ammonia. After the exposure to light, the plate is rolled with a fatty ink, then the unhardened albumen film is washed away, leaving the ink only on the lines,



protecting them from the action of the acid in which the zinc plate is immersed. After a slight etching, the plate is removed from the acid and dried, then powdered dragon's-blood is brushed against the sides of the line. The zinc plate is heated, the powdered dragon's-blood combines and forms a resinous coating, which protects the sides of the line from the further action of the acid. This process of drying, dusting with the powder, heating, and etching is repeated many times till the requisite relief is obtained, the finishing line showing, as in the diagram, a series of steps down the side corresponding to the number of etchings.

The finest illustrated newspaper in the world prefers the plate produced by this process, but, as stated, it cannot compete in this country with its more mechanical rivals.

Correspondence.

WANTED, A PRINTING PROCESS FOR INDIA.

Sir,—I see a brother amateur away in Gaubati, Assam, whose letter appears in your issue of the 25th ult., is desirous of being informed of a "simple process" which will enable him to take a few prints off his negatives without much trouble. As he says he has tried most of the known processes, but has found them all unsatisfactory, I am afraid his wishes cannot be gratified, for there is not a single process expected to produce good results that does not give some sort of trouble to the manipulator. Of the three processes he has named, the silver works the best in India, and I would advise "Assam" to cling to it.

With regard to the "messy" part of this process, a great part of it can be removed by following the plan I have recently adopted. I use ready-sensitized paper from England, which keeps good for four or five months after its arrival. It turns yellow after the fifth month, but the small quantity which I import from time to time is used up before it becomes really unfit for good work. I find it does very well in a climate like Tavoy, and I am sure Gaubati is not a worse place.

For the benefit of "Assam," allow me to make a few suggestions. Let him send for half a quire at a time of paper, and let him keep this carefully excluded from light and damp air in a tin tube.

For travelling, the following are required:—

2 wooden trays* large enough to wash prints in.
1 porcelain dish, 10 by 8, for toning.
1 porcelain dish for receiving toned prints.
1 porcelain dish, 10 by 8, for fixing.
1 porcelain dish, 10 by 8, for receiving fixed prints.
1 large wooden tray to wash fixed prints in.
1 2-ounce stoppered bottle containing 15 grains gold, dissolved in 15 drachms of water or alcohol.
1 small bottle containing ½-ounce soda bicarb.
1 wide-mouthed bottle containing 6 pounds hyposulphite of soda.
1 small box of scales and weights.
2 8-ounce glass measures: one for measuring water for the fixing bath, and the other for the toning.
1 1-ounce measure (8 drs.)
A few printing-frames of the required sizes, and a few empty brandy-bottles.

All these, with the exception of the wooden trays, which must be packed separately, will go into a box or leather trunk not too large for a man to carry. In his tent, let him set apart a small portion, made dark by means of blankets. This to be used for changing the paper in the frame. The paper should be cut up to the required sizes the previous night, and placed flat between the leaves of a book. Print during the day, and tone and fix in the cool of the evening, after the sun has set, by candle light. The toning bath may be made up just before beginning to wash the prints, by taking 3 grains soda bicarb., 1 drachm gold solution, and 8 or 10 ounces water. This bath tones very fast, and great care should be taken that the prints are moved about continually. The fixing solution should be made up during the day before he commences to print. The paper is to undergo four thorough washings. By following these few suggestions, I am sure "Assam" will get on first-rate.

Asking your pardon for taking up so much of your valuable space, I remain, yours faithfully, A. W. Lonsdale.

Tavoy, Br. Burma, 26th May, 1884.

PACKING PLATES WHEN TRAVELLING.

Sir,—A good way to store plates which have been exposed, during travel, is to lay between them slips of clean paper of the exact size of the glasses, but about a quarter of an inch longer.

The excess quarter inch should be folded over twice, one-eighth of an inch, and the double thickness of paper thus formed at the edge will be found sufficient to prevent the glasses or films from rubbing together.

Moderately stout, smooth note paper will suit, and if the paper is cut half an inch longer than the plates, and folded at both ends, the protection is more perfect.—Yours faithfully, J. C. Hannyngton.

GELATINO-CHLORIDE PAPER.

Dear Sir,—Will you allow me through the columns of the News to call the attention of manufacturers to a quotation from an address delivered at the Liverpool Amateur Association in February last by Dr. Kenyon on the subject of the heading of this letter. The portion of the paragraph to which I allude runs thus:—"And I venture to hope that through gelatino-chloride emulsion, we may come to a perfect paper process, one which will give the perfection of a glass transparency on paper free from the loss of detail and finish sustained in the toning and fixing of ordinary paper prints. This, it occurs to me, might surely be attained by some such process as by coating enamel paper with gelatino-chloride."

* These are red circular trays sold in the bazaars in almost all the large towns of Burma. If "Assam" has a friend in Akyab or Rangoon, he can get him to buy him a few at Re 1/4 or 1/8 each.

My object in writing also includes the hope of again drawing to the subject the attention of such influential workers as Dr. Kenyon, Rev. H. J. Palmer, and others whose names are familiar to us in the NEWS as pioneers in photography, with a view of inducing them to use their influence (by the introduction of the subject at their societies, or by the use of their pens in the journals) in urging manufacturers to the production of an article the desirability for which has been alluded to in the NEWS in your article on gelatino-bromide paper, 11th January, 1884.—I am, dear sir, yours faithfully,

G. F. WEBBER, jun.

Proceedings of Societies.

London and Provincial Photographic Association.

The annual meeting of this Society was held on Thursday, the 26th ult., Mr. W. M. ASHMAN in the chair.

Mr. F. W. HART exhibited a quarter-plate developing kit, suitable for travellers, consisting of a case for chemicals, two celluloid trays, three zinc trays, draining stand, and washing trough fitted with adjustable syphon. The total size when packed was 6 by 4½ and 3 inches.

The subject of diffraction was then introduced, and a discussion ensued, several members taking part.

Mr. W. B. B. WELLINGTON directed attention to a peculiar opalescent appearance in certain portions of a sample of sheet gelatine, the markings not being discernible until the gelatine had been soaked for some time in water. He thought it probable that the substance which caused the gelatine to appear opalescent might prove to be one of the causes of green fog.

Mr. A. L. HENDERSON related a curious experience of a friend, who invariably obtained green fog when he added strong liquid ammonia to his emulsions; but not so when he reduced it with water, the amount of ammonia being the same.

The technical business being disposed of,

The SECRETARY read his annual report. The following is an abstract. The past year has been one of progress financially, and in actively maintaining the objects of the Association, the balance in hand proving that the experiment of fixing the qualification at a low rate has lead to a successful result. The characteristic feature during the past year has been the series of lectures given by members on subjects of photographic interest. Many demonstrations have been given, and discussions taken place weekly. Donations of photographic and other scientific literature have been made, also some apparatus. While it is an agreeable duty to recount the gains of the Association during the past year, on the other hand the contemplation of a loss in the death of a distinguished and valued member, Mr. H. B. Pritchard, caused profound sorrow among the members, creating a loss in the photographic profession sensibly felt and not easily supplied. Distinguished for those abilities which secured for him the love and esteem of all with whom he was associated, it is only natural that his death should be referred to with no common feelings of regret. A letter of condolence was forwarded to Mrs. Pritchard, and duly acknowledged by her.

The Secretary further says, that members should not be content with merely paying their subscriptions; but they should take an active interest in the proceedings of the Society.

Forty-four members have been elected during the past year, making a total of one hundred and twenty.

The report and balance sheet was adopted, and a vote of thanks passed to the auditors Messrs. Cowan and Mackie.

Mr. HADDON (Curator) read a report embodying a resumé of the lectures and general work of the Society (see page 422).

Upon motion, a vote of thanks was passed to the officers *en block*, for the services rendered during their year of office.

The following gentlemen were then elected officers for the ensuing year:—

Trustees—Messrs. W. K. Burton and W. Cobb.
Curator—Mr. A. Haddon.
Treasurer—Mr. W. H. Prestwich.
Secretary—Mr. J. J. Briginshaw.

Rule 7 was slightly modified, so far as concerns the date of subscription becoming due.

Liverpool Amateur Photographic Association.

The monthly meeting of this Association was held on Thursday, the 26th ultimo, Dr. KENYON, President, in the chair.

The minutes of the May meeting were read and confirmed, and Messrs. Barker, Evans, Hartley, Hughes, and Moore, were elected members of the Association.

The Rev. H. J. PALMER proposed, and Mr. A. W. BEER seconded, a resolution that the Shrewsbury excursion to Condover, Acton Burnell, Pitchford, and Buildwas Abbey be held on Thursday, July 17th, in lieu of the excursion to Churchtown, and this was carried unanimously.

The Rev. H. J. PALMER read a paper descriptive of a recent visit to Hawarden, and exhibited a number of specimens of his work there, including some fine portraits of the Premier.

Mr. R. CROWE described a number of exhibits sent by Mr. Atkinson, of Liverpool, including some bottles of corrugated metal for the safe carriage of concentrated developing solutions, Samuel's very ingenious changing-box slide, a camera fitted internally with Kirkby's shutter, and Blair's tourograph. The last exhibit excited much interest from its many novel and ingenious features. Mr. Crowe pointed out many of its advantages over other cameras, and especially its lightness and strength, the capital arrangement for the rising front and swing back, and the exceedingly clever double dark slide.

The CHAIRMAN announced the donation to the Society of fifteen 10 by 8 prints, by Mr. Beer; three numbers of *Photography* from the Editor in Chicago; and one number of the *New York Photographic Times*, from the editor.

Mr. H. SIMPSON described a cheap and compact camera and case combined, invented by himself. The case consists of a box of quarter-inch baywood covered with American cloth, and measures 12 by 7 by 10 outside. The side is hinged to the body of the case at the bottom. The camera bellows are fastened to the centre case. To use the camera, the side is unfastened and laid down at right angles to the case. The bellows and rising front are drawn out and kept perfectly rigid by wire supports, as used in the scenograph. These supports are strongly hinged one-quarter of an inch inside the case, and when closed up, fold over the camera front. The side is hinged on the top, and a bag and frame is drawn out of the box. The bag is preferable to a bellows in this instance, as the former may be fastened within one inch of the edge of the case, thus leaving two inches of clear space inside between the end of the bag and the camera bellows. The frame is supported in the same way as the camera front. The plate is placed in an arrangement of metal gimbals held in position by brass screws and slides, thus giving the effect of a double-swing back. The gimbals are carried in a metal frame, which works in the two inches of space referred to, and is moved backwards and forwards by a rack-and-pinion motion. The pinion passes through the top of the inside of the camera, and through a packing-box at one end, where it is turned by means of a small stock key.

Messrs. Beer and Riley exhibited prints of negatives taken during the last excursion to Rivington Pike; Mr. Cornish, some views in Devonshire; Mr. Plympton, pictures in Hereford and Gloucester; and Mr. Crowe some instantaneous pictures taken with Kirkby's shutter.

After votes of thanks to the Rev. H. J. Palmer, Mr. Crowe, Mr. Simpson, and the other exhibitors, the meeting adjourned.

Edinburgh Photographic Society.

The eighth meeting of this session was held in 5, St. Andrew Square, on Wednesday evening, 4th inst., Mr. W. NEILSON presiding.

The minutes of the last meeting having been approved, Messrs. John K. Dawson, Alex. B. Dawson, and Richard Kerr Miller, C. E., were elected ordinary members.

A lengthy discussion took place on the new edition of the rules, proofs of which were submitted at last meeting by the Council. It having been agreed at last meeting to term them "laws," they were read *seriatim* and very fully discussed, Messrs. Forgan, A. B. Stewart, Forbes, and Craig Christie taking prominent parts.

Dr. HUNTER read a paper illustrated by upwards of ninety calotype prints, few being less than twelve by fifteen (see page 422). These were examined with very great interest, and a cordial vote of thanks to Dr. Hunter was passed by acclamation.

Mr. NORMAN MACBETH, R.S.A., brought before the notice of the members the importance and desirableness of making the

study of the picturesque more an object of this Society, and for its encouragement in this direction, handed for inspection the work which was awarded the first prize of the South London Photographic Society last year. That Society have instituted as one of their principal aims in their proceedings, the setting apart each month the best production then submitted for competition—without names of parties concerned, but having a title or motto attached to each work. These again at the close of the session are submitted to a competent judge (unknown to the members, or at least not having seen the works before), who adjudicates, and assigns the best.

Leeds Photographic Society.

The usual monthly meeting was held on Thursday, June 5th, Mr. W. Teasdale, F.R.M.S., in the chair.

Prof. Rucker, F.R.S., delivered a lecture upon lenses.

Prof. Rucker said: The ideal lens would so deflect the rays that fall upon it from any single point, that, after passing through it, they would meet in a second point, which would thus form the image of the first. In real lenses this condition is not fulfilled, for two reasons. In the first place, convenience dictates that the surfaces of lenses must in general be either plain or spherical, and rays of light which diverge from a single point cannot, by passage through a lens bounded by such surfaces, be made to converge to a single point. Hence a defect arises, which, since it depends on the spherical form of the surface of the lens, is called spherical aberration. In the second place, each ray of white light is broken up into its constituent colours, and to the separation of these is due (among other effects) that the position in which the best optical image is formed is not necessarily that in which the clearest photographic picture will be obtained.

In the lecture, the principal methods of diminishing these defects were briefly discussed. Spherical aberration may be minimized for objects at a given distance by giving the lens a suitable form, but the correction will be less perfect for other distances. The distance from the lens at which the image is formed is also dependent on the distance of the objects. A lens in which this defect is marked fails to form a clear picture of objects which are not all at the same distance from it. The blurring due to this is diminished by reducing the size of the pencils of light which pass through the lens by means of a stop. This, however, is attended with the disadvantage that the amount of light which falls on the plate is reduced, and therefore also the quickness of the lens is diminished. If the stop be placed close to the lens the rays which pass through it at different angles are brought to a focus at different distances, so that either the centre or the edges of the field are indistinct. In this case the field is said to want flatness. By moving the stop away from the lens, rays parallel to the axis pass through the centre, while those inclined to the axis are transmitted by parts nearer to the circumference of the lens. The fact that the focal length is different for the central and circumferential parts is thus utilized to diminish curvature of the field. This remedy, however, tends to produce distorted pictures, but the nature of the distortion is different according to whether the stop is in front of, or behind, the lens. By placing it between two lenses, opposite distortions may be made to neutralize each other. The use of too widely separated lenses is attended with the drawback that the quickness and angle are diminished. Finally, chromatic aberration, or the breaking up of white light into its constituent colours, has to be avoided, and this may be done by the use of achromatic lenses, the various parts of which are formed of different kinds of glass.

The principal faults referred to may be thus summed up. A small stop increases the depth, but diminishes the quickness of the lens. Moving the stop from the lens diminishes the curvature of the field, but increases the distortion, and reduces the field of view. A large aperture increases the quickness, a large focal length diminishes it, the time of exposure being inversely proportionate to the square of the diameter of the opening, and directly proportionate to the square of the focal length.

The principles above enunciated were illustrated by the case of a combined objective for landscape and portrait work.

Messrs. Pearson, Warburton, Reffell, Bransom, and others took part in the discussion.

North Staffordshire Amateur Photographic Association.

The ordinary monthly meeting was held on Monday evening, June 30th, at the Mechanics' Institute, Hanley, Mr. C. Alfieri occupying the chair.

The Secretary presented his financial report for the past six months, showing a balance in hand of £1 7s. 9d. This was adopted, and, the minutes of the last meeting having been read and confirmed,

On the motion of Dr. Griffiths it was resolved that an excursion to Alton Towers and Croxton Abbey be made on Saturday, July 5th, the party to meet at Stoke Station at 2 p.m., and proceed thence per rail to Alton.

The Chairman cautioned the more inexperienced of the members against over-exposing their plates, he having found the light in the Derbyshire district last week very actinic, one second's exposure having spoilt a plate devoted to Haddon Hall.

Mr. Allison passed round some fine platinotype prints from negatives of groups of ferns.

After some conversation upon various topics photographically interesting, the meeting terminated.

Talk in the Studio.

Major Waterhouse's Photo-mechanical Processes.—An exceptionally fine series of collotypic pictures illustrative of Indian art at the Calcutta Exhibition, have been sent to us by Major Waterhouse. Excellent specimens of heliogravure are also forwarded by Major Waterhouse, and although the general character of the latter is remarkably similar to the collotype, there is a boldness and vigour about the impression from the *intaglio* plate which one seldom sees in the collotype.

Ready Sensitized Paper Made by Mr. Valentine Blanchard.—Some paper which Mr. Blanchard sends us proves exceptionally sensitive, and tones very well in a chloride of lime bath. There can be but little doubt that the use of ready-sensitized paper is becoming more general, and many fail with it because they cannot be brought to see the importance of keeping it in a cool place, and where the atmosphere is uncontaminated with sulphur compounds conditions; which are generally practicable if a little care be exercised.

The Book Trade Exhibition in Leipzig.—This Exhibition has been notable for the great prominence it gave to artistic matters as bearing on the publishing trade, and the catalogue of the Exhibition will form a permanent memorial of many interesting features of the Exhibition, as it contains numerous illustrations of photo-mechanical processes.

The International Exhibition at Turin.—A correspondent who has just come from theExhibition writes:—"For several hours I wandered about without finding anything whatever of photographic interest, but at last I made enquiries of an attendant, who took me to the place. There was fairly good every-day photographic work, and there were some good portrait enlargements, but nothing very noteworthy. The apparatus seemed to be well made, but presented no points of novelty worth specially mentioning."

Trichlorpyrogallic Acid.—Indications of the existence of the above-mentioned body, and also of the corresponding bromine derivative, were obtained by Stenhouse and Groves some years ago; and quite recently Mr. C. S. E. Webster has carried on investigations in the same direction. To prepare the chlorine compound, the following method is now adopted:—To 5 grams pyrogallol in a large test-tube, 12·5 c.c. of strong acetic acid (60 per cent.) are added, a quantity insufficient for its solution. The test-tube is kept cool by being surrounded with water, and a rapid current of dry chlorine is passed through the liquid. Volumes of hydrochloric acid are then evolved, the colour changes to a deep reddish-brown, and in about half an hour the liquid, which is saturated with chlorine, coagulates to a semi-solid mass of fine needles of the new compound. These are well drained from the mother-liquor, washed with acetic acid of sp. gr. 1·04, in which they are only slightly soluble, and recrystallised with the usual precautions, from one of its several solvents. Trichloropyrogallic acid is only slightly soluble in cold water, but dissolves in its own weight of boiling water, recrystallising on cooling in fine white needles. By prolonged contact with water it is decomposed. It is freely soluble in alcohol and in ether in the cold. In acetic acid, benzene, chloroform, carbon disulphide, and carbon tetrachloride, it is only slightly soluble in the cold, soluble in boiling. It dissolves in boiling hydrochloric acid, and recrystallizes on cooling in transparent needles. On adding a solution of barium hydrate to its ethereal solution, a deep blue colouration is obtained. With solution of sodium

sulphite it gives a red coloration, which is fugitive. It is decomposed by concentrated nitric acid with evolution of nitrous fumes. The bromine compound is obtained by the direct action of bromine on tannin, and it is very similar in its general character to the chlorine derivative.

PHOTOGRAPHIC CLUB.—At the next meeting, on July 9th, the subject for discussion will be "On Focussing." On Saturday afternoon, out-door meeting at Kew Gardens, west end of Lake, and afterwards at hotel, on Green, near Bridge.

To Correspondents.

*** We cannot undertake to return rejected communications.

C. Q. N.—In the case of a gelatine emulsion, all you have to do is to add about twice its volume of alcohol (methylated will answer), and to well compress the curdy precipitate in a cloth.

JOHN THOMPSON.—If a reflector is placed in front of the objective, a reversed negative will be obtained; but ordinary looking-glass will not answer, as a portion of the light would be reflected from the outer surface of the glass, but the greater part from the metallic layer. Confusion of the image would consequently result. In order to obtain a suitable mirror, silver is deposited by the so-called chemical process upon a piece of accurately surfaced glass, and the outside of this silver is carefully polished by means of a soft leather and rouge. Of course, such a reflector is liable to become tarnished: and when a reversed negative is only occasionally required, many persons prefer to use a reflecting prism in front of the objective.

DASWIR.—1. The pictures are extremely good; indeed, we have seldom seen better instantaneous photographs. 2. We have written to you.

V. D.—Imperfect fixation. Either you do not leave them a sufficient time in the hyposulphite bath, or else you use the solution when it is quite freshly made, and consequently colder than the surrounding atmosphere.

E. J. RUSSELL.—It appears rather to be a matter for litigation between yourself and the party mentioned, than for our interference. Still, we shall be pleased to help in any way if possible.

Capt. S——.—We have sent a number containing very nearly what you require, but we intend to insert an article on the subject in the course of a few weeks.

PHOTO.—In each case a mixture of stiff starch paste and lamp-black is one of the best materials to use. Apply it with a soft sponge.

WET PAINT.—It has nothing to do with the nature of the paper upon which you work, and the only way is to obtain your colour and materials from another source; or perhaps you have used some non-drying oil in mixing.

JAMES HANSON.—Information as to the best methods of colouring at the back of the print is to be found on pages 611 and 740 of our last volume; but such pictures have very seldom a high artistic value. 2. Details as to photographing on canvas will be found in Pritchard's "Studios of Europe," which is published at our office, price 2s.

MABEL.—Mr. Pancoast's shutter is not made commercially as far as we know, but any skilled mechanic could construct it for you. 2. Doubtless they can be obtained from the makers of the apparatus, Messrs. Marion and Co., of 22, Soho Square, W.

X.—1. We think nothing is so reliable and practically useful as glass, and we should not think of using anything else ourselves, even if about to undertake such work as you propose. 2. The ordinary gelatino-bromide process will give you less trouble than any other; but unless you have had experience, you should put yourself through a rigid course of schooling. If you have much leisure, you may do this by working alone; but if, on the other hand, you are pressed for time, it would be well to arrange for instruction under an experienced photographer.

PRINTER.—An article on the subject appeared on page 226 of the present volume. The principal causes are: first, the use of a very strong sensitizing bath in conjunction with highly albumenized paper; second, the employment of freshly albumenized paper; Third, sudden changes in temperature in working, as when a fixing bath which is abnormally cold from the recent dissolving of hyposulphite is used; fourth, transferring the prints from a very dense liquid to a very light one, and *vice versa*. This state of things can be obviated by adding common salt to the last rinsing water before fixing, and to the first washing water after fixing—about a handful to each two gallons of water.

GEORGE LEE.—1. The series is not yet finished, but when complete it is quite possible that it may be reproduced in book-form. 2. Several of the numbers are out of print.

SMITH AND B——.—We have forwarded your enclosure.

A. PETITT.—We do not keep such a list, but you may find what you require by referring to our advertisement columns.

W. G. HONEY.—The shutter has merits, but we do not think there is any point about it which would be worth your while to patent. The primary idea is old, and you can only claim some details of secondary importance.

G. C. C.—Such a change in colour is not uncommon when it is kept in a room where much gas is burned. No ready-sensitized paper will remain in good condition if exposed to an impure atmosphere.

OMEGA.—1. Our own experience is that Easter is a more favourable time for making a holiday tour in Holland, as during the hot months the stagnant water in some of the canals is occasionally very foul; and moreover we have found the atmosphere very much clearer in the early spring. 2. Duty will be charged on your apparatus, but not enough to make the impost burdensome. 3. There is so much of interest in all the towns you mention, that you would be unwise to omit any of them: and moreover they can all be visited in a few days. 4. We believe that there are no restrictions, and do not think you would be interfered with unless you made an obstruction. We shall have pleasure in giving you any other information in our power.

J. S.—See a letter by Mr. Hanyngton in our present issue.

F. STEWART.—There are several ways of transferring printed titles to the negatives, and in the case you refer to an impression is probably taken from the type on a piece of transparent gelatine, and this is grafted on the negative by cutting away the film and cementing the strip of gelatine down in the vacant space.

W. H. B.—We think it no longer exists, but cannot speak with absolute certainty.

SOLUBLE COTTON.—It is hardly reasonable to expect so old a sample to be in good condition, and you had better either prepare some yourself, or obtain it from a dealer.

The Photographic News Registry

Employment Wanted.

Mounter, Spotter, &c. (lady).—A. H., 12, Crogsland-rd., Chalk Farm-rd.
Emulsion Maker, expe.—I. X. L., 28, De Gray-st., Newcastle-on-Tyne.
Operator and Retoucher, good.—Artistic, 32, Twyford-st., Caledonian-rd.
Lady, to Tint, Spot, &c.—A. G., 5, Heaton-villas, Heaton-rd., Peckham.
Printer, &c., age 21.—H. O., 17, Market-hill, St. Austell, Cornwall.
Ret. & Col. (lady).—Miss Edwards, Conway-villa, Dunstan-rd., W'hampton.

Employment Offered.

Lady Artist, Opals & Paper.—Nigra, *Photo. News* Office.
Oper., clever with children.—A. McLeod, 29, Stockwell Street, Greenwich.
Operator & Retoucher, indoor.—Hills & Saunders, Cambridge.
Printer, to assist Operating & Retouching.—Dew, Jesson-st., Coventry.
Operator & Retoucher for W. Indies.—J. Haddon, 3, Bouverie-st., E.C.
Printer for West Indies.—J. Haddon, 3, Bouverie-st., E.C.
Operator, clever all-round.—H. Grant, 73, Newport-st., Swindon.
Operator, good at posing.—E. W., 36, Richmond-gardens, W. Kensington.
Gen. Assist. to print, tone, &c.—Mr. Villiers, Llandrindod Wells, Radnor.
Operator & Negative Retoucher, first-class.—F. G., *Photo. News* Office.
Printer, Toner, Vignetter.—C. D. Lavender, Tweedy-bldgs., Bromley, Kent.
Silver Printer & Toner.—W. W., 33, Tulse-hill, S.W.
Plate-Coaters, several.—21, Charles-st,, Royal-cres., Notting-hill.
Operator & Retoucher.—A. Pettit, Keswick, Cumberland.

Photographs Registered.

Messrs. VALENTINE & SONS (Dundee)—Photo. of Steamship "Austral."
Mr. W. MERRICK (26, Castle Street, Bristol)—Photo. of Mrs. Mary Slater.
Mr. LAMBERT WESTON (Dover)—Photo. of Yachts.
Mr. G. TAYLOR (Bishop Auckland)—2 Photos. of Sir George Elliott, Bart.
Mr. W. J. ANCKORN (Arbroath)—Photo. of Mortuary Chapel in Arbroath Cemetery.
Mr. E. WILLIAMS (Hawkhurst, Kent)—4 Photos. of "Leather Bottle" Inn, Cobham.
Mr. J. HUBERT (Mare Street, Hackney)—Photo. of Rev. Brook Picton.
Mr. A. H. HILL (Prestwood, Stourbridge)—2 Photos. of Tomb of the Earl of Stamford.

CONTENTS.

DIFFRACTION OF LIGHT: ITS BEARING ON THE USE OF VERY SMALL STOPS WITH LENSES.

THE subject of the effect produced by the use of very small stops has been discussed in our paper during the past few weeks, two correspondents having, in connection with it, afforded us valuable information. As the matter is one of interest to photographers in general, we think a few words on the phenomenon known as diffraction, which is what produces the disturbing element noticeable when very small stops are used, may be of use to our readers. We shall try to explain the matter in the most simple manner.

It is not generally known how nearly complete is the analogy, as regards manner of propagation, between light and sound. It is supposed that light passes always in straight lines, that sound may travel round any corner, and, as a matter of fact, we know that we may hear a sound distinctly when there is an obstacle between us and the source of the sound, whilst we cannot see a light when there is any opaque object between us and it. The matter as here represented is, however, not strictly correct. The apparent difference is due to the enormous difference between the wave-length of sound and the wave-length of light. As a matter of fact, an object lying between us and a source of sound casts a sound shadow which is, in proportion to the wave-lengths, as well-defined as the light shadow cast by an opaque body. On the other hand, the rays of light which pass nearest to the edge of a body which casts a shadow are bent into the shadow (and, in fact, in all directions at right angles to the boundary line of the body), preventing the edge of the shadow from being abrupt even when the rays reaching the shadowing object are parallel.

To prove this experimentally, we have but to place ourselves where the sun is shining in the shade of any well-defined object—a house will do quite well—and, gradually approaching the edge of the shadow, to keep our eyes fixed on the portion of the limits of the object where the sun will appear when we have moved out of the shade. Long before we get into the sunlight we will see the edge of the obstacle brilliantly lighted; in fact, some of the sun's rays have reached us coming "round the corner."

It is precisely this bending of the rays which produces want of definition when a very small stop is used. We suppose the case of any lens with a stop of, say, a quarter of an inch diameter, and for the sake of simplicity, suppose that we place it opposite the sun, so as to get an image on the ground glass. We will now have a certain amount of light passing through this aperture. All which does not pass close to the edge of the opening will pass on to be deflected by the lens to form an image, but that which passes close to the edge of the aperture will be dispersed in all directions. The greater part of it will be deflected only a little out of the straight line, but some small portion will be deflected through a very considerable angle. If we were to look at the stop from the very edge of the space for the ground glass we would see a bright fringe round that side of the stop which is nearest us, and from which, therefore, there cannot possibly be any reflection.

It will be seen so far that a certain amount of the light passing through the aperture of the stop has been scattered in all directions, causing, of course, more or less loss of definition—making, in fact, the boundary of the image of the sun less sharply defined than it otherwise would be. Whether or not the falling off of definition is sufficient to be practically discernible will depend on the proportion of the scattered rays to those which have not been changed in their course. The total amount of rays passing through an aperture varies as the aperture varies. The amount of light diffracted, scattered, or diffused, varies as the linear measurement of the boundary of the aperture. Now we know that the boundary of the apertures of stops are the circumferences of circles, which of course bear a constant ratio to their diameters, and that, moreover, the *areas* of the circles vary as the *square* of their diameters. Now from this it follows that as we decrease the diameter of our stops we decrease this area in a quicker ratio than we decrease the linear measurements of the boundaries of the stops; so that the smaller the stop the larger is the proportion of scattered rays to those which pass on in the direct course. It follows that we must certainly reach a point where the scattered rays will form so large a proportion of all which pass though the stop, that a practical falling off of definition *must* ensue. Indeed, if we go far enough, we may have the greater number of the rays scattered, and fail almost to get any image at all.

Lest this last paragraph be not clear to all, we shall revert to an actual case, taken any measurement. We have supposed already a stop quarter of an inch diameter. Let us now suppose this replaced by one half that diameter; that is to say, one-eighth of an inch. The area of this latter circle is one-quarter that of the former, so that only one quarter as much light will pass through it. The circumference of a circle one-eighth inch diameter is, however, *one-half* that of a circle one-quarter inch diameter, so that whereas with the smaller circle we have only a quarter as much light passing as with the larger, we have half as much light scattered by diffraction; that is to say, we have twice as large a proportion of the light scattered.

A certain proportion of the scattered light is practically annihilated by a phenomenon known as interference, which we have not space to discuss here. This gives rise to series of rings around any point of light, which may be focussed with a lens. As, however, the proportion of light neutralized by interference bears almost the same proportion for all apertures to the total amount of the scattered light, it is unnecessary to take it into consideration.

It will be seen, from what we have said, that the effect produced in the way of loss of definition by diffraction, when very small stops are used, depends on the diameter of the stop alone, and is entirely independent of the focal length of the lens.

It will be farther evident that the limit of smallness permissible, before reduction in size tends to cause definition to fall off, instead of increasing, will vary with the qualities of the lens. If the lens be an indifferent one, reduction in the size of the stop will continue to increase definition long after, in the case of a good instrument, definition would have commenced to decrease. There must, however, be in the case of every lens some diameter of aperture to decrease, which will be to *decrease* definition. This is a subject for some of our mathematicians to investigate. Meantime, we may say that in practical work we have sometimes imagined a falling off in definition in the case of a fine lens of sixteen inches focus, with a stop one-tenth of an inch in diameter. We do not care, however, to be positive in this matter.

PHOTOGRAPHING A PISTOL BALL AND SOUND WAVES.

THERE is nothing absolutely novel in the photographing of a cannon ball during its flight, but such an experiment is ordinarily regarded as a mere curiosity.

Professor E. Mach, of the Physical Laboratory in Prague, has recently secured some remarkable photographs of a bullet during its flight, and has also obtained camera representations of other extremely transitory phenomena.

No mechanical exposing apparatus of the drop or spring-shutter type was used, but the required instantaneous exposure was secured by illuminating the object with the light of the electric spark. The ball was fired in the direction of a battery of Leyden jars, and in such a manner that it itself made the contact which produced the electric discharge serving to illuminate the projectile. In this way a far shorter exposure was realized than one could hope to attain by any kind of mechanical shutter. Professor Mach's experiments were made in a darkened room, and the objective remained uncovered during the whole of the time, but of course the plate only received the luminous impression of the instant when the ball was illuminated by the electric discharge.

The negatives are extremely small and transparent; but with a magnifying glass it is easy to distinguish the clear and sharp image of the projectile.

Not only has Professor Mach photographed the bullet in its course, but also the air streams which one may see over a Bunsen burner when bright sunlight is allowed to play on it; and, what is more surprising still, he has actually secured camera representations of waves of sound, these last being made visible by Toepler's method, in which advantage is taken of the irregular refraction of light by the air set in vibration by sound. It is to be hoped that by taking advantage of the intense and instantaneous light of the electric discharge, many physical phenomena may be registered by the camera; and we shall look forward with interest for further details of Professor Mach's experiments.

WATERPROOF VARNISH FOR PAPER.

IN very many cases waterproof varnishes are useful, and among their uses may be mentioned their application to laboratory labels, and their use for the fixing of drawings.

There are many such varnishes, but, according to our own experience, one of the best is a thin solution of gutta-percha in benzole, and such a varnish may be made by dissolving one or two parts of fine gutta-percha foil in a hundred parts of benzole. The heat of a water bath serves to make the gutta-percha dissolve tolerably quickly, but if it is necessary to have the preparation at once, the gutta-percha may be dissolved in a little chloroform, and this is then mixed with the required bulk of benzole. Paper which has been coated with this varnish can be easily written, drawn, or painted upon; and it must be remembered that the gutta-percha varnish does not make the paper transparent or spotted. It is known that gutta-percha slowly oxidizes in the air, and becomes converted into a brittle resin; but this oxidation product is itself a waterproofing agent.

Alcoholic solutions of resins tend to make papers more or less transparent, but the following varnish, prepared with acetone, is not subject to this drawback.

One part of dammar is dissolved in six parts of acetone, the materials being allowed to digest together for some weeks: the clear liquid is now decanted off, and mixed with its own volume of plain collodion.

Another method of making a waterproof varnish for paper consists in digesting 30 parts of white shellac with 300 parts of ether, and then agitating the solution with 15 parts of finely-powdered white lead; on filtering the solution, it will be found that the white lead has been very effectual in clarifying the solution.

The above resinous varnish gives more lustre than the gutta-percha varnish, but the latter gives far more flexibility, a considerable advantage in many cases.

Not only silver prints, but also collotypes, and often photo-mechanical impressions, may often be advantageously treated with one of the above varnishes; and it must not be forgotten that anything which protects a silver print against damp serves to diminish the tendency to fading.

THE INTERNATIONAL CONVENTION FOR THE PROTECTION OF INDUSTRIAL PROPERTY.

THE Governments of Belgium, Brazil, Spain, France, Guatemala, Italy, Holland, Portugal, Salvador, Servia, and Switzerland, have constituted themselves into an Union for the Protection of Industrial Property, and it has been arranged that the subjects or citizens of each of the contracting States shall, in all the other States of the Union, as regards patents, industrial designs or models, trade marks and trade names, enjoy the advantages that their respective laws now grant, or shall hereafter grant, to their own subjects or citizens.

Consequently, they have the same protection, and the same legal remedy against any infringement of their rights, provided they observe the formalities and conditions imposed on subjects or citizens by the internal legislation of each State.

Subjects or citizens of States not forming part of the Union, but who are domiciled or have industrial or commercial establishments in the territory of any of the States of the Union, will be treated as subjects or citizens of the contracting States.

Any person who has duly applied for a patent or trade mark in one of the contracting States will enjoy, as regards registration in the other States, a right of priority during the periods of six months for patents, and three months for industrial designs. A month longer is allowed for countries beyond sea.

The introduction by the patentee into the country where the patent has been granted of objects manufactured in any of the States of the Union will not entail forfeiture. Nevertheless, the patentee will remain bound to work his patent in conformity with the laws of the country into which he introduces the patented objects.

Every trade mark duly registered in the country of origin will be admitted for registration, and protected in the form originally registered in all the other countries of the Union, and that country will be deemed the country of origin where the applicant has his chief seat of business.

Each of the high contracting parties must agree to estab-

lish a special Government department for industrial property, and a central office for communication to the public of patents, industrial designs or models, and trade marks; and an international office will be organized under the name of "Bureau International de 'Union pour la Protection de la Propriété Industrielle." This office, the expense of which will be defrayed by the Governments of all the contracting States, will be placed under the high authority of the Central Administration of the Swiss Confederation, and work under its supervision; its functions to be determined by agreement between the States of the Union.

States which have not taken part in the Convention will be permitted to adhere to it at their request.

Such adhesion must be notified officially through the diplomatic channel to the Government of the Swiss Confederation, and by the latter to all the others. It will imply complete accession to all the clauses, and admission to all the advantages stipulated by the present Convention.

Time alone can show how far the new Convention will work advantageously for the interests of trade; and although in its constitution there is no special reference to property in photographs, we have no doubt that if it be found that this class of property does not come within the letter of the Convention, arrangements will be made to include it.

By-the-Bye.

THE CAP, THE SHUTTER, AND THE CLOTH.

Workers by the old processes, such as calotype and waxed paper, had seldom occasion for a quick-shutter, and even lens caps were occasionally discarded, the exposure being made by simply drawing the slide of the dark back, and leaving the camera during a sufficient number of minutes.

About twenty-five years ago, when people had learned to look without special wonder on the so-called "instantaneous" street views, an occasional picture of breaking waves, or a ship under sail, there was a similar seeking after new exposing arrangements to that which we have experienced in the present day, and most of the shutters which have recently been brought out as new are mere resurrections of old and almost forgotten forms; but among the shutters of a quarter of a century ago, the simple drop found most favour, an india-rubber band being used to give it quick speed when a short exposure was desired; and a very common method of releasing it was to apply a lighted match so as to burn through a fine thread which held the shutter back. The revolving disc shutter was described and advocated by Mr. Sutton, while the double-slide shutter, known as Noton's, in which two diamond-shaped openings cross each other, was made by Mr. Hockin. Yet, in the face of these, which are fairly typical of shutters as existing at the present time, it is interesting to find that the most successful instantographers of twenty-five years ago rejected all mechanical shutters, and exposed with the lens cap or the focussing-cloth.

But we can now work in a fraction of the time we could a quarter of a century ago—certainly we can, and occasionally do—but the general exposure for an instantaneous street view is now, as it was then, about one-tenth of a second; and such an exposure can be very well given without resorting to highly complex mechanical arrangements or cumbrously long drops; but when a much quicker exposure is required, some mechanical aid becomes a necessity.

Before proceeding to fix to his camera an intricate piece of cog and lever work, about equal in weight to a complete quarter-plate outfit, the beginner would be wise to learn how far he can do all that he may require with the simple cap or the focussing cloth. As regards the cap, it is generally advisable to work with two caps rather than with one, as immediately the first is removed, the second can be slipped over the lens—neither should fit too tightly—and the extra cap is useful for protecting the back of the lens in travelling, as most lenses are now made with the mount of the same size at each end.

Then, again, the focussing cloth may be used either in its normal condition, or with a round hole about the size of the lens-mount cut in it, this hole being rapidly drawn over the objective. Need it be said that the cloth must be of a sufficiently dense material to allow no light to pass, and we have found a piece of fine broadcloth to be very much better and more convenient than velvet.

Only one step removed from the plain cloth is the excellent arrangement proposed by Dr. Vogel, and one which in skilful hands will give a really short exposure—let us say, one-fiftieth of a second—and this without shaking the camera.

The Vogel exposing arrangement consists merely of a tube or sleeve of black material fastened over the lens, and allowed to hang loosely down until the moment for exposure arrives; the open end is now gently and quickly lifted up and passed over the top of the camera.

FIG. 1.

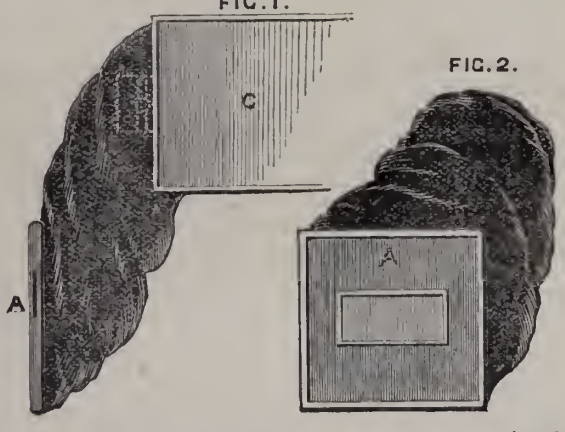

FIG. 2.

The open end of the sleeve at A is represented in the drawing as being fitted with a wooden frame; but it is better to use a rectangle made of the light U-section steel of which umbrella ribs are made, and a very thin black material indeed will serve for the body of the sleeve if the precaution be taken to attach an extra thickness or so to those parts which cover the lens when the sleeve is at rest.

Excellent, light, and convenient as this arrangement is, it has serious defects; defects which will not only much lower it in the eyes of many amateur photographers, but will also tend to prevent the dealer in apparatus supplying it to his customers—it is neither complex nor expensive, hardly worth either buying or selling.

To use the cap, the cloth, or the Vogel sleeve with the best result requires a certain amount of personal dexterity and skill; but the skill is by no means difficult to attain, and the amateur who goes out viewing with such simple exposing gear as we have described, has nothing to fear from damage to his shutter while travelling.

We do not mean to say that of all mechanical shutters, the simple drop is the very best, but we may say with truth that it possesses many important advantages over most of the very highly complex arrangements over which inventors have so much exercised their brains. There is not much chance of its being broken or damaged by careless handling, unless it be that the long slip of ebonite or wood which forms the dropping-piece may be snapped in two if negligently packed in the tourist's knapsack. But what is easier than to make a substitute out of a sheet of cardboard blacked with ink, and made to run easily in the groove by the application of a little black-lead to the edges? Then, again, how simple a matter it is to so far quicken the action of the drop-shutter as to make it give the shortest exposure one is likely to require, or to retard it so as to

make the exposure a third or a fourth of a second; elastic bands being applied in one case, and the shutter-frame being turned over into an oblique position in the other case.

The more highly organised shutters are all very well sometimes, and it may be a satisfaction to know that the instrument opens from the centre, or that by inspecting a scale one can learn the exact fraction of a second during which the exposure lasted; but it is well to bear in mind that every additional complication means increased risk of damage in use, and adds to the probability of something being out of adjustment just at the moment when one wants the shutter to do its work.

PINHOLES IN NEGATIVES.

BY CAPTAIN W. DE W. ABNEY, R.E., F.R.S.

The season has now come when many of our photographic brethren will be taking themselves to the bracing air of the Alps, or to the more torrid climates of Belgium, France, and the Continent generally. Pedestrians, whether they carry their cameras on their shoulders, or have it carried for them either on mule-back or by porter, may now and then meet with a photographic experience far from pleasant, and which may mar the pictures which would otherwise be technically perfect. That experience is a peppering of pinholes all over the plate, and more particularly near the margins. The plates may be dusted before putting in the slides, and they may be dusted before development, but yet these plagues put in an appearance, and their very shapes and sizes clearly indicate that they are due to dust. No one who has traversed such a road as that between Vispach and Zermatt on a dry day will be astonished at dust being found in the slides. Foreign dust seems to penetrate everywhere, and to be ankle deep. To escape from it one almost prays for the advent of a storm, and would certainly do so if the dust were not immediately turned into slippery slush. Anyhow, such dust has to be faced and battled with, and the question arises, "How to do so?"

A camera case is no protection; in most instances, dust penetrates into it, and from it into the slides, so something more must be found to cope with it. Very thin rubber sheeting bags with flaps, which can be securely tied, just fitting each slide, the opening end of the slides being first inserted, are a great protection. But even these are not sufficient. The dust will work itself even through these. Of course, if you have your slides securely packed in a portmanteau, or leather travelling bag, and wrapped in clothes, or other such protecting articles, no further precaution is necessary. But then there are usually on such dust-formed roads "bits" which the photographer may wish to secure without unpacking all his articles of toilette, so that such a security becomes impracticable.

There is one golden recipe against dust spots which we can recommend. Take a little glycerine on a rag, and rub the inside of your slides and the rebating well with it, and then rub off as much as possible with a dry cloth. It will be found that sufficient is left on the wood to secure the adhesion of all the fine dust which may try to find its way to the plate. A recent experience showed that so much dust was collected, in some cases, that the front board of the slides almost refused to draw out, and when they were drawn, the inside surfaces and rebates were found covered with minute particles, which, without the glycerine, would doubtless have lodged on the plate. A handkerchief carefully removed the dust, and the slides were ready for fresh occupants. The plates developed free from all pinholes, and the cure was complete. To make the deductions here given doubly sure, one slide was kept unmoistened with glycerine, with the result that the plates were covered with pinholes, showing that the right tack had been taken in applying the glycerine to the others.

The attention of our readers is drawn to this mode of combatting one of the evils to be met with in their travels when pursuing our fascinating art.

THE SPECTROSCOPE AND ITS RELATION TO PHOTOGRAPHY.

BY C. RAY WOODS.

XI.—The Diffraction Spectrum.

Hitherto we have only considered the spectrum produced by refraction—that is, the effect produced by a narrow beam of light passing through a prism, the rays being more or less bent out of their course according to their wave-lengths. In Art. No. III. it was stated, however, that this was not the only method of obtaining a spectrum. The other method depends on what is known as "interference."

If two stones be dropped into a pool of water, each one gives rise to a series of waves propagated in all directions. It will be noticed that when the two circles meet, where the summits of the two sets of waves coincide, they reinforce one another. On the other hand, where the summit of one wave coincides with the depression of another wave, there is comparative quiescence; the particles of water at that place are being acted on by two forces working in opposite directions, their resultant depending, therefore, on their difference. This "interference" is to be met with in all kinds of wave motion—in sound, for instance, where the interference of the waves gives rise to what are known as "beats" in music. A similar phenomenon takes place when light waves strike a thin film, such as a soap-bubble. Some of the waves are reflected from the surface of the film; others penetrate the outside of the film, but are reflected from the inner surface: if one such wave emerges half a wave-length behind the other, the two waves mutually destroy one another. But as a ray of white light is made up of a number of ethereal vibrations of different wave-length, a film whose thickness is suitable for producing interference with one set of vibrations will not produce interference with vibrations of a different wave-length; some vibrations, therefore, destroy one another, and by their absence from the rays which finally reach the eye, give rise to colour.

Again, if a series of waves—such, for instance, as may be set up in a pool of water—meet with an obstacle, a new series of waves is set up at that point. Hence the facility with which water or sound waves turn a corner. Light, however, is usually regarded as travelling only in straight lines, and it was this general experience that was the great obstacle to the acceptance of the wave theory of light. Newton contended that if light was due to wave motion, the waves should bend round opaque bodies, and produce the motion of light behind them, just as waves of water wash round a rock. It has since been shown that this does actually take place, but the amount of interference is so great as to render it unnoticeable except under favourable conditions.

The "diffraction" or bending round of light-waves can be shown in a number of ways, but it is proposed here to give only a few simple experiments which can easily be performed by the photographer in his darkened room, and which will readily demonstrate the action of the diffraction gratings used by spectroscopists.

Take a piece of tinfoil, and, with thin gum or gelatine, attach it to a piece of glass. Now draw a sharp knife across a portion of it; this will give a fine slit. Place a lighted candle at one end of the room, and retiring to a distance of four or five yards, hold the tinfoil in front of the eye, with the slit perpendicular, covering the slit also with a piece of red or ruby glass. The flame of the candle, appearing of course red, will be seen considerably broadened out, and at each side of it a series of bands of red separated by intervals of darkness. Now replace the

red glass by a piece of blue; the blue bands will appear narrower and closer together than did the red. If no coloured glass be used, a series of spectra appear, the blue ends appearing nearest the central flame.

If the room is a very small one, it is advisable to place a slit in front of the candle also. This slit need not be narrower than one-sixteenth of an inch for observations at about two feet distance. Or, again, a piece of tinfoil may be fixed on the glass of the dark-room lantern, and a fine slit be made with a sharp penknife; observations through the other slit may then be made at a few inches distance.

For an explanation of what takes place, let us consider theoretically what should be the result of the interposition of an obstructive body in the path of the waves.

In the accompanying diagram we have a series of waves coming from a luminous point in the line B A produced.

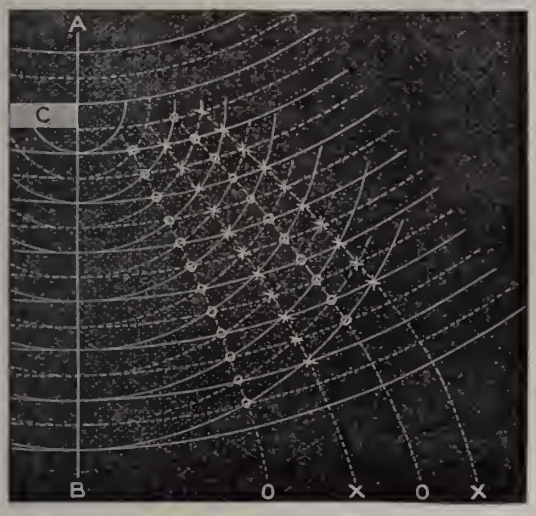

Fig. 13.

The summits of the waves are represented by continuous lines, and the depressions by dotted lines. Where the diffracting body C comes in, we have another series of waves sent up, meeting the original waves. At points marked O, where a continuous and a dotted line meet, we have two waves of conflicting phase tending to mutually annul one another. At the points marked X, where the waves are in the same phase, they strengthen one another, producing alternate spaces of light and darkness.

This is a simple case. In the experiment detailed, we have two such diffracting bodies, viz., the two edges of our slit, giving us a series of light and dark spaces on each side of the bright space in the centre. By somewhat complicated diagrams, it could be shown that the distance apart of the two edges of the slit would have an important effect on the appearance of the diffraction images. This effect can be best shown by a simple experiment similar to that already detailed.

Take the piece of tinfoil on glass, and cut with a sharp penknife a slit of gradually increasing width, that is, slightly wedge-shaped. On looking at the candle through different parts of this slit, it will be noticed that the wider the slit the narrower the spectra appear, and the closer together are they.

In the diffraction grating we have not one slit only, but a series. A number of fine lines are ruled by means of a diamond upon glass or speculum metal, at equal distances apart, this being regulated by a screw. Gratings containing as many as three thousand lines to the inch have been produced by photography; but this is far below the number that can be got into that space by mechanical methods. The lines, whether produced by photography or by the diamond, and if by the latter, whether on glass or on a reflecting surface, act as so many opaque edges to set up secondary waves, which, by meeting the original waves which pass through, are reflected from the intermediate spaces, produce a series of spectra. If the lines are far apart the dispersion is small, if close together the dispersion is considerable, as in the experiment with the wedge-shaped slit. Whatever be the number of lines to the inch, it is of the greatest importance that the distances apart of the lines should be regulated to a nicety, or errors must come in.

The greatest advantage that the grating possesses over the prism lies is the fact that the wave length of any particular line is easily determined by it. It is only necessary to know the distance between the scratches and the angle between the axes of the collimator and the observing telescope, and the wave-length may be obtained by a simple calculation.*

The grating is becoming of more importance than ever since Professor Rowland introduced his grating ruled on spherical surfaces. For photographic purpose no lenses whatever are required with them, and steps are being taken to bring them within the reach of those who may require them. At present, however, the demand is greater than the supply. There is no reason why, before long, the photographer should not be able to get a very efficient spectroscope for a very small outlay. In the next and concluding article, therefore, when reference will be made to the use of photography in spectroscopy, a brief description will be given of the simple mechanical arrangements that render the Rowland grating so easy of manipulation.

IN SEARCH OF THE PICTURESQUE.

BY H. P. ROBINSON.

When the east winds are over, April wanes into the merry month of May, and the dweller in town feels an irresistible longing for a breath of the country; when the birds are in full song and the apple trees in blossom; when the trees are putting on their summer verdure; when in pasture and wood and lane and by the river it is song and music, blossom and perfume everywhere;

> "When Beauty walks in bravest dress,
> And, fed with April's mellow showers,
> The earth laughs out with sweet May-flowers,
> That flush for very happiness";

then that photographer, whether professional or amateur, is to be envied who, finding he can spare a few days for a spring holiday, packs up his traps, and, perhaps with a fishing-rod tied up with his camera-stand, starts off into the country in search of the picturesque.

When Dr. Syntax went his famous tour on the same quest, he had not the advantages possessed by modern travellers for bringing home authentic reminiscences of his wanderings. In those days a meagre pencil sketch was often all that was possible for the amateur to obtain, while the most courageous artist seldom went beyond a timidly-tinted performance—every effort in art and literature was a performance then—in weak water-colours or neutral tint, and these were of a very unreliable character, giving but a poor idea of the places they were intended to represent. We have changed all that. The camera enables the novice to secure, if not perfect photographs, at least accurate representations that all will believe in, of the most remarkable scenes he meets with in his journey; while the more skilful will collect, not only the most striking views, but will also find simple scenes that have nothing to recommend them but the best of all qualifications, their beauty. Where the sketcher of old time did his one sketch, the modern photographer exposes a dozen plates; the range

* $\sin \delta = n\frac{\lambda}{d}$ where δ = observed angle
n = order of the spectrum
d = distance between scratches
λ = wave length.

also is more extensive. In those days, not one in several thousand could afford to do more than the "grand tour," then an affair of months, but now nothing but a slight excursion for an Easter holiday; but in our time photography garners its crop from the uttermost ends of the earth.

I often wonder why some photographers should consider it essential to travel so far after the picturesque. There are those who cannot see anything beautiful within many miles of home, while others find a picture at every turn. It is a saying of a well-known artist, that there is quite enough beauty at your own back-door, if you had only the power to see it, to provide materials for many pictures. He perhaps does not mean this to be taken quite literally, but merely as an illustration that it is the want of artistic insight, rather than a lack of objects, that compels photographers to travel afar for food for their cameras.

It is not difficult to see a view, but it is not so easy to see a picture in it.

It is this power of *seeing* a picture that makes the artist. Partly a divine gift, it is yet to be fairly acquired by study, and the more a photographer knows of what are the elements or constituents of pictorial effect, the more will beauty display herself to him, and, as Browning makes one of his characters say:

> "If you get simple beauty and naught else,
> You get about the best thing God invents."

It is fortunate that there are many different tastes and predilections in the followers of all arts. If we all thought alike, or preferred the same thing, the monotony of this world would be unbearable; but, happily,

> "To those who in the love of Nature hold
> Communion with her visible forms, she speaks
> A various language."

There are those who can only see beauty in inaccessible places, and care nothing for a picture easily obtained. I once knew a man who cared nothing for the most perfect effects if they gave him no trouble to reach, and went into raptures over an indifferent view obtained at some risk of his life. This is a curiosity of taste that I know is not an isolated example. Then there are others who only care for castles and abbeys and the usual stock subjects known as local views, and obtain at much trouble and expense, but with much healthful amusement which is worth any reasonable trouble or expense, pictures they could buy at small cost. But there are others who cannot see any beauty in their own country, but must go abroad for it, and are not content until they plant their camera where

> "Hill peeps o'er hill, and Alps on Alps arise."

All these do work that is useful and often beautiful. But my object, when I commenced to write, was to show that there is as much material, and of as good quality, in our own country as can be found elsewhere. There may be more magnificent views, higher mountains, vaster distances, grander buildings to be found on the Continent than in England, and these have been wonderfully photographed. But as I write, there floats up to the surface of the memory many a simple scene "by ruin, rock, and river," or in quiet country lanes, in farmsteads and meadows, of haymaking and harvesting, of valley and heath-covered upland, of fields studded here and there with cattle, and of cattle cooling themselves in the quiet pool under the trees, and the combination of field and wood and sky, the stillness of water and the grace of landscape form, not unmixed with the simple incidents of country life, that have seemed to me to contain more poetic beauty than the whole world beside, from China to Peru. If we look round a photographic exhibition and select the dozen pictures having the most pleasing effect, we should find the majority of them are simple scenes from English nature. There is a quiet poetic touch in a "bit" of England that appeals to our feelings and seems to suit our art. Then the atmosphere! We hear constantly that foreign photographs must be so much better, because the air is so much clearer; but I never saw any landscapes taken abroad to equal, in all that goes to the making of a picture, the same class of subjects taken in our own country; and until lately there have been no painters of landscape to equal our own. It is a curious fact that most of the great French landscapists give up their bright skies and clear air, and prefer the more solemn effects, such as are only to be got on duller days when their climate more resembles ours, and there is atmosphere to separate their distances, and to give the poetic charm that cannot, possibly, exist without a little mystery.

All this may be called a mere question of taste. Well, perhaps it is, but I do not think it would be difficult to adduce other sufficient reasons why simple bits of nature make better pictures than "the mountain and the flood." In all the photographs of what is called magnificent scenery that have come before us, the very quality on which the scene depends is absent. The sense of vastness or sublimity is not there. Why this is so, is difficult to explain. It is not that the effect cannot be given in black and white in a small space; for Turner, in his vignette illustrations—such as those to Rogers, Byron, or Scott—manages to put into a few engraved square inches, miles of scenery, expressing all the magnificence and grandeur of the original nature. Photography as yet, except in rare instances, gives us only the literal facts of a landscape—the landscape of form, not the landscape of expression. Time and experience will alter this. We have made great advances in the right direction of late years. We seldom omit the sky now, and are beginning to recognise the value of atmosphere; we no longer want the microscopic details of things afar off, and we are beginning to feel our way to the poetic beauties of landscape apart from its prosaic facts; we are trying to see landscape with our own eyes, not only with that of the lens, and are on the way to make our tools obey our will.

So there is still hope that one may in time bring home scenes full of grandeur and majesty represented with some approach to the feeling with which the real scene inspires the spectator; but at present we must allow that simple scenes are most suitable to our art, and that the every-day life and scenery of our own country is as much, or more, adapted to picturesque effect than anything else in nature.

Photography represents the quiet nooks and corners of our own country fully and sufficiently, but when it tries to make pictures of grander scenes, there is always, however fine the forms, however perfect the technical photography, a sense of something wanting.

Notwithstanding all I have said, I do not wish to discourage those who prefer to go far afield for their subjects; they have their uses, they bring home to those home-loving people who, Shakespeare rather impertinently says, have ever homely wits, facts from abroad that are always interesting. My object when I began this little essay was to encourage that vast army of photographers who have to be content at home by showing them that they have a wealth of beauty around them that should be sufficient to supply food for their art for the remainder of their days.

MR. DEBENHAM ON "THE ILLUMINATION OF THE DARK ROOM."

BY C. RAY WOODS.*

At the last meeting of this Society, when Mr. Debenham read his paper on "The Illumination of the Dark Room," I brought up the result of a few experiments in connection with this discussion, but the lateness of the hour prevented me bringing them forward. I wish to do so now, and am desirous at the same time of drawing attention to a few points in Mr. Debenham's communication.

Here is the result of an experiment to which I referred in

* Read before the Photographic Society of Great Britain.

the discussion on Captain Abney's paper. A negative is formed of one or two thicknesses of orange paper and canary medium placed side by side. The common orange paper lets through, it will be seen, much more light than the canary medium. Here is a transparency taken by contact, the source of illumination being an ordinary paraffin candle at a distance of twelve inches. At a first glance the orange paper seems to have the best of it, but it will be found on closer inspection that the inequalities in its texture bring it down to about the same level as the canary medium. With two thicknesses the canary medium has a slight advantage in protective power, but the superiority of the orange paper in the illuminating power of the light transmitted is most marked. I show here a similar experiment with canary medium, orange paper, and the yellow paper which Mr. Debenham uses in his lamp. The latter is a thin paper of very uneven texture, but it is a decided improvement on canary medium. Three thicknesses transmit as much illuminating power as two thicknesses of orange paper, the two thicknesses of orange paper being the safer medium, though only slightly so. The weak point, however, in all papers and fabrics is that so much of their safety is due to *general* absorption.

Here is a comparison of orange paper with three coloured glasses. Holes were cut in a sheet of orange paper, a little smaller than the pieces of glass, but corresponding in shape. The paper was then placed on a gelatine plate, with the coloured glasses covering the holes. The edges of the plate were then protected with black velvet placed loosely round, and the whole presented square to a fish-tail gas flame at a distance of four feet. Where the plate was only protected by orange paper (which has already been shown to be about equal in protective power to canary medium, by gas or candle light) the light has had a considerable effect. A slight effect has been produced on the part protected by stained red glass. The second glass—an orange glass, sometimes called stained red—shows protective power very little superior to that of the orange paper. The third glass is a piece of very dense ruby, equal in tint to about *three* thicknesses of the ordinary ruby glass. The exposure was not sufficiently prolonged to produce any appreciable effect through it, but its safety is purchased at the expense of illuminating power.

I have here a piece of the stained red glass used in this experiment. A portion of the surface at each end had been removed, leaving the centre untouched.

Here is a plate which was exposed beneath it. The part protected by central portion of the glass remains untouched with an exposure sufficient to impress two ends. This slip of glass forms part of a large piece I obtained from a glass merchant at Kensington, and it is similar to the stained red glass used by Captain Abney, which was labelled "Chance's Stained Red." In his paper of March last, Captain Abney makes use of the expression—"I do not mean orange or flashed silver glass, which is often spoken of as stained red." Before making any experiments, therefore, Mr. Debenham should have endeavoured to obtain the precise glass which Captain Abney used. Instead of doing so, he obtained a glass which he himself describes as a silver flashed glass. In a communication to the Society in February, 1883, Captain Abney describes this silver flashed glass as unsafe, inasmuch as it lets through some ultra-violet rays. The reason why Mr. Debenham found cathedral green a more protective supplement to it than cobalt glass is therefore apparent. Cobalt glass lets these ultra-violet rays pass through, and cathedral green cuts them off. I may here mention that the rays which produce the greatest effect on bromide of silver are generally recognised to be in the dark blue, not in the violet and ultra-violet, as Mr. Debenham states in his communication. In the experiment by which Mr. Debenham endeavoured to show the inferiority of stained red glass to canary medium, had he used the glass recommended by Captain Abney, he would have obtained some such result as I now pass round. Here stained red shows itself superior to orange paper, orange paper to canary medium, canary medium to orange glass, whilst the thinner flashed silver appears very bad indeed. This was taken by lamplight, and is a fairer test than that given by Mr. Debenham, for photographers do not use a light so rich in rays of high refrangibility as that emitted by burning magnesium. But even when so actinic a light as that given by magnesium ribbon is used, the stained red holds its own, and the others appear in the same order. As might be expected, a much stronger impression has been produced through the orange glass on account of the richness of the light in ultra-violet rays.

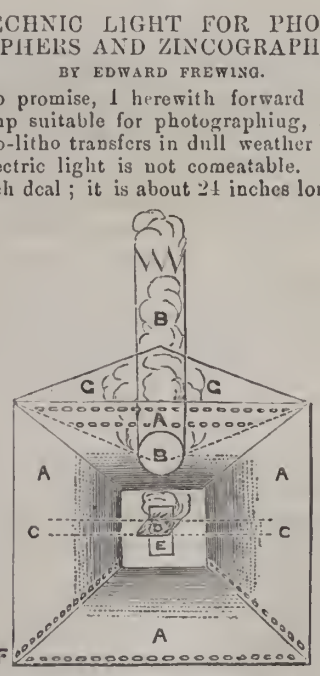
One word in reference to green glass. I have seen no green glass that does not let any blue light through, and photographers will do well to follow Mr. Debenham's advice to take "obvious precautions" when using a lamp part of the light from which comes through green glass unsupplemented with any other colour-absorbing medium. In Mr. Debenham's arrangement for using two lanterns, one glazed with orange-red, and the other with green, the approximation to white light is produced not by the mixture of red and green rays only, but by a mixture of red, orange, yellow, green, and, in a lesser degree, blue rays. Such a mixture of coloured rays is not unlike that which passes through canary medium, excepting that it contains a larger proportion of blue rays, and is, therefore, less safe, and, at the same time, whiter.

I beg, finally, to refer to a previous discussion in this room, when Mr. Debenham corrected me for making use of the expression "cathedral green;" I have since found that that expression is in common use amongst glass merchants, one of whom showed me a transparent glass which he called "cathedral white." As I see such glasses are quoted in Chance's lists as "cathedral tints," *not* "tinted cathedral glass," I consider that myself and others who have spoken of "cathedral green" were perfectly justified in using the expression.

A PYROTECHNIC LIGHT FOR PHOTO-LITHOGRAPHERS AND ZINCOGRAPHERS.

BY EDWARD FREWING.

According to promise, I herewith forward you a small sketch of lamp suitable for photographing, and printing zinco or photo-litho transfers in dull weather or at night, where the electric light is not comeatable. The lamp is made of ½-inch deal; it is about 24 inches long from front



A A A A, Wooden box, whitewashed inside; B, Chimney to carry off fumes; C C, Two wires to carry fire saucer; D, Fire saucer; E, Door in back of box for inserting fire pot; F, Ventilation holes, to make draught up chimney; G, Holes to take off smoke above glass.

to back; the front 18 inches square, the back 10 inches square; a glass in front, and a door in the back, and it is whitewashed inside.

To make the fine composition (pyrotechnic) suitable for the lighting of the picture to be copied, take o

Nitre	...	...	...	17 pounds
Sulphur	...	...	...	6 ,,
Orpiment	...	...	...	2½ ,,

Finely sift each separately, and then mix carefully together with the hands until thoroughly mixed together; the better they are mixed the steadier the light.

To copy a 15-inch picture (line) down to a 12-inch for the above process, about four to six ounces of the mixture is put into the iron pan and ignited, and the reduced wet-plate negative will be finished, as far as the exposure goes. It may be printed, if frame is held close to the glass of lamp, with about four times the quantity of fire used in four batches.

I trust this may be of some use to some of your readers, as it often has been to me. But care must be taken to avoid inhaling the highly poisonous arsenical fumes resulting from the orpiment.

Notes.

Dr. Koch, whose photographs of bacteria have contributed so much to our knowledge of the lower organisms, is now at Toulon making investigations regarding the cholera.

Photographers will hear with equanimity that the Works of Fine Art Copyright Bill has been withdrawn. As we pointed out some weeks ago, the Bill was framed simply in the interests of print-sellers. Photographers had not been consulted in the matter, and every reference to photography in the measure was confined to all manner of pains and penalties for infringement of certain clauses. The collapse of the Bill is probably due, to a great extent, to the vigorous onslaughts of the *Pall Mall Gazette*, which pointed out clearly that the only section of the public benefitted would be the Print-sellers' Association.

The Berlin Society proposes to inaugurate a competition for out-door outfits, and to offer two silver medals and two bronze medals. There are two classes, the first comprising complete outfits and apparatus to be transported by beasts of burden; while the second class is to include portable arrangements for pedestrians. Articles for competition may be sent to Dr. Fritsch, 35, Dorotheenstrasse, Berlin, N.W.

An exceptionally interesting paper which Mr. Purdon Clark recently read before the Society of Arts dealt with the street architecture of India, and the lecturer showed on the screen some excellent transparencies taken from his own negatives; We are glad to see that photo-lithographic prints from these negatives (sixteen in number) were issued with the last number of the *Journal of the Society of Arts*. We do not find, however, that the production of the prints is accredited with his work.

Amongst the multiplicity of labours carried out during the past year at the British Museum, Professor Sydney Calvin, the recently-appointed Keeper of Prints and Drawings, announces that 4,919 prints, drawings, and carbon photographs have been impressed with the departmental stamp. In all, 6,012 prints, drawings, and photographs have been acquired during the period named. Of the photographs, the most important were 50 by M. Braun, of Dornach, of celebrated pictures in the Madrid Gallery.

M. Braun has for some time been engaged in preparing these carbon photographs of the master-pieces of the Spanish National Collection, and the above form Part 8 of the series.

But a much more important photographic event has been the arrangement, in the second Northern Gallery—which, as visitors to the Museum will recollect, used to be filled with the stuffed specimens of the Zoological Department, now removed to the new National History Museum at South Kensington—of an admirable selection of carbon photographs of original studies by Raphael, Michelangelo (for this is how Professor Calvin insists on writing the great sculptor-painter's name), Leonardo da Vinci, and other great Italian masters.

These valuable examples do not fill the Gallery, the remaining space being occupied by Autotype reproductions of early Italian and German prints. A guide to this exceedingly interesting exhibition has been issued, we notice, by the Museum people.

Three powerful electric lights shone from the stage of Baldwin's theatre in San Francisco, and so bright was the light that the ladies held up their fans, and the gentlemen covered their faces with their hats, while photographs were taken of the visitors.

Several cameras were at work, and each person who had taken a ticket in advance received a print. Our managers might take a hint.

One of the worst sitters is a young officer who has just dressed himself in his regimentals; and the photographer who can make a picture of such a subject, in spite of the conscious dignity of the youth, and the bright unbroken surface of his newly tailored attire, must indeed be an artist.

Among the most valuable properties of the art photographer may be mentioned old clothes; and although the infant who is brought in the full glory of starch and stiffness may be readily re-attired in soft and coffee-tinted garments, no such course is practicable with the young officer.

The Emperor of Brazil, that exemplary potentate who, when in London, used to so upset the staff at Claridge's by getting up at 4 in the morning, and doing a hard day's sight-seeing before breakfast, is known to be a monarch of liberal views and exceptional enterprise. He is always introducing vagaries into his Empire, and he now intends, it is said, to apply photography to the postal service.

Photographic postage stamps will be doubtless interesting to collectors, but that they will prove a practical success is not at all clear.

The late Mr. Charles Reade had a craze that all that was right about the human body should be left. He proclaimed that the left side of the face was the right, that "artist's always put the best touches, finest shading, and most delicate tints on the left side of the profile." Photographers have long since found out that one side of the face is gener-

ally better than the other side, but is it invariably the left side which is better? Mr. Francis Galton might well incorporate this enquiry in the data that he is collecting about family history.

It was a photograph representing an extraordinary incident which really happened some time ago at Brompton, near Chatham. A horse had taken fright and bore its rider on to some railings which bordered a stable-yard situated some thirty feet below the level of the road. The horse leaped the railings and came down over twenty feet on to a wooden landing, from which steps ascended to the road. The rider kept his seat, and, strange to say, neither man nor horse was hurt in the least. The photograph of the scene is kept hung up in the bar of a suburban public-house, and of course excites much wonder. The other day two men were looking at it. One said: "Well, I've heer'd about instantanerous photography, but that's about the instantanerousest picter I've ever seen. Why, its got the 'oss actooally a-leaping the rails." Says the other: "Ah! but what beats me is as the photographer should ha' been there at the very time and got everything ready to take the picter." If the critics had known that a large photograph of the surroundings had first been taken, the man and horse painted in, and the whole photographed, then they wouldn't have been so much puzzled.

Photographers play very "low down" in the State of Kansas. At Kansas city in the finest street are to be seen notices, "tintypes ten cents." No wonder a member of the Chicago Photographic Society was compelled to say that this did not heighten his idea of photographers.

The close competition the German paper manufacturers are running against the English manufacturers, to which we alluded in a recent issue, is not confined to photographic papers. Mr. Fawcet had to own in the House of Commons the other evening that paper for post cards was now procured from Germany cheaper and better than it could be supplied in England.

Sulphite of soda as sold frequently contains carbonate of soda, and many persons spoil their work by using such sulphite in the developer. The salt is often prepared by dissolving a quantity of carbonate of soda in warm water, and after saturating the liquid with sulphurous acid, a quantity of carbonate of soda, equal to that first used, is added. If, however, the amount of sulphurous acid first used was not sufficient to entirely convert the first quantity of carbonate of soda into bisulphite, the resulting sulphite will be contaminated with carbonate, and may cause mischief if used in the developer.

The best method of testing a sample of sulphite is to add nearly sufficient of a strong acid to convert the salt into bisulphite, and to notice if any effervescence occurs. If effervescence takes place, carbonate of soda is present, and the sample of sulphite should be rejected.

Now as to the exact method of testing. First, put four drachms of the sodium sulphite to be tested in a glass flask; add six fluid drachms of water, and heat gently so as to cause the salt to dissolve. Allow the solution to cool down to about 85° Centigrade, and add a mixture of one fluid drachm of strong hydrochloric acid, and two fluid drachms of water. The slightest effervescence, or the formation of minute bubbles of gas on the sides of the flask, will indicate the presence of carbonate in the sulphite.

Judging from personal observation during a recent visit to the West of England, we should imagine that the Great Western, Paddington, and Exeter Express, known as "The Flying Dutchman," can claim the honour of being the "most photographed" train on the metals. In nearly every town bordering on the line we found that one at least of the local photographers had seized an opportunity, as the train flew by, to secure a likeness, which for once is none the worse, but rather the better, for being a "fleeting" one.

There is necessarily a sameness, however, about the series. An express engine has not the manifold facility of pose possessed by a "professional beauty" or a famous actress; and its expression, whether it be going at fifty-eight or fifty-nine miles an hour, is grimly the same. The only relief, in fact, to the similarity of the photographs is furnished by the change of background and the varied positions of the stoker and driver.

In an amateur performance of "Macbeth," in the small town of Lawrence, Mass., U.S.A., it is reported that a local photographer played the part of the wicked Thane. He commenced the famous soliloquy in Act II. thusly:—

> "Is this a 'Daguerre' which I see before me,
> Within my reach? Come, let me gaze at thee!
> I see thee now; and now I see thee not.
> What art thou, then, a thing impalpable,
> A changing vision, or a false creation
> Proceeding from my heat-oppressed brain?"

At this point, however, the stage-manager summarily intervened.

"When I used collodion in the house on Saturday afternoon last, there was quite a commotion, windows being thrown open, and suffocation talked of," says an amateur; but he tells us that in the old time, when he worked with ether nearly every day in the week, no remarks were made. Here is a touch of nature; but the home photographer has now the satisfaction of knowing that he is not quite such a nuisance as he was a few years back.

Mrs. Malaprop was amongst the ladies who braved the tropical heat of a London photographic studio last week, and, in spite of the precautions taken, was so overcome by the temperature as to show signs of collapse. But she insisted on completing the sitting, assuring the artist that she would "soon be all right if he would only sprinkle a little *eau-de-collodion* over her handkerchief."

Photography acts sometimes as a check to the imagination. The residence of Prince Bismarck at Friedrichsruhe

has long been an object of curiosity to the outside public, very few persons having seen little more than the chimney pots of the house owing to the high red-bricked wall which surrounds it. By permission of the Chancellor, a Hamburg photographer has been allowed to photograph the interior and exterior, and sixteen plates have been taken. Everyone, however, who has seen the pictures has been disappointed, as the supposed sumptuous mansion turns out to be an ugly whitewashed building with low windows without the least approach to ornamentation from top to bottom.

Patent Intelligence.

Applications for Letters Patent.

9612. Alfred George Brookes, 55, Chancery Lane, Middlesex, Fellow of the Institute of Patent Agents, for "Improvements in the method employed in the preparation of surfaces for printing or etching by the aid of photography." A communication to him from abroad by Edward Kunkler, St. Gall, Civil Engineer, and Jacques Brunner, Küssnacht, Zurich, photographer and art printer, both in Switzerland.—Dated 1st July, 1884.

9641. Richard Charles Wittmann, 47, Great Marlborough Street, Middlesex, glass and china merchant, for "Self-acting and self-supporting frames for fastening photographs to glass."—Dated 1st July, 1884.

9792. Robert Royou Beard, 33, Balaclava Road, Bermondsey, London, S.E., Engineer, for "The propelling and repelling and self-centering of photo transparences and views."—Dated 5th July, 1884.

Specifications Published during the Week.

4144. William Blair Anderson, 26, Union Terrace, Aberdeen, in the County of Aberdeen, Scotland, Photographer, for "Improvements in colouring photographic prints."—*Provisional only.*

I take unmounted print (which has been previously toned, fixed, and washed in the usual manner), mount it on plate of opal glass or other prepared surface. After pressing out all air-bells it is allowed to dry. Thereafter, the plate is heated, and bees'-wax, paraffin, naphtha, or other substance applied till the print is perfectly transparent. The superfluous wax or other substance is then wiped off with a cloth, and when cool, the print is gently polished with silk handkerchief or other suitable soft material, when it is ready for being coloured or painted in monochrome, which is done by the application of oil colours, according to the effect desired.

What I claim is:—The absolute and exclusive right to take an unmounted print (which has been previously toned and fixed in the usual manner), and to mount it on a plate of opal glass or other suitable or prepared surface, and after pressing out all air-bells and allowing the same to dry, to heat the plate and apply bees'-wax, paraffin, naphtha, or other substance, until the print is perfectly transparent. Then to wipe off the superfluous wax or other substance; and when cool and gently polished, to colour according to the effect desired, by the application of oil colours.

5681. William Robert Lake, of the firm of Haseltine, Lake, and Co., patent agents, Southampton Buildings, London, "Improvements in and relating to colour-printing, also partly applicable for producing coloured photographs and for similar purposes." A communication to me from abroad by Auguste Bisson, of Paris, France, Heliographic Engraver.

This invention relates to colour-printing, but is also applicable for producing coloured photographs and for similar purposes. The said invention comprises an improved method or process which is applicable to all kinds of photographic or other pictures, amongst which I will particularly mention the proofs obtained by means of carbon or salts of silver, such as those obtained by photoglyptic or phototype processes; these pictures may be portraits, reproductions of natural objects, or pictures of any other suitable description. The said method or process consists essentially in printing, impressing, or applying, in the special manner hereinafter described, the necessary colours either directly upon one or the other face of the gelatine film, bearing the carbon proof or the photoglyptic proof, or upon a proof obtained upon a translucid support, such as mica, vegetable parchment, dioptric paper, transparent mineral paper, and paper mounted upon cloth or the like, to which substances I impart complete transparency by means of an operation which I carry into effect either before or after the production of the picture. This operation consists simply in immersing the paper or other substance which is to be rendered completely transparent in a bath of varnish composed of the following ingredients, viz.:—

Volatile or rectified benzine ...	1000 grammes
Resin	150 ,,
Linseed oil	10 ,,

This mixture is prepared in a water-bath, and by a simple agitation which ensures an intimate mixture of the materials.

I claim—

First. The printing or impression of colours upon one or the other face either of the transparent gelatine film, of proofs obtained with carbon or by photoglyptic engraving, or of these proofs transferred upon perfectly transparent supports, or of photographic or phototypic proofs obtained upon paper or other equally transparent supports.

Second. The method of treating in a cold bath formed of rectified benzine, resin, and linseed oil, various partially transparent supports, such as vegetable, dioptric, or mineral paper, or vegetable parchment, in order to give to such supports a complete transparency.

Third. The method of successive printings or impressions by flat tints of the different colours to be obtained, by means of thin patterns made of opaque substance, such as metal, cardboard, or the like, which have been previously cut out to the exact outlines taken from a photograph of the picture, of the different shades to be produced, and which are applied upon a lithographic stone treated with bichromate of potash to obtain parts representing the exact forms of the tinted parts, and which are then imprinted successively on the proofs suitably registered and prepared in the manner above indicated.

Fourth. The modification of the method of printing, consisting in operating by hand, when only a few reproductions are required, by means of the cut-out patterns above indicated, which facilitates the rapid application, by flat tints put on by means of a brush, of the different colours which it is desired to obtain.

Fifth. The method of mounting the coloured proofs obtained as above indicated, upon Bristol-board, wood panels, or cloth, according to the appearance which it is desired to give to the picture.

7191. Alfred Julius Boult, of 323, High Holborn, in the County of Middlesex, Engineer, for "Improvements in rings for containing portraits or the like."—Dated 3rd May, 1884.

This ring is first opened at the top by raising the part under the bezel which carries the stone at the side opposite, then the two lateral lids are opened, or they open by themselves by means of springs. The portraits, figures, or the like are fixed in place by means of movable frames so that they may be placed into the ring or taken out at pleasure. The rings are made flat or half round, and a gold plate or a stone is placed upon the top lid as may be desired. The lids are attached by hinges on which they move. To close them the two at the sides are retained by the one at the top. To this end the latter takes into two little spurs or claws on the side lids, and keeps the same in place when closed. These rings are also made with two portraits only; in that case the side wings are dispensed with, and only the upper lid remains, this containing one portrait, the other being placed on the body of the ring. What I claim is—A ring for containing portraits, figures, or the like, as described.

SILVER PRINTS.

BY EDWARD DUNMORE.*

The paramount importance of ensuring permanency in our silver prints has induced me to put together a few notes, as supplementary to the interesting paper on "Fading" read by Mr. John Spiller at the last meeting of this Society. It will be well, in the first place, to decide upon the standard we are to set up as

* Read before the Photographic Society of Great Britain.

to permanency. Will a picture on paper, an engraving in fatty ink, *e.g.*, supply it? or are we to put silver prints in competition with flint or wrought-iron, expect them to resist boiling, or even soaking, in strong solutions of hyposulphite of soda without injury? The phrase permanent is very elastic, and at best is but an expression used to indicate durability, not by any means indestructibility; but, for all intents and purposes, if a silver print will remain good as when made if treated as most pictures of any value are treated, hung on the wall or placed in the portfolio, it in my opinion fulfils all the requirements that can reasonably be expected of it; what more do we seek? Many silver prints produced in the early days are as good and perfect now as they were then, no especial care having been taken of them, and not in only one or two isolated instances, but in many. Now it is an axiom that anything that can be repeated must be subject to certain rules, or the reproduction could not take place, therefore it is absolutely certain that if we knew the precise conditions attending the manufacture of these particular prints, by following the same routine exactly, we should risk no failure nor have fading prints; in fact, permanency would be assured.

As an aid to permanence, many years ago Mr. Spiller suggested the use of ammonia carbonate in the hyposulphite bath as assisting the solution of the unstable silver salts formed in the paper; at that time I was using carbonate of soda, but with a different intent. I had been complaining of the reducing action of the hyposulphite solution on my proofs to a brother photographer, who attributed it, as many faults were attributed in those days, to acid hypo. If this was the case, I thought the addition of a little alkali might remedy it, be a reasonable precaution, or, at any rate, do no harm. I made the addition of sodium carbonate to the hyposulphite bath, with a decided improvement in the results, for which I substituted the ammonium-carbonate after reading Mr. Spiller's remarks thereupon, and continued its use afterwards. About nine years ago I adopted it as an improvement at Mr. Bedford's works, and after using up a hundredweight or so of the ammonia-carbonate, discontinued it, finding that a whitish deposit was formed on the surface of the prints, which, though very slight, still injured their appearance, as the light fell upon them at certain angles. This deposit was loosely attached, a rub with a soft rag easily removing it, but the trouble incurred was considered to more than overbalance the advantages gained; the use of ammonia was in consequence discontinued.

We will now, for the present, leave the matter of permanency to consider of what in reality a silver print consists; a definite understanding on this point is very material to any argument that may result thereupon. To get an idea of this it will be necessary to sketch out the process of silver printing *ab initio*, taking the paper itself for a starting point. Photographic paper is, and has been from the first, almost exclusively supplied from foreign mills, the words Rive and Saxe being almost synonymous with photographic paper. This, the foundation of our prints, seems now somewhat inferior to earlier makes. The inferiority is not in appearance or texture, but in the increased difficulty of causing it when sensitized to retain its whiteness without extraordinary precautions, that were unnecessary at an earlier date; an hour or two in warm weather is sufficient length of time to gain a decided yellowness, when formerly, under similar conditions, the colour would be pure and white for a day or two. I am not sufficiently acquainted with the manufacture to suggest the reason, I can only record the fact. This seems to be the only portion of a silver print that is actually beyond the control of the photographer, if we except metal spots, which in the Saxe make of paper seem more numerous now than formerly; these are, however, local troubles, and have no effect on the permanence of the print, and are probably due to particles of metal abraded from the machinery during the process of manufacture, or hot-pressing afterwards, or rolling.

Albumenizing is the next process, which is now so seldom done by photographers that it is practically out of their control, although they could do it, if they so willed; and much depends upon it. This should consist of pure fresh egg albumen mixed with a definite quantity of some chloride, and applied to the surface of the paper, *secundum artem*. Ammonium-chloride is, I believe, generally preferred as giving a better colour than other salts. In addition to this, some makers add other substances for the purpose of increasing the gloss, or to improve the keeping qualities of the paper. Citric and acetic acid are added, more especially during warm summer weather. If albumen from blood or gelatine is used, mixed with or in lieu of pure egg albumen, imperfect results are more likely to occur, the proofs on such paper are wanting in richness and evenness of colour, acting themselves as a caution against the use of that particular sample of paper. Stale albumen is well known to give a higher gloss, but its offensive smell and doubtful qualities, as a rule, cause such paper to be rejected; prints upon it have, however, been found to remain bright and pure, as with fresh albumen, and to show no signs after the lapse of years, either of fading or yellowness. The paper, being albumenized and dried, is now floated on a bath of silver nitrate, of a strength of between 60 and 70 grains per ounce. The strength is, however, somewhat regulated by the amount of salt in the albumen, care being taken to have a considerable excess of silver salt. A large amount of uncombined silver nitrate facilitates both printing and toning. The prints are richer in colour, and tone more readily, and, to my thinking, if strong baths are used, are more permanent.

The paper thus prepared is dried and exposed to the light under a negative to make the positive print. The resulting action has been, and still continues to be, somewhat a matter of conjecture, but not less important on that account. A number of complex changes undoubtedly take place, and, according to various careful experimenters, the principal change is that the chloride of silver is reduced to the form of a subsalt and a red substance, which is left on decomposing the subsalt by hyposulphite of soda in the act of fixing. This is the theory set forth in "Hardwich's Chemistry." It is, however, somewhat incomplete, and will not account for the varying results continually brought before us; therefore, again adverting to the axiom that anything to be repeated must be subject to some definite rule, we undoubtedly require further knowledge of this particular part of the process. What, for instance, is the "red substance" that forms an important part of the photographic image? When silver nitrate is applied to organic matter, darkening of the substance takes place, not only in the light, but in the dark, the silver being reduced to a metallic state, light greatly accelerating the change, which bears some relation to the intensity of the light acting on it. Suppose, in addition to the subsalt theory already advanced, that the silver became reduced partly to a metallic state, and partly to a state of oxide, nitric acid being liberated. Many years ago M. Deville found that by acting on silver nitrate with chlorine, dry nitric acid was formed. Is it unreasonable to suppose that free nitric acid being liberated by the reduction of the silver nitrate to a metallic state, which, in its turn, is partly deoxidized by the light, the oxygen attacking the reduced silver, nitrous acid escaping and acting on the organic matter with which it is in such intimate contact that xanthoproteic acid results, which we know is of a deep yellow colour, and darkened by alkalies? This may form the basis of the "red substance" to which Hardwich refers.

The preservative effects of a carbonated paper on sensitized paper is well known, and the effect is especially noticeable when placed in the printing-frames at the back and in close contact with the sensitive paper during the operation of printing. Its preservative qualities are attributed to this power of neutralizing any liberated acid. In connection with this, I may remark that addition of a considerable quantity of nitric acid to the silver bath somewhat expedites the printing, and that the ready-sensitized, and some samples of unsensitized paper, contain a very large amount of free acid. The result tends, in all instances, to more rapid impressions. The silver print seems to principally consist of coloured organic matter, oxide of and metallic silver, previous to toning, which inclines me to the opinion that a silver print consists of *two entirely distinct images: one an organic, and the other of a metallic nature*, and that these images exist in varying proportions one to the other, and may be produced at will, depending almost entirely on the force and continuance of the light used in their production. With a weak light and short exposures, the image will be principally organic; with a long-continued and powerful light, metallic. This quality of the image seems to me to have been the stumbling block over which we have so long continued to trip, and will explain the varying amount of permanence in proofs prepared in a seemingly identical manner. The organic image is, I believe, the image that fades, and this idea is supported by a variety of evidence. For instance, the lasting qualities of prints from delicate and thin negatives that are printed in a very subdued light to get the best impressions are allowed, on all sides, to be less permanent than stronger impressions. For my own part, notwithstanding their attractiveness, I believe they are the most unstable of all photographs, and that such prints, without any doubt, no matter how carefully prepared, have but a short existence—ten years at the very outside, and frequently one or two. On the other hand

a strong metallic image—that is, one printed in a good light from a fairly dense negative, is, to all intents and purposes, quite permanent, if prepared with reasonable care. This theory of the quality of the silver print is not, if I may so term it, an upsetting theory, but merely an additional one. The ultimate forms that the varied and complex changes that take place lead up to, is the production of a metallic and an organic image intimately combined, which, although having different proportions one to the other, cannot exist entirely separate.

The next stage in the production of a silver print is the toning. The substitution theory is the one generally accepted—that is, the silver chloride is abstracted from the image, and its place supplied with gold; the double chloride of gold and sodium or calcium becoming, by enterchange of elements, the double chloride of silver and sodium or calcium, according to the salt used. If these reactions take place the abstracted silver should be found in the exhausted gold bath. May I ask if this has been satisfactorily determiued by actual experiments? I have heard this query put before, but have not heard the reply. Supposing, however, a somewhat different action takes place, and instead of the abstraction of silver from the image, each particle of metal becomes coated with gold, electro-plated, as it were, then an explanation is offered of the somewhat obscure changes that take place in this part of the process. An organic image would be obviously incapable of attracting deposit of gold, otherwise of being toned, and the attempt to make it would result in the partial or entire destruction of the image. Adopting this theory, it is easily understood why a print from a weak thin negative can never be made of a rich deep colour, the small amount of metallic image with which it is comoined being too little to attract sufficient gold, before the bleaching effects of the touing bath upon the organic image has partially obliterated the impression. If the image is strong and rich, printed from a fairly dense bright negative, the toning can be carried much further without this destructive effect taking place. By coutinuing its action the colour gradually loses its richness, but the image will uot be destroyed in any reasonable length of time. The effect is, however, precisely the same. The destruction of the orgauic image takes place more or less according to the depth of the impression; but there is sufficient of the metallic image present to prevent the dual image being altogether effaced. The orgauic portion acts throughout as a coloured medium, to which most silver prints owe their warmth and richness, and the metallic part, to which they owe their permanency. We find by actual practice there is no *necessity* whatever to carry the toning process past a certain stage to ensure permanency. Even by stopping short of the most *perfect effect with regard to permanency*, we get an impression that will be sufficieutly durable, so that there is considerable licence in the matter of colour, without incurring any particular danger. I think the very highest point to which toning can be carried with advantage is to stop it just before any reduction of the organic image takes place, known by the disappearance of half tones; to carry it further is at the sacrifice of richness and quality.

The desired colour being obtained, we come to the last chemical process the prints have to undergo—that is, fixing. To effect this, we immerse the prints, well washed from the gold bath, in a solution of sodium hyposulphite, or thiosulphite, as it is, perhaps, more correctly called. Much stress is to be laid on the importance of using freshly made solutions, and continuing the action sufficiently long to dissolve all that is soluble in the hyposulphite solutions from the paper. The time required varies with the temperature and the kind of paper—about a quarter of au hour to twenty minutes usually suffices. No exact time can be stated, a very thickly albumenized paper requiring longer than samples thinly albumenized. The print should look clear when held up to the light, showing the more opaque salts are removed. This part of the process, in my opinion, with a print rightly prepared in other respects, determines if it shall yellow and spoil, or remain bright and permanent. When the hyposulphite has effected its purpose and dissolved all those compounds we know, by experience, lead to after trouble, the proof must be thoroughly washed and dried. The results, I am firmly convinced, are permaucnt impressions, and, so far as I can see, this is the result at which we wish to arrive.

WHAT TO MAKE FOR ONE'S ALBUM.

THERE are so many pleasant and promising fields, and each one is, perhaps, in such a position, that he is tempted to enter upon some corner of it. In making a selection, he should first consider his opportunities. What places are most easily and most generally accessible to him? He should next consider his time. If time permit, inclination call, and opportuuities present, then he may enter a field with a view to success. For a busy man who has only mornings and evenings at his disposal, and a long summer vacation for uninterupted work, it would be folly to attempt portraiture. His progress would be so slow, and his opportunities so few, that his time would be in a great measure wasted. Such a person will usually find landscape work by far the most profitable, and a summer vacation will bring a harvest of good things.

Having selected a line on which the greatest atteution is to be devoted, something more is necessary. If the pictures are to have a connection and to illustrate a subject in the city, for example, the landscape photographer will find that series of subjects will give zest to his work, and possess considerable value.

A geutleman in Brooklyn and another iu New York have made views of the exteriors of the leading churches. Another has devoted himself to the interiors as well as the exteriors, and in this way formed a gallery of pictures which will become more and more interesting and valuable as time passes. A series of views of remarkable houses and buildings of a city would be a source of interest aud pleasure to the possessor. These would have artistic as well as historic value.

To the artist the picturesque points of a great city appeal strongly. In order, however, to make a very complete collection of such photographs, the artist should have some one to accompany him, otherwise he may find himself hampered by a crowd of the curious, which will be annoying, to say the least. When one has an iustantaneous apparatus this annoyance is, of course, reduced to a minimum, and he is comparatively independent of the curiosity of the omnipresent small boy and loafer. With such an apparatus, street scenes, celebrations, aud moving vessels offer few difficulties. The possessor will easily make a collection unique in its way. In a city like New York or Brooklyn, a most picturesque series of pictures can be made along the wharves and among the vessels; and with a little diplomacy a great many favours and much assistance may be obtained from the longshoremen and sailors in getting into favourable positions and finding suitable subjects.

The amateur photographer in the country will find the illustration of his town a work well worth all his energy. Morning and evening, winter and summer, all bring phases which the camera can render with peculiar advantage. If leisure enables him to take portraits, he can easily increase his collectiou by taking the more noted characters; and these, if introduced as figures into characteristic surroundings, will make a history of the most interesting description. Manners and customs can be illustrated, and picnics, weddings, and public gatherings made the subject of photographs.

The traveller has an opportunity to include in his album a great diversity, while at the same time a single purpose gives unity to his work.

A gentleman in this city has for some time past beeu illustrating his journies by photographs taken along the way. The engines which drew his trains, the hotels at which he stopped, views from windows, characteristic scenery along the way, the steamers, the landings, and in many cases groups of people, have all beeu worked up into effective pictures, which adorn his albums. Summer journeys which, previous to his adoption of photography, were mere idle rambles, are uow undertaken with a purpose, aud new reasou is added to each summer vacation, and he brings home with him a record of his tours intelligible to every chance visitor.

To many enthusiasts in photography such organization and systematic labour may seem useless. Their own interest and eagerness seem a sufficient reason for anything they may do. The pleasure of taking a negative, seeing it developed, and printing from it afterwards, appears to be a sufficient reward. This is true for a time; but they will find that as months and years pass by, unless some plan is adopted which they are anxious to carry out, their interest will flag to a greater or less extent, and they will perhaps see, when it is too late, that had they commenced in a different way they would still be obtaining as much enjoyment from their work as when they first commenced.—*Anthony's Photographic Bulletin.*

COMMERCIAL FABRICS SUITABLE FOR DARK-ROOM ILLUMINATION.

BY J. R. SAWYER.*

The tone of Mr. Debenham's paper, and the warmth of some of the observations that it elicited at its close, brought to my mind some remarks made by my friend Mr. Bird, at the meeting on March 28th, and which I will venture to quote. Mr. Bird said:—"The great discrepancy between the scientific evidence and the experience of skilled observers indicates that something is wrong somewhere. May it not happen that our knowledge of the chemical effects of the spectrum is not so exact as it might be? When some observers are convinced that a light modified with yellow paper and a green glass will give the maximum of luminosity and the minimum of chemical action, it is bewildering to be assured that spectrum analysis demonstrates the contrary. Further inquiry is necessary to clear up the subject." Exactly so; further inquiry is necessary to clear up the subject; but permit me to ask is there any reason why this inquiry should not be carried on in a friendly spirit—why it is necessary that there should be any personal feeling imported into this question, or any question that may come before the Society; is it not possible to discuss this matter without ranging ourselves into two hostile camps, the one taking ruby red as their ensign, the other orange? In my contribution to this matter I mean to be entirely practical. I have endeavoured to carry out the experiments, the results of which I shall lay before you, with a view of enabling you to pronounce upon certain fabrics, readily procurable, a verdict as to their suitability in all respects for the illumination of the photographer's work-room. I wish to steer entirely clear of all the subjects that excite so much feeling. Spectral analysis, coloured glasses, whether stained red, flashed, canary, green, are all out of my province; the materials I shall recommend are easily procurable, easily adaptable, and in my experience as a commercial dry-plate maker, answer the purpose most thoroughly.

But, first of all, great stress has been laid upon the hurtful effect of red light upon the eyes; but it seems to me as if the persons who urge this argument imagine that those who make, and those who use dry plates, did nothing but stare at their red light; but in all well-arranged works the eyes of the workers are not directed to the light, but to the work they have to do. The light, whatever it may be, should be arranged to illuminate the work, and shielded from the eyes. When you read a book or write a letter, your eyes are directed to your book or paper, not to the light, and the working of dry plates is, or ought to be, no exception to this rule.

As to the real cause of the evil, Mr. Bird, I think, hit the matter exactly, when he said:—"There can be no doubt that the sudden transition from dark to light is extremely trying to the eyes." If we consider for a moment the anatomy of the eye, we shall soon see how this is. The iris is the thin membranous coating, in the centre of which is seen the pupil of the eye. This pupil varies in size according to the action of the muscular fibres of the iris admitting more or less light into the interior of the eyeball, and the diameter of the pupil is so varied from about $\frac{1}{3}$ to $\frac{1}{10}$ of an inch. Now these muscular fibres, known as ciliary muscles, are brought into play by the amount of light presented to the eye; the stronger the light the more they contract the pupil, and the weaker the light the greater is the dilation of the pupil. But these muscles come into play comparatively slowly; if you go from bright sunlight into an obscured apartment, you can at first see but little; in a short space of time the muscles effect the dilation of the pupil, and you are enabled to see more or less perfectly; on the contrary, you go from an obscured chamber to brilliant sunlight, and you are pained and dazzled by the glare of light, but in a short time the ciliary muscles have succeeded in contracting the pupil of the eye, and, allowing no more light to enter than is requisite, vision becomes normal.

But here comes the moral of the story: the ciliary muscles act *slowly*, and *sudden* transitions from obscurity to bright light are hurtful; the sudden access of light strains the muscles in the effort to rapidly close the pupil; the remedy, of course, is to avoid sudden transitions; if necessary, to wear a veil, or enclose the eyes in protectors of gauze wire and coloured glass of the proper tint when leaving the dark room.

More than a year ago I read a paper before this Society upon "Photography in Relation to Colour." It will probably be within the recollection of those who heard that paper, and of those who afterwards read it as it appeared in the *Journal* of the Society, that of all the coloured bands I exhibited on the screen—which I have again placed before you—the yellow gave a greater sensation of brilliancy to the eye, while its photographic effect on a bromo-iodized gelatine plate was much less than any of the other colours. This fact, to my mind, showed the direction in which experiment should be made, for, other things being equal, there could be no doubt that the red light, then so common for laboratory illumination, was *per se* more trying to the eyes than a yellow light. The next step was to discover a material easily obtainable, which could be purchased commercially, either of the right tint, or capable of being made of the most suitable tint. After some search, I have found a fabric called bookbinder's cloth, no doubt procurable in many places. My samples were procured at Messrs. Berry and Roberts', 21, Bride Street, near Ludgate Circus. This fabric, in combination with a yellow paper, procurable wholesale of Messrs. Spalding and Hodge, Drury Lane, and retail at many dealers in photographic goods, has given in my hands a diaphanous screen which, while having quite sufficient illuminating power, is absolutely innocuous to the most sensitive plate.

To elucidate the question as to the best colour, I fitted up the lantern which I now place before you. You will observe that it is not unlike a magic lantern; it contains a paraffin lamp, and is opaque on three sides; it has a double bent chimney, to prevent the passage of white light and to afford ventilation. The fourth side carries two glasses, connected by a hinge of cloth, and so arranged that pieces of material to be tested can be readily placed between them. When this apparatus is used the lamp is lighted, the colour or combination to be tested placed between the glasses, and the sensitive plate exposed at a distance of eighteen inches from the screen, through which the light from the lamp must pass to reach the plate.

Before going further, permit me to call your attention to a chart of colours and combinations, with their symbols. The symbols have been written on pieces of clear glass, the size of the sensitive plates, in bold characters, with opaque varnish. It is evident that the portion of a sensitive plate underneath the characters will have been shielded by them from the light, whilst all the rest of the plate will have been exposed to its full power. Thus we shall find that the characters should come out clear, even though the rest of the plate has been fogged by the action of the coloured light.

THE CHART.

Colours and Combinations.	Symbols.
Ruby Fabric	R. F.
Orange ,, ...	O. F.
Yellow ,, ...	Y. F.
Ruby and Yellow Fabric	R. Y. F.
Orange and Yellow ,, ...	O. Y. F.
Ruby and Orange ,, ...	R. O. F.
Yellow Fabric, treated with Aurine ...	Au. Y. F.
White Paper ,, ,, ,, ...	Au. P.
The above two in combination ...	Au. Y. F. and Au. P.
Ditto, but with two sheets of the paper	Au. Y. F. and Au. P_2.

I made also many experiments with green fabrics of various shades, but I found a tremendous loss of light without the slightest corresponding advantage, and as I have no wish to overload my paper with useless material, I have thought it best to omit all reference to them, and only to bring before you those experiments which tend to practical usefulness.

I must now ask to have the light lowered, that I may pass before the paraffin lamp in my lantern the various colours and combinations that I have to bring before you.

I place between the glasses with which my lantern is furnished a single piece of the ruby fabric, and also exhibit the sensitive dry plate that has been exposed five minutes to the light passing through this ruby fabric, at a distance of eighteen inches from the coloured screen. Upon the sensitive plate was imposed a piece of clear glass bearing the letter "R," in thick opaque pigments; the portion of the plate under the letter has consequently been shielded from the light, whilst the rest of the plate has had the light full upon it for the five minutes. All the plates I shall show you have been fully developed for four minutes with a maximum dose of alkali. You will see that the R comes out clear on a decidedly dense ground, showing that one thickness of ruby lets through a great deal of actinic light. I now place a piece of the orange fabric in the lantern, and show you the result; you will notice that the orange has been even less efficient than the ruby.

* Read before the Photographic Society of Great Britain.

Now we pass on to the yellow fabric: you will notice how much brighter the light appears—that is, there is much greater illuminating power; yet the action upon the sensitive plate is actually *less* than with either the orange or ruby.

We will now put into the lantern combinations of these colours. We will take first, ruby and orange; the result is still a considerable veiling of the plate. Yellow and orange give less veil than ruby and orange. Ruby yellow give less veil than either of the other two, due no doubt to the protective power of the yellow.

It being quite clear that yellow gives more illumination, and has at at any rate as great a protective influence on the plate as either red or orauge, I decided upon adopting yellow as my standard colour, and my experiments were then directed to finding materials most suitable for a coloured screen, whether fabric or paper, or a combination of the two. I took some thin close texture white paper and coated it on both sides with a solution of aurine in varnish: dry plate negative varnish, 1 ounce, aurine, 1 dram. This had the effect of making the paper both tough and transparent. I also coated the yellow fabric with the same solution, and the results I will now place before you. The first is a thickness of aurined paper; this shows the veil considerably. I now put in a piece of the yellow fabric treated with aurine; the veil is still there in a very slight degree, much less than with the yellow fabric *minus* the aurine, the illuminating power being about the same. On placing the aurine paper and fabric together we get a screen that gives a good illumination and affects the plate very little; as a matter of practical experience, this screen is perfectly safe either for the making or the development of sensitive plates. I now place in the lantern one piece of yellow fabric and two pieces of aurined paper; this gives a fair amount of light, and its effect upon the sensitive plate is absolutely *nil*—no trace of the lettering can be made out. I consider this last combination absolutely perfect, either for daylight or artificial light, and should have no fear about working in a room lighted by a window of any size if covered by these materials.

As reference has been made to the *greens*, I tried them both as fabrics and coated glasses, and found them eminently unsatisfactory. Whenever a green can be got to have but little influence on the plate, it is always terribly low in illuminating power. I have brought a few of my experiments to show you, as the results were at any rate unexpected by me. I have here a dark green fabric, one thickness; it allows very few illuminating rays to pass, yet its action upon the plate is very great. The next is a light green—plenty of illumination, and the action upon the plate actually less than with the dark green. Dark green in combination with orange is better, but a lot of actinic light still passes. Dark green with yellow is a slight improvement on the former. Light green and orange is actually better than dark green and orange.

I think it is clear that of the three colours experimented upon—yellow, red, and orange—yellow has most illuminating power, combined with the least actinic effect upon the plate. I find for practical purposes one thickness of yellow fabric with one piece of paper treated with aurine to be absolutely perfect, to give a light comparatively pleasant to the eye, and to be perfectly innocuous to the most sensitive plate. For daylight I would advise one thickness of yellow fabric with two thicknesses of aurine paper to form the covering for a window of almost any size, with absolute security.

A most practical and convenient way of arranging these materials for the window of a photographic laboratory I find to be as follows:—Have an inner frame made to the window, let the lower third have another frame, which can be open to admit white light when necessary; cover this third with one thickness of yellow fabric and two thicknesses of aurine paper. Let the middle portion have one thickness of each; let the top portion have one thickness of fabric. Now, have a rolling blind, made of American cloth, fitted to the top of the frame. In taking the plates from the packet, placing in the dark slide, and commencing the development, use only the light of the lower third. When the development is well started the blind may be drawn up two-thirds of the way, and when the development is completed the blind may be drawn up entirely, and a flood of useful non-actinic light will pervade the apartment.

In some such way as this the working of dry plates will be found as easy and as pleasant as our old friend collodion, and by increasing the quantity of light gradually, the strain on the ciliary muscles of the eye will be reduced to a minimum, and we shall have fewer complaints of damage to the eyesight.

Correspondence.

THE REPRODUCTION OF DAGUERREOTYPES.

SIR,—In a recent issue of the PHOTOGRAPHIC NEWS, you adverted to it as a matter of fact, that, when faded silver prints are skilfully copied under the now attainable conditions, many of the details that by lapse of time or exposure had become altogether invisible, are satisfactorily reproduced.

I am led to enquire, whether the same success might be likely to attend the reproduction of any of the original plates of Daguerre and his *collaborateurs*, or whether within your knowledge any successful attempts to do this have been made?

It is now over forty years since, for the first time, I saw exhibited in a window in lower Holborn, one of the earliest Daguerreotypes ever brought into England. The picture was at that time an especial object of attraction and inspection, arising naturally from its seemingly miraculous minuteness of detail. Yet, unless looked at in a side-long manner, and from a particular stand-point, nothing could be seen but the spotless sheen of the silver plate. If I correctly remember, the view was of the Tuileries as it then stood.

Am I right in assuming that your remark, above referred to, might prove equally true as it respects these early productions of the camera?

That an unskilled attempt to copy such Daguerreotypes would be uniformly successful, I have some reason to doubt, for I happen to have in my possession more than one reproduction of a Daguerreotype portrait of a now celebrated personage—the original picture dating so far back as January, 1854.

In the best of these examples, a singular detail can be made out at a given spot—nothing less than a faint tracing of the crest of the family of which the individual was a member. This curious enblazoning would seem to have been etched into the epidermis with much skill and minute accuracy. Possibly it was effected in very early life, either with a pencil of caustic, the point of a lancet, or a needle. In any case, there is nothing to indicate the presence of colouring matter. Hence, no disfigurement would ensue; but only upon close inspection, that slightly enamelled appearance which a superficial cicatrice always presents.

As an unlooked-for agency of legal identification, the value of an authentic copy of that Daguerreotype, taken with all the accessories essential to a vivid reproduction of details, may be readily estimated. And the whole matter is one in regard to which photographers might be expected to entertain a lively interest.—With much respect, I am, sir,

W. MATHEWS.

THE FALMOUTH JUDGES.

DEAR SIR,—We notice that the judges still persist in saying our yacht studies are "elaborately retouched" in their report which appeared in last week's NEWS. After the explanation which was given last year, proving that they were not retouched, we consider that it has now become a malicious statement, and unless an apology or explanation is forthcoming, we shall not let the matter rest, as we consider our reputation at stake, and the accusation made most defamatory.—Yours truly,

G. WEST AND SON.

PACKING PLATES WHEN TRAVELLING.

SIR,—A correspondent recently asked in your columns for hints as to packing exposed plates when travelling. The plan I adopt, and find very satisfactory, is to obtain zinc boxes similar to those in which the makers pack the plates, the top fitting well down over the bottom. In each I place a good sized piece of washed Turkey red twill. As the plates are removed from the holder, I put

them on the twill, with a piece of clean paper between, and fold the twill over the top, and replace the cover. These boxes are quite light-tight, and two or three plates travel as safely as a boxful, if distributed in the portmanteau so as to have a good cushion of soft things, such as clothes, between them and the exterior.

I mentioned this method before in your paper, but repeat it, in case your correspondent may not have seen it.—Yours truly, GREENWOOD PIM.

Proceedings of Societies.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

A MEETING of this Society was held on Thursday, the 3rd inst., Mr. W. K. BURTON in the chair.

In a communication from the President of the Society of Amateur Photographers of New York, the following developing formula, emanating from Mr. H. J. Newton, was sent:—

Alkali Solution.

Granulated carbonate of soda	3 ounces
Carbonate of potash	3 „
Sulphite of soda	3 „
Water	1 quart

Dry pyro recommended, but if kept in solution, then formic acid is to be added, in the proportion of 1 minim to 4 grains of pyrogallol. Thus pyro 48 grains, formic acid 12 minims, water 12 ounces; 1 ounce of this pyro solution, ¼-ounce of alkali solution, and ¾-ounce of water, being the normal developer for an 8 by 5 plate.

Mr. A. L. HENDERSON could not see any advantage in the use of formic acid, which most likely would be inert; he thought the addition of glycerine quite as good.

Mr. W. COLES mentioned that in making up the formula it must be remembered that an American pint contains only sixteen fluid ounces.

Mr. W. E. DEBENHAM, after referring to an experience related some time ago by Mr. Cole—viz., that of a film completely dissolving when left during the night in the hyposulphite bath—passed round two commercial plates, presumably from the same batch, which had been left in separate hypo baths during the night. One image had disappeared, the other was uninjured. The bath in which the film dissolved was the older of the two, and somewhat weaker.

Mr. HENDERSON thought it due to an accumulation of ammonia through insufficient washing after development. He (Mr. Henderson) enquired if any great difference had been noticed in the speed of plates during the last few days. He found plates which four months ago registered 15 on the sensitometer, were as rapid as some recently made registering 22.

The CHAIRMAN said it was no doubt attributable to the high temperature. According to Abney, an increase in the temperature of a plate increases the speed, and *vice versa*.

Mr. HENDERSON had tried the experiment of thoroughly desiccating plates on a water oven; after the water became quite cold, the plates were exposed, and found to be quicker, and denser images were obtained. He also wished to know what is meant by the term hard gelatine—whether it is a gelatine that takes up a large or small quantity of water, dissolves at a high temperature or sets at a high temperature.

Mr. A. COWAN'S definition of a hard gelatine was as follows:—With given weights of any samples of gelatine dissolved in given quantities of water, the one which presents the strongest jelly when set is the hardest gelatine.

Mr. W. M. ASHMAN enquired if any one had given the ferridcyanide of potassium and hypo reducer a trial; he found it was all that could be desired, and perfectly under control. The proportions used were those published in the April number of the *American Photographic Times*, *i.e.*, a few drops of a five per cent. solution of red prussiate of potash added to sufficient hypo solution to cover the plate.

Mr. COLES preferred using stronger solutions; the strength he recommended in his recent lecture contained three grains of ferrid-cyanide per ounce.

A Member said he had succeeded very well by using the ferridcyanide first, then following with hypo; in fact, it was beyond all doubt the most perfect reducer known.

Mr. SUTTON passed round two prints from a Woodburytype block; one printed in the usual way, the other by the copper-plate system; in the latter case the centre was perfect, but the margins were not. Mr. Sutton considered he had been so far successful as to warrant him continuing his experiments.

A discussion then took place on the effect of pieces of cardboard and other papers used in packing dry plates. Several members gave their views on the subject, while some attributed the markings to pressure, others to atmospheric conditions, and some to impurities in the cardboard or paper employed.

The CHAIRMAN called attention to a useful table he had compiled (see "A B C of Modern Photography"), for calculating the stops of a Darlot's, or other series, according to the Great Britain Society's Standard.

Mr. J. BARKER had tried the plan of adding a small quantity of decomposed gelatine to an emulsion with a view to obtain density and speed, as suggested by Mr. Henderson and the Chairman at a recent meeting (see page 415). The suggestion was a valuable one, but care must be taken not to add too much, and the plates should be dried quickly.

Talk in the Studio.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The Exhibition of this Society, for 1884, will be held in the Gallery of the Royal Society of Painters in Water Colours, 5A, Pall Mall East, London, S.W., and will be inaugurated by a *conversazione*, open to members and their friends, at 8 p.m., on Saturday evening, the 4th of October. The Exhibition will remain open daily (Sundays excepted), from Monday, the 6th of October, until Thursday, the 13th of November. Admission (from 10 a.m. till dusk), one shilling. It will also be open every Monday, Wednesday, and Saturday evening. Admission (from 7 to 10 p.m.), sixpence. Members have free admission at any time, and will also be supplied with tickets to admit their friends. All packing cases must be sent (carriage paid), addressed to the "Photographic Society of Great Britain," care of Mr. James Bourlet, 17, Nassau Street, Middlesex Hospital, London. They may be sent *before*, but must arrive *not later* than, Thursday, September 25th, but no packing cases can be received at the Gallery. Pictures by hand will be received at the Gallery, 5A, Pall Mall East, on Thursday, September 25th, until 9 p.m. Photographic transparencies will be shown with the Society's optical lantern on Monday evenings during the Exhibition. Slides (which must not exceed 3¼ inches in height) must be sent in either on or before Thursday, September 25th (to come with other exhibits before the Judges of Awards), and will only be eligible for award when both the negatives and slides are the work of the exhibitor. Each exhibitor must send a letter of advice containing a description, as also a statement of process and any further detail, to be inserted in the Catalogue (and it is suggested that when the work shown is taken by a special process, prepared and made by the exhibitor, information as to particulars should be communicated), addressed to the "Hon. Secretary," Photographic Society of Great Britain, 5A, Pall Mall East, London, S.W. Each frame or picture may have the exhibitor's name and subject neatly inscribed, but no address or anything in the shape of an advertisement will be permitted. No pictures in Oxford frames, and no pictures previously exhibited in London, will be admitted. Photographs coloured by scientific or mechanical means will be admissible. Photographs coloured by hand will not be admitted. Negatives and transparencies will be admissible. Photographic apparatus and appliances may be sent for exhibition. No charge will be made to members of the Society for exhibiting their pictures; but to non-members, a charge of one shilling per square foot will be made for wall space—the minimum charge being five shillings—but no charge for wall space will be made to foreign exhibitors. It is proposed to lay on the table a catalogue containing the price of pictures to be disposed of; those who wish to avail themselves of this proposal will please state the price of their pictures in the letter of advice. Any further information respecting the Exhibition and *lantern slides* can be obtained from the Assistant-Secretary, Mr. Edwin Cocking, 57, Queen's Road, Peckham, S.E.

INSTANTANEOUS PICTURES.—An excellent series has been taken by Lieutenant David and Herr Seolik in Vienna; and the picture of the Corpus-Christi procession is of special interest, as the whole of the Court take part in this ceremony, the Emperor and the Imperial family accompanying the procession on foot from the Hofburg as far as the Church of St.

Stephen. The instantaneous picture secured by David and Scolik contains excellent portraits of the notable personages taking part in the procession.

DEATH OF MR. HENRY WATTS.—Chemical science has lost one whose name will always be remembered in connection with the literary history of the science, and although his magnificent Dictionary of Chemistry, now consisting of nine quarto volumes, may be regarded as his greatest work, his translation of Gmelin's Chemistry, his new edition of Ure's Dictionary of Arts, and his minor works, represeut no inconsiderable amount of labour. Mr. Watts held for many years the appointments of editor of the *Journal*, and Librarian to the Chemical Society, having been appointed to the former iu 1850, and to the latter in 1861. He was a Fellow of the Chemical Society, a Fellow of the Royal Society, and a Member of the Physical Society ; also an Honorary Member of the Pharmaceutical Society, and a Life Governor of University College. He was engaged at the time of his death in writing a new and abridged edition of the "Dictionary of Chemistry," and was also editing a re-edition of "Richardson and Watts's Technology," and the 13th edition of "Fownes's Manual of Chemistry," of which the second volume is left in manuscript. He died of syncope of the heart on the 30th ultimo.

GELATINO-CHLORIDE PAPER.—Dr. Just, of Vienna, has, during the past half year or so, manufactured sensitive gelatino-chloride paper according to the method given by Dr. Eder and Captain Pizzighelli. This paper is very convenient for making positive prints, and is exposed by a self-acting electrical arrangement. Good use is made of it at Vienna in preparing pictures of criminals. Stellmacher, the anarchist, when he recently attempted serious outrages, in Vienna, was not known by name, but in one night several hundred gelatino-chloride copies of his portrait were made, and by means of one of these portraits he was recognized at Dresden as a deserter. Dr. Just now manufactures the gelatino-chloride paper on a considerable scale.

DAGUERRE MONUMENT.—The Committee has rendered an account of its work to the subscribers. The subsriptions raised amount to fr. 8,119 95, but in the completion of the work much is due to the generosity of those engaged in its execution. M. A. Leclerc, for instance, architect of the Palais Nationaux de Versailles, who designed the monument, gives back his honarium as a subscription to the fund. A commemorative ceremony is fixed for the 27th inst., when M. Petersen, President of the Danish Photographic Society (among others) has signified his intention to be present. The unveiling of the statue took place in August last (see page 545 of our last volume).

PHOTOGRAPHIC CLUB.—At the meeting of this Club on July 16, the subject will be the adjourned discussion on "Focussing." Saturday out-door meeting at Hadley Wood. Train to Barnet, main line station, meeting afterwards at the "Old Salisbury Arms," High Barnet.

To Correspondents.

W. P.—Tolerably thick oil colour is best, only time must be allowed for it to dry. If this is inconvenient you may grind up water colour with albumen, and after having applied the colour you can render the material insoluble by the application of alcohol.

THE REV HENRY GEARY.—Your suggestion is an excellent one, and shall be attended to. 2. This matter is one which requires a few expertiments, but it shall be remembered. Thanks.

FLARE.—1. The stop is too near the lens; try the effect of removing it an eighth or a quarter of an inch further. 2. You may paint over the chipped part of the lens with black varnish, but this is not of so much importance as might be supposed.

CLAUD DOUGLAS.—As regards the shutter question you can read an article on page 435, and our advertisement columns will afford you the means of selecting suitable plates.

C. D. CUNNINGHAM.—1. Make a solution of one ounce of acetate of lead in eight ounces of warm water, and add two ounces of this solution to each gallon of the wash water. Half an hour should be sufficient if you adopt the lead method; but we do not recommend the use of lead unless in exceptional cases. 2. The best thing to use is Cowell's clearing solution (see the Formulary). 3. One ounce dissolved in a pint of water; but there is no objection to making it somewhat stronger than this.

CONSTANT READER.—1. It is difficult to give an approximate estimate of the cost, as so much depends on the extent to which upper part of the house will require alteration, and the condition of the roof; but between £50 and £100 may, perhaps, represent the probable expense. 2. You are more likely to lose than to economise by the use of second-hand building material.

R. S. BARRETT.—1. You put your muslin in the wrong place; it should be tied over the top of the teapot, not over the spout. By adopting this method you keep a reserve of filtered emulsion. 2. An ordinary chemical thermometer, with the scale either engraved on the stem, or enclosed in an interspace between the stem and a second tube. 3. Yes, to the boiling point. 4. It will make about four ounces. 5. Flood the plate and pour off the exeess, putting it back into the teapot through the strainer.

TONING.—The whole picture is fogged, excepting a rectangular patch, which includes the left arm. Probably this patch corresponds to a less sensitive place on the plate. Give less exposure.

PHOEBUS APOLLO.—(A) It has not come into general use, although the idea has been brought forward time after time, and films for negative work have been several times introduced into the market; and we cannot help thinking that the inconvenience of developing film negatives would be especially felt in a cross-country expedition. We would rather recommend you to obtain the thinnest glass, and either get it coated by a plate maker, or coat it yourself. (B) So have we, but except in a very few cases the film had been stripped from the plates, the original exposures having been made in the usual way. If you rub the glass plate with powdered French chalk, and dust off the excess before coating it with collodion, the film may easily be stripped off; and for this purpose all you have to do is to soak a sheet of plain gelatine in water until it is flaccid, and to squeegee it on the film. The edges must be clamped down with strips of wood while the film is drying. In the case of gelatino-bromide work, after having French-chalked the glass, coat it with plain collodion, and upon this pour the emulsion, after which the sheet of plain gelatine is squeegeed down as before. The sheet gelatine is the thick kind used by lithographers, and we have obtained it from Cornelissen, of Great Queen Street, Lincoln's Inn. (C) This we hardly think practicable, especially when far from the base of operation. (D) Well worth trying; and if you do not wish to enlarge the pictures very much, we think it would answer admirably. The address of the gentleman to whom you refer shall be sent to you by post.

H. and D.—We have not any doubt that the firm in question can supply what you require, and we have sent your letter on to them.

A. C. A.—1. A rather rapid exposure, and the use of a developer containiug a full proportion of bromide—perhaps twice the weight of the pyro. 2. Artificial light is to be preferred, as being less subject to variation than daylight, and you cannot do better than to use the "fabric" to which you refer. 3. For out-door work we may say that it has been entirely abandoned in favour of gelatine plates.

MUSICUS.—The pictures are very good indeed, and we are especially pleased with that containing only three figures. The remaining two would have been better if you had given a little more exposure, as there is hardly sufficient detail in the deeper shades. We have no hesitation in saying that they are fully equal, and perhaps superior, to the average of work shown at Pall Mall, and we hope that you will send us pictures occasionally in order that we may see how you get on.

The Photographic News Registry.

Employment Wanted.

General Assistant.—H., 115, Westmoreland-rd., Walworth.
Operator and Retoucher, from Paris and Italy.—N. E., *Photo. News* Office.
Recep. Room, Spot, &c.—A. B.—Orwell Cottage, London-rd., Twickenham.
Reception Room or Manageress.—M. E. C., 19, Oakley-cres., Chelsea.
Retoucher (pemanency).—Retoucher, 29, Brook-green-rd., Hammersmith.
Operator (Copyist) quick with children.—C. O., 25, Duke-st., Bloomsbury.
Operator or Manager, good all round.—W. W. 59, Queen's-sq., Bristol.
General Assistant at 30s.—A. B., *Photo. News* Office.
Improver and Assistant Operator.—E. D. G., *Photo. News* Office.
Retoucher & Reception-room.—A. D., 147, Victoria-pk-rd, S. Hackney.

Employment Offered.

Operator & Retoucher, dry-plate.—W. P., 5, Atkinson-place, Brixton.
Oper. (wet or dry) & Retoucher for country.—Apply, 70, Victoria-st., E.C.
Out-door Operator for groups, &c.—Hills and Saunders, Cambridge.
Neg. Retoucher, first-class.—T. William, 63, Darlington-st., W'hampton.
Operator & Retoucher (in-door).—Hills and Saunders, Cambridge.
Operator of ability.—Morgan & Kidd, Kew Foot-rd., Richmond.
Retoucher, Colourist, Spotter.—Photo. Co., 2, The Pavement, Clapham.
General Assistant (instantaneous work).—H. R. Sherborn, Newmarket.

CONTENTS.

REALISTIC PHOTOGRAPHS OF METALLIC OBJECTS.

ALTHOUGH many persons will prefer to have a plain print of such an object as a medal or a piece of plate, there are others who may think that a photograph showing a metallic lustre, and consequently very nearly resembling the original, is more satisfactory; and as it is very easy to make an excellent reproduction of a bright metallic object by transferring a transparent photograph to a metal or metallized surface, we propose to give some practical directions which will enable any person to make such reproductions.

The negatives for such pictures must be taken with uniformly dark backgrounds, as any light places would naturally show the metallic lustre of the backing, and the effect of the picture would consequently be completely spoiled. In short, the background should be uniformly black, and ought to be reproduced on the negative as clear glass, or something very near to it.

As far as our experience goes, the best reproductions of metallic objects are made by developing a carbon print directly upon a metal plate—copper, either gilt or silvered, being most convenient. The prepared copper plates, which are sold at a moderate price for use by the engraver, are extremely convenient, as they may be had in a great variety of stock sizes, while the prepared surface is smooth, and in a good condition for being gilded or silvered. It is not worth while for us to give directions for gilding and silvering, as such work is done at a very low price by the trade platers and gilders, who abound in Clerkenwell. The commercial "brown" tissue is a good colour for general work. As vigorous reproductions are generally required, it is well to use a rather weak bichromate bath for sensitizing—say about two per cent.; and in other respects the mode of working is precisely that recommended for making carbon transparencies on page 359 of the present volume, the metal plate being used instead of glass.

The direct method on metal renders it necessary to use a reversed negative, and when an ordinary negative is to be printed from it is necessary to transfer the carbon print from the support upon which it is developed, and this transfer may either be made upon a plate of metal, or upon a sheet of metallised paper. When the carbon print is to be transferred after development, it is best to develop it upon a flexible support, as directed upon page 332, and to transfer it to the metal plate or paper—gilt or silvered—in the manner directed for ivory on the one hand, and for canvas on the other hand.

As many of our readers are not so far practically acquainted with the process of carbon printing as to be in a position to make an occasional print with a tolerable certainty of success, it is satisfactory to know that excellent metallic pictures may be obtained by making a transparent picture upon glass, in such a way that the image shows unreversed when looked at through the glass, and backing up the transparency with a piece of gold or silver paper. Transparencies made by the gelatino-bromide process of Mr. Wellington (page 79) are excellent for this purpose, but collodion, gelatino-chloride, collodio-chloride, or, indeed, transparencies by any other process, may be used.

M. Geymet recommends a somewhat complex process of transfer with collodio-chloride, which we may summerise as follows:—A stout paper is coated with a moderately thick layer of plain gelatine, such a layer as would be produced by drawing the paper quickly over a solution of one part of gelatine in four of water, and this is coated with collodio-chloride, and printed as directed by Dr. Liesegang on page 772 of our volume for 1883. When toned and fixed, the print is placed in water at a temperature of about 80° Centigrade, and as soon as the edges of the collodion film become loosened by the dissolving of the gelatine, a clean glass plate, which is about half-an-inch smaller each way than the print, is laid on a table, and the collodion print is laid down smoothly upon it, and after all enclosed air has been expelled by stroking with the hand, the loosened edges of the film are turned over the edges of the glass. It will now, in all probability, be easy to strip the paper away, leaving the collodion on the glass plate; but if the gelatine should not be sufficiently softened for this, the back of the paper must be treated with a sponge saturated with hot water. When the paper has been removed, the same sponge serves to clear away all traces of gelatine from the film. A sheet of white paper is next taken and laid upon the film, care being taken to ensure contact all over by stroking it down with the hand or with a squeegee. The edges of the collodion film which were previously turned over the glass are turned back on the paper, and the paper, now carrying the film, is slowly stripped off the glass.

All is at last ready for transfer to the final support, whether this be gold paper, silver paper, or a metal plate; but this support should have been previously gelatined by having a solution of six parts of gelatine in one hundred parts of lukewarm water poured over it. The surface thus gelatinized is allowed to dry, but should be dipped in water immediately before the final transfer is made. The collodion film (now supported by the paper) is laid down on the final support, and the paper backing is next smoothed down with the hand so as to expel all air-bubbles, and the whole is allowed to dry. It is now easy to strip off the paper covering, and the picture should be varnished with an amber and chloroform varnish.

If it be desired to imitate the appearance of an old and

tarnished metal object—say antique bronze—a little green and yellow aniline colour should be added to the gelatinous mixture used in making the final transfer.

"SPARKLE" IN DRY PLATE NEGATIVES.

ONE of the very oldest complaints against gelatine dry plates is being revived. We used, when dry plates were first at all largely used, to hear on all sides complaints of their lack of power of giving density, contrast, or "sparkle." These complaints grew less frequent, and finally appeared to die out almost entirely. Certainly the work at exhibitions showed that a want of sparkle was at any rate not a *necessary* fault in a print from a dry plate. Now, again, after a year or two, during which there has scarcely been a complaint, we hear from all sides of a difficulty in gaining sufficient contrast in negatives.

What may be the cause of this we cannot say, but it is at any rate well to consider what can be done in the way of development to produce a negative of strong contrast.

There are some subjects in which the contrast of light and shade are so strongly marked that there is not much difficulty in getting strong negatives on almost any tolerable plates, but these subjects are possibly the exception. Under the class showing very strong contrasts, we can seldom class those, for example, which commonly come under the so-called "instantaneous" treatment which is now so popular. Subjects which are suitable for very rapid exposures have always very bright high-lights, but at the same time, even the shadows reflect much light, so that although there is a great deal of brightness, there is possibly not nearly so much range of brightness as there may be with a subject looking much darker, and requiring a very much longer exposure.

It is with the subjects of the kind mentioned, where the range of light is not great, that we require to use all our skill in the operation of development, so as to prevent the production of a thin useless negative.

We have in the case of most plates found that the greatest density could be got by the alkaline development, but there have been exceptions to this rule. We have occasionally had plates which would give considerably most density with a concentrated ferrous oxalate solution. We have found plates which gave green or red fog with alkaline development frequently give very dense images with ferrous oxalate.

It should be known that the strongest possible ferreus oxalate developer is made by shaking up dry protosulphate of iron in a saturated solution of neutral oxalate of potassium. The solution thus gained will, when there is added to each ounce of it about a quarter of an ounce of bromide of ammonium, make a very powerful developer, which will with some plates give a denser image than will any alkaline developer that we have tried. As a rule, however, we have found that the alkaline developer properly managed will give the best result. Here, at any rate, we have the means of introducing more variety than in the case of the iron developer.

In the alkaline developer we have three ingredients, the variation in the quantity of any one of which will almost as completely alter the nature of the developer as the alteration of either of the other two.

The three ingredients to which we refer are of course pyrogallol, ammonia, and ammonium or potassium bromide. It is generally conceded that the effect of increasing the first or the third of these—that is to say, either the pyro. or the soluble bromide—is to get a negative of greater sparkle. In considering, however, which of the two it is best to increase, it will be well to bear in mind that the two act quite differently. The pyrogallol is the active developer, and it is natural that to increase it causes increase of density. It might appear that we have nothing to do but to add in each case whatever quantity of pyro we find necessary, and we could put the requisite sparkle under any circumstances. This will not be found to be the case, however. It would appear that for every plate there is a certain strength of developer—as regards pyro—which gives a maximum of density, and that to increase pyro beyond this is simply to waste it. Exposing a number of plates for the same length of time, and using developers with constant quantities of ammonia and bromide, but varying quantities of pyro, we have found that increase of pyro meant increase of density up to a certain point; beyond that there was no effect at all produced except in some cases fog. With different plates the maximum useful amount of pyro appears to vary from one to four grains per ounce.

The action of the bromide in giving density is quite different from that of the pyro. The bromide has no active developing power, nor has it any power or even tendency in itself to produce density. On the contrary, it increases the time taken for density to be acquired. For example, if we expose the whole surface of two plates for similar lengths of time to the light of a candle, and develop them with developers the same in all respects except in that of the quantity of bromide contained, we will find that after a certain time has elapsed, the plate developed in the solution containing the less bromide will be the denser. Nevertheless, contradictory as it may appear, the developer containing the most bromide would give a denser negative than the other would.

The reason for the density-giving property of bromide is that it will keep the shadows of a negative clear, whilst the pyro and ammonia do their work for however long is necessary to get the required density in the high lights. Soluble bromide prevents the reduction of silver bromide which has not been affected by light. It has the effect of retarding the reduction of silver bromide which *has* been affected by light, but not of preventing it altogether—at any rate, not unless it (the soluble bromide) is in very large quantity.

There is thus no limit to the use of soluble bromide, as there is to the use of pyro; that is to say, there is no maximum to go beyond which will have no effect. The only question is how much bromide we may use without actually requiring a longer exposure to be given. Here we may say that no rule can be given. Some plates will be slowed by using a developer containing quarter as much bromide as there is ammonia. Others will not be slowed if there be a larger quantity of bromide than of ammonia. It depends entirely on the quality of the plate. As a rule, very rapid plates, and especially those made by the ammonia process, will stand large quantities of bromide without being perceptibly slowed. In any case it must be borne in mind that the thing which is of importance is the ratio of the bromide in the developer to the ammonia, not to the pyro. It is quite possible to have a very rapid developer with twice as much bromide of ammonia in it as there is pyro. All we have to do is to have in it several times as much ammonia as there is bromide. Again, we may have a developer as slow as we like with much less bromide in it than pyro, simply by keeping the quantity of the ammonia small.

The amount of sparkle obtainable varies greatly with the manner in which development is carried on. We have only to expose two similar plates similarly, and to develop one by allowing it to lie still in a dish of developer, whilst over the other we keep the solution in brisk motion. The latter will be astonishingly the brighter negative of the two. Again, those who have the patience, will find a marvellous amount of sparkle to be obtainable by the method of adding only a very little of the ammonia to the developer at first, and gradually adding more. We know some operators who will spend thus from half an-hour to an hour in developing a single negative.

RETOUCHING GELATINE NEGATIVES.

Many photographers varnish their dry-plate negatives, and then retouch them just as they were in the habit of retouching their collodion negatives, while others retouch directly upon the gelatine film; but it not unfrequently happens that the film is not in a condition to readily take the pencil markings, and in such a case the following mixture is useful:—

Ordinary oil of turpentine	...	100	parts
Common resin	...	2	,,
Venice turpentine... ...	...	4	,,

A little is applied to the film with the tip of the finger, and rubbed until dry.

Some years ago, Carroll recommended the use of a solution made by dissolving twelve grains of tannin, ten grains of gum, and one grain of salicylic acid in one ounce of water; this solution being distributed over the surface of the plate by means of a glass rod, and the excess drained off, after which the plate is allowed to dry.

An aqueous solution used in an analogous way is recommended by Re, of Jeletz, the fixed and washed plate being allowed to remain for a quarter of an hour in a solution of acetate of aluminium, after which it is allowed to drain and dry; and this mode of treatment can be repeated if the surface is not rendered sufficiently matt by the first operation. Negatives which have been properly treated with acetate of aluminium are as easy to retouch as gummed collodion negatives.

The acetate of aluminium solution for the above use can be readily prepared by dissolving one part alum in ten parts of hot water, and adding sufficient ammonia to throw down all the alumina—or sufficient ammonia to make the mixture smell of this reagent after a thorough stirring. The gelatinous precipitate of alumina is now collected on a cloth, and well washed; after which it is dissolved in a mixture of two parts of glacial acetic acid and one part of water. The acetic acid must be thoroughly saturated with alumina, and one can only be sure of this after it has remained for two or three days in contact with a portion of the precipitate. The solution of acetate of alumina should be filtered before use, and it must be kept in a well-stoppered bottle.

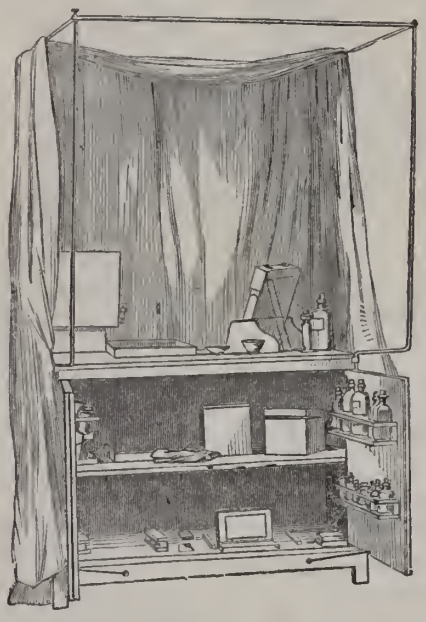
Practical Papers for Beginners.

HOW TO FIT UP A DARK-ROOM.

Photography depends upon the altering action of light upon the chemical preparations which are used in the making of the so-called sensitive surfaces, and in order to obtain an original photographic image (as distinguished from copies made by the numerous photographic printing methods) the well-known image of the *camera-obscura* is allowed to fall for a short time upon the sensitive plate. It must be noted that when the sensitive plate is removed from the camera no image is visible, and the action of light is only made apparent when the exposed plate is subjected to a process called development, and considering that the action of light on the properly-prepared sensitive surface is so energetic that an exposure of a fiftieth of a second to the subdued light of the camera-obscura is sufficient to determine the production of a picture, one might well suppose that the plate would have to be prepared, and the image developed, in absolute darkness. Fortunately, however, this is not so, as certain coloured lights exercise so little action upon the sensitive chemicals that the photographer can venture to use just sufficient of the coloured light to see what he is about. The dark-room of the photographer is not, then, an absolutely dark apartment, but a room lighted with coloured light, and as little of this as it is practicable to get along with, as no light is absolutely without action upon the plate.

The light admitted to the dark-room is filtered through a coloured medium, this medium being either placed over the window, or serving as a lamp screen if artificial light is used. But what colour is this medium to be? Yellow, orange, and red are the colours having the least photographic action, and either one of them may be employed.

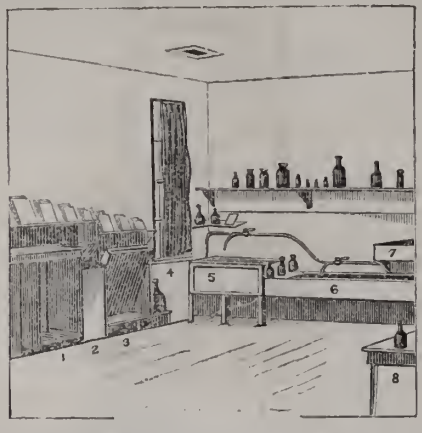
Before saying more about the dressing of the window of the dark-room, or the screening of the lamp, let the beginner determine what kind of a room he will have. In the old days of photography, when it was usual to "develop" a picture immediately after exposure in the camera, almost everyone possessed a tent or portable dark-room which could be taken out anywhere; but now-a-days, when tents are used at all, they are employed at home, and are erected in the corner of a study, in a library, or in a spare room. We do not recommend a tent for general work, but one who does not wish to prepare sensitive surfaces or plates for himself may manage to develop his pictures fairly well in such a tent as is represented below. No explanation is required, except to say that the black cloth covering must



hang over the rails in front, so as to entirely enclose the worker, who is enabled to see by the light passing through a small window made of coloured fabric. It is seldom, however, that the beginner cannot find some apartment which may be converted into a dark-room, either altogether, or as occasion may require. Even when the beginner knows that he will be the sole tenant of his new dark-room, he will seldom have sufficient determination of purpose to begin by taking all the white glass from the window of his future dark-room, and replacing it by two thicknesses of the stained red glass recommended by Captain Abney, as this would be equivalent to nailing his colours very firmly indeed to the photographic mast; but he will construct a light framework which will fit accurately outside or inside the frame of the window, and cover this with two or three thicknesses of the non-actinic fabrics which are, sold commercially; one thickness of the so-called ruby fabric and one thickness of the yellow or golden fabric as ordinarily sold, makes an excellent combination. Some shades of orange paper are also good. The frame should be so made as to be readily removed and readily replaced; this being a very essential precaution if exclusive possession of the room is not to be had. A few shelves for bottles, some kind of a portable sink—the outlet tube of which may lead into a pail—a large can of water, some square porcelain dishes, and a light-tight box or so for holding packages of plates that have been opened, completes the list of essential arrangements. The incipient

photographer who can obtain sufficient control of a bath-room to be allowed to fit up a few shelves and a small cupboard, is especially fortunate, as he has water supply—perhaps hot as well as cold—and a magnificent sink. In spite of the excellent qualities of a bath as a sink, it is convenient to so place the lid of an old box across the bath so as to afford a steady support for the photographic vessels; but a hole should be made in the box-lid, so as to allow the waste fluids to run freely out into the bath.

The subjoined cut represents a more completely fitted photographic dark-room or laboratory than the beginner will ordinarily possess, but it is easy to see how one may



arrange something which may serve very well as a substitute. Of conrse it is all very well for the advanced unprofessional photographer to fit up a comfortable laboratory, as represented above, with washing trough (5), sink (6), water supply, ventilator, and other convenient arrangements; but the beginner must generally make shift with something far less elaborate.

If it is intended to do all work by daylight, the arrangement described for screening the window with the coloured fabric or paper will serve very well; but as daylight is very variable in its intensity, and the photographer should have the means of regulating the amount of light admitted through the coloured window, it is advisable to provide a black blind mounted on an ordinary roller, this blind serving to more or less completely cover the coloured window, according to the intensity of the light. If the window is glazed with the "stained red" glass, the blind roller should be fixed in the usual position; but if, on the other hand, the wooden frame covered with the coloured fabric is made use of, the blind roller should be fixed on the top of the movable frame. Some prefer a black curtain running with rings on a rod, as shown in our sketch. At any rate, it is essential to have a means of partially shading the window when daylight is used, as during dull weather the

whole window may only give barely light enough to work by, whilst if the sun shines brightly it may be essential to stop out nine-tenths of the window area in order to ensure against such an excess of coloured light as would act injuriously upon the sensitive plates.

Owing to the constant variation of daylight, many prefer to completely block out the light of the window, and to work altogether by lamp or gas-light; and it is often better to purchase a dark-room lamp, whether for gas or for oil, than to make one. The foregoing drawing shows an excellent form constructed to burn paraffin oil.

As Mr. J. B. B. Wellington points out on page 407, a very convenient dark-room lantern may be extemporised by wrapping a piece of golden fabric round an ordinary tricycle lamp, the fabric being kept in position by means of an elastic band or string.

Before using the dark-room, it is necessary to very carefully cover any chinks which may admit white light, this being commonly done by tacking on strips of American cloth or other opaque material; and it is often essential to fasten such strips all round the door.

Our next Practical Paper will be on—"Preparing for Work with the New Camera."

FRENCH CORRESPONDENCE.

Progress of Photography in its Application to Ceramic Decoration.

This week's letter is dated from Limoges, where I am about to give my annual course of photo-ceramic lectures at the National School of Decorative Art.

It is becoming more necessary than ever to say a few words upon the use of photography applied to the decoration of porcelain.

Limoges is an important centre for porcelain manufacture, bringing in annually a considerable amount of business: and the art of decoration plays a part worthy of attention in the completion of the productions.

To decorate the ware, implies necessarily not only the use of various methods of painting or special printing, but also, in a country the good taste of which is incontestable, competent artistic knowledge. Unfortunately, talented artists are difficult to induce to make sacrifices, and the manufacturers, whose working principle is to make a profit, find it impossible to pay a good artist well, and have recourse to a decorator of second-rate talent. It therefore comes to pass that the work of the present day has depreciated in value and taste.

It is of no use thinking of introducing figures, copies of pictures, or landscapes, for they might appear as shapeless drawings badly coloured. One is therefore reduced to conventional flowers and ornament as being good of their kind, and superior to an ill-executed figure or landscape.

In the absence of good artists, however, by employing photography there is still a method open for the reproduction of pictures, figures, &c.

I have called the attention of the Limoges manufacturers to this important consideration, and moreover in the conferences have demonstrated the practical method of setting to work.

First of all recourse must be had to a means of transferring the original photograph, as in the Ives, Meisenbach, &c., processes. The negative being transformed into a typographic block, prints in blue ink are taken off to trace on tinted or striated paper. These papers are used instead of the lithographic stone in former demand. Each monochrome executed in black with pen, pencil, or brush, has only to be reproduced its actual size in the camera on plates capable of giving intense blacks and transparent whites. From these plates the images are printed on zinc coated with bitumen, and set to bite in acid, so that prints may be taken from them as from lithographic stone. To prepare the zinc plate, choose one thin and very smooth, coat with bitumen for receiving the

negative impression, and develop with spirits of turpentine. A bitumen image is therefore formed on the plate. It is next placed in a solution of copper, so that the plate is covered with that metal wherever the bitumen is absent. After washing with water and drying, it is finally immersed in benzine to remove all traces of the bitumen. It is then made to bite for forty seconds in a two per cent. aqueous solution of nitric acid. This gives a lightly grained surface, and the plate is ready for printing purposes.

Each print is made with fatty varnish in which is suspended the enamel colour. By employing this process, the services of a clever artist may be dispensed with. It is only necessary to have a man of taste in choosing the subjects to obtain charming effects. These details are taken from one of the most practical processes indicated by me at Limoges. It is to be wished that the industry of ceramic decoration will seriously take up photography, as it is capable of rendering such good service. Leon Vidal.

CARBON PRINTING.

Lesson V.

Carbon Tissue and Transfer Papers.

The foundation of both carbon tissue is gelatine, and, in order to simplify the manufacture of the tissue, the first step is to make a jelly as follows:—

Nelson's transparent sheet gelatine ...	10 parts
White sugar	4 ,,
Water	25 ,,

Soak the gelatine in the water until soft, then gradually raise the temperature until the gelatine is dissolved, and add the sugar; now submit to the action of a churn for half-an-hour, and allow to set. When set, scald off the frothy top with hot water, then turn the jelly out, and cut off the bottom portion so as to get rid of any grit that may have settled down, and the jelly is ready.

For a tissue giving a good photographic purple brown, take—

Vegetable black	72 grains
Alizarine lake	60 ,,
Indigo	13 ,,

Grind these materials with about four ounces of melted jelly, using a muller and slab or a cone paint mill, and add to six pounds of the above mentioned plain jelly, and mix well. In order to avoid the labour of grinding, one may make use of the ready-ground water colours sold in tubes, but in this case it is difficult to ensure making one's tissue of definite composition. In ordinary cases one may estimate the tube colours to contain about half their weight of colour.

For a black tissue—

Jelly	2 pounds
Paris black pigment ...	... 50 grains

For red or Bartolozzi tissue—

Jelly	2 pounds
Venetian red	3 ounces
Indian ink	8 grains

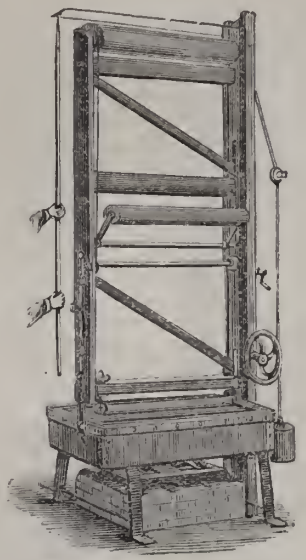
For transparencies—

Jelly	2 pounds
Indian ink	... 200 grains

The tissue compound being made, it is strained through muslin into a dish, this standing in a larger dish containing hot water, and if this outer dish is of metal, a spirit-lamp or Bunsen-burner will be convenient to keep the water at a constant heat, and so prevent the tissue compound from setting.

The paper that it is desired to coat is now rolled up tightly face outwards, and the roll is laid upon the surface of the tissue compound, the loose end being gradually raised, when the surface of the paper will gather up a thin and even coat of pigmented gelatine. The length of paper being coated, it is placed over a stick and allowed to dry.

For commercial purposes the paper is coated by means of a machine, an illustration of the late Mr. Spencer's being here given.



At the bottom will be seen a water-bath arrangement for keeping the composition warm, and after a long strip or band of paper has been placed over the system of rollers, and the ends made fast to each other with sealing-wax, the whole is lowered down till it comes in contact with the composition, and the band of paper is made to pass over the gelatinous mixture at the rate of about a foot in two seconds. When the whole of the band has been coated, it is divided at the join and hung up to dry. The roller which is shown as hinged on projecting arms, serves to keep the band of paper tense, and the rod shown as being held at the left hand side of the machine, is for taking off the wet tissue; the horizontal extension-piece being placed under the band at the top.

For making double transfer paper, take of—

Hard gelatine	1 pound
Fine sulphate of baryta or permanent white	8 ounces
Water	5 pints

Mix thoroughly, and stir in a solution of 50 grains of chrome alum in four ounces of water.

For a single transfer paper take—

Hard gelatine	1 pound
Water	5 pints

Churn for a quarter of an hour, then add 300 grains of chrome alum dissolved in a pint of water; this will make the liquid somewhat thick and ropy, but sufficient acetic acid must be added to restore it to its original fluidity.

Paper is coated with either of these two compounds in the same way as with the tissue compound.

THE SPECTROSCOPE AND ITS RELATION TO PHOTOGRAPHY.

by C. Ray Woods.

XII.—The Application of Photography to Spectroscopy.

The aid which photography has given to the work of the spectroscopist pure and simple has been great; but to give it in detail would be beyond the limits of a series of articles written for photographers. In considering this subject, therefore, it is advisable to consider, mainly, the methods which the spectroscopist has adopted, more than

the results he has arrived at. The subject may conveniently be divided into two parts—1st. Solar and chemical work, which are too closely connected to be treated as separate subjects; and 2nd. Stellar spectroscopy.

When the chemist has recourse to the spectroscope in a purely analytical examination of some compound, or mixture of compounds, there is no real necessity for photography to be brought in at all. The elements are recognized by their most important lines which the chemist is in the habit of observing, and even when some unlooked-for line is noticed, the eye observation and measurement are relied on as affording the quickest and readiest means of determining its cause. In advanced research, however, when it is desired to notice the molecular nature of the substance under examination, photography has proved a valuable auxiliary, more especially in recording what takes place in parts of the spectrum that the eye is not able to take cognizance of. And when, again, the source of light is too weak for eye observations to be definitely made, photography, by its power of accumulating impressions, as it were, has done a great service; for instance, in examining faint flames, or in resolving the comparatively faint light given by the electric spark in highly rarified medias. In such cases, however, the simple method of procedure is to obtain as high a dispersion, either by prisms, or by the diffraction grating, as may be found necessary, and to direct the spectroscope to the source of light, and insert a plate in the camera attached to the instrument.

But when examining the light from the sun, it is found that so innumerable are the number of lines in the spectrum, and so greatly does that number increase when a higher power is brought to bear upon them, that eye observations are too tedious, and many lines are found to be overlooked. One has only to refer to the celebrated map produced by Dr. C. W. Vogel, of the Potsdam Observatory, and to compare it with the celebrated map produced by Angström by eye observations only, to see how great an advance the former is upon the latter. A few figures bearing on the subject may not be without interest. In a portion of the blue near G, a region accessible to both the eye and the plate, but more so to the latter, Angstrom measured 94 lines, Rutherford photographed 275 lines, and Lockyer photographed 412. In regions which are only just within the ken of the eye, the reader need scarcely be told that the superiority of the photographic record is still more marked. In solar work, when the behaviour of some particular line or lines is in any way remarkable—and this is frequently the case—it becomes absolutely necessary to ascertain what element the line or lines in question belong to. It is for such work that careful and elaborate mapping of the lines of all the metallic and non-metallic substances known here is most desirable, and for this work the photographic plate is most in request, except in recording the lines in such portions of the spectrum, such as the green and yellow, that lend themselves most readily for eye observation. At present we have chiefly to rely on the work of Kirchoff, Angström, and Thalèn, for the coincidences of terrestrial spectra with dark solar lines. These workers did not make use of photography, and it is worthy of note that the first-named lost the use of one of his eyes in compiling the laborious piece of work that established the existence of

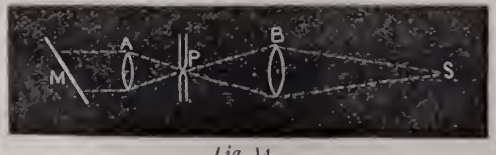


Fig. 14.

many terrestrial substances in the sun. Some time since, Lockyer commenced mapping the metallic spectra on an extended scale, but only a very small portion of it has as yet been published. The foregoing diagram will explain his method of working.

The sun's rays are thrown by means of the mirror M, driven by clockwork, on to a lens A, which forms an image of the sun between the carbon poles, P, of the electric arc. A second lens, B, throws the image of the sun, and also of the carbon points, on to the slit, S, of the spectroscope. By this means the light of the sun, and also that of the metal placed on the poles, come from the same point before entering the instrument. The slit of the spectroscope has an arrangement for opening only one-half of the slit at a time, so that first the arc and then the sun, or *vice-versâ*, are impressed on the plate, one appearing above the other. A little consideration of the conditions of working will show that the coincidences of metallic and solar lines cannot fail to be very precise.

The best map until very recently of the ultra-violet portion of the spectrum, that we have, is that produced by Cornu, and Professor Hartley has been assiduously mapping the metallic lines in that region. Professor Rowland has lately, by means of his beautiful gratings, produced a magnificent map of the solar spectrum by means of photography, and by drawing a scale of wave-lengths on the original negatives, the whole can be reproduced by photo-mechanical methods without the intermediation of the draughtsman. The mechanical arrangement adopted by Professor Rowland in using his curved gratings, in which the focus is obtained automatically by means of trammels, is shown in the following sketch.

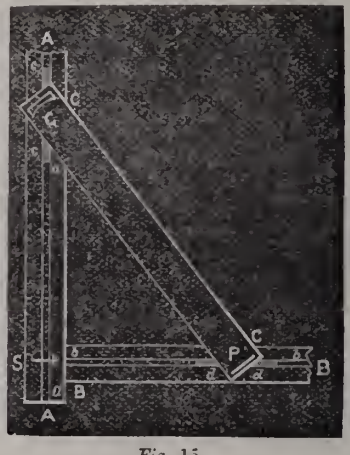

Fig. 15.

A A is board with a groove, *a a*, along its centre. At the point where the slit S is fixed, another board, B B, is joined on at right angles. This board has a similar groove, *b b*, the position of the slit being opposite the centre of the groove. C C is a board carrying the grating G, and the ground-glass or photographic plate P, the distance of the two apart being exactly equal to the radius of curvature of the speculum on which the grating is ruled. At points exactly beneath the centre of grating and plate, the board C C is fixed by means of a single screw on to pieces of wood, *c c*, and *d d*, that slide along the grooves. In whatever position the board C C is placed, the plate is always in focus. Of course it is necessary to keep out extraneous light by covering the whole arrangement, or using long bellows or boxes open at both ends. Photographers will probably find this the most convenient arrangement, but there is another method shown diagramatically on the following page.

From the centre, C, a circle is drawn with a radius equal to half the radius of curvature of the speculum. The grating G, the slit S, and the plate P, may be placed at any part of this circle, and the plate will always be in focus for whatever part of the spectrum may be at that place; of course the slit must always be directed towards the grating, and

the plate be tangential to the circle. It can be stated from the writer's personal knowledge that this method has been adopted by at least one eminent spectroscopist in America, and another in England.

Fig. 16.

In photographing the spectra of stars, planets, nebulæ, &c., the difficulty to be overcome is the feebleness of the light when it is spread out in the form of a band. Dr. Huggins, the principal worker in this direction, uses the reflecting form of telescope, and focusses the image of the object upon the slit of spectroscope, and throughout the long time of exposure has to carefully keep it there, it being practically an impossibility to get the clock of the telescope so accurately adjusted as to follow the motion of a star with unfailing accuracy. The spectroscope has lenses of quartz and a prism of Iceland spar, both these substances being highly transparent to the ultra violet rays. The minute, but sharp and beautiful spectra which Dr. Huggins has been able to produce of the light from some of the stars and nebulæ, and of those occasional celestial visitors, the comets, testify to the usefulness of photography, and more especially modern rapid dry plates, in this delicate research. On the other side of the Atlantic, too, the late Dr. Draper has done useful work in this direction. The evidence, too, which Dr. Draper obtained of the probability of the existance of oxygen in the sun is yet another valuable outcome of photo-spectroscopic research.

Nor must mention be omitted of the work of Captain Abney in examining that invisible portion of the spectrum which lies beyond the red, and his work in conjunction with Colonel Festing in investigating the absorption spectra of organic compounds, and establishing evidence of the existence of hydrocarbons between the earth and the sun. Without photography, such research would have been impossible. The utility of photo-spectroscopy in eclipse work, and its discoveries in relation to the corona, has too recently been before the readers of the NEWS to need more than a passing remark in this place.

This article, and the preceding ones, profess to be little more than a sketch, and there have necessarily been many omissions, but, it is trusted, not important ones. It has afforded the writer considerable pleasure to write them, and in concluding them, he trusts that he has at least made good use of his space, and that his readers will kindly pass over any shortcomings there may have been in them, apart from actual inaccuracies, which at least he hopes he has avoided.

A Dictionary of Photography.

AMADINE, an old name for *dextrine.*

AMMONIA AND AMMONIUM SALTS.—Ammonia is, at ordinary temperatures, a gaseous body, and contains hydrogen and nitrogen in the proportions indicated by the formula NH_3. It is possessed of the well-known pungent smell and very powerful alkaline properties. At a temperature of about —40° C. it becomes liquid, at —75° it solidifies. The substance sold in the shops as liquid ammonia is a saturated solution of the gas in water, and the commercial preparation has usually a specific gravity of about ·881, and contains something over one-third of its weight of ammonia. Ammonia is very largely used in the arts, and also by the photographer, one of its most important uses being in compounding the alkaline developer; and it is also used by many for fuming albumenized paper before exposing in the printing-frame (*see* ALBUMENIZED PAPER, PRINTING ON). Ammonia enters into combination with acids, forming salts which are supposed to contain a quasi-metal, NH_4, this group appearing to act in combination like a metal. Several of these salts of ammonium are of considerable importance to the photographer. The **Bromide of Ammonium**, $NH_4Br=98$, is very soluble in water, and is appreciably soluble in alcohol or ether; its main photographic use is to form bromide of silver by double decomposition with the nitrate. The **Carbonate of Ammonium** is a salt which occurs commercially in semi-transparent lumps having a strong ammoniacal odour, and when exposed to air for some time a large portion is lost by evaporation, and a compound remains which may be regarded as a bicarbonate. Carbonate of ammonium, when used for photographic purposes—as, for example in compounding the alkaline developer—should consist of translucent lumps without any friable incrustation on the surface. The **Chloride of Ammonium**, $NH_4Cl=53·5$, commonly known as **Sal-Ammoniac**, is a salt which has been known from very ancient times, and has many commercial uses. The photographer makes use of it in salting paper, and in other cases when chloride of silver is to be produced by reaction with the nitrate. The **Hydrosulphate of Ammoninm** and the **Sulphide of Ammonium** may be obtained in solution by passing a stream of sulphuretted hydrogen gas into an aqueous solution of ammonia; the former being formed if the ammonia is in excess, and the latter when the sulpheretted hydrogen is in excess. The solution of hydrosulphate or sulphide thus obtained is used occasionally in certain intensifying processes, as, for example, that of Eder or Toth. Its action depends on its power of converting certain metals of the first group into black sulphides. The **Iodide of Ammonium** is a somewhat unstable salt, and is almost always met with discoloured from the presence of free iodine; but if kept *absolutely dry* and in the dark, it may be preserved without change. Being much more soluble in alcohol and ether than other iodides, it has been extensively used for iodizing collodion. The **Sulphocyanate of Ammonium** is a deliquescent salt which is manufactured from the ammoniacal liquor of the gas works, and it has been proposed to use it as a fixing agent; but, up to the present, it has been very little employed by the photographer.

AMMONIO CITRATE OF IRON. *See* IRON.

AMMONIO NITRATE OF SILVER. *See* SILVER.

AMORPHOUS (à negative prefix, and *μορφή* shape)—A term applied to any modification of a substance which exhibits no crystalline structure; such forms of carbon as lamp-black or charcoal being termed amorphous to distinguish them from the crystalline varieties, like diamond or plumbago.

AMPHITYPE (*ἀμφί*, on both sides).—A process of Sir John Herschell, in which light produces either a positive or negative. Paper is first prepared with a solution either of ferro-tartrate or ferro-citrate of mercury, and then with a solution of ammonio-tartrate or ammonio-citrate of iron, the latter solution being in excess. On exposure in the camera, a negative results. This gradually fades in the dark, but may be restored as a black positive by immersing it in a solution of nitrate of mercury, and ironing it with a very hot iron.

ANGULAR APERTURE.—The angular aperture of a lens is the angle which its diameter subtends at its focus; or, in the case of a lens stopped down, the angle which the opening in the diaphragm subtends.

ANHYDRIDE (à negative prefix, and *ὕδωρ* water).—A term applied to those oxides which form acids by unity with water.

ANHYDROUS (derived as above), free from water. Anhydrides are often spoken of as anhydrous acids.

ANILINE PROCESS.—A process of printing originated by Willis in 1864. Paper is sensitized with:—

Saturated sol. of bichromate of potassium	4 ounces
Sulphuric acid	1½ drachms

Exposure is made under a positive if a positive is required, and development is effected by placing blotting-paper saturated with aniline at the bottom of a dish, and the exposed paper is supported over it. Simple washing serves for fixation. Sometimes it is convenient to dilute the aniline with fifteen times its volume of benzole. Exposure is about one-third that required for a silver print.

ANTHOTYPE.—A process of printing which depends on the sensitiveness of the colouring matters of certain flowers, the coloured juices being extracted by pressure.

ANTHRAKOTYPE.—(*ἀνθραξ*, charcoal).—A method of copy-

ing tracings, &c., due to Pizzighelli. The process gives—like the aniline printing process—a positive picture from a positive; it depends on the same principle as the (so-called) dusting process. Paper is coated with gelatine, sensitized in a chromate bath, dried, and exposed behind the drawing to be copied, immersed in water a short time, is blotted off, and dusted with any fine powdered pigment, washed again, and rubbed with a soft sponge for removing the superfluous colour. In this way pictures in any colour can be produced—plumbago, ultramarine blue, green, sepia, cinnabar, gold, silver, bronze, &c.

Notes.

In reproducing some of the photographs taken by the late Mr. Baden Pritchard during his trip to the Sahara, we are doubtless meeting the views of those who would like to have some memorial of his last holiday-trip.

The first of the series, which forms our supplement this week, is a view of Algiers. Can we do better than quote some remarks from Mr. Pritchard's own account of his journey?—"Algiers is never seen to better advantage than when you first sight its white-terraced houses, tier above tier, bordering the sunny bay, the blue water flecked here and there with snowy sails. The Grand Mosque, with its huge white dome, is a wonderful landmark, while the magnificent stone quays—all seen at their best as you come round the bend of the railway—and the fine old-fashioned harbour, compose a superb picture."

No profession requires more tact and talking power than photography. As a rule, people don't know what they want, and have to be gently pilotted into what the photographer knows is best for them. But when somebody who has made up his mind as to what he does want presents himself, the task of the photographer is a hard one, for in ninety-nine cases out of a hundred, the sitter, without knowing it, has made up his mind to be ridiculous. Some time ago a clergyman waited upon one of our best known photographers, and insisted upon being taken in a devotional attitude—"not exactly praying, you know, but with the eyes uplifted to heaven." He had his wish gratified, but speedily came back with the proofs, observing that the photographer had utterly failed in making him look pious, for on showing the picture to an old college chum, the latter irreverently remarked that he "looked like a dying duck in a thunderstorm." He asked for a re-sitting, adding that he had come to the conclusion that in the matter of portraits there was nothing so safe as the common-place, with which sentiment the photographer cordially agreed.

To write home on a post-card is an advantage which was not enjoyed by the tourist of a few years ago, and at the present time anyone who writes from Heidelberg on a post-card can at the same time send an excellent photograph of the castle.

The collotype occupies about one-fourth of the space on the card, and contrasts very favourably with the old-fashioned steel-engraved note-paper heading of English holiday resorts.

Let us suppose a series of twenty or thirty views of London, each to be had on a post card. How many thousands would go to the uttermost ends of the Postal Union with such a remark as "St. Paul's, as seen when fog, dust, and smoke were absent": or we can imagine one of Mr. Cobb's instantaneous pictures of active street traffic in London being sent into the wilds of Texas endorsed, "This is the dangerous river I have just crossed.' If the cards were to be had, some visitors would send hundreds away to their friends.

Post-cards can be had in sheets. The printing could be done by collotype, or the method by which Messrs. Sprague and Co. print our supplements; and the cards when cut up might be sold at a penny with a good margin of profit. Will Mr. Cobb or Mr. York take the hint?

We wish we could name the Heidelberg photographer whose idea is such an excellent one, but there is no imprint on the card.

The very latest photographic "fad" in Paris is for the fashionable swain to have the portrait of his lady-love photographed on his thumb-nail! At least, so says the *Graphic*.

A suggestion made by Captain Abney, to be found in our last number, will prove valuable to the tourist who takes a camera along dusty Continental roads. The inside of the dark back is to be rubbed over with glycerine—a mere trace, of course, as all excess must be wiped off with a dry rag.

The glycerine forms a veritable trap for that dust which will penetrate even the very best cabinet work; and the dust adheres to the sticky surface instead of making pinholes on the plate. Of course, the slides must be carefully wiped before fresh plates are put in.

The amateur photographer looked sad and troubled. It was his first attempt, and he had been trying for an hour and a-half to weigh out pyrogallic acid on the kitchen scales with a quarter of a pound weight and small shot from the gas chandelier!

A barge race on the Thames is hardly suggestive of much romance, and yet Messrs. West and Sons, of Gosport, have made a series of excellent pictures of the "event" which took place on the third instant. The photographs of the *Gibbons*, the *Electric*, the *Louisa*, and the *Bessie* show that the heavy river craft may be really elegant and even graceful when rigged out in full sail. The last-mentioned picture pleases us most, as the white foam thrown up by the bows, the tense sails, and the long trail behind, all give an excellent idea of motion; while the almost microscopic

detail is really surprising. A small whitish streak attracts us—no doubt a trifling defect in the negative—but by using a magnifier we find it is merely the name and address of the sail-maker—"Gill and Sons, Dorchester."

It is to be regretted that the Cornwall Polytechnic Society should so persistently state Messrs. West's pictures to be "elaborately retouched"; and after the correspondence which took place in our columns last year there is no excuse for a repetition of such a statement in the judges' revised report as just printed. We have noticed no evidence of retouching in any one of Messrs. West's yacht pictures which we have seen, and we have seen nearly all.

What Mr. Rockwood says:—"My ideal of the best photographer is one who is most the Chesterfield in his manners. A Daniel Huntington in his art, a Bacon in his range of information, a small edition of Shakespeare in his knowledge of human nature, and is possessed of the genial humour of Dickens." "But why should a photographer be all this?" asked the interviewer. "Because," answered Mr. Rockwood, "as sure as the chameleon reflects the hue of its surroundings, so is the sitter to reflect in some measure the mood of the photographer who sits him."

An Electrical Exhibition will be opened in Philadelphia during September.

The second period of excitement regarding electric lighting may now be considered over, and each week we find that an Electrical Company has quietly passed out of existence.

When electric light was talked of and exhibited twenty-five years ago, comparatively little capital was invested in it—perhaps not ten thousand pounds altogether; but the case is different at present, as individuals have now risked and lost as much as this.

Still much good has been done. New points have been elucidated, and knowledge has been gained. It might have been better, however, to have invested the money in technical schools: but the public would not have put down the money for educational purposes, so the greed of wealth has advanced science.

The student may now purchase electrical apparatus cheaply enough. Indeed, at the odds and ends market which takes place near the Caledonian Road of a Friday afternoon, we have bought incandescent lamps, carbons, the armature of a dynamo, and resistance coils for as many sixpences as they cost pounds a few months ago. "If you will not give seven pounds, what will you offer?" said the proprietor of a lumber shop in the Waterloo Road to us this week, as he pointed to a dynamo of the Siemens type; "there is five pounds worth of copper-wire on it." Here is a fall!

Lord Rayleigh, in speaking of his colour-mixing apparatus the other day, remarked that he himself was exceptionally insensitive to red, and Professor Guthrie claimed for himself exceptional sensitiveness to the blue rays. It is very easy to now understand the difference of opinion as to the relative brightness of the lights recently shown at the meeting of the Photographic Society.

The colour-mixing apparatus referred to above is an optical arrangement for combining different parts of the spectrum.

A spherical water lens, an old camera box, and a strip of sensitive paper, are the three elements which build up Professor McLeod's sunshine recorder. The record is a well-defined black line.

Colonel Hoe, the printers' engineer, says that printing will ultimately give way to photography. He thinks that through a negative of one side of the journal it will be possible to flash a ray of electric light a hundred times a minute, which ray may be made to fall on a web of paper passing under the negative.

We should like to know whether Colonel Hoe reads the NEWS, and more especially if he ever read the remarks contained in an editorial on page 2 of our volume for last year.

A correspondent who is good enough to call our attention to the very poisonous nature of the fumes from the pyrotechnic mixture recommended by Mr. Frewing in our issue of last week, failed to notice that Mr. Frewing himself says a word of caution. But in dealing with arsenical vapours one can hardly be too careful, so those who use Mr. Frewing's lamp for photographic purposes should especially note the last paragraph of his paper (page 440).

Papers of photographic interest at the British Association are rare now-a-days; but we may note this year the British Association at Montreal will almost join hands with the American Association at Philadelphia. The former meets on August 27, while the latter has fixed its opening day for September 4th, so as to be able to receive such of the Britishers as can be present.

Mr. S. P. Langley's article in the American *Journal of Science* on "Experimental Determination of Wave-lengths in the Invisible Prismatic Spectrum" has been translated into the *Annales de Chimie* for June, and is pronounced by the *Athenæum* to be of great importance in connection with the article published by M. H. Becquerel in the *Annales de Chimie*, and Captain Abney's Map of the solar spectrum.

Mr. Francis Galton's efforts to secure tabulated records of family history by means of his "Record of Family Faculties," in which all that one knows of one's ancestors is to be set down, have, we understand, been very successful. He now possesses reliable data concerning the history of a hundred-and-fifty families, and five thousand persons. This material

abounds with curious and interesting facts, but of course requires to be sifted and arranged, a task which Mr. Galton will doubtless enter upon with much zest. Mr. Galton's second proposition, the "Life History Album," which, besides the details of your life, is to contain a photograph of you taken every five years, is much more difficult of attainment, and from its very nature can only be dealt with by a philosopher upon whom Mr. Galton's mantle may fall.

THE USES OF A BACKGROUND.

BY A. H. WALL.

There is a stale old story about Sir Joshua Reynolds which I've no doubt you have often heard. The great P. R. A. was asked why he did not engage inferior artists to paint his backgrounds. Sir Joshua replied, "The man who could paint my backgrounds could paint my pictures."

These words gave expression to a very simple commonplace truth, which every artist recognizes; but for the young in art here are a few briefly expressed reasons, more fully illustrative of Sir Joshua's meaning, intended to demonstrate, for those who are students of art photography, that a background is really a most important and powerful agent in the production of a good picture.

1. The background, by conveying an impression of space behind the head and figure, gives that very important and effective quality, relief.

2. By a set of creative contrasts, cleverly realised, it gives to the high lights increased brilliancy, and to the deepest shadows greater intensity.

3. By excluding *destructive* contrasts, it increases the refinement, delicacy, and subtlety of the half-tones in light, gives new value to the intermediate uniting tints, and transparency to the deepest shadows and reflected light.

4. By enabling the artist to increase greatly the scale of gradations between the highest lights and the strongest shadows, the modelling, or rounding out, of the heads and figures becomes more powerful or vigorous.

5. It enables him to give the outlines that mellow softness which conveys the idea of surfaces retiring from the eye, and thereby gradually becoming invisible, instead of an appearance of flat sections with abrupt terminations. By blending with itself some of these boundary lines, and giving others prominence, it introduces that variety which makes the general effect rich and pleasingly picturesque, while it at the same time emphasises the expression of both space and relief.

6. By the background's aid we can soften, render less conspicuous, or altogether conceal any portions of a figure, face, or drapery which are unavoidably inelegant or ugly, or, for other reasons, undesirably conspicuous; and, on the other hand, by its assistance we may increase the prominence of parts which are elegant and beautiful, or most powerful in conveying the ideas we desire to impress upon the spectator's mind.

These are but a few of the many important uses an artist finds for his background, and as they concern chiefly light and shade, they of course apply as forcibly to photographs as to pictures painted in colour. A background of one uniform tint, upon which a flat even light falls, is, in reality, no background, for it does not serve the purposes of a background. It is a flat wall with nothing on it to convey ideas of space or atmosphere, and in a painting or a photograph gives, consequently, a flat cut-out-and-inserted effect (which is altogether inartistic) to the object placed before it. I know that our ordinary photographer is commonly apt to consider light and shade effects solely with reference to his living models. But this is a mistake. An enclosed space behind the model, with its own real light and shade, its own depths of space and reflected lights, will give effects strikingly superior to those obtained by a flat screen placed a foot or two behind a sitter. A space running back for some little distance, dimly lighted and containing objects which will indicate various degrees of retirement, enable you to vary your light and shade behind the sitter, or to vary the sitter's position relative to them, until you see upon the ground glass that the very best effect attainable has been achieved. You would then photograph real space, not pretended space, and you could choose from a wide diversity of effects, created by admitting or excluding subordinate lights and shadows, that which would be most desirable, instead of having either a never-changing blank flatness of wall surface upon which the only shadow thrown must be that of the sitter, or effects of chiaroscuro which are alike for all sitters, and suppress the exercise of everything like taste, judgment, sentiment, or artistic feeling. Then the individuality of the artist could find expression in his work in a much higher degree, and to a much wider extent than it now does, and one good photographer's work would not look so much like that of all the others. The mind that conceived could then take precedence over the lens that created this or that image, and the suggestions embodied in my six short paragraphs would be of solid, practical value and importance. All the possibilities I have briefly enumerated are impossibilities with the ordinary painted screen background, which never really looks like anything but a painted screen. A background chamber so ingeniously constructed and arranged that one could readily vary its effects, with a plan to enable us to re-arrange and alter its lighting, always subordinating its lights and darks to those on the model, and covering so much space lengthways that the artist could move his models to the right or left with the above ends in view, is, I think, the background most to be desired.

For those operators who have not the requisite space at their disposal, the best substitute would be, perhaps, a graduated background, moving from right to left, panoramic fashion, upon upright rollers, and painted in gradations of simple light and shade, so that the smallest turn of this or that roller would give a change of lights and darks, and successive turns changes more strongly marked. With such a background delicate features in a portrait need not be rendered feeble and flat by too strong contrast with a dark, vigorous background, while features too staringly prominent need not have greater prominence awarded them by contrast with the soft and delicate gradations of light and shadow in the background.

Examine a fine collection of portraits by our best artists, and you will find each has a background peculiarly its own. Study them, bearing these few hints in mind, and I fancy you will quickly see the reason why.

The author of "The Art of Portrait Painting" (published by Windsor and Newton) says:—"Nothing so materially aids the effect of a picture as a judiciously-disposed background"; "and nothing," he says, "so readily destroys the best-intentioned production as the injudicious treatment of a background, or the careless neglect of its advantages." He adds: "The background must support the figure in such a manner that the latter may not have the appearance of having been cut out and pasted on a dark or light surface, an effect continually seen in the works of the fathers of the art—and in photographs. No painter, with any love for his art, could be satisfied with painting his figures in one pose, or employing one stereotyped background on all occasions. Were it so, it would not be difficult to copy almost every circumstance from some good picture. In the course of practice every painter is continually experimenting with his backgrounds."

Sir Joshua Reynolds points out, as indicating the masterly powers of Teniers, that he surpassed all others

REMOVED APR 1959

in knowing what proportions of outline to leave sharp and distinct, and what to lose in the shadow of his backgrounds.

Many of the French portrait painters begin with the backgrounds, and paint their heads up to them, often with wonderful richness and variety of effects. In this way the photographer might make studies of his background effects preparatory to posing and lighting the sitter. It would be capital practice in an artistic direction.

Breadth is a quality in a picture the importance of which is constantly enforced in the R.A. lectures and in all the works of our best painters. This also cannot be ensured without the background's assistance; but as this is a subject deserving more detailed treatment, I reserve it for a separate article.

DR. DRAPER'S RESEARCHES ON ASTRONOMICAL SPECTRUM-PHOTOGRAPHY.

BY DAVID P. TODD.

AT the time of his death, in November, 1882, Dr. Henry Draper had, for a number of years, been largely occupied with very tedious and costly investigations connected with the photography of the spectra of the heavenly bodies, his unusual adaptedness for the prosecution of which research conducted him to results of the highest importance. With true scientific spirit, Mrs. Draper has generously placed at the disposal of Professor Young and Professor Pickering all the data necessary for the proper publication of the work; and, in a monograph of about forty pages, the former gives an introduction to Dr. Draper's researches, together with a description of the apparatus with which they were made, extracts from the original note-books, and a list of the photographic plates in Mrs. Draper's possession; while the latter, who took a number of these plates to the Observatory of Harvard College in the spring of 1883, presents the results of his measurements, accompanied by a discussion of the plates.

Dr. Draper's attention appears to have been first turned towards spectrum-photography in 1869 and 1870, although his photographic work in other fields previously to this time had been singularly successful. His first work in science, conducted while a medical student in New York, and which related to the function of the spleen, was illustrated with micro-photographs of great excellence; and very soon after taking his degree, while on a visit to Parsonstown, Ireland, he became so thoroughly impressed with the photographic possibilities of the great reflecting-telescope of the Earl of Rosse, that, soon after his return home, he began the construction of a metallic speculum of fifteen inches diameter, which was soon replaced by a number of silver-on-glass mirrors of about the same size, the details of the construction and mounting of which formed the subject of one of the Smithsonian contributions to knowledge, published in 1864. Seven years later, he had completed with his own hands the entire construction and mounting of a twenty-eight inch silvered-glass mirror, with which he obtained, in May, 1872, his first photographs of the spectrum of *a* Lyrae by merely inserting a quartz prism in the path of the rays, just inside the focus of the small mirror, and employing neither slit nor lenses. Three months afterwards, the same method secured for him plates showing four lines in the spectrum of the same star. For two or three years following, Dr. Draper's time was, for the most part, occupied with other lines of work, connected with investigations of the solar spectrum, and the superintendence of the photographic preparations for the transit of Venus of 1874. He returned to the subject of stellar spectra in 1876, obtaining a number of photographs with a fine twelve-inch refractor by Alvan Clark and Sons. This instrument, now the lesser telescope of the Lick Observatory, was replaced in Dr. Draper's establishment, in 1880, by an eleven-inch Clark refractor, which was provided with a correcting-lens fitted to be placed in front of the object-glass to adapt it to photographic work. This instrument was mounted on the same set of axes with the twenty-eight inch Cassegrain mirror, as were also a finder of five inches aperture, and one of two inches,—all of which are well shown in the picture of the telescopes in the Hastings Observatory, vol. i. of *Science*, p. 31.

Dr. Draper's eminent successes in celestial photography were due in large degree to his own skill and discoveries in the manipulation of the sensitized plates. Until 1879, wet collodion plates were used in all his experiments; but after that time he employed exclusively the dry plates made by Wratten and Wainwright, to the admirable performance of which, in the hands of Dr. Huggins, his attention was called by that distinguished astronomical physicist, on a visit of Dr. Draper to England in 1879.

Professor Young directs attention to the fact that the investigations of stellar spectra were by no means carried on continuously, but only during Dr. Draper's summer residence at his country-place, and in the intervals of other, to him, even more absorbingly interesting researches and urgent business occupations. The difficulties proved to be well-nigh insurmountable; for at first the limitations imposed upon the time of exposure by the use of the wet process made it almost impossible to get impressions of sufficient strength—a difficulty which vanished on the introduction of the modern dry-plate processes: and another difficulty, increasing with the length of the exposure, was that of securing a sufficiently accurate movement of the driving-clock. No less than seven such clocks were constructed before he succeeded in getting a perfect one. Its regulator was a pair of heavy conical pendulums, so hung that their revolutions were sensibly isochronous through quite a range of inclination. The gearing and driving-screw were constructed, for the most part, by Dr. Draper himself, with the utmost care and accuracy; and Professor Young says that, in its ultimate perfected condition, the driving-clock was as good as any in existence, being able to keep a star upon the slit for an hour at a time, when near the meridian and not disturbed by changes of refraction.

And besides, the effect of changes of temperature upon the spectroscopic portion of his apparatus, and the difficulty of securing nights on which the atmosphere would not cut off the actinic rays to an unusual degree, not to mention the fact that the observatory was more than two miles distant from his residence—these and many other conditions hindered the progress of the work. Spectrographic operations are, as Professor Young well says, much more sensitive to atmospheric conditions than are visual observations.

As regards the spectroscopic apparatus, a great many forms were employed, the first of which has already been mentioned. Later, direct vision prisms were used in the same way, and spectroscopes made up of such prisms, some with a slit, some without, and some with a cylindrical lens to give necessary width to the spectrum. In the definitive arrangement of the apparatus, with which all the plates measured by Professor Pickering were made, a re-modelled form of Browning's star-spectroscope formed the basis of the instrument; the telescope and collimator each having a focal length of six inches, and an aperture of 0·75 of an inch. The eye-piece and micrometer being removed, a block of hard wood was fitted on in such a way as to carry the photographic plate (a small piece of glass about an inch square); and a small positive eye-piece was mounted on the block, so that the yellow and red portions of the spectrum, projected beyond the sensitive plate into the field of view, could be examined at pleasure. It was thus possible to be sure that the driving-clock was running properly, and that all the adjustments remained correct. The whole apparatus weighed less than five pounds, and could be screwed on the eye-end of whichever telescope it was desirable to use it with. The development of the plates was usually by ferrous oxalate, though the alkaline development and pyrogallic acid were both used on some occasions. The pictures were about half an inch long, and one-sixteenth of an inch in width, extending from a point between the Fraunhofer lines *F* and *G* to a point near *M*.

Professor Pickering divides his work on these plates into three parts: first, the determination of the relative positions of the lines in the various spectra in terms of any convenient unit of length; second, from the known spectra of the moon and Jupiter, a determination of the relation of these measures to wave-lengths; third, a reduction of the measures of the stellar spectra to wave-lengths, and a discussion of the results. The stars whose spectra have been measured are *a* Aquilae, *a* Lyrae, *a* Aurigae, *a* Boötis, and *a* Scorpii. The spectrum of the first of these stars is remarkable for containing, in addition to the intense broad hydrogen-bands which characterize the spectrum of *a* Lyrae and similar stars, a multitude of very fine lines, which are easily seen between *G* and *H* in several of the plates, but are too delicate to be satisfactorily measured. Dr. Draper considered these fine lines very important as showing that Altair should be regarded as a sort of intermediate link between *a* Lyrae and Sirius on the one side, and Capella and the sun on the other.

On the plates of the spectra of *a* Aurigae and *a* Boötis, not only do the lines appear to coincide in position with those of the sun, but their relative intensity seems to be nearly the same. Of the twelve lines seen in at least seven of the nine spectra of the moon and Jupiter, every one is contained in the spectra of both *a* Aurigae and *a* Boötis. Of the fifteen lines which are so faint as to be contained in but one or two of the spectra of the moon or Jupiter, only four are contained in the spectrum of *a* Boötis, and but one in that of *a* Aurigae. There is therefore no room for doubt of the correctness of Professor Pickering's conclusion that the evidence afforded by these photographs is very strong indication of the sameness of their constitution with that of our sun.

Professor Pickering's method of deriving his results from these plates is worthy of note here, as indicating the great degree of confidence to which they are entitled. To secure entire independence in the results, the measures were completed before the reductions were begun. The lines in each plate were measured without comparison with any map, and no search was made for lines which appeared to be wanting. When two similar spectra were photographed side by side, care was taken to cover one when measuring the other. Under these circumstances, the agreement in the measures of certain plates is strong evidence of the identity of the spectra.

Appended to this monograph are three of the papers of Dr. Draper, reprinted from the *American Journal of Science*: 1°, On photographing the spectra of the stars and planets (December, 1879); 2°, On photographs of the spectrum of the nebula in Orion (May, 1882); and, 3°, Note on photographs of the spectrum of comet *b* 1881 (August, 1881). The first of these papers gives, in brief form, a very lucid statement of the conditions of the problem of celestial spectrum-photography, as well as the obstacles which he had, up to that time, overcome in solving it.—*Science*.

Patent Intelligence.

Applications for Letters Patent.

9,899. LORENTZ ALBERT GROTH, K.G.V., Civil Engineer and Managing Director of the Universal Inventors' and Patentees' Financial Company, Limited, 10, Finshury Pavement, London, E.C., for "A new or improved photograph and pictnre-stand."—A communication to him from ahroad by Theodor Münch, Vienna, Austria.—(Complete Specification.)—Dated 8th Jnly, 1884.

9,914. ERNEST DANIEL ADCOCK, St. Giles Street, Norwich, Photographer, for "An improved vignetting apparatus for photographic printing-frames."—Dated 8th Jnly, 1884.

10,029. JAMES BROWN, 49, Southampton Street, Pentonville, Cahinet Maker, and FRANK BISHOP, of the firm of Marion and Co., 22, Soho Square, Photographic Stationers and Pnhlishers, both in Middlesex, for "An improvement in plate-changing apparatus for photographic cameras."—Dated 10th July, 1884.

Patents Sealed.

1,898. CHARLES SANDS and JOHN JAMES HUNTER, both of 20, Cranbourn Street, Leicester Square, in the county of Middlesex, Manufacturers of Photographic Apparatus, for "Improvements in the construction of photographic cameras."—Dated 22nd January, 1884.

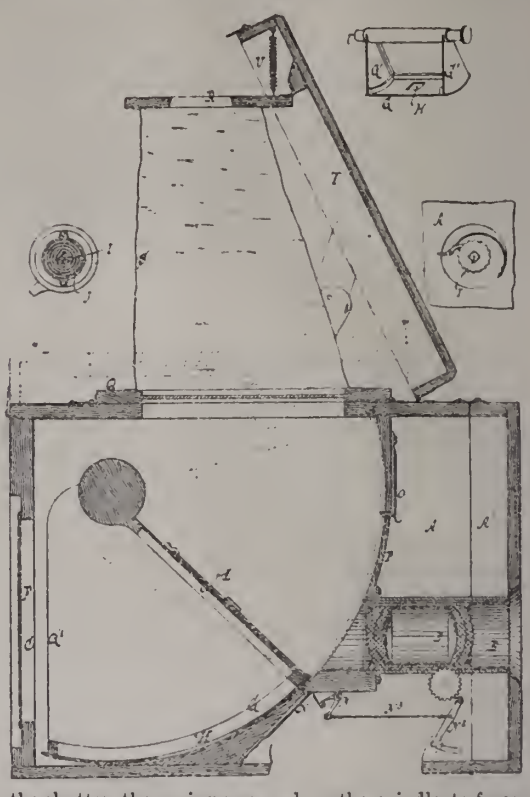
3,026. JOHN and ALFRED GEORGE HOPKINS, of Amwell Cottage, Hoddesdon, in the county of Herts, Photographers, for "A new apparatns for the exposing of photographic sensitive plates in cameras."—Dated 9th February, 1884.

Patents Granted in America.

301,400. CALVIN RAY SMITH, New York, N. Y. "Photographic Camera." Filed, April 17th, 1884. (No model.)

Claim.—1. The combination, substantially as hereinbefore described, of the camera-box having a lens-opening and plate-opening in opposite sides, and a focussing-glass in the top, the swinging shutter adjacent to the lens-opening having an exposure-opening to register therewith, and the mirror arranged on the shutter to reflect the image in the focus of the lens on the focussing-glass when the shutter is moved to an opened position.

2. The combination, substantially as hereinbefore described, of the camera-box having a lens-opening and a plate-opening in opposite sides and a focussing-glass in the top, the swinging shutter adjacent to the lens-opening having an exposure-opening to register therewith, the mirror arranged on the shutter to reflect the image in the focus of the lens on the focussing-glass when the shutter is moved to an open position, the axial spindle



of the shutter, the spring arranged on the spiudle to force the shutter from an opened to a closed position, and the catch arranged to engage the shutter in its opened position.

TAKING BABY'S PICTURE.

WITH the photographer, as with the mesmerist, it is necessary that the subject should he passive. A baby is never passive. He or she, as the case may he, is always either acutely belligerent or intensely responsive. Another serious obstacle in the way of the photographer's success with babies is the unaccountable propensity many of them exhibit for sleep at all times and in all places, which, coupled with their capacity for growing alarmingly red in the face whenever awakened, makes the operator's life anything but a bed of roses. The greatest man on earth—the hero of a hundred hattles, who can look grim death in the face without winking—is like wax in the hands of the photographer. He submits meekly to snch indignities as having his chin rudely elevated to suit the reqnirements of art, and allowing his neck to he sharply twisted until his jugular protests in vain; but the puniest habe in arms will permit no such liherties. Strategy is the only power it recognises.

The worst of all habies to photograph is the fat baby. Set the boneless mass of misshapen flesh in the operating chair, he leans forward on his stomach, lolls out his tongue, and, while leering at the carpet, two streams of saliva course down the sides of his chin, making him a sight to behold. A little worse, and he would break the camera. All efforts to brace him up into an attitude of semi-respectability proviug fntile, he is finally "taken" in a recliuing position, or is giveu up as a had job.

Then comes the animated baby—an India-rubber institution, augmented by the elasticity of conutless steel springs. Nothing comes nearer perpetual motiou than the animated baby. Lay her on her back, and she kicks; roll her over, and she kicks and squirms with untiring perseverance; stand her on her head, and she will go up through the roof if she is not held down. If the photographer is sharp enough to catch her hetween jumps or kicks or sqnirms, he will get a very decent uegative; otherwise it will be all legs and arms, and flannel petticoats, and things.

When tired nature asserts itself, and the squalling baby is perforce in a state of momentary repose, the photographer can, if he is quick enough, secure a very passable representation; but as nature, in this instance, fails, oftentimes, to get tired for some weeks at a stretch, the country is not flooded with such representations. It is unnecessary to add that the squalling baby is invariably a girl.

Some photographers make a speciality of "taking" babies, but as all babies, up to a certain age, are quite similar in appearance, it is presumed that a photograph of this class reduces the strain on his system by making use of an adjustable dummy for the foundation of his picture, incorporating with the finishing touches a few objective points of the supposed original.—*The Chicago News.*

AMATEUR PHOTOGRAPHY

BY SIGMA SMITH.

THE ease with which photographs can be taken by the modern dry plate process leads the tyro to roam about always on the look-out for whomsoever he may focus.

When I first took up the rôle of an amateur photographer, I made myself a veritable terror to the neighbourhood, and those who knew of the new bent of my mind went by my domicile in fear and trembling and with an anxious aspect, just, for all the world, as if they were actually in a studio—for a portion of my paraphernalia was an instantaneous shutter, by the aid of which I was able to secure rapid views. Sunday was my great day, and just as the people began to file past on their way from church, out came my camera, and, concealed amongst the lilac bushes in my front garden, I was wont to lay in wait, like a tiger ready for its spring—and almost as much dreaded by my friends—and, so soon as a notable group came within range, click went my trigger, and lo! the picture only needed to be developed and otherwise prepared. Thus I was in the habit of producing pictures in which highly respectable and decorous old gentlemen would be shown standing on one leg, with the other lifted in the air, as if hopping; another would be portrayed in the form of an animated letter X, as he happened to be taken just as he was making a stride; another would be shown in the act of taking off his hat with a sweep, but appearing in the photograph as though committing a violent assault, with the said head-gear, upon the lady who was in reality being gracefully saluted; others would be blowing their noses and looking ridiculous; others who happened to be walking past at a more brisk pace than usual, might be presented sans legs at all—each looking like a head and trunk with some diaphanous cloudy-looking support that gave a very phantasmal general aspect to the object; one gentleman—who wore a white hat, and who stooped in his gait—always gave the impression, in the resulting photo, that he was carrying his nose by the shortest cut to the ground; and this gentleman, in particular, who was of a meek, retiring disposition, became a livid object of terrified apprehension as he neared the spot, and hastened onward in the greatest trepidation in order to avoid being, as it were, lampooned—for I took great care that any striking picture was duly circulated among the group of friends.

This was of course all very wrong and unchristian, but, fortunately for my victims, many of these attempts were failures—either from one cause or another—but sufficient survived the various vicissitudes of the perfunctory treatment of the novice to "get my name up." People got at last to carefully put up their umbrellas as they passed, and all I could focus was an apprehensive nose; and those who had been in the habit for years past of grouping themselves at the corner where the cross roads divide—just opposite my house—became afraid to do so, but went a little way onward, so as to be covered from the baleful glance of my searching lens—much to my chagrin.

It was curious to see those who were in the secret, and did not mind being photographed, so long as they could be made to appear dignified, pass by my hiding place. They drew themselves up to their full height, and scrupulously turned towards the possible camera their best side face, and generally placed themselves in the most romantic and interesting attitudes; but all in vain, for so fell was the spirit that then actuated the amateur photographer, that, so soon as he saw them all ready, he turned the angle aside, and sought for other and more noticeable subjects.

Passing traps and bicyclists were aimed at by the score, and sometimes only the hind wheel was secured on the plate; or sometimes a cart appeared to be but a square mass of fog, or the horse's legs did not show, or it had two heads.

In the earlier stages of the craze, for such it was, my family fell into the groove I thus prepared for them with the greatest enthusiasm, and were ready to be photographed whenever and in whatever combination I, the pater, chose to fix upon; but even they—long-suffering as families are to the fads of their progenitors—became at last so thoroughly sick of the constant posing and focussing, that at last it was only by dint of unlimited bribes—in the shape of sweets and toffified presents—that even the youngest of the clan could be induced to submit his rubicund countenance and podgy form to the influence of the camera; the bulldog, too, became so familiar with the whole business, that she actually sniffed when her master assumed a wheedling air, with the well-known camera and black velvet in his grasp. The times that that bulldog has been focussed would use up the computations of a multiplication table, and unhappily, as a rule, the result has been dire failure—as that very estimable quadruped generally winks, or becomes conscious of the possibility of eats and starts away, thus spoiling an otherwise unblemished photo.

In nothing so much as photography does wisdom come from experience, and the tyro soon learns to moderate his aspirations, and to confine his efforts to more practicable subjects, until he gains more skill in the manipulation of his lens and his chemicals.

To the tourist the camera is a most interesting adjunct, as, by its aid he can secure an ever-living view of each place of interest, and when he returns home, instead of seeking to laboriously describe in words the sights he has seen, all he need do is to proceed into the darkness of his cellar, or dark-room, and develop his negatives, and then scatter his prints broadcast among enquiring friends.

During a tricycle tour in England, and in Normandy and Brittany last year, the present writer took something like fifty or sixty views of different places and scenes of interest. Most of these turned out fairly well—although he was then but in the first months of his novitiate—and, therefore, it can readily be understood that the art is not difficult of acquirement. One of these views was an impromptu picture of his *compagnon du voyage*, fast asleep in bed at nine o'clock in the morning, when the breakfast-bell was ringing, and the amateur photographer had been out for a couple of hours in the early sunshine, and had been luxuriously bathing in the sea in St. Aubyn's Bay, Jersey. This picture is an everlasting memento of a lazy man, and is duly labelled as such.

The whole of the apparatus, stand and six plates included, only weighs 5 lbs. 8 ozs., so that there is no difficulty in transport.—*Time.*

Correspondence.

MR. C. PURDON CLARKE'S PHOTOGRAPHS.

SIR,—In your last number you remark on the absence of the name of the producer of the prints illustrating my paper on Indian Street Architecture in the Journal of the Society of Arts of the 4th inst.

These photo-lithographs were prepared by Mr. W. Griggs, of Peckham, who had a difficult task in producing such a large number of prints (from rather poor negatives) on a very short notice. The transparencies were prepared by Professor Hodgkinson, of the Science and Art Department, South Kensington, to whom I am greatly indebted for so successfully producing 3¼-inch slides, which stood enlargement on the screen in several cases to nearly full-size, and in one to over the full-size of the original objects.—I remain, sir, yours very obediently,

C. PURDON CLARKE.

Indian Section, South Kensington Museum.

Proceedings of Societies.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

A MEETING of this Society was held on Thursday, the 10th inst., Mr. A. L. HENDERSON in the chair.

The discussion on gelatine negatives dissolving in the fixing

bath was again resumed. Mr. Coles having placed plates in new and old hypo solutions for three days, a slightly reducing action took place in the fresh solution, but not any in the old and discoloured bath. Mr. Ashman, to test whether an accumulation of alkali would cause reduction, added ten per cent. strong ammonia to an old bath; no reduction took place in a plate immersed thirty hours therein.

The Chairman said, if negatives were treated with alum, there would be very little chance of the film dissolving; he wished to know if Mr. Newton's formula, given last week, had been tried, and whether anyone had found formic acid to be a developer as claimed? He had made several experiments with formic acid some years ago, and found it reduced nitrate of silver.

Mr. W. M. Ashman said formic acid alone would not develop a gelatine plate. If poured on a film it would dissolve it completely. Concentrated acid would do this in two or three minutes, permitting the whole to be poured off.

Mr. A. Cowan passed round an American cutting wheel, suited for cutting prints against a flat rule. The wheel was much larger than those hitherto sold in this country, and permitted sharpening on an oil-stone with great ease.

Mr. W. Coles showed negatives locally intensified with mercury and Schlippe's salt, illustrating the absence of colour complained of by Mr. Barker. The importance of prolonged washing after the mercury was insisted upon.

The Chairman, speaking of pressure on bromide films, showed several plates much veiled in the shadows, which veil he attributed to the pressure exerted by the strips of cardboard packed between them; a few months ago they were perfectly bright and clear, registering 23 on the sensitomer; where the pressure had been greatest, the markings were opaque.

Mr. W. H. Prestwich had similar markings when he used good cartridge paper for packing; but with common paper, he was free from them.

Mr. W. Cobb attributed the marks to dampness. A few months ago he prepared a special batch of 10 by 8 plates, which took a long time in drying; these were packed with paper not previously dried, and markings resulted. When the packing is thoroughly dry, markings of this kind are absent; he recommended the adoption of parchmentized paper.

Mr. Graham (Derby) agreed with the last speaker; he used common orange paper which had been stored some time in a room always heated to 70° F. by hot water pipes. Some plates made by a similar process to those shown by Mr. Henderson had been so packed for two years; he would forward a few of them to the Chairman to develop. They were quite free from the marks now shown, which he was sure were due to dampness.

Mr. F. York spoke in favour of parchmentized paper.

Mr. A. Haddon recommended Swedish filtering paper.

The Chairman exhibited an opal picture sent by Mr. Crosby, of Rotherham. It was printed out on gelatino-chloride emulsion, and toned as in the collodio-chloride process. He also passed round plates made by mixing a quick and slow emulsion together, some of which occupied half-an-hour in setting, causing a subsidence of the silver bromide, as suggested by Mr. Prestwich, whose idea was that frilling is due to a separation of the sensitive compound, rather than decomposition of gelatine. Another curious thing about these plates was, that one exposed for two seconds through the film—*i.e.*, from the glass side—appeared to have received double the exposure another plate showed, which was exposed three seconds in the ordinary way. Upon motion, Mr. Henderson was requested to act as delegate from this Society when attending photographic meetings during his stay in America.

Mr. Henderson could not promise to attend the Cincinnati Convention, but other photographic meetings he should be pleased to attend in the capacity of delegate.

Mr. A. Richards and Mr. L. Waltenberg were elected members of the Association.

Glasgow and West of Scotland Amateur Photographic Association.

A special meeting was held in the new rooms of the Association, 180, West Regent Street, Glasgow, on the evening of Thursday, the 10th July, Mr. Hugh Reid, President, in the chair.

After the adoption of the minutes, the following new members were admitted:—Messrs. John Colson, David Pratt, James Kirkwood, Samuel Walker, Mr. B. Smith, and James Torrance.

It was agreed that any amateurs visiting or passing through, but not resident in Glasgow, should have the use of the dark room, &c., without charge on the introduction of any member of the Society.

After a little discussion it was arranged that the next out-door meeting of the Society should be held at Kilmun and Holy Loch on Saturday, 9th August; members to leave by the 8.30 a.m. train from St. Enoch's.

The members present were very much pleased with the new rooms, and it is expected that the Association will derive great benefit from the increased accommodation for meetings, and the conveniences of the dark room for developing, enlarging, &c.

After the usual votes of thanks the meeting adjourned.

Derby Photographic Society.

An out-door meeting of this Society was held at Matlock on July 12th. Among those present were Messrs. C. E. Abney, C. Bourdin, S. J. Cholerton, T. Scotton, F. Shute, F. W. Simpson, and R. L. Warham. Starting from Derby at 2.5, the party alighted at Matlock Bath Station, and immediately set out for the well-known High Tor. The weather at starting was everything that could be desired, but no sooner was the formidable array of cameras pointed at the gigantic rock, than a black cloud obscured the sun. "Everything has an end," and this proved true with the cloud, for after waiting patiently for some time the weather cleared up, and the sun shone again. After securing this picture a move was made to the Lovers' Walk, and here the party met two members of the Manchester Photographic Society. Some views of the river and Lovers' Walk having been taken, the members next drove to Cromford, where they met the rest of the members of the Manchester Society, and returned with them to Matlock, where the two Societies tea'd together at the "Peverill" Dining Rooms. The President of the Manchester Society, Mr. J. Pollitt, in the course of a few remarks after tea, invited the Derby Society to join them in an excursion to Dovedale during the summer. The members then separated.

Oldham Photographic Society.

On Tuesday, June 24th, the members of this Society, with a few friends, visited Bakewell, Haddon Hall, Chatsworth, and Rowsley, in Derbyshire. The day was favourable, fourteen cameras were at work, and about one hundred plates, varying from 12 by 10 to stereoscopic size, were exposed. On development the quality of the majority of these plates has turned out satisfactory. After passing an enjoyable day, the party, numbering thirty-one, partook of an excellent tea at Rowsley, and returned by a quick train at 8 o'clock p.m.

The monthly meetings of this Society are now held at the Oldham Lyceum, the first meeting at which place was on the 26th of June, when thirty members attended, Mr. John Risley, President, in the chair.

A good show of work by members was exhibited, and the Chairman brought a new drop-shutter of his own invention before the meeting, the simplicity and perfectness of which won great praise.

Six new members were proposed at the meeting. This Society was established in 1867; it now consists of over fifty members, and is in a most healthy condition.

Photographers' Benevolent Association.

This Association held its usual board meeting on 2nd inst., at 181, Aldersgate Street, E.C. The minutes of the previous meeting were read and confirmed.

Mr. T. W. Cowper was elected a member of the Association. The correspondence and other matters having received attention, the meeting terminated.

Leeds Photographic Society.

The usual monthly meeting of this Society was held on Thursday, July 3rd, at the Philosophical Hall, J. W. Ramsden, Esq., in the chair.

After the confirmation of the minutes, Mr. Whitham was elected a member of the Society.

Mr. Washington Teasdale called attention to a number of very fine lantern slides he had taken on Ramsden special lantern plates. He said the plates were very slow, requiring from thirty seconds to two minutes twelve inches from a fish-tail burner, according to the density of the negative, the tone of colour obtained by pyro being a rich brown; the great characteristics of the

plates being clear glass in the shadows, with the best gradation of tones and half-tones he had ever seen. He also drew attention to two or three slides that had been transferred from the hypo to a solution of alum, the result being a red stain.

Mr. Pocklington had also been using the same plates, and got very fine results, some of the most effective being those toned by immersion in a bath of:—

No. 1.—Nitrate uranium	20 grains
Water	1 ounce
No. 2.—Ferridcyanide potassium	20 grains
Water	1 ounce

Two parts No. 2 to one part No. 1.

In answer to a question as to the cause and best cure for flare in double-combination lenses, it was suggested that flare was very frequently caused by a dirty condition of the front lens.

Mr. Rodwell remarked that the lens attached to one of his cameras always gave flare when used with the smallest stop; and, as a preventive, an additional stop was supplied to fix in front of the other.

In answer to a question as to what was the best way to recover the silver from a quantity of soda and water in which had been disolved the films of several gross of negatives, and was it worth doing,—

Mr. Ramsden suggested a number of methods that might be employed, but thought the best would be to add a quantity of sawdust to the liquid, and then reduce in the ordinary way. But taking into consideration the very small amount of silver used to build up the photographic image, the result would not be worth the trouble.

A Member put the following question:—He had a copyright etching of a very valuable painting. Supposing he were to make a lantern slide from the etching for his own use only, and for private exhibition at his own home to his friends; would he be liable to any prosecution if it were known to the owner of the copyright that he had done so?

A long and interesting discussion on the subject took place. At the close it was generally agreed that in so doing he would be liable to prosecution, and, if convicted, the owner of the copyright could obtain damages. But if the slide was used only in the way described, the damages would be so small that it would not be worth the while of anyone to incur the trouble and cost of a long legal process to obtain them.

An enquiry was made as to whether any of the members had seen the vulcanized fibre that had been recommended for making shutters for dark slides, &c. Although several of the members had heard of it, none had seen it, and it was not known where it could be obtained.

Mr. Teasdale said he deprecated the use of brass for stops, and had used for some time stops made of ebonite as being much better; but thought that if the Willesden paper was supplied in black it would be most useful not only for this purpose, but for many others where thinness, toughness, and lightness were required.

Talk in the Studio.

Photographic Society of Great Britain.— The next meeting of this Society will take place on Tuesday next, July the 22nd, at 8 p.m., at the Gallery, 5a, Pall Mall, East.

Mr. Woods' Remarks on Dark-Room Illumination.—Mr. W. E. Debenham writes to us as follows:—"One point that Mr. Woods addresses himself to is the defence of his use of the term cathedral green. What I object to is the use of that term as employed by Mr. Woods to indicate any particular colour, seeing that blue-green, and yellow-green, each in a variety of depths, would all be included. A matter that Mr. Woods particularly criticises is my statement that green glass (of the colour I showed) is a better protective supplement to stained red than is the cobalt glass recommended by Capt. Abney, and he states as a fact, not as a mere supposition, that the reason I found it so was because I had not employed the precise red used by Capt. Abney. Now, as I showed the results of two experiments with stained red glass, each of them being like the pattern shown by Mr. Woods as Capt. Abney's, flashed red on one side and stained silver yellow on the other, but not precisely of the same depth of colour, one being rather lighter and the other rather darker than Capt. Abney's, and as with each of these pieces the green had given more illumination and more protection to the plate than the cobalt, there seems no probability that the use of a stained red intermediate in depth between these two would cause a reversal of the result. If Mr. Woods, however, is still of opinion that with any shade of stained red glass cobalt is as good a supplement as green, I invite him to send a piece of red and cobalt to any competent independent judges, and I will, on seeing the depth of blue to be competed with, supply a piece of green. I leave Mr. Woods free to select lamp light, magnesium light, or daylight, if he thinks that the choice will make any difference in his favour. He complains of my having used magnesium in this particular experiment, but as this light comes between lamplight and daylight in actinic richness, it seems to me the fairer to use them either alone, when trying mediums that are to be used with both. It is noticeable that Mr. Woods leaves most of my arguments untouched. The proposition that red light has at least as much effect, or more, upon the sensitive film in proportion to its luminosity, as yellow, and which was so strongly exemplified by Mr. Sawyer, cannot be said to be affected by Mr. Wood's experiments and remarks, as the relative luminosity of the red was not taken into account. The arguments that the great difference of relative sensibility of the ordinary gelatino-bromide and collodion bath plates to different coloured light which had so long been insisted upon did not exist, and therefore that the different colour of light required in the dark room in the two cases which had been insisted upon on that account was a mistake; and that the great effect upon the colour-sensitiveness of a bromide plate caused by the addition of iodide was also a mistake; these changes of conditions being favourable to the transparent medium, which happened to be the red—were all passed over; and it is satisfactory to see that Mr. Ray Woods found, after a month's preparation, no answer to my argument."

Some friends of Mr. Scharf, for a number of years Keeper of the National Portrait Gallery, propose to commemorate his services by asking him to sit for a portrait to be permanently placed, with the assent of the trustees, in the board-room of the gallery at South Kensington. A committee has been formed for the purpose of giving effect to the scheme. It includes Lord Derby, Lord Stanhope, Sir Richard Wallace, and Sir Frederick Leighton.

Albumenized Paper for Packing Butter.—The butter should be first wrapped in a linen cloth, and then in a double fold of albumenized paper; at least, so says the *Archiv*. The albumen coating is not easily penetrated by grease, and of course it is easy to make a cheaper albumenized paper than that used for photographic purposes. Thirty grains of nitre to the white of one egg may advantageously replace the ordinary preparation.

Macdougald's Developer Tubes.—Messrs. Marion and Co. send us some samples of these as introduced into the market. Two glass tubes with ends melted together by means of the blow-pipe are supplied, both these tubes being fitted into a block of wood for safety of transit. When the developer is required for use the ends are broken off, and the solutions mixed with the proper quantity of water (see "Patent Intelligence," pages 153 and 219).

The Exhibition of Photographic Portraits.—"Several correspondents," says the *Liverpool Courier*, "having asked the question whether or not photographers have a right to display in their show-cases the portraits which they may take, and conflicting opinions having been given on the subject, we submitted the question to the head of a firm of photographers, who has been courteous enough to furnish the following explanation of the usage with reference to the exhibition of portraits. —'I beg to say that, so far as I am aware, there is no law to prevent a photographer placing in his window a print from any negative he may take of a customer. In the recent Copyright Act a clause was inserted making it illegal for a photographer to so exhibit a photograph of a customer without the consent of the individual represented. But whilst it is not illegal, we should consider it exceedingly improper to exhibit the portrait of any person if it was thought for a moment that it would be an annoyance to the person represented, and no photographer with any judgment would refuse at once to remove such photograph upon request. We have not altogether met with a dozen persons who have objected to our exhibiting, as samples of our work, their photographs, though we are always careful to select such as we think will not be objected to, generally choosing persons of note, members of the theatrical profession, and children's portraits. During all the period we have named we do not think there have been a dozen instances in which we have been asked to remove a photograph from our windows or cases. We

should consider it not only very discourteous to refuse, but, in addition, a very impolitic course to pursue, it being manifestly the interest of the photographer to please his patrons, and not to vex them.'"

FOLIAGE AT CLOSE QUARTERS.—Having always, at our Photographic Exhibition, plenty of views of *distant* foliage, would it not be *apropos* for our brethren of the camera, and especially lady amateurs, to devote themselves to studies of *near* objects in foliage, and other small matters in nature? In almost every garden, if looked for with a discriminating eye, there will be found little bits of foliage, pretty combinations of flowers, all in a natural state; little nooks and corners containing most exquisite arrangements of beauty; aye, and why not make a study of bird-nests, from which the artist painter produces such beautiful little pictorial gems? All these, if taken on a small size, say a half-plate, would not only demand the exercise of artistic skill to make into a picture, but would also be excellent practice in the use of lenses and their stops. Studies like these would show one of the great powers of photography, viz., the possibility of giving detail in all complications of intricacy, and which, when brought to bear upon near foliage, ought to result in some most charming pictures.—*Journal of the Photographic Society*.

STAR MAGNITUDES DETERMINED BY PHOTOGRAPHY.—The Rev. J. E. Espin's printed catalogue contains the magnitudes of 500 stars in *Auriga*, *Gemini*, and *Leo Minor*, all determined from photographs taken with the equatorial stellar camera at the Liverpool Society's observatory. The instrument was presented to the Society by Mr. Howard Grubb, and it has been turned to excellent account. The magnitudes obtained agree fairly well with those of Argelander, and this result speaks well for the future usefulness of a method almost untried, and necessarily beset with the difficulties incident to a new line of research.

PHOTOGRAPHIC CLUB.—At the next meeting, on July 23rd, the subject for discussion will be on "The Effect of Coloured Media on Sensitized Paper." Out-door meeting at Hadley Wood—to High Barnet Station—meeting afterwards at "Old Salisbury Arms."

To Correspondents.

*** We cannot undertake to return rejected communications.

H. EVANS.—1. You can get the gutta-percha foil in small quantities from any druggist, as it is used for surgical dressings; but if you require it wholesale, you should apply to the Gutta-Pereha Company, Wharf Road, City Road, London. 2. Benzole can he obtained where you get your other photographic chemicals. 3. We do not know the price, but you can easily write to the publishers and enquire.

LENS.—The instrument is not suited for the most rapid work, but if you do not require good definition all over the plate, you may enlarge the aperture to half an-inch, or even five-eighths. 2. The flap opening is not so convenient as a cap in ordinary cases.

WM. GAMBLE.—The process to which you refer is not the Pretsch process, but that of Asser, and your failures may possibly result from general inexperience as regards the behaviour of bichromated organic matter. We may suggest the following as the most likely causes of such a general insolubility of the sensitive mixture as would cause the ink to take all over:—(*a*) The exposure of the sensitive paper to the fumes of burning coal-gas, or gases escaping from a drain. (*b*) Extremely slow drying of the sensitive paper. (*c*) The use of paper sized with alum. (*d*) Allowing too long an interval to elapse after exposure, and before soaking out the unaltered bichromate. (*e*) Non-removal of all traces of unaltered bichromate before the application of heat to the exposed sheet. Even when partial insolubility has set in, it is sometimes possible to obtain passable results by the application of warm water. 2. We are glad you have succeeded, and shall be pleased to have a communication on the subject. 3. You are quite right as to the merits of the asphalt process, as it will give much finer results than the ordinary transfer method; and if you get a good specimen of asphalt, and follow the directions—especially as regards agitating at intervals during about five hours—the powder will not consolidate at the bottom of the bottle, and you will have no difficulty. There is no need to work in the dark. Read the information as to the kind of asphalt to select.

WM. BIRRELL.—1. Between four and five ounces. 2. Probably not less than ten times. 3. The formation of the bromide of silver in coarse curds. 4. It would be so if the sides were exactly vertical, but the sides are never vertical. Consider how your theory will hold when a series of easy gradations is concerned.

R. X. R.—Dilute nitric acid is best, about one part with forty of water. A series of articles on the subject appeared in our volume for 1882, pages 673 to 770.

W. LAWRENCE.—See page 6 of our present volume.

W. H. HARRISON.—You have, apparently, overlooked the concluding paragraph on page 440, where attention is called to the danger of which you speak; but we are very much obliged to you, and you will see that we have again referred to the matter.

NOVICE.—Obtain a four-inch stove-pipe elbow and pass one branch of it horizontally through the external wall of the dark room, the bent part being inside, and the mouth directed upwards. To the external end of the horizontal arm attach a second elbow with the open end directed downwards.

F. C. B.—On a main route, such as that which you intend to follow, there is not much probability of any trouble in getting the dry plates through the Customs. Simply explain what they are, and if the officer insists on opening the packages, demand to have them opened in a room illuminated by your own lantern. This might possibly cause you to lose your train. There is no duty chargeable.

FRANK GORSTON.—As far as it is possible to judge from the details you give, your general plan of working is good, and we cannot very well suggest a probable cause of your failure. Possibly you may be using a sample of sodium sulphite contaminated with carbonate. See Note as to this matter on page 441.

AGENCY.—There is nothing of the kind at present, as such business is usually transacted through the advertising columns of the PHOTOGRAPHIC NEWS.

CARBON.—It was at one time thought that considerable advantage resulted from the addition of soap to the composition, but we believe that it is not used at the present time.

BEGINNER.—The prints have been insufficiently fixed. Allow them to remain longer in the hypo bath. Remember that the solution is very cold when freshly prepared, and that it is far less active than at the ordinary temperature.

JOHN B.—1. Acetic acid answers very well, and is to be preferred to a stronger acid; but if you are careful there will be no difficulty in obtaining a good result with nitric acid. 2. Yes.

W. G.—Eder's method of intensification with lead is one of the best. The well-washed negative is immersed in a solution containing six parts of potassium ferricyanide and four parts nitrate of lead dissolved in one hundred parts of water. When this has become yellowish it is well washed, and the plate is allowed to remain in a bath compounded of one part of sulphide of ammonium and four of water. With this latter it becomes intensely black.

The Photographic News Registry.

Employment Wanted.

Printer & Toner (age 19).—A. B., 45, George-st., Hastings.
Assistant Operator or Retoucher (25 s.).—A. Z., *Photo. News* Office.
Manager, good Poser.—M., Mr. Nicholls, High-st., Shanklin, I.W.
Operator, good all round.—B. M., 3, Laurel-ter., Park-lane, Tottenham.
Assistant Operator, high-class.—W. H. May, Poolend-st., Malvern.
Dry-plate Examiner & Packer (lady).—M. Latimer, 9, N. Audley-st., W.
Recep.-room, Spotting, &c.—F. P., 12, Dorchester-pl., Blandford-sq.
General Assistant.—H., 115, Westmoreland-rd., Walworth.
General Assistant, Printer, Vignetter.—B. R., *Photo. News* Office.
Recep.-Room, Spotting, &c. (15 s.).—H. K., 75, Azenby-sq., Peckham.
Retoucher, or Operator & Retoucher.—C. N., 310, Gray's-inn-rd.
Oper., exp. with dry plates.—L., 23, Orbel-st., Castle-st., Battersea.
Retoucher (young lady).—L. Francis, 16, Linom-rd., Bedford-rd., Clapham.

Employment Offered.

Lady as efficient Spotter.—Maull and Fox, 187, Piccadilly, W.
Retoucher, Colourist, Spotter—2, The Pavement, Clapham Common.
Retoucher, first-class.—25, Old Bond Street (first floor).
Reception Lady.—C. F. Wing, 13, Beak-st., Regent-st. (Friday 6 to 8 p.m.)
Operator to manage small Studio.—E. Taylor, Eastboro', Scarboro'.
Printer, Toner, Mounter (male or female).—W. J. Suter, Cheltenham.
Operator for first-class work.—P. G., 328, Upper Brook-st., Manchester.
Printer, for permanency.—J. S. Catford, 5, High-st., Ilfracombe.
Youth, as Assistant Printer.—Ergland Brothers, 25, Charles-st., W.
Retoucher.—Van der Weyde, 182, Regent-st., W.

CONTENTS.

STRIPPING GELATINE NEGATIVES OR POSITIVES BY THE AID OF HYDROFLUORIC ACID.

OUR readers will remember that in 1882 we published a method of stripping the film from gelatine negatives by the action of hydrofluoric acid, and we have commented several times on the ease and convenience with which the separation of the film from the glass can be effected, but M. Bory has recently published* a suggestion to use hydrofluoric acid for a similar purpose, apparently without knowing anything about Mr. Plener's prior publication. As, however, M. Bory appears not to have worked out the practical detail of the method so thoroughly as was the case with Mr. Plener, we will now point out the main features of the proeess as given on page 225 of our volume for 1882.

Mr. Plener's method of stripping is best carried out by building up a wall of cardboard strips round the negative, and, after levelling, pouring on a warm solution of gelatine. When the film is dry, or nearly so, it is immersed in the dilute acid until it can be easily stripped off, after which it is rinsed thoroughly, and allowed to dry. If the wet film be carefully squeegeed down on a sheet of waxed glass, it can be easily separated as soon as dry, and under these circumstances the film negative is of course obtained with a beautifully even surface. Another method, which may be occasionally useful, is to immerse the stripped and still wet film into a bath of methylated spirit, a proceeding which causes the swelled film to rapidly shrink to near about its original size; after which drying between sheets of blotting-paper serves to remove almost every trace of spirit, so that the negative may be ready for printing from in a very short time.

When a positive on paper is wished for, it is very convenient to make the picture on a plate in the first instance, and then to transfer it to paper. In such a case the positive picture on glass may first be coated with a thin layer of gelatine, to which a sheet of smooth-faced paper is next attached, or the paper itself may be brought into contact with the film under a warm gelatinous solution, as when prints are mounted in optical contact with glass; remaining operations being so similar to those already mentioned as to require no special description. Mr. Plener has shown us many pictures which had been transferred to paper in this way; and those negatives which had been transferred to a fine or close-grained paper had evidently lost none of their printing qualities, exeepting so far as the paper backing would, unless waxed, eonsiderably retard the process of printing.

Mr. Plener also pointed out that hydrofluoric acid is an extremely valuable agent for cleaning glass plates (PHOTOGRAPHIC NEWS, 1882, p. 232), and so many have adopted and described this method of cleaning plates to whieh foreign matter adheres with exceptional tenacity—that we are rather surprised to find that M. Bory recommends it for the purpose without any referenee to its previous use in this connection.

M. Bory uses one part of strong hydrofluoric acid to about two hundred and fifty of water for stripping the film, and one part with fifty or a hundred of water for cleaning glass; but we have used it with advantage of this latter strength for separating the gelatine pelliele from glass.

M. Bory says nothing about the use of aleohol for causing the expanded film to eontract to its original dimensions, and it may be mentioned that, as in most cases the stripped negative is required to be of the same size as the original, it is of very great importauce to be able to bring back the exposed negative to its original size.

Mr. Plener also suggested the use of moderately diluted sulphuric acid for the purpose; but it is hardly so convenient as alcohol, owing to the difficulty of removing the last traces of acid except by long washing in alcohol; still, by the use of sulphuric acid, the stripped negative can be re adily reduced to less thun its original dimensions.

FINISHING PHOTOGRAPHS.

INDIVIDUALITY is as often discernible in the ultimate finish of a photograph as in skilful posing, management of lighting, or arrangement of accessories; and keen business men, being convinced of this, take care their reputation shall not suffer from indifferent retouching, printing, mounting, &c., any more than they would tolerate the employment of a bad batch of dry plates, resulting in negatives of scarcely mediocre quality. All photographers are not keen business men, however, or the opportunity would not occur to point out a few of the bad traits met with in every-day photography. It has often been remarked that "a good picture is worthy a good frame." If sueh is the case, then a good print should be worthy a good mount; but it does not always become attaehed to one. The difference in the cost of good mounts and those of an inferior quality is very trifling, and it is not any more difficult to mouut pictures neatly and cleanly, than it is to perform the operation carelessly, so that it is a little difficult to understand—with nearly half a century's experience before us—how sueh a mechanical department as finishing should be open to severe criticism.

Twenty years ago, when mounts were more expensive, and the rolling-press did the duty now performed by the burnisher, one scarcely ever saw scratches, scorchings, tears, broken edges, and twisted mounts; neither was it eustomary to ornament (?) the mounts with a mixture of

oil and soot. Prints intended to be flat were made so, and convexing was carefully done, as many of the "Diamond cameos" then in vogue still remain to testify.

The Diamond cameo photograph was one of the most effective styles of portraiture that has yet been introduced; moreover, it was exceedingly popular with the public; but owing to certain restrictions—which have ceased to exist—it did not receive that support from the profession generally, which was necessary to ensure its continued success.

It will be within the recollection of some of the readers of the NEWS that this class of picture, which was introduced by Messrs. Window and Bridge in 1864, consisted in taking, by means of a suitable registering dark slide, four busts giving different views or positions of the same head on one plate. From the negative so obtained, and suitably masked, prints were taken, which, after mounting, were embossed in a press fitted with dies corresponding in shape to the printed portions, the result being a series of four convex portraits on a white ground—carte-de-visite size. The drawback these pictures were liable to, was unskilful posing and lighting, a defect which would hardly be likely to operate against them should they be again placed in competition for public favour. Since the period mentioned, retouching and Rembrandt lighting have been introduced; the tendency, too, has been growing in favour of larger sizes, therefore it seems highly probable that the introduction of the essential elements of this old favourite, embodying some of the later improvements, such as increased size, effective lighting, mezzotint grounds, border printing, gelatine enamelling, &c., would, in the hands of a few energetic photographers, prove a success.

From observation it will be noticed that the public, as a rule, are more fastidious over the finish of a photograph than the technicality involved in negative-making or the printing thereof; that they are exacting as regards colour, it is true; but having formed an opinion of the photograph as a portrait or pictorial representation, they devote a full measure of attention to the details of finishing.

Enamelled surfaces appear to be much appreciated for sizes up to Boudoir; when nicely mounted they please the public, but whether the high glaze is artistic or not is quite another matter, which does not concern us just now, it being sufficient for the purposes of this article to mention that a very large proportion of these highly glazed prints are daily put into circulation. Unfortunately, the tendency of air-bells forming during the glazing process causes a good many defective prints to be sent out, while the supposed difficulty of removing the spots which are caused in printing deters many from adopting it. The latter difficulty does not in reality exist, since by mixing the touching-out colour with spike oil instead of water (as frequently recommended in these pages), the colour remains, the solution of gelatine having no tendency to remove it. A full description of the methods ordinarily adopted for obtaining enamelled surfaces with and without gelatine will be found at page 330 in the last volume of the PHOTOGRAPHIC NEWS. The majority of glazed prints being embossed, it may not be considered out of place here to say that the duration of convexity is largely influenced by a padding of cotton wool, which is placed in the space that exists between the embossed photograph and the flat mount used as a base. When this padding has been neglected, it requires very little atmospheric change to cause a depression in the centre of the shape, and thus mar the work. Before leaving the subject of enamelling, it might be worth mentioning that pads of cotton wool laid between convexed prints during their transit by post tend in a great measure to avoid damage, without sensibly increasing the weight; while the plan of appending a label bearing the address and postage stamp, and wrapping the package in *black* paper, does away with the risk of the photographs becoming marked by an over-zealous manipulator with the date stamp.

Those who do not care to push their work to the limit of enamelling, and are content with the results obtained by the burnisher, are apt to be troubled a good deal by loss of convexity. Stout mounts retain their shape longer than thin ones, but are more liable to burst under considerable pressure; the best results being obtained when a mount of medium thickness is used, and a little moisture is present. When the mounts are very dry, embossing is not satisfactory; the same remark also applies to burnishing with still greater force, since its importance has the most potent influence on the attainment of perfect results.

Scratches detract very much from the value of a photograph, and may often be seen on burnished prints. If every print were well rubbed with a piece of clean cambric after lubricating, and before burnishing, less scratches would be observed. When scratches make their appearance the burnishing tool should be well rubbed on an emery knife-board for a few seconds, which generally removes the offending particle.

Soiled and damaged mounts offer the very best evidence of general carelessness, and a very good estimate may be formed of the general characteristics of a business house when callousness is shown in this particular. Let the negative be ever so good, and no matter how much care has been exercised in retouching and printing it, the value of the work becomes largely depreciated when, after mounting, it is surrounded by dirty finger-marks, creases, tears, jagged or otherwise damaged edges, also blurred or indifferent letter-press printing.

Besides slovenly finishing, slovenly packing has its influence on the public mind, and should be avoided in all cases. Photographs are frequently sent through the post with little more protection than is afforded by an ordinary envelope, which offers every facility to the officials to damage the work by stamping, cording, or forcing into the letter-box, thus causing disappointment at the outset. Much more could be said on this important subject, but the space is already exceeded; it must therefore be deferred until a future opportunity presents itself.

By-the-Bye.

PRINTING PHOTOGRAPHS BY MACHINERY.

Is a collotype, or an impression from a phototype block, a photograph? Here is just one of those troublesome questions which can never be answered, and which may be discussed to infinity without any result. All, indeed, depends on the sense in which the word "photograph" is used; and in the present day, when impressions by photo-mechanical methods are so common, it is perhaps as well to include such prints under the designation photograph, instead of limiting the word to those pictures of which each individual copy has been formed by a separate exposure to light. Every picture which fairly owes its origin to the camera, and in the re-duplication of which the mind or hand of the artist has taken no part, may be fairly called a photograph when the term is used in its widest sense.

Those, on the other hand, who prefer to use the word photograph in a more restricted fashion will only consider a picture as being a true photograph when light has exercised a special action in producing the copy under consideration; no such productions as collotypes, Woodburytypes, photo-block prints, photo-lithographs, or heliographic engravings being regarded by them as true photographs.

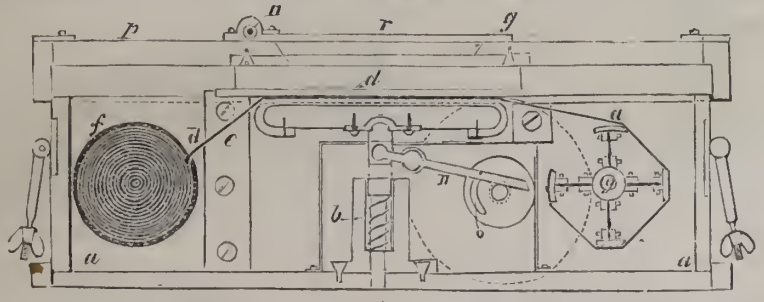
It is so usual now-a-days to connect the rapid production of photographic pictures with a photo-mechanical method, such as Woodburytype or photo-lithography, that but

little attention has been given to the possibility of rapid photographic printing by methods involving a special exposure to light for each individual print.

As stated in the Photographic News of last week, Colonel Hoe, a member of the celebrated firm of Hoe and Co., New York, has recently expressed an opinion that ordinary printing methods may ultimately give way to photography, a beam of light being flashed a hundred times a minute through a negative, and the impression being received on a moving web of sensitive paper.

Colonel Hoe's suggestion, although of some interest as coming from such a quarter, is by no means novel. On page 270 of our volume for 1860 there is an account of a machine constructed by Mr. Fontayne, of Cincinnati; this machine being capable of giving no less than two hundred exposures a minute on a band of sensitive paper, or at the rate of twelve thousand per hour, just double the number which Colonel Hoe suggests as possible. Fontayne did not use the electric light, but used sunlight concentrated upon the negative by means of a large condensing lens; and at a meeting of the American Photographical Society held on August 13th, 1860, Mr. C. H. Babcock exhibited bands of photographic prints obtained by means of the Fontayne machine. The principle of the machine is simple. A band of sensitive paper is set beneath a negative, and drawn forward at intervals; the pressing of the paper into close contact with the glass and the opening of the shutter by which light is admitted being performed automatically by suitable mechanism. Some editorial remarks, which will be found on the second page of our volume for 1883, refer to the possible use of the Fontayne machine for newspaper work, and in the same volume will be found (p. 531) mention of the machine-printed photographs exhibited by Dr. Just at the Brussels Exhibition; while in another place (p. 771) is an account of the form of the Fontayne apparatus recently patented by Herr Schlotterhoss, who has called prominent attention to the matter, so it may be well to once more give a short description of the arrangement as carried out by Schlotterhoss.

What one may call the platen of the press, or the padding of the frame, is central in the accompanying drawing, and when this platen is brought into action, it is forced up towards the negative by a spring, *h*, the negative being held by rebated and adjustable strips, *e e*; and, at other times, the sensitive material can pass freely between the plates and the negative, as it is drawn off the stock roller, *f*, on the left-hand side of the platen, towards the receiving roller (or cross), *a*. A slide, *z*, serves to cover the sensitive paper when it is necessary to change the negative. A cover or exposing shutter, 2, turns on a spindle, *h*, and this shutter



is opened by a cam at the moment when the platen presses the tissue against the negative. The general action of the apparatus, and the functions of the various mechanical organs, are sufficiently elucidated by the drawing.

Perhaps one may be hardly justified in expecting the photographic printing machine to come into general use just at present as a competitor of the usual type printer, but as highly sensitive bromide emulsions can now be made to yield excellent positive prints on paper, our readers would do well to ascertain how far they can profitably employ the Fontayne machine for the rapid production of photographic prints.

As bearing on the subject of rapid printing, it must not be forgotten that the mechanical photographs obtained by the agency of lithography or typography are already finished when they leave the machine; but that the operations of development, fixation, and washing are necessary after the band of paper leaves the Fontayne apparatus; still there would be no insuperable difficulty in making the development, fixation, and washing automatic.

Now that the quick production of photo-mechanical prints is a matter of every-day practice, let us hope that the automatic printing machine may be no longer neglected.

BRUSH AND CAMERA IN WALES.

BY H. P. ROBINSON.

Are readers tired of hearing of what others have done, descriptions in cold words of delightful hours, or is there room for one more paper on where we have been with the camera?

The anticipations of a well-organized holiday and the remembrances of a perfect success are often more enjoyable than the actual realization. However that may be, nothing could be more enjoyable or enjoyed than our "Artists' Party," as it has always been called, in North Wales, in 1884.

These same parties have become respectable from their age, for they are now a venerable institution. Not always on land, for some of them have taken the form of yachting; but for several years they have come off in North Wales, where a useful relative, whose special mission in the world is to find enjoyment for others, and pick up by the way a few crumbs of the pleasure himself, if he can, incidentally, rents a shooting estate whose covers in Autumn supply sport on the largest scale, and which, with the river in summer, is one of the loveliest spots in the most beautiful part of the Kingdom.

This estate is not the one on which I have photographed during the last three or four years. Owing partly to the operation of the Ground Game Act, which seems to have been passed for the purpose of setting landlords and tenants by the ears, and breaking contracts, we shall see no more of Gwysaney. But all things happen for the best if you will only think so; it was a paradise in its way, and the grand old hall was delightful, but I was beginning to feel, or tried to persuade myself, I had used up the best parts of it, and the change to Gelli Gynan has given me the run of another place differing greatly in the character of the scenery.

The party met at Euston Station about the middle of June, and consisted of several artists whose works are well known to frequenters of exhibitions, and some to whom hope at present has only whispered a flattering tale. A merrier party seldom went by train. On our way the subject, which always seems to come on for discussion when painters and photographers get together—"What is an artist?"—cropped up. The discussion was hot, but

we unanimously agreed that the owners of a good many well-known names in art, including a fine collection of Royal Academicians, were not artists. It was also generously conceded by the painters that it was not the materials a man used that made him an artist, but the way he used them—this from the material painter who cares only for the way a thing is expressed, and not the quality of the subject, so that it was not pretty, like a Christmas card. The ideal painter was inclined to think that the true artist was the one who had the greatest thoughts, it mattering little how they were set forth so that they were expressed according to the rules of art. But a third painter, whose pictures are conspicuous in the Academy and Grosvenor, settled the matter by enunciating the following definition :—"The man who does what he can do is not an artist; the man who does what he cannot do *is* an artist." So it was settled that, to be an artist, requires the achievement of the impossible! I hope this settlement of a much-discussed question will suit all sides of it, and all photographers who wish to be considered artists had better at once look out for miracles.

Arriving at Chester, we had an hour to wait, which enabled us to take a walk into the town and admire the curious and very picturesque Rows. Then, in half-an-hour more, we arrived at Mold, where we were met and driven seven miles through lovely country, on a glorious summer evening, to Gelli Gynan.

Now to be seven miles from a railway station is a delight in itself.

Gwysaney was made beautiful by its magnificent timber : Gelli cannot boast of many exceptionally fine trees, but the compensation comes in a heather-covered mountain, with grouse, overlooking the Vale of Clwydd; an extensive and very wild looking lake, or tarn, situated half way up the mountain; and two or three miles of the river Alyn. These are the three great features of the place, filled in with all the beauties such a country would suggest; but for my purposes, the great attraction of this kind of place is its solitude. Here you can do as you like; here your models can dress as they please, and no prying eyes come to disconcert the photographer and turn his mind away from the composition of his picture to how best to get rid of the intruders. I can always be satisfied with any moderately picturesque scenery, providing I can have it to myself. In the retired parts of Wales the few natives soon get to know you and give you all the help they can—always excepting that they do not care to be photographed. The belief in the evil eye and kindred superstitions still exist in Wales. They believe that the painter or photographer takes something necessary to their life from them. Three years ago, as I think I have said in a former paper, I had great difficulty in getting a Welsh girl to allow me to photograph her. I have only just discovered that her reluctance was due to this superstitious feeling, and it is a curious and startling coincidence that the girl died three months afterwards, a circumstance which was proof positive in the eyes of her friends of the truth of the belief.

The first duty of a photographer when he goes to a new place is to prospect it and see of what it is artistically capable. I was at Gelli last November for the shooting, and occupied part of the time in looking out for pictures, making sketches for subjects as the scenes suggested them to me; but I now found that my preparations were not of much avail, for nature presents a very different aspect in summer to what it does in winter, as I ought to have known. It is seldom worth while, and is always a loss of time, to rush all over a place for subjects, when you can get them pretty close together; so we agreed to *do* the place in sections, and as the river, or about a mile of it, suited the painters as well as myself, we elected to pass our time on its banks, leaving the mountain and the lake for future use. Now, in November the river was full of water, in June it was nearly dry—this being the dryest summer for fifteen years, and the sheep were dying on the hills—presenting a quite different class of subjects. But these were very easy and obvious ones. What artist, whether painter or photographer, can resist such subjects as stepping stones, fords where the river crosses the road, and the bed of a rocky stream, and a three hundred year old mill, and a two hundred year old miller, for this genial old gentleman said he (must I explain? he meant his family) had lived all those years at the mill. In his delightful Cymraeg-English he said, "It is two hundred years tomorrow-day since I shall see it." His great desire was to travel and see the British Museum, where he heard all the pictures were. Being a man who read his newspaper weekly, and knew the world, he defied the superstitions of his country, and did not entirely believe that being photographed would accelerate his death; he therefore appears in several of my pictures. The miller was a great treat to us, and made himself useful. The mill was useful, if dusty, for stowing our heavy apparatus in, and he literally placed at our disposal his ox and his ass and everything that was his, for he was a farmer as well as a miller, and had cows, and calves, and donkeys, and pigs, and there was an amiable young bull that always came up to "assist" in our operations. The miller, too, could give advice upon occasion. One morning I was evidently going to waste a plate on a scene that would be better lighted in the afternoon, and he said, with the air of a judge, "It will be betters perhaps before if you will take it afters." And he got a charming "rise" out of one of the painters who was finishing a two-foot canvas by saying, "I suppose you will take that for a pattern, and do the others that you want with the machine."

With all these adjuncts to picture making, to which may be added a picturesque game-keeper who carried my camera, and three or four "models" dressed in the clothes of the country, the making of pictures was an easy matter.

It is quite impossible for anyone who is in the habit of composing pictures to help getting them when he has such capital materials to his hand. He scarcely requires to have ready-made ideas; ideas, as it were, *jump* upon him. Happy thoughts arise to time with the greatest punctuality. But all this must be by the kind permission of the wind, of which we had more than enough. A slight breeze will sometimes make a close scene with figures impossible. It is easy enough to wait and take snatches of exposure between the gusts if you have no life in your picture, but with models and near trees in the same subject the difficulties are increased a thousandfold.

It often happened that a subject occurred and was secured in a few minutes, with very little demand on the skill of the photographer. As an example, I will mention one subject, for which I can only take the credit of seeing it when it happened. One day I could not have the keeper who usually attended me, and I had to take an undergardener. This man was a pictorial treasure. He was old, and had scarcely been further from the estate than Mold in his life. He was essentially a happy-looking old man, and full of native wit. I had been looking for a view some way off, and returning, saw my old man sitting on a rail in the hedge, surrounded by the models, who were chaffing him in Welsh and English. They made a picturesque group, and I heard one of them say, "He never told his love." Here was subject and title together, and was at once secured.

I don't think I need trouble my reader with anything but the photographic part of the trip. It is not necessary here to say anything about the fishing, which was not very successful, owing to the want of water, but the energy of one of our number supplied trout for breakfast every morning; or the tennis, of which there was a furious hour or two every day; or the visits to the young pheasants, of which vast numbers are reared, and which I hope to meet again in November; or the indoor amusements,

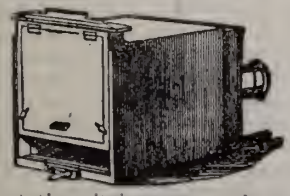
which sometimes carried us so far into the night that we saw the sunrise and heard the early village cock do salutation to the morn. But we consoled ourselves that towards the end of June there is no real night according to the almanacks, so what else could we do?

But have I said anything photographic? Have I said anything that would be of use? Have I, in short, been eminently practical? Not a bit of it. I perhaps ought to have been so, but I meant this at starting to be a purely holiday paper.

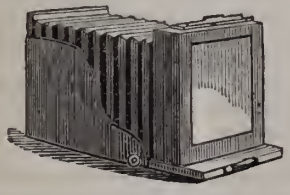
Practical Papers for Beginners.

No. 2.—PREPARING FOR WORK WITH THE NEW CAMERA.

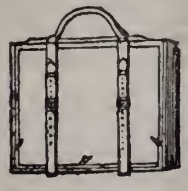
Any convex lens—as, for example, an ordinary reading glass—will be seen to form a picture of a landscape if a sheet of white paper be held up to receive the image at the proper distance behind the glass, but we have not the remotest intention even to allude to the optical laws which govern the formation of an image by a convex lens; still we may remark that opticians have succeeded in constructing compound lenses which are very much better for photographic purposes than any single magnifying glass can be. The photographic camera in its simplest form is a box with a lens at one end, and at the other a pane of ground glass; this glass being set in a sliding frame, which frame can be removed at pleasure, and replaced by a shallow light-proof box, in which the sensitive plate is carried from the dark room to the camera. This shallow light-proof box, ordinarily called the dark slide, and the simplest form of camera, are sketched in the subjoined diagram; but the dark slide is shown as not quite down to the bottom of the groove in which it slides.



At the present time it is very usual to make cameras with compressible bodies, a bellows something like that of a concertina being provided, and such a folding camera is



very convenient when the apparatus is to be used away from home, as, when compressed, the camera forms a nearly solid block of mahogany and leather which may be conveniently carried by means of a strap.



After the beginner has examined his camera, and learned how to open and close it, the tripod stand may be put together, and the camera mounted upon it: a screw for this purpose being ordinarily provided with the camera.

Sometimes a stand with divided legs is used, the lower branch of each leg being capable of sliding between the upper branches, an arrangement which is convenient for the

traveller, not only on account of the fact that the length of the packed stand is reduced to about one-half of what it otherwise would be, but it is also a very great advantage

to be able to shorten one leg of the stand when working upon uneven or hilly ground.

Let us now suppose the apparatus to be firmly mounted upon its stand, and the lens placed in position. The first thing is to see that all working parts fit properly, that the frame bearing the ground glass (focussing screen) works freely on its hinges or in its grooves, and that the dark slides can be placed in position and removed without involving the use of so much force as to put the camera out of gear. Most cameras are now provided with a rack-and-pinion action for adjusting the focus, and it is well to run the movable part along the whole length of the rack once or twice, taking care to search out the cause of any unsteady movement or difficulty in working the pinion. A black cloth must be provided, not only for covering the camera during exposure, but also as a shade to enable the luminous image to be distinctly seen on the ground glass. Many use black velvet; but a fine quality of black woollen cloth, such as coats are made of, is perhaps to be preferred. Having covered the lens with the leather cap—which, by-the-bye, must fit quite easily—the camera is taken out in the full light, and after having removed the ground glass focussing-screen, the black cloth (focussing-cloth) is carefully tied stocking-fashion round the open end of the camera, so as not to lap over the cabinet work more than can be helped, and diligent search is made for any minute holes or cracks which may admit stray beams of light, the head being pushed up into the tube formed by the focusing cloth. It is hardly possible to give one universal prescription for stopping out light, as it may not only enter through a minute pinhole in a joint, through a perfora-

tion in the material of the bellows, or by ill-fittiug arrangement of the sliding front; but any one of a dozen faults in the workmanship may make the camera pervious to light. Slips of shaving moistened with glue may be used to fill out chinks in bad work, and little patches of thin leather glued on may be used in other cases.

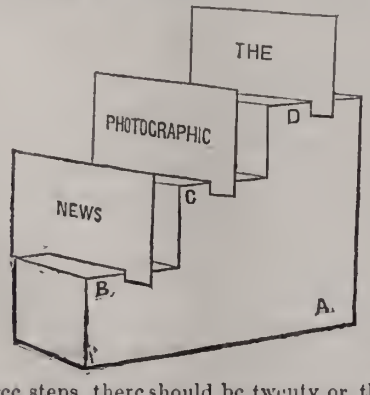
Next remove the cover or cap from the lens, and direct the instrument toward a brightly-illuminated sky, and take an observation inside as before. This time all those parts of the inside of the camera and lens-mount which become brightly lighted up should be noticed, and an attempt should be made to reduce the amount of stray light reflected from them by the application of a mixture of starch paste and lamp black, or by covering with black velvet, this being glued on with the ends of the fibres or "nap" directed towards the aperture of the lens.

It is well known that ordinary white light is a composition of many tints of coloured light, the decomposition of a beam of ordinary light into its component tints by a prism being exemplified in the case of the ordinary prismatic lustres used for decorative purposes; and it should be remembered that the coloured radiations which affect the sensitive plate most energetically are not those which produce the most vigorous impression upon the eyes. In a well-constructed photographic lens, the optician makes an adjustment to make the photographic focus coincident with the visual focus, so that if a view is focussed as to appear on the ground glass with the maximum of sharpness, the position occupied by the ground glass will be exactly that best suited for obtaining a sharp impression on the sensitive plate. Not only is this correction sometimes made imperfectly—especially in the case of the cheaper lenses—but it occasionally happens that the camera is so badly adjusted that the position of the sensitive plate in the dark-slide does not exactly coincide with the position occupied by the ground glass of the focussing-screen.

If the beginner has but one lens, and he intends always to use this on the same camera, it is easy to test for both faults conjointly, and to apply a correction which shall correct either or both faults.

For this purpose take a board about an inch thick, and cut a series of steps along one edge of it, and in the tread of each step make a saw-cut, a small piece of card, upon which there is printed or written matter, being now placed in each saw-cut.

The subjoined drawing represents the arrangement as far as three steps are concerned; but instead of only



having three steps, there should be twenty or thirty, each card being about an inch apart.

Place this "focimeter" on a table or other support, about the same height as the camera-stand, and adjust the camera opposite to it, so that an image is formed which will extend about two-thirds of the distance across the plate. It is convenient to so place the camera on the tripod that one leg comes exactly behind the instrument, and having firmly planted the two remaining legs in front, it becomes easy to make all adjustments as to level and inclination with the hind leg; and as during the work this hind leg goes conveniently between the legs of the photographer, the chance of capsizing the camera is less than it would otherwise be.

The middle card is now carefully focussed with the full aperture of the lens—that is to say, any movable screens or diaphragms which are intended to reduce the amount of light passing through the objective are removed. In order to ensure the production of the sharpest and best defined image of the printing or writing on the middle card, it is convenient to use a magnifying-glass while the adjustment is being made with the sliding part of the camera; and it is scarcely necessary to say that the head and the back of the camera must be screened with the dark cloth while the work of focussing is in progress.

When the central card is focussed sharply it will be noticed that there is a gradual falling off of sharpness as regards the remaining cards, those at the two extremes of the series being probably quite indistinct; and the object of the experiment is to find if the card which gives the sharpest and best defined image on the ground glass will yield the sharpest impression on the sensitive plate. As our next practical paper will deal with exposing and developing dry plates, we will defer our directions for actually making the trial on a sensitive plate.

PHOTOGRAPHIC AND SPECTROSCOPIC OBSERVATIONS AT GREENWICH DURING THE PAST YEAR.

BY W. H. M. CHRISTIE, ASTRONOMER-ROYAL.

The solar prominences have been observed with the half-prism spectroscope on 21 days, and four sun-spots have been examined on 5 days with reference to the broadening of lines in their spectra. Displacements of the hydrogen lines in the spectra of the prominences and chromosphere, and reversals of the metallic lines, have been noticed much more frequently than in preceding years.

For the determination of motions of stars in the line of sight, 412 measures have been made of the displacement of the F line in the spectra of 48 stars, 91 measures of the *b* lines in 19 stars, and 2 measures of the D lines in one star, besides measures of the displacements of the *b* and F lines in the spectra of the east and west limbs of Jupiter, and in the spectra of Venus and Mars, and comparisons with lines in the moon or sky spectrum made in the course of every night's observations of star-motions, or on the following morning, as a check on the adjustment of the spectroscope. Some preliminary measures have also been made of the F line in the spectrum of the Orion-nebula. The progressive change in the motion of Sirius, from recession to approach, alluded to in the last two reports, is fully confirmed by numerous observations since last autumn, and a change of the same character is indicated in the case of Procyon. A discussion of the measures of all the stars observed here, on which I am now engaged, shows that the results of the four periods—1875 June to 1877 May, 1877 June to 1880 December, 1881 January to 1882 March 10, 1882 March 11 to 1884 March 31, in each of which the instrumental conditions were different—accord generally within the limits of the probable errors, and that there is no systematic change from recession to approach, so that the presumption against error arising from defective instrumental adjustment appears to be strong.

The spectrum of Comet *b* 1883 (Pons-Brooks) was examined on two nights, and at the request of Dr. Konkoly a search was made on five nights for bright lines in the spectrum of η Ceti, but their supposed existence was not confirmed.

In the twelve months ending 1884 May 20, photographs of the Sun have been taken on 219 days, and of these 507 have been selected for preservation. There were 4 days on which the sun's disc was observed to be free from spots.

The mean spotted area of the Sun was slightly greater in 1883 than during the preceding year, although the faculæ have shown a small falling off. For the year 1883 Greenwich photographs are available on 215 days, and Indian photographs filling up the gaps in the series on 125 days, making a total of 340 days out of 365 on which photographs have been measured. In 1882 the total number of days was 343, viz., Greenwich series 201 days, supplemented by Indian photographs on 142 days.

By the application of a new secondary magnifier and longer camera, the Dallmeyer photo-heliograph has been adapted (since April 4) to take eight-inch photographs of the Sun instead of four-inch. A new and improved micrometer adapted to the measurement of photographs of the Sun up to 12 inches in diameter has been made by Messrs. Troughton and Simms, and is now used exclusively in the measurement of the solar photographs.

The Indian photographs received from the Solar Physics Committee have been measured to the end of 1883, and the measures have all been completely reduced so as to exhibit heliographic latitudes and longitudes of spots and areas of spots and faculæ.

The continuous record by photography of changes in the magnetic declination, horizontal force, and vertical force, and of earth-currents, has been maintained with perfect regularity, whilst absolute values of the magnetic elements are determined periodically by eye-observation.

The time of vertical vibration of the vertical magnet has been adjusted (relatively to the time of horizontal vibration), so that the same length of ordinate on the photographic sheets represents very nearly the same absolute amount of disturbance for vertical force as for horizontal force and declination. The movements recorded in the three elements are thus immediately comparable.

The identity and insulation of the earth-current wires have been recently tested and found satisfactory, except that the insulation of the "Blackheath" line seemed a little defective.

The new position of the Dip and Deflection instruments in the new Library appears to be generally satisfactory.

The ironwork of the Lassell dome did not affect the magnetic registers in the slightest degree when it was brought into the South ground on 1883 December 31. Although there is a large mass of iron in the Lassell equatoreal and dome, it is at such a distance from the magnets, and so nearly in the magnetic meridian passing through the declination magnet, that no appreciable effect was to be anticipated.

As regards the magnetic reductions, the eye-observations of the upper declination magnet, and of the horizontal and vertical force magnets, are completely reduced to the end of 1883. The time-scales for declination, and horizontal, and vertical force are complete to the end of 1883, and the base line values, deduced from the eye-observations, are entered on the photographic sheets.

The hourly ordinates of the photographic curves are read out to the end of 1883 for declination and horizontal force. The daily and hourly means are taken for declination to the end of 1883, and for horizontal force to last June. The time-scales for the earth-currents are laid down to the end of August 1883. The observations of dip are completely reduced to the present time, and those for absolute horizontal force to the end of 1883.

In the year 1883 there were only five days of great magnetic disturbance, as against 15 in 1882, but there were also about 30 days of lesser disturbance, for which it appears desirable to publish tracings of the photographic curves.

As proposed in the last Report, tracings of the photographic curves of magnetic movements and earth-currents, reproduced by photo-lithography on a reduced scale, have been given in the volume of "Greenwich Observations," 1882, for 34 days of greater or less disturbance, in substitution for the tables of ordinates measured from the photographic trace. Besides these, a brief description of all magnetic movements (superposed on the ordinary diurnal inequality) has been given for other days with a view of affording facilities for comparing them with solar phenomena. In the preparation of these particulars, as well as of the plates, Mr. Ellis has rendered very valuable assistance.

The meteorological instruments and the Thomson electrometer have been maintained in good order. In the gale of Jan. 23 the short connecting chain attached to the pressure plate of Osler's anemometer gave way, having perished in course of many years' exposure to the weather. After some delay through our having to wait for a quiet day before the pressure plate could be examined, a new chain was substituted on Feb. 26. The flexible brass chain connecting the external chain with the recording pencil continues to give very satisfactory results.

A new photographic thermometer apparatus, in which I have arranged that the dry and wet bulb traces shall fall on the same part of the photographic cylinder as regards time-scale, is being made by Messrs. Negretti and Zambra, and, after many delays, is now nearly finished. By means of a long air-bubble in the wet-bulb thermometer, with a column of mercury above, the degrees and decades of degrees are registered for this thermometer just below the trace of the dry-bulb thermometer, and without any interference of the two records. The scale of time for the thermometers will in this arrangement be the same as for all the other registers, both magnetical and meteorological.

A slight shift has been made in the positions of the rain gauges in the magnetic ground.

The observations of the temperature of the Thames made at the Deptford Cattle Market are regularly communicated to the Royal Observatory, and appear to be quite satisfactory.

The meteorological reductions are in the following state:—The observations of barometer, thermometers, anemometers, rain-gauges, and sunshine instrument (corrected, where necessary, for instrumental error), are reduced up to the present time. On the photographic sheets all the time-scales are laid down to the end of 1883. The hourly ordinates are read out for the barometer to 1883 February, for the dry-bulb thermometer to 1883 July, for the wet-bulb to the end of 1882 only, and for the electrometer to 1883 June. Commencing with the year 1882, the electrometer results have been drawn up so as to exhibit the mean diurnal inequality in each month for rainy days and for non-rainy days, as well as for all days taken together.

Notes.

The *Hotel Sahara* at the Biskra Oasis is shown in our supplement this week. In the account of his trip, Mr. Pritchard told how the journey over the desert terminated here, and how the French colonists have not failed to provide some of the characteristic features of Parisian life, even though this green spot, bounded by an ocean of sand, is but two miles long and half a mile wide.

Strolling, recently, on one of the South London Commons much frequented by the itinerant photographer, we spied one of the fraternity with an enormous carriage-umbrella under his arm. Our curiosity was stimulated, and we watched his proceedings. He was not long before he caught a sitter, and while he focussed and exposed the plate, his assistant held the umbrella over the sitter. "I wouldn't be without that umbrella for anything," said he to us afterwards. "Why, I can take 'em in the open sunshine, and get a nice shade over the face, and they come out with the

eyes fust-class." This was very likely, but the *tout ensemble*—the simpering sitter, and the anxious assistant shielding her almost lovingly with the umbrella—made an extremely funny picture, quite worthy of the detective camera.

The important subject of photo-lithography in half-tone will be treated of by Major Waterhouse in some of his future articles; and in these chapters our readers will find much that is novel, also a great deal that has been almost forgotten.

An etching process on copper for the reproduction of half-tone, like that of Klic (present number, page 477), is very much more rapid than an electrotyping method like that of Waterhouse; but we hear that Major Waterhouse is now working with an etching method which offers interesting points of novelty. Our readers shall have particulars before long.

Which is the more rapid, the wet process, or the dry? If one only considers the time of exposure, there can be but one answer to the question; but if exposure and development are taken together, the case is altogether different.

Hence it is that those who have to photograph a series of inanimate objects—as, for example, drawings and other subjects for reproduction by photo-mechanical methods—almost invariably prefer to use wet collodion. "I can do three times as much work by the wet process, and it costs me less," said a photographer who does little else than copying and making negatives from the inanimate.

The competition having reference to the novel posing of photographic "sitters," to which we lately referred, has duly come off, and the results are even more disappointing than we expected they would be. There are innumerable suggestions made, it is true, but most of those which are new are not practicable, whilst those which are most practicable are certainly not new. One wag suggests that the most novel position which a "professional beauty" could assume would be "to be taken with her husband"; and two or three competitors propose that to avoid all danger of artificial expression, it would be advisable for sitters to be taken asleep!

Several correspondents think that ladies with shapely arms in search of novelty would do well to be taken in a coquettish cap and bibbed apron, making a pudding; an alternative occupation suggested being the much more poetical one of picking roses growing well nigh out of reach. That people should be taken blowing bubbles, playing cards, swinging in hammocks, skating, playing at "bob cherry," bicycling or tricycling, stepping in and out of carriages, doing fancy work, threading needles, darning stockings, playing the piano, rocking cradles, picnicking, feeding fowls, and riding "property" horses. Here we have but a selection of the suggestions, more or less anticipated, which are forthcoming.

One competitor, however, thinks he has hit upon a good notion in saying that a sitter should have a back view as well as a front one taken, and that the resulting pictures should be stuck on either side of the card mount. These portraits would, like medals, have their obverse side. Another proposes that the pose and attitude of the sitters in well-known paintings should be imitated; whilst a third, evidently "a funny dog," thinks it would be effective for photographic "subjects to be posed in attitudes identical with those of our best known London statues. Only fancy being taken in a carte *à la* "Griffin," or in a cabinet *à la* "Queen Anne in St. Paul's Churchyard!"

By one original genius, photographers are advised to provide themselves with a huge practicable "Jack-in-the-box" kind of arrangement, and to "take" their "sitters" "coming out" of that! Yet another proposal is that during a hot summer a "property" bathing machine would form a good background, and that photographs in bathing costumes might become quite the fashion. The suggestion that portraits should be taken in relief as medallions, and worked up in the shape of porcelain or terra-cotta plaques, has to a great extent been anticipated; in fact, as we have said, there is little in the competition which can be considered practically useful, and it will be curious to note which of the suggestions is considered worth the two guineas offered as a prize.

Immediately in front of the National Gallery, a galvanized iron building, about thirty feet long, and surrounded with a galvanized iron fence, may be seen; and this turns out to be a studio in which some of the pictures are to be photographed. We are glad to have photographs taken of the pictures, but how easy to have done this work without putting up a studio of the very ugliest type, and in such a position as to disfigure the finest open square in the metropolis. Perhaps the authorities are of opinion that Mr. Williams' pepper-castored building is already so hideous, it can scarcely be made worse.

Apart from all questions of ugliness, the studio should be of a kind suited for photographing paintings, not a portrait studio of the worst type; and it should have been placed in a proper position as regards the light—quite an easy matter if the work were done on the roof as formerly.

The *Daily News* exults much at the prospect of the pictures being photographed "*with the advantages of a proper position and a good light.*"

Mr. Spiller informs us that there is some probability of the paper-makers acting on his recommendation to use sulphite of soda as an antichlor instead of the hypo-sulphite; and his recent paper, "Observations on Fading," has been reprinted in the *Stationery Trades Journal*. It is a very good thing for the matter to be ventilated in the paper trade circles; but a few successful actions for damages against those who supply faulty mounts or paper will be the best means of bringing about so desirable a change.

When goods are supplied for a definite purpose, there is held to be an implied guarantee that they contain no substance which is *well known* to unfit them for that purpose; and that, as regards the intended use, there is no latent defect which might have been avoided by reasonable care in the manufacture.

A photographer who purchases mounts which cause his pictures to fade, owing to the presence of hyposulphite, may recover full damages for loss of trade and reputation, provided that the mounts were bought of a firm accustomed to supply mounts to the photographic profession, and that the vendors had reasonable ground for knowing to what use the mounts were to be applied.

Similarly, a photographer may doubtless recover consequential damages from the maker of defective dry plates, provided he can prove his case.

The celebrated suit of Turner *v.* Ermen illustrates the law of implied guarantee. Cotton thread was supplied to Turner, a manufacturer of elastic webbing; and as this cotton contained a trace of fatty matter—well known to be injurious to rubber—the plaintiff gained his case.

The fear of being taken for a dynamiter on the one hand, and of having his plates spoiled by anti-choleraic fumigatious on the other hand, may perhaps have influenced a holiday maker or so not to take the camera to the Continent this summer.

Any readers who may have thought of leaving their cameras behind may reassure themselves, as the dynamite scare is practically confined to our own shores; and it is quite easy to avoid frontier stations where fumigation is the order of the day.

If plates are done up in light-tight packages of four, and each three of these packages is wrapped in a sheet of tinfoil, the tourist need not fear, as on all principal routes the Custom officers are quite used to photographers and their belongings.

Only once has our statement as to the nature of a dry-plate package been questioned, and this was in passing alone and on foot from Switzerland to Italy, at the village of St. Remy.

We took out our candle, lighted it, put the red shade in position, and said the plates must be examined by this light, if at all. Curiosity, rather than a desire to search after contraband articles, was the motive that led the soldier to fit up a dark-room, and to watch us as we emptied our slides and re-charged them. Half-an-hour afterwards three Italian soldiers and an Englishman might have been seen smoking and chatting outside the village inn, *Hotel des Alpes Pennines*, this establishment being conveniently situated nearly opposite the Custom House.

After the recent inspection of the Yeomen of the Guard in the garden of St. James's Palace, as they were standing drawn up in line in their picturesque Henry VIII. uniforms, an equerry arrived suddenly on the scene with a message from the Queen for the commanding officer. Her Majesty had, it seemed, given orders for the corps to be specially photographed for her, and accordingly several successful negatives were soon after taken, and the results have since been submitted to and approved by the Queen. If Her Majesty would permit these photographs of her faithful Beefeaters to be published, they would doubtless prove popular.

Photography as a means of verification has many applications, and we see that the proprietor of an advertising circular has hit on a new one. He proves that he has posted the six thousand copies he agreed to post, by a phototype reproduction of the official receipt for the postage of the six thousand copies of No. 1 of his circular, posted in bulk and without stamps.

The nation cannot complain of the cost of photography to the State. As we mentioned a month ago, the total amount spent last year was £2,620, and of this science and art absorbed £1,000 for photographing of art objects and the reproduction of pictures; £760 went to the Photographic Department at Woolwich Arsenal, and £860 was spent in reproducing the unlovely faces of our criminals at the various gaols in the three Kingdoms.

That photographic curiosity in journalism, the *Nutshell*, is a curiosity no longer. It may be presumed that either the photographing of each page was unworkable, or the smallness of the reproduced type a drawback, since the paper now appears in the conventional form, and a little larger in size.

The solution of amber in chloroform, occasionally used by photographers as a varnish, finds a new application in giving lustre, weight, and pliability to silk goods. The solution having been applied with a sponge, the materials are heated in a dry box, which is so arranged that the chloroform can be condensed and recovered.

Seven thousand patents were applied for during the first four months of this year, and of these only four were refused. The largest number applied for on any one day was on the 1st of January, when 266 applications were made; but on the 2nd of April only 40 persons wanted to patent.

Some of the photographs of Venus taking during the transit of 1882 show elevations of surface which MM. Grye and Arago seem inclined to attribute to a large continental plateau, or to some kind of cloudy matter; possibly a combination of both.

It will not be forgotten that photographic measurements of Venus have indicated a Polar flattening of about $\frac{1}{3}\frac{1}{0}\frac{1}{3}$rd,

this being not very different from that of the earth. As regards the projections recently put on record by the camera, it may be mentioned that their position is such as to confirm the observations made sixteen years ago by Trouvelot.

Patent Intelligence.

Applications for Letters Patent.

10,226. BENJAMIN JOSEPH EDWARDS, 6, The Grove, Hackney, Middlesex, Photographer, for "Improved apparatus for dissolving and changing pictures in the magic-lantern."—(Complete Specification.)—Dated 16th July, 1884.

10,334. JAMES STURROCK, Bank Street, Dundee, Forfarshire, for "Improvements in washing baths for photographic purposes."—Dated 19th July, 1884.

10,370. CHARLES STORTZ, 33, Bonchurch Road, Hassocks Gate, Sussex, Photographic Printer, for "An improvement in washing apparatus for photographic negatives."—Dated 19th July, 1884.

Patents Granted in America.

301,706. THOMAS D. FITZSIMMONS, Philadelphia, Pa., assignor of one-half to Robert W. Witham, same place. "Process of preparing canvas for photographing." Filed February 20th, 1884. (No specimens).

Claim.—1. The herein-described process of preparing canvas and similar material, so that a photograph may be taken thereon, consisting of coating the surface of the canvas with ordinary paint mixed with megilp, varnish, or a similar material, and afterward covering the painted surface with collodiou, and submitting the prepared surface to a bath of nitrate of silver solution, substantially as shown and described.

2. The herein-described process of photographing upon canvas and similar materials, consisting of painting the surface of the canvas with a mixture of ordinary paint and megilp, or varnish, coating with collodion, then submitting it to a bath of nitrate of silver solution, afterward placing the prepared canvas in position in front of a camera having a negative of the picture to be taken placed in the back part thereof, said camera being placed in front of a window in a room from which the light has been excluded, except as it strikes the lens of the camera after passing through the aforesaid negative, substantially as described.

EOSINE.

BY CH. EHRMANN.

EOSINE is not, as erroneously believed by many, an aniline colour, but is a dye-stuff, belonging to the series of phtaleïns, which are compounded in various forms by synthesis.

Diphenylphtaleid, $C_{20}H_{14}O_2 = C_6H_4C\ (C_6H_5)_2$, C_6O, is the substance from which other phtaleïns are derived, and is formed when chloride of aluminium is gradually added to a mixture of four parts of benzole and one part of phtallyl chloride.

When resorcin, which is made by the melting of galbanum, ammoniacum, asafœtida, &c., with caustic potash, is heated with anhydrous phtallic acid, a red precipitate occurs, which is quite insoluble in water, and the solutions of which in alkalies show remarkable fluorescing qualities. Sufficiently diluted, such solutions appear yellowish-red by transmitted, and yellowish-green by reflected light. This matter is called fluoresceïn. When its solution in glacial acetic acid is subjected to the action of bromine, there is formed tetra-bromo-fluoresceïn ($C_{20}H_8Br_4O_5$), a yellowish-brown powder, crystallizable from alcoholic solutions. Its soluble potassa salt ($C_{20}H_6K_2Br_4O_5$) has been termed eosine. It is fluorescing, and colours silk a beautiful pink. Tetra-bromo fluoresceïn, tetro-iodo-fluoresceïn, and auother stuff of blue colour, cyanosin (of which but little is known), are substances which now, on account of Vogel's great invention, will occupy the minds of all studious and progressive photographers.

The chemistry of the phtaleïns, like that of many other organic compounds, is difficult to learn, and far beyond the knowledge of chemistry possessed by photographers generally. Nevertheless, it is interesting to know something of the matter we employ or expect soon to use daily. Pyrogallol, hydrokinone, and pyrocatechin, treated with sulphuric acid, or anhydrous phtallic acid, give substances similar to fluoresceïn as obtained from resorcin.

Dr. Vogel, as we learn from foreign communications, has resumed his labours, commenced about eleven years ago. Others have worked in the same direction, and it is fair to say that a magnificent result is the consequence of Vogel's investigations. With proper application of those colour-stuffs, either to collodion or gelatine emulsion, colours can now be reproduced photographically in the same proportion of value that the human eye sees them. The dark blue and the light yellow can now be photographed dark and light—not light and dark, as heretofore

When knowledge of these great inventions reached our shores I, probably with many others, commenced to make experiments in their direction, and although I have not met with the success wished for, I have become acquainted with some interesting facts, which may also be interesting, possibly instructive, to others. Dr. Vogel's process having only recently come to us, was not known to me at the time in all its details as described in the latest number of foreign journals. With collodion I progressed but poorly, and as I cared more for the working with gelatine plates, I devoted my attention to Tailfer and Clayton's patented isochromatic process.

The first and possibly the greatest difficulty was to procure the right sort of eosine. I obtained at last three different samples—a light yellow, a light ruby, and a dark red. By mixing the two first in the proportion of 1 : 2, I had what I thought would do, and commencing operations, I took of the

Mixed colours	5	grams
Water	120	c.c.m.
Ammonia (stronger)	30	,,
Alcohol	50	,,

dissolved and well mixed.

I used bromo-iodide gelatine plates (5 per cent. iodide). I washed the plates first in water till it ran smoothly over the plate, and immersed them for one minute in the eosine solution and washed again, till the water dripping from the plate was quite colourless, and dried them in an ordinary drying-box. The plates were of deep orange colour. My first pictures were the most encouraging. I copied two highly coloured chromos in which yellow, orange, and blue predominated. Of several developers used I found pyro, soda, and sulphite to be the best, and I actually obtained a reproduction in which the value of colours is perfectly well represented. With dark blue and light orange silk ribbons I did not succeed as well, although the yellow showed much lighter than on an ordinary collodion plate. With a dark purplish blue lily and some yellow buttercups, I made a decided failure. I have tried one portrait (face red and much tanned). Result: over-exposure, but showing the desired qualities. No success with collodion. With the portrait, I gave two seconds more than usual. Without it, the negative might have been better. Dr. Vogel's formula just having arrived, I have not had a chance to try it. I doubt whether the colours used were really those he described. Through the kindness of Dr. Vogel, I will soon be able to work with the same colours as he uses himself. When I have them, I will resume my experiments, and let you know the results.—*New York Photographic Times.*

PHOTOGRAPHY FOR LADY AMATEURS.

BY F. J. ERSKINE.

FOR many years photography was a sealed book to any but those of wealth and leisure, or making it their profession. A donkey-load of apparatus and some most fearfully poisonous ingredients were required. The baths left ineffaceable stains on the fingers; the whole apparatus was cumbersome, heavy, and costly.

Makers of photographic appliances are now making up tourist sets of quarter-plate size, and more expensive ones to take half-plates. A whole set, with camera, tripod, three double dark backs, each holding two dry plates, chemicals, and all requisites, can be obtained from £4 4s.

Many will say, however, that a properly-fitted dark room is necessary; but although, if possible, it is best to requisition a dark cupboard or attic for a "den," it is by no means indispensable. When away from home, a ruby glass lantern should be carried, and light may be effectually excluded from the plates by developing at night the negatives taken during the day. If a lamp or the moonlight comes through a window, a sheet of brown

paper pinned across with drawing-pins will effectually make all sure. Apparatus required:—Three or four developing-trays of ebonite, one being legibly marked "hypo;" a bottle of pyrogallic acid, a small drop bottle for containing the ammonia bromide solution, a jar containing hyposulphite of soda for "fixing," a couple of graduated glass measures for fluids, a box of scales and weights, some bromide of potassium (useful in case of over-exposure), a small package of alum to clear and harden the gelatine film, and a nest of three developing-cups.

A certain amount of care is requisite in the use of the dark slides. Each should have its own separate case of black American cloth, fastening with buttons, and when taken out of the case it should be covered with the focussing cloth. More caution is required in the brilliant days of summer than at other times. Some people say that the sun is not as bright now as some time ago. All I know is that, if dark slides are carelessly exposed to the summer rays, the plates run a very good chance of being fogged, and it is very aggravating, when pains have been taken to get a good view, when developing to find out all the trouble has been wasted on a fogged plate.

It need not be taken for granted that, because a person cannot draw, she is deficient in artistic feeling. Most people can pick out a pretty "bit" to photograph.

The weather which is best for photography is when there are gleams of sunshine, with plenty of clouds about to give the requisite soft variation of light and shade. A cloudless sky and a hot sun are not good. A photograph should never be attempted with the sun shining on the lens, as fogging is certain to ensue. Many beginners spoil their plates more by under-exposure than by over. Hearing of instantaneous photography of races, Flying Scotchmen, and other miracles of rapidity, they must needs give their unfortunate plates so short a time that no image can be impressed.

In the first place, the plates must be put in the slides. It is as well to decide how many photos to take, and not have more plates out of the boxes than are absolutely necessary. The slides are parted by divisions of blackened metal. A plate is first laid prepared side downwards, the metal division put in with the spring piece uppermost. Then another plate with the prepared side facing the operator, two tiny clips are pushed forward to hold the plates down, the shutters are closed, and all is ready. N.B.—Of course this must be done by ruby light.

I may here give a practical hint.

Write, stencil, or otherwise mark the shutters A, B, C, &c. The object of this is to avoid exposing the same plate twice. I went one day to photograph the inmates of an incurable home, and, after the general amount of putting in a good light and stacking the patients who were movable on the steps, I got them quiet and exposed my plate. After this I got the superintendent and the home cat, posed them prettily, took off my lens cap, and went home rejoicing.

I developed, out came faces black and well; but a most singular muddle was apparent, even by the dim light of my red lantern. As soon as safe I examined by naked light. Horrors! The cat's tail was meandering over a couple of the patients' faces. The garden seat and brick wall were in apparently mid-air, and a general confusion was visible. Since then I always mark the slides, and would advise others to do the same.

A tourist camera is generally on the "bellows" and "folding-type" system, so as to be compact. In some, provision is made so that the lens screws in either way, thus saving a separate package. The travelling stands are composed of ringed detachable sticks, three in number, which joint on to a triangular top. The camera is attached by a small thumbscrew.

Lightness has to be considered; but this very lightness is an intolerable annoyance if there be much wind. It is to be hoped that some more steady arrangement may ere long be introduced.

The focussing cloth is generally of either black alpaca or velvet; velvet, being more opaque, is much the best.

To take a photograph in the field or open country the apparatus requisite is generally held in a wallet or satchel, comprising camera, stops, two double dark backs, or three, tripod top, thumbscrew, and focussing cloth. The total weight may be 5lb. The legs of the tripod are carried separately. Arrived at the place of operations, fit the stand together, unfold and adjust the lens of the camera, connect the two by the thumbscrew, and the camera is all right. Focussing is done either with a screw adjustment and winch handle, or slackening the screw belonging to the sliding side of the camera. The screw adjustment is about 15s. extra. Sliding adjustment is nearly as good. The lens-cap must be taken off and the ground-glass screen secured by its clip. This screen occupies the same space as the plate does when the shutter is raised; so the carefully focussed image thus falls exactly on the plate. If indistinctness is observable by the edges, a stop inserted will condense the light, and although it will darken the picture a little, will give the requisite sharpness. No picture should be taken without a stop. In most lenses revolving stops are inserted; this is a great advantage, as divided stops are very easy to lose. The images being clear and well defined, the glass screen is turned back on its hinges, and the dark-slide inserted, being carefully covered with the focussing cloth. The lens cap is in position. If a sunny day with light clouds, wait until a cloud passes over the sun. If windy, and there are trees about, wait for a quiet moment. Carefully draw up the slide, uncap the lens, letting hand and lens-cap fall down. Give from two to five seconds (counted), cap the lens, shut down the slide, and, after noticing the distinctive mark, repeat process as many times as you have plates.

To develop, go to the dark room. Light the ruby lamp. Carefully exclude all white light, and place the plate in a tray of water (plain hard water will do) to swell the gelatine and render it more easy to develop free from spots. Measure out three grains of pyrogallic acid and dissolve in one ounce of water. Place this in one developing-cup. Drop into another three drops of the ammonia and bromide solution from the drop bottle, take out the plate carefully, and put into another tray. Pour the pyrogallic solution over with a kind of swinging motion, so that it covers the plate entirely. Pour the solution from the tray into the cup containing the ammonia bromide and bromide solution, then, with the same "swinging" motion, return the mixed contents upon the plate.

If the exposure has been of the right duration, the picture in a few seconds will begin to appear. Black lines and patches will appear, and in a few seconds the details will be out. In a negative everything white is black. If a landscape is taken, the sky will be black, and the trees and houses white and grey black. When all detail is fully out, which may be known by looking at the back of the plate, if a faint representation of the picture is visible, the plate must be washed—either douched from a jug or held under a tap for a few minutes. It should then be placed in a strong solution of alum and water for five minutes, then rinsed and dropped into a fixing bath of freshly-made hyposulphite of soda (about a dessert-spoonful of hypo to a pint of water). Hypo, as it is technically called, dissolves out all the sensitive ingredients remaining unacted upon, and renders the negative impervious to light. It may now be well washed, and examined in daylight. All the lights, it will be seen, are reversed, the deepest shadows being plain, white, clear glass.

The ammonia and bromide solution mentioned above consists of—

Bromide of potassium...	2 drachms
Water	4 ounces
Strong liquid ammonia	2 „

This must be kept in a glass-stoppered drop-bottle. Above all things, keep dishes, cups, and all utensils perfectly and thoroughly clean—never grudge water. The best books on photography are not very expensive. Capt. Abney's "Instruction in Photography" is invaluable.

Photography is not difficult. It requires care and study, and cannot be done off-hand any more than any other pursuit; but there is no sham about it, no copying and imitating. All is straightforward, and as a fascinating pursuit it has no equal.—*The Queen.*

ECHOES FROM THE ORIENT.

BY EDWARD L. WILSON.*

HOSPITALITY is exceedingly profuse on the part of the Arab, but no more so than the exactions which will be made of you for a "return present," or a return kindness, before you are permitted to bid him adieu and receive his blessing for the rest of your journey. But I believe this also was somewhat the way in the olden times, and perhaps this conservative people are not so much to blame. I have spoken several times of the way in which the women of the Desert carry upon their persons such property as they may have in the way of gold and silver and precious stones. Sometimes this seems to be carried to an extent that is hard to understand. We are taught to look upon this people as a poor people, having but little in this world; but

* Continued from page 551.

they do collect together from time to time some little property, and, inasmuch as they are liable to be turned away from their homes at any time, they practise carrying what they own about their persons. It is no new thing. If we ever go to the plain of Jezreel together, we will have brought to our minds the time when Gideon said unto his people, "I would desire a request of you, that you would give me every man the ear-rings of his prey." (For they had golden ear-rings, because they were Ishmaelites.) "And they answered, 'We will willingly give them.' And they spread a garment, and did cast therein every man the ear-rings of his prey. And the weight of the golden ear-rings that he requested was a thousand and seven hundred shekels of gold; besides ornaments, and collars, and purple raiment that was on the kings of Midian, and beside the chains that were about their camels' necks." (Judges viii. 24-27.) And so to-day we find these women oftentimes wearing ornaments of the precious metals upon their persons in considerable quantities, or, if they do not wear them, they carry them along. What we more than once noticed was this, that the Sheykh of the tribe with whom we settled at any time for our camels or for escort was exceedingly "human" on the gold and silver question. Our conferences with him were always secret. In making a bargain it was always agreed that first we should pay him a certain amount for himself, and then a certain amount further was to be paid which he would divide with the members of his tribe. It was very curious to see his humanity when paying him those sums, for with the greatest care and secrecy he would tie up his own portion in one corner of his garment, and then, after receiving a second sum, would either allow his *confrères* to come in our tent and receive their portion, or would go out to them and settle it. But if you ever travel in the Desert, do not delude yourself with the idea that a strict fulfilment of any bargain he may make will be received as final on the part of the Bedouin, even though you make the contract after the strictest form. He will expect you to make him a present of backsheesh in addition. Well do I remember to what extent we were expected to do this when leaving Petra and Akabah, and some other favourite resorts which we visited during our winter excursion.

I observed that our Bedouin attendants, as we crossed the desert, frequently ate no food from morning until night, and very rarely did they drink. They seem to have really but one meal per day, and that was at the evening time, after the travel of the day was over. Arriving at the camping-ground, certain ones would dispose themselves to the work of erecting their tents and making them ready for our occupation when we should arrive. The others would join together in clubs or "messes," as we used to do in the army, and, choosing the ground in the neighbourhood of the tents, make themselves a little semicircle by turning their camels' backs towards the ring. Then, placing the baggage against the camels, they would proceed to make their bread and coffee. Each man carried with him a little bag or package of barley flour. This flour was taken in fair proportion from each man, placed together, and made into a paste or kind of dough, then baked in a little rude oven made by digging a hole in the sand or gravel. The fuel was supplied by bits of Tufta bush, or brush and dried camel-dung, and thus the bread or paste was baked. When done, it was taken from the ashes, a measure of the dirt relieved from it by pounding or wiping on the skirts of the garment, and divided among the members of the club. This portion of the food, sometimes garnished with a bit of onion or some roots that had been pulled up on the route during the journey of the day, seemed to constitute all the means of food for twenty-four hours, unless it be division of a little coffee occasionally. It must not be thought, however, that we were compelled to live in this way. The genius of the tin-can and the inventor of the indispensable egg have guarded against any such miserable living as we have described as being the support of the Bedouin. In the morning we were served with coffee or tea and baked potatoes, and a chop or boiled egg, with perhaps some jam or preserved fruit. At noon-time we spread out our little lunch tent under the shadow of a rock or in the sun, as it happened to be, and were seated at a lunch of bread and cold chicken and jam, or dates, or oranges, with cold tea or lemonade, and eggs hard-boiled. The principal meal of the day, however, was at night, after our travel was ended. Then we had soup, one or two kinds of meat, vegetables, fruit, and oftentimes a pudding of one kind or another. We always carried live chickens and pigeons with us, and plenty of eggs. Sheep or lambs were always driven along with us. And when having used up our supply of them we purchased others on the way.

A word about the temperance principles of the Bedouin. They are Rhecabites—*strictly* temperate. I had to employ perhaps a hundred of them from time to time, and I met thousands of them. I never saw one of them either drink or drunk. And I am happy to say that our quartette made our whole tour without one drop of liquor or beer, drinking only the water of the country, as we found it from time to time, when our water skins were empty.

APPLICATIONS OF PHOTOGRAPHY IN SURGERY.

BY C. E. WEBSTER, M.D.*

SEVERAL years ago, an acquaintance, then studying dentistry, thought that he would try the experiment of taking a plaster cast of his arm. How was it to be done?

"It's easy enough," said a friend; "rest your arm flat on the table thus, and I will pour the plaster over it."

"But," said the dentist, "how shall I get my arm out of the mould?"

"Straighten it, and the plaster will break," was the reply; "and afterwards you can fit the pieces together and take the cast."

"Won't it stick to my arm?"

"I will prevent that by greasing it," said the accommodating friend.

So the brawny arm, well rubbed with olive oil, was laid with clenched fist and flexed elbow upon the table, and as the creamy plaster was being poured over its hairy surface, my acquaintance complacently reflected on what a striking object it would be as an ornament to his office, for it was a well-formed arm, and certainly in quite a striking attitude. His pleasant dreams awoke to sad reality when the plaster set, for not only was it impossible to straighten out the arm, and thus crack the mould, but after the hammer had been vigorously applied for that purpose it was found that each individual hair was so firmly embedded in its gypsum envelope that it would sooner leave the flesh than come out of the plaster. So, mid imprecations and blood, the fragments were removed. His pains were rewarded by a more complete success than had been anticipated, for, on fitting the parts of the mould and taking the cast, which was slightly tinted pink, it was discovered that the bulbs of the hair held more strongly to the cast than their tapering ends did to the mold, and the result was a life-like reproduction of the arm, ornamented with its own natural appendages.

The incident illustrates one of the many practical difficulties in the way of taking models of portions of the body, and suggests the desirability of other methods whenever possible. The difficulties can be overcome, and I have taken admirable casts of hairy parts without either shaving the hair or hurting the patient; still a good cast is not an easy thing to make. It tries a sick person greatly. It can't be done in a hurry, and requires skill and experience in the manipulation of plaster. Drawings are unreliable and hard to make. Outlines taken from shadows or with flexible metal strips are good as far as they go. But in photography we find a ready means of recording the outlines and surface features of a particular region or of the whole body with little trouble to ourselves, little expense, and no inconvenience to the patient.

We may consider its applications in surgery as a means of recording facts, of establishing diagnosis, and of assisting treatment.

In the progress of any science the accurate recording of the facts on which that science rests is of first importance. This record should be complete even to the most trivial detail, for it often occurs that what has at first appeared a minor point, shows itself to be on more extended research a constant characteristic. Photography records impartially that which is important and that which is thought to be trivial. It is particularly adapted for recording outlines, as in deformities of the limbs, the general appearance of solid parts, as tumors, dislocations or fractures, surface markings, as in diseases of the skin, and lastly, in those conditions that affect the personal appearance or attitudes of the patient, where description is impossible and the highest artistic skill necessary for truthful drawing.

It is unnecessary to enumerate the diseases that may be included under these headings.

There is probably no disease, some feature of which might not be better recorded for comparison and study by photography than by any other method. I may mention in illustration bow legs, cancers and other tumors, the varieties of eczema, and the

* Communicated to *Photography*.

facial expression in certain kinds of paralysis or varieties of insanity.

A diagnosis can best be reached in many slowly progressive diseases by a careful noting of the successive changes which occur in the early stages of the case. Thus in progressive muscular atrophy the changes are very gradual, affecting a few muscles, which, slowly wasting, finally leave depressions in place of their former prominences. Photographs taken at intervals in the early stage of the disease would much more accurately measure its progress than can be done by the eye, and render, in doubtful cases, the diagnosis much more positive. The art is also applicable to slowly progressive deformities, as in curvatures of the spine, where the comparison of photographs on the same scale would give the best possible means of estimating the changes taking place, and thus give valuable hints to the surgeon as to the best method of treatment.

The art is useful in the treatment of certain diseases. Thus in deformities where apparatus is necessary a good photograph may supplement or render unnecessary a plaster cast. I have found the following method useful. Photograph the patient in various positions with a scale of inches or centimeters in the field, thus enabling the mechanic, while constructing the apparatus, to measure directly from the picture the proportions of the various parts, rendering the subsequent fitting and adjustment quite a simple matter.

Photography can be used to deceive as well as to enlighten. I recollect two pictures representing a case of spinal curvature. In one the shadows are so arranged as to exaggerate the curve, and the body so turned that the tip of the farther shoulder-blade puts an extra point to the real deformity. In the other, which is to illustrate the benefits of treatment, all this is reversed. Strong lights obliterate minor features, and the position is such as to render the curves as inconspicuous as possible.

I trust that these hurried and incomplete notes may serve to call to the minds of physicians and photographers the advantage of their mutual relations. If a surgeon has sufficient need of it, an amateur outfit will be exceedingly useful; if not, he should make an arrangement with a photographer whereby the various valuable observations of his professional life shall not perish with his memory, but be preserved to form a part of that great common fund of knowledge which gives the staple foundation of our art.

Often an honest photograph is the best statement of a patient's case. Here we find the *chief* use of photography to medical science.

HOW TO EXPOSE A DRY PLATE.

BY S. L. PLATT.

The most convenient way to expose a dry plate is by using a small mirror, say three inches wide by five inches long. When a person is seated, draw the slide and get the position by looking in the mirror; continue watching the sitter during the exposure, and as he will not be conscious of your observation, you can tell when everything is right, and will find it unnecessary to develop your plates until the day's work is done. I have never found anything yet superior to the wet plate. Sometimes I still use them in preference to my own dry plates, and we are all apt to think ours are the best. Many things can be said in favour of both processes, but I believe they must always be friends. When I find a man all dry-plate, I set him down as having an axe of his own to grind, or as having but little experience in either. No honest man who fully understands dry plates will go back on an old friend, though it be a wet plate. I believe they must always stand side by side as being useful servants, and nowadays both are indispensable. For outdoor work or interiors, in making pictures of dogs, cats, horses, children, and other moving objects, the dry-plate is superior to the wet, undoubtedly; but for ordinary work in my hands I do not find it so.—*The Philadelphia Photographer.*

Correspondence.

ROYAL CORNWALL POLYTECHNIC SOCIETY'S EXHIBITION.

Dear Sir,—Allow me to remind intending exhibitors at the above exhibition that pictures for exhibition must arrive not later than August 5th, at the Polytechnic Hall, Falmouth.

I shall be most happy to supply forms of entry and prospectuses, which must be at once filled up.—I am, sir, yours faithfully, Wm. Brooks.

Laurel Villa, Wray Park, Reigate.

Proceedings of Societies.

The Photographic Society of Great Britain.

A meeting was held in the Committee Room attached to the Gallery, 5a, Pall Mall East, on Tuesday last, the 22nd inst., Mr. John Spiller, F.C.S., in the chair.

The Chairman referred to the new sunshine recorder recently made by Professor McLeod, but pointed out that several fairly efficient instruments are already in existence, as that of Campbell and the Whipple-Casella instrument (see our vol. for 1883, p. 509). McLeod's instrument depends on the reflection of the solar rays from a glass hemisphere silvered inside. The Chairman also alluded to the great value of prompt and accurate reports of the meetings of the Society.

Mr. Annan, of Glasgow, exhibited some photo-engravings done by the method of Klic, and it will be remembered that a specimen of work by the process in question (a portrait of Mungo Ponton) was issued with the Year-Book for 1882. An account of the method of making the plates will be found on page 67 of our present volume.

A copper plate is dusted with powdered asphalt, and the plate is heated, so that the asphalt becomes nearly melted. A negative carbon print is next transferred on to the copper plate, and the plate, now covered with the negative in carbon, is etched, at first by a strong solution of perchloride of iron, which penetrates only the thinnest parts of the picture; then by a weaker solution of the same salt, the solution etching through the thicker parts. By employing more and more diluted solutions, it is possible to etch through thicker and thicker layers of gelatine, so that only the high-lights remain unacted on.

The specimens exhibited by Mr. Annan comprised examples of work direct from negatives after nature, line work, and the reproduction of drawings in wash or tint. One of the copper plates was shown, but the depth of the *intaglio* appeared to be considerably less than is ordinarily the case with plates made by the method of Waterhouse.

Mr. Annan remarked that when long numbers are to be printed it becomes desirable to coat the surface of the plate with steel (method of Joubert).

The Chairman referred to the labour of Pretsch in producing *intaglio* plates, one of his engravings having been issued with the Journal of the Photographic Society in 1859.

Mr. Ashman gave the results of trials which he had made with several developers, and he spoke very highly of the sulphite of soda developer, recommended by Monroe, no restraining bromide being required. It is prepared as follows:—

Solution No. 1.

Sulphite of soda	4 ounces
Water	11 „
Sulphurous acid, enough to make the solution slightly acid	
Pyrogallic acid	1 ounce

Solution No. 2.

Carbonate of soda	3½ ounces
Sulphite of soda	6 drachms
Water	64 ounces

To develop a normal plate, one drachm of No. 1 is mixed with one ounce of No. 2.

Mr. Ashman also obtained excellent results with the formic acid developer of Newton, this being made up as follows:—

No. 1.

Carbonate of soda (dried washing soda)	3 ounces
Carbonate of potash	3 „
Sulphite of soda	3 „
Water	40 „

No. 2.

Pyrogallic acid	48 grains
Water	12 ounces
Formic acid	12 minims

In ordinary cases, ½-oz. of No. 1 is mixed with 1 ounce of No. 2, and ¾-ounce of water.

Mr. Sebastian Davis asked whether any members had experience with the water-glass substratum for emulsion work (see Formulary.)

Mr. Cowan pointed out that not only does the use of such a substratum cause the film to adhere to the glass, but it makes the emulsion flow over the plate almost as readily as collodion.

Newcastle-on-Tyne and Northern Counties' Photographic Association.

The third of the current year's series of out-door meetings of this Society was held last Saturday afternoou at Dilston, near Corbridge-on-Tyne. The ruined hall at this romantic spot was formerly one of the residences of the ill-fated Earl of Derwentwater, and it, together with its surrounding picturesque scenery of wood and water, has oftentimes formed a happy subject for artists of all kinds—the wielders of pen, pencil, brush, and photographic lens alike. Mr. E. Goold, of Elswick Lodge, Newcastle, was the leader of the expedition ; and under a propitious sun and sky, a fair number of plates were exposed, and have since turned out satisfactorily.

Mr. J. P. Gibson, of Hexham, with characteristic hospitality, entertained the members to a substantial tea, and afterwards showed them through his large studio of photographic views, which for variety and good workmanship are equally admirable. Altogether the gathering was most agreeable ; the next will be held at Bywell on Wednesday, August 6th, under the leadership of Mr. E. Dodds, of Low Fell, Gateshead.

London and Provincial Photographic Association.

A meeting of this Society was held ou Thursday, the 17th inst., Mr. A. Cowan in the chair.

Mr. J. H. Hare exhibited Messrs. H. and E. Dale's electric chronograph, which is an ordinary clock movement attached to a dial some fifteen inches in diameter, the circumference of which is divided into sixty sections, which require one minute to traverse ; this chronograph is in electrical connection with a shutter made on the principle of Mr. Cowau's double drop. Upon establishing electric continuity by means of a press button, an index hand is thrown into gear, and starts contemporaneously with the fall of the first shutter, which uncovers the lens ; when sufficient exposure has been given the button is released, the second shutter theu falls, covering the lens ; the hand, being thrown out of gear, returns to zero.

Mr. W. M. Ayres passed rouud a number of 12 by 10 silver prints from negatives recently taken iu the north of Scotland ; these comprised subjects of varied character, such as interiors, exteriors, marine, and floral, some of which were very fine. In response to a request by the Chairman, he showed his method of cutting circles in ebonite, hard wood, and like substances ; the peculiarity consisted in fluting the cutting tool which he employed in a wimble.

Mr. Sutton showed some negatives which had been entirely spoilt by beetles eating the gelatine whilst drying.

Mr. W. M. Ashman, speaking on silver prints changing in the light, more if burnished than if simply rolled, showed four prints which were burnished in April last : two had been exposed out of doors in the interval, the corresponding pair having beeu stored in a dark room. Those exposed to the light had changed from a rich purple to a brick red colour, but had not otherwise faded.

Mr. W. K. Burton preferred the changed colour. He remembered seeing prints of a similar colour in Ediuburgh which he was much pleased with ; upon euquiry for the toning formula he learned that the priuts had beeu exposed a long time to the sunlight.

Mr. A. Mackie had found prints which were not burnished turned much bluer by keeping when not exposed to light.

The Chairman thought damp had more to do with prints changing colour than anything else, and instanced specimen show-cases at railway stations ; one, he remembered, situated under a leaky water-pipe which had been overlooked, was in a most dejected condition.

The subject of printing on opal coated with gelatine chloride emulsion was next discussed, and Mr. H. E. Moule mentioned that an excess of silver was absolutely necessary if purple tones were desired, otherwise no reasonable amount of toning would give a good colour ; the drawback to using an excess of silver was found in the plates not keeping beyond a few days.

The Chairman found no difficulty in keeping chloride plates (washed) such as he used for transparencies, and thought the tarnishing of the free silver would be arrested if the plates were re-coated with a suitable substance : gelatine had been suggested for the purpose.

The Secretary thought the result shown at the last meeting gave great promise ; he would endeavour to obtain the formula for publication shortly.

A Member said good results could be obtained with the following :—

Gelatine	160 grains	in 3½ ounces	of water
Nitrate of silver ...	150 „	1 ounce	„
Chloride of sodium	40 „	1	„
Citrate of potassium	40 „		„

Mix, boil five minutes, set, wash, re-melt, coat, &c.

St. Helen's Association of Science, Literature, and Art.

Photographic Section.

A meeting of this section was held on the 25th ult., Mr. Heather in the chair.

Mr. Tees presented the section with an illuminated copy of the rules. A cordial vote of thanks was accorded to Mr. Tees for his present.

Mr. Brook showed about a dozen negatives of views taken at Lynn ; three of these, which should have been the best, were fogged. An inquisitive young lady at the above place had opened the slides to see the "pictures" whilst Mr. Brook was in the next room. Mr. Brook will lock the bag in future. The rest were very good, including two negatives of three St. Helen's celebrities, viz., the most corpulent men in town, total weight 980 pounds.

The Chairman described a number of experiments he had been making with boiled and cold emulsions ; he was not very successful with cold emulsions, and was now more than ever a disciple of the boiling process.

After the inspection of a number of prints and chemical photographs (not by Mr. Sherlock's new process), the meeting adjourned.

Talk in the Studio.

The International Exhibition at the Crystal Palace.—From the report of the awards in the Fine Art Section, we learn that a Silver Medal has been awarded to Mr. Horatio Nelson King for his photographs. The award made to Mr. King is, we believe, the only one made for photography.

Curious Case.—At the Liverpool County Court, before Mr. T. E. P. Thompson, judge, Mr. A. Vandyke, photographer, Liverpool, sued Mr. Geary, of Birkdale, to recover £3 3s., the agreed charges for an opal enlargement of the figure of a lady made from a glass picture at the defendant's request. Mr. H. F. Neale, who appeared for the plaintiff, stated that the picture was well executed, but the defendant rested his contention of the claim upon the fact that no proof had been supplied to him. Correspondence was then read in which the defendant alleged that he was dissatisfied with the picture, as he had bargained for a proof, and the plaintiff had agreed that he should not be bound to accept the finished portrait unless he (defendant) approved of it. Evidence having been given for the plaintiff, Mr. Broadbridge, who appeared for the defendant, in cross-examination of Mrs. Vandyke, elicited that she might have said the defendant was not bound to take the portrait unless it was satisfactory. Mr. Broadbridge then called the defendant, who said he objected to the picture because it seemed to show the lady represented as a sufferer from liver complaint, and there was a cadaverous expression about the face. Mrs. Vandyke said that he was not bound to accept it unless satisfied with it, and, being dissatisfied, he repudiated the contract. Mr. Neale contended that the fact of a proof not having been delivered was not an indispensable condition to the bargain, and that the mere crotchet of the defendant would not entitle him to succeed in the absence of evidence that the picture was not a good production. His Honour, in giving judgment for the defendant, said he was sorry for Mr. Vandyke, as he (the learned judge) was surprised that such an excellent picture could be produced from such a vague original ; but as Mrs. Vandyke had admitted that the bargain with the defendant was that he was not bound to

accept unless satisfied with the picture, he was reluctantly compelled to give judgment for the defendant, at the same time expressing an opinion that Mr. Van Dyke had been very badly used.—*Liverpool Post.*

Photographs of Coast Lines.—The German naval authorities have made arrangements for preparing a series of pictures of some of the more important coast lines as viewed from the sea, and it is easy to understand the considerable value of such a series to naval officers. The arrangements for the production of the series of photographs have been entrusted to Professor Vogel. The camera employed takes plates 16 by 4 inches, and a horizontal spring shutter is used behind the lens. In order to keep the camera in a horizontal position, a long rod and balance weight are used, the rod being attached to a hemisphere fastened to the bottom of the camera; and this hemisphere works freely in a corresponding depression in the top of the stand. Herr Schmid, who has been working with the apparatus at sea, reports very favourably of the arrangement.

Amateur Art Exhibitions.—*Cassell's Magazine* says :—"To make an exhibition successful, it stands to reason that the neighbourhood should be an artistic one, in order that there should be plenty of contributors. Next, it should be in a large and populous town, if possible at some distance from London, in order that there may be plenty of people to visit the exhibition, and to buy, if need be, when it is opened. Lastly, the exhibition should not be open for more than three days (unless the visitors continue to be very numerous, when it might be kept open an extra day or two), and the whole time the admission fee should be as low as possible. To make it pay its expenses, the secretary and the committee should do as far as possible all the office work, and the unpacking and packing of the works for exhibition. But expense should not be spared, in the first instance, in making the exhibition well known by means of notices in the papers, &c. A fault, which it may be well to mention, is the absurd prices amateurs are apt to place upon their works, pricing them at a fictitious value, and all the time they appear to be confident that their work will sell ; whereas, if the object is to dispose of the work, an artist should be content with a fair rate of profit—at any rate, at first." Among these suggestions organisers of local photographic exhibitions may possibly be able to gather an idea or so ; at any rate, some points for consideration.

Rendering Paper Waterproof.—Labels may be fixed upon tin boxes, &c., exposed to damp by the following method : White of egg is diluted with one half part of water, and applied with a brush to the surfaces to be united. A hot iron is then passed over the paper, so as to coagulate the albumen. By means of successive layers of paper and albumen, waterproof boxes, &c., may be formed.—*Cosmos.*

The New Silver Country in Australia.—New South Wales can boast the possession of one of the newest silver-producing districts in the world. It is situated in what are designated the Barrier Ranges, near where the Colony joins South Australia, but is at present extremely difficult to reach in consequence of the absence of ordinary travelling accommodation, though the road is described as being much better than the average Australian bush track. The country through which the coach passes is purely a saltbush one, and in dry weather natural feed for cattle is scarce. The existence of silver-bearing ores in the district was first discovered by a shepherd in the year 1876, whilst out with his mob of sheep on the range. He brought samples of the ore to some of the local magnates, but as their nature was little understood, the treasure lay undisturbed until a Mr. Green raised some of it with the intention of sending it to England ; through some mishap in transit no returns ever came to Mr. Green. About two years ago, however, another lot of ore was shipped to England to be sold, this time with better results, though through inexperience the miners selected the lowest grade ores, viz., argentiferous galena, leaving out the rich sulphides of silver. They netted the handsome return of £7 per ton on the shipment, after the highest commissions and charges had been exacted. The second and larger group of mines is situated at a distance of 28 miles from Silverton. They are called the Lakes Camp group. The ores here are purely sulphides of silver, and very rich. Two tons of ore recently sent to England for assay were sold for £600. Shafts have been sunk in many parts of the ground held by the syndicate, and ore has been discovered everywhere, but, of course, all of it is not of the richest quality. The shafts vary in depth from 10 to 75 feet. In one put down, on a "big bonanza," the lode is found to be of enormous value (£300 per ton), and it is said that a great portion of the money paid by the syndicate for the entire ground has already been secured to them in profits from this one shaft. The lodes have all the appearance of permanency. In one shaft, the deepest of this group, the lode has been traced to the total depth, 75 feet, and at the bottom it is six inches thick, with indications of continuance and improvement. A great drawback to the rapid development of these mines is the scarcity of labour.

Two Hats.—An Englishman, who was recently having his photograph taken, desired to be represented sitting with his hat on, but the photographer insisted that he should occupy the stereotyped attitude sanctified by thousands of previous "subjects." When the photograph was sent home, the wife discovered that her husband had not only one hat on his head, but another on his knee.—*New York Daily Graphic.*

Photographic Club.—At the next meeting, on July 30th, the adjourned discussion on "The Effect of Coloured Media on Silver Prints" will take place. Saturday afternoon outing at Hampstead Heath, meeting afterwards at 6 o'clock at the Bull and Bush, North End, Hampstead.

To Correspondents.

*** We cannot undertake to return rejected communications.

Legal.—The fact of your not having registered them earlier is a complete bar, and we think that you have no remedy whatever.

E. Gould.—Thanks.

T. Coan.—1. It is very probable that they will be published in a separate form. 2. Thank you.

Amateur.—1. We will have a practical article on the subject shortly. 2. It is not sold commercially ; attach it to the lens tube by means of an elastic band.

W. Stannard—We do not know the address of the gentleman you mention ; but if we can ascertain it we will send it to you.

Thos. George.—1. See our volume for last year, page 221, for the best formula as regards the emulsion. We recommend the developer given on page 98 of the same volume. 2. Fairly good, but the back-ground is stained and spotty. Mr. Swan has patented such a machine, and a description has been given in our pages.

J. Tisett.—See leader in this week's News.

Miss Levere.—No process of the kind will enable a person who has not artistic power to do valuable work ; and the working of the so-called "process" is little else than a fraud. Money paid for instruction may be considered as quite thrown away, and the materials sold for the purpose are not worth more than one-fourth the price charged.

J. G. R.—This Correspondent complains that although he is, as a rule, successful in obtaining bright and vigorous negatives on commercial plates of a certain make, he has come to the conclusion that one batch was bad. He remarks: "I feel that it would be useless for me to write to the makers of the dry plates. They would be sure to reply that that the fault must be with me. Now I have honestly tried hard to find out if this were so, and I cannot detect a flaw. Makers of plates are but men, and are fallible, and I am beginning to suspect that the causes of want of 'sparkle' may lie with them quite as often as with us poor victims ; and I and many more, I am sure, will be grateful to you if you will push this revival of the old complaint against gelatine dry plates. If we are all duffers and cannot develop 'sparkle' in really good plates, why I, for one, shall be only too glad to know it and acknowledge the error of my ways ; but if there be no 'sparkle' in the plates to develop ; if we are paying a big price and good money—cash—for an inferior article, I think it would be well all round in the long run, to know that too." That defective plates are occasionally sent out by makers there can be no doubt ; although we believe that close competition has much improved the general character of plates of late. When a person who ordinarily obtains satisfactory results has plates which he considers bad, the best way is to go to the maker and request him to produce a satisfactory negative on one of them. Should he refuse, some of the plates might be taken to another photographer for trial, or, perhaps, to two reliable photographers, and in the event of an unfavourable report a claim might fairly be made upon the maker of the plates.

A. J. Hilder.—We cannot give a very decided opinion, but it seems probable that they arise from dust settling on the films, and locally reducing the sensitiveness. This may have been while the plates were drying.

G. P. Cartland.—It is very good of you to send us the photographs. Thanks.

Studio.—Ammonia will not remove it, but it dissolves readily enough in dilute acids—one part of hydrochloric acid and six parts of water being as convenient as anything for removing it.

C. RICHARDS.—1. Although it contains a very large proportion of sulphur, it is very doubtful whether it will exercise any injurious action; at least, we have used it in many cases, and have not noticed any mischief to follow. 2. Clean them by means of nitric acid, but take care to wash away any trace of the detergent before using them.

COLD.—You have overlooked the minus sign, —, before the figure, indicating the thermometric degree.

H. Z. G.—Either will do; indeed, there is little or nothing to choose between them; but we strongly recommend you to purchase it ready-made until you have gained some general experience in its use.

P. BRIGGS.—1. Your collodion must have been far too thick: dilute it with a mixturo of two parts of ether and one of alcohol. 2. It is very cheap, perhaps two pounds a ton if you purchase on a large scale; but in buying a few pounds, you must be prepared to pay sixpence or eightpence a pound. 3. It will answer very well, but plain white paper will answer better. 4. It rapidly absorbs oxygen from the air, and has probably become quite useless by this time.

NITRATE BATH.—1. Add enough carbonate of soda to make the solution just alkaline to litmus paper, expose to full sunlight for some days, filter, and make feebly acid with nitric acid. 2. See Captain Abney's "Photography with Emulsions."

WESTMINSTER.—Far too much has been added, as one-tenth of the quantity would have been sufficient.

The Every-day Formulary.

THE GELATINO-BROMIDE PROCESS.

Emulsion.—A—Nit. silver 100 grains, dist. water 2 oz. B—Bromide potassium 85 grains, Nelson's No. 1 gelatine 20 grains, dist. water 1½ oz., a one per cent. mixture of hydrochloric acid and water 50 minims. C—Iodide potassium 8 grains, dist. water ½ oz. D—Hard gelatine 120 grains, water several oz. When the gelatine is thoroughly soaked, let all possible water be poured off D. A and B are now heated to about 120° Fahr., after which B is gradually added to A with constant agitation; C is then added. Heat in water bath for half an hour, and stir in D. After washing add ½ oz. alcohol.

Pyro. Developer.—No. 1—Strong liq. ammonia 1½ oz., bromide potassium 240 grains, water 80 oz. No. 2—Pyro. 30 grains, water 10 oz. In case of an ordinary exposure mix equal vol.

Iron Developer.—Potassium oxalate sol. (1 and 4) 80 parts, ferrous sulphate sol. (1 and 4) 20 parts, dist. water 20 parts. To each 4 oz. of the mixed developer add from 5 to 30 drops ten per cent. sol. potassium bromide, and 30 drops sol. sodium hyposulphite (1 and 200).

Substratum or Preliminary Preparation.—Soluble silicate of soda 1 part, white of egg 5 parts, water 60 parts. Beat to froth and filter.

Fixing.—Sat. sol. of sod. hypo. 1 pint, sat. sol. of alum 2 pints, mixed.

Cowell's Clearing Solution.—Alum 1 part, citric acid 2 parts, water 10 parts. Edwards makes this sherry coloured with perchloride iron.

Eder's Method of Intensification.—The negative is whitened by soaking in sat. sol. of mercuric chloride, and after thorough rinsing immersed in potass. cyan. 10 parts, potass. iod. 5 parts, mercuric chloride 5 parts, water 2,000 parts. As film becomes dark brown, the actinic opacity is increased; but prolonged action causes brown tint to become lighter, until at last the negative is no denser than at first.

Fol's Backing Sheets.—A chromographic paste is prepared with gelatine 1 part, water 2 parts, glycerine 1 part, and a very small addition of Indian ink. Strong paper or shirting is coated, and the sheets are laid, ace downward, on waxed glass to set. Press to back of glass plate.

THE WET COLLODION PROCESS.

The Nitrate Bath.—Water 14 oz., nit. silver 1 oz., nitric acid 1 drop. Before using coat a small plate, and immerse it for 20 minutes.

Cleaning Preparation for New Plates.—Alcohol 4 oz., Jeweller's rouge ½-oz., liquid ammonia ½-oz.

Film-removing Pickle for Old Plates.—Water 1 pint, sulphuric acid 4 fluid oz., bichromate potassium 4 oz.

Negative Collodion for Iron Development.—Alcohol 1 pint, pyroxyline of suitable quality 250 grains, shake well and add ether 2 pints, *Iodize this by mixing with* one-third of its volume of alcohol ½ pint, iod. ammon. 80 grains, iod. cadm. 80 grains, brom. ammon. 40 grains.

Normal Iron Developer.—Water 10 oz., proto-sulphate iron ½ oz., glacial acetic acid ½ oz., alcohol ½ oz. The amount of proto-sulphate iron may be diminished to ¼ oz. when full contrasts are desired, or increased to 1 oz. when contrasts are unduly marked. With new bath quantity of alcohol may be reduced to ½ oz.; but when bath is old more is wanted.

Substratum.—Whites of 2 eggs well beaten, 6 pints of water, and 1 dr liq. ammon.

Intensifying Solution.—Water 6 oz., citric acid 75 grains, pyro. 30 grains. When used, add a few drops of the silver bath to each ounce.

Lead Intensification.—After neg. washing, immerse in dist. water 100 parts, red pruss. potash 6 parts, and nit. lead 4 parts. When it is yellowish white wash and immerse in liquid sulphide ammon. 1 part, water 4 parts.

Fixing Solution.—1. Potass. cyanide 200 grains, water 10 oz. 2. Sat. sol. of sod. hypo.

Varnish.—Shellac 2 oz., sandarac 2 oz., Canada balsam 1 dr., oil of av ender 1 oz., alcohol 16 oz.

PRINTING PROCESSES.

Albumen Mixture for Paper.—White of egg 18 oz., 500 grs. ammon. chlor. in 2 oz. of water. Beat to a froth, stand, and filter.

Sensitizing Solution.—Nit. silver 50 grs., water 1 oz., sod. carb. ½ gr.

Acetate Toning Bath.—Chl. gold 1 gr., acet. soda 20 grs., water 8 oz.

Lime do.—Chl. gold 1 gr., whiting 30 grs., boiling water 8 oz., sat. sol. chl. lime 1 drop. Filter cold.

Bicarbonate do.—Chl. gold 1 gr., bicarb. soda 3 grs., water 8 oz.

Fixing Bath.—Sodium hypo. 4 oz., water 1 pint, liq. ammon. 30 drops,

Reducer for Deep Prints.—Cyan. potass. 5 grs., liq. ammon. 5 drops, water 1 pint.

Sensitizing Bath for Carbon Tissue.—Bichromate potash 1¼ oz., water 30 oz., ammonia 1 dr., methylated spirit 4 oz.

Enamel Collodion.—Tough pyroxyline 120 grs., methylated alcohol 10 oz., ether 10 oz., castor oil 20 drops.

Mountant.—1. Fresh solution of best white gum. 2. Fresh starch.

Collotypic Substratum.—Soluble glass 3 parts, white of egg 7 parts, water 10 parts.

Collotypic Sensitive Coating.—Bichromate potash ½ oz., gelatine 2½ oz., water 22 oz.

Collotypic Etching Fluid.—Glycerine 150 parts, ammonia 50 parts, saltpetre 5 parts, water 25 parts.

Printing on Fabric.—Remove all dressing from fabric by boiling in water containing a little potash, dry, and albumenize with ammonium chloride 2 grammes, water 250 cubic cents., and the white of 2 eggs, all being well beaten together. A 70-grain silver bath is used, and the remaining operations are as for paper.

Cyanotype Printing.—Water 1 oz., red prussiate of potash (ferricyanide) 1 dr., ammonio citrate of iron 1 dr. Prepare and preserve in the dark. Float the paper and dry. Fixation by mere soaking in water.

VARIOUS.

Luckardt's Retouching Varnish.—Alcohol 300 parts, sandarac 50 parts, camphor 5 parts, castor oil 10 parts, Venice turpentine 5 parts.

Matt Varnish.—Sandarac 18 parts, mastic 4 parts, ether 200 parts, benzole 80 to 100 parts.

Encaustic Paste.—Best white wax, in shreds, 1 oz., turpentine 5 oz. dissolve in gentle heat, and apply cold with piece of flannel.

FERROTYPES.

Collodion.—Ammonium iodide 35 grains, cadmium iodide 25 grains, cadmium bromide 20 grains, pyroxyline 70 grains, alcohol 5 oz., ether 5 oz.

Bath.—Silver nitrate 1 oz., water 10 oz., nitric acid 1 drop.

Developer.—Ferrous sulphate 1 oz., glac. acetic acid 1 oz., water 16 oz.

Fixing and Varnish.—Same as wet collodion process.

The Photographic News Registry.

Employment Wanted.

Printer.—F. Knight, 40, Brooksby-street, Liverpool-rd., N.
Recep.-room, Book-keeper, &c.—R. H., 12, St. Peter's-st., Tunbridge Wells.
Assistant Operator & Retoucher.—A. B., 24, Cavendish-st., Chesterfield.
Gen. Assist. (25/-)—W. W., Whiteman's Library, Uligh-st., Hastings.
Assistant (lady).—A. B., 5, Heaton-villas, Heaton-rd., Peckham.
Artist & Retoucher.—W. F., 90, Chesterton-rd., Notting-hill.
Assistant Operator.—E. Hopkins, 51, Cossack-st., Southampton.
Dark-Room Operator at seaside.—H. N., London Institution, Finsbury.
Artist, well up in opals.—Artist, 28, St. John-st., Islington.

Employment Offered.

Operator who can retouch.—H. Mower, 31, Park-st., Bristol.
Retouchers (two).—J. Lafayette, 30, Westmoreland-st., Dublin.
Operator & Retoucher.—J. Rosenberg, 79, Wood-st., Glasgow.
Printer.—J. Rosenberg, 79, Wood-st., Glasgow.
Printer & Dark-Room Assistant.—T. O'Connor, George-st., Limerick.
Operator, for dry plates and copying.—B. H., Post Office, Derby.
All-round, for travelling studio.—Relph, Layton-rd., Forest-gate, Essex.
Reception-Room & Retouching.—W. J. Suter, Cheltenham.
Reception-Room & Retouching.—Photo, 32, Cambridge-rd., Hastings.
Operator & Retoucher.—Russell & Sons, 29, Union-rd., Tufnell-pk.
Assistant Printer.—Russell & Son's, 29, Union-rd., Tufnell-pk.
Retoucher & Operator.—Charles F. Treble, 371A, Brixton-rd.

Photographs Registered.

E. HAWKINS & Co. (108, King's Road, Brighton)—3 Photos. of Lord Sheffield's "Eleven," 3 Photos. of Australian Cricketers.
Dr. THOS. HENRY MORTON (Don House, Brightside, Sheffield)—2 Photos. of Interior of St. Mary Magdalene Church, Newark-on-Trent.
Mrs. WILLIAMS (Wolverhampton)—2 Photos. of Mr. Philip Horsman.
Mr. H. FAULKNER WHITE (Cambridge)—Photo. of Mr. W. J. Peale and Mr. Joseph Newman at Billiard Table.
Mr. W. V. AMEY (Landport, Portsmouth)—4 Photos. of Mr. C. Bradlaugh and Mr. G. W. Foote.
Mr. C. HAWKINS (Bath)—3 Photos. of Roman Baths discovered at Bath.
Mr. T. ERWIN (Ballymena)—Photo. of Group of Royal Irish Constabulary.
Mr. J. KENNEDELL (Wisbech)—Photo. of Bicycle Sports at Colville House, Wisbech.
H. B. PRITCHARD—5 Photos. of Constantine, Algeria, &c.

VOL. XXVIII. No. 1352.—*August* 1, 1884.

CONTENTS.

THE PRODUCTION OF PANORAMIC PHOTOGRAPHS.

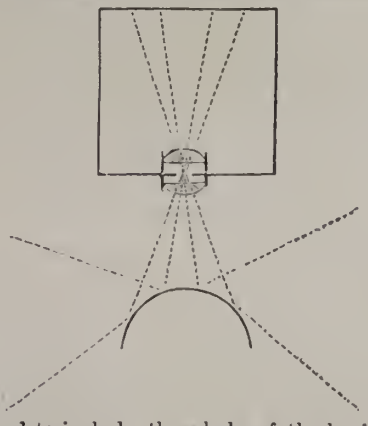
AN APPLICATION OF THE PRINCIPLE OF MCLEOD'S SUNSHINE RECORDER.

A PHOTOGRAPH in which the whole extent of the horizon is represented as a long strip has necessarily many qualities which are quite the reverse of pictorial, as when such a production is viewed as a whole the direction of light will, of course, differ in the various parts of the photograph. Notwithstanding this, such a panoramic photograph, if cut up into a sufficient number of parts, say a dozen, each embracing an angle of thirty degrees, or half a dozen, each including sixty degrees, will give a series of pleasing pictures, these being without any fault as regards perspective or cross lighting. Notwithstanding all this, some panoramic views possess qualities which make them popular, and we need only instance Gutekunst's celebrated picture of the "Centennial," at Philadelphia, to illustrate this. Here we have, however, not such a production as we alluded to at the beginning of our article, but a picture embracing, as far as we remember, an angle of about one-third of a circle of a hundred and twenty degrees. Gutekunst's picture was not taken as a whole, but impressions from several negatives were ingeniously vignetted into each other on one sheet of sensitive paper. That the desire for panoramic pictures is by no means great is pretty obvious from the fact that not one of the ingenious panoramic cameras which have been introduced from time to time is a stock article in this country, any person wishing for such an apparatus having no alternative but to have one constructed, or to endeavour to obtain one in the second-hand market.

There are, however, other uses of the panoramic photograph, and these were fully recognized when the photographic plane table of Chevallier was introduced as a surveying instrument rather over a quarter of a century ago. In the usual form of this apparatus, the lens travels round, so as to embrace all points of the horizon in succession, and the image is impressed upon a circular plate. The panoramic photographs thus obtained have a very remarkable appearance, and although admirably adapted for making photogrammetrical measurements, are valueless as pictures. The chief objection to the Chevallier plane table is its complication and delicacy of construction, consequently it has never come very extensively into use.

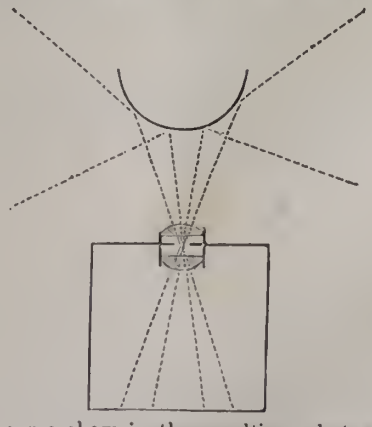
On becoming acquainted with the principle upon which Professor McLeod's sunshine recorder is constructed, it appeared to us that by photographing the reflections from a silvered ball, by means of a camera having its axis corresponding with the perpendicular, it might be possible to obtain a representation of the whole horizon on a flat plate with an instrument far less delicate in construction and far simpler than the Chevallier plane table; and, moreover, with the considerable advantage of making the exposure simultaneously for the whole of the horizon.

In order to make a preliminary experiment, one of the silvered glass balls sold for ornamental purposes was taken, and the camera was placed perpendicularly over it, as shown in the diagram. The resulting photograph was, of



course, found to include the whole of the horizon, and a sufficient vertical angle for most surveying or military purposes.

When such an instrument is used in actual practice, it would doubtless be advantageous to place the reflector uppermost, so that the heavy portion—consisting of the camera—should be at the base, as indicated by the following sketch. The vertical rods supporting the reflector



would of course show in the resulting photograph, and

would of necessity conceal—or, at any rate, render indistinct—a portion of the view; but in actual practice it might be possible to make them so narrow that the parallax of the objective would be sufficient to prevent any important obstruction to the view.

In connection with this subject many points may be raised. In the first place, it would not do to use a glass reflector silvered inside; but as there is no difficulty in silvering the outer surface, it is not necessary to say more regarding this point. The question of the shape of the reflector is one which cannot be determined without consideration, as under any circumstances the photographic representation will be very much distorted, and in making measurements from it the curve of the reflector will have to be known and taken into account. The spherical curve, a parabolic curve, and a cone suggest themselves for consideration.

It should, however, be quite possible—and, perhaps, convenient—to construct the reflector and part of the objective all in one piece, and this course would render it unnecessary to use any opaque support to hold the mirror in position.

Let us suppose a polished cylinder of glass, one end of which is concave and silvered inside, while the other extremity of the cylinder is so worked as to form part of the photographic objective. If this cylinder of glass were made to project from the mount, and the camera were set vertically, the light from the horizon, entering the cylinder, would be reflected from the silvered concavity at the top, and would pass downwards through the glass to the sensitive plate. Such an arrangement may be regarded as being virtually that figured above, but with the interspace between the outside of the objective and the reflector filled with glass, this glass being allowed for in the construction of the objective, just as is the case with the immersion-fluid in which some microscopic lenses act.

The fixed arrangement referred to above would, besides possessing the advantage of having a mirror not subject to tarnishing, be far easier to adjust than an apparatus with a detached mirror.

It might be possible to construct special optical apparatus to undistort the photographs obtained by means of the instrument just described; but as such photographs would be taken mainly for making surveys and measurements, or for military purposes, there would be no special inducement to undistort them in ordinary cases.

HINTS ON TONING, FOR AMATEURS.

The art of toning is one which the amateur is apt to give too little attention to. It is a delicate operation, and although it may appear rather a matter of detail than one of great importance, yet on the manner in which toning is done depends to a very great degree the excellence of a photograph as a picture.

Excellence in all the manipulations connected with the production of a negative, even including the making of the plates, and, indeed, excellence in every operation in the production of the finished picture up to that of toning, is common enough with amateurs. Excellence in toning is not so common.

"Nothing is easier than to tone, nothing more difficult than to tone well," has been said; and there certainly is much truth in the saying. By excellence in toning we mean not only the ability to get a good colour with pure whites and transparent shadows, but also the power of getting any tone we require, of course confining our requirements to the possibilities of the matter.

The variation produced by varying the toning bath and manner of toning is not confined to the colour obtained only, but shows itself in the general quality of the print. We have before us two prints taken from the same negative, and printed on portions of the same sheet of paper. The colour of the tone cannot be said to be very different. It would be described as a warmish brown in each case. The difference in the general appearance is, however, great. The one is a clear brilliant and pleasing picture; the other, though it would scarcely be placed in the category of "mealy prints," is a flat, dirty, uninteresting looking object. Now these two prints were toned in the same bath. They were the result of experiments in the small details of the process merely, and show how much depends on these same.

Beginning at the beginning, and taking in succession the various small matters which we have found worthy of attention if we desire to get a pleasing colour in our prints, we may take first of all the quality of the negative. As is generally known, the influence of this on the tone of the finished print is very great, but wherein this influence exists is apparently not quite fully understood. It is commonly said that a negative showing strong contrast will give a print which may be toned to a rich colour: but something more than this appears to be required. A negative with a contrast ever so great, if under-exposed, will not give a print readily toned to a pleasing colour. It is difficult to see why it should be so, but it is evident that the gradation of density of the negative is a great factor in the colour of silver prints obtainable from it. We will get, as a rule, a better tone from a negative which might be described as "somewhat delicate but full of detail," than from the densest possible negative which is even a little under-exposed.

We do not intend at present to enter into the question of the manufacture or sensitizing of the paper, because, as a rule, amateurs use ready-sensitized paper. We therefore pass on to the actual printing. It is an opinion commonly held that the longer, within limits, a print remains exposed in the frame—that is to say, the poorer the light—at the time of printing, the better will be the tone. It is certainly the case that prints done in very brilliant sunshine, and therefore in a very short space of time, do not, as a rule, tone as well as those which have taken longer to print; but we have not found the difference to be very great.

The manner of keeping the paper both before and after printing is a matter of importance, as we all know ready-sensitized paper turns brown from being kept. It may, however, turn in two totally different ways. It sometimes turns of the same colour that it would were it slightly exposed to light. This appears to be the effect of the action of pure air and damp, and does no harm so far as the colour obtainable by toning is concerned. There is, however, a very different discolouration which results from exposure to the smoky impure air of London, and probably comes about from the action of sulphur in some form. It is distinguished by a metallic lustre; the effect of this is disastrous on the tone of the print. Nothing but the most sickly colour is possible from paper which has turned its colour in the manner described. From this we gather the importance of keeping ready-sensitized paper in a place where the air is as pure as possible.

It is probable that the stage at which the most can be done to make or mar the tone of a print is that of the washing which is performed previous to the toning. If, for example, the prints be placed in the water in masses, and be allowed to adhere one to another for any length of time—or, in fact, if they be allowed to remain for any length of time in water which contains a considerable quantity of the free nitrate of silver which washes out of them—ruination of the tone will be the result.

It appears to be of importance to get the first silver which is washed from the prints away from them as quickly as possible, and for this reason they should be placed first in a large vessel, and should be removed from this first washing vessel to a second, after a very short immersion.

The next point of importance is the extent to which the

washing should be carried. Here let us say that we are in favour of eliminating all, or very nearly all, the free silver nitrate by very thorough washing, and by a fairly thorough washing followed by the application of a solution of common salt to convert what silver nitrate is left into chloride.

There appear to us to be various objections to the presence of free silver nitrate in the prints at the time of toning. For one thing, it is a very uncertain factor in the process. We never can tell how much we have washed away and how much we have left, and consequently there is uncertainty introduced in the result. When we wash out all the silver nitrate the uncertainty ceases; and not only that, we find that if, as certainly is the case, the toning takes much longer, or requires a much stronger solution of gold, the result is infinitely better than that got when silver nitrate is present. A further great advantage lies in the fact that prints toned without the presence of silver nitrate do not change their colour in the fixing bath; those toned in its presence do. We have, therefore, if we have thoroughly washed our prints, merely to wait for the colour we require, and then to remove the print from the toning bath. It certainly is the fact that with most ready-sensitized paper it is impossible to get a very good purple tone. We can, however, get a very warm brown.

Concerning the use of the salt solution, it would appear from mere theoretical reasoning that there can be no need for any washing at all before using it. It is difficult to see why it should be objectionable to get rid of the whole of the silver nitrate by converting it into chloride, but the fact remains the same that we do not get a good result if we place the prints direct from the printing frame into the salt water. It is also a fact that if the salt solution be beyond a certain strength, the prints refuse to tone at all. Considering these two facts, it becomes merely a matter of experiment to determine how to use the salt. We have proceeded as follows with good results.

We wash the prints till the greater part of the muddiness of the washing water has disappeared; this means three or four changes of water. We then dip for ten minutes in water which contains half-an-ounce of common salt to each gallon. After that we wash in other three changes of water, and proceed to tone.

The only difference in the manipulation in toning the two prints mentioned above was that the first was allowed to soak for some time in its first washing water, and was then but imperfectly washed. The second was at first rinsed briskly in running water, and was afterwards treated with the salt solution as described. It took five or six times as long to tone as the first.

For the sake of completeness we give the formula we were using, although we believe the difference in result produced by different toning formulæ is vastly less than the difference which may be brought about by varying mere details of manipulation:—

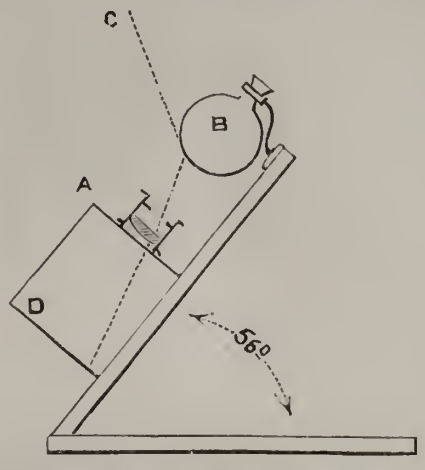
Chloride of gold	...	...	...	1 grain
Borax	...	...	...	60 grains
Water	...	...	...	12 ounces

McLEOD'S SUNSHINE RECORDER.

This instrument, to which we have already referred, possesses characteristics which seem likely to make it more generally adopted than the forms of recording apparatus now in use, the most notable feature being the use of a glass sphere (or rather hemisphere, for it is only one-half of the sphere which acts) silvered inside as a means of reflecting the solar rays into an ordinary camera; and we cannot but think that Professor McLeod's ingenious idea may receive other important applications in photography (see page 481).

McLeod's sunshine recorder consists of a camera fixed with its axis parallel to that of the earth, and with the lens northward. Opposite to the lens there is placed a round-bottomed flask, silvered inside. The solar rays reflected from this sphere pass through the lens, and act on the sensitive surface.

The construction of the instrument is illustrated by the subjoined cut, A being a camera supported at an inclina-



tion of 56 degrees with the horizon, and B the spherical flask silvered inside, while at D is placed the ferro-prussiate paper destined to receive the solar impression. The dotted line C may represent the direction of the central solar ray at one particular time, and it is easy to see how the sunlight reflected from the flask always passes through the lens. As the sun moves (apparently) in a circle round the flask, the image formed by the lens moves round on the sensitive paper, forming an arc of a circle.

Although it is obvious that any sensitive surface might be used in the McLeod sunshine recorder, the inventor prefers at present to use the ordinary ferro-prussiate paper as employed by engineers for copying tracings, as this paper can be kept for a considerable length of time without change, and the blue image is fixed by mere washing in water; another advantage is the circumstance that a scale or set of datum lines can be readily printed on the paper from an engraved block, and if the printed papers be made to register properly in the camera, the records obtained will show at a glance the time at which sunshine commenced and ceased.

We understand that a description of the apparatus will shortly appear in the *Philosophical Magazine*, but the above account is quite sufficiently detailed to enable any person to fit up the apparatus in an extemporised form. Instead of specially silvering a flask inside it will be found convenient to make use of one of the silvered globes which are sold as Christmas tree ornaments.

The sensitive fluid for preparing the ferro-prussiate paper is made as follows:—One part by weight of ferricyanide of potassium (red prussiate) is dissolved in eight parts of water, and one part of ammonio-citrate of iron is added. This last addition must be made in the dark-room. A smooth-faced paper is now floated on the liquid and allowed to dry.

By-the-Bye.

GLASS AS A BURDEN TO THE TOURIST.

In computing the weight of the various items for a photographic tour, the glass almost invariably comes out at the head of the list, and the farther or longer the journey, so much more does the weight of the plates stand out pre-eminent: indeed, if one goes out on a trip with only three dozen half-plates, the glass will probably weigh nearly as

much as camera, backs, and tripod, in spite of the stipulation with the maker to supply plates on "thin glass."

For all this, one must not look hardly on glass, for it seems to us that the glass plate has made photography what it is: and we may very well date the birth-time of photography as a really popular pursuit from the time when Archer introduced his collodion process rather more than thirty years ago. As a material upon which to make negatives, glass is simply incomparable; its beautifully smooth surface, its rigidity, the ease with which it can be cut without interfering with the general flatness of the surface, and its unalterability when subjected to all ordinary chemical reagents, are qualities of so much value, that one can see no probability of its place being usurped by any of the substitutes which have been suggested, unless under very exceptional circumstances. Before, however, considering the practicability of the tourist making use of a less weighty support than glass for his sensitive films, it may not be amiss to enquire how far the glass itself may be made more useful.

If one purchases plates without any stipulation as to thinness, they are often supplied on thick glass weighing nearly two pounds to the square foot, or even more: while any request for "thin glass" may not only prevent the delivery of the plates in due time, but may necessitate the accepting of a portion of a batch which, under other circumstances, would have been considered hardly good enough to send out, or, what is perhaps worse, the customer may merely get a selection of the thinnest glasses from several batches of plates. Indeed, as a matter of fact, a request for "thin glass" seldom secures plates weighing much less than 16 or 18 ounces to the square foot.

There is in the market—or, perhaps, one might more correctly say out of the market—an exceptionally thin glass, either patent plate or extremely fine sheet, which sometimes is so thin as to weigh no more than six ounces to the foot. Such glass being altogether an exceptional article, and very seldom asked for, is by no means cheap; but it can hardly be doubted that if a demand were created for it, the price would drop to something quite reasonable.

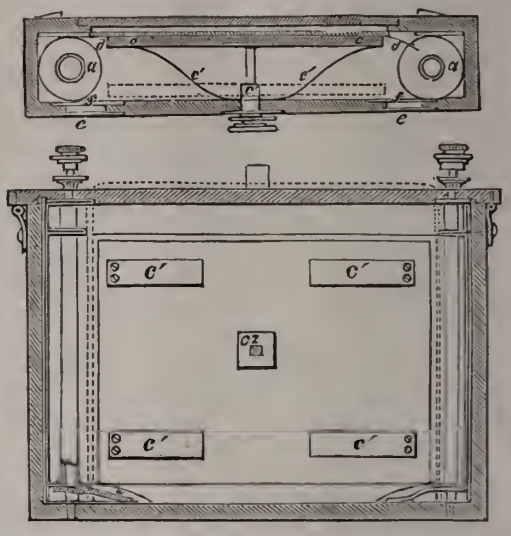
To reduce the weight of his glass packages to one-third, and perhaps of his whole kit to one-half, is by no means a trifling consideration to the photographic tourist, and if the manufacturers of dry plates were to obtain such thin glass as we allude to, and to hold a stock of plates prepared upon it, it is probable that more plates would be used, and that both they and their customers would be gainers.

For very small sizes it might be possible—indeed, it is possible—to use the thin glass sold for covering microscopic objects; but the general use of this extremely thin glass would perhaps offer difficulties as great as those arrising from the employment of one of the substitutes for glass to be alluded to presently. Still, for the small plates—say two inches square or so—used in photographic artillery, whether in gun or revolver form, the microscopic glass is excellent.

Next in importance to glass as a support comes paper, and it is quite easy to understand that the tourist in out-of-the-way parts might be able to take an apparatus containing a roll of sensitive paper, when it would be altogether impracticable for him to take an equivalent surface of coated glass, and in such a case the roller slide becomes of especial value.

The roller slide of Melhuish is to lerably well known, and is, we believe, now obtainable as an article of commerce. The slide is fitted up with two rollers, *a a*, and the sensitive sheets, *b b*, are gummed together, making one long band, the ends of which are gummed to pieces of paper always kept on the rollers. The sensitive sheets are wound off the left or reserve roller on to the right or exposed roller, until all are exposed.

The rollers are supported on springs a^1 a^1, to render their motion equal; they are turned by the milled heads *m m*, and clamped when each fresh sheet is brought into position by the nuts a^2 a^2; *c* is a board which is pressed forward by springs, *c' c'*, so as to hold the sheet to be exposed, and keep it smooth against the plate of glass, *d*; when the sheet has been exposed, the board is drawn



back from the glass in order to release the exposed sheet, and allow it to be rolled on the exposed roller: the board is kept back while this is being done by turning the square rod c^2 half round, so that the angles of the square will not pass back through the square opening until again turned opposite to it; *e e* are doors, by opening which the operator can see (through the yellow glass *y y*) to adjust the position of the sensitive sheets when changing them.

The remarkable similarity of such a slide to the automatic printing-frame described last week will strike the reader; and, like the printing-frame, it possesses the advantage of speed in working—no small consideration to the photographer in a distant, and possibly hostile, country.

Fine paper well sized with an insoluble size, and coated with a sensitive emulsion, is, we believe, the very best material to use in the roller slide, and such a paper might be made in long lengths at a very low price, a coating machine similar to that constructed for use in making carbon tissue being employed. We have used such paper with success, and hope that some manufacturer will introduce it into commerce before long. But the question suggests itself, how are the paper negatives to be rendered transparent, and how is the grain of the paper to be obliterated? Simply by pressure, as extremely heavy rolling will render such paper almost as transparent as glass, a fact abundantly demonstrated by Mr. Woodbury in his experiments on the Photo-Filigrane Process, and confirmed by some trials which we have made.

It must be confessed that roller slide experiments which we have made with sensitive films supported on gelatine sheets, or on such composite sheets as the alternate rubber and collodion pellicle of Mr. Warnerke have been hardly satisfactory—possibly, however, from our own want of skill; while no form of the Calotype Process which we have tried has proved so satisfactory as gelatino-bromide paper.

NOTES FROM NEW YORK.

PROPOSED NATIONAL ASSOCIATION OF AMATEUR PHOTOGRAPHERS—A CONCENTRATED ALKALINE DEVELOPER—THE COMING ANNUAL CONVENTION OF THE PHOTOGRAPHERS' ASSOCIATION OF AMERICA.

At a recent meeting of the Society of Amateur Photographers, the results of the first field excursion made up the

Hudson River on June 20th were compared, and among the interesting things brought out was the uncertainty of gelatine plates. One gentleman had used two plates of English manufacture which were packed in the usual manner, film sides together, and separated by a thin sheet of paper. During development, a large, irregular, insensitive patch appeared on each plate, one and a-half inches diameter. After the plates were fixed and dried, it was found that the patches matched each other when the films were placed in contact. On explaining the cause, Mr. Beach said he had had a similar experience a year ago, and produced two negatives with patches which exactly matched. The insensitiveness was supposed to be due to some chemical action between the paper and the damp gelatine film, the probability being that the plates had been packed before the film had become thoroughly dry, or else the dampness of the ocean voyage had affected the film. The experience described will not tend to promote the use of gelatine plates, unless they are packed in a better manner. Two excellent negatives were ruined from this provoking defect.

The subject of the formation of a National Association of Amateur Photographers was discussed, and the officers were authorized to correspond with fellow societies to further that object. By some, a national association composed of representatives of amateur clubs from all parts of the country is regarded as of much importance, as it would bring together amateurs, and give them facilities for comparing and exhibiting their work which they would not otherwise possess. One meeting a year is all that is contemplated, which would include exhibitions of choice work.

Mr. Beach, having met with much success in the development of his negatives taken on the Hudson trip, gave to the meeting the following formula for a pyro developer which he used :—

No. 1.—*Pyro Solution.*

Warm distilled or melted ice water ...	2 ounces
Sulphite soda (chem. pure) 437 grs. to ounce	2 ,,
When cold, add—	
Sulphurous acid...	2 ounces
Then add—	
Pyro (Schering's) ...	½ oz. of 218 grains

which is done by pouring the sulphite solution into the half-ounce of pyro bottle, repeating the pouring until the pyro is dissolved. The resulting solution should be filtered, and kept in a tightly-corked bottle, and will measure about five fluid ounces. Its strength will be 44 grains of pyro to each ounce, or approximately, a ten per cent. solution.

No. 2.—*Potash Solution.*

which is made of two separate solutions prepared as follows :—

A.—Water	4 ounces
Chem. pure carbonate of potash (437 grains to ounce)	3 ,,
B.—Water	3 ounces
Chem. pure sulphite soda (437 grains to ounce	2 ,,

A and B are then combined into one solution, which will be concentrated and of uniform strength, always ready for use, and will measure between eight or nine fluid ounces. To develop an 8½ by 6½ plate which has had a drop-shutter exposure, take water three ounces, and add thereto half an ounce of No. 1 and 3 drams of No. 2 or the potash solution, increasing the latter to 5 drams in case the image hangs back. For a plate which has had the proper exposure, or which has been somewhat over-exposed, add to the 3 ounces of water 3 drams of No. 1 and 1 dram of No. 2. After a minute's time, if the image fails to appear, add a second dram of the potash, repeating the additions at intervals of a minute until development commences. By adopting such a plan of development, Mr. Beach claimed that almost any plate could be successfully developed without the use of a bromide; the development can be prolonged, will be under perfect control, and there is no fear of fogging the plate. The danger of the green fog is avoided, and bluish-grey, clear, quick-printing negatives are obtained at once without the necessity of using alum or other clearing solutions. The developer remains clear, and from four to five plates can be developed in succession with one solution.

Mr. H. J. Newton exhibited a specimen of starched glass as a substitute for a ground glass. Many formulas had been given, but he claimed they did not go far enough. His method was to add to three ounces of water thirty grains of starch, which must be thoroughly mixed, and all particles broken up and well incorporated. It must then be thoroughly cooked or boiled for five minutes, strained through fine muslin—such as a handkerchief—cooled, and lastly poured on the plate, being carried uniformly to the edges with a glass rod. When drained and dry the plate is ready for use. The specimen shown possessed a very fine grain.

In reply to a question about silvering paper, Mr. Newton remarked that he had an excellent formula by the use of which fuming with ammonia was not necessary. It may not be new to your readers, but I give it as follows :—

Water	1 ounce
Nitrate of silver	40 grains
Nitrate of ammonia	30 ,,
Liquid ammonia	3 minims

The paper is floated upon this solution for three minutes, and is then drawn off the edge of the dish next to the operator in such a way that the paper is held by capillary attraction to the edge. The object is to avoid the use of a glass rod; no fuming is required. The bath should be kept in the light when not in use. It will test from 54 to 56 on the hydrometer, and will always remain clear. It must always be kept alkaline, and as it becomes acid from continued use, more ammonia must be added.

Another gentleman, Mr. Partridge, exhibited a few excellent transparencies made on the new Anthony transparency plate which is being manufactured under the supervision of Mr. T. C. Roche, who is the inventor of the process. The plates possess great latitude of exposure, are of the insoluble type, and dry with remarkable rapidity. They promise to be of much value to our amateurs.

I have lately seen an announcement published in one of the English journals, of Mr. A. L. Henderson's intention to sail for this city on the 11th inst. Should he come he will be welcomed by all of our photographers here. Had it not been for the sudden outbreak of cholera in France our enterprising and popular photographer here, Mr. George G. Rockwood, would have taken his usual summer European tour. He had intended to have sailed by the new steamer, *America*, on the 16th. Among the first to avail themselves of the dark room of our Amateur Society was a young English amateur who came over on the same steamer when she made her maiden trip. He secured some excellent drop-shutter views from the deck of the steamer, and one or two fine interiors of her beautiful grand saloon.

The coming photographic event is the holding of the fifth annual convention of "The Photographers' Association of America" at Cincinnati, Ohio. It is to convene in Music Hall, one of the largest halls, on July 29th, and will continue till August 2nd. The officers are :—J. H. Kent (President), Leo. Weingartner (Secretary), W. A. Armstrong (Treasurer), J. F. Ryder, and E. Klauber (Executive Committee). One of the attractive features will be the awarding of prizes by the different plate makers for the best photographs made on their respective plates. Considerable rivalry has been exhibited, which will terminate for the time being at the Convention. Some rivalry also exists in current photographic literature, as we are to have a weekly *Photographic Eye* in competition with *Photography*, a bi-monthly, both emanating from our energetic Western city, Chicago.

THE AMATEUR PHOTOGRAPHER.

New York, July 19th, 1884.

Practical Papers for Beginners.

No. 3.—EXPOSING AND DEVELOPING THE FIRST DRY PLATE.

In the first place one must provide the necessary chemicals, and arrange them conveniently for work, and in our present instructions we shall only deal with development by pyrogallic acid, as this is the method ordinarily employed, at least in England; and which perhaps is, on the whole, to be preferred for a beginner.

The solutions required are as follows:—

No. 1.—Developing Solution.

Strongest liquid ammonia ...	½ fluid ounce
Bromide of potassium ...	70 grains
Water	1 pint

A stoppered bottle is convenient for containing this solution, and the ammonia should be measured out in a glass measure, such as those used by the druggist, while the bromide of potassium must be weighed out by means of a small pair of druggist's dispensing scales having pans about two and a half inches across. Very often the pans are made of glass, and in this case the bromide may be weighed out directly on the pan. In any other case it is convenient to select a watch-glass which will easily go on the pan, and to make a metal counterpoise exactly balancing it; this counterpoise being, if preferred, permanently soldered to the pan in which the weights are placed. After having used the watch-glass for any chemical, it should be washed and dried before using it again. Instead of measuring out a pint of water in a separate measure glass each time a solution is made up, it is convenient to make a file scratch on the outside of the bottle, showing the height of the fluid when the batch of solution is first prepared; so that subsequently it is merely necessary to make up with water to the mark. The water supplied to towns is generally sufficiently pure for making up the above solution; but extremely hard water is undesirable, so that if the water supply is very bad, it may be desirable to make use of distilled water. Distilled water may be obtained from any druggist. The bromide of potassium soon dissolves, and when this has taken place, the contents of the bottle should be once agitated, as it generally happens that a dense stratum of strong solution is formed, and this may remain at the lower part of the bottle a long time.

No. 2.—Developing Solution.

Pyrogallic acid	60 grains
Water	1 pint

It is convenient to make this up in a bottle of a different pattern from that containing No. 1 Solution, as by so doing the probability of mistaking one for the other in the gloom of the semi-dark-room is diminished. The pyrogallic acid dissolves almost instantly in the water, and as putting it through the neck of the bottle is rather a troublesome operation, it is convenient to tilt it out of the scale pan into a glass tumbler or beaker, and pour a little water on it. The strong solution thus obtained is poured into the bottle, the glass being rinsed with a little more water, and the rinsings are added; after which the volume of the solution is made up to one pint by adding sufficient water to come level with the file mark (which we may suppose to have been previously made on the bottle). A slight agitation ensures the uniformity of the solution.

The above solutions are all that are required to develop a dry plate, although, as we shall point out subsequently, it is convenient to have the three factors of the developer—ammonia, pyrogallic acid, and bromide of potassium—at hand in a convenient form for adding, should there be occasion, and other preparations are occasionally required. Still, at the present stage it is necessary to prepare the so-called "fixing solution," the use of which is to remove from the developed plate all that excess of sensitive bromide of silver which has taken no part in the formation of the image.

Fixing Solution.

Hyposulphite of soda	4 ounces
Water	1 pint

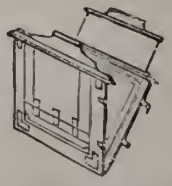
During the dissolving of the hyposulphite of soda in water, a considerable degree of cold is produced, and it should not be used until it has acquired the normal temperature.

A few glass or earthenware cups, and two or three flat dishes—say of ebonite—complete the set of apparatus necessary for a first attempt at development, it being assumed that the beginner purchases his sensitive plates ready made.

The dark slide, or shallow box which serves as a vehicle for taking the plates from dark-room to camera, and *vice-versa*, is represented by the subjoined figures.

The so-called single dark slide has a door at the back, which opens on hinges. When this door is opened, the grooved or recessed corners which support the plate in position are shown, and the plate having been put, film downwards, in position, a spring attached to the hinged door serves to hold it firmly in the recess. After the dark slide has been fitted into its grooves on the camera, the plate can be uncovered by withdrawing the sliding shutter which is next the sensitive film, this shutter being shown in the subjoined diagram as partially withdrawn.

For dry plate work it is usual to make use of the so-called double dark slides, which contain two plates back to back. Such a dark slide usually opens in the middle, as indicated below, and in closing it a little care must be



exercised to see that the two plates are fitting properly in the recesses, and that the thin light-proof partition which separates them is clear of the hinged part. A dry plate camera is ordinarily provided with several double backs, so as to allow of a number of plates being taken out on a tour: the sliding-shutters being usually numbered in regular order.

The beginner will, of course, purchase plates of the size corresponding to the rebates or recesses of his dark slides; but as cameras are almost invariably made to stock sizes, no difficulty is likely to occur in this respect.

The package of plates having been carefully undone in the dark room, the film side of each plate should be carefully dusted with a broad camel's-hair brush before putting into the slides; and as even the best slides are not perfectly proof against a strong light, it is well to provide a kind of envelope of American waterproof cloth for each slide.

We assume the central card of the focimeter to be carefully focussed on the ground glass, and that the dark slide containing plates Nos. 1 and 2 is placed in position, so that all is ready for the withdrawal of the shutter which intervenes between No. 1 plate and the lens; but, before withdrawing the shutter, it is necessary to determine the time of exposure.

Exposures may vary from a minute fraction of a second

to several hours: one main difficulty with beginners being to judge the length of time during which the luminous image formed by the lens shall act on the sensitive film, and many very complex systems of actinometry have been devised as aids in the matter. As there is one great variable in all these calculations—namely, the photographic energy of the light—the remaining calculations become stultified, and the most successful photographers trust to experience alone to guide them. We therefore do not intend to now enter into any one of the various modes of estimating the time of exposure, but recommend the beginner to adopt an empirical or experimental method.

Having everything adjusted as described, place the cover or cap upon the lens, draw the sliding shutter which comes between lens and plate, after which remove the cap for an instant and replace it as quickly as possible, taking great care not to shake or shift the camera in removing or replacing the cover.

Now remove the dark-slide and take it into the developing room, and place the exposed plate film upwards in one of the flat dishes. In order to screen it as much as possible even from the coloured light of the dark-room, a sheet of millboard or other opaque material should be laid over the dish while the developer is being mixed.

For a first experiment, pour out into two separate cups or glasses about equal parts of developing solutions No. 1 and No. 2, an ounce and a-half of each being sufficient if the plate is 5 inches by 4, and mix these solutions by pouring the content of one cup into the other. Now uncover the plate and pour on the solution with a steady and even sweep, at the same time rocking the dish. If the whitish surface of the plate becomes instantly darkened all over, it is pretty clear that the exposure to light was too long; but if, on the other hand, the darkening sets in very slowly, and after a minute or so only a dark patch can be seen here and there, the exposure has been insufficient. In the former case, the developer should be rinsed off with abundance of water, and in the latter case it should be allowed to act until the darkening has set in more or less all over the plate, or this failing, for about ten minutes. In any case the developed plate must be rinsed in four or five changes of water, allowing half a minute or so for each rinsing, and some of the fixing solution is now poured over it.

The dish containing the plate may now be taken out into full daylight, and as soon as all traces of the milky-white or yellowish bromide of silver have disappeared, the plate may be held up to the light and examined. If the writing or printing shows clearly on any one of the focimeter cards, the plate is a success as far as our present object is concerned, and it should be placed in a dish of water in order that the excess of hyposulphite may soak out. If, however, the plate is so far under-exposed as to be almost transparent when held up to the light, with scarcely any image whatever, excepting a dark shade where the extreme lights of the subject have acted, another exposure must be made, allowing, perhaps, four times as long; while in the case of the writing or printing being undistinguishable from over-exposure, indicated by a very weak image with faint details all over the plate, there is no alternative but to set up the apparatus in a place where the light is less intense, as the ordinary expedient of cutting off some of the light by the insertion of a small stop or diaphragm (a perforated disc of metal, of which several are ordinarily supplied with a photographic lens), is not allowable when testing the lens by means of the focimeter.

It is, however, most probable that the first plate will show the figures on the focimeter with quite sufficient distinctness, and it is now necessary to determine which of the cards has given the clearest and best-defined impression on the sensitive plate. Let us suppose that it is one six degrees from the central one. In order to bring camera and lens into adjustment, it is now necessary to remove the sheet of ground glass from the focussing-frame, and to reset it in such a position that the card which appeared sharpest on the photographic plate shall show most distinctly on the ground glass, the relative position of camera, lens, and focimeter not being disturbed meanwhile.

The ground glass can be set deeper in its frame by cutting away the rebate, or it can be brought forward in its setting by using strips of cardboard, so as to make the rebate shallower. In order to ensure that the correction is satisfactory, the central card should be once more focussed, and another plate should be exposed. The correction by the focimeter as described above is not theoretically perfect for all distances in case of a difference between the photographic focus of a lens and its actinic focus, but it is sufficiently exact for all ordinary purposes.

If the beginner wishes to preserve his first negative, he should soak it in four or five changes of water, leaving it for ten minutes or so in each; after this the plate should be placed in a nearly vertical position to dry, one edge being allowed to rest on a clean piece of blotting-paper.

In our next Practical Paper we shall deal with the adjustment of the exposure to the developer, and also say a little about adapting the developer to the exposure.

Notes.

Our pictorial supplement this week is a photograph of the *Diligence* on the point of starting from Bordj-bon-Arreredj for *Ménérville*. Mr. Pritchard thus described the incident of taking the picture:—"As I wanted to take the machine at the moment of starting, with the driver on the box, ribbons in hand, and the passengers in their places, it was necessary to get the driver's good will first of all. Now, many men in this world are nice unassuming fellows enough until you ask them a small favour, and then the unexpected position of exercising patronage suddenly changes their nature. Our driver was one of this class, and he suddenly became very official in his demeanour as soon as I preferred my request. He hummed and ha'ad, and really did not know whether he could sanction such a thing. 'It won't take two minutes,' I urged, as he looked so serious over it all. No doubt he meant to comply from the first, but it would not do to, accord permission out of hand. So, after due deliberation he said: 'Pas plus que deux minutes? Eh, bien, soit.'"

The fifth annual convention of the Photographers' Association of America commenced on Tuesday. The meetings this year take place in Cincinnati. Why should not a similar gathering of associations be held in England?

A member of the City of London Bicycle Club thinks he has solved the problem as to the best tricycle for carrying purposes. He used a "carrier" tricycle, similar to the one adopted by the *Standard* newspaper and the Post Office, and in the wicker basket he placed his two younger daughters, who, with luggage, weighed one hundred and forty-four pounds! With these *impedimenta* he journeyed to Bath, and reports that the weight was so admirably adjusted that it *facilitated rather than hindered* speed. The occasions are very few when photographic apparatus would weigh a hundred pounds.

Madame Modjeska once gave a hint which persons who sit for their photographs would do well to bear in mind. The charm of Madame Modjeska's features lies in their expression, and, when in repose, her face is not what would be called beautiful. She sat for her portrait to a well-known painter, and some friends, criticising the picture afterward, and comparing it with the animated face of the original, declared it was not like her. "Wait," said she, "and you will see;" and putting on the exact expression which the painter had caught, it was admitted that, under certain aspects, the picture was a faithful reproduction. Photographers are sorely tried by sitters with mobile features, and if the possessors of the latter would only look, when they show their photographs, as they did when sitting, the photographer would be saved much unmerited blame.

The prize in the competitions referred to last week, which had for its object the suggestion of an original pose for a photographic sitter, has been awarded to a competitor with the *nom de plume* of "Grosvenor." This is Grosvenor's answer:—"Pose after well-known pictures in the National Portrait Gallery, or after the statues in Westminster Hall and Corridors; or after the advertising pictures of the 'Monks' or 'Dirty Boy'; or in the dress of an Arab, Turk, Norwegian; or steering a property gondola; or seated in ear of a balloon; or take the front and back of sitter at the same time, fixing both photos on same card—one on front, the other on back."

The Puzzle Editor states that the two guineas are given with special reference to "Grosvenor's" last suggestion, which was one, by the way, to which we drew special attention last week. The notion is worth consideration, perhaps.

Photography and electro-plating cause a constant loss of the precious metals; the gold and silver which are sent into the market as finished photographs, or in the form of plating, but seldom returning to the refiner.

Gold is, however, of quite secondary importance to the photographer, and would no longer be required if the photo-mechanical methods of printing were to become universal; while the constantly-increasing turn-out of silver seems to point to a notable reduction in price. Last week we gave some particulars regarding the new silver districts in Australia.

The standard of pureness for silver coin varies much, even at the present day. According to Mr. W. Chandler Roberts, Dutch silver stands highest, as it contains no less than 945 parts of the precious metal in a thousand; while the English standard is 925, the Brazilian 917, and that of British India 916. The Monetary Convention of 1865 fixed 900, or ten per cent. of alloy as the standard in France, Italy, Belgium, and Switzerland, the United States having subsequently adopted the same degree of pureness; and below 900 we have Russian roubles containing 868 of silver in the thousand parts, the Turkish piastre containing 830, Javanese currency containing 720, while Austrian kreutzers often contain less than half their weight of silver.

Why that irrepressible but generally inaudible nobleman, Lord Denman, was so anxious to have photographs taken of the head of the "Iron Duke's Statue," he did not inform the House of Lords last Monday. The result, we should imagine, would not be of a very pleasing character, and it is just as well, perhaps, that, as Lord Sudeley explained, the application has been made too late.

It seems that the Great Commander's head has positively left London for Aldershot—packed, possibly, in its own "trunk;" and if Lord Denman really wishes a carte of it so much, he should return to the charge, and ask that it may be photographed on its arrival at the Camp, and before it is again placed *in statu quo* on the appropriate site selected for it at "head"-quarters.

There was a photographic question in the House of Commons, too, last week. Mr. J. Huntley McCarthy wanted to know all about the galvanized iron excrescence which now constitutes such an eyesore in front of the National Gallery. It is so far satisfactory to learn that this hideous erection is to be of a temporary nature only, but it would overtax Mr. Shaw Lefevre's ingenuity to have to explain why even for a single hour the "finest site in Europe" is disfigured by the abortive studio. Even if so studiously ugly an edifice were required—which we deny—there can surely have been no need to plant it in, perhaps, the most prominent position the whole of the vast metropolis is able to furnish.

We alluded, a week or two since, to Colonel Hoe's suggested plan of printing newspapers by photography. The gallant officer now says that 360,000 copies of a journal could be easily produced by his method in an hour. The only drawback to the realization of his plan is the high price of the sensitive paper which would be requisite. But doubtless if we wait a little, the Colonel will surmount this difficulty. The newspapers of the future, in fact, will probably be flashed to a wondering world without the use of paper at all.

Since the famous farewell banquet to Henry Irving last year, when the table napkins used were each adorned with a copy of his photograph, the fashion thus set has largely developed. Instead of the ordinary marking, by the use of worked or written initials or monograms, many people now have their photographs in miniature reproduced on their handkerchiefs, table-cloths, counter-panes, &c.; and the fact that the said photographic impressions come unscathed through the ordeal of washing is likely to place marking-ink at a discount ere long.

A contemporary, in advocating this new mode of marking, suggests that one of its chief merits will be that the most hardened laundress will scarcely dare to retain articles which would actually haunt her with visions of her wronged customers if not promptly returned. The plan

might be extended to the linings of hats, too, and surely some genius will be able to show us how to adapt it to our umbrellas as well. The most confirmed "gamp lifter" would surely be moved to restitution should he, on opening his most recently-annexed umbrella, find the face of its injured owner gazing reproachfully down at him from some point in its concavity.

A Brooklyn photographer who has been disposing lately of a number of M. Grye's photographs of Venus, taken during the transit of 1882, has caused much amusement by putting in his window, side by side, a "cabinet" of the famous Louvre Venus, with one of the above astronomical views, and labelling them "The Venus of Milo!" and "The Venus of Twenty-seven Million Mile 'Oh!" respectively.

Some weeks ago we noticed the gradual way in which a plate 6½ by 4¾ has become very generally regarded as a "half-plate," instead of the old legitimate half-plate, 6½ by 4¼. The Chicago fortnightly *Photography*, commenting on this, remarks that the Americans have altered the proportion of the half-plate in a somewhat similar way, but instead of increasing the width they have reduced the length. The "half-plate" generally used in the United States is 4¼ by 5½.

Truth brings forward, as a photographic *novelty*, the method of producing life-size portraits in oils adopted by the Société Parisienne. This method, according to our contemporary, is the idea of a Frenchman who had noticed that the pupils in the Viennese Art Schools were unable to turn their artistic talents to account, and suggested that they would find plenty of work in the painting of life-size reproductions from photographs. The reflection of the portrait is "thrown from a camera-obscura (optical lantern?) life-size on to canvas, and the pupils then set to outline it, filling in with oil-colour on the same canvas afterwards." *Truth* is informed that the invention is already becoming a source of income to many a poor art student in Vienna. This is possible, but the plan is by no means the new idea which *Truth* supposes.

Photography was of signal service to the picture connoisseur a few weeks ago. In the Leigh Court collection recently offered for sale was a "Venus and Adonis" of Titian, and this picture, it was asserted, was painted for Phillip II. of Spain, because of a fold across it, the presence of which blemish the monarch, in a letter to Francesco Vargas, December 6th, 1554, laments. On the other hand, it was claimed by Messrs. Crowe and Cavalcaselle that this picture is now at Madrid, as it not only contains a furrow across the centre, but two others lower down, showing that it had been rolled and squeezed flat. These markings are distinctly shown in a photograph, by Laurent, of the Madrid picture, and on comparison with the Leigh Court Titian, it was found there was a considerable difference, the marking in the English picture being clearly caused by a join in the canvas, two lengths having been joined together to form one. The honour has therefore been awarded to the Madrid Titian.

An ingenious artist, dating from the Isle of Thanet, amuses himself every day after dinner by photographing the state of the joint as it leaves the table. By thus taking it, he says, he makes it inexpedient for the landlady to take it.

Satisfactory photographs of brightly coloured objects are rare, but so much attention is now being given to the conditions under which good pictures may be obtained from coloured originals, that one may hope for real progress in this direction.

Dr. Vogel sends us a chromo-lithograph in which bright blue, crimson red, and clear yellow are the main components, and the whole colour scale is exaggerated beyond anything to be seen in nature. A print from a negative taken on an ordinary plate shows the yellow and red as nearly black, while the blues are reproduced as white; but it is altogether different in the case of a print from a negative made on one of Vogel's azaline plates, as here blue and yellow have almost the same value, while red shows nearly black. In the first instance the character of the original is lost, in the latter it is maintained.

Although it has been denied that any great advantage is to be expected from the use of isochromatic plates for ordinary landscape work, we have received an exceptionally fine landscape picture by Senhor Anthero Araujo, of Oporto, taken on one of Clayton's isochromatic plates. We do not remember ever to have seen a better reproduction of the shades of green in foliage.

The Maori king has been photographed by Mr. Mayall. It would be interesting to know whether his Majesty's opinion of the photographic process corresponds with the description once given by a native of New Zealand, who said that the photographer "looked through his one eye at the trees, and then he took a piece of glass, spat on it, put it in a box, and then the trees came on the glass. It was very wonderful!"

The United States now possess a weekly photographic journal, the *Eye*, which has hitherto been issued in Chicago as a general paper, with merely a few columns devoted to photography, having commenced a new series as No. 1, Vol. I. of the *Photographic Eye*.

The old newspaper size of the pages being retained, the journal will hardly be a very convenient one for reference and binding.

Applications for Letters Patent.

10,558. Count Stanislas Julian D'Ostroróg, 5, Conduit Street, New Bond Street, Middlesex, trading under the name of "Walery," for "Improvements in obtaining pictures on enamel fixed by fire."—Dated 24th July, 1884.

10,567. Fredk. Wm. Mousell, Eglantine, Leeson Park, Dublin, for "A circular drop shutter for taking instantaneous photographs."—Dated 25th July, 1884.

Specification Published during the Week.

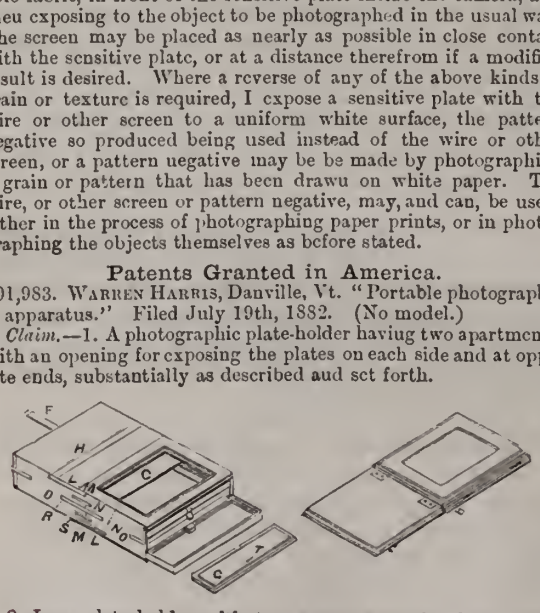
5896. ALEXANDER BORLAND, of Wilmslow, in the county of Chester, "Improvements in and apparatus for the production of photographic negatives to be used in the processes of photo-lithography, photo-zincography, photo-engraving, photo-etching, or photo-type productions." Dated 28th December, 1883. (*Provisional Protection only.*)

This invention has for its object the production of photographic negatives having suitable transparent lines, dots, or stipples so that such negatives may be used in the processes of photography, photo-zincography, photo-engraving, photo-etching, or photo-type productions, such negatives being either portraits, views of buildings, machinery, or landscape or other objects. Hitherto, the means employed in making such negatives has been to take a paper photograph, and stipple the same by hand or by impressing the same with any rough substance such as sand-paper, glass-cloth, or muslin, made hard by steeping in glue, or by fine wire gauze, and after being so impressed, filling the indentations with some kind of soft and dark pigment, and then making a negative of the same. In my process I obtain a like result by placing a screen of wire or hair gauze or perforated metal or paper or other substance having suitable perforations, or by means of a screen of muslin, net, or crape, or other suitable fabric, in front of the sensitive plate inside the camera, and then exposing to the object to be photographed in the usual way. The screen may be placed as nearly as possible in close contact with the sensitive plate, or at a distance therefrom if a modified result is desired. Where a reverse of any of the above kinds of grain or texture is required, I expose a sensitive plate with the wire or other screen to a uniform white surface, the pattern negative so produced being used instead of the wire or other screen, or a pattern negative may be be made by photographing a grain or pattern that has been drawn on white paper. The wire, or other screen or pattern negative, may, and can, be used, either in the process of photographing paper prints, or in photographing the objects themselves as before stated.

Patents Granted in America.

301,983. WARREN HARRIS, Danville, Vt. "Portable photographic apparatus." Filed July 19th, 1882. (No model.)

Claim.—1. A photographic plate-holder having two apartments, with an opening for exposing the plates on each side and at opposite ends, substantially as described and set forth.



2. In a plate-holder with two apartments, the double back with an interior space, into which the slide C may be drawn, substantially as described, and for the purpose set forth.

3. In a plate-holder with two apartments, the interior moveable partition, substantially as described and set forth.

4. The combination of slide I, levers L, P, and the moveable partition, substantially as described, and for the purpose set forth.

5. In a portable photographic apparatus for taking pictures on dry plates, the combination of folding camera-body, hinged-front, plate-holder with two apartments, openings for exposure at each end and on opposite sides, sliding partition, double plate-frames with single grooves, and with shoulders in openings, all substantially as described, and for the purposes set forth.

302,104. BARNET M. CLINEDINST, Baltimore, Md., assignor to Thomas H. McCollin, Philadelphia, Pa. "Means for mounting photographic cards." Filed March 19th, 1884. (No model).

Claim.—1. The combination of a sheet or base of card or other paper board, and flexible ears or clips, substantially such as described, adapted to be bent to clamp the edges of cards and hold them against the face of the sheet, as specified.

2. The combination, with a sheet of paper-board, of a number of flexible ears or clips arranged with relation to the sheet and with each other, as shown and described, whereby a number of cards may be clamped and held with their edges adjacent to each other for simultaneous display, substantially as described.

3. The combination, with a sheet of straw or other board, of clips of flexible material extending through said boards, adapted to be bent over the edges of cards on opposite sides of the sheet, substantially as described.

4. The combination, with a sheet of paper-board provided with a raised border, of flexible clips adapted to be bent over and to clamp the edges of cards or pictures, substantially as described.

PHOTO-ASTRONOMY AT THE RIFFEL.

BY C. RAY WOODS.

No. I.

EIGHT thousand five hundred feet above the level of the sea! Surely the clearness of the atmosphere at such a height should be almost as favourable as one could wish for astronomical work. The English climate is tantalizing enough where very delicate work has to be done, and for performing such a piece of work as photographing the solar corona without an eclipse, the glare of the atmosphere is, except on rare occasions, sufficient to overcome the comparatively faint light of the beautiful "glory" that has attracted the astronomer on occasions when the orb of day suffers a temporary extinction.

Eclipses of the sun take place at long intervals, and are extremely short in duration. Even then they are only visible over a very minute portion of the earth's surface. In the course of a century, the sun is only eclipsed for an hour or two, all told; and many efforts have therefore been made to render us independent of them. It is fourteen years now since Janssen and Lockyer independently arrived at a spectroscopic method of observing the red prominences at will, and at many European observatories observations are made of them from day to day. But the silvery light of the corona defied all efforts till Dr. Huggins considered he had succeeded in accomplishing the task by means of photography.

Dr. Huggins' first results were obtained as follows:—An image of the sun was formed by means of a reflecting telescope, and thrown into a camera. Just in front of the plate, which was well backed with asphaltum, a piece of clear blue glass, and later, a cell containing a solution of permanganate of potash, was placed. By this means all rays, except those of very high refrangibility, were cut off. The object of this was to use only that kind of light which the spectrum-photograph of the corona taken in Egypt, 1882, showed the corona chiefly to emit, the H and K lines in the ultra-violet being the strongest. The results Dr. Huggins obtained were by Captain Abney pronounced to be genuine, after he had compared them with the photographs of the 1882 corona. It was only at rare intervals that the English sky was good enough to enable Dr. Hug-

gins to prosecute his research; and in 1883, while Mr. Lawrence and myself were on Caroline Island, Dr. Huggins was only able to obtain photographs a month before and a month after the day on which the eclipse of the sun took place. When we came to compare results, the form of the corona in the Caroline Island photograph appeared to occupy a place midway between those of Dr. Huggins, a fact which favourably impressed me as to the truth of Dr. Huggins' method. It was scarcely to be expected, however, that Dr. Huggins' photographs should show the fine detail that is to be obtained during an eclipse; that they showed, though vaguely, the general form of the corona, was in itself a satisfactory result.

But it must be remarked that the results obtained by Dr. Huggins under the unfavourable climatic conditions prevailing in England were not sufficiently good and sufficiently definite to obtain the unqualified approval of scientific men. They were sufficiently good, however, to justify the expense entailed in more extended observations under more favourable conditions. Moreover, could a series extending over a short space of time be obtained, they could be of immense value in determining the nature of the corona, and possibly settle this vexed question in solar physics. As your readers already know, the Royal Society, through a committee appointed for the purpose, have entrusted me with the work.

I will endeavour briefly to describe my equipment, not as it exists now, under the tent of Willesden canvas beneath which I am writing this letter, but as it existed when I started from England. Four heavy cases contained the equatorial stand of a Greenwich photo-heliograph. Two cases contained a new instrument, a "coronagraph," constructed by Messrs. Grubb, of Dublin, and which I shall describe in detail later on. Several more packages contained the wooden frame-work for my observing-tent and dark-room, as well as the canvas and Willesden roofing necessary to cover them. Another case contained a stock of plates; yet another was full of chemicals. I brought out chiefly chloride plates, which, on account of their selective nature and sensitiveness in the ultra-violet, Dr. Huggins had found to be most suitable for his work, and which, in fact, enabled him to dispense with the blue glass or permanganate of potash solution. Altogether I had fourteen packages, weighing in all nearly a ton. These were sent by rail as far as Visp. How I was to get them from Visp to Zermatt, and thence up the Riffel, goodness only knew—I didn't! I set out, however, with as light a heart as I could under the circumstances, trusting a little in my usual good luck, and still more in the friendly offices of Herr Seiler, the well-known hotel-proprietor of "Zermatt" and the "Riffel."

It is impossible for me to refrain, here, from calling to mind a remark made by a facetious friend, as he viewed the array of packages that were gathered together in London previous to being placed in the hands of my shipping agent.

"What a sensation you'll create, old fellow! They'll take you for a German count or an English fool."

I've thought a great deal about this, and I want to know what my friend meant. I have looked several times in the glass lately, when the words have been brought to my mind, and I feel perfectly confident that I bear very little resemblance to a Teutonic nobleman.

All these things, however, had been sent on before me. My personal baggage consisted of my 7½ by 5 camera and tripod stand, two small portmanteaux containing clothing, and a large hamper containing a further stock of plates, and some few chemicals, &c., that I could not get ready previously. And here is a wrinkle for photographers about to travel. Pack all your things in portmanteaux, and, provided you do not make them heavy enough to excite suspicions of dynamite, you can register them in London as far as the Swiss frontier. My unfortunate hamper the railway company refused to register. It was examined by the Customs at Calais, and on arrival at the Swiss frontier, when a small selection of baggage was examined, my hamper attracted foremost attention. The ordeal had again to be gone through, and a duty of a franc or two on some of its contents had to be paid. On arrival at Visp, again, it was the last thing to be lifted out of the luggage van, and was unceremoniously bounced out upon the platform as the train moved off. I anxiously rushed to the rescue, and, to the astonishment of onlookers, applied my olfactory organ to it to ascertain whether the bottles containing my ether or alcohol had suffered damage. Happily, nothing was injured.

Speeding along by the lake of Geneva, by the beautiful castle of Chillon, the remarkable railway at Glion that ascends the hill with such a steep gradient, and the pretty town of Vevey, it seemed hard lines that one could not stop to take a shot or two. Had I only known that on reaching Visp I should find that my instruments had not arrived, I should have made less haste. The town of Visp offers very few subjects for the photographer, but, having to stay there for a few days, I tried my hardest to make good use of a few plates.

At last my packages arrived, and were consigned to the care of Mr. Seiler's men. The road is very narrow and very steep, but a long cart, not more than two feet wide, enabled them to be taken to Zermatt. Packing my personal baggage upon a mule, and placing my small articles and my camera upon the back of one of the native porters (as steady-going as the mules), I started on the road. Along the little road on the edge of the precipice one met occasionally with the subject of a characteristic picture. Here was a little châlet standing against the hill, there the turbulent Visp river rushing along the valley, and eddying round the rocks and stones that obstructed its course. The little village of Stalden, snugly nestling in the valley, was too good to be passed over, the spire of its little church forming a centre round which the white buildings picturesquely grouped themselves. But of natives—natives, that is to say, suitable for being incorporated in a picture—I met none. Switzerland may have its quaint costumes, but over the little part I have traversed, a road well trodden, and yet more often ridden by Europeans, I have not met with one. And if the rest of Switzerland is at all like this, they must have very few passable looking, not to say pretty, women.

At St. Nicholas the journey is broken, and from there to Zermatt the tourist usually takes a carriage, the road being good. A covered carriage was necessary on this occasion, for the weather, which had hitherto been very fine, now underwent a change for the worse. Rain fell heavily when one was not surrounded by mist which completely obstructed the view. At Zermatt, in the evening, however, clear weather again prevailed, and before retiring to rest I was greeted by a sight of the Matterhorn, unobstructed by clouds, standing out against a blue sky, and illuminated by the moon. Unique in its rocky pyramidal character, sharply chiselled as if by the hand of man, it is a sight worthy of admiration at all times; but not, as yet, have I seen it grander and more imposing than when I gazed upon it from the window of my room in the "Mont Cervin Hotel."

Next morning I was up with the lark, or whatever bird takes the place of it here. Many of my heavy packages had already been placed on the backs of mules, and were on their way up the mountain. Some of them still remained at Visp, and were to be brought up next day. But I had enough to go on with, and before the day was over was able to make a little progress in constructing my observatory. On the way up I was able to expose a plate or two. The châlets and the pine forest, the termination of the Gorner glacier, and the Matterhorn as it appeared from sundry points along the zigzag path, demanded more time and care, though, than I was then able to give them.

It took three days for all my baggage to be brought up and placed on the site I selected close to the Hotel on

the Riffel. I had to make several journies down to Zermatt, and even to take some of the heavy portions of apparatus to pieces, guarding the more delicate parts under my personal charge. When I had them all to my hand stormy weather set in, and progress was very slow. But the longest task must have an end, and I am now settled. What I have already accomplished I must leave for my next communication.

THE CAMERA AND ITS APPURTENANCES.

BY LIEUT.-COLONEL W. T. NOVERRE.

To amateur photographers the proper choice of apparatus is a matter of considerable importance, and of much difficulty to those who have not the opportunity of inspecting the various manufacturing establishments, but are obliged to depend upon the information to be obtained from catalogues and advertisements of rival manufacturers, which must considerably mystify the inexperienced, cameras and other articles of various forms and prices being recommended as excelling each other in cheapness and efficiency.

The selection of a camera is the most difficult, as it is the most expensive article in the amateur's outfit; and on its proper selection depends much of his future comfort and pleasure in working. There are many sizes and patterns to select from, and the prices vary from a guinea to twenty times that sum. Moreover, the size of the camera will rule the sizes of all the other apparatus required, as well as the sum to be expended on dry plates, chemicals, and other materials.

It may be stated that the most popular form of camera with amateurs is, without doubt, the folding bellows camera with side flaps, the invention of Mr. Meagher, who introduced the folding tail-board in 1862, and the side flaps in 1865. Its great popularity is very clearly shown from the fact that it has been copied by nearly every maker of apparatus, and takes the principal place in their catalogues. It does not, however, follow that by simply writing for a camera of this description the photographer will get the instrument best suited to his requirements, for the camera has several modifications, and in ordering a camera and enquiring the cost the particular form required must be clearly specified.

The camera in its simplest form is oblong, and has no swing-back; as pictures often require to be taken vertically as well as horizontally, a camera of this kind must be set up on its side where an upright picture has to be taken In price lists it is invariably noted that a single swing back will be charged so much extra, and a double swing-motion can be added at a further additional cost. The single swing gives the swing motion only when the camera is used in the horizontal position. A camera so constructed has no swing adjustment when the camera is turned on its side to take an upright picture, whereas it is in this description of picture that the swing-back is mostly required: yet it is surprising the number of cameras that are sent out with the single swing only. The double swing permits of the swing motion being given with the camera in either position, but it has the objection that it lessens the stability of the back portion of the camera, the attachment being on one side only of the framework.

To obviate this defect, and to overcome the inconvenience of turning the camera on its side for upright pictures, the square camera is frequently preferred. In this form of camera the slide is square, and the plates can be placed in it either way, so that a single swing-back will give the swing motion whether the plate be placed horizontally or vertically in the camera. A square camera with swing-back would seem then to be all we require, but there is an inconvenient defect in the arrangement, namely, that the plates must be placed in the slides in their proper position according to the number of horizontal and upright pictures respectively which it may be our intention to take; but we seldom have this information unless the subjects have been carefully inspected beforehand. To overcome this, the camera should be made with a reversible frame or holder; the square form of the instrument is retained, but the slides are made oblong, and by means of the moveable frame can be placed in the camera either in the horizontal or vertical position. A saving, too, in the size and weight of the slides is gained, which are similar in size to those used in an oblong camera. The camera under notice is made square with single swing-back, and provided with a reversible frame is probably the most perfect form of portable camera in the market. The bulk and weight is greater than that of an oblong camera, and the price is higher, especially when compared with the price of an oblong camera without swing-back; this latter description of camera will answer perfectly well for the ordinary work of an amateur photographer, while it has the advantage of being less bulky, lighter, and cheaper. The only case in which a swing-back is likely to be required is in photographing high buildings, when the camera has to be considerably tilted: for buildings of ordinary height, such as usually come into a country view, the swing-back may be dispensed with, and, indeed, is better out of the way. There are two or three ways of attaching the swing-back, depending chiefly on the size of the camera, and the extent to which the purchaser is prepared to sacrifice rigidity to portability. The expense will be about the same whichever method is adopted.

Nearly all camera-fronts are made to rise and fall, so as to bring more or less of the foreground or sky into the picture without tilting the camera. The lens flange is screwed to the rising front, and if you possess two or three lenses, a front is ordinarily required for each lens; but there is an improved form in which a small panel takes in and out of the sliding front, and to this panel the lens flange is screwed, a panel being required for each lens. A neater plan is to have the sliding front fitted with the flange of your largest lens, and to have brass adapters to take the smaller lenses. An objection to this is that if you purchase a new lens, the adapters require alteration. The camera should be provided with a strap-handle to carry it by, and for raising it out of its box or leather case. For some reason this is rarely added by makers of cameras. Another useful adjunct to the camera is a small spirit level; it may be let into the base-board behind. A small dial indicator to show which plates have been exposed, attached to the body of the camera, would be valuable, and an arrangement for telling when the centre object is in the centre of the plate will be found very useful. All that is necessary is a small piece of brass plate with a V-shaped notch cut on the upper edge. This is screwed on the back frame of the camera, and a small pin is fixed on the front, both being in the centre, and resembling the fore-sight and back-sight of a rifle; the contrivance is specially useful in photographing animals or moving objects, as it enables you to see at the last moment that the object is properly centred, and to adjust the camera, if necessary, without recourse to the focussing-screen.

The focal length of the camera, or the distance from the lens to the focussing screen, requires attention. Ordinarily the amateur will be contented to use the lens which is made to cover the sized plate he has selected to use. In this case he will find the camera as usually made is sufficiently long, but it has been pointed out that a given subject can often be taken to greater advantage when a longer focus lens is employed than is necessary to cover the plate. The effect of thus using a large lens to cover a small plate is that a smaller angle of view is included; or, in other words, in place of having a large amount of view on a small scale, we get a small amount of view on a large scale. The same object may sometimes be gained by placing the camera nearer the subject, but very often in landscape work this is impracticable, besides having other objections. If it is intended to use extra long focus lenses, the camera-maker should be informed, that he may construct the camera accordingly.

THE ITINERANT PAINTER.

BY H. P. ROBINSON.

When a well-established photographer takes a portrait, he looks for his profit, not only to the sum he receives for the first order for copies, but to the contingent potentialities which may arise from the possession of the negatives, and to that end he goes to a great deal of trouble and expense in cataloguing and storing them. Of course the great proportion of these negatives are never wanted again, and are an incumbrance; but all professional photographers know that there is so good a demand for copies from old negatives, that they find it to their interest to keep all they take, and to print prominently on the back of their cards, "All negatives are preserved. Copies or enlargements of this portrait can always be had." Talking on this subject the other day to a photographer, he said, pointing to a beautifully-finished enlargement, "Here is an instance. One day, some years ago, a shabby old gentleman came into the reception-room, and said he wanted his portrait taken. He was shown specimens, but he said they were all too dear; he could only afford half-a-guinea, and if I liked to do it for that sum, he should be glad to have it done. I liked the appearance of the old man, who looked poor but respectable, so as a kind of charity I took a negative of him. I was so pleased with him, that I offered to send him a dozen copies without charge, but he would not accept this offer, saying he had to drive a bargain sometimes, but he could pay his way, and paid his half-guinea. I found afterwards I had entertained an Angel—a business Angel—unawares, for I have done nearly £300 from that negative since. The fine old gentleman died soon afterwards, and then I found he was a famous manufacturer, and that the portrait I had taken had a peculiar expression in the eyes of his friends, that had never been got before in any portrait he had had taken, and the orders for enlargements poured in, and still continue." This is, of course, an extreme instance of the value of a kept negative; but "back orders," as they are sometimes called, are so constant that many photographers who keep careful statistics of their business can tell to a few pounds how much their old negatives will bring in every year. Then they constitute one of the bases on which businesses are valued—in short, they are property.

It is a constant complaint of photographers that they are always open to, or suffering from, the attacks of those who want to rob them of this property. There is a class of people who misuse the great name of artist—as, indeed, for the matter of that, some photographers do, by applying it to themselves—who go round the country, and by means of introduction or impudence, obtain orders for portraits, usually enlargements painted from photographs. As they never take an original portrait themselves, they require the negative, and use every means, fair or foul, to obtain it, and are usually successful. The method of proceeding is something like this. The father of a family has been dead a short time, the itinerant hears of this, and before she has had time to apply to a photographer, gets an introduction to the widow. A great part of his success in his business depends on fluent and persuasive speaking, and the lady is soon induced to order a portrait of her late husband. And some of the "tramps" are so pressing and plausible that they compel orders against the will, or certainly against the calmer reason, of their victims. When the order is booked, they ask to see a portrait of the husband, and take down the name of the photographer. They usually get the widow to write for the loan of the negative, taking great care to explain that no injury shall happen to it, and that he is sure the photographer will be delighted to lend it to a brother artist, especially as it is of no further use to himself. Perhaps the photographer reluctantly consents, seeing no way out of it, or he more properly and wisely refuses to lend the negative. In this case the itinerant brings more pressure to bear, showing to his patron how selfish and inconsiderate the photographer is in preventing her having a splendid portrait of her husband now there is such a fine opportunity. The result is that the unfortunate photographer is placed on the horns of a dilemma: if he consent to lend the negative, he loses the benefits for which he has speculatively kept it for years; and if he refuse, he runs the risk of losing an old and good customer.

There are grades, even in this low class of art. There is the "perfect gentleman"—of that class of gentlemen who are never seen without their gloves—who selects a suitable town and takes a good house or grand apartments, and works all the country round. This is one of the princes of the profession who occasionally gets as much as £100 for a picture. This practitioner can afford, and often does pay, the photographer for the use of a negative, but he oftener induces him to join him in risky practices that are certain to bring him into disrepute with his patrons. For instance, amongst the photographer's specimens he will see a fine-looking man or a beautiful woman, and, first ascertaining if the game is worth the candle—that is, if their proposed victim is rich and amiable, or able to pay and timid. He then paints his picture, sends it to the victim beautifully framed, explaining as his reason for painting it that the head was so fine that he really could not help trying to do it justice, and he thinks he has succeeded. No mention of price is made in this first experiment. He probably gets it back with a letter of thanks, and a civil word or two about it being very well done, &c. Then begins a series of puttings on the screw, running sometimes at the last to the most unscrupulous proceedings, until the victim succumbs—and pays. It is astonishing what a quantity of orders these men will get, until at last they make the town too hot to hold them, and move on to another.

These itinerant painters are not all of the male persuasion; a good many are ladies, ranging from the old miniature painter—the Miss La Creevey's are not yet extinct—down through students who have failed in original art, to the merest tinters. I hear of them from all quarters, and am often requested to give advice as to what is the best manner of treating them. This is very difficult to give; different circumstances require different treatment, but in most cases the best policy would be to refuse to have anything to do with the poachers. It should be easy to explain to a client that a photographer ought not to be expected to give up the fruits of his foresight and care, that he could scarcely afford to warehouse negatives for the benefit of others, and, above all—and he must show this—that he can produce as good a picture as the itinerant at the same price.

Whether one photographer should occasionally lend a negative to another is quite a different question. I am inclined to think there are many occasions when they should oblige one another—it may be for their reciprocal advantage; but I can see nothing to be gained by encouraging those who prowl about the country trying to get work out of the hands of those to whom it legitimately belongs.

Correspondence.

VOGEL'S METHOD OF COLOUR PHOTOGRAPHY.

Sir,—Under this title I find, in the Journal of the Photographic Society, June 27, p. 151, the following remarks:—

Vogel's Method of Colour Photography.—In our last issue we gave extracts of Dr. Vogel's experiments in rendering different colours in their proper gradations, and it seems that this was brought about by using eosine, or some dye very similar to it, with an excess of silver nitrate. In 1876 the Editor of this journal made a communication to the Photographic News, in which the following experiment was described:—"An emulsion of eosine with excess of silver it was endeavoured to form in the ordinary way, a calculation having been made, which subsequently

was corrected by experiment as to the amount of silver necessary. The addition of silver nitrate to the eosine showed that a combination had taken place, for fluorescence was annihilated, and a crimson colour resulted. An emulsion at first formed, but finally nearly totally dissolved in the solvents of the collodion; but after coating a plate with it and drying it, no crystallization was apparent, and on exposing it a feeble image was obtained. . . . . A plate coated with emulsion and this 'collodio-eosine' and silver gave a picture of the spectrum extending from the blue to a line below A. We may state that the intensest part was in the green." On January 9th, 1878, Dr. Robert Amory presented to the American Academy a "Memoir on the Theory of Absorption-bands in the Spectrum, and its bearing in Photography and Chemistry." After alluding to the above quoted paragraph, Dr. Amory goes on to show that he obtained a picture on pure eoside of silver, in which the action of the spectrum was united to a part of the spectrum from below D (the orange) to above F in the blue-green. A short time after that Dr. Amory forwarded to us a plate showing this, in which he had used a grating spectrum, and where the local sensitiveness of the "eoside of silver" had enabled him to photograph with the third order between the above indicated limits, without any impression being made by the blue rays. Here, then, was a salt which, if judiciously mixed with ordinary sensitive salts, Dr. Amory showed was capable of producing the effect which Dr. Vogel has done. Later still, and only some two years ago, Professor Rowland stained his bath collodion films with eosine to photograph the same region, and we have by us exquisite examples of the spectrum in the orange-green region executed by this method.

In March of this year the Editor demonstrated at the Royal Institution that the yellow of a colour chart could be made as photographically intense as the blue, and indeed more intense, by using cyanine blue. This was shown in reference to Dr. Vogel's experiments made in 1874. Thus we see that though Dr. Vogel may have worked out the process further than others, yet as regards eosine he is not in advance of other experimenters. Dr. Amory perhaps can claim the highest credit in this particular branch of the research, though to Dr. Vogel undoubtedly, in 1874, belongs the credit of having first called attention to the action of the dyes in general. We have thought it right to give this slight historical sketch.

I beg to say, with respect to this note, that I have never claimed to have been the first who has worked with eosine; on the contrary, I have mentioned the earlier trials with this substance made by other investigators, especially Waterhouse, who was the first who worked with eosine. If I have not mentioned the investigations of Abney and Amory, regarding eoside of silver, the reason is that I did not know them.

I agree now the eoside of silver was known before me, but I mention that my intention was not the study of eoside of silver *per se*, or only its behaviour in the sun spectrum. I made experiments with wet and dry collodion plates, dyed with eosine, and also with dry gelatine plates, and I observed that in the wet collodion process eosine gave the best results. It has the highest sensitiveness for yellow and green rays (PHOTOGRAPHIC NEWS, May 23, page 325), and I asked, "But why is this?" (*ibid*) This question I have answered by my researches, and I pointed out that the formation of eoside of silver is the reason why eosine works better in wet plates than in dry ones.

Nobody before me has answered the above-mentioned question in the way I did. On the other hand, I have shown the importance of such dyes (for photographing coloured rays) as give silver compounds like the eoside. I pointed out the fact that there are other derivates of eosine—*i. e.*, cyanosin (the methylated eosine)—whose absorption bands are situated more towards the red end of the spectrum, and which are, therefore, more favourable for taking red colours than the ordinary eosine.

Captain Abney says in the above notice that he has demonstrated in March of this year, at the Royal Institution, "that the yellow of a colour chart could be made as photographically intense as the blue, and, indeed, more intense, by using cyanine blue." I highly esteem the works of such an eminent investigator as Captain Abney, but I beg to remark that I showed on the 21st of March, in the Berlin Society for the Advancement of Photography, the first results of my practical process for taking colours in the right proportion of their brightness (*Photographische Mittheilungen*, xxi., p. 6), the action of the yellow being far more intense than the blue, a process rewarded with the prize of honour by the Society, and worked out now practically in German studios for reproduction.

H. W. VOGEL, PH. DR.

STRIPPING GELATINE FILMS BY MEANS OF HYDROFLUORIC ACID.

SIR,—The method of stripping a gelatine film described on the 25th inst. seems complicated. I do it in a much simpler manner.

Take a developing tray larger than the negative to be stripped, pour in sufficient water to cover, and, for a whole-plate, drop in eight or ten drops of hydrofluoric acid (the exact quantity cannot be given, as the strength of the acid is constantly diminishing, though kept in a gutta-percha bottle), place the negative in the acidulated water, and in a minute or two the film will frill all round the edges and gradually leave the glass. If the operation is slow, add two or three more drops of acid, and gently rock.

When the film is loose, hold it at one end and pour off the acid water, and wash by repeated changes of water; this lengthens the film wonderfully, but if the last washing is done with equal parts of methylated spirits and water, it will return to its original size. This may be varied considerably by using more or less spirit. But on no account should undiluted spirit be used, as it makes the film coil out of all control.

Clean a plate with nitric acid—larger than the stripped film—dust with French chalk, polish with a dry cloth, and with a wet one wipe a quarter of an inch all round, coat with plain collodion, and when set, or even quite dry, introduce under the film. Adjust the film, and with a little care there will be no bubbles. Allow the film to dry, and coat with plain collodion. When this is dry, run a sharp penknife three-eighths of an inch from edge of plate, and you have the gelatine film between two collodion films, impervious to moisture, quite flat, and may be printed from either side. The acid is so dilute that any developing tray may be used. CERAMIC.

THE LAW OF IMPLIED GUARANTEE.

SIR,—In your paper of the 25th inst., the case of Turner *v.* Ermen is referred to, and the plaintiff is said to have gained his case because "a trace of fatty matter, well known to be injurious to rubber," was contained in the thread supplied by the defendants. This is not correct. The statement of case settled by the *Arbitrator* says on this point:—"Upon experiments being made during the hearing of the case, it was ascertained that the injury was caused solely by the chemical action of certain ingredients used in the processes of dyeing and sizing, but it was not a previously known fact that the said ingredients, either alone or in combination, would produce such chemical action." The decision of the court (Justices Field and Watkin Williams) was for the plaintiff. An appeal was strongly urged upon defendants by their counsel, but the matter was settled by compromise. We do not think the case is one which furnishes a trustworthy precedent.—Yours faithfully, ERMEN AND ROBY.

Proceedings of Societies.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE first outdoor meeting of the season was held at Hampstead Heath on Saturday last, the 26th inst.; the tea at the "Bull and Bush," which followed a pleasant ramble on the Heath, being the main feature of the gathering. Mr. W. ACKLAND occupied the

seat at the head of the table, and Mr. W. Brooks took the vice-chair.

The loss sustained by the Society by the death of the Rev. F. F. Statham was referred to by the chairman, who also made some remarks regarding the agreeable and non-formal character of the outdoor gatherings—not very photographic it is true, as a camera is but rarely seen—the members of the Society being glad to cast away the remembrance of the studio and dark-room, and spend a few hours in genial conversation.

Shortly after nine o'clock the gathering broke up, but the heavy rain which had set in served rather to mar the prospects of a pleasant journey home, especially for some members who had a ten or twelve-mile tricycle ride before them.

London and Provincial Photographic Association.

A meeting of this Society was held on Thursday, the 24th ultimo, the chair being occupied by Mr. J. H. Hare.

Mr. A. Cowan showed a method of cutting circles in ebonite, vulcanized fibre, and similar hard substances, wherein he employed a pair of fixed compasses, bent about two inches from the points to form an arc of a circle; one point forged to a graver edge formed the cutting tool, and either the compass or work could be moved as required. Circles ranging from half-an-inch to nine inches in diameter might be easily cut in this manner.

The Chairman considered the edges much cleaner than those produced by Mr. Ayres at the previous meeting.

Mr. H. S. Starnes exhibited his camera and changing-box combined, a description of which will be found on page 431 of the volume for 1882. He also showed strips of zinc grooving suitable for metal plate-boxes, made by passing strips of zinc between cog-wheels.

The Secretary had recommended the use of cog-wheels for that purpose some time ago; he found it necessary to use wheels having deeply-cut cogs.

A communication was read enquiring the best mode of parchmentizing paper.

Mr. Sutton said a very good paper was imported from Japan, in thicknesses varying from thin tissue to that of cardboard; he believed it was made from mulberry leaves, and would obtain examples in time for the next meeting.

The Chairman remarked that the querist was desirous of ascertaining the best method of parchmentizing paper. Had any one tried the proportions of acid and water that Mr. Ashman recommended on the last occasion?

Mr. J. Barker said the strength of the paper had to be considered; he had recently made some, using equal parts of acid and water, immersing ten minutes, and washing very thoroughly.

Mr. J. B. B. Wellington showed how a weak solution of ferricyanide of potassium and hypo will clear away green fog when the solutions are too weak to reduce the density of the image. In the example shown, portions of a green fogged and under-exposed negative were cleared in a most perfect manner.

Mr. W. M. Ashman had noticed, when using the solutions stronger for reducing purposes, that any green fog was quickly changed to grey.

Mr. W. Cobb mentioned that some new dark slides just made with leather hinges had hopelessly fogged a lot of his plates. After coating the leather with alcoholic solution of thymol, and exposing them to sun-light for a few days, the evil ceased.

Mr. Cowan said Mr. Cobb's was not the only case; he was shown a plate with an insensitive band two inches broad, supposed to be caused by American-cloth.

The Chairman considered it very important, seeing that most camera-makers employ leather hinges. He should be more inclined to blame the composition used in attaching the leather to the wood.

Mr. Cowan referred to an experience of their late member, Mr. C. G. Collins, who observed an effect on plates when the interior of the slide was painted with an oily medium, but not with vegetable black and spirit varnish.

Mr. Barker agreed with the Chairman; he doubted whether leather would cause markings; it might be light entering the camera or slide.

Mr. Riemann enquired if sulphite of soda had been found to develop an image without the addition of another alkali.

Mr. W. E. Debenham remarked that most samples of sulphite of soda contain carbonate, which is sufficiently alkaline to set up developing action.

Mr. W. Coles thought it was stated in the article just quoted that neutral as well as ordinary commercial sulphite of soda was used, whereas the same amount of alkali as found in the ordinary sample gave fog.

Mr. Barker looked upon it as another illustration of of a retarder being also a developer. Either tannin or coffee would develop a gelatine plate, provided sufficient exposure be given.

A letter from Mr. Crosby was read, stating that he had arranged to publish his formula for producing gelatino-chloride opals shortly in the Photographic News, therefore could not comply with the Secretary's request.

Much interest seemed to be shown in this class of picture, several members signifying their intention to try to obtain a plate which will keep well.

Mr. Ashman showed an opal of rich purple brown tone made according to the formula given last week, except that he boiled ten minutes, employing a high temperature for mixing and digesting; he also pased round an opal somewhat bluer in tone, which had been produced by Mr. Offord some time ago, who had no difficulty in obtaining any colour he desired.

Talk in the Studio.

The International Exhibition at the Crystal Palace.—Last week we announced the award of a silver medal to Mr. Horatio Nelson King for his photographs in the fine art section of the Exhibition, and we pointed out that the award was the only one made in this section for photography, the judges in this case being artists of well-known repute. Some photographic exhibits were displayed (for what reason we cannot tell) in Section IV., and these pictures were adjudicated on by the gentlemen charged to report on educational works and apparatus, printing, stationery, book-binding, painting and drawing materials, &c., while the fine art section had, as before mentioned, its special jury of artists. The collection of photographs in Section IV. is, however, a very small one, and the exhibits are so scattered about the building as to be difficult to find; but some good work is shown, and the report of the jury shows that Messrs. Baudaux and Son, of Jersey, are awarded a gold medal "for artistic and technical excellence of photographs printed in carbon," and the frames exhibited contain numerous and meritorious examples of portraiture and of carbon transparencies. Mr. Robt. Faulkner has a silver medal for "children's portraits"; and M. Eugène Pirou, of Paris, is similarly honoured. We noticed that M. Pirou's photographs were, perhaps, a little "retouched," but the lighting is excellent, the pose artistic, and the expression characterized by a happy and natural ease. An award of a silver medal has also been made to Messrs. Hunter and Sands "for excellence of workmanship and ingenuity of construction of photographic cameras and apparatus." It is to be regretted that all the photographs were not placed together in the fine art section.

A Vitreous Coating or Enamel for Medals.—The following is said to form a good enamel for cast iron, wrought iron, or steel, and we are informed that it will not crack on being subjected to moderate changes of temperature. When an opaque enamel is required, let us suppose as a basis for vitrified photographs, about 8 parts of oxide of tin should be added. Take about 125 parts (by weight) of ordinary flint glass fragments, 20 parts of carbonate of soda, and 12 parts of boracic acid, and melt. Pour the fused mass out on some cold surface, as of stone or metal, and pulverise when cooled off. Make a mixture of this powder with silicate of soda of 50° B. With this coat the metal to be glazed, and heat in a muffle or other furnace until it is fused.

The Stereoscope.—Professor Himes, of Dickenson College, Carlisle, Pennsylvania, has published a handbook of the stereoscope, in which he gives much useful information. It seems strange that an instrument once so popular is now so little used. Indeed, it may be said that the making of stereoscopic slides is hardly a branch of photographic industry at the present time. The notes on the selection of a stereoscope are worth reproducing. Since the lenses, as a rule, in the instruments exposed for sale are not adjustable in a horizontal direction, and have consequently in case of each instrument a fixed deflecting power, it is well to see that their distance from each other is such that they will cause the pictures of the average sized stereograph to unite readily for the person who is mainly to employ it, or for persons whose eyes are the average distance apart, otherwise the lenses, if too near, will not cause the picture to overlap, or if too far apart will cause them to overlap too much—in either case

the work left for the eyes to do has a tendency to cause fatigue. . . . . This may be most readily ascertained by simply drawing two vertical lines, about ½ inch long 2¾ inches from each other, on a card (the back of a stereograph will answer), and placing it in the stereoscope, and observing how readily, or how nearly, the lines are superposed at first glance. If a series of such lines, different distances apart, are drawn on different cards, and placed in the instrument one after another, and looked at for an instant, the separation of the pictures for which that instrument is best adapted will soon be recognised.

FATAL FIRE AT A PHOTOGRAPHER'S.—About half-past eleven on Friday night, the 25th ult., a fire broke out at 78, High Road, Lee, a hair-dresser's, with a studio attached. The whole of the premises, consisting of the studio, shop, and seven rooms, were covered by the fire, and were in the end totally gutted. Two men were sleeping on the premises, and one of them, Richard Lensley, jumped from the second floor to the ground, but escaped uninjured. The fire gained so rapidly that it was impossible to save the other man, an Italian named Francisco, whose charred remains were found at three o'clock by Engineer Bradley. Very extensive damage was occasioned at the adjoining shops, Nos. 80 and 76, by the same fire.

PHOTOGRAPHIC CLUB.—At the next meeting, on August 6th, the adjourned discussion on the "Effect of Colour-media on Silver Prints," will take place. On Bank Holiday, an outing has been arranged to Watford, meeting at Watford Station at 10.47; train leaves Euston at 10.15; afterwards meeting at the Essex Arms.

To Correspondents.

*** We cannot undertake to return rejected communications.

J. PENNINGTON.—A very good way of packing your exposed plates is to tie them in bundles, the films being face to face with a cardboard rim between each pair; the outside of the rims should be of the exact size of the plates, and a width of three-sixteenths of an inch is enough. Of course sufficient opaque paper must be used to protect the plates from light, and the old wrappings will come in for this purpose. An external covering of tin or lead foil is useful as a protection against damp or sea-air.

J. H. P.—1. We are pleased with the group, and think, if you continue to work hard, you will produce some very fine pictures. The only fault we can find is that the figures are arranged a little too symmetrically, and without any balancing object. Try again with the same models, and send us the result. 2. We would suggest "The Story Teller" as a title, and think it would be well to register it; but until you get a series of studies, you will find it difficult to make any money by them.

EMULSION.—1. We rather doubt whether it will give No. 25; indeed, we hardly think it will, and are inclined to think that the older method referred to is better, and will give a more sensitive product. No iodide is used in the more recent method. 2. We take it that if it is nearly neutral—that is to say, either *very faintly alkaline, or very faintly acid*—the conditions are fulfilled; but we should prefer acidity of the two. About one-tenth of the whole quantity of gelatine. 3. The gentleman referred to is mistaken, if we may judge by the results of our own experiments. 4. It should be added just before the final filtration of the emulsion, and a temperature of 120° Fahrenheit, and not too hot for keeping it while the work of coating is going on.

A. A. CAMPBELL SWINTON.—The best account is to be found in Watts' Dictionary of Chemistry.

J. HOLME.—Next week.

H. HOWARD.—1. We should recommend rather more glass, as it is occasionally useful, and it is very easy to block out with suitable blinds. 2. As regards the blocking out of the side light, it does not seem to us that you would be in any worse position than very many of the first-class photographers; but if you could manage to make the whole building a couple of feet higher from the ground line, there should be no fear whatever as to the result.

LUSSAC SMITH.—We quite agree with you that tin dishes are often very convenient for use in developing dry plates, but it seems to us that ebonite is to be preferred on the whole.

G. B.—We think you can obtain it from Hopkin and Williams, of Cross Street, Hatton Garden, London; but perhaps it will be more convenient for you to prepare it yourself. For this purpose dissolve about a quarter of an ounce of nitrate of silver in four ounces of hot water, and add a warm solution of oxalate of ammonium until no further precipitation takes place. Collect on a filter, wash, and dry at a gentle heat. These operations must be performed in the dark room.

JOSEPH TAYLOR.—Soak good glue in water till quite soft, melt it in the water bath, and stir in a sufficient quantity of methylated spirit to make it tolerably fluid, adding a little more water if necessary.

J. H. B.—We cannot tell unless you describe the instrument, as we believe the optician named is still manufacturing excellent lenses. A rough sectional diagram will be best.

E. M. R.—You had better have nothing whatever to do with any of the advertised "methods" of colouring photographs, unless you wish to lose money and time. There is scarcely any market for the sale of such coloured photographs as you refer to. We will try to find some number of the PHOTOGRAPHIC NEWS containing information useful to you.

THOMAS STOWER.—1. We should prefer to use a mixture of starch paste and lamp-black, as the preparation you mention might be expected to injure the films in the course of a few weeks, especially during hot weather. 2. The formula generally prescribes it dry; but you need not dry it if you bear in mind that the crystals contain about 60 per cent of water.

Employment Wanted.

Artist & Operator.—W. F., 90, Chesterton-rd., Notting-hill.
Amateur for Instruction.—G. P., *Photo. News* Office.
Operator & Retoucher or Assistant.—E. S. T., 14, Lancaster-st., Hyde Park.
Operator in Ceramic Enamels.—W. G., 163, Park-rd., Barnsley.
Assistant Operator & Retoucher.—B., c/o F. York, Notting-hill.
Managing Printer.—Photo, *Photo News* Office.
Negative Retoucher.—T. G., 2, Hallam-st., Westbourne-ter., N.

Employment Offered.

Apprentice or Improver.—T. Vipond, Grantham.
Operator & Manager.—E. D., Lansdown Studio, Stroud.
Artists (either sex) for Black-and-White.—Morgan & Kidd, Richmond.
Printer, exceptional references.—H. Stiles, 8, Kensington High-st.
Negative Retoucher, first-class.—R. H. Lord, Market-st., Manchester.
Lady for Reception-Room, &c.—W. J. Suter, Cheltenham.
Retoucher & Oper., Also Printer, Toner.—W. L. Shrubsole, Norwich.
Printer, for Sunderland.—A. & G. Taylor, 70, Queen Victoria-st., E.C.
Retoucher & Operator.—Charles F. Treble, 371A, Brixton-rd.
Oper. & Retoucher (first-class).—T. Williams, Talbot-pl., Wolverhampton
Young Lady for Recep. Room.—T. Williams, Talbot-pl., Wolverhampton.
Outdoor Operators (4).—Berlin Photo. Co., 160, Victoria-rd., Aldershot.

CONTENTS

THE BEHAVIOUR OF GELATINE PLATES AT A HIGH TEMPERATURE.

NOT very many weeks ago we recorded Abney's experiments, in which he demonstrated that a gelatino-bromide plate is more sensitive to light when warmed, and less sensitive when cooled (pages 296 and 306), and it is interesting to notice the observations of Herr V. Schumann in the same direction. Schumann had his attention called to the matter by noticing that some plates, which had been considerably heated during the drying, were fogged by an exposure to the dark room lantern, which was insufficient to produce a sensible effect on normal plates; and, in addition to this, he found that the films of those gelatine plates which had been exposed to a high temperature in the drying box had become so brittle as to make it easier to cut them with the diamond than is the case with ordinary plates. At the time Schumann made these observations, he was not aware of Abney's prior experiments.

Herr Schumann next proceeded to expose corresponding plates—one warm and the other cold—to the solar spectrum, and to the spectrum of burning magnesium, Stolze's potash developer being used, and he found that the sensitiveness for both ends of the solar spectrum was very notably increased; while, in the case of the magnesium spectrum, the gain in sensitiveness was most notable in the blue-green and in the beginning of the ultra-violet. The delineation of the magnesium lines was much more satisfactory on the warmed plate; and the experimenter says that he has seldom taken the B group of magnesium lines as perfectly as on the warmed plate.

During the exposure the warmed plate was supported on a slightly concave metal block, which itself was kept warm by means of a spirit lamp. Under these circumstances the corners were somewhat over-heated, and a partial reduction of the haloid salt was noticeable, showing that heat has an action which is more or less analogous with that of light.

Subsequent experiments were made at known temperatures, and it was found that a plate heated for ten minutes to a temperature of 130° Centigrade fogged completely on the application of the developer; but, in another case, when the heat only reached 105° or 110° Centigrade, a plate (exposed hot) gave a clear and unfogged image of the spectrum, the gain in sensitiveness being very notable. In the case of similar plates which had been heated for five minutes to 110° Centigrade, and *cooled* before exposure, a certain gain was noticeable as regards sensitiveness, but this was far less than in the case of the plate exposed hot.

Whether there will be any practical gain in heating plates to a temperature somewhat over the boiling point of water before using them is a matter which practical experience can alone determine; but that the gelatine film will be less subject to deterioration from accidental chemical action if thoroughly dried, no one can doubt, and the above-described experiments indicate that it is rather desirable than otherwise to increase the temperature in the drying-box before removing the plates. Interesting results may be expected to follow the further elucidation of the subject.

PHOTOGRAPHY AT THE CITY AND GUILDS' EXAMINATION.

TAKING the results of the whole work of the City and Guilds of London Institute for the Advancement of Technical Education, one must confess that they have fallen short of expectation when viewed in comparison with the system at many Polytechnical Schools in Germany; but it is hardly reasonable to expect a new organization to work as smoothly as a system which has grown up with a people, and has, by a process akin to that of natural selection, become adapted to the spirit and wants of the community. It is, however, very satisfactory to know that the photographic department stands out prominently as one of the most successful branches of the work of the Institute.

Captain Abney's report on the examination of last May is now in our hands, and the following extract indicates that he is satisfied with the progress made since last year. He says:—

"In forwarding the results of the last examination in photography to you, I wish to draw attention to the still improving character of the answers which is to be found in the papers of those candidates who have been systematically taught. Nearly every Honours paper sent in is highly creditable, and some are excellent, as showing an extent of reading and practical work which, in the early days of these examinations, was conspicuous (except in some few instances) by its absence."

We find that 61 candidates entered for the examination,* and of these 37 passed. Of the passes, ten were in the Honours grade, and twenty-seven in the Ordinary grade; while of the failures, 39 per cent. were pupils taught by certified teachers, and 40 per cent. were pupils taught independently, or who qualified themselves by private study.

The following is a list of the successful candidates as given officially, and arranged alphabetically, although we only find thirty-four out of the thirty-seven.

Abbott, George Pearce, ordinary grade (second class).
Ashman, William Middleton, honours grade (first class).
Ayling, Joseph James, ordinary grade (second class).
Ballard, Edmund George, ordinary grade (second class).
Beeson, Francis Thomas, ordinary grade (second class), and second prize of £3, and bronze medal.

* For the questions see page 348.

Bowen, Alfred Walter, honours grade (second class).
Cartwright, John, honours grade (second class).
Chambers, Henry, ordinary grade (second class).
Coles, William, honours grade (first class), and first prize of £5 and silver medal.
Colls, Walter L., ordinary grade (second class).
Cotou, Charles, ordinary grade (second class).
Davies, George F., honours grade (first class), also second prize of £5 and bronze medal.
Dixon, Thomas James, ordinary grade (second class).
Dugon, Frank, ordinary grade (second class).
Gamble, Charles William, ordiuary grade (first class).
Gover, Herbert James, honours grade (second class).
Gray, William Edward, ordinary grade (first class), and first prize of £3 and silver medal.
Hare, Elizabeth Luey, ordinary grade (first class), and second prize of £2 and bronze medal.
Hare, Emily, ordinary grade (second class).
Hayward, Wyatt, ordinary grade (first class).
Ingle, Herbert, honours grade (first class).
Lowndes, Alfred Barry, ordinary grade (second class).
Lynes, George, honours grade (first class).
Nicholas, William, ordinary grade (second class).
Parsons, Harry S., ordinary grade (first class).
Porter, William, ordinary grade (first class), and fifth prize of bronze medal.
Rainey, Herbert Titus, ordinary grade (second class).
Smith, James Johnson, ordinary grade (second class).
Spencer, Ernest, ordinary grade (first class).
Spurge, James Blewitt, honours grade (second class).
Velasco, Frederick A., ordinary grade (first class); also fourth prize of £1 and bronze medal.
Watson, George, ordinary grade (second class).
White, Harry E., ordinary grade (second class).
Winks, Benjamin Foulkes, honours grade (first class).

The distribution of prizes will not take place till December next.

By-the-Bye.

PROGRESS IN LANTERN MATTERS.

One may learn something by looking back upon the gradual improvements of the lanteru as a scientific instrument, and tracing some of the steps in its progress. If we are to believe all that is said iu a recent number of a Philadelphia paper termed *The Exhibitor*, we owe every one of these steps to Philadelphia. She "discovered and perfected" the oxy-hydrogen light, and "her inventions" are copied by the European opticians, who are able to do but little else! We certainly do owe to America the Sciopticon pattern of body, which has its uses and advantages; but this is uot what our best lanteruists use.

Putting aside all this "brag," the historical development of the lanteru is really interestiug, aud we were looking with attentiou the other day at the first genuine exhibitor's lautern we ever possessed. This, the possession of which we acquired about the age of fourteen, was one of the pair (for dissolving views) which had actually been used by a professional lecturer who discoursed upon Australia. With the aid of these, aud an entertainment magniloquently termed a "panorama," he had amassed a competence, the greater part of which, we regret to say, he afterwards lost through speculating in a real panorama, which, later on, he too ambitiously substituted for the lantern show. The lanterns he used were by Carpeuter aud Westley, the best house then in the lantern trade. These opticians had almost a monopoly of the best goods for years, aud it seems a wonder that they ever allowed other houses to so completely take the lead in popularising the lantern. The condensers were a shade over three inches, both lenses bi-convex, the objective being a pair of single meniscus leuses; the lamp a "solarized" Argand, burning either sperm oil or Russian tallow.

Yet these lauterns did really good work, and were used successfully in large rooms ou a ten-feet disc. We saw it done, repeatedly. The curves of the objective were calculated with care, and they were large—at least 2¼-inches diameter. This is necessary to use all the light from any spreading source, such as a flame; a small objective will transmit most of the light from a lime, but it is easily shown by diagram that from a larger light the rays must spread more, and that a larger lens is needed to use the light to advantage. Aud the slides being hand-painted, were all very transparent, which makes a wonderful difference.

As to the matter of slides, better ones have never been produced than the best class produced then by Polytechnic artists; but of the cheaper class of painted slides it is difficult now to say much that is appreciative. Carpenter and Westley supplied what were considered superior goods of this cheap class, and called by them "copper-plate sliders"—it was sliders, and not slides in those days—and we were looking at one of these only the other day, and it seemed impossible to believe that anyone could ever have had the boldness to show them to an audience who had paid for admission. But the best hand-painted slides were exquisite; and remembering what was done then with such a poor light, it seems a pity that more attentiou is not paid uow to tone and transparency in photographs. There are many slides sent out by first-class houses, even uow, through which it is almost impossible to drive sufficient light; and out of those shown at any lantern meeting not twenty-five per cent. are as yet what they should be.

Of course we all know that the lime-light was the great improvement, it having been first used for some rough microscope work; and the oxygen was at that time made by literally driving off the gas from manganese oxide by a red heat in an iron bottle in the manner described in very old chemical treatises. The process needed a regular coal furnace, and was a long and hot piece of work. At first, also, the light was kept on in two lanterns, and dissolved by fans as before; this required a great deal of gas. Not till years after did the dissolving tap appear to remedy this waste. The two lanterns used together gave us the modern biunial, which owes its present form more to the skill and invention of Mr. Dancer, of Manchester, than anyone else; and when the making of oxygen was simplified by the cheapening of potassic chlorate, the modern state of things may be said to have been fairly inaugurated.

The more powerful light necessitated optical improvement, especially as photographs came to be used. To show the detail of a photograph sharply, achromatic objectives became necessary; while as these were perfected, it was found that the old condenser of two bi-convex lenses was not good enough, the strong spherical aberration blurring the image. Thus were generally introduced the two general forms of condenser know as the Herschel and the double-plano forms, in both of which the spherical aberration is far less. Even yet, however, the optics of the double-plano condenser are far from being generally understood, and this form is capable of being greatly improved by the simplest means. The two lenses are usually made of the same diameter and of the same curves; and hence it has been repeated over and over again, that in using large condensers, which have advantages for square photographs, there is a loss of light for ordinary-sized slides. But this need not be the case. A lens next the lime of 3¼ inches diameter, of short focus, takes up rays which require a second lens of 4¼ inches diameter to collect them. If, therefore, the second lens is the same size, all the extra marginal rays are utterly lost. They may just as well be utilised to illuminate a disc 4¼ inches diameter; and yet a 3¼ disc will receive just as much light as if the second lens were that size. Moreover, by this construction the small lens may be made much deeper in curve without increasing its thickness, and by this the spherical aberration is brought to a minimum. The greater quantity of light may easily be all passed through even the small slide, by placing

the slide-stage further forward in the cone of rays, and in this way nearly 90° of the rays from the lime may be gathered up instead of a little over 60°. It requires the triple condenser to take full advantage of these principles; but so much may be done even with a pair of lenses, that it is surprising opticians jog along so uniformly in the old grooves. In all the usual condensers, the second lens loses much light which enters the first, and requires to be nearly an inch greater in diameter to save it. If more disc is not wanted, the slide may either be brought forward in the cone, or the lens next the lime made smaller and thinner, enabling it to be brought closer to the lime with safety.

This matter is mentioned here because much of the work of the lantern in future is likely to consist in the exhibition of scientific detail; either minute detail in large diagrams and sections, or micro-photographs, which are now advancing with giant strides, and reaching a perfection and sharpness undreamt of some years ago. Now in such photographs we never get to the bottom of the detail. We go as far as the light, or scale, or our optical means permit; but there is always more behind. Even when the photograph is thrown upon the screen the human eye itself cannot distinguish all which the lantern lens really puts there; more can always be seen on going close up to the screen than can possibly be seen at average distances. Now more light means, always, that more of this detail can be seen by the audience. From this point of view the taking-up of the greater angle of rays by the condensers is beginning to assume an importance it has never had before, and it is so very easy to get in this way fifty per cent. more light than is usual, that the matter really ought to receive attention.

The necessity for clear, transparent photographs applies still more to slides of this sort than to ordinary views, though even in them it is high time the old opaque style was a thing of the past. Many slides are sent out to the opticians which really, from houses "in the trade," are a disgrace to modern progress, even as regards figure and landscape subjects. Much allowance may be made for amateurs, or even professional photographers who are only learning what lantern requirements are, but professed lantern houses should be far more particular than they are. Some appear to be supplying even worse slides now than when they were seeking a connection. No names are mentioned, as no special reference to any house is meant to be made; but all who work for the opticians ought to keep at home what are not good as lantern photographs. Upon more care in this respect for the future will very much depend the rapid development of the really scientific branch of lantern demonstration. The matter may be said now to rest almost entirely with the photographers; but there is becoming felt the want of some recognized medium through which any who have produced slides of real value may be able to place them where they are wanted. The supply of slides available for special purposes has been far too much a monopoly of one or two houses, with the result of the occasional carelessness above hinted at.

Another way in which the modern lantern may be made exceedingly useful scientifically, is in the projection on a screen of actual apparatus, whether in motion or not. At the Royal Institution, at South Kensington, and elsewhere, the electric camera is constantly used in this way. Just as an example of what is meant, at one of the recent meetings of the Physical Society, in the course of some experiments relating to the velocity of sound in tubes, it was desired to show that for the column of air contained in a tube to vibrate in unison with a given note, it must be shorter when closed by a membrane, than when closed by a rigid plate. The tube was fixed horizontally in front of the electric camera, and brought into unison with a fork (so as to give the greatest resonance) by sliding in a metal cap. A membrane was then substituted for the metal plate, in the same place, against the centre of which membrane a small pea was gently strung by a thread. The apparatus was then focussed on the screen, and when the fork was struck, no movement was perceptible; but as the membrane was pushed in, resonance was attained, and the pea was seen to start into energetic vibration.

Such experiments are constantly projected by the camera lantern; but it seems to be thought that they cannot be so well shown with an ordinary lantern. The exact contrary is the case, for it is very rarely the camera form of lantern gives such a steady light as our old friend the bi-unial. One reason is, that philosophical instrument makers stick to the four-pillar metal camera form, even with the lime-light. With the arc it is a necessity, but for the lime-light, with the usual form of jet, it is the worst construction possible; while the lanternist's jet, fixed on the pin of a sliding tray, is the "survival of the fittest" through the experience of hundreds, and gives readily a beautiful disc, almost before the laboratory assistant has begun to adjust his jet. It is wonderful, and a little amusing, to see how the instrument makers repeat their favourite, expensive, cumbersome, and antiquated construction when so much better is at hand; but that is their affair.

All that is necessary for such projections is to adjust the instrument or apparatus in the parallel or slightly conical beam from the condensers, after removing the objective. The objective must be temporarily mounted on a cradle or stand of some kind at the proper height; and all that is further needed is to surround the objective tube with a flange of black card, to stop stray light from reaching the screen. Then the lens is adjusted on the table by hand to focus the apparatus. The longer focus lenses must be used to get good results: or, if there be no long-focus lens, a simple (or unachromatic) lens of eight to ten inches focus, and three inches diameter (which can be got for a few shillings), and mounted on a pillar, will do everything perfectly well. Almost anything in reason that fairly comes within the circle of the condensers can thus be projected on the screen quite as well as in any lecture theatre, and better than in many. Of special slides, tanks, or apparatus for use in the ordinary slide-stage, there is no need to speak, as they are described in all catalogues.

Practical Papers for Beginners.

No. 4.—Exposing and Developing.

Having made a first attempt at exposure and development, in testing the lens by means of the focimeter, we will suppose that in the second place the beginner rather directs his energies to view work than to portraiture; but for the first time or so he had better not attempt anything far from home, as his next few plates will be as strictly trial plates as that exposed on the focimeter.

For a first trial a view looking over a fair expanse of scenery—whether country or town—should be selected, and the sun should be shining, but the camera should be placed so that the sun is behind it, or towards one side; indeed, it is only under very exceptional circumstances that it is desirable to photograph with the sun shining directly in front of the camera, so that the rays strike towards the open lens when the picture is taken.

Before going any farther, let us say a few words about the cleaning of the glasses of the objective. If they are clouded or dirty, they must be cleaned before the camera is used. A piece of soft wash-leather is the best material for wiping the glasses, and, when once clean, care should be taken to keep them so, as frequent rubbing is likely to take off the polish, and thus seriously interfere with the working qualities of the lens. The lens being clean, the camera is directed towards the view selected, and set as level as practicable; after which it must be set to focus. Before focussing exactly, the stops or diaphragms should be removed, and the image on the ground glass should be

examined, to see if it can be improved by bringing the camera forward or moving it farther back, so as to make it include more or less of the subject. In focussing, it must be remembered that the perfection of sharpness cannot be obtained all over the picture, and it is sometimes a little embarrassing to know what part to focus exactly. When the view is a general one, and all parts are about equally important as regards details and definition, it is a very excellent plan to select some object in the middle distance, the image of which is formed at a point about mid-way between the edge of the focussing screen and its middle. When, on the other hand, there is a leading or principal object in the view, it is often better to secure the greatest possible sharpness of this principal object. Having focussed sharply, the next thing is to insert the diaphragm or stop selected, as it is not very often that landscape pictures are taken with the full opening of the lens, and a stop, having a diameter about equal to one-fortieth of the focal length of the lens, may be used; but if a smaller one is provided with the apparatus, it will answer very well. For the present purpose the focal length may be taken as the distance from the centre of the lens to the sensitive plate. The lens is now covered with the cap, and the double dark back, containing plates Nos. 1 and 2, is placed in position for exposing No. 1 plate; but the main thing is now to get a lesson in exposure, and not to take a remote chance of hitting a correct exposure for the whole plate.

The beginner should first take a good look round, and try to fix in his mind the conditions of the illumination of the scene, making some kind of effort at remembering the intensity of the light. The sliding shutter of the dark back is now withdrawn, so as to cover about two-thirds of the plate, and the lens is uncovered during a period of fifteen seconds, as nearly as can be judged by counting seconds from memory. The shutter is now withdrawn, so as to uncover two-thirds of the plate, and an exposure of ten seconds is given by uncapping the lens. The next step is to draw the covering slide to the full extent, and to give an exposure of five seconds, making a total of thirty seconds for the first third, fifteen for the second third, and five for the remainder. Plate No. 2 is now exposed in the same kind of way. Give an exposure of two seconds to the first third, one second when the shutter is drawn so as to uncover two-thirds of the plate, and an exposure with cap off and on as quickly as possible when the shutter is entirely drawn. During the whole work care should be taken not to shake or move the camera.

We thus have on the two plates a series of widely differing exposures, which may be estimated as follows:—

30 seconds
15 ,,
5 ,,
2 ,,
1 second
Short exposure—perhaps a fourth of a second.

Unless the light was quite exceptionally bright, the least exposed section will be much underdone, and then it is likely that the section which has had thirty seconds will be over-exposed. At any rate, the beginner will obtain the required lesson on exposure by developing these two plates in the same dish with the standard developer, or equal proportions of No. 1 and No. 2, as mentioned on page 486. After having allowed the developer to act for about six or eight minutes, the plates should be washed and fixed as recommended in the last paper. The photograph obtained on the sensitive plate is a negative, and we will suppose that one section shows the image boldly, clearly, and with proper vigour and gradation when the plate is held up to the light, and the exposure of this section may be taken as the correct one. Let a couple of plates be now exposed under similar conditions, and be developed with the same developer; and these plates we will hope will turn out passable negatives. One point must, however, be remembered: if the negatives look good enough to be kept for printing, the plates should be allowed to remain in the hyposulphite bath twice as long as is necessary to make the yellowish-white bromide of silver disappear, and after fixing they ought to be soaked in six or seven changes of water, allowing about ten minutes in each. The beginner must repeat the above process of graduated exposure until he gains that experience which is the only safe guide in photography, and during his earlier experiences it is well to use the same stop throughout, and to endeavour to obtain good negatives by adapting the exposure to the normal developer, or equal parts of No. 1 Solution and No. 2 Solution, made up as described in our last paper.

It is, however, probable that the enthusiastic amateur photographer will not long be able to restrain his ardour, but he will boldly take the camera away from home, and will find that his plates are over or under-exposed. By a study of his trial plates, and attention to the remarks made last week, he will be enabled to immediately recognise a much over-exposed or under-exposed negative, to say nothing of the circumstance that development will be extremely slow in the latter case; and although we propose to say something more about exposure and development next week, we will now indicate how the developer may be modified to more or less perfectly compensate for under-exposure or over-exposure. If the image appears very slowly, prepare a fresh developer with three, four, or even five parts of No. 1 to one of No. 2, and, after having poured off the first developer, allow this to act on the plate. Should one of a batch of similarly exposed plates turn out to be much under-exposed, the remainder may be treated in the first instance with a developer containing several parts of No. 1 to one of No. 2. When a plate is a little over-exposed the reverse holds good, No. 2 solution being used in considerable excess; but in the case of considerable over-exposure other treatment is required.

It is to be hoped that the beginner who has followed our instructions thus far, begins to feel a forshadowing of something like certainty in his work, and next week we will suppose the camera to be taken a little way from home, and we shall treat in greater detail of development and exposure.

VOGEL'S METHOD OF COLOUR PHOTOGRAPHY.

BY CAPTAIN W. DE W. ABNEY, R.E., F.R.S.

Dr. Vogel's letter in your last issue has made it incumbent on me to offer a few remarks on his method of colour photography. I may preface them by saying that I am somewhat surprised that the method he indicates is called new in any sense of the word, as I always imagined that the principles of the process dated from 1874, when Dr. Vogel told the world the practical action of dyes, though his theoretical explanation thereof was to my mind not so satisfactory as the experiments themselves. So much did I personally imagine that this method of rendering colours in the true value of their illumination was an accomplished fact, that in the course of lectures in March last I illustrated Vogel's discovery by the staining of films with both eosine and cyanine, and showed that, more especially with the latter, the brightest yellows were rendered with greater intensity than were the blues in a negative taken from the most admirable colour chart which forms a plate in Professor Piazzi Smyth's "Madeira Spectroscope." I did not describe it as a novelty, though the lecture was delivered in March of this year, almost at the same time that Dr. Vogel made his communication to the Berlin Society for the Advancement of Photography. I need scarcely say that the lecture was prepared some weeks before it was delivered.

Now as to a practical manner of rendering colour in even better illumination gradation (if I may coin a word) than cyanine gives. I have tried a mixture of cyanine and eosine together, and that gives a better result than either

separately. An emulsion, whether it be collodion or gelatine, can be rendered sensitive to red, yellow, and green, by mixing with it a mere trace of cyanine, and a rather stronger proportion of eosine. The absorption spectrum of the mixture is not exactly that compounded of the absorption spectra the two give separately, but rather more complicated; but at any rate it acts in the manner indicated above. The plates should show a faint rose colour. The cyanine should be dissolved in a small quantity of alcohol, and the eosine will dissolve in water, and then the two may be mixed and added to the emulsion. Plates prepared with emulsion so stained do give an increased value to yellows and reds; but with gelatine, in order to tone down the blue, it is preferable to illuminate the object with light passing through a canary yellow glass. Dr. Vogel also recommends taking the negative through yellow glass, a method which I have used with ordinary gelatine plates for colour photography, and which I mentioned when Mr. Sawyer read his paper last season on a kindred subject to that now under discussion.

To use eosine effectually, an emulsion of eosine can be made in an aqueous solution of it by adding silver nitrate to it. This should be rapidly washed, and added in very minute quantities to a gelatine emulsion, where it will be found to help the greens of the picture favourably. This plan I adopted when experimenting on the action of dyes some two years ago for the benefit of Professor Rowland And if eosine is to be used *per se*, I recommend this plan of getting the full benefit of its action rather than merely staining the film with it. I am speaking now of a gelatine plate in which silver nitrate is in defect.

I should be much interested in trying Dr. Vogel's new dye which he has found answers so much better than eosine. Perhaps he would present me with a minute quantity to test.

In conclusion, I would add that to any one possessing an electric light, the method of illuminating with feeble yellow light is very easy. A condenser placed in front of the light should be made to form an illuminated disc, in which is the picture to be photographed. By placing a piece of canary or even rather yellower glass between the lens and the condenser, the desired illumination is at once obtained. Sunlight may also be reflected on to a picture in a somewhat similar manner, and this is also effective

AN AMATEUR'S EXPERIENCE.

BY ONE OF THE LATEST VICTIMS TO PHOTOGRAPHY.

I ALWAYS had a hankering after art. I once took some lessons in drawing at South Kensington, London, and these were so successful that I drew a prize at a lottery shortly after.

At last, the drawing master said to me, "You have evidently a wonderful talent for landscape." I admitted that I had. "But," he continued, "you are labouring with the wrong implement. A camera, not a pencil, is what you need."

I was a little nettled at this; it seemed like telling a pianist that a hand organ was what he wanted. I said sarcastically:

"I suppose you would recommend one of those photographic cars to go round the country, with a team hired from the local livery stable to haul it from village to village?"

"Well, not at first," he answered gravely. "Of course, you may rise to that in time. But don't be too ambitious. Get a 4 by 5 camera, or one even smaller, and try landscapes to begin with."

I gathered up my drawing materials, and South Kensington lost one of its most promising art students.

Shortly after I became acquainted with an amateur photographer who had an instrument made in New York. I was astonished to see an American camera in England, but the photographer said that unless a person went to a very high price, American instruments were the best, and that it paid to import them. Score one for American mechanism. A Dallmeyer lens, and I think a Ross—although of that name I am not sure—he said, were better than anything America had yet produced, but the cost was something appalling, and not to be thought of by an amateur with whom money is an object. We did some fine tramping over the hills of Kent and Sussex, and little that was picturesque escaped us. Old churches were the favourite. They remained very still, and the grave-yards around them never required to be told not to move.

On coming to America I got myself an amateur outfit, and began a still hunt for victims. My camera will take a picture 5 by 8 inches. This is a little too big, or would be if there was not an arrangement by which a 4 by 5 plate can be used. The large plates cost $1.75 a dozen, and the smaller ones only 90 cents, so the initiated will speedily find that for experimentiug the smaller plates are preferable, especially if he develops a genius for spoiling plates.

The best plan is to get a real photographer to give you the points about trimming and developing. The real photographer will despise you as an amateur, but you'll survive that, and you can pick up information quicker from him than from a book, especially at first. It is a little trying to go through the street with a tripod under your arm and a camera in your hand if many people know you, but as I have undertaken to show you the way out of some of the difficulties attending amateur photography, I will give you a hint on this.

One morning, as I went up Woodward Avenue with my outfit, I met more people than ever I met before in a similar space of time and distance.

"Hello!" said the first, "what's this you've got?"

"Photographic arrangement."

"You don't say so? Where are you going to start? I should think that with so many photographers in town, and cabinets at $2 a dozen, there was not much money in the business."

"Oh, I'm only an amateur. Good-day."

Next block, another friend stopped me. "What have you got there? Surveying instrument?"

"No."

"'Tisn't one of those bird-case fortune telling affairs is it?"

"No, it isn't."

"Haven't taken to peddling, have you?"

"No, I haven't."

"Well, what in thunder is it?"

"In this box, my inquiring friend, is a camera with a Morrison lens. I don't know who Mr. Morrison is, but 'distance lens enchantment to his view.' The patent arrangement by which the plate is turned is by some one else whose name I forget. The tripod is covered with varnish and four patents, and if there is any more information you want, I'll call around at your office."

"Never mind," he said, "I've had all I can stand at present."

As he left, I thought over what he said about peddling. The next man who said "hello" to me I shook cordially by the hand and said: "I'm an agent for the new work to be completed in twenty-four parts, at fifty cents a part. Just let me show—"

"Excuse me," he cried, hurrying off, "I want to catch that 9.15 train."

This hint will protect the amateur as he walks abroad with his instrument of destruction.

There is no use in my giving instructions about photography. The best man to give you the preliminary hints is your friend the photographer. Everybody knows at least one photographer. Even with the best instructions you will make awful work at first. Your plates will be overdone and underdone, just like the plates you order at a poor restaurant. But let nothing dismay you. The simplest matter is to get a good lens and use a drop-shutter. Then you have no trouble. There is a young man, a clerk on the steamer running out of Detroit, who uses a Morrison lens and a Scovill camera, and who made a drop-shutter that enables him to to take schooners on the wing and steamers as they hurry past. It is hard to find a nicer subject than a schooner with white bulging sails, and the white feathery spray dashing up at her bows. As I was saying, this ingenious young man made his own instantaneous arrangement, and it works as well as one costing $10.

I undertook to photograph a steamer from a small boat on the Detroit River the other day. The boat wabbled round a good deal, but I succeeded in getting a couple of shots at the steamer. On developing the plates, I regret to say that, owing to the motion of the small boat, my pictures were incomplete.

The first was a beautiful view of the clouds with the top of one smoke-stack and the one mast, and the other was an equally beautiful view of the water, with the black rim on top, which, I presume, represents the lower part of the steamer's hull. I always bring my pictures to a photographer to be developed and printed. The man said to me, "What I like about your pictures

is their unconventionality. You get out of the old routine. There is a spice of originality in all you do with a camera, and I wouldn't be surprised if you stumbled on to some valuable discovery before long."

I think that was pretty high praise for a fellow who had only recently begun photographing.

Of course, the first thing an amateur photographs is his house and the surroundiog. I took half a dozeu of my house, with the family scattered round the grounds, and I laid the holders, with the plates inside, away carefully in a dark drawer till I was going down to the photographer. Next day I brought the six to him, and we went together into a close little room, with the dim ruby light as the only illumination. He took out a plate and placed it in a shallow tray. Of course, until developed there is no picture visible. The developer was poured over the plate and the tray gently moved in an oscillating way, so as to keep the liquid moving and not allow any air-bubbles to staud on the glass.

"It don't seem to come out very well?" I veutured.

"No," said the phrtographer; "it's fogged."

"Fogged? I don't see how that can be. There was no a sign of mist in the air."

"Well, you've 'mist' it this time, anyhow. Light got on the plate. How did you put the plates in the holder?"

"I did it in a dark-room, by the light of my ruby lantern."

"No white light got at it?"

"Impossible."

"Did you leave the holders in the sun? Sometimes they are not as tight as they should be."

"No, I kept them wrapped in a black cloth."

"Well, that plate's spoiled. Let's try another."

We tried another, and another, but they were all bad, all "fogged."

"Perhaps the plates were spoiled in the package?"

"I have used thousands and never got a spoiled plate yet," said the photographer; "you've let light in on them somehow."

When I got home, I said to my wife, "All those plates were spoiled, so all the grouping you and the childreu did will have to be tried over agaiu. I can't imagine what spoiled the plates."

"I was going to tell you they were spoiled, and so save you the trouble of taking them down, but I forgot all about it. I don't think you uuderstaud it rightly."

"How did you know they were spoiled?"

"Oh, Mrs. Butterwick was here, and she wanted so much to see how the baby took, and I opened the cases and there wasn't the sigu of a picture on one of the plates."

If this should chance to meet the eye of the wife of any amateur photographer, I hope she will resolve to leave his photographic studies alone, at least until they are developed, unless she wants to develop in him an unexpected proficiency in profanity.—Luke Sharpe in the *Detroit Free Press*.

A Dictionary of Photography.

ANTIMONY.—Printing Process. The metal antimony is the main factor in a somewhat remarkable printing method, due to Mr. F. Jones. The process depends on the circumstance that antimonuretted hydrogen or stibine, NH_3, is decomposed by sulphur in the presence of light, orange sulphide of antimony being formed. Paper is impregnated with sulphur, and placed behind a negative, a stream of antimonuretted hydrogen being passed into the printing frame while it is exposed to the light.

For the preparation of the sulphur-paper Mr. Francis Jones saturates ordinary writing paper with a solution of sulphur in carbon disulphide, and allows the solvent to evaporate in the air. By this means minute crystals of sulphur are left deposited in the pores of the paper; and any excess remaining on its surface can be rubbed off with a tuft of cotton wool, so as to secure uniform impregnation. No fixing process is required, for as soon as the printing has advanced sufficiently far, it is only necessary to stop the evolution of the gas, or disconnect the generator, whereby all further action is prevented, and the image remains as a permanent metallic sulphide imbedded in free sulphur. The tint thus resulting is identical with that of the pigment used in the production of red rubber goods, and is believed to be equally permanent. Spiller finds that an after treatment with silver or copper salts in solution transforms the orange sulphide of antimony into the darker coloured sulphides of those metals; so that the process, thus modified, lends itself to the production of photographs of a more agreeable tint.

The prints may be toned by immersion in a cold solution of ammonio-nitrate of silver, which quickly blackens the sulphide of antimony. In a similar way, ammonio-sulphate of copper may be used as a toniug ageut, an agreeable chocolate or brown tiut resulting.

The antimonuretted hydrogeu is prepared by dissolving a granulated alloy of zinc with one-twentieth of its weight of antimony in dilute sulphuric acid, the usual hydrogen apparatus being made use of; but the greatest care is required to avoid inhaling any of the antimonuretted hydrogen, as it is extremely poisonous.

APERTURE.—By aperture of a lens is generally understood the smallest clear way for the light, whether this be the diameter of the glasses or that of the diaphragm.

APLANATIC.—*See* Lenses.

AQUA REGIA.—A name applied to a mixture of nitric acid or hydrochloric acid, say one volume of the former in three or four of the latter. Such a mixture dissolves gold, the terchloride heing formed.

AQUEOUS.—Watery: prepared with water, as aqueous solution, the liquid obtained by dissolving a substance in water.

AREOMETER, synonymous with hydrometer. *See* Specific Gravity.

ARGENTOMETER.—A hydromcter specially graduated, to indicate the strength of a nitrate of silver solution. For testing the bath, whether for printing or for collodion work, the following method is satisfactory:—Prepare a solution of 32 grains of pure chloride of ammonium in 12 ounces of water; 1 drachm of this solution will, therefore, precipitate 1 grain of nitrate of silver. Measure out very carefully a known quantity of the bath to be tested (2 drachms, for instance), place it in a 2-ounce phial, and add a few drops of nitric acid. Now measure out exactly 1 drachm of the solution of chloride of ammonium, and add it, by a few drops at a time, to the silver solution in the bottle, corking it up and shaking violently between each addition, until a white precipitate is no longer produced on the addition of another drop of the test solution. If, before this is accomplished, the first drachm of test solution be exhausted, carefully measure out a second drachm, and so on until the desired point is attained. When finished, the nnmber of drachms of test solution nsed will indicate the nuumber of grains present *in the phial*. Thus, supposiug 2 drachms of the nitrate bath had been placed in the phial, and it required 7½ drachms of test solution to precipitate the silver, that would have shown that the 2 drachms of bath contained 7½ grains of nitrate of silver, or 30 grains to the ounce.

ARROWROOT.—This name is generally applied to a form of starch obtained from the tubers of the *Maranta arundinacea* and other plants. It is occasionally used in preference to other forms of starch as a sizing material.

ARSENIC.—An elementary substance which is sometimes classed among the metals, and at other times among the non-metals. The compounds are very poisonous, and have not many photographic applications. Prints can be obtained by the action of arsenuretted hydrogen on paper containing free sulphur, just as in the case of antimonuretted hydrogen. *See* Antimony Printing Process. Bromide of arsenic has been used in collodion.

ARTIFICIAL LIGHT.—*See* Light.

ARTIFICIAL PARCHMENT.—*See* Paper.

ARTOTYPE.—A name applied to a mode of working the collotype process. *See* Collotype.

ASPHALT OR BITUMEN.—A substance also known under the name of Jews' pitch, mineral pitch, or compact bitumen. It is found in abundance in several localities, especially near the Dead Sea, and the famous *pitch lake* in Trinidad. It resembles in appearance common pitch, sinks in water, melts easily, and is very inflammable, burning with a red smoky flame. Asphaltum is a body of great interest to the photographer, as it was one of the substances used by M. Niépce in the early days of the art for the purpose of preparing a coating sensitive to light. The process was called by the inventor Heliography, and is thus described in his own words:—I about half fill a wine glass with this pulverised bitumen. I pour upon it, drop by drop, the essential oil of lavender till the hitumen can absorb no more. I afterwards add as much more of the essential oil as will cause the whole to stand about three lines above the mixture, which is then covered, and submitted to a gentle heat until the essential oil is fully impregnated with the colouring matter of the bitumen. If this varnish is not of the required consistency, it is to be allowed to

evaporate slowly, without heat, in a shallow dish, taking care to protect it from moisture, by which it is injured, and, at last, decomposed. A tablet of silver is to be highly polished, on which a thin coating of the varnish is to be applied cold, with a light roll of very soft skin; this will impart to it a pure vermilion colour, and cover it with a very thin and equal coating. The plate is then placed upon heated iron, which is wrapped round with several folds of paper from which, by this method, all moisture has been previously expelled. When the varnish has ceased to simmer, the plate is withdrawn from the heat, and allowed to cool and dry in a gentle temperature, and protected from a damp atmosphere. The plate thus prepared may be immediately submitted to the action of light in the camera. But after exposure nothing is apparent to show that impressions exist. The forms of the future picture remain still invisible. The next operation, then, is to disengage the shrouded imagery, and this is accomplished by plunging the tablet into a solvent consisting of one part, by volume, of essential oil of lavender, and ten of oil of white petroleum, until the operator, observing it by reflected light, begins to perceive the images of the objects to which it has been exposed gradually unfolding their forms, and, though still veiled by the supernatant fluid, continually becoming darker from saturation with varnish. The plate is then to be lifted out, held in a vertical position till as much solvent as possible has been allowed to drop away, and then carefully washed under a stream of water. This process was very uncertain and tedious, as exposures of six or eight hours in the camera were required.

The asphalt process of Niépce is an excellent method for obtaining an image of a line subject on stone or zinc, for surface printing or typographic etching, and the following directions for working on zinc are equally available for stone:—

The asphalt selected for preparing the sensitive solution should be light brown in colour, and have a decided odour, and, at the same time, should not be so exceedingly dry and resinous as to be easily crushed into an extremely fine powder. A quantity of the sample selected should be powdered as finely as possible, and put into a bottle so as to about one-third fill it; after which the bottle is nearly filled with ether. The bottle should now be corked, and agitated at intervals during about five hours, when the powder is allowed to settle, and the clear etherial liquid is poured off. This washing with ether is repeated several times—in fact, as long as the ether dissolves anything out of the bitumen—after which the remaining asphalt powder is collected on a filter, and allowed to dry in a warm and dark place. The dry powder thus obtained is dissolved in benzole, so as to form a solution having about the consistency of ordinary black varnish or Brunswick black, and the solution is stored up in a dark place for use.

The zinc plate having been carefully cleaned and prepared, a portion of the bitumen solution is diluted with about its own bulk of anhydrous benzole, the solution being filtered if necessary; after which the plate is coated, just as a glass plate is coated with collodion, and placed in a warm and dark place to dry. Before exposure under the reversed negative it is well to dust the surface of the bitumenized plate over with French chalk, in order to prevent its adhesion to the negative; but, of course all excess of French chalk should be wiped off before the plate is placed in the printing-frame. In ordinary cases, an exposure of one or two hours is required in good diffused daylight. It is scarcely necessary to say that great care must be taken to ensure the complete contact of the negative with the coated zinc plate.

The exposure being ended, and the plate taken into the dark room, its surface is carefully mopped over with a tuft of cotton-wool moistened with oil of turpentine; after which, extremely gentle friction may be applied with the same tuft of wool, the greatest care being necessary to treat all parts of the film with equal force. Under these circumstances, the unexposed portions of the film gradually dissolve away, and the device appears in sharp brown lines on the plate. The development being complete in all parts, a similar tuft of wool charged with olilve oil is applied in like manner, this operation serving not only to arrest the solvent action of the turpentine, but also to remove the bitumen already dissolved by the essential oil. The excess of oil having been wiped off, the plate is gently scrubbed with a tuft of cotton charged with a lather of soap and water, this operation being alternated with washings under a water rose. When all traces of oil have been removed, the bulk of the water is removed by means of blotting-paper, and the plate is fanned till perfectly dry, and placed in a good light for an hour or so, in order to thoroughly fix the bitumen film.

The stone or zinc is now gummed, and treated in the usual way for printing.—*See* Lithography and Zincography.

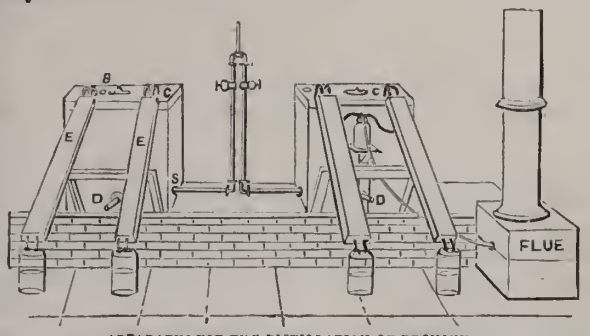
THE MANUFACTURE OF BROMINE AT POMEROY, OHIO.

BY CHARLES C. SEEBOHM, PH.G.*

Bromine is produced from the bittern of our salt-works, and was formerly a waste product. At the present time, however, it is utilised, and produced on an extensive scale.

Before proceeding with the details of its manufacture, I will give an idea of the bromine shop. This is a small wooden structure, usually situated between two or more salt works, with which it is connected by means of hollow log pipes, in order to easily obtain the supply of bittern. Inside the shop two wooden reservoirs are placed for storing the bittern; a furnace in which the bittern is heated preparatory to entering the stills, and two large stone stills or retorts, from which the bromine is distilled. The shop to which I have referred is located near the Excelsior and Buckeye Salt Works, and is run by Mr. Herman Lerner, of Mason City, W. Va. The above-named works supply this shop with bittern. After it enters the shop it is allowed to cool, after which it is passed into the purifier. From the purifier it enters the furnace where it is heated preparatory to passing into the stills, which are two in number. These stills are rude stone chambers hewn out of blocks of our native sandstone. Each is about six by eight feet in size, the tops being capped. In this cap or top there are two funnel-shaped openings, the one in the centre for introducing sulphuric acid, and the other near the corner for inserting the black oxide of manganese, and these funnel-shaped openings extend by a pipe thirty-two inches into the stills.

Each still is connected with two condensers, which in turn are connected with the receivers. The condensers consist of wooden troughs made of heavy poplar wood, and they are kept cool by allowing cold water to run over them. The receivers are large glass bottles, capable of holding the product of one distillation. The condensers and receivers are connected to the stills by means of lead pipe, and are made air-tight by means of bank clay.



APPARATUS FOR THE DISTILLATION OF BROMINE.

A, opening for introducing sulphuric acid, funnel-shaped; B, opening for introducing oxide of manganese, funnel-shaped; C, lead pipes connecting still with condensers; D, opening for letting out exhausted material; E, the condensers; F, flue which receives the impurities; I, receiver which contains impurities before passing into the flue; S, pipes for passing in steam; R, receivers for the bromine.

Between the condensers, and connected with them, a large glass bottle is placed, and here the uncondensed vapours escape together with a little bromine, which remains in the bottle while the vapours pass through a large lead pipe into what is termed the flue.

This is made of square hollow sandstone pipes about two by three feet, placed upon one another, surmounted by two fire-clay chimneys. These chimneys are filled with common coal cinder, or with charcoal, and this is kept moist. The escaping vapours pass into these flues, and if appreciable amounts of bromine are present it is purified, and condensed, and is obtained at the bottom of the flue. The stone retorts spoken of are capable of holding a charge of four hundred gallons of bittern, seventy-five pounds of sulphuric acid, and thirty-five pounds of black oxide of manganese. After filling them with this mixture, steam is passed into the charge. Chlorine gas is thereby liberated, which acts upon the soluble bromides, and decomposes them with the liberation of bromine, which distils over into the condensers. The resultant chlorides, after the charge is exhausted, are at the present time run off as waste products. After the bromine condenses and is collected in the receivers, it is drawn into glass

* A thesis presented to the Cincinnati College of Pharmacy, 1884.

stoppered bottles, each capable of holding from ten to twenty pounds, and it is now ready for market.

On an average, the bromine shop I have named manufactures five hundred and twenty-five pounds of bromine per day. During the past year our shops, nine in number, with a running average of three hundred days, yielded 159,500 lbs. of bromine. This yield was over and above the demand, and in consequence its production was followed by some cutting of prices. Two parties control all of the bromine manufactured, and yet they endeavoured to undersell each other.

Some years ago, they received three dollars per pound for it, but the year which has passed returned them but twenty-six and twenty-seven cents.

Notes.

The striking photograph of an encampment in the desert, which is our supplement this week, was taken by Mr. Baden Pritchard one morning soon after sunrise. He thus told the tale of its production:—"There are plenty of encampments to choose from, so we are not long in getting what we want. At one point a dozen camels lie together in a picturesque group, and we approach to within twenty paces. Alas! before I have done focussing, a wretched dog has jumped out of the circle, and is baying and barking at the legs of the tripod. Some half-sitting figures rise to their feet precipitately—women almost black—and the camels stretch out their snake-like necks. A rapid exposure is made, but before I can turn the slide round to get a second one, Jones cries to me to 'look out.' It is a couple of Arabs who are striding along as fast as they can without running. Neither of us is afraid, of course, but we think we had better move off, and so we do."

A correspondent suggests to a contemporary that the judge's box on every race course ought to be supplied with a camera, by which the official who occupies the judge's chair could obtain an instantaneous photograph of the finish of the race as the winning horse rushes by. The object of the suggestion is explained, though it is of course obvious. It is intended that the judge should be able to justify his verdict of a short neck, a short head, or possibly a dead heat, by producing a negative on which the actual position of the first two or three horses was clearly shown.

Our contemporary concludes that as the *Flying Dutchman* can be "taken" as it rushes by at a rate of sixty miles an hour, race horses could assuredly be photographed as they fly past the winning post; whilst the only extra trouble necessarily imposed on the judges would be to press a knob or pull a trigger at the supreme moment.

It is even said that the suggestion has been laid before the Jockey's Club, and that action with regard to it is not unlikely. May we then assume that at the Derby of the future the hoisting of the winning number will be followed by the public exhibition of Judge Clarke's photograph of the finish, that the "c'rect card" will be supplemented by the "c rect carte" of the race?

Only fancy the public's anxious suspense whilst the said "c'rect carte" was being "developed" in some dark recess under the Grand Stand! Fancy, too, how copies of a close finish would sell on a crowded race course, and, perhaps, found the fortunes of a photographic Dorling. And lastly, though not leastly, fancy what jokes the comic journals would make about the Derby winner being "drawn in a carte and developed" after the race, and all the rest of it. Certainly we would pray, with John Gilpin, that when Judge Clarke first uses his instantaneous camera, may we be there to see!

From a technical point of view there are difficulties, but not more than might be overcome by energy and application. A white background on one side of the course, and a powerful beam of electric light streaming from underneath the judge's box, would certainly be required in dull weather.

The Director of the Note Printing Department of the Imperial Bank in Vienna thought that photo-engraving might be useful in his department, so he availed himself of the services of Herr C. Angerer (the head of the firm of Angerer and Göschel), the well known photographic engraver of Vienna. Herr Angerer, who represents the technical skill and energy, received the somewhat bare reward of mere *Imperial recognition*, while Herr Mayer, the Bank official, was promptly invested with the knightly order of Francis Joseph. This savours a little of South Kensington.

A society journal tells us that the cost of sitting for a photograph is being discussed—it does not say where, nor by whom. It is instructive, however, to be told that photographers "have much to learn," as they "make it by far too rapid an act, and seem intent on 'work' the moment they get a sitter in the chair and have screwed the holdfast into the back of the head (*sic*)." The writer in question says he was told by a distinguished sculptor that a certain great actress was a most difficult sitter, for she was in the habit of "changing her chin—that is, the size and form of it varied on different occasions—and asks what a photographer would say to the difficulty. Clearly a sitter with this Proteau-like propensity would be extremely awkward. Nothing short of Mr. Galton's system of composite portraiture could possibly do her justice.

The realistic spirit in realism which the idea of the "Old London" street has developed at the "Healtherics', is so correct, as a rule, that little slips and anachronisms are all the more noticeable. It is not surprising, then, that the presence in one of the mediæval shops of a young lady, carefully dressed in the costume of the sixteenth century, and busily engaged in selling photographs, should be criticised. But it is difficult, nevertheless, to decide what kind of views she could sell in their place that would be in keeping with her surroundings.

Daguerreotypes seem, it is true, to carry us back to the dark ages, but they would be, as a matter of fact, only a little less anachronatic than the photographs themselves. "Scissorgraphs," again, by which we mean those sable

silhouettes with the eyes and hirsute appendages touched in with gilt, which were so numerously produced by the artists' scissors, until finally "cut out" by the invention of photography, would not really be more characteristic of the "Old London" Mr. Waterhouse has designed, than the cartes and cabinets actually on sale there. To put the matter briefly, even those who complain of the disposal of the photographs would find it hard to suggest a suitable substitute for them.

The mention of "scissorgraphs" recals the fact that there still exists in London—Modern London we mean, not "Old London"—a misanthropic "Scissorgraphist" who is only seen at night when he prowls about the bars and buffets of Fleet Street and Ludgate Hill, bearing a ragged portfolio under his arm, and bitterly lamenting the good old days when he cut out half a hundred profiles before dinner. This "Old Master," to whom the mention of photography is as the sight of a red rag to a bull, has no pupils, we believe, and when he passes away there will be no capable hand, probably, to which his well-worn scissors can descend, and his "black art" will die with him.

Talking of lost arts, each successive Royal Academy Exhibition tends to show that miniature painting is now well nigh a lost art also. Before the invention of photography, however, there was not a town of any importance that had not its miniature painter, who produced in any quantity those pale, wishy-washy portraits (save the mark!) on ivory, which, as a rule, possessed such a strong family likeness to one another. Their production was, in fact, too often much more like manufacture than an art.

At Cork, for instance, whence, in the days of the Miss La Creevy miniature, a large number of military officers used to sail for foreign service, there was an artist who did a most extensive trade in supplying families with miniatures of their departing relatives. He had often, indeed, to paint two or three dozen of them in the course of a few days. And this was how he used to manage, according to Mr. T. G. Whaite, who was entrusted with his confessions. His plan then was to keep in stock something like half a gross of painted bodies in uniforms of varied rank, from an ensign to a general. These were all practically finished, and all that was necessary on getting the order was to hastily paint in the faces, adding the necessary local colouring for either black, brown, or auburn hair, and the colour of the eyes, with the necessary alterations or additions to make the facings of the uniform correct. Customers thought more of these facings, in fact, than the faces, as we may easily gather from the survivals (not always of the fittest) which have come down to us.

Of the uses to which photography is applied there is assuredly no end. One of the latest is to assist leather merchants in imitating alligator skin. A photograph of a genuine alligator hide is taken, and a copy of it produced in bichromated gelatine, from which a metal die in turn is executed. This die is then pressed heavily on skins of cheap calf and other leather, and, as a result, all the curious markings of the alligator hide are transferred to them so exactly, that only experts can detect the imitation.

The increase in the manufacture of pyrogallic acid has been something enormous since the advent of dry plates. It can scarcely be said that there has been quite a corresponding decrease in price, a result which generally follows when a chemical compound is much in request.

A correspondent asks: How long are gelatine plates supposed to keep? He asks the question because he recently bought a batch which were very insensitive, and has reason to suppose they were a portion of old stock. He suggests that makers should date each batch, so that photographers might know what to do. It would be interesting to have the opinion of manufacturers on this point.

Young men about to start as itinerant photographers would do well to take advantage of the experience of a writer in a Brighton paper, who has had ample opportunities on the Brighton beach of watching the ways of the fraternity. According to this observer they shun papa and mamma and family, but cautiously broach their business to groups of young men, insinuatingly approach sentimental couples, and bear down boldly on any young gentleman who has two ladies in his charge. The last named are nearly always safe game.

At Potsdam, in the Villa Liegnitz, several members of the Imperial family may be seen at work with the camera or the brush almost daily (a spacious apartment having been set aside for oil painting), while frequent excursions with the camera are made by Prince Henry, Prince William, and others. Most visitors take away their own portraits when they leave, or perhaps a few views of the neighbourhood.

Photographers are not alone in their complaints of the badness of the season. The sale of pictures in the Royal Academy, just closed, has been smaller than for many years past.

The collodion and silver bath have done good work, and are not yet altogether ousted by their rival—the gelatine plate. It is, therefore, almost unkind to speak of the negative bath in the way a member of the Chicago Amateur Club did the other day, "as a sloppy business." It takes away all romance to say, as this gentleman said, that "for twenty-five years he had worked in the slops of silver!"

That it is possible to make an improper use of the photographic portraits of convicts is indicated by the complaint of Wright, a prisoner at Worship Street, who said that the policeman who identified him when he was brought out with other men in the yard of the police court had been previously prepared for the occasion by a study of his (Wright's) photograph. The authorities should investigate the matter, and, if the imputation is true, all concerned ought certainly to be removed from the public service.

An American paper has just got hold of a wrinkle that was discussed on this side of the Atlantic at least a year ago, when we told the story of Mr. Trueman Wood and others photographing the vocal organs of famous singers, with a view of obtaining actual visual information as to how the larynx, &c., was shaped in forming this or that note, and so on, and so forth.

Now this is quite enough, of course, to set off our American contemporary, which gravely suggests that it supposes the public will soon be enabled to procure *cartes* of Patti's "upper C" and Sims Reeves' "chest D." We shall have æsthetic vocalists, it asserts, striving to live up to Mr. Oscar Wilde's "A sharp"; or sitting up all night by the side of his "much resounding C." Whilst curiosity, it adds, will doubtless lead to a large sale of copies of the Duke of C.'s well-known "big, big D." The sale of the new "Photographic Notes" would, in fact, according to our contemporary, be almost as brisk as that of the old-established variety.

Patent Intelligence.

Specification published during the week.

7,746. THOMAS FURNELL, of 1, Matlock Villas, Lordship Lane, East Dulwich, London, in the county of Surrey, Civil Engineer, for "An adjustable instantaneous shutter for photographic purposes."—Dated 15th May, 1884. (*Complete Specification.*)

A double flap-shutter with a number of very complex adjustments. The inventor prefers to make the flaps of ferrotype plate or other similar material faced with velvet, but he winds the material, nearly one turn, round the spindle before attaching, apparently with the view of giving elasticity. Although there are no less than twenty diagrams accompanying the specification, we find none of them, or the details illustrated, to be of sufficient interest to justify us in allowing them to occupy as much space as they would fill.

Patents Granted in America.

302,386. CHAS. E. DRESSLER, New York, N.Y. "Machine for grinding the rims of lenses." Filed February 27, 1884. (No model.)

Brief.—Adjust the clamp-support for one required bevel, and set it at one side of the centre of the grinding-surface and grind it. Reset the lens at the same angle, with opposite inclination at the other side of the grinding-surface, and grind the other bevel of the rim of the lens. The arm which supports the clamp is held by spring-pressure at predetermined distances from, and toward, the grinding-wheel. The clamp has a continuous step motion to and fro across the face of the grinding-wheel. The bed of the lens-holder is adjustable to and from the emery-wheel.

THE CAMERA AND ITS APPURTENANCES.

BY LIEUT.-COLONEL W. C. NOVERRE.*

NEXT in importance to the camera is the lens. Here there is not the same difficulty in selection. It may be said that the amateur has only three or four kinds of lenses to select from. It is not intended to describe the various lenses in general use, as full descriptions of them are given in the last volume of the NEWS. The choice will probably be between a simple or a wide-angle landscape lens, and a lens of the rapid rectilinear type. The former instrument will usually be found to answer all the requirements of the amateur landscape photographer. It has many advantages over the rectilinear lenses; it is a much cheaper lens, and it has greater depth of focus; the diaphragm, being in front of the lens, protects it from diffused light; and a rotating plate, pierced with suitable holes, attached to the lens, takes the place of the set of Waterhouse diaphragms. The single combination lens went out of fashion in the days of wet collodion because of the long exposure it required; but with gelatino-bromide plates this lens will be found quick enough for ordinary work, and for landscape photography is preferable to any other form. For architectural subjects, and for photographing moving objects, the rapid rectilinear, or a lens of similar construction, will be preferred. When using this kind of lens, it is important to close the diaphragm slit carefully, even when a stop is used. When a stop is not used, an elastic band, passed round the mount, so as to cover the slit, is the simplest arrangement. When a stop is inserted, two bands may be used, so as to press against the stop on both sides; or a small velvet or thin leather cap may fit over the diaphragm, and may be held in its place by an elastic band on each side; the bands alone, if properly adjusted, are, however, sufficient. When a lens of the above type is used, the lens, having its front combination exposed, must be sheltered from the sun's rays and from all diffused light. Although the necessity for such a precaution has been insisted upon for years by many critics, it is a singular fact that none of the camera-makers supply any arrangement of the kind. A simple plan, and one that has been often suggested, is to have light wood or metal struts to screw on either side of the camera-front; by throwing the focussing cloth over these during exposure, the lens is protected to a great extent. It is not, however, a very perfect arrangement; it does not cut off the light which is reflected from the foreground, and the wind may blow the cloth across the lens. A stiff pasteboard funnel fitting on to the lens is effective, but is an awkward thing to carry about. A funnel of black velvet, projecting in front of the lens about five inches, attached to it with an elastic band at one extremity, and sewn to a metal ring about five inches in diameter at the other, is effective and portable. The exact dimensions will, of course, depend upon the size of the lens; the ring should be hinged to a light metal rod. Blinds can be screwed into the camera-front either above or below the lens. When an instantaneous shutter is to be used in front of the lens, the funnel must be attached to the shutter.

In photographing brightly-lighted subjects, or with objects near the camera which reflect much light into the lens, the want of some protection is a frequent and unsuspected cause of fogging and weak pictures. The short exposures required with gelatino-bromide plates, and the facilities afforded by their use for photographing moving objects, has caused the introduction of many so-called instantaneous shutters. Those selected for notice are in general use, and though more imperfect, all are more or less effective, and show much ingenuity in their construction. The drop shutter is the simplest of all, as it is the cheapest and most rapid; the drawback to it is that it is bulky in size, and the rapidity cannot be greatly varied for different lengths of exposure without making the shutter very long, and consequently more cumbersome. In the flap and drop-shutter combined, the flap is raised for exposure in the usual way, and when it is fully open, the action releases a drop-shutter, which instantly closes, the lens being drawn rapidly down by means of an elastic band. This shutter works rather stiffly, and is in consequence liable to shake the camera; it seems on the whole to possess no advantage over the simple drop.

Jackson's shutter is an ingenious contrivance; it has a pair of flaps connected by a light metal bar; these flaps move across the lens in opposite directions, so that in making the exposure, the shutter opens from the centre, and it closes from the sides. The exposure is rapid, depending on the tension of a rubber band; but it is not

* Continued from page 492.

so rapid as the drop-shutter. This instrument may be worked by hand when long exposures are required, the elastic being removed. This shutter is rather a large affair to fit in front of the lens, but is well adapted to go behind the lens.

Watson's snap-shutter is a neat contrivance, but does not give a very quick exposure, as the aperture is opened and closed by a single flap, which is drawn aside to expose, and drawn back again to close, the aperture; it takes less space to work in than the drop shutter, and is a good form of instrument for slow exposures, as the shutter may be left open any time; it works very easily. An ebonite drop-shutter by the same maker is very nicely made. Watson and Co. also sell the Addeubrooke shutter. With this instrument the exposure can be exactly timed: the standard size admits of twenty-seven progressive exposures from $\frac{1}{4}$ to $2\frac{3}{4}$-seconds. The instrument is necessarily heavy and expensive, £3 10s.: its only recommendation is that the length of exposure can be accurately timed. The patent shutter invented by Mr. Sands is also graduated for various durations of exposure from 1 to 6. These are not calculated by fractions of a second as in Addeubrooke's; it is, however, less bulky, and works more rapidly, owing to the fact that the shutter works between the lenses, and therefore has less space to travel, the opening to the shutter being no larger than the aperture in the diaphragm plate between the lenses. A more even exposure is obtained with the shutter working between the lenses than in any other position. The price of this shutter is necessarily high, but is somewhat less than Addenbrooke's.

A new shutter has lately been introduced by Marion and Co., called by them the "Ebonite Drop Shutter;" it is not, however, strictly speaking, a drop-shutter, the aperture being opened and closed by a flap which moves up and down by an arrangement of levers, the exposure in consequence being not very rapid. Attached to the shutter is Cadett's patent pneumatic apparatus. The exposure is made by squeezing a rubber ball which is attached to the shutter by a length of flexible tubing. On squeezing the rubber ball, the flap of the shutter is raised, and remains up till exposure is finished, when by removing the pressure from the ball a spiral spring acts as the lever, and the flap falls, closing the lens. The shutter is made of ebonite, and is very portable; it is fitted with removable leather collars, so that one shutter may be fitted to lenses of three or four different sizes. Cadett's pneumatic apparatus can be fitted to any of the shutters noticed above, the piston being made to fall on the trigger of the shutter. The duration of the exposure cannot, however, be controlled by the operator. The special feature in Marion's shutter is that an exposure of any length may be given by means of the pneumatic ball. When ordering a shutter, of whatever kind, the diameter of the wood of the lens should be given.

Cases of leather or canvas are made for carrying cameras and slides, and afford protection in travelling, but add to the weight to be carried. If the photographer intends to carry his own camera, it is a good plan to wrap the camera and slides in a piece of waterproof material, and fasten round them a pair of light straps with handle. The lens is conveniently carried in a leather case with straps to pass over the shoulder.

The selection of a good stand is somewhat difficult. We want a stand that shall be rigid and light, and high enough to enable us to focus without stooping; most persons prefer a folding stand, as more convenient to pack. A stand for a whole-plate camera to answer these requirements usually weighs about three and a-half pounds, a considerable addition to the weight of one's kit. The most rigid kind of stand is that in which each leg is made of two pieces, with a metal struck between them, the legs being attached to a metal top. This form affords six points of support to the top, and the struts make the legs very stiff. When each leg is in one piece, or in two pieces fixed at the same point to the top, the staud is always more or less shakey. The sliding-leg stands are open to this objection, though in many respects more convenient. When rapid exposures are to be given, the rigidity of the stand is of far more consequence than in the case of long exposures. The camera is attached to the stand by a movable screw, which is very apt to be mislaid or left behind when taking out the camera; a screw-hole should be tapped in the top of the stand, in which the screw may be screwed when not in use.

SUBSTITUTES FOR GROUND GLASS.

A good substitute for finely-ground glass, as a focussing-screen, is often needed, especially by the out-door photographer, who may be many miles, or hundreds of miles, from any place where such an article can be obtained.

The various kinds of "matt" varnish rarely give a fine enough grain; white wax dissolved in benzole is said to give a very satisfactory surface for focussing, but we have never tried it.

A piece of plain glass coated with ordiuary hard negative varnish may be rubbed with flour emery and oil by means of cork, until a fine ground glass surface is produced, but it takes some time to do it, although not nearly so long as would be necessary to produce the same effect on bare glass.

A gelatine emulsion plate, slightly exposed to light, developed and fixed, is an excellent focussing medium. But it may be wished to abolish glass altogether, and substitute some lighter and less fragile material.

For small sizes—say up to $4\frac{1}{4}$ by $5\frac{1}{2}$—mica ground with flour emery may answer well, but it is difficult to get mica free from defects, although it can be obtained of suitable quality; and for sizes larger than the above it would hardly be stiff enough, even if it could be obtained sufficiently homogeneous and transparent.

There is a kind of tracing paper in the market known as "French vegetable," which optically leaves little to be desired; but as it possesses no stiffness, it must be damped and pasted on a frame to make it "taut." Care is required not to make it too wet, or it will split in drying. It may be stretched on glass by wetting it and pasting the edges.

Tracing cloth has been used, but it is not sufficiently transparent, and its grain is too coarse. We have an idea that the fine oiled silk sold for surgical purposes might make a good focussing-screen, if stretched on a frame, but have never tried it.—*Photography.*

A NEW SENSITOMETER.

BY PROF. G. W. HOUGH.*

Various methods have been employed for ascertaining the sensitiveness of photographic plates, but we do not know that any hitherto used are capable of giving directly the sensitiveness as referred to any convenient standard. The use of blackened gelatine films may give sufficiently reliable results, but, from the nature of their construction, no two instruments will be precisely alike, and even in the same instrument there is no definite relation between the different parts of the scale.

The use of a series of tubes having unequal areas might answer under certain conditions, but such an apparatus would be complicated. I imagined that a single long tube—a stove-pipe, for example—in which was arranged a series of numbers at different distances from the opening, would solve the problem; but on examining such a device, it was at once concluded that it would not answer the purpose, unless the source of light and the camera were placed at a considerable distance from the opening.

It occurred to me that if a perforated disc was made to revolve in front of a scale of numbers, the light received by each would be directly proportioned to the angular opening in the disc. To illustrate, suppose we have a semi-circular disc, fig. 1, which is made to revolve rapidly, then any number covered by it when in rotation would receive only one-half as much light as one outside of its circumference. If the disc revolves with sufficient speed, both numbers will be constantly visible to the eye, but one will receive only one-half as much light as the other. On this principle is based the sensitometer about to be described. In our first experiments we constructed a snail on a scale of one to twenty, so that the figure 1 should receive one-twentieth of the whole light, 5 five-twentieths, &c.

* Communicated to *Photography.*

It was soon found, however, that the scale was too short for accurate determination of sensitiveness; since, when the proper exposure was made for a fully-timed negative, the whole scale was photographed. Our second snail was on a scale of 1 to 50; in this case also a large part of the scale was shown in the negative, both for collodion and emulsion plates.

Fig. 1.

In order to get a longer scale in a compact form, an opening was made in a cardboard disc, fig. 2, based on the ratio of one to five hundred, starting with 100 or one-fifth of the light entering the camera. For the upper part of the scale, from 100 to 30, only every tenth number was inserted; below 30 the numbers decrease by units.

The opening in the disc, fig. 2, is not drawn to scale, but any

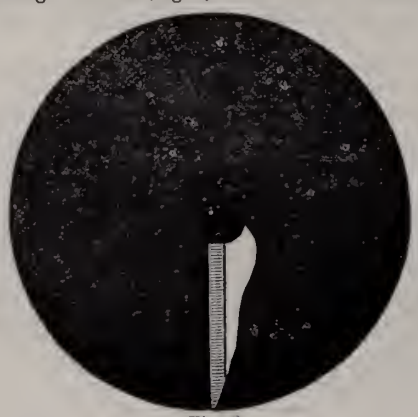


Fig. 2.

one may easily construct the opening for any scale desired. For the beginning of my scale the angular opening is 72 degrees, equal to one-fifth the whole light. For one-tenth of the whole light, the angular opening will be 36 degrees at that point, and for one one-hundredth of the whole light the angular opening will be 3·6 degrees, &c.

The following is the scale. The numbers as they now stand represent the time of exposure. It may, however, be reversed so as to give sensitiveness directly.

Now when the disc is put in rotation, and an exposure is made, each number developed shows at once the amount of light it received. If the last number visible was 5, the light equivalent for that number would be $\frac{5}{500}$ of the light employed. If the full aperture of the lens was used, and the time of exposure was ten seconds, the equivalent exposure for the figure 5 would be $\frac{10\times5}{500}=0{\cdot}20$ sec. We will suppose a similar plate is exposed, with the aperture of the lens reduced to 1·15 of the area, the time being the same. In this case the last number printed should be 75 of the scale. The light equivalent will then be $\frac{75}{500}\times20\times\frac{1}{1{\cdot}5}=0{\cdot}20$ sec. Having ascertained by a number of experiments the time required for the last number which can be seen, for any standard plate, the relative sensitiveness of any other can be ascertained. In the example given above, we will suppose the plate exposed was wet collodion, of which the light equivalent was 0·20 sec. In case the sensitiveness of an emulsion plate is wholly unknown, we may expose for the same time and with the same stop as was used before; suppose in such an experiment the last number printed was 6, then the light equivalent would be $\frac{6}{500}\times20\frac{1}{1{\cdot}5}=\frac{1}{6{\cdot}2}$ sec. As the collodion plate gave $\frac{1}{5}$ sec. the emulsion plate is twelve times as rapid.

If another plate shows the number 4 under the same conditions, its light equivalent would be $\frac{1}{9{\cdot}4}$ sec., or 19 times more rapid than the standard. In order to secure more accurate results, and also to assist in development, it is preferable to give approximately the correct exposures for the matter outside the scale; then the last numbers visible will fall near the middle. In this case any error of reading would not materially affect the result. The apparatus which we have used is simply a blackened card-board disc eleven inches in diameter, having a suitable opening, and rotated by a Yankee-clock movement. A scale of numbers, written with Indian-ink on white paper, is placed underneath it.

The disc makes about two revolutions in one second; but the speed of rotation is a matter of no consequence. With this simple device the relative sensitiveness of different plates is readily ascertained within five to ten per cent. from a single exposure.

In comparing dry plates by different makers, we used the pyro developer (Cramer's formula). The same strength of developer was used for all, and the plates were left in the tray for five minutes, in order to carry the development as far as it would ever be required in actual work.

The following experiment will indicate the working of the apparatus, using the same stop, and giving the same time. Four different brands of commercial plates were successively exposed, and then developed. The last numbers visible in the scale were, 10, 8, 6, 10.

In this example the relative sensitiveness of the plates is shown directly by the numbers 10, 8, 6, 10; the plate showing 6 being $1\frac{3}{3}$ times more rapid than those showing 10.

Commercial plates by nine different makers were compared with the wet collodion plate with the following results:—

The sensitiveness of the collodion plate being 1, the following numbers indicate the rapidity of the emulsion plates:—21, 20, 18, 16, 16, 14, 13, 13, 13.

An inspection of these numbers indicates a good deal of difference in the speed of plates.

It may be desirable to give some idea of the time of exposure which is necessary according to these numbers.

Now the collodion plate required for the minimum exposure one-half second, with the full opening of a Darlot No. 1 Rapid Hemispherical, to make a negative of a brick building or a well-lit landscape. Ordinarily, however, we give one second, in which case the plate is fully developed inside of thirty seconds.

On the basis of one second an emulsion plate having a speed of 20, when exposed on a similars ubject, should have not more, than 1-20 second with the full aperture of a Darlot No. 1 lens. In order to approximately secure a correct exposure it is necessary to use the smallest stop (3 mm.) and simply uncap. For the slower plates the 5 mm. stop may be used, and the lens simply uncapped.

These times refer, of course, to a well-lit out-door subject when there is sunlight.

With this form of sensitometer the relative intensity of the light at different times, or in different places, can easily be ascertained. It is simply necessary to expose a plate for a given time, and note the last number developed. A similar plate exposed in the same way at any other time or place will show a certain number, and the intensity of the light will be directly proportional to the numbers.

It has been stated that if a plate is exposed to a small amount of light previous to being used, it becomes more rapid. A simple experiment was made to ascertain whether the statement was true.

An emulsion plate was cut in four pieces. One was exposed without seeing light; the others had respectively, ten seconds', thirty seconds', and sixty seconds' exposure through the red-glass window of the developing-room before being used. The four pieces were all developed together. The one which was submitted to the red light for sixty seconds flashed right out like any over-exposed plate; then the others in proper order. All

were left in the developer for five minutes; when fixed, the first was found buried under a dense fog, so that only a portion of the scale could be read. The second showed considerable fog, and the third a trace; the fourth, of course, was perfectly clean. The numbers shown in the three pieces were precisely the same—if anything, a little advantage in favour of the piece which was handled in the darkness. The explanation of the foregoing belief is simple. A plate which has been submitted to other light than that belonging to the exposure will necessarily begin to develop quicker, but there will not be as much film left for the negative. Whatever light has been on it, either in its manufacture or elsewhere, will impair its usefulness in proportion to the amount of light it received.

The question occurred to me whether it was possible to use the foregoing method and mechanism for an absolute standard of sensitiveness, so that plates tested in Chicago and London should be directly comparable. With a lens of given area and focal length this may be readily accomplished, provided we have a standard light. The electric light might be used, but there would be a good deal of trouble and some uncertainty in determining its intensity. The same would be true of the magnesium light or any other. On the whole, I believe a wet collodion plate would be the most convenient standard, and could be made to give comparable results within small limits of error, provided a uniform standard was adopted for the collodion and the bath.

This sensitometer may be made to give absolute results without much difficulty.

Let any scale of numbers from 0 to 100 be photographed or painted on clear glass. The plate to be tested may then be placed behind it, to make a contact negative. In front of the scale the snail or perforated disc may be rotated, so as to give each number its proper amount of illumination; the light being a standard candle at one foot distance.

If the time of exposure be 100 seconds, and the last number visible in the negative 10, the equivalent exposure will be,

$$100 \times \tfrac{10}{100} = 10 \text{ seconds.}$$

If another plate under the same circumstances shows the number 8, its equivalent exposure will be 8 seconds. In other words, the apparatus will give the actual time required for the light of one candle at one foot distance to make a legible record, and this time is the standard of sensitiveness; the only source of error will be in the standard candle.

THOUGHTS BY THE WAY.

BY ONE WHO THINKS.

"There's a chiel amang us takin' notes,
An' faith he'll prent 'em."

Those who commence this paper with the hope of learning something new, of picking up a fresh developing formula, or of obtaining the latest "safe light," will find themselves sadly disappointed, and I warn them to desist reading at once. I am simply committing to paper thoughts bearing on photography that have passed through my mind when reading the photographic papers, and when engaged in my work. These will, I fear, sometimes savour of sentiment; but, to my thinking, a man without some sentiment is little better than a bagful of sawdust: he must first feel the poetry there is in nature and in human life, before he can pourtray it to his fellow-creatures. "In the Gloamin'," "When the Day's Work is Done," "There is Sorrow on the Sea," would never have been made had not their authors possessed the power of feeling the pathos existing in all around us. I am a professional photographer, and I think my initiation into the profession would have disgusted the most enthusiastic. In the smoke and fog of a huge city, I commenced my instruction with a large club firm. The class of work disgusted me, but in shop windows I saw prints by men of mark rendering some beauty spot with exquisite delicacy, and I know there was a power yet to be reached. I worked hard, and was rewarded by gaining the ability to make the soft and airy pictures I had so much admired.

There has been much said about over-exposure and restrainers, but I cling tenaciously to the belief that there should be only one exposure, and that the correct one; an error on either side causes the loss of that beautiful gradation that is so characteristic of gelatine plates, for there is a beauty in the gradation of a dry-plate (properly exposed that I have never seen in a wet plate. When photographers learn to give correct exposures, and to modify the developer according to the requirements of the view to be represented, then, and not till then, will dry plates assert their supremacy over wet.

I cannot speak too highly of first soaking the plate in pyrogallic, bromide, and water, and then developing by small doses of ammonia, added at intervals; the image is thus completely under the control of the operator, and is gradually built up, it seems, more in the *body* of the film, and less superficial than does one where the full strength developer is applied at once. Before adopting this course, I really got a negative to please me. I never care how long a negative takes me; half-an-hour is the time I usually spend in developing one, but when finished am rewarded by great brilliancy and gradation. When at work in the field I am most careful to screen the lens during exposure, as in my opinion this helps to give a brilliant negative. My screen is of the simplest, being two light strips of blackened wood, which I lay across the top of the camera, and which project a suitable distance in front; over these, when ready to expose, I throw the focussing cloth, and as this falls down on either side the lens is effectually screened.

In case of known under-exposure, where drop shutters are used, for instance, I always give a preliminary soaking in dilute ammonia and water, and use a good proportion of bromide. My advice with respect to developing, is: get a good formula, and work at it until you thoroughly understand it; do not try every developing formula you may see published; they are all good when well understood, and without being understood the best is useless. There are countless changes to be rung on a very simple formula; and remember you do not want three grains of pyro to the ounce of water for every subject you develop.

I remember, before commencing to develop dry plates myself, frequently standing by one of my principals when he was developing, and being amazed at his *modus operandi*. He held the opinion that dry plates had great latitude of exposure (truly a comfortable opinion!) Anywhere between one and twenty seconds ought to give a good result, he thought, where perhaps the correct exposure was five seconds. Arrived in the dark-room, he would proceed to develop, his light that of a single thickness of what had once been orange paper; the developer would then be mixed, probably the remains of some three or four different developing formulæ. If under-exposed, he would add undiluted ammonia ·880 *ad libitum*; if over-exposed, some bromide would be dashed in from the stock bottle. Then commenced the "pushing-up" process (this, he explained to me, was to give the print the vigour and character of a wet print), and when finished, I had a negative to print from that in dull weather I didn't get half-a-dozen prints from in a day. The negative, as may be guessed, was not a success, but then, "arn't you surprised at such a well-known firm sending out plates like these? Will try some one else's!" And so I suppose he is still trying some one else's. This was no second-rate artist, according to public estimation.

For many reasons I am compelled to use commercial ready sensitized paper, but for beauty of result, think none can equal paper sensitized at home. For a long time I had the greatest difficulty in toning the commercial paper; tried the acetate, borax, phosphate, and various other baths, but all in vain. At last I settled down to a tungstate of soda bath, and with care got very good tones, and great uniformity. I always add a little ammonia to the washing-water, which greatly accelerates the toning.

These are my "thoughts by the way." That there is nothing new in them, I am only too well aware of, and for which fault I am quite ready to apologize.

Correspondence.

THE INTERNATIONAL EXHIBITION AT THE CRYSTAL PALACE.

DEAR SIR,—The absence of exhibits from the majority of our first-class photographic artists from the above exhibition was most remarkable, but more remarkable still the manner of adjudicating, and, if such a system of awarding medals be followed up, will disgust deserving artists, and materially lessen their desire to compete for such sham and questionable honours. Of course it could not be looked upon as a representative photographic exhibition, but it won't do to give medals away indiscriminately, or make them cheap, or they lose their charm.

Although there was not a strong display of talent, surely such men as Messrs. King, Faulkner, &c., were second to none in all the photographic productions displayed, which must have been observable to any possessed of judgment. And again, why should the distinction be made of judging Mr. King's pictures by gentlemen capable of giving an opinion, when the gold medal was awarded by those who could not be expected to come to a proper conclusion? And if this sort of thing is allowed to proceed, gold medals will be at a discount.

One could not but be struck, in passing Section IV. of the Exhibition, at seeing the frames scattered here and there, reminding a visitor forcibly of advertisement frames at a station.

Under your heading "Talk in the Studio," where, quoting the scattered exhibits in Section IV., and their being adjudicated upon by judges really not qualified, you state you are unable to account for the reason. But that there is a motive must be transparent even to the most unbiassed, and unless competitions of the kind are carried on with a straightforward principle, medals will not be sought after or valued much by our leading men.—Respectfully yours, C. A. GREGORY.

Froddington, Somers Town, Southsea.

Proceedings of Societies.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

A MEETING of this Society was held on Thursday, the 31st ult., Mr. W. E. DEBENHAM in the chair.

Mr. S. C. Salmon was elected a member of the Association.

Mr. A. COWAN exhibited an arrangement of standard diaphragms he had devised to suit a combination, or any other series of lenses. This ingenious contrivance is obtained by causing two diamond-shaped openings in plates of ebonite to pass each other, gradually diminishing the aperture until it is completely covered. The position is on the camera front, half the combination being screwed into a flange in front, and the other half at the back, so that the stops may work between the lenses. Below is an index plate, around which is marked a scale of standard stops for all the focal lengths of lenses with which it can be used. Starting at full aperture, by means of a trigger having a cam action, operating to raise one shutter whilst lowering the other, a given mark in the index is reached corresponding to (say) $\frac{f}{32}$; a clamping screw then secures the shutters in that position, or rather prevents a larger aperture being employed when the exposure takes place; the exposures being made by causing a button suitably fixed to traverse in a slot as shown in the accompanying figure.

The CHAIRMAN said it was certainly very ingenious; he was sorry Mr. Cowan had not adopted the round form of aperture instead of the square.

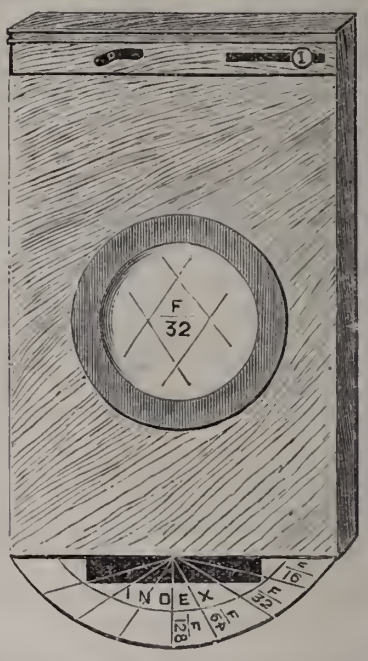
Mr. COWAN replied that the present form was easier to make, and from repeated experiments he saw no disadvantage; in some cases a slight elongation was advantageous; circular diaphragms, as in microscopes, would be as costly as the lens.

The CHAIRMAN differed as to the results obtained; he thought an approximate difference in definition would be as four seconds to five in favour of the round stop.

Mr. COWAN maintained that for all practical purposes one form was as good as the other.

A Member having suggested its suitability for the dissolving lantern,

Mr. COWAN said he had employed it for that purpose with excellent effect.



Mr. W. COLES showed the result obtained by him on an opal plate handed to him by Mr. Ashman at the last meeting; the print was exceptionally good.

The CHAIRMAN enquired whether it printed quicker or slower than an ordinary silver print?

Mr. COLES had not noticed that carefully; he found toning took longer, and he employed five grains of borax to each ounce of toning bath.

Mr. W. H. PRESTWICH found they printed very much quicker than ordinary sensitized paper.

Mr. W. COBB showed a sample of corrugated paper suited for packing dry plates; it was not delcterious, and was very cheap. He also passed round some 10 by 8 prints of the recent procession on its way to Hyde Park.

A discussion then arose on the advantage or otherwise of the glass in studios being partially obscured with tissue paper or other media, and the Chairman pointed out how it was often possible to get a similar effect to that of a passing cloud by stippling a few feet of the glass roof with a mixture which permitted easy removal; while another member showed the advantage gained by glazing those portions which are obstructed in confined situations with ground glass, and causing light to fall on its surface by means of reflectors. The principal objection urged was the largeness of the spot in the eye caused by the reflecting surface below the line of sight. This, however, was shown to be avoidable by interposing screens when necessary. Some gave preference to glazing entirely with ground glass, and others to rolled or fluted glass similar to the kind known as "Hartley's."

Talk in the Studio.

THE PHOTO-CHEMICAL LABORATORY OF THE NEW TECHNICAL HIGH-SCHOOL AT BERLIN.—The accommodation at the Technical High-School in Berlin has long been recognised as inadequate to the requirements of the present day; but in the new building ample provision is made for photographic work on a considerable scale. One building in connection with the Technical School comprises the chemical laboratory, the metallurgical department, and the photographic laboratory. On the ground floor is a machine room which contains a five-

horse power gas engine and a Siemen's dynamo capable of producing six arcs of 1,200 candles each; the conductiug wires passing up into the studio on the third floor, where the photographic work can go on iudepeudently of daytime or weather. A museum and exhibition room is also provided, and as a nucleus for a collectiou, Professor Vogel has presented the various specimens which he has so iudustriously collected during the past quarter of a century. Conveuieut rooms are provided for the various branches of photographic work, such as solar and mechanical printing, gelatino-bromide, photo-spectrography, and photometry. A conveniently fitted lecture and demonstration room has also been fitted up.

Dry Plates Specially Adapted for Stripping.—A special dry plate, from which the film can be readily stripped, is made by Messrs. Werth and Co., of Frankfort, it beiug merely necessary to set the negative in a horizontal positiou, and to pour on sufficient of the following gelatine solution to form a layer about a sixteenth of an inch thick :—

Gelatine	60 parts
Water	220 „
Glycerine	10 „

When the compositiou is dry it is easy to strip off the film by lifting the edges with the point of a knife. Plates for strippiug can be readily made by rubbing the glasses with powdered Freuch chalk, and collodiouising before coating with emulsion. All excess of French chalk should be dusted off, and the collodion should be dry when the plates are coated with emulsion.

A Frenchman's Dream of Electricity Abolishing Night.—*La Vie Moderne* amuses its readers with one of those visions of the future which have been in vogue since science began to astonish the present age with its marvellous performances. The coal mines were giving out, and their use was almost discontinued except for mauufacturers; gas had become extraordiuarily dear, and an American had conceived the project of erecting a tower 350 metres high on the open space in front of Notre Dame, from whose summit an enormous nickel-plated reflector 187 meters in circumference should shed down a flood of light over all Paris that would simply abolish night. On the top of a column a dynamo was to be required merely to keep the gigantic carbons at due distance from one another; at the base in great cellars were 2,000 elements, each couple of which was to absorb daily 1,200 kilograms of acid. In six months it was done, and Paris awaited the first lighting with an interest brightened by the news that three men, who, during one of the experiments being in the focus, had been melted and evaporated, and that the American chief engineer, M. Attison, who was taking a spectroscopic observatiou, had been fortunate euough to note the lines of the human spectrum—or spectre. Their expectations were not disappointed. A flood of light poured over the city, and (unlike, we must say, any electric light which we have succeeded in producing in our country) it turned round corners, entered the houses, went up stairs, and lighted not merely the parlours, but the passage-ways. But now came a difficulty. Paris always keeps late hours, but it ends by going to bed; those who amuse themselves moderately seek home at midnight; those who try hard to enjoy life leave off at three or four at latest. But why leave off at all in broad daylight, or perhaps we should say, in broad nightlight? And how could one sleep without darkness? For a few days Paris was perplexed. It lost its reckoning of time entirely, and at last it was found necessary to fire a morning and evening gun in every arrondissement to let the people know when the change was made from artificial to natural, and from natural to artificial sun, "and the Lutetian race, constantly bathed in living light, acquired a force, a beauty, an energy worthy of the Homeric ages."

Photo-Micrographs of Bacteria.—In the report of the Surgeon-General of the Navy for 1881 (Washington, 1883, p. 70) are to be found photo-micrographs, and a short account of a comma-shaped bacterium, a rather unusual form, observed by Surgeon J. H. Kidder in water through which air had been aspirated (summer of 1881), and in well-water near Washington (1883). Until we have more precise descriptions of Koch's cholera bacillus than are yet available, it will be judicious for microscopists to bear in mind, in case of the appearance of cholera on this side of the Atlantic, that similar forms have been found in water when no case of cholera was known to exist. Dr. Kidder supposed the form which he photographed to be the same as, or very similar to, that noted and figured by Billroth (*Untersuch. über coccobacteria septica*, Berlin, 1874, taf. ii. *B.*, *C.*), found in the droppings from an imperfect water-faucet in his work-room. —*Science.*

In Bathing Costume.—It is reported that photographs in bathing-costume are now called for by Philadelphia and New York belles.—*Waltl's Monthly.*

Printing Magnetic Curves.—Mr. A. D. Stephens, writing in the *Electrician*, says:—"While making some experimeuts in magnetism several months ago, I made use use of a method of preserving the diagiams of 'magnetic lines of force' obtained by the use of iron filings, which was new to me at that time, and which is extremely simple and effective. The process is as follows :—The figures are formed by the filings in the usual manner, but on a sheet of prepared blue print paper (see page 483) which is exposed to the sunlight as soon as the figures are formed. After a few moments' exposure, the paper is washed in clear water. If care is taken to have the light strike the paper as nearly normal as possible, the print obtained will be very sharp and clear.

The Vitiation of Air by Different Illuminants.—The following table, prepared for the *Engineering and Mining Journal*, shows the oxygen consumed, the carbonic acid produced, and the air vitiated by the combustion of certain bodies burnt so as to give the light of twelve standard sperm candles, each candle burning at the rate of 120 grains per hour.

Burnt to give light of 12 candles, equal to 120 grs. per hour.	Cubic feet of oxygen consumed.	Cubic feet of air consumed.	Cubic feet of carbonic acid produced.	Cubic feet of air vitiated.	Heat produced in lb. of water raised 10° F.
Cannel gas	3·30	16 50	2·01	217 50	195·0

Photographic Club.—At the next meeting, on August 13th, the adjourned discussion on the "Effect of Colour Media on Silver Prints" will be concluded. On Saturday, 9th inst., there will be an out-door meeting at Blackwall Pier. The members will meet at London Bridge Pier in time for the first steamer after 2 p.m. Late comers may proceed by rail to Blackwall from Fenchurch Street.

To Correspondents.

*** We cannot undertake to return rejected communications.

Frank Colbourne.—1. You cannot be at all sure of being able to remove the spots; but sometimes a careful treatment of the whole negative with a solution of cyanide of potassium—say, ten grains to the ounce—will answer. 2. To prevent this, take care that your negatives are very thoroughly washed and perfectly dried before being varnished. Your sensitive paper and the padding of the printing-frame should always be perfectly dry.

Belfast in Trouble.—If your camera has a rising front, you will get over your difficulty by sliding it upwards about an inch; if not, you must tilt the camera and overcome the consequent distortion by pushing the top of the swing-back in towards the lens—if, indeed, your camera is provided with a swing-back—otherwise you must be contented with a distorted picture in the first instance, and obtain a corrected one by copying it with the top portion rather nearer to the lens than the bottom. The correct angle for placing it in relation to the lens can only be determined by experiment, and a small stop must be used.

Beginner.—You should obtain Abney's "Instructions," of which a new edition will be ready in a few weeks.

Carl Norman.—Any maker of photographic apparatus will construct it for you; but it is not an ordinary stock article, because few persons care to use it.

Amateur.—They were not carried, but walked; look again at the construction of the sentence.

South Devon.—We are inclined to think as good a one can be made, but cannot offer any opinion as to whether you could obtain it. The work is difficult to one not engaged in it constantly.

A. C. A.—The only perfectly satisfactory way is to use the black varnish, and in the case of astronomical photographs, this is invariably done. 2. About ten grains to the ounce. We think not, 3. You are quite right; most prefer a light tending towards orange or greenish-yellow.

FRED. E. BELLAMY.—1. The back combination of a portrait lens is not suitable for view work, but the front combination answers very well if reversed and mounted in the back of the tube, so that the stop is in front of it. It is also possible to use the front lens with the stops behind; that is to say, simply remove the back combination. In the latter case the distortion is of the "pin-cushion" kind. 2. About one-fifth of the focal length. 3. Ordinary collodion is used. Warm a glass plate, and rub it over with a lump of beeswax, after which polish off all excess with a piece of flannel. Next coat the plate with collodion, and allow it to dry. The print and collodionised plate are now immersed in a warm solution of gelatine—say, one in ten or fifteen of water—and the plate is brought out of the solution with the print resting evenly, face downwards, on the collodion surface. Perfect contact between the collodion film and the picture is now ensured by gently stroking the back of the paper with a squeegee; that is to say, a strip of rubber mounted scraper fashion in the edge of a piece of wood. Now allow the print to dry, raise the edge all round with a pen-knife, and strip from the glass.

A. G. B.—1. Either a square or an oblong. 2. About twice the diameter. 3. The material should not be stiff, and the sleeve ought to be no longer than is necessary for easy manipulation—let us say three or four diameters. 4. Equally well either way. 5. It is merely a case of educating the hand, and requires rather practice than directions.

H. P. V.—1. We fear it is useless, but you might try on the assumption that it contains about half its weight of the unaltered salt. 2. See answer to Frank Colbourne.

W. G. B.—It is one of the coal tar colours, and can be obtained from Messrs. Hopkin and Williams, of Cross Street, Hatton Garden.

EDWARD KUNKLER.—Messrs. Chance and Co., Glass Makers, Birmingham, is sufficient address. 2. See answer to W. G. B.

JANOS.—Probably you admit too much light into your dark-room.

J. Y. BRETT.—The results are very satisfactory, and we are glad to find that your own experience confirms the observations of others.

ANXIOUS.—You would certainly do yourself no harm by coming up to London and calling on some of the leading photographers: but without knowing somewhat more of your qualifications, we can hardly judge of your chance of success.

J. HOWSON.—Your friend cannot claim the negative, the ownership of which rests in the photographer.

The Every-day Formulary.

THE GELATINO-BROMIDE PROCESS.

Emulsion.—A—Nit. silver 100 grains, dist. water 2 oz. B—Bromide potassium 85 grains, Nelson's No. 1 gelatine 20 grains, dist. water 1½ oz., a one per cent. mixture of hydrochloric acid and water 50 minims. C—Iodide potassium 8 grains, dist. water ½ oz. D—Hard gelatine 120 grains, water several oz. When the gelatine is thoroughly soaked, let all possible water be poured off D. A and B are now heated to about 120° Fahr., after which B is gradually added to A with constant agitation; C is then added. Heat in water bath for half an hour, and stir in D. After washing add ¾ oz. alcohol.

Pyro. Developer.—No. 1—Strong liq. ammonia 1½ oz., bromide potassium 240 grains, water 80 oz. No. 2—Pyro. 30 grains, water 10 oz. In case of an ordinary exposure mix equal vol.

Iron Developer.—Potassium oxalate sol. (1 and 4) 80 parts, ferrous sulphate sol. (1 and 4) 20 parts, dist. water 20 parts. To each 4 oz. of the mixed developer add from 5 to 30 drops ten per cent. sol. potassium bromide, and 30 drops sol. sodium hyposulphite (1 and 200).

Substratum or Preliminary Preparation.—Soluble silicate of soda 1 part, white of egg 5 parts, water 60 parts. Beat to froth and filter.

Fixing.—Sat. sol. of sod. hypo. 1 pint, sat. sol. of alum 2 pints, mixed.

Cowell's Clearing Solution.—Alum 1 part, citric acid 2 parts, water 10 parts. Edwards makes this sherry coloured with perchloride iron.

Eder's Method of Intensification.—The negative is whitened by soaking in sat. sol. of mercuric chloride, and after thorough rinsing immersed in potass. cyan. 10 parts, potass. iod. 5 parts, mercuric chloride 5 parts, water 2,000 parts. As film becomes dark brown, the actinic opacity is increased; but prolonged action causes brown tint to become lighter, until at last the negative is no denser than at first.

Fol's Backing Sheets.—A chromographic paste is prepared with gelatine 1 part, water 2 parts, glycerine 1 part, and a very small addition of Indian ink. Strong paper or shirting is coated, and the sheets are laid, face downward, on waxed glass to set. Press to back of glass plate.

THE WET COLLODION PROCESS.

The Nitrate Bath.—Water 14 oz., nit. silver 1 oz., nitric acid 1 drop. Before using coat a small plate, and immerse it for 20 minutes.

Cleaning Preparation for New Plates.—Alcohol 4 oz., Jeweller's rouge ½-oz., liquid ammonia ½-oz.

Film-removing Pickle for Old Plates.—Water 1 pint, sulphuric acid 4 fluid oz., bichromate potassium 4 oz.

Negative Collodion for Iron Development.—Alcohol 1 pint, pyroxyline of suitable quality 250 grains, shake well and add ether 2 pints, *Iodize this by mixing with* one-third of its volume of alcohol ½ pint, iod. ammon. 80 grains, iod. cadm. 80 grains, brom. ammon. 40 grains.

Normal Iron Developer.—Water 10 oz., proto-sulphate iron ½ oz., glacial acetic acid ½ oz., alcohol ½ oz. The amount of proto-sulphate iron may be diminished to ¼ oz. when full contrasts are desired, or increased to 1 oz. when contrasts are unduly marked. With new bath quantity of alcohol may be reduced to ¼ oz.; but when bath is old more is wanted.

Substratum.—Whites of 2 eggs well beaten, 6 pints of water, and 1 dr liq. ammon.

Intensifying Solution.—Water 6 oz., citric acid 75 grains, pyro. 30 grains. When used, add a few drops of the silver bath to each ounce.

Lead Intensification.—After neg. washing, immerse in dist. water 100 parts, red pruss. potash 6 parts, and nit. lead 4 parts. When it is yellowish white wash and immerse in liquid sulphide ammon. 1 part, water 4 parts.

Fixing Solution.—1. Potass. cyanide 200 grains, water 10 oz. 2. Sat. sol. of sod. hypo.

Varnish.—Shellac 2 oz., sandarac 2 oz., Canada balsam 1 dr., oil of avender 1 oz., alcohol 16 oz.

PRINTING PROCESSES.

Albumen Mixture for Paper.—White of egg 18 oz., 500 grs. ammon. chlor. in 2 oz. of water. Beat to a froth, stand, and filter.

Sensitizing Solution.—Nit. silver 50 grs., water 1 oz., sod. carb. ½ gr.

Acetate Toning Bath.—Chl. gold 1 gr., acet. soda 20 grs., water 8 oz.

Lime do.—Chl. gold 1 gr., whiting 30 grs., boiling water 8 oz., sat. sol. cbl. lime 1 drop. Filter cold.

Bicarbonate do.—Chl. gold 1 gr., bicarb. soda 3 grs., water 8 oz.

Fixing Bath.—Sodium hypo. 4 oz., water 1 pint, liq. ammon. 30 drops.

Reducer for Deep Prints.—Cyan. potass. 5 grs., liq. ammon. 5 drops. water 1 pint.

Sensitizing Bath for Carbon Tissue.—Bichromate potash 1½ oz., water 30 oz., ammonia 1 dr., methylated spirit 4 oz.

Enamel Collodion.—Tough pyroxyline 120 grs., methylated alcohol 10 oz., ether 10 oz., castor oil 20 drops.

Mountant.—1. Fresh solution of best white gum. 2. Fresh starch.

Collotypic Substratum.—Soluble glass 3 parts, white of egg 7 parts, water 10 parts.

Collotypic Sensitive Coating.—Bichromate potash ½ oz., gelatine 2½ oz., water 22 oz.

Collotypic Etching Fluid.—Glycerine 150 parts, ammonia 50 parts, saltpetre 5 parts, water 25 parts.

Printing on Fabric.—Remove all dressing from fabric by boiling in water containing a little potash, dry, and albumenize with ammonium chloride 2 grammes, water 250 cubic cents., and the white of 2 eggs, all being well beaten together. A 70-grain silver bath is used, and the remaining operations are as for paper.

Cyanotype Printing.—Water 1 oz., red prussiate of potash (ferricyanide) 1 dr., ammonio citrate of iron 1 dr. Prepare and preserve in the dark. Float the paper and dry. Fixation by mere soaking in water.

VARIOUS.

Luckardt's Retouching Varnish.—Alcohol 300 parts, sandarac 50 parts, camphor 5 parts, castor oil 10 parts, Venice turpentine 5 parts.

Matt Varnish.—Sandarac 18 parts, mastic 4 parts, ether 200 parts, benzole 80 to 100 parts.

Encaustic Paste.—Best white wax, in shreds, 1 oz., turpentine 5 oz. dissolve in gentle heat, and apply cold with piece of flannel.

FERROTYPES.

Collodion.—Ammonium iodide 35 grains, cadmium iodide 25 grains cadmium bromide 20 grains, pyroxyline 70 grains, alcohol 5 oz., ether 5 oz.

Bath.—Silver nitrate 1 oz., water 10 oz., nitric acid 1 drop.

Developer.—Ferrous sulphate 1 oz., glac. acetic acid 1 oz., water 16 oz.

Fixing and Varnish.—Same as wet collodion process.

Employment Wanted.

Improver and Assistant.—A. W., *Photo. News* Office.
Lady, to Spot and Colour.—K. S., 82, Claybrook-rd., Fulham.
Printer, first-class, 30.—J. E. Moore, 62, Thornhill-rd., Barnsbury.
Studio Assistant in Country.—F. W., 2, Royal-cres., Weston-super-Mare.
Lady as Improver.—A. G., 5, Heaton-villas, Heaton-rd, Peckham.
Assistant Operator & Retoucher.—H. S., *Photo. News* Office.
Printer, Toner, Vignetter.—H., 42, Lockton-st., Old Ford-rd.
Managing Printer, first-class.—Photo, *Photo. News* Office.
Operator, wet and dry.—C. O., 25, Duke-st., Bloomsbury-sq.
General Assistant, at 25s.—W. W., 13, South-ter, Halton, Hastings.

Employment Offered.

Printer, Vignetter, & Toner.—W. V. Amey, Landport, Portsmouth.
Negative Retoucher (Lady).—Adams & Scanlan, Southampton.
Printer, thoroughly competent.—F. Guy, 70, Patrick-st., Cork.
Lady (for 3 months) to work up.—Lambert, Weston & Son, Folkestone.
Spotter (Lady).—Lambert, Weston, & Son, Folkestone.
Assist. Oper. & Retoucher at 25s.—W. Mountain, 211, Clapham-rd.
Apprentice or Improver, with board.—T. Vipond, Grantham.
Lady of education in quiet business.—E. S., The Studio, Sutton.
Lady Negative Retoucher.—Adams and Scanlan, Southampton.

THE PHOTOGRAPHIC NEWS.

VOL. XXVIII. No. 1351.—*August* 15, 1884.

CONTENTS.

"FULL APERTURE" OF LENSES.

THE "full aperture" of a lens is the largest aperture with which it can be worked to give what is considered a desirable amount of definition in a photograph. Correctly speaking, it is always the diameter of the largest stop used, or of the diaphragm cell: or, if the smallest combination of the lens be smaller than the cell, of that combination. This is, strictly speaking, the "full aperture:" but when we come to take the diameter of the opening of a lens for the purpose of calculating its rapidity, we have in certain cases to take something a little different from this as the aperture. The reason of this is, that in the case, for example, of a double combination lens, the light passing the front combination is somewhat condensed, and therefore a larger quantity of it passes through the diaphragm. This is due to its area alone. We may go over the various forms of lenses most commonly in use by photographers, and indicate what in each of these has to be taken as the "aperture" in calculating the rapidity of the instrument.

The single lens naturally comes first. This lens is never worked with a stop nearly the size of the lens, and when the stop is in front, as is usual, its diameter precisely may be taken as the "aperture." If the diaphragm be behind the lens, a certain correction has to be made which we will mention further on.

In a double combination lens, either of the portrait, rapid, symmetrical, or doublet pattern, if the lenses be of the same size as each other, and the opening of the stop or diaphragm cell be as large as the lenses, the diameter of the front combination is the aperture. When, however, the front lens is larger than the stop, or than the back combination, a correction has to be made.

There is a very neat mechanical or graphic method of doing this, which is, if we mistake not, due to the ingenuity of the late Mr. Dallmeyer.

The lens to be tested, and the camera, are placed in front of the window of a room which can be darkened by closing the shutters. A distant object is focussed. The focussing screen is replaced by a piece of cardboard in the centre of which is a pinhole. The shutters of the room are now closed, and behind the pinhole—that is to say, outside the camera—is held the flame of a candle. If we now observe the front combination of the lens we will see a circle of it illuminated by the light coming through the pinhole. The diameter of this will be a little greater than that of the stop, and may be taken as the "aperture."

Clever as this method is, it has one or two drawbacks. In the first place, the arrangement of darkened room, and so forth, is somewhat troublesome. In the second, the illumination of the wick is very feeble, and there is considerable difficulty in measuring it with accuracy.

Even a small error in the measurement is serious, as the rapidity of the lens varies as the square of the diameter of the aperture, so that any error in measurement means an error about doubly as great in the final result. There is a very simple method of getting at the correct aperture by calculations which we think will be found useful to many.

The back lens of the combination is unscrewed. The focal length of the front lens is now ascertained. It is not necessary to be very accurate in this; so long as there is no error which forms a considerable fraction of the whole focal length, we are near enough.

We may now state the following sum in proportion. As the focal length of the front lens *less* the distance from the front lens to the diaphragm: the focal length of the front lens:: the diameter of the stop: "aperture." To make this somewhat cumbrous statement plain, we will take an example.

A portrait lens has its two combinations, each 3 inches diameter. The diaphragm cell is $2\frac{1}{2}$ inches diameter. The distance between the front combination and the diaphragm cell is $1\frac{1}{2}$ inch, and the focal length of the front combination is found to be 16 inches. We now have the following:—

$$16-1\tfrac{1}{2} : 16 :: 2\tfrac{1}{2} : \text{"aperture"}$$
$$\text{or } 14{\cdot}5 : 16 :: 2{\cdot}5 : 2{\cdot}75$$

Therefore the "aperture" is to be taken as 2·15, or $2\frac{3}{4}$ ins. Here it will be seen that the correction is by no means inconsiderable, the ratio of the squares of 2·5 and 2·75 being somewhat greater than that of 5 to 6.

It might happen that on performing the following calculation we got a figure greater than that of the diameter of the front lens. This indicates that in spite of the fact that the fixed stop is a little smaller than the front lens in diameter, the latter is nevertheless to be taken as the aperture.

If the back lens is smaller than the front lens, the calculation is made in the manner just described, except that for diameter of stop we take diameter of back of lens; for "distance from front lens to diaphragm" we take distance from front lens to back lens.

This method is useful in calculating the rapidity of lenses of the orthoscopic pattern, and in these it will be found that the correction to be made is very considerable. The reason for this is, that in the first place there is a considerable distance between the lenses, and in the second place the front lens is a very powerful condensing one. In fact, it is of less focal length than is the whole combination, the back lens being of the dispersing nature, and partly counteracting the front one.

In triplet lenses, the diameter of the centre lens is taken for the diameter of the stop, and the distance from the front to the central lens is taken for the distance from the front lens to the stop.

As we have already said, it is necessary to make a correction even in the case of a single lens if the stop be used behind instead of in front of the lens. In this case, the correction is made precisely as for a double combination lens,

the single lens being of course considered as the front lens of the combination.

We may say that for practical purposes the only lenses in which it is necessary to make the correction are the portrait lens, the orthoscopic, and possibly the rapid rectilinear and symmetrical.

Tables have been given in our columns for calculating the diameters of stops of lenses according to the Parent Society's standard, the focal length being given. Here, too, it is, however, necessary to make a correction in the case of double combination lenses. To be correct, the stops must be cut as for a lens of somewhat shorter focal length than is the one we are actually cutting them for. To get the exact allowance to make, we may take the following proportions.

As the focal length of the front combination : the focal length of the front combination *less* the distance from the front lens to the diaphragm : : the actual focal length of the combination : the focal length from which to calculate the diameters of stops.

To revert again to our example, if a lens 3 inches diameter with front lens 16 inch focus, and with 1½ inch distance between the front lens and the stop, let us take the equivalent focal length of the combination at 11 inches, we now have the following :—

16 : 14½ : : 11 : the focal length from which to calculate the diameters of stops.

Or, 16 : 14·5 : : 11 : 10.

The last figure is not precisely correct, but it is very nearly so.

In the case we have taken, then, instead of calculating our standard diaphragms for the correct focal length of the lens—that is, 11 inches—we calculate them as for a lens of only 10 inches diameter.

ISOCHROMATIC GELATINE PLATES.

It is very interesting to note how much attention is now being given to the problem of reproducing coloured objects with the proper gradations of intensity by means of stained plates, and the circumstance that there is a constantly increasing demand for good photographic reproductions of paintings is doubtless one reason why so many persons are now engaged in working out the difficult problems of isochromatic photography.

It will be remembered that a short time ago (present volume, p. 327 and 370) we gave some particulars as to the experience of Professor Lohse, of Potsdam Observatory, with turmeric as a staining material for gelatine films, and it is interesting to take note of some more recent investigations made with yellow colouring matters by Dr. Lohse.

The following materials were tried among others. Orthonitrophenol, orthonitraniline, paranitraniline, metanitraniline, thymochinone, chrysophanic acid, quercitrine, diamidobenzole, hydrochlorate of diamidobenzole, amidoazobenzole, hydrochlorate of amidoazobenoole, nitrosodi methylanaline, picramic acid, Martin's yellow, and nitrate of chrysaniline.

In each case ·02 gramme of the colouring matter was dissolved in a hundred cubic centimetres of water, and ten per cent. of ammonia was added ; the plates being soaked in this solution and dried.

The results were very diverse, some of these reagents having no perceptible influence, and others, perhaps, a very lessening action on the colour sensitiveness ; but the only two that showed a more decided action than eosine were the hydrochlorate of diamidobenzole and nitrate of chrysaniline. These substances are very notably active in bringing out the green and the yellow prominently, so that in the photographs of the solar spectrum produced on plates treated with these, a second maximum of action is noticeable between the Fraunhofer's lines D and *b*. Near F, but a little towards G, is a locality of feeble action as in the case of eosine.

The nitrate of chrysaniline in conjunction with ammonia seems to exalt the sensitiveness of bromide of silver generally, and for this reason it may be well to add a trace of nitrate of chrysaniline to emulsions prepared with ammonia.

The difficulty of determining how far the action of those substances which render sensitive surfaces more suitable for the reproduction of coloured objects is a chemical action, or how far it is physical or optical (that is to say, depending on colour alone), is considerable, and one can only hope to arrive at a satisfactory solution of this problem by laborious and careful work. Indeed, it is by no means improbable that in certain cases there may be both optical and chemical action ; perhaps in cases when the most perfect isochromatism is obtained both these conduce to the result ; but it is easy to imagine instances in which the chemical and optical action of a dye stuff may be contrary, and the difference alone tells as effective result.

It is satisfactory to know that the most distinguished photographic investigators are now labouring in their endeavours to throw light on the problem of properly reproducing coloured objects in the monochrome of the photograph, and one may expect that before long very much light will be cast upon the matter.

Surely it would be by no means an ill use of a portion of the funds of the Royal Academy of Arts to promote a thorough investigation of the conditions under which paintings and analogous subjects can be best photographed ; and art in this country would certainly be much popularised if a really good photograph of every important picture in the national collections could be purchased at a small advance on the actual cost of production.

DEATH OF MR. C. JABEZ HUGHES.

Another of those names which have long been familiar to every photographer is now added to the long list of those who have gone ; Jabez Hughes having died on Monday, the 11th instant, at three o'clock in the morning. Mr. Hughes had been seriously ailing since the beginning of the year, and about a month ago he went to Harrogate for the benefit of his health ; but he returned home a fortnight since, being so weak that he had to be carried from the train. After this he kept his bed until the time of his death.

The immediate cause of his death was weak action of the heart, but both bronchitis and dropsy had served to bring him down. Mr. Hughes was between sixty and seventy years of age, and he commenced his photographic career about forty years ago, when he assisted Mr. J. E. Mayall at his studio in the Strand, near Lowther Arcade. Subsequently to this, he established himself as a photographer in Glasgow, and afterwards he returend to London, and established himself in the Strand.

In 1859 he removed to Oxford Street, and three years afterwards he took Lacey's Studio in Ryde, Isle-of-Wight, and Mr. Werge succeeded to the London business. At Ryde he soon rebuilt the old premises, and the fact of the Queen very frequently commissioning him to do photographic work for her served to make his establishment much frequented. During the last few years, almost the whole of the work turned out from the Ryde Studio was in carbon, a circumstance which adds much to the value of the work done.

Mr. Hughes was a very regular attendant at the meetings of the Photographic Societies, and he identified himself very actively with the work of the Photographic Society of Great Britain, he being a member of the council. He took the chair at the first meeting of the Photographic Club ; and he also presided at the last meeting which was held in the old quarters at Ashley's Hotel.

During the past quarter of a century Mr. Hughes kept up a constant succession of papers which he communicated to the Photographic News and to the societies; and it is interesting to note that in a paper which appeared in our volume for 1860 he referred in dicided terms to the possible advantages to be realised by using chloride of silver in conjunction with iodide when a latent image is to developed.

The funeral took place yesterday at Abney Park Cemetery, many faces well known in the Photographic world being recognizable among those present.

Practical Papers for Beginners.

No. 5.—MORE ABOUT EXPOSURE.

Making and Graduating Stops according to the Standard of the Photographic Society.

We may now suppose that the beginner has gained some notion as to exposure, but up to the present he has worked exclusively with tolerably small stops; and the next step is to consider how far exposure is to be modified when larger stops are used, and the light is unusually bright. Of course a change either in the direction of brighter light or of a larger stop means a possibility of giving a shorter exposure, and under favourable circumstances it will become easy to work so quickly as to obtain good representations of moving objects—the so-called instantaneous photographs. When the atmosphere is clear, and a few light fleecy clouds are visible here and there, is a good time for a first attempt at instantaneous work, and it may now and again be possible to work with the small stop previously employed, but generally a larger stop will be essential. Now the amount of light admitted through the lens by various stops is proportioual to the squares of the diameters of the stops, and the exposures are inversely as these numbers. If, for example, we have a series of stops having apertures one-eighth of an inch, a quarter of an inch, half an inch, and one inch respectively, the proportion of light admitted by them will be as follows, and the relative exposures required are shown in the last column, the amount of light passed by the one-eighth stop being taken as unity: —

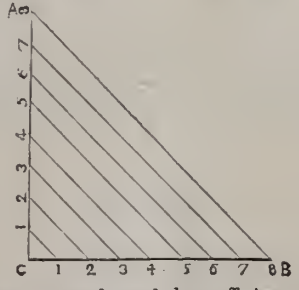
Diameter of opening of stop in eighths of an inch.	Relative amount of light passed by each stop.	Relative time of exposure require
1	1	1
2	4	$\frac{1}{4}$-th
4	16	$\frac{1}{16}$th
8	64	$\frac{1}{64}$th

The numbers in the second column are merely the squares of those in the first column, the squares being obtained by multiplying each number by itself; and a glance at the above brief table will show how the required exposure shortens very rapidly with the increasing diameter of the stop.

The Photographic Society of Great Britain has recommended that all stops should be marked according to the relative exposure required when they are used, a very excellent system, and probably before long opticians will adopt the plan of so making the stops. As a standard, the Photographic Society adopts for unity the stop having a diameter equal to one-fourth the focal length of the lens, this being the largest stop which is likely to be used, unless on quite exceptional occasions, and this is marked No. 1. Now it must be understood that all lenses are assumed to act with approximately the same rapidity when stopped down to the same fraction of their focal length, and although this is not absolutely true, it is sufficiently near the truth for most practical purposes, so that with the standard No. 1 stop (having a diameter equal to one-fourth the focus of the lens), the exposure will be approximately equal, whatever lens is employed. Stop No. 64, according to the standard of the Photographic Society, will have a diameter equal to one-thirtieth second of the focus of the lens, and will require an exposure 64 times as long as would be given with No. 1 stop. It is quite obvious that there are considerable advantages in numbering all stops according to a uniform system, as this plan makes the experience gained with one lens available with other lenses, and tends much to diminish the difficulty of becoming proficient in making correct exposures; but it is quite unnecessary to be provided with a stop corresponding to every number in the imaginary series, as the accuracy with which photographic exposures can ordinarily be made is not sufficient for there to be any need for two stops so near together as, let us say, 64 and 60. We will therefore assume that starting with No. 1 the following series is to be constructed: 1, 2, 4, 8, 16, 32, 64, 128, and 256; these being abundantly sufficient for all ordinary work.

We will suppose that the beginner wishes to construct standard stops for his lenses, and that he is provided with some thin black card, thin sheet ebonite, or metal plate for making them, and, moreover, that he has the means of cutting out holes of any required size. Ferrotype plate, by-the-bye, is an excellent material; but the newly-cut edges of the aperture must be blackened.

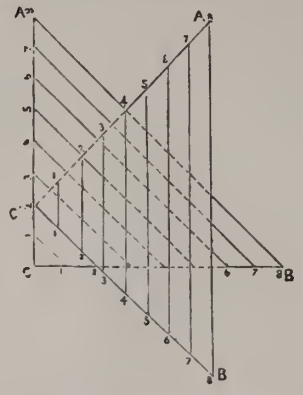
First determine the focus of the lens, this being done with sufficient accuracy by focussing some distant object, and then measuring the distance from the ground surface to the centre of the lens if a single one, or to the plane of the diaphragm if the lens is a doublet, one-fourth of this is the diameter of No. 1 stop; but it may be found that so large a stop cannot be used, and the next step is to determine the size of No. 2, or the stop requiring double the exposure of No. 1; and, again, from this, the size of No. 4 stop, or that requiring double the exposure of No. 2, and so on. The diameter of each member of the series recommended above will be to the preceding one as the square root of 2 (1·41) is to 1; and by taking advantage of the Pythagorean problem in Euclid's "Geometry," where it is demonstrated that the hypothenuse of a right-angled triangle is to either remaining side as the square root of 2 is to 1, it is easy to find a simple graphic method of setting out the size of the stops. This excellent method was recommended by Mr. Wilmer in our volume for 1881.



Take a piece of card, and lay off two lines at right angles to each other, and from the point of intersection, C, mark off equal divisions on the lines C A and C B, number the divisions horizontally and vertically, making the zero of the scale at C as shown, and join the corresponding points so obtained by diagonal lines, as indicated in the diagram. No. 1 stop ($\frac{1}{4}$) having been chosen to start with, is measured on the diagonal portion of the scale, let us suppose from 4 to 4; the distance from 4 to zero (C) will then be the diameter of the next stop, or No. 2. In the same way the diameter of No. 2 is set off on the diagonal scale (let us suppose from 3 to 3), and the distance from the scale point indicated, to zero, is the diameter of the next stop, No. 4 (or that involving double the exposure of that required with No. 2).

The diagonal lines are not absolutely essential, neither is it a strict necessity to have the figures on those sides of the triangle which are at right angles with each other; but the lines and figures are convenient, as enabling one

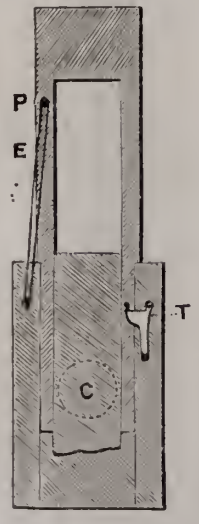
to make sure, that when setting out, the diameter of a stop on the diagonal, the distance from C is the same on the horizontal side of the triangle and on the vertical side. Mr. Wilmer recommends it as convenient to use two identical scales as in the next figure.



The diameter of the largest stop having been measured off on the diagonal of one scale, this first scale is so placed that the diameter of the next smaller stop, as indicated on one of those sides forming the right angle, can be measured off directly on the diagonal of the other scale; so that the reading of the third stop of the series is obtained at once.

Owing to the mechanical arrangement of many lenses, especially those with rotating diaphragm plates, it is not practicable for one who is not a skilled mechanic to replace them by others, and in such a case the best way is to set out the diameter of such a series as we have alluded to (1, 2, 4, 8, 16, 32, 64, 128, 256), and either to note how nearly the existing stops correspond to them, or to reamer out the apertures so as to make them to correspond.

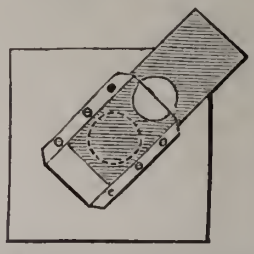
Unless the beginner has made himself very proficient in the use of the cap or of the Vogel sleeve (p. 435), he will do well to provide himself with some sort of a quick or so-called "instantaneous" shutter before taking the camera and a supply of dry plates out on an expedition away from home; and if he does take out an instantaneous shutter, it is very questionable whether he can do better than to take out the simple drop shutter, with the addition of a rubber band to somewhat quicken the exposure in case of need. The form represented below can be



fitted over the mount of the lens, and it is neither complex nor expensive. Of this form Captain Abney says:—

"The form, as will be seen, is a drop shutter, the aperture of which can be shortened by a sliding piece of ebonite. The opening for fixing on the lens is shown by the dotted circle, C. The total opening that can be given to the drop is six inches. At one side is a pin to which is secured a loop of elastic, E, which, when the shutter is ready for action, can be caught up by a pin, P. When the trigger, T, is withdrawn, the elastic causes the aperture to pass rapidly over the circle, C. By adopting this plan the full aperture of the lens is used during nearly the whole time of exposure, hence there is more light than when the length of opening is shorter, and where it drops by its own weight. This shutter can, however, be used to drop by its own weight by making the length of opening only four inches; it then begins to fall two inches above C, and the total length of exposure is then the same as if the drop commenced just above the opening of the lens with an aperture of two inches. By this plan, though the time of exposure is the same as in the last case, the total light admitted is increased by at least one-half, which is an important point."

When it is desired to make the action of a drop shutter slower, it can be turned round on the mouth of the lens so that it slides down obliquely, and in this way an exposure of a second or more may be given.



Of the methods which have been recommended for rapidly estimating the intensity of the light out of doors, we can recommend none to the beginner, but suggest he should trust to experience and observation: and it must not be forgotten that the subject has much to do with the exposure required. Water or sea scenes require, for example, much less exposure than deep-tinted foliage.

The success of the amateur photographer out in the field will depend much on his artistic perceptions, and it is not possible to give such directions as shall infuse the power of artistic perception into the would-be photographer; but we may mention that it is generally desirable to avoid having any prominent object very near to the camera, and the camera should not, as a rule, be so placed that the sun shines directly on either its front or back. During exposure the lens ought to be shaded when possible (an umbrella answering admirably), and when short (instantaneous) exposures are attempted, there should be no rapidly moving objects passing *across* the field of view in the immediate foreground. The effect of haze or smoke is generally exaggerated by the camera, a circumstance which should be remembered, as a little haze in the distance often improves a picture much, while more damages it. In gusty weather one must often wait for a lull before making the exposure, and it is often an excellent plan to hang a bag or net from the tripod top, the bag being quite close to the ground and filled with stones. Dark slides must be exposed to intense light as little as possible, as the thin wood used in making them is by no means absolutely impervious to light.

Careful notes should be taken of the condition under which each plate is exposed, and the beginner may be expected to return with his slides loaded with plates, some over-exposed, others under-exposed, and, we will hope, many which have had a correct exposure.

Notes on developing such a mixed collection must stand over until next week.

Formula . . tan ½ angle × focus × 2 = base line.

For lenses of foci containing fractional numbers, multiply figures in column headed Diff., and on same line as the angle of view, by the numerator of the fraction, and divide by denominator, adding the result to that previously ascertained for the whole number.

Example.—Required base line of picture enclosed by an angle of 65°, focus of lens being 8⅔″.

Opposite 65° and under 8, will be found base line for 8″ = ... 10·19

On the same line will be found Diff.=1·274 which ×2 ÷ 3= ... ... ·51 nearly.

Size of picture ... ... 10·70 ins.

Note.—The angle obtained on a plate twice the length of the focus is... .. .. 90°

Ditto	ditto	1¾	ditto	82
Ditto	ditto	1½ times	ditto	74
Ditto	ditto	1¼ „	ditto	64
Ditto	ditto	same as	ditto	53
Ditto	ditto	⅔	ditto	37
tto	ditto	½	ditto	28
Ditto	ditto	⅓	ditto	19

When the focus of a lens is doubled, the angle remaining the same, the size of the resulting picture is doubled likewise.

The base line and equivalent focus being known, the angle of view is equal to

$$2\left(\tan \frac{\frac{1}{2}\text{ base line}}{\text{equi focus}}\right)$$

Example.—Wanted, the angle of view subtended by a base line of 10 ins., focus of lens being 7 ins. Half base line divided by 7 = ·71428, &c. On referring to a table of natural sines and tangents, we find in the column of tangents the number ·71417, &c., the nearest to the above; and opposite to this the number of minutes (32), the degrees (35) being given at the head of the page. The result—

$$35°\cdot32'\times2=71°$$

is the angle required.

The angle can be ascertained by diagram as follows:—Draw a line of exactly half the length of the base line, erect at one extremity a perpendicular equal in length to the focus, join the extremities of the two lines by a third. The angle included between the diagonal and the perpendicular, multiplied by 2, is the angle of view.

For distance of camera from nearest object in foreground to include a certain view, as longest side of plate is to equivalent focus of lens, so is base line of view to distance of camera.

Example.—The focus of a lens is 10½ ins., effective size of plate 7 ins. Two objects in the foreground, the

boundaries of the views are 13 yards apart. At what distance should the camera be placed in order to include the view within the given 7 ins. ?

f=10·50ins. =focus.
p=7·00ins.=plate. $p : f :: b$: dist.
b=468·60=boundary of view. $\frac{468 \times 10{\cdot}50}{7}$=702 ins. or (say) 19 yards.

THE ETCHING PROCESS FOR RELIEF AND *INTAGLIO* PRINTING, DECORATION OF CHINA, ETC.

BY GEO. G. ROCKWOOD.*

On a recent occasion I brought to the notice of the Photographic Section of the American Institute a process which I had introduced and practised for the decoration of china or stone-ware by the aid of photography. The process as then outlined was as follows, and is taken from the report of the meeting :—

"What is known as printed ware, formerly in common use, and now being reintroduced, was decorated by a process of 'offset,' so to speak, from impressions made from engraved copper plates. The design for a dinner set was first drawn by an artist, and then engraved in *intaglio* on large copper plates, costing from six to a hundred guineas, depending, of course, upon the elaborateness of the design. When these copper plates were engraved, they were filled with a mineral pigment ink of any desired colour for the design. Soft paper made for the purpose was pressed upon the plate, and the ink printed on the paper in the same manner as in ordinary copper-plate printing. These sheets were trimmed and cut into the desired forms, and then applied to the ware while in the bisque or unglazed condition. The paper was then removed, leaving the picture or design upon the dish, after which the glaze was applied. It occurred to Mr. Rockwood that by reversing the action of photo-engraving or etching process, these expensive plates could be produced by our art. Securing a 'line subject,' he first made a negative, and from it a positive on glass. He then coated a smooth sheet of zinc with bichromated albumen, and exposed the plate under the positive. It was of course apparent that, when inked up, the parts unaffected by the light would be washed off by the water, and that the lines of the image would be bare instead of being covered as when printed with a negative. When etched, the lines only were attacked, and they formed an image in intaglio, or below the surface, instead of being in relief. This plate, upon being filled with the pigmented ink, served the purpose in every way as well as the engraved plates. As zinc would not retain heat—a necessary condition in a stage of the printing—he tried the same experiment with a copper plate, and secured at a trifling expense very delicate designs which would have cost a large sum to engrave. He next exhibited a tea plate with a humorous design on it, and also the zinc plate from which the picture was printed, remarking that any gentleman desirous of experimenting in this line would be furnished further information, if desired, as he had no idea of pateuting the process, if patentable."

In reponse to the invitation extended I received a large number of letters, the answers to which are herein given :

To cover the ground touched upon in this correspondence, it is necessary to explain the whole process of photo-etching on zinc or copper. I shall at first attempt to make plain the process for relief printing for press work, and then the intaglio or sunken lines for artistic decoration.

The glass should be treated with nitric acid (and potash when using old glass) in the usual manner, but not albumenized, as the film or negative in one stage of the process has to be stripped from the glass in order to obtain a reverse image. When the glass is perfectly clean and dry, a solution of the finest talc or French chalk should be flowed upon the plate.

Talc solution is made of one ounce of talc and eight ounces of alcohol. This should be gently rubbed off with canton flannel ; enough will remain on to cause the film to leave the glass after the negative is made.

Preliminary rubber coating.—When prepared with talc, cover the edge of the glass to the width of a quarter of an inch with rubber solution made as follows :—

Benzine	8 ounces
Rubber cement	½ ounce

The cement may be obtained of the rubber companies at a cost of 25 cents a can. It readily dissolves in the benzine, and is best applied with a brush.

The glass being in order, we next need a collodion which will give vigorous results. This is made as follow :—

Collodion for Black and White Negatives.

Ether	1 ounce
Alcohol	1 „
Iodide of ammonia	5 grains
Bromide cadmium	1 grain
Cotton, 7 grains to the ounce	

The silver bath must be 45 to 50 grains to the ounce of water, and strongly acid to test-paper in five seconds—nitric acid, C. P.

The Developer.

Protosulphate of iron	15 grains
Water	1 ounce
Acetic acid, 1½ ounces to 20 of solution	

The exposure should be only long enough to bring out the fine lines—a rule always to be regarded—as they are the most difficult to preserve.

The development should be stopped the instant the details are well up, and the plate cleared with a weak solution of cyanide of potassium, after which it must be thoroughly washed.

The washing of the negative at this and at all subsequent stages of the intensification is very important. There should not be a trace of the fixing solution remaining in the film when the next solution is applied.

The bleaching is accomplished by a solutiou of—

Sulphate of copper	30 grains
Bromide of potassium	30 „
Water	1 ounce

It can be used as a dipping bath, but is generally poured on and off till the film becomes opalescent. Wash again, and allow the water to cover the plate well. A "rose" or shower spout is best. Constantly move the plate till thoroughly washed ; then,

Blacken by pouring over the entire plate a solution of :—

Pure nitrate of silver (not bath) ...	30 grains
Water	1 ounce

Ordinarily the negative is sufficiently intense ; if not, repeat the bleaching and blacking (constantly looking after the washing). If thin, the plate is probably under-exposed ; if thick, with tendency to closed lines, the plate has been over-timed. If the lines are perfectly clear, and more density is required in the whites, make a solution of hydrosulphuret of ammonia 1 ounce, and water 1 ounce, and flow over the plate. Wash again thoroughly. When dry flow with the rubber solution, and let that also dry.

Stripping plates. When dry, flow with collodion made as follows :—

Alcohol	10 ounces
Ether	10 „
Cotton (10 grains to ounce) ...	180 grains
Castor oil (5 drops to ounce)	102 drops

Let dry, which will take four or five hours if done spontaneously, which is the best. It can be hastened by heat. Then, with a sharp knife, cut around the edge of the plate inside of the india-rubber safety edge, and set in a tray of acidulated water. In a few moments the film will loosen. Gently take it by the corners and reverse it on another clean plate which has been placed in the water. When in place, carefully lift the plate out of water and squeegee it into perfect contact, removing all bubbles. When dry, which can be accelerated by heat, it is ready to print on the zinc for relief plates.

For intaglio plates the stripping can be omitted, and reverse positives can be made in the camera by working through the negative. The positives should be made black and white, in the same manner as the negatives. Negatives from which positives are to be made need not be as intense as when they are to be used for printing upon the zinc.

To continue the process for relief printing we use the reversed negative which has been described.

The zinc for etching purposes may vary in thickness with the subjects to be reproduced. Coarse or outline subjects require deeper etching and thicker plates ; fine, close subjects may, of course, be put upon thinner plates. The metal is now rolled by the manufacturer of the proper thickness and of any size that may be required. It is also sometimes obtained with such an excellent surface as to leave but little to be desired. In establishments where the process is worked commercially a planer

* Communicated to *Anthony's Bulletin.*

is necessary, and powerful presses for bringing large sheets to a perfect plane. The experimenter will, however, find but little difficulty in getting small sheets with small surface and proper plane. Slight imperfections and inequalities may be removed with Scotch stone. A specially good charcoal may be had, which gives the plate an excellent polish. The zinc being prepared, it receives a tooth and an admirable surface by a short preliminary etching in the acid bath.

The sensitive surface is obtained by bichromated albumen. Either fresh eggs may be used, or the dried albumen of commerce. We found the latter to work more uniformly in the various seasons. Where the latter is not at hand we found the former can be used in these proportions:—

Albumen (free from yolk)	4 ounces
Water	1 ounce
Bichromate of potash	30 to 40 grains

The dry albumen can be used as follows:—

Dry albumen	1 ounce
Water	6 ounces
Bichromate, as before	

Either solution should be carefully filtered through paper, and a few drops of ammonia added. When not in use, keep carefully corked and away from the light. It is best to prepare it frequently for use rather than retain the solution long on hand. Now secure some form of rotating disc upon which the zinc plate can be secured. We inverted a Yankee egg-beater, and upon the end adjusted a flat piece of wood in which were catches or buttons which held the zinc plate in its place and always horizontally. Carefully cover the zinc plate with the solution, drawing it to the corners with a piece of paper or a clean finger.

When completely covered, pour off into a different vessel to be filtered before use again. Now place the coated zinc plate upon the rotating table and begin slowly to revolve the plate; then increase the speed until the coating has by centrifugal force left but a thin even coating on the surface of the zinc. Remove the plate, and with a gentle heat (from 100° to 120°) dry the surface. Too much heat destroys the film. So soon as dry let the plate cool to ordinary temperature, when it is exposed under the negative. The time of exposure must be ascertained by experiment, a clear open line negative printing very quickly.

The printing press should be very strong, with four or five strong back strips which have powerful wood or metal hand-screws running down to the back-board of the printing-press, by which perfect contact can be assured. It is needless to say that the front glass of the printing press should be very thick and of plate glass. Three-quarters of an inch in thickness is about the right thing.

After the exposure the plate should be rolled with a very thin but even coating of lithographic ink softened and worked down in oil of lavender. The ink is best applied with a fine lithographic roller, though small plates may be covered with a "proof" dabber, such as is used by engravers for inking their blocks.

The development is quickly and easily accomplished in a pan of water—some prefer it slightly acid—and a soft tuft of cotton. By gently rubbing the surface, all of the zinc plate which has been protected from the action of light washes away, leaving the image in black lines upon a clear and bright surface. If the surface refuses to clear it would indicate over-printing; if the lines wash away it signifies that the exposure has been too short.

We now have an image on the zinc surface which is covered with a fatty ink, and which will resist in a measure the action of the acid. If the subject is pretty close, a brief etching may be given it in weak nitric acid.

The etching bath is made of nitric acid 1 ounce, water 6 to 8 ounces. The strength of the acid varies with the subject and the progress of the work. Weak acid is used at first in all cases. If the subject is close and fine, the etching solution should be kept weak, and the etching proceed slowly in order to keep the lines intact, and for the reason that such subjects do not require deep etching. In open subjects and coarse lines the work may progress more rapidly after the first etching. The lines would be quickly "cut under" if no other precaution was used to preserve them. So, after the first etching, the plate is washed off in clean water, and placed on a sheet of planed iron, under which is a series of Bunsen burners, and brought to a strong heat, and dried. It is now cooled to the temperature of 80° or 90° F., and placed in a tray containing finely-powdered resin or dragon's blood. This substance is gently brushed over the plate with soft, broad brushes. A small quantity adheres to the lines, when the plate is returned to the hot table, and brought to such a temperature as will melt the gum employed. This operation of cooling and brushing the resin over the plate is often repeated by careful workmen three or four times before exposing the plate to the action of the etching bath. When the lines have been thus covered, the plate is placed in the etching bath, and the latter kept in constant motion by rocking. The baths are usually suspended on pivots or arms, in order to receive this rocking motion. This second etching goes quite rapidly with an increase in the quantity of acid. The image already stands out in strong relief, and if a copy of a steel engraving or other close, well-covered design, the relief is sufficient. If not, and there are large patches of white with considerable open work, the heating and application of the protecting gum is repeated once or twice more. When the etching is complete, a little turpentine will remove the plate clean, and in order for printing, after blocking and routing. Before etching at all, the back and edges of the zinc plate should be painted with a good thick coat of asphaltum varnish. This obviously will prevent the etching fluid from dissolving the zinc. The same material (asphaltum) can be used to cover such portions of the plate as may be fully etched, and a necessity still exists for further etching in other parts of the plate.

We have thus gone through with the relief process. We will now briefly discuss the *intaglio* (or sunken line) plate, from which we get our "offsetts" for decorative purposes. Going back to the negative, we find that the film does not require to be stripped or reversed. After a good, strong black and white negative is secured, it is placed in a copying box, face outwards, and copied precisely as we would make a stereopticon slide or other transparency. This gives a reversed positive. The same care should be taken to preserve the background clear and the lines opaque, as already suggested while making the stripping negative for the relief process. The after stages are precisely the same up to the point of etching. It will be seen that while in the relief process we had an image of black lines on a polished metal surface, we now have the reverse, the lines being white, clean metal against a black ground.

In almost all cases of engraved or *intaglio* plates, a single etching, and that a very brief one, is quite sufficient. Some use for this purpose, especially with copper, the perchloride of iron dissolved in strong alcohol—one part by weight of the former to two parts by measure of the latter—or perchloride of iron 100 grams, alcohol 200 grams.

To make the distinction clear as between relief and *intaglio* an

example of the latter, used in the decoration of some china, is given above.

Etching Trays.—As metal pans will not do for etching purposes, wooden trays should be made of the proper size, and lined with—

Common brown resin	½ pound
Bees'-wax...	2 ounces

Melt these together in a tin pan; when quite fluid, run the solution rapidly where required. The wood should be perfectly dry. If lumps appear, apply a hot smoothing iron to level them.

NOTE.—Since preparing the above, I find in the photographic journals,* a very interesting and illustrated article by Mr. S. H. Horgan, entitled "Photography and the Newspapers," in which he briefly describes various processes, and by diagrams shows admirably the various steps towards their production.—G. G. R.

Notes.

The view of Constantine which we issue as a supplement this week gives a good general idea of the city, mounted, as it is, high on its rocky eminence; and next week we shall publish a very characteristic picture which Mr. Pritchard obtained in one of the by-streets of the Arab quarter.

Photography has of course often found its way into the Board-room ere this; but the other day, at the meeting of a well-known railway company, the chairman laid upon the table, for inspection of the shareholders present, several photographs of new locomotives and other improved rolling stock, with views of a bridge of more than usual importance which had been completed during the past half-year. The evidences of advancement thus furnished were accepted by the meeting with much satisfaction.

The burnished brass photograph frames now to be seen in the stationers' windows are the latest novelty, it may be presumed, in this particular direction. There is a suggestiveness of perpetuity about these frames which it would be well, perhaps, for all photographers to "try to live up to" in their work. A good portrait study—not necessarily a "brazen faced" subject—might then, in fact, in this new metallic surrounding, be considered to be a memorial literally in monumental brass.

A National Portrait Gallery for Scotland may soon be in existence: the offer of £20,000 recently made by an anonymous donor becoming void, unless some action is taken before the first of next month. Government proposes to give £5,000 towards a site.

A portrait gallery in the old sense of the expression means a collection of paintings; but may one not expect that some day a collection of photographs will be regarded as being far more valuable from an historical point of view than any collection of paintings can be?

At any rate, photographs should be secured in all cases where practicable, and added to the collection—certainly not silver prints, but rather carbon prints made to a uniform size, say 48 to 36 inches.

A burnt-in or enamel photograph of each portrait might be made, let us suppose on a tile five or six inches square, and these ceramic pictures should be stored in a fireproof vault.

Although fireproof in one sense, a photograph on porcelain cannot be expected to pass unscathed through an ordinary fire in a building, therefore a fireproof room would be necessary.

Crude and clumsy as is the recent endeavour of the authorities of the National Gallery to make some use of photography for the multiplication of the national art treasures, it at any rate shows that they have a vague idea of the importance of the matter, and it is to be hoped that they will soon realise the fact that the hideous structure of galvanised iron with which they have disfigured Trafalgar Square is altogether unsuited for the copying of paintings—although, perhaps, more or less adapted for making sixpenny ferrotype portraits. They may then be disposed to take capable advice on photographic matters, and adopt means for overcoming the exceptional difficulties which attend the reproduction of paintings by the camera. Certainly, when a good negative is secured of a picture, a ceramic photograph should be made and stored in a safe place.

M. Pedrono has it that some persons can in a certain sense recognise a colour in sound—that is to say, sounds produce a certain luminous effect on the optic nerve; but, to do this, the sounds must rise above a definite minimum of intensity. Among those to whom sounds appear to produce coloured impressions, he has found a uniformity of experience which leads him to regard the phenomenon as truly objective, rather than subjective.

The character or stamp of the sound determines the colour rather than the pitch or truly musical value, a tune executed on a saxophone or an harmonium recalling red, while the same music performed on a clarionet recalls blue. If there is even what Herbert Spencer calls a *soul of truth* in this matter, it is worthy of being thoroughly investigated.

Those who, hearing by chance of the invention of a new process known as Phytochromotypy, may have imagined it a rival to photography, will be relieved to hear that it is only a new way of producing impressions of leaves of plants. It also produces an impression, on the minds of those who read the details of the process, that the game is hardly worth the candle.

Amongst the numerous methods adopted in the States to push the candidates for the Presidency, Mr. Blaine's friends have hit upon the notion of distributing packs of playing cards, on the back of each of which is a photograph of the republican nominee. And now it seems Governor Cleveland's backers are taking steps to follow suit in the new card game—a game, by the way, which the playing card manufacturers hope both parties will continue to play at.

"Is the celebration or inauguration of the Daguerre Monument at Corneilles to be an annual ceremony?" may be asked. We recorded it last autumn, and it took place

* "PHOTOGRAPHIC NEWS," 1881, p. 427.

again on the 27th ultimo. There was some speech making, M. Letellier taking a prominent part; but justice was hardly done to Niepce, who was unquestionably before Daguerre in the production of a permanent camera photograph.

M. Glaise, the treasurer of the fund, said:—"On peut, Messieurs, associer au nom Daguerre ceux de Nicephore Niepce et de Poitevin, au monument duquel notre Comité s'est fait un devoir et un honneur de souscrire; mais si ces deux grands noms ont aussi leur part de gloire, il est incontestable, aujourd'hui, que Daguerre, l'enfant de votre pays, est celui qui a obtenu le premier résultat cherché: *Fixer, d'une façon durable, l'image vue dans le chambre noire.*

No one seems to have had a word more than this to say for the first inventor of photography, Nicephore Niepce, and Talbot was not even mentioned.

A new phase is gradually creeping into photographic portraiture. We refer to the taking of portraits at the sitter's own home, thus saving the trouble of a visit to the studio. A well-known Parisian photographer makes this branch a speciality, and no doubt finds it pay, since only wealthy people can afford the luxury, the fee charged being necessarily high. The series of photographs in photogravure of "Statesmen at Home," now being prepared by Messrs. Sampson Low and Co., as a pendant to the successful series "Artists at Home," will give a spurt to this kind of thing; and it is quite possible that before long to send for the photographer when one has nothing to do will be an accepted amusement in fashionable circles. Naturally, to be successful in these "At Home" portraits requires special study; but any photographer who identifies himself with this particular branch will not find his time thrown away.

Those who are behind the scenes with regard to that wonderfully developed trade in Christmas cards, know that the wholesale manufacturers are now busily engaged in producing new patterns and notions for the Christmas of 1885. Those for next Christmas have been manufactured and were delivered to wholesale houses months ago. We only allude to these facts in this column to mention that among the novelties for the coming Yuletide, photographic cards will be unusually numerous. The use of views of well-known "Beauty Spots" in the various parts of our islands as Christmas cards will be considerably extended.

One photographic series consists of a number of studies of very pretty and charmingly dressed children, cabinet size; and another contains a number of densely-grouped scenes from well-known novels, such as "Bleak House," "Orley Farm," and "Westward Ho."

It is usual to photograph a prisoner on the completion of his sentence as well as at its commencement, and the "Claimant," whose release will take place in October—the 14th is the day which will restore him to his admirers—has made application to the Directors of Convict Prisons that he may not be photographed before he leaves Portsmouth, but that the operation may be deferred until he arrives at Pentonville, whither he will be transferred just before his discharge.

He gives as a reason for his application, his fear lest if he be taken at Portsmouth the likeness may get in the hands of a local photographer and copies be disposed of, as he asserts once happened at Milbank. If this was indeed the case, it is certain that an irregularity has taken place, and that the "Claimant" has a right to protest against its repetition. Prison photographs are taken for police purposes only, and should on no account be turned to outside use. Mr. "Castro" has special reason to guard against such a breach of prison discipline as he fears, for on his reappearance amongst us he will doubtless find in the sale of his photographs a profitable source of income for a time. Those who possess a carte of him in the days of his corpulent prosperity, ere cross-examination and protracted seclusion played such havoc with his fleshly form, will be anxious to compare that picture with one of the reduced and attenuated "Roger" who will leave Pentonville in two months time; and it would be indeed hard if he should be prevented from reaping the results of the "fining down" of which he has been the subject.

In the course of two or three hours' stroll through the streets of Brussels last week, with an especial eye to the photographs in the shop-windows, we were struck with the almost total absence of photographs of the places of interest. The light is so delightfully pure in Brussels that one would have thought the impulse to seek out and secure instantaneous views of the street scenes would have been irresistible. But no one seems to have done anything of the kind, and the traveller who wishes to secure mementoes of little Paris has to put up with very indifferent specimens.

The latest fashion at French watering places is to be photographed in your bathing dress. If the fashion comes over here, it will give a spurt to the business of the itinerant seaside photographer. It is to be hoped, however, before this comes about that the hideous bathing dress of Margate and elsewhere will be a thing of the past.

It would be interesting to know the exact terms which the much-photographed Mrs. Langtry now makes with photographers. Before proceeding to San Francisco, she sat to an Eastern photographer, binding herself under a heavy penalty not to be taken in San Francisco; and the natural inference is that she was paid by the Eastern photographer, for without some valuable consideration no one would enter into so one-sided a bargain. Mrs. Langtry, while in San Francisco, kept strictly to her agreement, but her portrait nevertheless was taken; for an enterprising photographer sent an assistant to the Yosemite Valley, and secured two instantaneous portraits of the Jersey Lily—one as she was getting into the stage coach, and another as she sat on the hotel verandah.

There is an attempt being made in France to grapple with

the artistic copyright question. So far as photographs are concerned, the initial difficulty has not yet been overcome—that is to say, whether a photograph is, or is not, a work of art; some of the courts of law having decided in the affirmative, and others the reverse. Be this as it may, it is now proposed to protect the photographer, but in a less degree than the painter. Thus there is to be no copyright in photographs for more than five years, none will be protected unless copies have previously been deposited in some public office, and finally, in any case, only such photographs as "show artistic worth" will be entitled to the benefits of the Act. The report of the committee which has investigated the subject fails in one important particular—it does not say how the question of "artistic worth" is to be settled.

The Bill prepared and brought in (not for the first time) by Messrs. Hastings, Hanbury-Tracy, Agnew, Gregory, and Sir Gabriel Goldney, to amend and consolidate the Law of Copyright in works of Fine Art and in Photographs, has, as already stated, been again involved in the usual autumnal "massacre of the innocents." The clauses more specially interesting to photographers were 9, 10, and 17, and their purport has been already stated in these columns.

Mr. Hastings, M.P., fully intends to re-introduce his measure next spring, and he will probably again have the names of the same colleagues on its back; but meanwhile the law as to the copyright of a photograph remains in that curiously unsatisfactory condition that the Master of the Rolls described when he said that, were the existing law carried out to its logical end, the actual copyright of a view taken by natural light would be vested in the very sun itself! What a *cause célèbre* we might have with the Solar Luminary as the plaintiff, and with Phœbus Apollo, say, joined to the suit as *amicus curiæ*.

Now that the tourist season is upon us again, it may be well to remind continental travellers that foreign Customs officials have occasionally prejudiced views, not only as to photographic chemicals and other accessories, in which they of late have persisted in scenting dynamite, but actually resent the undeclared presence in one's portmanteau or hand-bag of anything like large collections of finished photographic views. The French *douane* generally, as we have reason to know, is especially strict as to the latter, and unless the officer in charge at Vintigmilia, on the Riviera frontier, has been lately changed, particularly absurd notions on the subject are current here.

We were returning from a visit to Italy some few years since, and had bought at Naples, Rome, Florence, Genoa, and elswhere, a large selection of the inevitable photographic views of the localities. Well, at Vintigmilia, not thinking that so harmless an indulgence in normal tourist extravagance could in any way bring us into the clutches of the *douane*, we failed to declare the said photographs, the result being that a few minutes later we were being marched off by a gendarme—we have a notion that he drew his sword, the more to overawe us—into the offended presence of the *chef de douane*. Had we been caught red-handed in the act of trying to pass Orsini bombs or tobacco in bulk, that official could not have assumed a more seriously tragic air. The tone in which he dwelt on the enormity of our offence, and enlarged on the *grande amende* to which we had rendered ourselves liable, we shall never, never forget. It seemed to foreshadow detention in some dark and deep local dungeon at the very least; and when ultimately our explanations and apologies were accepted, and we found that we were to be allowed to proceed to Mentone—photographs and all—the reaction was so great that, in our state of relieved tension, we positively treated the gendarme—his sword was sheathed now, however—at the local *buffet*. Moral: Take care to "declare" any photographic views you may carry from one Continental country to another.

Patent Intelligence.

Applications for Letters Patent.

10,950. ALEXANDER HENRY REED, 90, Cannon Street, London, Engineer, for "Certain improvements in photographic cameras." A communication to him from abroad by Calvin Rae Smith, New York, United States, Artist.—Dated 5th August, 1884. (*Complete Specification.*)

10,970. FREDREIC SAFE, Photographer, 28, Grove Road, Holloway, N., London, for "Enamelling (as termed in photography) surface-coloured photographs, whether the same are coloured or painted in water or oil colours."—Dated 6th August, 1884.

Specification published during the week.

3392. T. CARTILE & PARK. "Manufacture of bichromate of soda." *Provisional Specification.*

Our said invention has for its object to obtain bichromate of soda in an anhydrous crystalline form. In carrying out our said invention, we adopt any well-known or suitable process, so far as to obtain the bichromate of soda in the form of a concentrated solution, or in the form of hydrated crystals. We take the concentrated solution, or the solution obtained by heating the hydrated crystals until the salt becomes dissolved in its water of crystallization, and subject the same to heat in any suitable vessel fitted with mechanical agitating or stirring apparatus. We prefer to apply the heat by means of steam admitted to a jacket encasing or surrounding the vessel; but the heat may be applied in any other convenient way, care being taken to have it uniform at all parts of the vessel, and to keep temperature below the fusing point of anhydrous bichromate of soda. Whilst the heat is being applied constant agitation is kept up; and as the water evaporates small anhydrous crystals are formed, the entire mass being ultimately converted into an anhydrous crystalline powder. The final specification gives details as to the evaporating of a solution of bichromate of soda to dryness by the aid of heat or stirring.

7678. A. MCDONALD & T. WILLIAMSON.—"Washing unmounted photographs, &c."—*Provisional Specification.*

A rocking washing trough, the following points being claimed:—

1st. A divided trough with a syphon at, or near, each end in combination with a source of water supply, and a pivoted washing trough in an outer trough or reservoir, substantially as and for the purposes described.

2nd. In a photograph washing apparatus, the pivoted trough suspended in water receptacle having perforated bottom and automatic means for periodically tilting it, whereby the water is caused to rise through the perforations and gently stir up the photographs.

3rd. In a photograph washing apparatus, the application of the constant water supply to first actuate the stirring or shaking mechanism, and then to fall into the washing apparatus and be used for washing, substantially as described.

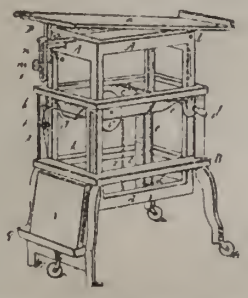
Patents Granted in America.

302,836. Jean Francois Geesbergen, and Alfred Geruzet, Brussels, Belgium. "Photographer's electric retouching device." Filed Oct. 24, 1883. (No model.) Patented in Belgium, July 28, 1883, No. 62,164; in France, Sept. 19, 1883, No. 145,263; in England, Sept. 24, 1883, No. 4,557; in Germany, Oct. 9, 1883, No. 27,091; in Italy, Oct. 24, 1883, 491/16,006; and in Austria-Hungary, Dec. 26, 1883, No. 37,177, and No. 53,504.

A description of the apparatus will be found in our vol. for 1833, p. 645.

302,639. James H. Smith, Quincy, Ill. "Photographic camera-stand." Filed Aug. 20, 1883. (No model.)

Claim.—1. In a photographic camera-stand, the combination, with a main frame, B, and an inner vertically-moving frame, A, of the crank *d*, shaft *c*, cross-frame *g*, band *e*, and roller *d'*, and suitable means for locking together the frames A and B.



2. In a camera-stand, the combination, with the frames A B, of the posts K K on frame B, forming with the frame A the openings *i i*, the rod J, and the wheels or cams *h h*, for the purposes herein described.

3. In a camera-stand, the combination, with the frames A B, of the crank *d*, shaft *c*, belt *e*, and roller *d'*, and the locking device consisting of the posts K K, rod J, and wheels or cams *h h*, all arranged substantially as described.

4. In a camera-stand, a locking device consisting of the knob or wheel *m*, having the hollow threaded shank *m'*, screw-head *u*, block *v*, and screw *t*, in combination with the slotted pendant *n*, and the support P attached to the table, as described.

5. In combination with the frame of a camera-stand, the bolster K', journaled in said stand, the platform *a*, hinged support P, block *a'*, slotted pendant *n*, knob *m*, threaded hollow shank *m'*, washer *s*, screw *t*, guide-block *v*, screw-head *u*, perforated flange *o*, and pivot *p*, arranged substantially as described.

6. The herein-described photographic camera-stand, formed of a main frame B, and inner frame A, and having suitable rollers, a tray *q*, crank *d*, shaft *c*, cross-frame *g*, belt *e*, roller *d'*, posts K K, rod J, wheels *h h*, spring *b*, grooved wheel *b'*, cord *z*, the bolster K, table *a*, hinged support P, block *a'*, slotted pendant *n*, knob *m*, hollow threaded shank *m'*, washer *s*, screw *t*, guide-block *v*, screw-head *u*, flange *o*, and pivot *p*, all arranged substantially as herein set forth.

PHOTO-ASTRONOMY AT THE RIFFEL.

BY C. RAY WOODS.

No. II.

Wind, hail, rain, mist, and snow. Weather is as changable here as in England. One day the wind blows with such force that I almost expect to see my little observatory loosed from its moorings and carried down to Zermatt; the next day the sun blazes down upon it with almost tropical energy; then comes a day of rain and mist; then a day of thunderstorms and hail; next a fine day with a mackerel sky, tantalizing one more than downright bad weather. And so it goes on. Pick out all the terms used in meteorology, they are sure to be applicable some time or other, with possibly a few exceptions such as "tornado," &c. That is a refreshing word, "tornado." We have not had a tornado yet, and so I will not grumble any more.

And yet had I come here for pictorial work I think I should have been very well satisfied. Meteorological changes would then have been welcome, conferring fresh beauties on the scenery. But when one is condemned to remain at one spot, everything that interferes with the purpose one has before him is almost intolerable. The Visp Valley, the Matterhorn, the Breithorn, Riffelhorn, and a score of other peaks are magnificent objects, doubtless, but, looked at day after day from one point of view, are apt to become a little tiresome. This is more particularly so when the weather is somewhat unfavourable, and there is little to do but look at the mountains while one hangs about the observatory in hopes of getting a shot at the sun. "How exquisitely lovely!" said a sentimental lady tourist, as she looked along the valley to the mountains beyond; "I could gaze upon it for ever." I said nothing in reply, but not being in the best of tempers at the time, I thought a great deal.

This is a nice beginning, is it not, Mr. Editor? But then this is a bad day for my work, and my liver is out of order. Now to business.

My first piece of work was to erect the observatory. The shape of it is that of the triangular prism. The ends were formed by screwing together three pieces of 2½-inch timber, each piece being 10 feet 6 inches long. These triangular frames were temporarily propped up at a distance of twelve feet apart, and were then joined by a strong beam at the top. Two similar beams of the same length were fixed along the sides at a height of about four feet from the ground. This was all that consituted the framework, and it combined lightness with rigidity. At the four corners narrow iron feet, about ten inches long, were screwed on, and by the help of a cold chisel were firmly let into the solid rock of the little hillock behind the Riffel Hotel. Strong ropes attached to iron tent pegs furnished additional security, and with the aid of a native labourer the framework wassoon together, and soon secured. To put on the covering was a more difficult matter, as a strong breeze was blowing. It would not do to wait for the wind to lull, however, and with "pure cussedness" it continued until the last stitch of canvas was firmly fixed in its place. Then, of course, the air became still. To the side beams, a length of Willesden's waterproof canvas was fixed with battens; its width, 4 feet 6 inches, allowing just to reach the ground, to which it was attached by cords passing through eyelet-holes, and tied to iron pickets driven into the rock. A large sheet of the Willesden canvas, 13 feet square, formed by sewing three widths together, completely roofed the rest of the structure. This was battened on to the top beam and on to the rest of the framework on the North side. On the Southern side, the bottom part of the canvas was fastened between two strips of wood tightly screwed together. Ropes attached to the ends of the wood, passing through eyelet holes in the sides, and over little pulleys on the top beam, enabled the canvas to be drawn up, exposing a space 12 feet long by 6 feet high. The telescope was thus free to be pointed at the sun throughout the best working portion of the day, from sunrise to about three o'clock in the afternoon. The Eastern end of the observatory was then covered with two overlapping pieces of canvas, entrance being obtained by drawing them apart. The dark-room, a separate structure, was attached to the northern end. Its size is 6 feet by 4 feet 6 inches, and was formed by battening Willesden cardboard roofing on to a light framework of wood. The reader will perhaps remember that this same material, a capital one for dark-rooms, was used on Caroline Island, and served its purpose well. On the night when we were all washed out of our beds, mine was the only set of instruments that escaped a wetting; and when we left the place, the little cardboard hut was presented to the Kanakas, and is probably still serving them for a country residence, as, unlike more civilized people, they do not object to being crowded.

The tent once erected, the telescope had to be put in position. My man was a young, and, to all appearance, slightly-built fellow, and I was preparing to get some one

to assist him in carrying the parts on to the mound and into the tent. He did not seem to think much, however, of taking two hundredweight on to his shoulders for a short distance of thirty or forty yards, and the work proceeded with far greater ease than I had anticipated. The part of the equatorial stand that carried the polar axis, and which had to be taken to pieces at Zermatt, gave me a little trouble, as I had to put the cogs and friction-rollers on again, as well as repair the clock. With this exception, all my work was straightforward. The essential part of the instrument, the coronagraph, which was expressly constructed for the occasion, is nearly twelve feet long, and consists of a mirror of six feet focus, and stopped to three inches diameter, giving an image of the sun nearly three-quarters of an inch in diameter. Before reaching the mirror, the light passes through a long tube with a number of diaphragms a short distance apart, in order to stop reflection from the sides of the tube, and to minimise diffraction. The light is then reflected from the mirror, and the sun's image is brought to a focus at about the centre of the instrument, where it is allowed to fall on the ground glass or the dark slide, the latter being carried on a circular piece of apparatus, about twelve inches in diameter, containing a revolving shutter which passes just in front of the plate.

To get the tent and instrument erected and adjusted was a matter which occupied some little time, and before everything was finished, bad weather set in. The tent had then to stand some very rough usage, but its shape and the way in which it was fastened down enabled it to resist the strong wind that blew, without suffering the slightest damage. For the first few nights it caused me some anxiety, and even now I look to the ropes every night before retiring to rest, to see that all is safe; but I have little fear of it now, unless that tornado comes. I flatter myself that it is rather ornamental than otherwise, and it has excited considerable curiosity. Of course I dignify it with the title of observatory, and believe I am right in saying that it is the highest in Europe. A German artist who is studying here, however, declines to give it the same high-sounding title, and calls it "the Wigwam." I am glad to say, though, that it does not offend his sense of the "eternal fitness of things;" in fact, he says that the wigwam only wants a squaw to render it perfect.

It was only natural to expect that even among the members of the household here, my erection should give rise to a little misapprehension. They knew I was a photographer, and the idea entered into the minds of some of them that I was going to start a business, for landscapes at least, even if not for that branch of photographic high art which finds expression in the utilization of tin sheets and brass frames. One morning I was woke at five o'clock with a prereemptory message from two American gentlemen who wanted a photograph taken. Now I do not mind them waking me at five o'clock on a fine morning—in fact, there is a standing order here to that effect—but it is quite another thing to be roused at the order of a gentleman who wants his picture taken. It did look a fine morning, and of course I got up, venting my wrath upon the unfortunate domestics, the most innocent getting the largest share of it. For a brief period terror reigned. The American gentlemen, as soon as matters were explained, amply apologised, with the explanation that believing I was a professional photographer, they did not think they were taking an unusual course, it being the custom in America to regard the photographer as entirely the servant of the public. I do not know what my professional friends in England think of this, but I rather fancy they expect to have a say in the matter as well.

It was a remarkable morning. Beneath one's feet was one wide ocean of cloud, the billows of vapour, with their gentle undulations of light and shade, lapping the sides of the peaks that rose above them like a rocky shore towering abruptly above the sea. "I wanted you to photograph me in the middle of this." Great Scott! Is this the American sense of the eternal fitness of things?

But the beautiful view soon disappeared. The mists rose from the valley, and for the rest of the morning we were bathed in cloud. The sight was a very fine one while it lasted, and one may excuse the elegant expression of another American gentleman, who said, "I was darned near kickin' myself for coming up here last night, but I guess I'm satisfied now."

As the reader will have guessed already, the weather has not been very favourable for the particular class of observations I came here to make. There have been no blue-black skies as yet, of which I was in hopes; and even when bad weather or clouds have not obtruded themselves, the freedom from glare has not been so marked as in previous years, according to the opinion of annual visitors to this part. There has been a very marked haze, almost a halo, round the sun, of a light copper-coloured hue, and I have been asked by many people whether it is due to the dust from Krakatana, the supposed cause of the brilliant sunsets last autumn. That it must be due to suspended particles in the atmosphere at a high altitude is certain, but there have been no red sunrises or sunsets here to connect it with the cause put forward for the displays of the latter part of 1883. I hear from England that a similar reddish haze has been observed in Spain.

The plates I use are backed with asphaltum dissolved in benzine, to prevent halation from the back of the plate. I do not know of any substance that acts so powerfully in this respect, and though other media may be more than sufficient for such work as interiors, it would be difficult to beat asphaltum for astronomical work. My most promising results have been obtained on chloride plates, but slight defects in the apparatus—defects which I have now eliminated, or nearly so—have rendered my task no easy one apart from unfavourable atmospheric conditions. Under the circumstances, therefore, I trust I shall be excused from expressing any definite opinion as to what the result of my expedition is likely to be.

It was my intention to have described here a little photographic excursion I took upon a day which was unfit for my solar work, and showed no promise of improving. This letter is already so long that I must leave my visit to the Gorner Glacier for my next communication.

FRENCH CORRESPONDENCE.

Artistic Copyright Law — Colour Photometer — Photography in Colours—Article in "Figaro"—Freeing Gelatine from Grease—Preparing and Preserving Sensitized Paper—Shutters—Concentrated Solution of Pyrogallic Acid—Photographic Camera and Dark Box.

Copyright Law.—The law with reference to artistic copyright passes through singular phases. Presented for the first time before the Chamber of Deputies, it was not allowed to be brought on: then referred back to the Senate by M. Bardoux, it met with great opposition. So many objections were raised, that at this pass M. Bardoux, finding his original proposition completely distorted, demanded that the subject should be dropped. As to the article concerning the copyright of photographic works, it has not been discussed yet, and it is to be hoped that when it is taken up photography will fare as well or better than M. Bardoux's proposal intended. The more one thinks about it, the more it seems likely that photography will need to have a law of exceptions made. The wisest thing to be done would be to group all the graphic arts together, no matter how the results are produced.

Colour Photometer.—Since MM. Tailfer and Clayton on the one side, and Capt. Abney, Dr. Vogel, and others, on the other, occupy themselves in making plates capable of reproducing colours in their relative tones, it seems to me

that a photometer for colours should have a place among instruments of photographic research. A transparent solar spectrum seems as if it should form an excellent actinometer for testing the nature of sensitive products. One can quickly see, with this transparent scale containing the colours of the spectrum, which are they that allow the luminous source to act upon more or less. An easy method of constructing such an actinometer consists in the use of sheets of coloured gelatine, ranging from the violet to the red, passing through the various colours of the spectrum. The strips, stuck on glass in the desired order, are applied when in use to the sensitive film to be tested, and solar or any other light allowed to pass through the coloured strips.

M. Baudran's Invention.—An inventor, M. Baudran, of Versailles, must be taken as seriously in earnest. This happy mortal is said to have discovered a substance sensitive to light, so that by mixing it with all the oil colours necessary for the picture, and submitting a film of this substance to solar action behind a negative, a composition results in the colours found in the picture. Here the sun does not make the colours, but places them in their proper places and relative tones. From what I have seen of the process, I do not feel authorised to speak with much certainty. In the meantime, the solution of the problem of photography in colours is as far off as ever.

Article in Figaro.—The *Figaro*, at the instance of *XIX*ième *Siècle*, and other daily journals, gives a photographic propaganda, and so much the better, only it must not be permitted to say that with our regretted friend Monckhoven rests the invention of gelatino-bromide, an invention, continues the journal, of which the public ought to have been allowed to profit gratuitously. The inaccuracy is too flagrant to be overlooked.

Freeing Gelatine from Grease.—In accordance with a method indicated by Dr. Vogel for freeing gelatine from grease, there was a pretty long discussion at the Photographic Society of France, on the doubtful efficacy of washing in distilled water. It was proposed to wash in pure benzole, and also with a mixture of 1,000 parts of benzole and 250 of alcohol. It is certainly inconceivable that water alone will suffice to detach the grease adhering to the surface of the gelatine.

Formula for Sensitized Paper.—To preserve sensitized paper it has been again suggested that albumenized paper should be floated for four or five minutes on a bath of 1,000 parts of distilled water and 150 parts of nitrate of silver. Then when dry it is placed sensitive face upwards on the surface of a bath of citric and oxalic acid.

Instantaneous Shutters.—Instantaneous shutters seem to be of mushroom growth, and unfortunately come forth in greater quantity than quality. This time M. Braun, of Angoulême, produces his shutter of circular form, while M. David shows a tubular one somewhat similar, if my memory serves me, to a shutter brought out two or three years ago by M. Candèze.

Concentrated Solution of Pyrogallic Acid.—M. Audra has been trying to make concentrated solutions of pyrogallic acid. He first made a twelve per cent. solution of sulphite of soda, and another containing one-tenth of sulphuric acid. The two solutions are mixed, and eight grammes of pyrogallic acid, so that the concentration is one gramme in fifteen cubic centimetres of liquid.

M. Keller's Photographic Apparatus.—M. Keller has brought out a camera of very light construction, and a dark box in which twelve plates may be superposed. The arms are encased in sleeves impervious to light, and the exposed plate is removed to the back of the box, a sheet of black paper being interposed between each plate. This bag system is, however easy to describe, somewhat inconvenient in the use.

LEON VIDAL.

Review.

DIE MOMENT PHOTOGRAPHIE, Von Prof. Dr. J. M. Eder. (*Wien: Verlag der Photographischen Correspondenz*).

DR. EDER'S monograph on instantaneous photography forms a readable little work of eighty-two octavo pages, and deals especially with those modifications of every-day work which are necessary for the production of the so-called instantaneous photographs.

Of course it will be quite understood that the term "instantaneous photography" is a vague one, although by it one generally understands a photograph of moving objects taken in such a short time as not to show blurring or indistinctness in consequence of the motion. The maximum time allowable in making an instantaneous photograph consequently varies considerably, according to the rapidity with which the moving body shifts its position, its distance from the camera, and the direction of its motion; but one may set down about one-tenth of a second as the longest exposure allowable for an "instantaneous" picture, while in some cases the exposure may be as short as a two-hundredth or even a one-thousandth of a second.

The following data will be useful to the beginner as approximately indicating the longest term of exposure in fractions of a second, which is ordinarily allowable under certain given circumstances:—

Distance of the moving object from camera in terms of the focus of the lens.	Distance traversed by moving object in one second.		
	1 metre	5 metres	10 metres.
100	1/100	1/500	1/1000
500	1/20	1/100	1/200
1000	1/10	1/50	1/100

In the case of this table, one may regard the metre as being equal to a yard; and inspection will show that if a horse is moving at the rate of five yards per second at a distance from the objective equal to 1,000 times the focal length, a sufficiently sharp image is obtained if the exposure is one-fiftieth of a second or less; if, on the other hand, the horse is only at a distance of 100 times the focal length of the lens, the exposure must be reduced to one five-hundredth of a second.

Numerous illustrations of apparatus are given, and several examples of difficult instantaneous work are to be found in Dr. Eder's book; the frontispiece being an excellent collotypic reproduction of Lugardon's "Diver."

Something of value may be gathered from this, Dr. Eder's last work, by everyone who is engaged in photographic pursuits.

Correspondence.

THE KEEPING OF GELATINE PLATES.

SIR,—For the information of your correspondent who enquires "How long will gelatine plates keep?" I may inform him that I have recently exposed and developed several plates given to me by a manufacturer to keep and test. I have had them exactly three and a-half years, and find them in every respect as good and sensitive as when first received. If well packed and kept dry, I believe plates will keep indefinitely.—Yours truly,

T. G. WHAITE.

Proceedings of Societies.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

A MEETING of this Society was held on Thursday, the 7th inst., Mr. W. H. PRESTWICH in the chair.

Mr. A. COWAN, referring to Farmer's reducer, said it was quite as efficient for chloride as bromide plates; not only could an over-exposed positive be reduced, but the tone would become slightly warmer.

Mr. W. B. B. Wellington cousidered the colour very much improved in some cases.

Mr. W. Coles showed two very much under-exposed negatives which were badly fogged; these had been somewhat improved by treating with dilute ferri-cyanide and hypo reducer, but he was unable to remove all the fog, as Mr. Wellington had done on a former occasion.

The Chairman thought the reason Mr. Coles had not succeeded so well as Mr. Wellington was due to the plate having dried in the first iustance, and not in the second.

A question having reference to the compositiou of such leather as is usually employed by camera makers, and its influence in producing fog, was next discussed.

Mr. W. E. Debenham said fog did not proceeed from anything in the composition of the leather employed, but there might be some action from the paiut used to cover it. If it were worth enquiring into the chemical composition involved, then it should be that of the material used in covering.

Mr. Cowan exhibited a frame containing chloride transparencies from uegatives taken at the outiug on Bank Holiday. The subjects were well chosen, and, viewed as transparencies, were all that could be desired.

Mr. J. Smith passed round one of Singhi's 5 by 8 vignetting frames. The peculiarity consists in having a millboard frame large enough to cover an ordinary priuting frame, leaving the central portion open to be covered by a mask of suitable size and shape. By means of grooves these masks can be moved either vertically or horizontally, thus conferring a universal movement to the vignetting shield, so that any portion of a negative may be printed from. To obviate the harsh results obtained with some negatives when the mask is too close, horizontal bars are iuserted at either end, thus raising the vignetting arrangement the required distance.

Mr. Cowan had shown a similar sort of thing some months ago; all the actions were the same.

Mr. Debenham said his printing presses were similar, only he had no projecting parts.

The Chairman nsed blocks of wood bevelled underneath, instead of cardboard, and it was mentioned that it was an advantage to cover the bevelled portion with tin-foil.

A desultory conversation then took place on the subject of second-hand lenses. One member showed an old orthoscopic lens which was unmistakably genuiue, yet it was found to give very imperfect definition, which could uot be improved by the use of a small stop. It was thought that the workmen must have mixed the lenses wheu fitting the mounts, as the front lens was found to give good definition when employed with another of shorter focus.

Mr. W. Turner showed several negatives and positives on paper from drawings of large size, the lines being perfectly rendered. These were obtained by contact printing on salted paper sensitized on a 45-grain silver solution, the fixing bath being very old hypo solution. Some good examples of ferro-prussiate paper printing were also shown. To obtain positives from drawings on thick paper, the paper was brushed over with a mixture of lard and turpentiue, the proportions of these substances being determined by experiment.

Edinburgh Photographic Society.

The annual excursion aud picnic of this Society took place on Thursday, July 10, when about sixty ladies and gentlemen visited the grounds of Arniston House, by the kind permission of R. Duudas, Esq. On arrival, luncheon was served, and this was followed by the company being photographed in a group under the fine old leaning larch tree, which, as indicated by the nurseryman's bill, still preserved, was planted in 1735. A small stringed band provided excellent music for dancing. There was an interesting series of competitions for both sexes. In the following list of successful competitors the name of the donor, and nature of the prize, are placed in brackets :—

High Leap ...	1. Mr. Calder ...	(Mr. Bertram—Pipe).
	2. Mr. M'Kean ...	(Mr. Dougall—Series of 12 Carbon Prints).
100 yards Race ...	1. Miss Mary Tunny	(Mr. Bartram—Parasol).
	2. Miss Tunny ...	(Mr. Dougall — 12 Carbon Prints).
150 yards Race ...	1. Miss Pearson ..	(Mr. Crighton — Handbag).
	2. Miss Raynor ...	(Mr. Middlemas — Box Digestive Biscuits).
150 yards Race ...	1. Mr. Calder ...	(Mr. M'Kean — Illuminated Album).
	2. Mr. M'Kean ...	(Mr. Middlemas — Box of Albert Biscuits).
Barrow Race ...	1. Miss Taylor ...	(Mr. J. M. Turnbull—Graphoscope).
	2. Mr. Dougall ...	(Mr. Johnston—Pair of Skates).
Hopping Race ...	1. Miss Raynor ...	(Mr. Cox—Album).
	2. Miss Pearson ...	(Mr. Dougall — 1 doz. Carbon Prints.
Photographic Competition—Best "bit" taken in the Grounds at Arniston ...	1. Mr. Briglmen ...	(Mr. Baillie — 1 Bottle of Brandy 50 years old).
	2. Mr. M'Kean ...	(Mr. Wardale — Opera Glass).

Dinner was served at 2 o'clock, the President (Mr. Wm. Neilson) occupying the chair, and proposing the usual loyal toasts.

Mr. Wm. Dougall gave "Prosperity to the Society and the health of the President," which was happily replied to by Mr. Neilson.

Mr. Brodie gave "The Council and Office-bearers," replied to by Mr. Bashford, Hon. Sec.

Mr. John Gardner proposed "The Committee for the Picnic," coupled with the name of Mr. John Wardall, the convener, who suitably replied.

Mr. J. G. Tunny proposed the health of Mr. Dundas, of Arniston, who had personall/ welcomed the Society to his grounds, and granted every liberty and accommodation.

Mr. Dundas had studied photography thirty years ago under Mr Tunny, and was much pleased to see the Society at his place.

Mr. Crighton gave "The Ladies," replied to by Mr. Scott.

Several of the company took views of favouritc bits of scenery in the magnificent grounds. Some groups of Mr. Dundas and his daughters were taken, and the sturdy figure of one of the keepers served several for a picturesque model. After a most enjoyable day, the party returned to Edinburgh by the 7.13 p.m. train.

The Essex Field Club.

On an excursion through the earthquake region, some of the members of the above Club took cameras and exposed plates; but it was soon apparent that much had been done in the interim to repair damages, and to the local photographers belongs the credit of securing immediate and accurate records of damage done. A few things had been overlooked, which Mr. J. Spiller and Mr. Thorp at once endeavoured to supply. Foremost in this category were the ruius of St. Botolph's Priory, Colchester, where an arch had tumbled in, and a smaller portion of masonry fallen from the face of the buildiug. Views of these were taken from three points, showing the broken surfaces and the grotesquely iuterlaced stems of ivy.

A group was taken of the members of the Club as they assembled under the walls and round the tower of the old castle in Colchester. This building does not show structural damage, although it had a good shake, as evidenced by many of the objects in the Museum becoming displaced.

Mr. R. Meldola, ex-president, took occasion to address the members, giving the salient points of the report he is preparing, and referred to the fact that through all this wreck no lives were lost.

Leeds Photographic Society.

The ordinary monthly meeting of this Society was held on Thursday, August 7th, Mr. J. W. Ramsden, vice-president, in the chair.

After the confirmation of the minutes,

It was proposed by Mr. Marshall, and seconded by Mr. Branson, that the committee be requested to arrange for out-door excursions not less than once a month, nor more frequently than once a fortnight; the announcements of the excursions to be made on the Society's board in the window of the Phil. Hall, and kept two or three weeks in advance; the place of meeting and time to be arranged as best suiting the excursiou.

The meeting then arranged that an excursion should be made on Saturday, August 16th, to Mranwood Valley and Adel Moors, to meet at the "Three Horseshoes," Headingley, at 2.30 p m.

Mr. F. W. Branson called the attention of the meeting to some chemical reactions involved in the treatment of the bleached

image of a negative (produced by bichloride of mercury), with a half-saturated solution of recrystallized sodium sulphite.

From experiments made, the following facts were deduced :—

1. That a solution of bichloride of mercury is not reduced to calomel, nor is a sulphide formed when cold solutions of bichloride of mercury and recrystallized sodium sulphite are mixed.

2. That freshly-formed and washed silver chloride is not blackened, but is dissolved to a very appreciable extent by a solution of sodium sulphite of the strength recommended.

3. That mercurous chloride (calomel) is readily blackened, with production of a sulphide of mercury, by a solution of sodium sulphite.

It was explained that the white image caused by the action of a solution of bichloride mercury consisted of both mercurous chloride (calomel) and silver chloride, and that when sodium sulphite solution was added, the silver salt dissolved, and the mercury salt became blackened to form the photographic image. The removal of the silver salt probably explained the small degree of intensification given by this method, as contrasted with some other methods in use. That a strengthening of the image does occur is certain, and that no part of the plate is discoloured except the photographic image constitutes an important advantage.

It was also pointed out that a fact of considerable practical importance remains to be proved—viz., whether a sulphide of mercury as produced by the action of sodium sulphite, &c., or the amido compound as yielded by treatment with ammonia, gives the most permanent negative.

After a short discussion on Mr. Branson's communication, in which the Vice-president, Messrs. Teesdale, Thorton, Wildy, &c., took part—

Mr. W. L. Wildy passed round some prints on ferro-prussiate paper, and recommended the process as useful in a number of ways, and gave the following details as to his mode of working the process :—

Ammonia citrate of iron	15 drs.
Distilled water	8 ounces
Ferricyanide potas....	10 drms.
Distilled water	8 ounces

Mix the two solutions, and keep in a darkened bottle. Take unglazed paper of a fine grain, and damp the sheets you propose to sensitize. With a sponge or rubber brush float the solution over the paper as evenly as possible, and hang to dry in a darkened room. Do not prepare a larger quantity than you are going to shortly use, as the paper becomes slower by keeping. When printing, expose until the shadows assume a strong metallic grey colour, and detail begins to be lost. Wash well in cold water until, when held up by the corner, the drip from print shows no yellow tinge. If it is desired to write on the print, use a saturated solution of common washing soda as ink, and a clean steel pen to write with.

The Hon. Secretary (Mr. Thos. W. Thornton) then exhibited samples of Willesden paper, and spoke of the many uses photographers might put it to. Being perfectly water-tight, it could with advantage be used to form developing dishes, and also for making temporary dark-rooms. He said that by the kindness of Mr. Ashman, he had received samples of the vulcanized fibre respecting which enquiries had been made at the last meeting ; these he exhibited, and said he had been experimenting with them, and found that it was practically unbreakable, and could be worked in almost any conceivable manner ; he had grooved, planed, turned, and sawn it with great ease, and he was of opinion that it might with advantage be used to replace ebonite in the making of shutters, &c.

Mr. Branson said he had used the material, and found that it was affected by damp.

The Hon. Secretary also exhibited a changing bag for dry plates, which he had made after the design given by Mr. Brooks, and used it every day during a recent tour.

The meeting then proceeded to the examination of a number of transparencies, exhibited by Mr. W. Teasdale by means of the sciopticon lantern. Mr. Teasdale's portable screens, &c., were much admired.

Royal Cornwall Polytechnic Society's Exhibition.

The following is a list of the awards made in the Photographic department of the above Society. A detailed report will appear next week.

Professional Photography. — First Silver Medal. — W. W. Winter, W. Gillard, and H. P. Robinson.

Second Silver.—Geo. Hadley, L. Berry, and T. J. Dixon.

First Bronze.—W. P. Marsh.

Highly Commended.—J. Milman Brown and R. Faulkner.

Amateur Section.—A. Pringle—1st Silver Medal ; A. G. Tagliaferro—2nd Silver Medal ; W. J. Graut—1st Bronze ; P. H. Emmerson—2nd Bronze ; P. H. Emmerson—Highly commended.

Photographic Appliances, &c.—Second Bronze Medal.—F. B. Dajley and R. R. Beurd.

Talk in the Studio.

The Meeting of the British Association.—The mail steamers of the Allan Line sailing from Liverpool are at present crowded to their utmost capacity by members of the British Association *en route* for Montreal to take part in the meetings of the body, which commence in the Canadian city this month. The arrangements made for the reception and entertainment of the English visitors appear to be of a very complete description. The Canadian Government have voted £5,000, and reception committees have been formed not only in Montreal itself, but at Toronto and Winnipeg, which will be visited in due course by the members.

Another Lime Light Explosion in a Theatre.—A most serious accident, which may be attended with fatal consequences to one of the sufferers, occurred on Thursday night, the 7th inst., at the Curragh Camp. About eleven o'clock an explosion occurred at the theatre attached to the garrison canteen, a wooden building, filled by an audience to see "Maria Martin." Just as "the murderer" shot his victim, some limelight was being lighted, when a fearful explosion occurred. Private Jennings, of the 1st Royal Dragoons, had his right hand and part of his wrist shot off, and was so stunned that he has not recovered conciousness yet. The medical officers amputated his hand and part of his arm, but, although a strong man, his case is critical. Mr. Clarence, who played the part of Corder, is severely hurt, and was deaf for hours afterwards ; his arm is shattered. Miss Beaumont, who played the part of Maria Martin, was severely injured, and was with difficulty brought round. Some fifteen or twenty people were removed to hospital, but nearly all were allowed to leave the place after being treated. It is said that iron bottles were used.

Iridium.—This metal, the oxide of which forms one of the most intense black vitrifiable pigments, and which is used in enamel photography, has several more or less important commercial uses, of which a tolerably full account appeared in a recent number of the *English Mechanic*. We make the following extracts :—"Gold pens of the best quality are tipped with iridium, as are some of the stylographic pens, the extreme hardness and utter indifference to acids of the iridium rendering it very useful for the purpose. Iridium is generally found alloyed with either platinum or osmium, and the chief sources of the supply are the Ural mines in Russia, and certain districts in California. When cold it is brittle, but at a white heat it is slightly malleable. It is fusible only in the oxy-hydrogen blast or in the electric arc. Insoluble in all the simple acids, it is slightly acted upon by aqua-regia after the grains have been heated for some hours. Though the chief sources of iridium are the Ural Mountains and California, the metal is, in fact, widely distributed, but in the shape of platin-iridium occurs generally in the form of small cubes with rounded edges, and as osmiridium or iridosmine in flat irregular grains, or occasionally in hexagonal prisms. The gold-pen makers examine these grains with a magnifying glass, and pick out those suitable for pointing their pens. These are soldered to the nibs and slit with a copper disc charged with diamond dust and cotton-seed oil. Gold pens so finished are known as diamond-pointed, but, as a matter of fact, it is a particle of iridosmine with which the nibs are tipped. A few years ago, however, Mr. Holland, being engaged in the manufacture of the Mackinnon stylographic pen, found it necessary to procure some larger pieces of iridium than the dust yielded, and after many experiments he discovered that by adding phosphorus to the ore while at a white heat, he could obtain perfect fusion, and pour and mould the alloy into any desired shape. For his special purpose Mr. Holland cast the phospho-iridium in sheets between slabs of iron, and breaking the sheets into irregular pieces, soldered the latter to strips of brass, and

ground the iridium alloy to a flat surface by means of a copper lap charged with diamond dust. Drilling is accomplished in a somewhat similar manner, except that the hole is first started with a diamond splint. As soon as a little cavity is made, a drill fashioned out of soft copper wire is brought into requisition, and the little cavity being fed with diamond dust and oil, the hole is gradually worked through, though not very speedily, in spite of the fact that the drill runs at a rate of 3,500 revolutions per minute. Besides points for pens, the iridium alloy is used in making draw-plates for the production of wires of the precious metals. Wires of common metals are drawn through holes in a steel plate, but ruby plates are often employed for drawing down gold, platinum, and silver into wires. The ruby is very hard, but not harder than the iridium alloy, which has, moreover, the great advantage that it is not liable to splinter or chip by the rough handling or the heat engendered by the drawing operation, which is about the best example of intense friction. Iridium is also used for the knife-edges of chemical balances, and is steadily supplanting agate; but in that case it is the mere edge, which is firmly soldered to a brass piece attached to the balance. The hypodermic needles of the surgeon are also now made of gold tipped with iridium, and in many cases where extreme hardness is required with freedom from corrosion, the iridium alloy is coming into use. For the contact points of telegraphic and other electric apparatus, iridium is supplanting platinum, because it is found to last much longer, and to be almost perfectly free from oxidation or sticking, while the points can be readily cleaned by rubbing with a piece of emery cloth. Iridium was tried by Edison for making incandescence lamps, and it has also been tried with some success as the negative of an arc-light; but in both cases it may be safely assumed that it is not likely to supplant the simple carbon, the cost being altogether out of proportion to the advantage gained. Attempts have been made to deposit iridium on base metals by the galvanoplastic method, but not much success has been attained. There is a promising field for experiment in this direction, for a successful method of plating with iridium would be very valuable.

Photographic Club.—At the next meeting of this Club, on August 20th, the adjourned discussion on "Printing through Coloured Media" will be held. Saturday afternoon outing at Chingford, leaving Liverpool Street Station by the first train after two o'clock. Meeting afterwards at the "Forest Hotel."

To Correspondents.

*** We cannot undertake to return rejected communications.

Pierre Revon.—It appears to us that the spots are due to a trace of silver nitrate from the paper finding its way to the gelatine film through minute holes in the varnish. The tendency towards the formation of such holes is much reduced by thoroughly washing the negatives so as to remove all traces of hyposulphite, and very perfectly drying the films before varnishing. Even when the perforations in the varnish film exist, the staining of the underlying gelatine does not take place very readily if the sensitive paper is perfectly dry.

J. J. Dickenson.—Thank you for the description, which we will make use of shortly.

F. Brown.—1. The lubricating medium or paste is made by dissolving one ounce of white wax cut into shreds in five ounces of warm oil of turpentine, and a very little is applied by means of a piece of flannel. The burnisher should be warm and perfectly smooth. 2. White wax or solid paraffin is best. Lay the paper on a heated slab of glass or slate, rub over with wax, and remove the excess with a soft cloth.

T. B.—1. The remainder will be none the worse if reasonable care has been taken. 2. Probably it has been exposed to sulphurous fumes—perhaps from an open drain.

A Subscriber from the First.—We cannot tell you of a firm in Milan that will supply you with what you require, but when you arrive there you will douhtless be able to gather all the information you require by referring to the directory. 2. We believe that a book on the subject can be had from Newman, Artists' Colourman, Soho Square.

J. H. H.—1. In the case of the two small pictures, it seems to us that the indistinctness is due to the camera or lens having moved, not the boats; look carefully to the action of the shutter in order to find what causes the movement. 2. There is as much difference as could be expected, and we think that No. 3 is the best. If, however, you had used a somewhat less active developer, the result would have been more satisfactory.

L. Y. X.—Undouhtedly he may and can do this; but it is not quite the correct thing.

C. E. Lyon.—Clean the mirror, and make your drawings with a crayon of French chalk.

Pin.—1. Throw it away and make a fresh solution. 2. For small plates an ordinary Albion press will answer very well, but it will only serve for a plate of about one-fourth the size of the typographic forme it takes. 3. Ordinary yellow wax melted with about one-third its weight of fine black-lead. 4. Soak them in the following:—Water one gallon, sulphuric acid one pint, biebromate of potassium one pound. 5. Dry it at a lower temperature. 6. Yes, it is useful when the reticulation will not take place without. 7. They are printed from stone by an ordinary lithographic machine.

C. Osborn.—Plain collodion is the correct thing; but iodized may be used if ready to hand, as the iodising salts dissolve out and do no harm.

Wm. G. Honey.—The plates you mention are excellent, but that is no reason why you should not try how you can get on with those of other makers.

Fifteen Years' Subscriber.—Probably from the presence of some deleterious matter in the mounts. Cut a print in two, and mount one portion on one of the mounts you previously used, and the other on one of those now in use. If the portion on the fresh mount becomes spotted, you have sufficient grounds to ask for compensation from the firm supplying the cards.

T. P.—We will endeavour to give you the information you require in a private letter.

Exhibitor.—Full particulars regarding the International Inventions Exhibition of 1885 appeared more than a month ago in the Photographic News (page 418), together with the classification of exhibits bearing on photography.

Cambria.—1. If you paid the money for the plate, it is undoubtedly yours; but if you merely paid for the engraving of the plate, you cannot claim it. 2. Try first as it is: the result in such a case is often far better than one might expect.

John Jones.—1. You have evidently become a little confused as regards nitrates and nitrites; but in the case you refer to, the nitrate alone is used. 2. Add rather more water, perhaps one-third more.

The Photographic News Registry.

Employment Wanted.

Assistant Operator & Retoucher.—R. H., *Photo. News* Office.
Reception-Room for a learner.—M. E., 16, York-pl., Scarboro'.
Mounter & Spotter (lady).—H. V., *Photo. News* Office.
Artistic Retoucher, experienced & first-class.—J. S., *Photo. News* Office.
Mounting & Spotting.—A. A., c/o Mrs. Pavithy, High-st., Hadley, Barnet.
Assistant Printer.—H. W., Elm Cottage, Grove-rd., Richmond.

Employment Offered.

Head Printer, understand Carbon.—Annan, 153, Sauchiehall-st., Glasgow.
Retoucher, Lady or Gentleman.—F. Guy, 70, Patrick-st., Cork.
Good Oper. & Ret.—T. Williams, Talbot-pl., Darlington-st., W'hampton.
First-class Printer & Toner.—West & Son, Eagle House, Gosport.
First-class Operator, permanency.—Mr. Owen, Catherine-st., Salisbury.
Assistant Retoucher.—Ball & Co., 13, Narrow-st., Peterboro'.

Photographs Registered.

Mr. Jabez Sumner (Oxford)—2 Photos. of Rev. H. P. Hughes.
Mr. R. F. Blackett (38, Woburn Square, W.)—Photo. entitled "Dolce far niente."
Mr. A. G. Gibson (Penzance)—2 Photos. of Longships Lighthouse.
Mr. W. G. Lewis—3 Photos. of Roman Bath at Bath.
Mr. R. J. Houlson (Abergavenny)—2 Photos. of Father Ignatius and others.
Mr. S. Kirk (Nottingham)—Photo. of Notts. Cricket Team.
Mr. J. S. Green (37 Tything, Worcester)—3 Photos. of Rev. Canon R. Cattley
Mr. S. Thorn (Bude House)—3 Photos. of "Elizabeth Moore Garden" Life Boat; 1 Photo. of Chaple Rock, Bude Harbour.
Mr. W. McLean (Hunstanton, Norfolk)—2 Photos. of Lieut. R. Wells.
