CONTENTS.

THE TONING OF COLLODIO-CHLORIDE PRINTS.

DR. LIESEGANG, who has given much attention of late to the production of prints on collodio-chloride, and whose recent paper—published on page 772 of our last volume—has caused many persons to occupy themselves with this method of printing, has recently published some instructions for toning such pictures, and the substance of these instructions we now propose to place before our readers.

A solution of acetate of soda in water to which chloride of gold has been added some time before the commencement of the work of toning—in fact, a similar bath to that used for prints on albumenized paper—has proved excellent for collodio-chloride prints. It is not well to commence by preparing a bath containing a whole 15 grain tube of gold in two or three pints of water, as such a solution loses its toning power in some days, and one has no alternative but to add more gold; so that it is far more rational to add the gold gradually, and, in commencing, not to use more than is required for the number of prints to be toned.

To act according to this method one must prepare two solutions:—No. 1 containing an ounce of fused acetate of soda to a quart of water, and No. 2 containing fifteen grains of gold chloride to a pint of water. No. 1 is the stock solution, and is, of course, used over and over again, and from time to time the gold solution is added as required.

The gold solution should be added to the acetate of soda bath about an hour before the toning solution is required for use—more or less being added according to the number of prints to be toned, or the tint required; and it is easier to judge of the progress of the toning by looking through the prints than by merely looking at the surface. Experience alone will enable a judgment to be formed as to how much gold will be required for any given tone; but in the working it must be remembered that collodio-chloride prints tend to tone quickly. The prints may be directly transferred, and without rinsing, into the fixing bath, which should be made with about three ounces of "hypo" to a quart of water.

Five or six minutes suffice for the fixing, and less washing will suffice than is usual in the case of prints on albumenized paper.

PACKING NEGATIVES FOR SENDING BY RAIL.

IT requires no consideration to at once see that if a negative is to be sent by any of the ordinary means of conveyance, it must be so packed as to stand the maximum of ill-usage to which goods in transit are ordinarily subjected; and we all know that those who have the handling of rail or post packages are by no means tender-handed.

In ordinary cases a small negative is considered quite safe if enclosed in a moderately strong wooden box with a thickness of one-eighth of an inch of soft paper—such as the so-called *papier Joseph*—intervening all round between the glass and the wood. Although it is contrary to the postal regulations to send glass by post, a very large number of negatives enclosed in boxes are sent to and from enlarging houses packed in this way, and a fracture is by no means common: but it sometimes happens that the wood forming the top or bottom of the box will so far bend under the action of a vigorously applied post stamp as to strain the glass of the negative to the breaking point. This risk can, however, be tolerably well guarded against by wrapping the box in black paper, and putting both address and stamps on a small label or tally attached to one corner of the box; of course no one would think it worth while to stamp on the black paper. It is also just conceivable that, if a box containing a negative, packed as described, were thrown violently across a room—by no means an uncommon thing in the case of both rail and post packages—that the jar or shock might fracture the glass; and a very simple and effectual means of guarding against fracture from such a cause was brought before our notice the other day, when we received a small negative (half-plate) which a friend had sent to us from a distance. The negative was packed with a soft paper in a wooden box, a distance of about an eighth of an inch being allowed between the wood and the glass; but in order to render it practically impossible to communicate a dangerous shock to the wooden case, this was packed in an ordinary hat box, ropes or coils of soft paper serving to preserve at a proper distance the outer and inner case. Not only is a hat-box likely to command the nearest thing to consideration which a parcel agent or post official may be expected to possess, but such a package as we have referred to can hardly take any harm by being thrown about, as the bulk is so great in proportion to the weight as to preclude the notion of damage; while even if the hat-box were "pancaked" under a large packing case, the negative inside would stand a good chance of being uninjured.

A band-box thus backed is within the limits of weight and bulk imposed by the conditions of the Parcels Post, but the fact of there being no guarantee and no registration, prevents many persons from sending really important negatives by Parcels Post.

A delivery agency, such as Sutton, or the Globe Express, will accept responsibility up to ten pounds, or more if insurance is paid, and a receipt can always be obtained if a form is made out ready for the receiving clerk to sign. Instead of packing a negative in a box, it is a very good plan to send it in a portable printing-frame—that is to say, if the printing-frame is true, and the rebates are lined with rubber—the frame being, of course, itself protected

over the face with a board, and packed in some material calculated to diminish any shocks to which it may be subjected.

That there are people who will feel surprise at serious consideration being devoted to such a subject as the safe packing of negatives we are fully aware; but these persons are doubtless those belonging to the numerous class who, when they have to send a negative away, simply put it with a letter in an ordinary envelope, perhaps with a piece of cardboard on each side, but oftener without. We receive many negatives so sent—or rather, we should say, the fragments of them.

In conclusion, one may consider that security in transit is best ensured by a box within a box, the interspace being filled with a soft material, and by making the whole package bulky in proportion to its weight. Perhaps our readers will remember how some of the magnificently crystallized specimens of certain chemical preparations were sent from Germany to the International Exhibition of 1862. The order was this, commencing with the centre:—1. Group of crystals resting on a tray. 2. A set of gym-balls similar to the arrangement ordinarily used for swinging a mariner's compass. 3. Stretched rubber springs. 4. The outer case.

By-the-Bye.

WATER AND ITS IMPURITIES.

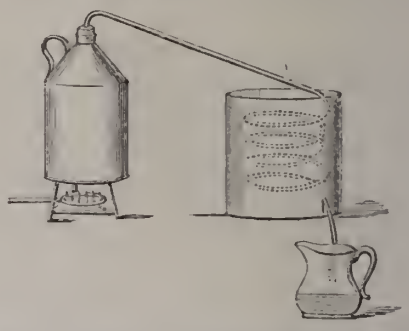
The alchemists dreamed and talked of that universal solvent which they so long and vainly endeavoured to discover; still, for all this, not only the alchemist of old, but his more immediate successor, the chemist of to-day, has found no solvent so universal as water. No liquid has nearly so wide a range of dissolving powers, and, taking things all round, no liquid exercises so slight an action upon the bodies dissolved—evaporate the water away, and the dissolved substance is obtained in an unchanged condition; at any rate, this is the general rule.

The function of water in nature is essentially that of a solvent or a medium of circulation; it is not, in any sense, a food, yet without it no food can be assimilated by an animal. Without water the solid materials of the globe would be unable to come together so closely as to interchange their elements; and unless the temperatures were sufficiently high to establish an igneous fluidity, such as undoubtedly exists in the sun, there would be no circulation of matter to speak of, and the earth would be, as it were, locked up or dead.

When we look upon water as the nearest approach to a universal solvent that even the astute scientist of to-day has been able to discover, who can wonder that it is never found absolutely pure in nature; for wherever it accumulates it dissolves something from its surroundings? Still, in a rain-drop just formed we have very nearly pure water; but even this contains dissolved air to the extent of about one-fiftieth of its volume, and as the drop falls downwards it takes up such impurities as may be floating in the atmosphere; so that if our rain-drop is falling immediately after a long drought, it becomes charged with nitrate or nitrite of ammonia and various organic matters—perhaps also the spores or germs of disease. Thus it will be seen that rain tends to wonderfully clear or wash the atmosphere, and we all know how much a first rain is appreciated as an air purifier, and how it carries down with it valuable food for plants. The rain-water, in percolating through or over the land, flows mainly towards the rivers, and in doing so it becomes more or less charged with mineral matter, lime salts and common salt being the chief of them; while some of that water which has penetrated more deeply into the earth takes up far more solid matter than is ordinarily found in river water. The bulk of this more or less impure water tends towards the ocean, taking with it its load of salt and lime. Constant evaporation, of course, takes place from the surface of the sea, so that the salt and lime accumulate, this latter being, however, ultimately deposited as shells, coral, and chalk; while nearly pure, or naturally distilled, water once more condenses in the form of clouds. This process, by which a constant supply of purified water is kept up in the natural economy, is imitated on a small scale when water is converted into steam by the action of heat, and this vapour is cooled so as to reproduce liquid water, the operation in question being known as distillation.

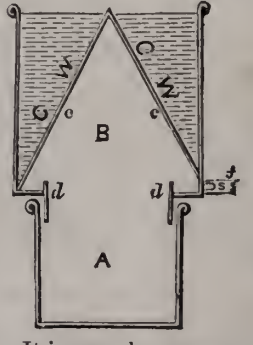
For this purpose an apparatus known as a still is required; and although by law one must pay an annual licence fee for the right to use a still, it is not usual for the Government authorities to enforce the law when a still is merely used for purifying water.

One of the best forms of still for the photographer to employ consists of a tin can or bottle in which the water is boiled, and to this a tin tube is adapted by means of a



cork, one end of this tin tube terminating in a coil passing through a tub or other vessel of cold water. A gas burner, as shown, is a convenient source of heat, and in order to ensure a complete condensation of the vapour, the water in the cooling tub must be changed now and again.

Sometimes the vapour is condensed by being allowed to play against the inside of a conical cover which is adapted to a saucepan, and is kept cool by the external application of cold water; and in this case the still takes the form represented by the subjoined diagrams; such compact and portable stills being largely employed in Ireland for the private manufacture of whisky.

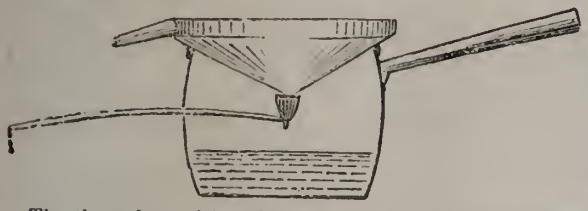


It is scarcely necessary to say that the condensed water trickles down on the inside of the cone, and flows out at the spout.

An extemporised arrangement of a similar character may be made by passing a tobacco pipe through the side of a tin saucepan as shown in next page, and inverting the lid of the saucepan; if the lid is now kept cool by frequent changes of water inside it, and the pipe is properly adjusted so as to catch the drippings from the convex side of the lid, a considerable quantity of distilled water may be collected in an hour or so.

The proportion of solid impurities present in water as ordinarily met with is extremely variable; rain water

which has been collected towards the end of a storm contains only a minute fraction of a grain per gallon, while river or spring water may contain from less than thirty grains per gallon or so and upwards. Ordinary sea water generally contains from three to four per cent. of saline matter, but that of the Dead Sea contains nearly one-fourth of its weight of salts.



The three impurities of water which most interest the photographer are lime or magnesia salts, which give the so-called hardness; chlorides (as, for example, chloride of sodium or common salt), which throw down silver salts; and organic matter, which may overturn the balance of photographic operations by causing premature reduction of the sensitive silver compounds. To test for them is easy. Hardness is easily recognisable by washing one's hands in the water, the soap being curdled; but in many cases one must rather seek for a hard water than avoid it, as the tendency of gelatine plates to frill is far less in hard water than in soft water. It is, indeed, a common and useful practice to harden the water used for washing, by adding half an ounce or an ounce of Epsom salts (sulphate of magnesia) to each bucket of water. Chlorides—chloride of sodium or common salt being that usually met with—may be detected by adding a drop or two of nitrate of silver to half a wine glass full of the water, a few drops of nitric acid being then added. A slight cloudiness indicates a trace of chlorides, and a decided milkiness shows the presence of a larger quantity. If it is wished to get a somewhat more definite idea of the amount, it is easy to make up a series of standards for comparison, by dissolving known weights of common salt in distilled or rain water, and testing samples of them side by side with the water to be examined.

Organic matters may be detected by adding a little nitrate of silver to the water, filtering off from any precipitate of chloride of silver, and exposing the clear liquid to sunlight; a clean stoppered bottle being the most convenient vessel to use. The extent to which a blackening takes place may be regarded as approximately proportionate to the amount of organic matter present.

Filtration on a small scale is not altogether a satisfactory mode of purifying water, as organic impurities often accumulate in the filter, and enter into active putrefaction when hot weather sets in.

FURTHER PARTICULARS REGARDING THE ACTION OF COLOURING MATTER ON GELATINE EMULSIONS.

BY DR. J. M. EDER.

I HAVE already recognized the fact that iodeosine acts more favourably than bromeosine; and I have recently made experiments with the so-called commercial eosine colours, as "yellow eosine," "blue eosine," "yellow erythrosine," "blue erythrosine," and "Bengal rose." The results of my experiments prove that "yellow eosine" (bromeosine) and "Bengal rose" possess a less decided action on a bromo or bromiodo emulsion (made with ammonia), than is the case with "blue eosine" (iodeosine), or erythrosine. Moreover, the band of the greatest action in the yellow was found to be nearer the orange when the "blue eosine" and "blue erythrosine" were used than when the colouring matters of yellow tint were employed; these results corresponding to the absorption bands.

In the case of all these colouring matters ammonia exalts the general absolute sensitiveness, and the sensitiveness for the yellowish-green in particular. If one, for example, soaks plates for two minutes in a solution of ·08 to ·12 gramme of eosine, erythrosine or "Bengal rose" in 100 cubic centimetres of water and 3 cubic centimetres of ammonia, the band of "yellow sensitiveness" is almost doubled in breadth.

An interesting experiment is to determine whether, in such a case, the bromide of silver is itself coloured: and, indeed, one may freely wash eosine plates with water without causing them to lose their "yellow sensitiveness," as is proved by the experiments of Attout, Clayton, and Schumann; but as so small a quantity of eosine as is scarcely sensible to the eye will give yellow sensitiveness, these experiments must not be taken as conclusively proving the case. I therefore separated the bromide of silver from an ammoniacal emulsion which had been treated with eosine, by the aid of Pleuer's centrifugal machine, and washed it repeatedly with water, so that the liquid finally came away colourless. Notwithstanding this, the bromide of silver possessed a faint reddish colour, and it did not lose this by further washing. This bromide was once more emulsified in gelatine, and the plates prepared showed the characteristic band of "yellow sensitiveness." After development and fixation the plates were slightly reddish.

This proves that the colouring matter holds firmly to the grains of silver bromide; or, perhaps, rather to that gelatine which the bromide holds enclosed. In such a case the gelatine may be regarded as acting as a medium between the silver bromide and the colouring matter, in the same kind of way that protein bodies serve to fix colouring matters on cotton fibre.

That bromide of silver fixes gelatine in some way, when it ripens, is proved by the following experiment. Bromide of silver was separated from an emulsion by means of Pleuer's centrifugal apparatus (PHOTOGRAPHIC NEWS, 1882, page 257), and thoroughly washed with water at 140° Centigrade; after which it was dried, the combustible organic matter being determined by ignition, and restoration of the reduced bromide by the usual means. One hundred parts of bromide from boiled emulsion proved to contain ·45 of gelatine; and in the case of another experiment with ammoniacal emulsion, ·52 per cent. of gelatine was found. A cold emulsion, which was prepared with much water and little gelatine, so that the bromide could settle, gave a bromide containing ·93 per cent. of gelatine.

The sensitiveness of bromide of silver may—among other causes—be due to the gelatine thus intimately united. As to a chemical combination between the bromide and the gelatine one can say little; indeed, it is difficult to believe in such a combination, as one must assume a compound of one molecule of gelatine with several hundred of silver bromide, and this is contrary to our general experience of similar protein compounds—as, for example, the silver compound of albumin, which contains equal molecules of albumin and silver nitrate.

Practical Papers for Beginners.

No. 6.—MORE ABOUT DEVELOPMENT.

IT is supposed that the beginner has returned from his outing with a collection of plates, some or all of which may have been over-exposed, under-exposed, or correctly exposed; but in order to have a fair chance in developing such a collection, it must be assumed that notes have been taken as to conditions under which the exposures were made.

Let us begin with a slide containing a couple of plates,

both having had the same exposure. Unless the photographer has a notion that the exposure was too much or too little, he will naturally try one of the plates with the normal developer, or equal parts of the following solutions:—

No. 1.—Developing Solution.

Strongest liquid ammonia ...	½ fluid ounce
Bromide of potassium ...	70 grains
Water	1 pint

No. 2.—Developing Solution.

Pyrogallic acid	60 grains
Water	1 pint

To begin with, let us assume that the trial plate shows signs of extreme over-exposure—that, in fact, it appears to blacken immediately all over under the action of the developer, and the resulting image is very thin and weak, although all, or nearly all, details are visible. In such a case the mere increasing of the proportion of No. 2 will not sufficiently retard the development of the second plate, it being necessary to add an additional proportion of bromide as well; and the following method of working will probably answer. Make up a standard solution containing ten per cent. of bromide of potassium as follows:—

No. 3.—Bromide Solution.

Bromide of potassium	1 ounces
Water	9 ounce

An ounce or so of this should be kept ready for use in a spirting or dropping bottle, such as is figured below;

the cork being perforated, and fitted with a short length of tube, contracted slightly at the outer extremity. To contract the tube a piece of double the required length is held in a gas flame till the middle portion is softened; force being then applied to stretch it out until it is sufficiently contracted. When cold, a file-scratch is made at the narrowest part, and a little strain causes it to snap at the scratch; the perforation in the cork may be made with a rat's tail file. The spirting bottle being held in the right hand, the jet is moved or swung rapidly towards the mouth of one of the developing cups, and suddenly stopped, a few drops of the fluid being ejected in consequence; and for the same bottle and tube, the quantity thus thrown out at each spirt is approximately equal. Let us suppose it to be half-a-dozen drops, and that a first trial is made with six spirts, which may represent about four grains of solid bromide. Three ounces of pyrogallic solution or No. 2 are next added, when one ounce of No. 1 (which we will suppose to be already poured out in another glass or cup) is mixed in. The plate is now flooded with this mixture, and if, even under these circumstances, the image appears to come too rapidly, the developer should be poured back into the glass, and more of the restraining bromide solution must be added a still further addition being made if circumstances appear to indicate the necessity. If, in spite of the above treatment, signs of over-exposure are apparent, and a third plate which one may judge to have been similarly over-exposed is among the batch, a preliminary treatment with potassium bromide solution is advisable, the plate being immersed for a few seconds in a ten per cent. solution, and afterwards developed with the normal developer (equal volumes of No. 1 and No. 2).

The above directions will make it clear that the remedies for over-exposure may be placed in the following order, the mildest measures being placed first on the list, and the mode of treatment for the most extreme case of over-exposure being placed last.

1. An increase of the proportion of No. 2 solution—say to the extent of three times the volume of No. 1.

2. The addition of a ten per cent. bromide solution (No. 3). From two to twenty drops to each ounce of developer.

3. The plate to receive a preliminary soaking in a ten per cent. solution of potassium bromide for a few seconds or longer according to circumstances.

Now let us assume the reverse case—namely, that the first or trial plate has been under-exposed, and that the mere increasing of the proportion of No. 1 solution is not sufficient to bring out a passable picture. In this case the developer is poured back into its glass, and some of the following is added from a spirting bottle:—

No. 4.

Strong ammonia solution	1 ounce
Water	9 ounces

The spirting bottle used for the above ammoniacal solution should be different in shape or size from that employed for No. 3 solution, as otherwise mistakes are likely to occur. Additions of ammonia may be made at intervals, the liquid being poured back into the glass each time ammonia is added. A point will be reached at which either the required detail will be brought out, or else a faint brown tint will appear all over the film, and after this one can do no more. The universal tinting produced by forced development may be distinguished from that arising from over-exposure by the circumstance that in the former case no details are to be found in the shades of the subject. It must, however, be understood that for extreme under-exposure there is no remedy; while extreme over-exposure may be controlled if the fact is known previously. In some cases two-thirds of the bromide, or even more, may be omitted from No 1 solution when a plate has been over-exposed; but it occasionally happens that plates will not stand this treatment, a general fog or darkening being the consequence.

There are other modes of development—as, for example, that with ferrous-oxalate—but it is, perhaps, better for the beginner to confine himself to one method, and for this reason we shall, in our next practical paper, treat of printing from the negative.

ROYAL CORNWALL POLYTECHNIC SOCIETY.

This Society opened its doors on Tuesday, August 12th, for the fifty-second annual Exhibition, and, as will be seen, the Society is getting into years. Until a few years ago it confined its Exhibition to the Polytechnic Hall, but, owing to the increased number of exhibits, the Society has been obliged to engage other premises in conjunction with its own. This year the spacious Drill Hall was engaged for machinery in motion, &c, whilst the Polytechnic Hall has been confined to the fine arts, such as painting (oil and water), photography, art pottery, sculpture, carvings, &c.

The Exhibition opened at eleven o'clock, a.m., when the building was very soon filled. The presidential address was given by the Right Honourable the Earl of Mount Edgcumbe, who was accompanied on the platform by the Revs. Canon Phillpotts, C. W. Curlyon, G. Bull, W. Iago, A. H. Malan, F. Cole, J. Mayne, Sir John St. Aubyn, Lord

Renshaw, General Aylmer, Colonel Curlyon, Major Ross, Major Haye, Major Pender, Captain Bridges, R.N., Messrs. T. B. Bolitho (High Sheriff of Cornwall), H. Liddicoat (Mayor of Falmouth), T. S. Bolitho, W. Cole Pendarves, Jonathan Rashleigh, Barham, M.D., Iago, M.D., Harvers, M.D., Howard Fox, Robert Fox, A. L. Fox, C. B. Beauchamp, H. V. Broad, J. H. Collins, F.C.S., R. N. Worth, F.G.S., W. Brook, and E. Kitto, F.M.S.

The President, on rising, said he was sure those present would forgive him if he performed this duty in a most formal manner, for he was sure they did not come there to hear desultory remarks from a person who had just arrived in town, and had hardly been able to look through the Exhibition. They came there to see an Exhibition of a peculiar character, which Falmouth had made its own, and of which that town and county had every reason to be proud. It was an Exhibition partly practical and partly artistic. The more practical exhibits were mostly designed for mining purposes, and were shown in the Drill Hall; but besides these they would find there an exhibition of gas lighting and heating apparatus introduced by Murdock, who was born just a century ago. Murdock at one time lived at Redruth, and was agent for James Watt, and was practically the inventor of gas lighting. The first house so lighted was his own house at Redruth, and the first large public building lighted was the Soho Works, Birmingham. The Earl then referred briefly to other sections of the Exhibition, and said the numbers and general excellence of the exhibits were, he thought, fully up to its average, and full explanation would be given by Mr. W. Brooks, to whom the Society was indebted for so fine a display in getting them together.

Sir John St. Aubyn, M.P., moved a vote of thanks to the Earl of Mount Edgcumbe, which was seconded by Mr. Jonathan Rashleigh, who said it was really a privilege to have the noble Earl presiding at any gathering, because he always brought wisdom, judgment, and discretion to bear on the proceedings. The motion was heartily assented to, his Lordship briefly returning thanks, and declaring the Exhibiton opened.

Lectures were arranged and given on scientific subjects in the evenings during the week, and a concert was also given on Thursday evening, which was well attended.

The attendance on Friday evening was very large, owing to the annual drawing of the Art Union prizes, which took place at nine o'clock, p.m.

The Art Union was established to enable professional artists and photographers to dispose of their works on exhibition. The prizes are generally allotted as money prizes, and the successful winners are bound to select any work by professional artist or photographer on exhibition, as it is well for photographers and friends of the Society to take a few shares, and by that means assist their brethren in art.

On Tuesday afternoon, at 4 o'clock, the foundation stone of the new Observatory was laid by the Earl of Mount Edgcumbe, a large and influential company being present. The building altogether is estimated to cost £1,300. After the stone had been laid, a subscription list was handed round, and £81 was promised in addition to that which had already been subscribed. The Observatory is conducted under the auspices of the Polytechnic, Mr. E. Kitto, F.M.S., being the chief observer in charge; and most of the records are made by means of photography.

Photographic Department.

Judges' Report.

The Judges have great pleasure in announcing to the Society that the exhibits of this department and its sections are fully up to the average, not only as regards numbers, but the excellence of the exhibits generally.

Of late years there has been a falling off in the professional portraiture department—that is, in the large size portraits.

The landscapes are exceedingly fine, especially since the introduction of the rapid gelatine plates, at the present time their manipulation being better understood than it was a few years since. There are a few specimens of instantaneous work which possess merit which was unattainable until the introduction of the rapid plates.

The amateur section is exceedingly well represented.

The judges call special attention to a series of large photographs of America, which possess great interest not only as photographs, but are very interesting from a geological point of view, which have been presented to the Royal Institution of Cornwall by Mr. Richard Pearce, jun., of Denvers, U. S. A.

In the photographic appliance and magic lantern department several ingenious inventions are to be found.

Professional Section.

Mr. H. P. Robinson (of Tunbridge Wells) is well represented by a large series of very fine studies in his well-known style. They are most admirable as gems of the photographic art, and each one tells its own tale, the expression and gesture of the figures being perfect. His large picture (No. 695) "The Cuckoo" carries off the first silver medal, the subject being a very difficult one, and exceedingly well treated.

Mr. W. W. Winter (of Derby) takes also a first silver medal for a portrait study, "Sad Moments," which, in the opinion of the judges, is simply perfect in pose and expression. He is also represented by several other charming studies, fully illustrating the high state of perfection in photographic art at the present day.

Mr. W. Gillard (of Gloucester) is again to the front, and has been awarded a "first silver medal" for his magnificent composition picture "The Miser," and the judges cannot speak too highly in its favour. He has also several other exhibits, which are very perfect.

Mr. C. H. C. Harrison (of France) sends three frames of instantaneous studies printed in carbon, which show careful manipulation.

Mr. W. P. Marsh receives a first bronze medal for his frame (No. 665), "High Seas" (instantaneous), which represent in a marvellous manner heavy seas breaking over beach and esplanade.

Mr. E. C. Bowker sends a frame of cabinet pictures (No. 666), some of which are very good.

Mr. F. Whaley sends some very excellent studies, the best of which is No. 667 ("This Little Pig went to Market").

Mr. J. Milman Brown is again represented by several productions, one of the best of which is "Autumn Sunshine," and is highly commended.

Mr. R. Faulkner (of London) shows a frame of very skilful studies of children in his well-known style, and also some highly finished vignette portrait studies.

Mr. J. P. Gibson sends some clever little artistic studies, principally river scenes.

Mr. J. Terras contributes some clever little studies.

Mr. A. Heudrey sends some studies of flowers; and also a river scene, "The First Bite," which is a pleasing little study, and is very highly commended.

Mr. Jno. Jackson sends three frames of views, the best of which is 696, which are of considerable merit.

No. 696, a frame of interiors of Lincoln Cathedral, by Mr. G. Hadley, has been awarded a "second silver medal," being well rendered.

Mr. P. M. Laws contributes a frame of ceramic enamels, which are well worthy of notice.

Mr. Luke Berry sends some charming pictures, both landscape and figure; to his "Llanberis Pass" has been awarded a second silver medal, being a most charming artistic production, and full of atmosphere.

Messrs. Byrne and Co. (Richmond) send some very fine portrait examples printed in red carbon, but the judges noticed several of the same studies that the firm have exhibited in former years.

Mr. G. Renwick sends two large studies of snow and frost scenes, which are interesting: and also a frame of children's portraits of merit.

The award for enlargements is a second silver medal to Mr. T. J. Dixon (of London) for a tiger; in the opinion of the judges it is the best enlargement they have ever seen from so small a negative. There is another one of an eagle equally good.

Mr. G. Honey has a very clever little composition picture, children in a boat feeding swans, and it is to be regretted that the picture is not of larger size.

Amateur Section.

The Rev. H. B. Hare sends examples of good work of river and wood scenery.

Mr. A. Pringle's productions are very perfect, and are fully up to that gentleman's former productions. To his frames Nos. 805-809 has been awarded first silver medal, and they are full of atmosphere, and the artistic treatment is perfection in every way.

Mr. A. Millar contributes a very careful figure study.

Mr. D. Barnett sends two frames of landscape and rustic studies.

Dr. T. H. Morton shows two very good interiors.

Mr. A. G. Tagliaferro sends frames of interiors, &c., to the best of which (frame 812) has been awarded a second silver medal, the subject being well treated.

Mr. W. J. Grant has been awarded a first bronze medal for a frame of his well known Polar subjects.

Mr. R. Hopkins sends three large size pictures printed from paper negatives.

Mr. P. H. Emmerson, B.A., contributes one frame of seascapes (instantaneous), to which has been awarded a second bronze medal. The same gentleman also sends two life-size pictures of heads printed in red carbon, which are highly commended.

Appliances, etc.

Mr. G. Atkinson sends a retouching desk, and Mr. F. B. Dagley a plate-washing cabinet which is well adapted for the use of amateurs, and which has been awarded a second bronze medal. The same contributor also sends a plate-box so made that the plates may be examined by the Customs without injury.

Mr. R. R. Beard (of Bermondsey) forwards a very ingenious self-centering lantern slide-carrier, to which has been awarded a second bronze medal. The same person sends also a case of safety tubes, the workmanship of which is very good. He also sends a drawing of a screw regulating the back-pressure valve and gas tap.

Review.

PHOTOGRAPHY FOR AMATEURS. By T. C. Hepworth. Price One Shilling. (*London: Cassell & Co.*)

JUST now, as the body of non-professional photographers is being rapidly recruited, it is only to be expected that the number of elementary hand-books issued will keep pace with the demand; and Mr. Hepworth has been successful in making an exceptionally good text-book for the beginner.

Ten pages serve for an abstracted history of photography, and this history is, perhaps, the weakest part of the book: after which come nearly a hundred and fifty pages of very practical matter, including, however, not much beyond the gelatino-bromide process; the description of the wet collodion process merely occupying about a dozen lines in the historical chapter; and we are here told that the collodionized plate is dipped for *several seconds* in a bath of nitrate of silver to make the plate sensitive to light.

Some remarks on out-door work may be worth reproduction. Mr. Hepworth says:—

"The success of a landscape photograph mainly depends upon the judgment with which the subject is chosen. The beginner will be apt to fall in love at first sight with any picture which he may focus on the ground-glass screen of his camera, and will probably imagine that as it looks so beautiful it is sure to make a fine photograph. But let the experienced worker peep over his shoulder for a moment, and whisper to him that the picture, pourtrayed in all its natural colours as it is, will look very different as a monochromatic photograph. Those moving clouds, with all their tender hues, and their lovely blue background, will, in the photograph, be represented by a blank white space. The brilliant carpeting of green will be almost black. That hedge bounding the field will, in the picture, be represented by a still blacker mass, forming an ugly band, separating the sky from the earth. In a word, the beginner wants educating by experience into what will and what will not make a good picture.

"Unfortunately, the power of really appreciating nature is much rarer than many people imagine. How many are there who seem to have no idea of noting the natural beauties of spots which are constantly before their eyes! One may perhaps cross the bridge over a canal every morning on his way to work, and will be familiar with the sight of the laden barge, and the patient horse toiling on the tow-path dragging it along. He may take the trouble to look at the scene, but he would laugh at the idea of there being anything beautiful about it. But show him a photographic print of the same view. He will be delighted at it; he will say that he never saw anything so beautiful. Then he will notice for the first time the ripples on the water; the reflected shadow of the girl steering the boat; the light tint of the load of straw relieved by the dark sail lying upon it: in short, he will for the first time see an artistic picture, which, when presented to him in all the wealth of colour which nature's palette affords, and with all the poetry of movement which belongs to living things, he had looked upon with a blind man's eyes."

The remarks which follow should be read by those who find all commercial plates uniformly bad; and we agree with Mr. Hepworth, that no maker who constantly, or even occasionally, supplies bad plates can hope to retain his business; indeed, we could mention instances in which dry plate manufactories have been closed in consequence of a few bad batches being sent out. Let us again quote the author:—

"I am certain that many amateur workers fail because they will persist in using different makes of plates. They perhaps admire the work of some more competent friend, when their first question is, 'Whose plates do you use?' The answer is given, and straightway a batch of the recommended plates is procured; but the work turned out by their aid is no better than before. I believe, although some commercial plates are better than others, that all are good. The man who supplied faulty ones would quickly lose his custom, and would drop out of the race. The beginner will do well not to commence by making his own, but to use commercial plates until he understands something of their capabilities."

THE SUN ELECTRIC LAMP APPLIED TO PHOTOGRAPHY.

EVER since lighting by means of electricity became practical, the idea has occurred to utilize it for photography. In fact, the new processes seemed to possess very great advantages over solar light, as the latter depends upon the state of the atmosphere, and is often insufficient in our latitude for full a third of the year.

The systems of lamps that were first used in the public streets, and which were consequently the best known, were the ones first employed, and for this reason it was the Jablochkoff

candle that, in France, served to establish those photographic installations which were attempting to make progress in a new route. Every one will remember the little gallery which was conducted by Mr. Liebert in one of the salons on the first storey at the Palace of Industry. Here the apparatus, which served to contain the electric light (which consisted of a Jablochkoff candle), and to project the same, were as yet very primitive and difficult to manœuvre. The large parabolic copper reflector was designed for concentrating the luminous rays upon a limited surface, in order to give sufficient luminous intensity to the parts of the subject to be reproduced; so nothing but busts could be taken, and, moreover, the lights and shades were extremely pronounced, and the flesh, on account of the violet rays emitted by the lamp, exhibited livid reflections whose colouration and intensity varied according to the caprices of the unstable light.

The sun lamp, which possesses all the qualities of colouration and steadiness of the incandescent light, and, at the same time, a luminous intensity as great as that given by the arc light, ought to be admirably adapted for photographic purposes. But while waiting for carriages to a distance and distribution of electricity to enter the industrial domain (which it will ere long) the management of a truly practical gallery for utilizing Mr Clerc's invention would have necessitated too great an expense, and it was a mere accident that permitted the installation to be arranged that we now have under consideration.

Alongside of the sun lamp works, in Wagram Avenue, is situated Mr. Boscher's photographic gallery, and it was therefore easy to arrange a few meters of cable to carry the current to lamps arranged for photographic operations. The steam engine is running all day long in the lamp works, and, in the evening, it is only necessary to notify the engineman to continue his work in order to have a beautiful light that permits of taking, just as in broad daylight, the most varied negatives.

The sun lamp is well known to the public, which has, at various times, had an opportunity of judging of its merits during the experiments at the Continental Hotel, on the Jouffroy road, in the picture gallery of the Exhibition of Electricity, and in the grand *foyer* of the Opera House. At present the lamp and machines are much superior to what they were at first, and it is indeed strange that this light has not found more applications in Paris, where it would give more satisfactory results than all

those that are at present illuminating the great industrial and commercial centres and the theatres and other places of amusement.

We give, in the accompanying engraving, the details of an application of this lamp to photography in Mr. Boscher's gallery. There are four of the sun lamps, and they are arranged as follows. The first is suspended from the centre of the posing room, beneath a white drapery. The illuminating surface, which is covered with a slightly ground globe, is directed toward the drapery, and the latter serves to reflect the light. The lamp, which is suspended from a longitudinal cable, may be slid along by means of a pulley, and be removed from, or brought near, the subject to be photographed, in such a way as to well light the upper part. Two like frames, which are mounted upon rollers, carry three other lamps (provided with opalescent globes), which may be placed laterally so as to send the light toward the centre of the body and that portion of the floor upon which the feet of the subject or of the persons forming a group are resting. In order to prevent the rays from falling too directly (which would give glaring whites, and shades without transparency), a large white screen of a thin, white fabric, upon which rose or other coloured gauzes may likewise be placed, is interposed between the lamps and the model. Another opaque screen is placed alongside of the objective during the operation, to prevent the luminous rays striking the gelatino-bromide plate too directly.

All the walls of the apartment, moreover, are of a very light tint, and, through the arrangements that we have just indicated, there is obtained a diffused light, whose intensity may be very easily varied at any given point. The time of exposure necessary in order to obtain good results is scarcely longer than with daylight, and the proofs of album cards that we have examined in Wagram Avenue demonstrate that hereafter lovers of beautiful photographs will not have to be dependent upon the caprices of the light of the sun.—*La Lumière Electrique.*

Notes.

The picture of every-day native life in Constantine, presented with the PHOTOGRAPHIC NEWS this week, shows a so-called "*Café Maure.*" They are bare-looking enclosures with a form or two as the only furniture. Most of the people prefer to sip their coffee couched on the bits of floor mat. The shop on the left-hand side of the picture is that of a sadler, and the holes shown over the shop are intended for ventilation.

Mr. Pritchard, referring to the taking of the picture, says:—"Here is a native coffee house, a 'Café Maure,' as it is called, for Moorish seems a term adopted by Arabs who are settled in a town. Two or three 'blankets' are squatting at the door, to give a *pièce de résistance* for the picture, and I hope to drop my shutter in time to get a few passers-by. I do get passers-by, but not a few. They come in troops. A friendly Arab shouts in French, a turbanned Turk roars in Turkish, a donkey-boy cries out in Arabic, and I holloa in English. The scene grows lively, but, thank goodness, everybody is delighted. A stalwart negro in blue breeches and gold-lace embroidery comes up chuckling, so I take him by the shoulders and push him beside the café door. Sambo enjoys the joke immensely, but won't stand. So the shutter has to fall on what it can. A second plate is pushed in; the crowd is beginning to enjoy my entertainment immensely, but they won't keep back. They think my juggling with the camera capital fun, and take it for a peep-show, evidently; they surround me closely. Again do I sally forth, and make a lane for the lens, and a second time I let my shutter drop because I must; it is a case of a crowd or nothing."

The fifth annual Convention of the Photographers' Association of America, the opening of which we announced in our issue immediately following the event, has been a great success in one way; but, perhaps, not quite as we understand success.

There was a good gathering at the opening on the 27th of last month—indeed, nearly a thousand were present—also a fine collection of photographs and apparatus, and those present had a real good festive time, but no papers of any great interest were read. Mr. W. H. Kent, the President, writes to us, under date August 1st:—"The Convention is opened, and exceeds our utmost expectations. It is a grand success, and I believe nothing approaching it has ever been seen in this or in any other country in the world. The display of photographs is wonderful."

It was such a gathering as is calculated to make a friendly feeling among the members of the craft, and there was an evident disposition to come to an understanding on the vexed question of prices.

There were two rival reports of progress during the past year handed in, and one was partly read: some amusement being created by the circumstance that advance slips had been sent out by the authors of the reports, each being represented as the genuine and veritable.

On the whole, the Convention appears to have appealed more to professional photographers than to amateurs.

Cincinnati seems to be an enviable place for photographers. According to a statement recently made by a member of the Illinois Photographers' Association, the prices obtained are very good, one firm charging ten dollars per dozen for cabinets, and another fifteen dollars per dozen. The Cincinnati photographers are sufficiently independent to do without advertising their prices, and announce them only when you enter the reception room.

Photographic riddles are not numerous, and they are not, as a rule, good. The last we have seen appeared in a Brooklyn paper, and ran thus:—"Why should the 'Foe-to-graphic' Art be called the 'Friend-to-Graphic Art?' Because it is so frequently metamorphosises dry "plates" into most interesting "pictures."

When the Queen heard of the death of Mr. Jabez Hughes, she immediately sent a letter of sympathy to Mrs. Hughes, and on the evening before the funeral she forwarded a wreath to be placed on the coffin.

The principle of McLeod's sunshine recorder (see page 483) may be applied to the making of a very convenient form of sundial, in which the spot of light which serves as an indicator travels at equal speed over its whole range. It is merely necessary to so place a long focus lens in relation to the reflecting globe that the image of the sun is projected on a suitable screen placed at right angles to the axis of the objective, and the graduation of this screen is an easy matter compared with the plotting out of the scale of an ordinary sundial. The reflecting globe may be fixed outside a window having a northern aspect, and the objective may be inside if the glass of the window is of fairly good plate.

Simple as the collotype method of printing is, there are practical difficulties, and few in this country manage to make a profit by working it commercially, while even in Germany, where collotype is very much more practised than here, it is by no means easy to get an order for ten or twelve thousand impressions executed with reasonable promptitude.

What can appear more simple or easier than to first coat a plate of glass with an adhesive substratum of albumen and soluble silicate, next to level it, and dry on a film of gelatine made sensitive by the addition of bichromate of potash? The plate is now ready for exposure under a reversed negative, and after this it is soaked in water so as to moisten those parts which are not rendered impervious to water by the action of light. It is now laid on the bed

of the press, and on applying the inking roller the exposed parts take the ink, while the damp parts refuse it; but what is of most importance, all intermediate degrees between these extremes are rendered by the adhesion of a proportionate amount of ink.

Simple as the above is in theory, we hear of troubles in practice. The sensitiveness of the gelatine film varies much according to the conditions under which it has been dried, and sometimes it becomes generally impervious to water, or insoluble. Again, the film is often figured all over by surface markings, such as those gelatino-bromide workers know so well, and these show on the print; but, worse than all, it is a common thing for the gelatine film to break up or strip as soon as the printing has been fairly commenced.

Months ago we mentioned the fact of excellent collotypes of paintings, about half-plate; and each mounted on a kind of *papier mache* plaque, embossed so as to represent a frame, being sent from Germany, being sold retail at a penny each in London. Photographs of seaside resorts are now issued in the same size and style, but we do not think our readers can get prints of this character from their own negatives at a corresponding price, as the German collotypers keep reserve plates of such stock subjects, to print when unforeseen circumstances prevent the execution of more profitable work.

Full directions for working the collotype process appear on page 642 of our volume for 1882, and Mr. Riley's simple and practical instructions, which are to be found on p. 412 of our present volume, will be found sufficiently detailed in ordinary cases.

"The Extraction of Metals from Carbon, or Substances known as such," is the strange title of a patent applied for on the 12th inst. (No. 11,170.) The applicant is a lady.

The latest novelty in the way of photograph frames is one which it will be easy to develop further. The notion we allude to consists in so arranging the velvet covering the frame that it assumes the shape of a bonnet, in relief, around the face of the carte or cabinet portrait. The face of the Princess of Wales, which we have seen thus framed, admirably suited the style of bonnet into which the folds of velvet had been shaped, and the effect in this particular instance was charming.

It is easy to see how this idea can be developed. Clever manipulation will doubtless result on the similar modelling in velvet, not only of ladies' hats of varied shapes, but of Glengarry caps, military helmets with plumes, &c., and many other descriptions of masculine head-gear. Nor is there any reason why the "fad" should not be developed downwards, and the photograph frame become in effect a kind of velvet costume, cut in the latest mode, in which we shall dress, rather than frame, the portraits of our friends.

One advantage which might follow is obvious. Photographic likenesses, as it is, become old-fashioned, not so much because the faces of the sitters change, as because sartorial *modes* change so rapidly and completely. If, then, we can in future bring up a portrait to date by merely putting it in a newly-devised costume frame, the current life of our cartes and cabinets will be certainly prolonged.

Germany sends an exploring expedition to Congo. The chief of the expedition, Lieutenant Schultze, has undergone a course of instruction in photography at the Technical High School in Berlin, and takes a good equipment of photographic necessaries. The exposed plates will be sent to Berlin for development.

The death of Mr. W. H. Mummler, of Boston, merits passing reference from the fact that his name became notorious some years ago in connection with a lawsuit he had to sustain for making spirit photographs. Several well-known English photographers whom we could name were at the time inclined to believe there was "something" in spirit photographs. It would be interesting to know what their opinion is on the subject now-a-days.

The "Healtheries" next year gives place to the "Inventories," in which photography will of course form a part. In looking over the long list of photographic patents for the last quarter of a century, and noticing the vast number which never had any practical outcome, and the number, almost as large, which had become obsolete, one is tempted to ask whether the authorities intend to lay down any rule as to what is, and what is not, worth exhibiting. And this difficulty will not be confined to photography. To prevent the admission of "fads," or of useless inventions, the services of an expert in each branch will be almost indispensable.

Editors can definitely fix the arrival of the silly season "without referring at all to the date box or the almanack. The day's correspondence unmistakably marks the period in the calendar which has been arrived at. Thus, when last week we found amongst our letters a card on which "A Correspondent from the First" ('tis ever thus!) asked whether Nicephore Niepce and Talbot were "at Daguerres drawn"? We knew only too certainly that the era of the big-gooseberry had dawned, and that the voice of the sea-serpent would soon be heard in the land.

The *Photographic Eye* is now issued with a page half the size of the earlier numbers—it being at present about the size of the *Graphic*; so our remark made three weeks ago about the inconvenience of binding the numbers for reference no longer applies. Mr. C. Gentilé evidently intends to make the Chicago weekly a leading journal on the other side of the Atlantic.

The Registrar-General's ledger for the present year should contain a fresh page in order to take account of the

recent death from looking too long at the sun. Few, however, are likely to commit the same folly as the lad Gee, who, in trying how long he could stare at the great luminary, found he could not endure it for quite a minute. He died the same evening after much suffering.

A series of about fifty photographs of the recent tricycle camp at Harrogate has been produced by Mr. Welford, of Birmingham, and the '*Cyclist* seems to think it wonderful that such "beautifully clear and expressive pictures" should have been obtained by the photographer, "despite the brilliant sunshine he had to contend against."

Brilliant sunshine is just what every photographer would like to contend against when he takes pictures of a tricycle camp.

In the effort to get out of the common-place, some very curious things were perpetrated in the early days of photography. A man with a bare neck and chest, and a table-cover thrown over his shoulders, immediately became a "study," though it was difficult to see where the "study" came in. A lady with a lace shawl on her head was considered more picturesque than if she had the same shawl arranged in the ordinary fashion. All kinds of drapery were pressed into service, and gentlemen who had the misfortune to have beards, and ladies who were equally unlucky in having pretty faces, were tortured into every conceivable attitude to satisfy the yearnings of the photographer after "fancy pictures." The photographer is more sensible now-a-days, and is contented if he can represent people truthfully as they are.

The sale of terra-cotta plaques ornamented with a photographic view from nature is assuming such large proportions that one firm has more than four hundred varieties of them on sale. The making of the *plaques* has given quite a fillip to the trade of the terra-cotta ware manufacturing companies at Watcomb, near Torquay.

HOW TO PHOTOGRAPH MICROSCOPIC OBJECTS

BY I. H. JENNINGS.

Introduction.

Photo-micrography is the art of making, by means of the microscope, photographic enlargements of microscopic objects. Properly employed it forms a valuable tool in the apparatus of the scientific worker, for, by its aid, he can record faithfully the results of difficult and delicate observations, or delineate the forms of minute bodies concerning whose true structure different observers may vary in opinion. A photo-micrograph allows no room for play of the imagination: it simply shows how a given object appeared at the time the observation was made. Seriously carried out, and more especially when using high powers, photo-micrography is hard and trying work. The arrangement of the apparatus, the placing and illumination of the object, are tedious and difficult. Beginners in this fascinating and important art are warned that they must be prepared to encounter not only all the difficulties and troubles incident to ordinary photography, but also others of a different nature peculiar to photo-micrography.

To become a skilful photo-micrographer it is first necessary to be a skilful microscopist; for if the operator does not know how to display an object to the best advantage, his photographs will be useless. Yet the microscopist who comes fresh to photographic operations will find himself in a sea of troubles, spoil a number of plates, produce failure after failure, and, perhaps, throw up photo-micrography in disgust. The writer would advise all who contemplate a beginning to first make themselves acquainted with landscape photography, and all ordinary photographic manipulation: this need involve little extra expense, and the profit and pleasure to be gained from this course will amply repay any little additional outlay. One of the most skilful photo-micrographers that the writer ever knew was a gentleman who employed the microscope regularly as an instrument of research, but who used the camera only on his holiday trips. Being engaged in writing a paper which required illustration, it occurred to him to try photo-micrography, as the objects which he wished to depict were beyond the skill of the engraver. He did so, and succeeded at once.

Beginners in photo-micrography should bear in mind:—1st. That they should themselves develop every plate they expose; 2nd. That the best results need not be expected unless they are also able to make their own silver prints. A professional photographer may be A1 at landscape and portrait work, but this does not show that he is fit to be entrusted with negatives of microscopic objects. To bring out the details of a photo-micrographic negative of a print properly, requires that the operator should thoroughly understand the nature of the object; and this cannot be done except by a microscopist.

All objects are not suited for photo-micrography. Very opaque ones are not the worst, but those which have any strong tint of red, brown, or yellow. On this account many beautiful insect preparations cannot be photographed successfully; and we would, therefore, advise the beginner to study the preparation of microscopic objects, so as to be able, in case of need, to prepare and mount his own objects. As an example, a fly's tongue forms a pretty microscopic object, and most of the slides met with are tolerably good; yet a photograph taken from these ordinary slides usually is a complete failure. The reason is, that the unequal transparency of the object makes some parts over-exposed, while, in the darker parts, the detail has not impressed the film. Here, the best way is to make, or have made, a special preparation.

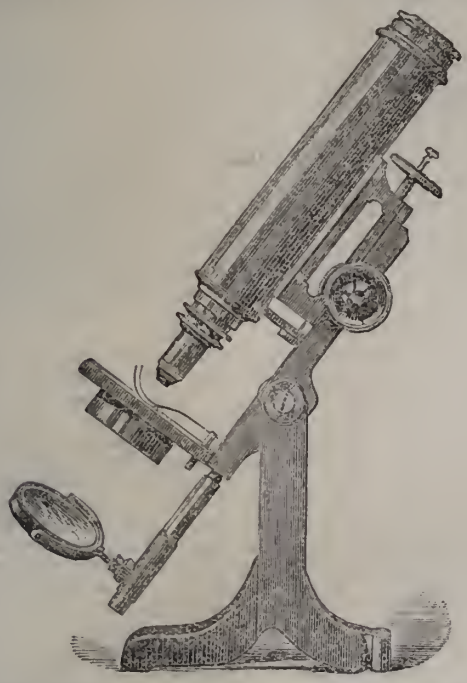
Lesson I.—Microscopical Apparatus.

Any good microscope stand may be employed for photo-micrography. It must be really good: an inferior instrument is useless. It must be firmly and solidly built, and the fine and coarse adjustments should be of the best construction. One of the cheap microscopes, with a fine adjustment that gradually moves the object from the field of view on being turned, will be found a source of continual annoyance, and should be avoided. If the student have, by ignorance or ill-advice, one of these things, let him part with it at any price, and procure one of the low-priced, but firmly built, well-adjusted stands made by Beck, Collins, Ross, or Swift. These will be found to give ample satisfaction.

The stand figured on p. 539, made by Mr. Collins, of Portland Street, is well suited to photo-micrographic work. It is well made, takes the full-sized eye-pieces, is furnished with a good one-inch and quarter-inch, and costs, with case, only £5 10s. A beginner could not have a better instrument. The writer uses a stand by Swift, which has a coarse adjustment so good, that a $\frac{1}{12}$th or $\frac{1}{16}$th inch may be focussed with ease and precision with it alone. The shape of the microscope is immaterial; both Ross and Jackson models will give good results if well made. A graduated draw-tube should be obtained, which had best be velvet-lined, to prevent flare. The usual dead black, after a while, wears out of the draw-tube, and

renders the microscope useless for photography; thus a more durable material, such as cloth or velvet, should be used to prevent reflection from the sides of the tube.

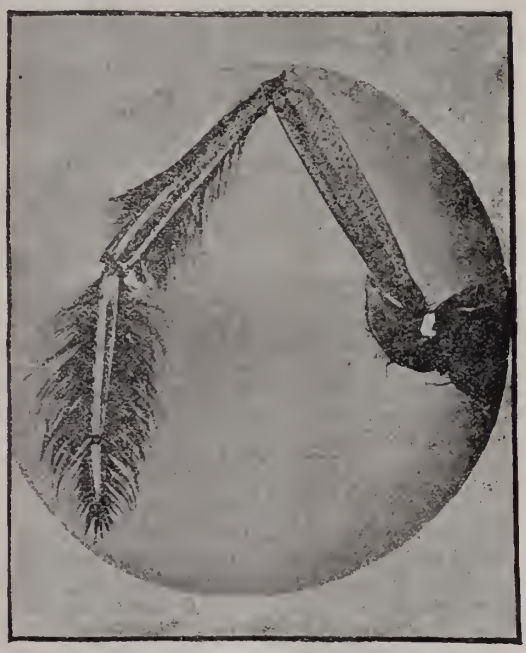
Several of the continental models, such as Hartnack's, would be useful for photo-micrography, from their compact shape and solidity; but their narrow body-tube, which



limits the field of view most seriously, and cramped stage, render it advisable to use only English instruments of the latest pattern. If cost be no consideration, then there is nothing to equal one of the large, first-class microscopes of the best English makers, fitted with every possible convenience in stage and sub-stage. It is true, an expert manipulator will obtain excellent results with the simplest arrangements; but it is no less true that it is the expert alone who can really appreciate and turn to good account the delicate mechanical contrivances which the skill of the optician has devised for his aid. Thus, a mechanical stage is not absolutely necessary, but it is a great help when working with high powers; and with the very highest powers, it is hard to see how it can be dispensed with. The same may be said of the sub-stage; but as this is in some respects more generally useful than the mechanical stage, it should be applied to all microscopes with which an achromatic condenser or paraboloid is to be used. The objections to the tube-fitting usually supplied with student's microscopes are, the difficulty of properly adjusting the sub-stage apparatus, and the very thick upper stage that they necessitate. For photographic work, the upper stage should be as thin as possible, certainly not more than $\frac{1}{8}$-inch thick, for frequently very oblique light must be employed, and this cannot be done with a thick stage, which cuts off the rays. Using a thin stage and bull's-eye lens, it is astonishing how easily a difficult diatom may be resolved, which, with a thick stage, would require the use of an expensive condenser. Most of the English makers now fit their microscopes with thin concentric stages, even when rack-and-pinion movement is omitted.

As to lenses, the student is advised strongly to buy the very best, if possible. Let him shun cheap French lenses, more especially the separating lenses, styled "French buttons," which are frequently supplied with £5 or £6 microscopes, and which are only useless rubbish. The stand and lenses should be purchased separately: the latter to suit the requirements of the photo-micrographer. If the very best lenses are too expensive, then purchase some of the cheap low-angle lenses, now sold by most good makers, for these, being well corrected up to the angle ascribed to them, are capable of performing a vast amount of real work. The beginner will probably find them much easier to handle than lenses of wider aperture, owing to their greater penetration and working distance; but the more experienced worker will require, especially for photographing very minute objects, lenses of the widest possible angle. Lenses of wide-angle admit more light, and have far greater resolving power than lenses of low-angle; but they have less working distance, and less penetration. The fact that they almost touch the object, in many cases, when in focus, forms no objection to their use for photography, but it is annoying to have a lens, say a $\frac{1}{2}$-inch, that will only show the surfaces of objects. This objection, however, can be easily disposed of, by using a contracting diaphragm, such as the "Davis Aperture Shutter," made and sold by Mr. Collins, whenever penetration is desired. The use of this shutter renders a lens of widest angle equal to any low-angle lens, as far as penetration is concerned; while even with the shutter, the wide-angle lens will give superior definition and admit more light than a low-angle lens of the same focus.

The choice of lenses will depend, in a great measure, on the photographic work to be performed. If the beginner proposes to limit himself to the photography of comparatively easy objects, lenses of 2-inch, 1-inch, $\frac{1}{2}$-inch, $\frac{1}{4}$-inch, will suffice. A $\frac{1}{4}$-inch of wide-angle will be found capable of resolving the majority of test-objects satisfactorily. A



LEG OF WATER BOATMAN (NOTONECTA).
Taken with a Ross' 4-inch.

5-inch or 4-inch will be found very useful for photographing large objects, such as whole insects, wood sections, and anatomical preparations; while if the student requires a few high powers, and cannot afford the expensive ones of the best English makers, he will find the moderate-priced immersion lenses of Seibert equal to all the work that will generally be required of them. These lenses are sold by Baker, of Holborn. Immersion lenses are specially useful in photography, as they admit a vast amount of light, and are, therefore, very rapid in action.

Some lenses are not well suited to photo-micrography, their visual and actinic foci not being coincident: that is, when an object is focussed accurately on the screen of the

camera, and a photograph taken, the picture will be found indistinct and blurred, owing to the fact that the rays forming the visual image do not lie in the same plane as those forming the photographic image. Such lenses *may* be used for photography, by making experiments, and determining the amount of allowance for this difference to be made when focussing; but it is far more satisfactory to use lenses which do not require such correction. The writer has used lenses by Ross, Wale, Swift, and Siebert, and the visual and actinic foci were coincident in all such as he has used.

Much difference of opinion prevails as to whether the eye-piece should or should not be used in photo-micrography. Some assert that the eye-piece spoils good definition. This is possible with a bad eye-piece; but the writer has for years used the eye-piece when photographing with low powers, and has found no difficulty in obtaining photographs absolutely sharp and well-defined to the very edge of the field. This is also the experience of many other photo-micrographers. In the writer's opinion it is a mere question of convenience: with low powers—say up to ½-inch—the eye-piece may be employed, as the loss of light attending its use is very slight; but with higher powers the loss becomes a serious matter, so it is then necessary to discard the eye-piece, or focussing will be very difficult, and the exposure of the plate inconveniently long.

An achromatic condenser is a very useful piece of apparatus, but may be dispensed with for general work; however, a good one will save much labour and "dodging" when using high powers with difficult objects. A bull's-eye lens accompanies most microscopes, and is really invaluable when the photo-micrographer has learnt how to use it. For a very oblique light a hemispherical lens is as good as anything. It is attached to the under-side of the slide with glycerine, and used in conjunction with the bull's-eye, the best position being found for the lens by experiment. As it will not keep in place unless the microscope be kept vertical, a slip of cardboard should be fastened to the slide below the hemispherical lens, or a little gum may be added to the glycerine. Unless the gum be perfectly white, it had best be avoided, as a yellow tint would ruin definition.

The paraboloid and spot-lens are sometimes used in photo-micrography, but even with the most rapid dry plates, dark-ground illumination is difficult, and seldom successful. As it, however, shows many objects to better advantage than any other mode of lighting, the student is recommended to see what results he can gain by its use.

Patent Intelligence.

Applications for Letters Patent.

11,212. JOHN V. ROBINSON, 39, Lower Sackville Street, Dublin, for "Photographic cameras."—Dated 13th August, 1884.

11,274. JAMES BOOKER BLAKEMORE WELLINGTON, 55 and 56, Chancery Lane, Middlesex, for "Improvements in changing boxes for photographic plates."—Dated 14th August, 1884.

Patent Sealed.

4144. WILLIAM BLAIR ANDERSON, of 26, Union Terrace, Aberdeen, in the county of Aberdeen, Scotland, Photographer, for "Improvements in colouring photographic prints."—Dated 29th February, 1884.

Patents on which the Seventh Year's Renewal Fee of £10 has been Paid.

1957. FREDERIC NEWTON, of Fleet Street, in the city of London, Optician, for an invention of "Improvements in magic-lanterns and in the lamps to be used therewith."—Dated 18th May, 1877.

Specification Published during the Week.

8643. BENJAMIN JOSEPH EDWARDS, of 6, The Grove, Hackney, in the county of Middlesex, Photographer, for "Coating photographic plates or paper with gelatine emulsion."—Dated 5th June, 1884.

My invention relates to an improved method of, and apparatus for, rapidly applying an even layer or coating of gelatine emulsion to sheets of glass, metal, paper, or other surfaces, for photographic purposes. In carrying out my invention, I make use of a trough or vessel containing the emulsion, and also of a metal roller working in bearings and made to revolve in the trough which contains the emulsion with which the plates are to be coated.

The length of the roller and trough must be slightly greater than the width of the largest plate to be coated, and I fix the said roller and trough above and across a travelling band or table which carries a continuous train of plates to be coated. In order to carry out my improved method of applying an even coating of emulsion to the surface of the plates, I make a scraper, preferably of sheet metal or ebonite, of suitable length and thickness, and I fix this scraper parallel to the roller so as to turn on pins or centres at, or near, the lower edge, and by means of a lever, weight, or springs, the upper edge of the scraper is made to press against the roller which revolves in the trough, and I make the scraper of a convenient shape and width, and fix it at any suitable angle so that the lower edge rests upon, or nearly in contact with, the surface of the plates or paper to be coated.

When the roller is made to revolve in the emulsion the solution which adheres to the surface of the roller is taken off by the upper edge of the scraper towards which the roller revolves; the emulsion then flows down the scraper to the surface of the plates which are carried by the travelling band below; by this means the plates are coated with an even layer of emulsion, the thickness of the coating being regulated by the relative speeds of the roller and the travelling band which carries the plates. In order to coat plates of various sizes I make the above-described scraper removable, and, when required, I replace it by another similar scraper of the length required to correspond with the width of the plates to be coated. In order to admit of coating plates of different degrees of thickness, I make the centres or pins at the lower edge of the scraper to work in bearings fixed to a movable frame or pair of side rods pivoted or hinged at one end, and carrying at the other end a roller or guide which rests upon the surface of the plates as they pass beneath the scraper; by this means the frame or rods carrying the scraper rises and falls in proportion to the thickness of the plates, which are thus allowed to pass under the scraper without obstruction; sometimes I attach the scraper to the side of the trough, and support the trough itself with the scraper attached by means of pivots or bearings upon the movable frame, or side rods before described. In order to facilitate the cooling or setting of the emulsion after it has been spread upon the surface of the plates, I cause the travelling band carrying the plates to pass over a table or slab artificially cooled by being kept partially immersed in ice-water or other cooling substance contained in a metal tray within which the slab rests, and I cover the table or slab with a metal tank containing ice or other cooling substance; the tank is supported so that the under side is only a short distance above the slab, thus forming of the space between the slab and the under side of the tank or cover a cooling chamber or tunnel, through which the plates pass. The cover or tank also serves to protect the plates from light and dust after they have been coated with emulsion; by the above-described means the the emulsion is rapidly set, and the plates are very quickly ready to be removed from the travelling band and placed in racks to dry.

In practice I prefer to make the travelling band in two separate portions of unequal length; that is, I make two endless bands to travel in the same direction. One of these bands, which I call the coating band, is used only to carry the plates under the trough and scraper; the plates then pass on to the other band, which I call the setting band, and which carries the plates over the cold slab and through the cooling chamber before described. Each of the above-mentioned bands works over a pair of rollers or drums fitted at one end with a driving-pulley, by means of which the band is made to travel in the required direction, the setting or cooling band being made to travel at a slightly greater speed than the coating band, in order to cause the plates to separate from each other as they pass into the cooling chamber.

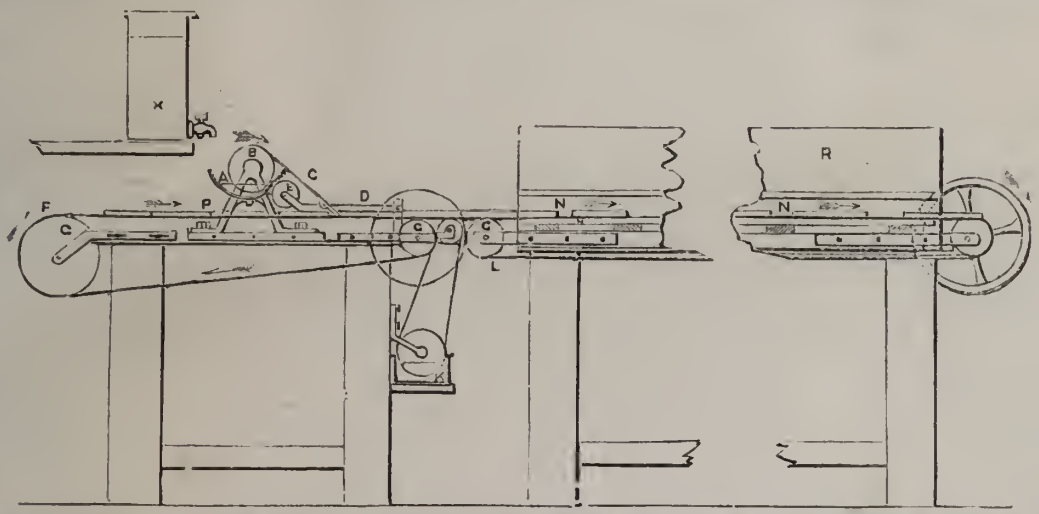
For the purpose of cleaning the back or under surface of the plates, and removing any emulsion which may have been spilled on to the coating band, I make another endless band of rubber cloth passing over a pair of rollers of suitable diameter, and I fix one of these rollers so that the cleaning band just touches the coating band and the under side of the plates after they are coated, and I arrange the other roller, which is driven by a pulley,

so that it revolves in and carries the endless band through a trough of warm water; by this means the back or under surface of the plates is cleaned, and the travelling bands which carry the plates are kept clean and free from emulsion.

For coating paper with gelatine emulsion for photographic purposes I use my improved machinery and apparatus substantially as above described, and in a similar manner, with the exception that I dispense with the cleaning band and one of the rollers, and I use the other roller and the trough for the purpose of wetting or damping the paper previous to its being coated, and I use another roller or squeegee for the purpose of removing the excess of moisture and causing the paper to adhere to the coating band before being passed under the trough and scraper; the paper when coated passes through the cooling chamber, after which it is cut into convenient lengths and hung up to dry. In this manner a continuous length of paper can be uniformly coated with a layer of gelatine emulsion of any desired thickness. In using my improved machinery for coating plates or paper I actuate the rollers and bands by means of pulleys of suitable diameters to give the speed required, and driven by a gas engine or other suitable motor.

The endless bands may be made of india-rubber cloth or other suitable flexible material; but I prefer to make the band which passes through the cooling chamber of woven wire or thin metal plate, in order to cool or set the emulsion as rapidly as possible. Sometimes instead of ice, as above described, I use a current of cold air or vapour for the purpose of setting the emulsion on the plates or paper in the cooling chamber; in any case, this chamber or tunnel must be of sufficient length to allow of the film of emulsion being perfectly set or stiffened before the removal of the plates or paper from the band; the length required will depend greatly on the speed at which the machinery is driven. With a moderate speed I find fifteen feet a convenient length for the refrigerating chamber or tunnel. By means of my improved machinery and appliances as above described, photographic plates or paper may be prepared or coated with gelatine or other sensitive emulsion with greater rapidity, certainty, and uniformity than has hitherto been practicable by any other method.

The accompanying drawings show the various parts of my improved machinery as described in the above specification. I do not, however, confine myself to the precise details of con-



A is the trough containing the emulsion; B is the roller; C is the moveable and adjustable scraper; D is the pivoted frame which carries the scraper and sometimes the trough; E is the grinding roller; F F is the travelling band for coating; G G G are rollers carrying the travelling bands; H H are similar rollers to carry the endless band for cleaning the plates; J is the cleaning band; K is the trough containing water for cleaning or washing the band; L L is the travelling band carrying the plates through the cooling chamber; M is the cooling chamber or tunnel closed at the sides and open at each end; N is the cold slab over which the travelling band passes; O is the metal tray in which the slab rests; P P are the plates, before and after being coated; R is the metal tank or cover over the cooling chamber; S is the spring which presses the scraper against the roller; X is a reservoir of emulsion for replenishing the trough.

struction as shown or described, as the same may be somewhat modified without departing from the principle of my invention.

Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I wish it to be understood that I do not claim any novelty in the use of a roller revolving in a trough of emulsion as heretofore used for applying a coating of emulsion to photographic plates and for other purposes, nor do I claim the use of an endless band for carrying the plates as described in Swan's Specification, A.D 1879, No. 4607; but I claim as my invention—

Firstly. The movable and adjustable scraper or scrapers of any suitable shape or size, in combination, with the roller and trough for the purpose of applying the coating of gelatine or other emulsion to the upper surface of the plates as described.

Secondly. The cooling chamber or artificially cooled table or slab, in combination with the endless band carrying the plates, in order to facilitate the setting or cooling of the gelatine emulsion after it has been applied to the surface of the plates or paper by means of the roller and scraper or by any other method.

Thirdly. I claim the endless band as above described for cleaning the back or under surface of the plates after they have been coated. I also claim the arrangement of the pivoted frame or rods which carry or support the scraper, and sometimes the trough together with the roller or guide in order to allow of the use of plates of various degrees of thickness.

Correspondence.

THE POTASH DEVELOPER.

Dear Sir,—Having lately been compelled to abandon the use of pyro and ammonia for considerations of health, I was at a loss to know what developer I should adopt in its place. Ferrous oxalate I had tried, and discarded; while what little experience I had of soda was not in its favour. A few days ago I was advised to try a potash developer made according to the formula given in the Photographic News for August 1st, page 485. I made it up exactly as there given; but as the dose of pyro recommended for developing one plate seemed excessive, I halved it, and with satisfactory results.

My first experiments were made on four of Swan's plates, which I had had in stock for about three years. They had been kept in a tin trunk in the kitchen, and consequently the films were very hard and dry, and repellent to the developer. The exposure was made by means of a Lancaster instantaneous shutter, which, as a more severe test, was used on subjects both in shade and in sunshine.

On applying the developer, each plate, after a few seconds, began to reveal the image, which steadily

increased in intensity, being at the same time full of detail. In five minutes development was complete. The negatives, after fixing, were clear and brilliant, without a trace of fog or stain, although no alum was used after development. Their printing qualities are excellent.

I have since used this developer with other makes of plates, some of which I had in stock, and some given me by friends for trial, and all have turned out equally well. It is true that the plates of one maker frilled most horribly after coming out of the hypo, unless dosed with chrome alum after development; but whether this was the fault of the plates or of the developer, I don't know.

The potash developer appears to me to present the following advantages:—1st. Freedom from noxious fumes; 2nd. Cleanliness—it does not stain the fingers or the plates; 3rd. It is completely under control; 4th. No bromide or other restrainer is required; 5th. It gives clear, brilliant, quick-printing negatives; 6th. It is far more powerful than the ordinary pyro and ammonia developer, hence far more suitable for instantaneous work and for photo-micrography. No forcing of the image is necessary: and the details in the shadows of an instantaneous picture come out with due strength.—I am, sir, yours faithfully,

J. H. Jennings.

THE KEEPING OF GELATINE PLATES.

Sir,—Mr. T. G. Whaite tells us in your last issue that he has kept gelatine plates for three and a-half years, and adds that he believes they will keep indefinitely, if well-packed and kept dry. As an amateur, I always use plates of my own make, and put by for experimental purposes any faulty ones out of a batch. A few weeks ago I alighted upon half-a-dozen which had been stowed away in a cupboard and forgotten all about. Now, this said cupboard, in the basement of my house, is the dampest place I have ever seen in any house, and totally unfit for any domestic use, and when I discovered these plates wrapped in a couple of sheets of brown paper, and then loosely in American cloth, I intended to throw them away, as they had been lying there for at least a year and a half: but before doing so, I tried an experiment, when lo, behold! the image came up with as much brilliancy as if the plate had just been taken out of a packet fresh from the manufacturer. I simply record this fact to prove that dampness cannot affect the gelatine plate so much as is generally supposed.—I am, yours truly, W. H. Plaister.

Proceedings of Societies.

London and Provincial Photographic Association.

A meeting of this Society was held on Thursday, the 14th inst., Mr. C. P. Salmon in the chair.

Mr. J. B. B. Wellington called attention to a recent communication in one of the journals respecting the restraining power of gallic acid when employed in conjunction with alkaline pyro development. Two plates were shown, one of which had received an exposure of three seconds, and the other forty seconds; the former was developed as follows:—

Pyro.	3 grains
Potassium bromide	3 ,,
Liquor ammonia...	3 minims
Water	2 ounces

The latter was similarly treated, but two grains of gallic acid were added to restrain the developer. There appeared to be very little difference in the resulting negatives, showing the restraining power of gallic acid to be very great.

Mr. A. Haddon also showed two prints from negatives which had been much over-exposed; finding the first plate over-done with the normal developer, he added a few drops of a sixty-grain alcoholic solution of gallic acid, which entirely corrected the excessive exposure in the second plate; both plates were exposed the same length of time, the stop being $\frac{f}{128}$ universal system.

Mr. W. Cole suggested glycerine as a solvent for gallic acid, which would likewise preserve it from decomposition. His opinion was favourable to the use of soluble bromide, which had precisely the same effect.

Mr. Haddon said that gallic acid was a far more powerful restrainer than a soluble bromide.

Mr. W. M. Ashman enquired whether any abnormal difficulties had been experienced in the treatment of gelatine plates during the recent high temperature?

The Chairman had found the rapidity was much increased.

Mr. Ashman mentioned a case in which the films dissolved in the developing solution, necessitating the employment of ice in the development of several others; he also said he had met with a difficulty in varnishing, part of the film dissolving, and having an effect similar to negatives which have been heated to accelerate drying.

Mr. A. Cowan thought the plates first spoken of contained no chrome-alum in their composition, and in the second case the varnish contained more water than it should do.

Mr. W. E. Debenham said probably the heat experienced during the last few days would cause alcohol to escape from the varnish, thus leaving a larger proportion of water, without precipitating the gum.

The Chairman then announced the presence of a distinguished visitor, Mr. Derham, of Boston, Massachusetts, and after extending him a hearty welcome, invited him to say a few words on American photography.

Mr. Derham said he was pleased to be present; he read the reports of these meetings with great interest, and thought if the English were slow, they understood the way to make quick plates. He then passed round some examples of the style of work made in Boston on gelatine plates. He thought the best results were obtained on slow plates, and preferred the method of precipitating a given quantity of silver and bromide, gaining sensitiveness afterwards by boiling, and adding a small quantity of ammonia and free bromide to the finished emulsion; this latter had to be determined by experiment, for if more than a given quantity either of ammonia or bromide be added, it had the effect of slowing the emulsion. The developer he preferred was as follows:—

No. 1.	
Water	5 ounces
*Lactic acid	2½ drachms
Bromide of potassium	60 grains
Pyrogallol	240 ,,
No. 2.	
Water	4 ounces
Sodium sulphite	360 grains
Dissolve, and add—	
Bromide of potassium	180 grains
Liq. ammonia ·880	5 drachms

Use one part each of Nos. 1 and 2 in twenty parts of water, or the proportion may be varied to suit the subject. Lactic acid appears to act as an accelerator.

Mr. W. E. Debenham said he was much pleased with the appearance of the prints, and wished to learn the details of their production.

Mr. Derham stated that the paper was floated, according to temperature, from half to three minutes on a 50 to 60-grain bath, fumed, well washed, and placed in salt and water before toning in the borax and gold bath. The vignetting was performed by means of a block of wood an inch and a-half in thickness, and bevelled inwards from the centre.

Mr. Debenham suggested the idea of having a series of transparencies made from a negative to be selected, and the results to be shown in the lantern at one of the winter meetings; he thought it desirable to choose a portrait, landscape, and seascape subject, and prevail on any member who was *au fait* at a particular process to produce a positive by his process, then pass the negative to another member. They would thus have a means of comparing the values of the different processes for enlarging or lantern work.

Amateur Photographic Association of Victoria.

Although New Zealand has been credited with having beaten Australia in the formation of an Amateur Society, it appears that such is not the case, as the above Association was formed on the

* An impure commercial article, manufactured, probably, to supply the place of acetic acid. It is used in Boston in the composition of iron developers and other photographic preparations.

18th of June, 1883, and is consequently a few months older than the New Zealand Society.

The Victorian Association has been doing useful work during the thirteen months of its existence, practical demonstrations of the methods of working the principal photographic processes having been given from time to time, including the manufacture of gelatine emulsion and plates, development of gelatine plates, enlarging on argentic bromide paper, enamelling, &c., and exhibitions of transparencies in the lantern, together with papers on various subjects.

The first anniversary was celebrated by an Exhibition, which was held on 23rd June last. This is worthy of note, having been the first purely photographic exhibition ever held in Australia; and it is something to the credit of an amateur society that it was a success in every sense of the word.

The commodious rooms of the Royal Society of Victoria were placed at the disposal of the Association, and the walls hung with photographic work of all kinds, tables round the rooms being utilised for the purpose of exhibiting apparatus, of which there was a magnificent collection. The rooms were crowded with visitors, there having been many more than the promoters of the Exhibition had expected.

The proceedings were opened by an address from the President, Dr. Browning, followed by an interesting paper on the "Rise and Progress of Photography," which was read by Mr. Ludovico Hart, who is well-known in European photographic circles (this gentleman was formerly manager of the photo-mechanical printing department of the Government of New South Wales, and Lecturer on Photography at the Technical College, Sydney), and the proceedings wound up with an exhibition of transparencies.

The great majority of the exhibits were from members of the Association, but there were several from a few of the leading professional photographers of the city. A great deal of the apparatus shown was also the work and invention of members, and the whole of the transparencies were amateur work.

The Association meet at the Royal Society's Hall monthly, the last monthly meeting having been held on Monday, 7th July, on which occasion the subject of the manufacture of gelatino-bromide and gelatino-chloride plates was practically demonstrated by one of the members (Mr. Musgrove) who has been very successful in making his own plates. He went through the whole of the processes, from the cleaning of the glass to the forming, washing, &c, of the emulsion, finishing with the coating and packing of plates, the whole details being plainly put before members, many of whom, who had not tried the making of their own plates, determined to make a trial after his explanation.

After a few questions had been asked, the meeting closed with a vote of thanks to Mr. Musgrove.

St. Helen's Association of Science, Literature, and Art.

Photographic Section.

The annual meeting of this Section was held at the Association Rooms on Wednesday, the 9th ult., Mr. Heather in the chair. The minutes of the previous meeting having been read and confirmed, the Hon. Sec. read the annual report, from which it appeared that the Photographic Section entered upon the second year of its existence this month. Eight new members had been added to the list since its formation, whilst on the other hand four had resigned.

Up to the present, Mr. Heather had been relied upon for demonstrations, of which the following had been brought before the members:—"Enlarging on Hutinet's Gelatino-Bromide Paper" (twice); "Preparation of Gelatino-bromide Emulsion"; "Preparation of Lantern Slides"; "Reduction of Negatives." One evening was devoted to photography by artificial light, and was fairly successful.

The Section took part in contributing to the interest of the Conversazione on January 24th, a large collection of photographs were shown, and Messrs. Heather, Morton, Taylor, and J. Houghton were busily engaged photographing the visitors by the collodion method on ferrotype plates.

A well-attended out-door meeting had been held at Knowsley, and a number of interesting exhibits of apparatus, lantern slides, prints, &c., had from time to time been made.

The Hon. Treasurer's statement was then laid before the meeting, showing a balance in favour of the Section of £1 13s. 10d.

The following officers were elected:—

Chairman—Mr. Heather. *Hon. Treasurer*—Mr. Crooks.
Hon. Secretary—Mr. J. F. Houghton.
Auditors—Messrs. Bewley and Loader.
Committee—Messrs. Brook (ex-officer), Morton, Sherlock, J. Houghton, Taylor, and Bewley.

It was resolved that a 15 by 12 burnisher be purchased for the use of members.

Mr. Taylor said a few days ago he was making a tranparency, and, believing the emulsion to be a slow one, gave a prolonged exposure. When taken out of the frame in the dark-room, he was astonished to find a positive picture on the plate; he fixed at once and got a negative from a negative.

Mr. Brook showed a number of very fine views, taken near Leek, North Stafford.

Mr. Heather also showed a number taken at Wenwick.

The meeting shortly afterwards closed.

Talk in the Studio.

Photographic Society of Great Britain.—The next meeting of this Society will take place on Tuesday next, August 26th, at the Gallery, 5a, Pall Mall, East; the chair will be taken at 8 p.m.

By command, Messrs. Downey, of Ebury Street, Eaton Square, attended at Osborne on Saturday last, and took photographs of the Queen in the act of presenting new colours to the Seaforth Highlanders. On Friday and Saturday the same artists photographed the Prince and Princess of Wales and their family on board the *Osborne*.

Balloon Photography.—Mr. Cecil V. Shadbolt furnishes us with the following interesting particulars of an "aëronaut's holiday" which he and Mr. Dale celebrated on Wednesday last, 13th inst.:—"At noon precisely we made a special private ascent from the Crystal Palace grounds in our new and lovely little balloon, the *Monarch*. Photography of course played an important part in the exploit, and, I am glad to report, with most successful results. At length, I think I have quite equalled, if not surpassed, my achievement of 1882. We made a rapid rise so as to avoid some trees, and shot up pretty quickly to an elevation of 5,200 feet. Here, finding the clouds were closing in rapidly underneath, and obscuring the charming panorama which lay below, we opened the valve and lowered the balloon somewhat. For a few minutes we were completely lost in the clouds, and could see nothing but mist all around us. We then came down very low, and crossed the Thames and the Royal Albert Docks at an altitude of 600 feet only, our shadow being distinctly visible on the surface of the water as we glided past. Some time after this we were somewhat astonished, after rising again, to fall in with a stray dandelion or thistle fluff which was sailing along 1,400 feet above the earth. The descent was safely effected in a field at Doddinghurst, some four miles from Brentwood, in Essex, and I am pleased to say that I was successful in securing several satisfactory photographic momentoes of the trip."

Death of Mr. Jabez Hughes.—We extract the following from *The Isle of Wight Observer*:—"We deeply regret to record the death of Mr. Jabez Hughes, the well-known photographer of Regina House, Union Street. Mr. Hughes had been in failing health for some time, suffering from a complication of diseases. He left Ryde for change of air and scene a few weeks ago, but soon had to return home in consequence of extreme weakness. We understand that he kept his bed about a week, finally succumbing on Monday morning. Mr. Jabez Hughes was one of the earliest and most successful students of the beautiful art of photography, which he aided to improve and develop. It is many years since he succeeded to Mr. Lacey's business in the Arcade, and rapidly attained a leading position in the photographic world, which is proved by the fact that he has been constantly employed by Her Majesty the Queen, and has exercised his skill in pourtraying, not merely Her Majesty, but every member of the Royal Family. He has also taken the photographs of many of the leading men of the day. The late Lord Beaconsfield had a notorious dislike to facing the camera, but, at the Queen's command, when his lordship returned with 'peace with honour' from Berlin, he was taken at Osborne by Mr. Hughes, who secured the only really reliable portrait of this remarkable statesman. Our space is too limited to enable us to give a catalogue of all the distinguished men and women whose

features Mr. Hughes has preserved for posterity. Not merely are Mr. Hughes' photographs like, as far as regards resemblance to the features of their originals, but he had a happy power of seeing the best aspect of a face. Mr. Jabez Hughes' skill was fully recognized by his brethren of the camera, and he belonged to more than one photographic society, the members of which did him the honour of making him their president. As a townsman Mr. Hughes was much liked and universally respected, but he refused to have anything to do with local politics."

A Daily Newspaper on Photography.—The *Daily Chronicle* of yesterday has the following:—"*Improvements in Photography.*—Last night a meeting of the members of the Photographic Club was held at Anderton's Hotel for the purpose of discussing recent discoveries in photographic art. Mr. Dallas presided, and in opening said they had met to consider how far the art could be advanced by the recent discoveries of photographic printing through the means of coloured media. Under the system of printing through plain white glass negatives, they had to guard against many difficulties. He then called on various members to address the meeting. A number of gentlemen gave their experience, and showed certain well-executed, delicate specimens of out-door photography, which were printed through coloured media, chiefly fine tissue paper of various tints, which being placed over the negative guarded against photographs being made too dark, by the strong and sudden action of the light in the printing. Mr. Cowan exhibited some fine views of Chingford. Mr. Wellington next exhibited a new dark slide box for out-door work, which was rendered exceedingly light and effective for the dry-plate process by means of a number of dark slides being formed with ready adaptation, by means of divisions composed of vulcanized ebonite, and which he had patented during the week. Mr. Duumore exhibited specimens of printing through coloured media at Hampstead. Mr. Hale exhibited a newly-constructed camera, the advantages of which were great lightness and ready adaptation for single or stereoscopic views. It was arranged that a meeting for experiments in printing by coloured media should take place between Highgate and Hampstead on Saturday next. By "the recent discoveries of photographic printing through the means of coloured media" is, we imagine, meant the practice of shading the printing frame during exposure when a weak negative is to be dealt with; and it has been suggested that coloured tissue paper is better for the purpose than white.

Photographic Club.—At the meeting on August 27th, the subject for discussion will be "The Artistic Monthly of Photographs." Saturday afternoon outing between Highgate and Hampstead; meeting afterwards at the "Bull and Bush" at 6·30.

To Correspondents.

*** We cannot undertake to return rejected communications.

L. N. C.—Simply use the tissue coating machine described on page 453.

K. Lloyd.—1. Develop ordinary carbon prints on flexible support, and transfer them as directed on page 332. 2. Not quite up to the mark.

Transfer.—It seems to us that the bath is out of order. Make it slightly alkaline with sodium carbonate, and expose it to the full sunlight for some days. Then filter it, and make it very slightly acid with nitric acid.

J. W. Robinson, Jun.—Such information, arranged in tabular form, would doubtless be useful, and the matter shall be considered.

T. Vodden.—It will not dissolve, because it has been vulcanized: obtain some of the so-called masticated rubber.

Errata.—The reader is requested to make the following corrections:—Page 506, column 2, 32nd line from bottom, for —*Blinds*, read , *which*. Same page and column, 20th line from bottom, for *imperfect*, read *are perfect*. Same page and column, 10th line from bottom, insert comma after lens. Page 507, column 1, 33rd line from bottom, for *as*, read *on*. Same page and column, 22nd line from bottom, for *wood*, read *hood*.

Bellagio.—1. You had better state distinctly in your order that the lantern must admit a plate 8½ inches high, or you will probably receive one which will be useless for the purpose. 2. Either will do, but the former is to be preferred as being of shorter focus. 3. You will do best to order it from the house with which you are in the habit of doing business, as we think there is only one *actual* maker in London, and you are tolerably sure to get his, whoever supplies it.

Out of Focus.—

Silver nitrate	...	...	...	950 grains
Sodium chloride	...	...	...	480 ,,
Heinrich's gelatine	...	...	...	960 ,,
Distilled water	...	...	...	30 ounces

Dissolve silver in 10 ounces of the water, and the chloride with half the gelatine in 15 ounces of the water, and allow the remaining gelatine to swell in the 5 ounces of water standing over. Bring all vessels to 120° F., and when the gelatine is melted, add the silver solution to the plain gelatine, and then emulsify gradually with the gelatine solution containing the salt. Allow to set, and wash in the usual way.

G. N.—It seems to us that they are iron stains; in fact, we are tolerably sure about it, and the remedy is, to be more careful in not using water containing the settlings of the cistern.

Henry Spink.—An ordinary blacklead pencil answers admirably.

Pin.—1. In order to get a good cast in type metal from the plaster mould, it is necessary that this mould should be quite dry and hot. In addition to this, the melted metal should remain in contact with the plaster for a considerable time. If you work in the following manner you will probably succeed. Lay the well-dried and hot mould, face downwards, in an iron dish, about two inches deep, but by means of a couple of strips of iron, a quarter of an inch square, keep the face at this distance from the bottom of the box. Now put a heavy mass of iron on the back of the plaster mould, so as to prevent it from floating up when the metal is poured in, and heat the whole apparatus over a gas burner until it is at about the melting point of type metal. The melted metal is now poured in, taking care to avoid all scum or dross, until the iron dish is full, and the heat is maintained for a quarter of an hour, after which the whole is allowed to cool. The stereotype must be cut out of the mass of metal by means of a saw. 2. A diapositive may be made by exposing an ordinary gelatino-bromide plate under a negative (a few seconds to the light of a gas flame) and developing as for a negative. 3. We do not know, but are inclined to think that they are done by the former method. 4. Because the light in passing through the transparent parts renders the gelatine insoluble. 5. Yes. 6. Quite as good, but perhaps rather more trouble. 7. Make a transfer by the Ives method.

Electro.—The surface must be very carefully covered with the finest plumbago, or the work is very uncertain. 2. It is possible, but very difficult, as a continual swelling takes place in the bath. 3. It is as you say, and it is not likely that anyone was misled.

One in the West.—It is owing to some feature in the manufacture which we cannot determine: try fuming it with ammonia in the first place, and if that does not answer, obtain a fresh sample.

The Photographic News Registry.

Employment Wanted.

Assis. (lady), tint, spot, &c.—G. L., 5, Heaton-villas, Heaton-rd., Peckham.
Oper. & Retouch, good all-round.—Operator, 162, Bristol-st., Birmingham.
Improver in Portraiture & Landscape.—P. Lloyd, Albury, nr. Guildford.
Spotter & Mounter.—Miss Govus, E. Barnet-rd., New Barnet
Recep.-room or General Assist.—K. L., 73, Ravenhurst-rd., Birmingham.
Retoucher or Operator.—Artist, 13, Fountain's rd., Hull.
Gen. Assist. & Improver.—W. B., 86, North-rd., Wolverhampton.
Operator & Retoucher.—W. J. D., Bildeston House, Maygrove-rd., N.
Assist. Oper. & Retoucher.—W. H., Imperial Studio, Beverley-rd., Hull.
Photo. Artist (lady).—Miss Hebbert, 45, Chesterton-rd., Notting-hill.
Assistant Operator or Printer.—E. W., 77, Sutherland-st., Pimlico.

Employment Offered.

Assistant Printer (male or female).—Vaughan & Whitfield, Bournemouth.
Improver or General Assistant.—Mr. Talbot, 90, Queen's-st., Ramsgate.
Dry Plate Coater, used to machine.—F. A., *Photo. News* Office.
Reception Room and Retouching.—F. W. Broadhead, Leicester.
Retoucher, Lady or Gentleman.—F. Guy, Manchester Hall, London.
Operator (Photo-etching).—P. N., c/o C. Tayler, 154, Fleet-st., E.C.

ADVERTISEMENTS IN COLUMN.

Not exceeding Five Lines (36 words)... 3s. 0d.
Each Additional Line ... ... 0s. 4d.

Repeated insertions, and special positions or style, by contract.

Advertisements should be forwarded (prepaid) to Piper and Carter, 5, Castle Street, Holborn, E.C., to reach the office not later than noon on Thursday. A fee of 6d. must be forwarded when the Publishers are expected to receive and forward replies to Advertisements.

THE PHOTOGRAPHIC NEWS.

VOL. XXVIII. No. 1356.—*August* 29, 1884.

CONTENTS.

PHOTOGRAPHS OF THE SUN.

SUN-SPOTS have been connected by popular imagination with very many terrestrial phenomena, and the fact is that but little is known about the actual nature of sun-spots; but there can be no doubt whatever that one of the first means of learning is to map out and record the constant variations which take place.

Dr. Lohse, of Potsdam, is now engaged in making photographic records of the appearance of the sun's disc, and each picture taken adds greatly to the value of the series, as it is only by a study of the variations of the spots that we may hope to be able to discover the conditions under which they arise. The opportunity of obtaining a really good photograph of the solar disc does not occur very frequently, so that the production of such a series as may give the means of drawing important conclusions may be the work of many years.

The picture which forms our supplement this week was produced by Dr. Lohse under exceptionally favourable atmospheric conditions, and he gives us the following particulars:—

"The photograph of the sun was taken with the heliograph of the Astro-Physical Observatory at Potsdam, on the 13th of October, 1883, at 2.43 p.m., Berlin mean solar time, when the atmosphere was unusually clear and undisturbed. The instrument is provided with a Steinheil objective having an aperture of 160 millimeters, and a focal length of 4,000 millimeters. It is set in a fixed position, while the moving heliostat serves to keep the beam of sunlight steadily on the objective of the telescope. The reflector of the heliostat consists of a glass plane silvered on the face, and as the axis of the heliograph is parallel to that of the earth, a heliostat of comparatively simple construction serves.

"The negative of the photograph now published was taken on a gelatino-bromide dry plate, and the exposure is estimated at one two-thousandth of a second. The line which crosses the disc is merely the image of the spider thread which crosses the field horizontally in the focus of the lens; the horizontal position of this thread being carefully adjusted by a level.

"The heliograph of the Potsdam Observatory has been in use since 1881, and during the period which has elapsed since its erection, more than 600 solar photographs of the size of that now published have been taken; and, besides these, some larger pictures (300 millimeters in diameter) have been produced, which show, in an exceptionally satisfactory manner, the fine details of the solar surface."

THE SWING-BACK AND THE RISING-FRONT.

A NOTE which we recently had from a correspondent has put us in mind of the difficulties which beginners frequently find in the use of that important adjunct to the modern camera, namely the swing-back.

That some confusion should exist in this matter is by no means unnatural, seeing that the swing-back of a photographic camera may be used for two objects entirely distinct and different, and that moreover their uses are closely connected with that of another movable part, the rising-front.

The two objects for which the swing-back is used are, first, the securing of definition in the negative, if placed at different distances from the camera; and second, the securing of parallelism in a negative such lines as may be vertical in the subject and may be placed considerably above or below the point of view of the photographer. The swing-back is frequently used for the latter purpose when the rising-front might be used with better advantage.

Taking, first, the case where we wish to bring places at different distances from the camera into focus at the same time, we shall imagine the simplest possible subject.

We wish to photograph a landscape in which the nearest objects will form the lower portion of the picture, somewhat more distant objects the centre portion, and what are usually somewhat indefinitely termed "distant" objects the upper portion. When we place our camera opposite such a landscape we will of course find the order of the objects reversed; that is to say, the foreground will be at the top of the ground glass, and so forth. We are also well aware that unless we are using a lens of short focus and small aperture, some of these objects will be rendered with imperfect definition. We may focus accurately for either the foreground, the middle distance, or the distance. For whichever one we focus, the other will be out of definition. The most natural course is the focus for the middle distance, and afterwards to bring the other two portions of our picture into sufficient definition by the introduction of a small stop. If, however, we have a swing-back attachment to our camera, we need not do this. The nearer objects will focus further from the lens than the more distant. The nearer objects have their representation at the top of the ground glass, therefore if we increase the distance from the top of the ground glass to the lens, we will improve matters. This we do by swinging the back of the camera away from the lens. There is no means of discovering the precise amount of swing required, except that of trial and errors. We clamp our back in a certain position, and focus a second time. If we are not pleased, we try a greater or less angle.

The very same operation may be gone through with advantage in portraiture, especially when the position of the subject is a sitting one. So far the matter is quite simple, and this means of bringing different planes into focus may be used whenever there are no vertical lines in the subject. We adjust our swing-back as described, and, to bring the correct amount of foreground, sky, &c.,

into our picture, either tip the camera, or raise or lower the front. It is best to tip the camera to a moderate degree, and, if still more adjustment be required, to raise or lower the movable front and lens till we have what we require.

The matter assumes a very different aspect, however, when we come to apply ourselves to the photographing of objects with vertical lines, especially buildings. We shall suppose that our object is to make a representation of the most ordinary possible house, that our point of view is level with the ground floor, and that we cannot get very far away from the building.

If we adjust our camera so that it is level, and look on the ground glass, we shall see that about half of it is filled up with the street, and that we have not nearly got in the top of the house We can put everything right so far as these two matters are concerned by simply tipping up the camera, but by so doing we at once introduce a third defect: the vertical lines of the house will all be found to converge considerably towards the bottom of the ground glass—that is to say, towards the top of the picture, in which latter, were the negative taken with the camera tipped up as described, the buildings would have the appearance of a truncated pyramid, or of leaning backwards.

Without entering at length into the cause of this peculiar effect, we may say that, without regard to the direction of the axis of the lens, so long as the ground glass of the camera is vertical, the vertical lines of the subject will come out parallel; so long as the ground glass of the camera leans away from the building, the lines will converge towards the top of the picture; so long as it leans forward, towards the top.

Now it is evident that if we have our camera tipped, and merely swing the back forward so as to be vertical, we shall get an undistorted image. But let us see what we have done with regard to the definition of our foreground and the house. The foreground in this particular example is likely to be the area railings. Still, it is nearer the camera than the plane forming the front of the house. To secure the best results as regards definition, we should therefore have to swing the back so as to have the top of the ground glass further from the lens than the bottom—that is to say, we should have done the precise opposite of what we have done. In fact, we have so used our swing-back that the definition of one part or another of the image must be particularly bad, and we have to use a very small stop to correct this. Frequently the smallest stop with which a lens is provided will be too large to completely counteract what we have done.

Another course was open to us instead of using the swing-back. We might have placed the camera horizontal, so that the ground glass would be vertical, without the use of the swing-back, and after that we might have raised the lens by means of the rising-front. We should thus have secured our object had the lens been capable of covering a large enough field. We should also have secured, on the whole, much better definition than when using the ground glass. It is quite possible, however, that when we had raised the lens, we might have found that the lower corners of the ground glass were quite dark—that the mount of the lens had cut off the oblique pencils of light reflected from the top of the building, and that, as a consequence, our picture was curtailed. In this case we can, of course, only resort to the use of the swing-back. We may state this, however, as a rule which will be found to hold very generally good: if the lens will permit of it without the picture being curtailed, it is better, for securing parallel lines from vertical objects, to use the rising-front, and leave the camera horizontal, than to tip the camera and use the swing-back.

It must not, however, be supposed that by using the rising-front we shall get as good definition as when we can point the camera direct at the object to be photographed, and can leave the swing-back in its normal position with the ground glass perpendicular to the axis of the lens. Whenever we use the rising-front, we make use of those parts of the combination of a lens which give the worst definition; that is to say, those parts farthest from the centre. Pencils going to form the image pass through the lens at greater angles with its axis than they otherwise would.

From what we have said the following may be deduced: the swing-back should never be used for securing parallelisms of lines when the rising-front may be used. Neither the one nor the other should be used (for the purpose mentioned) when it is possible to do without them.

Of course it is possible to use both the swing-back and rising-front at the same time: that is to say, to make part of the correction by the use of the one part by the use of the other. To what extent each should be used in such a case can only be ascertained by practice and experience.

We have spoken so far only of the vertical swing. The horizontal or side swing is only used to secure the first of the two objects mentioned, to bring planes at different distances from the camera into focus at the same time. It may be used when the objects at one side of the picture are much nearer the camera than those at the other. Of course it may be used in such cameras as are provided with it at the same time as the vertical swing. In any case, it will introduce no disturbance as far as the parallel rendering of vertical lines is concerned.

NOTES FROM NEW YORK.

A Resume of the Late Photographic Convention. Some Interesting Exhibits.

The fifth annual Convention of the Photographers' Association of America was held at Cincinnati, Ohio, between July 29th and August 1st, and proved to be more successful in exhibits and attendance than any previous Convention.

On the 29th, the Convention was called to order by the President, Mr. J. H. Kent. An address of welcome was delivered by Mr. Weingartner, and a paper, "The Progress of Photography," was read by C. Gentilé, of Chicago. The President also made an address, in which he discussed the question of cheap *v.* high-priced pictures, advising all to keep up the high quality of their work, and charge corresponding prices. There was some further discussion in regard to the business before the Convention, after which it adjourned.

The day of the 30th was occupied in discussing the question of prices to be charged for photographs, and also the discussion and voting on changes in the constitution and bye-laws. Mr. Ryder, of Cleveland, Ohio, read a paper "On the Business Management of Photography," bringing out many pungent hits, which elicited much applause.

The Committee appointed to award prizes offered for the best negatives on dry plates by three different manufactories rendered their report.

The first prize of $300 for best work on a 11 by 14 instantaneous larger Cramer plate was given to F. W. Guerin, St. Louis, Mo.

The first prize of $200 for best collection of cabinets and other sizes below 11 by 14 on Cramer plates was given to J. E. Hall, Seneca Falls, N.Y.

The first prize of $100 for best collection of views on the same plate was awarded to J. Landy, Cincinnati, O.

By the direction of the Committee, six $100 were awarded by the St. Louis Dry Plate Company for the best display of photographs on their plates to W. H. Potter, Indianapolis, Ind.; D. K. Clark, Indianapolis, Ind.; W. F. Guerin, St. Louis, Mo.; Strauss Bros., St. Louis, Mo.; C. W. Motze, Atlanta, Ga.; T. H. Doerr, Louisville, Ky.

Awards on the James's Inglis Dry Plates were as follows:—First prize of $100 on 11 by 14 plates to Mr. Cook Ely, of Oshkosh, Wis.; second prize of $100 on cabinets to Mr. Elton, of Palmyra, N. Y.; and also J. M. Brainer, of Rome, N. Y.

More than 150 separate exhibits of photographs, from every section of the country, were shown, and the general opinion prevailed that it was an improvement on former work, and illustrated the steady advance of dry plate photographs.

Among the distinguished persons on the platform was Mr. A. L. Henderson, of London, representing the London and Provincial Photographic Association. He was received with much applause, and responded with a few appropriate remarks.

The day of the 31st was taken up with the discussion on the subject of the reduction of postage rates on photographs, and a resolution was passed requesting the Postmaster General to restore the old rates. Resolutions of thanks were also passed, and ordered to be sent, to E. A. Burke, Director of the World's Exposition at New Orleans, La., in response to his invitation to the Nat. Association of Photographers to attend.

The election of new officers for the coming year then took place, resulting as follows:—

President.—James Landy, of Cincinnati, O.

Permanent Secretary.—Leo. Weingartner, of Cincinnati, O.

Treasurer.—G. M. Carlisle, of Providence, R. I.

Executive Committee.—Joshua Smith, Chicago, Ill., and W. A. Armstrong, Milwaukee, Wisconsin. Buffalo, N. Y., was the next place fixed upon to hold the Convention of 1885. The Convention then adjourned *sine die*.

The exhibit made by W. A. Armstrong, of Milwaukee, was very artistic. Some fine specimens in statuesque photography were shown by C. W. Motze, of Atlanta. Backgrounds and studio accessories were in immense variety, displaying to full advantage the artistic talent of Seavy, who was closely pressed by Spurgin, of St. Louis, Mo.

Among the curiosities of photographic apparatus was a novel photographic printing machine for automatically printing photographs. It resembled a clock, and was set in motion by clockwork within, which was regulated in such a way as to allow the sensitive paper to be held in contact behind the negative for a specified number of minutes, just as long as the operator set it for; and he is notified of the completion of a batch of one, two, three, or four dozen prints, by the automatic sounding of an alarm bell. There is also an attachment for varying the length of exposure as the power of the sun diminishes with the waning day. One of the best exhibits of apparatus was made by Messrs. E. A. and H. J. Anthony and Co., of New York. A detective camera of their manufacture was shown, a trifle larger than a cigar box, and was capable of being carried underneath one's coat. Its total weight, with lens, shutter, and double dry-plate-holder, is only three and one-eighth pounds. A small lens in the upper left-hand corner serves to throw the picture, not larger than a postage stamp, on a piece of ground glass on the top of the camera, thus showing the position on the ground glass. The focussing is done on the top, by the adjustment of a segment of a circle, and pointer which can be set for varying distances. If an object is supposed to be fifty feet away, the segment and pointer are set to point to the figure fifty, and so on. A shutter operated by a spring covers the lens, and is released by a small lever or button. The double plate-holders used with the box also possessed some novel points, and were made with a removable end, and peculiar interior springs, for ejecting the plates a little way out from the end of the holder, so that they may be easily taken hold of and removed by the fingers.

Another camera, mounted like a gun, for taking photographs of birds in flight and animals on the run, was exhibited. The instrument was about the size of a cigar box, and was secured upon the end of an imitation gun-barrel. Sight is taken on the object through a telescope three inches in length, that rests on top of the camera. When the bird is covered, the operator pulls the trigger, thereby automatically operating the shutter and taking the picture.

In lenses, one made by H. S. Suter, of Milwaukee, Wis., and known as the Suter lens, attracted much attention. With a small lens of this make it is said to be possible to make pictures of a large size, and some specimens of work shown seemed to substantiate all the inventor claimed.

The Blair Tourograph Company, of Boston, Mass., exhibited several novel forms of camera and plate-holders; also the Scovil Manufacturing Company, of New York.

Many forms and varieties of shutters were shown, including those that were simple, and others that contained enough machinery to operate a clock.

One of the newest, exhibited by D. C. Hoover, consisted of two vulcanised rubber slides, operated by a spring, and arranged to take the place of the diaphragms in the lens tube, and located between the front and back lenses. Each slide had a rectangular diamond-shaped opening, and both were adjustable to any opening of diaphragm desired, by a simple mechanical movement, and could be operated to make an instantaneous exposure either with a small or large diaphragm. The change from a small to any larger sized diaphragm could be effected in a second. The slides were encased in a neat rubber case, which, being arranged in the lens tube, formed a permanent attachment to it. The shutters are released by a lever at the upper side of the cases. Among the advantages claimed for it was the lightness of the shutter, its very rapid and free movement, its freedom from being interfered with by wind or dust, and the facility with which the size of diaphragms could be changed. Many kinds of plates, and also various forms of shutters, were tested each day. THE AMATEUR PHOTOGRAPHER.

New York, August 11, 1884.

By-the-Bye.

AIR, PURE AND IMPURE.

EXTREMELY impure water may generally be avoided, or at least only used when it is known that the impurities will do no mischief; but this is by no means so with air, as we are always taking in an approximately constant quantity, whether pure or impure. As regards the purification of air, we are almost entirely dependent on natural agencies, and in actual practice we can do but little more than endeavour to drive the impure air away from us, so that it may be replaced by that which is less contaminated.

One essential difference is to be noted between water and air: the former being a definite compound of its two constituent elements, and of course invariable in composition when free from accidental impurities; while the latter is merely a mechanical mixture of gaseous bodies. The two main constituents of air (nitrogen and oxygen) are always present in very nearly the proportion of four volumes of the former to one of the latter; and it is the oxygen which is of most essential interest to ourselves, not only as it is a main factor in the process of respiration, but also as an essential agent in the process of combustion; while the function of the nitrogen seems to be merely that of a diluent.

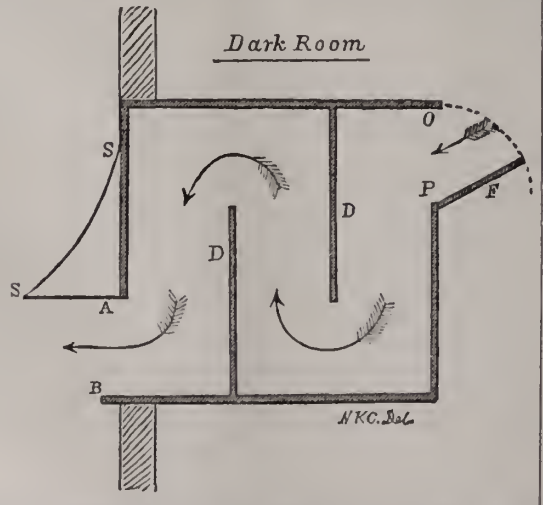
Respiration of animals and combustion are, indeed, essentially the same process, as in each case carbon and hydrogen unite with the oxygen of the air to form carbonic dioxide on the one hand, and water on the other hand; carbon dioxide being a compound of carbon and oxygen, while water is a compound of hydrogen and oxygen.

When the carbon and hydrogen unite with oxygeu from the air, heat is produced, as indeed is the case whenever two bodies enter into chemical combination or union. Now, vast as the store of air is round about the globe, it is obvious that this kind of thing must teli upon it in time, if there were no provision for balancing constaut withdrawals from the available stock of oxygen in the atmosphere. Plants, however, decompose carbon dioxide and water; the hydrogen and carbon being stored up by the plant as it grows, while the oxygen is liberated. This action is clearly the reverse of combustion, or respiration, and the fact that the heat, together with its physical equivalent light, disappears during the growth of plants, serves to make the respiration of a plant, if one may use the term, a complete antitype of combustion or the respiration of an animal.

In the coal beds we have an immense store of carbon and hydrogen which has been thus separated from the atmosphere by plants that flourished when solar light and heat were far more intense than they are at present, and in burning this coal we are drawing freely upon the stock of heat which was rendered latent and stored up long ago.

Thus we see that the ratio between the oxygen and the nitrogen of the air is kept up in nature by balancing influences; and taking the whole mass of the atmosphere, no permanent change in compositiou has been noted. Notwithstanding this, the proportiou of oxygen is very sensibly less in a crowded room than in the open air, and a slight difference may be traceable between the proportion in the air of a town and that in the open eouutry; in each case the increase of carbonic acid being proportionate to the diminution in the amount of oxygen. Still the unwholesome character of air which has been frequently respired is largely due to its contamination with organic impurities, and perhaps in some cases of germinal matter; but such substances are very soon oxidized and destroyed when the contaminated air can mix freely with the great mass of the atmosphere. Air purification in the strict sense is but rarely resorted to, free circulation, which brings into play the restorative agencies provided by nature, being the great remedy; and to the photographer the question of ventilation is an important one, as he may suffer in health from constantly working in dark-rooms where a sufficient change of air is not provided for.

In taking precautions against the entry of light into his dark-room, he frequently stops all circulation of air; still, there is not the least difficulty in providing for thorough ventilation without in any way incurring a risk of light



gaining ingress. A kind of ventilator excellently well suited for general use is one constructed on the baffle-plate principle, and a sufficient idea of such a ventilator may be gathered from the above sectional diagram.

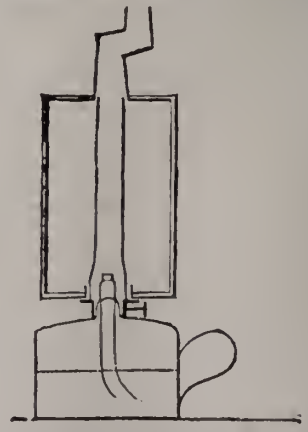
One or more ventilatois of this kind should be placed near the floor, and also near the ceiling; but if a little judgment be exercised in selecting suitable positions, far fewer bends will be required than are represented in the diagram. In fact, ventilators having a section such as is shown below, may be used; only in the case of those near

the floor, care must be taken that the openings look dowuwards and towards some dark and not very reflective surface; while those ventilators placed near the ceiling must have the openings directed upwards, and the outside openings should be screened from rain and the direct light of the sky by means of a strip of board inclined downwards. It is scarcely necessary to say that the inside of the veutilator should be painted black.

The dark-room lantern often serves to withdraw much oxygen from the air of the developing room, and it not unfrequently happens that owing to the imperfect circulation of air through the dark lamp, the carbon *monoxide* is formed, this being a product of the partial combustion of carbou.

The monoxide is extremely poisonous, very minute quantities being sufficient to produce headache and lassitude; while the dioxide may be present—and, indeed, always is present—in the air to a considerable extent without causing mischief; still, considering that an ordinary paraffin lamp or full-sized gas jet consumes as much oxygen in burning as is absorbed by the lungs of two men, the certain vitiation of the air is considerable, apart from the possibility of the highly poisonous carbon *monoxide* being formed.

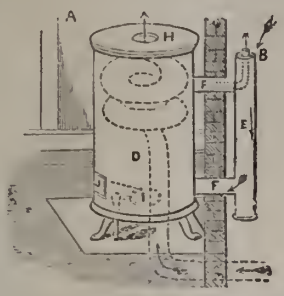
It is, then, an excellent plan to make the lamp itself serve as ventilator; this being quite an easy matter if the air outlet at the top of the lamp be connected with a sheet-iron chimney passing into the open air, there being no



difficulty in doing this, if a lamp constructed with a tubular outlet, like that represented above (Mr. Jarman's), be used.

When a gas stove is used as a source of heat in the

drying-room or in the dark room, it is very necessary to employ some form in which the products of combustion pass freely away, and in very many photographic establishments the so-called Calorigen stove of M. Georges is made use of. The subjoined diagram will explain its construction :—



A, the interior of the room; B, exterior of the building; C, wall; D, the Calorigen; E, a cylinder; F, pipes communicating to supply air for combustion and carry off product; G, pipe for passage of cold air to Calorigen; H, outlet for ditto, after being made warm; I, gas burner; J, door.

ON THE DEVELOPMENT AND INTENSIFICATION OF GELATINE NEGATIVES.

BY S. R. BOTTONE.

A great authority in photography, speaking of dry plates, declared that "he could teach anyone to make them, but that their development was a science."

The reason for this is clear to all who have had to do with our modern dry plates; and it lies in the fact that very little latitude is really admissible in the matter of exposure; or perhaps, to speak more exactly, that the sensibility of the film is so great, that a period of time, which would be a mere fraction of the total exposure in the case of a collodion picture, becomes a multiple of the normal exposure in the case of a gelatine plate. Suppose that the correct exposure for a portrait in a studio, with collodion, were fifteen seconds, and that inadvertently sixteen seconds were given, the result would undoubtedly be over-exposed; but the degree of over-exposure would be correctly represented by the fraction $\frac{1}{15}$. If, however, a gelatine plate, the normal exposure of which was half a second, were exposed one-and-a-half seconds, then it would have received an exposure three times as long as it ought to have had, and the result would ordinarily be a thin, flat, unsatisfactory image. It must also be borne in mind, that somewhat of the thinness of the images developed on gelatine plates depends on the condition of the plates themselves. Plates prepared with a large percentage of silver bromide or iodide are rapid and full of detail, but somewhat wanting in density; while those in which the haloid salt of silver is kept low are slower, harder, and capable of being made to give very dense images.

Again, the nature of the developer very much modifies the colour and density of the deposit. A slow-acting developer gives a hard black image; a strong, quick-acting developer gives one full of softness and detail, but with a tendency to flatness if the exposure has been at all prolonged.

If an image, the exact exposure of which is not known, be developed by a weak developer, and be found to come out too slowly, then the cautious addition of a stronger developer will remedy the defect, and bring out all detail *that is impressed*, without injuring the shadows.

Based on a knowledge of these facts, is the following mode of procedure, which, in the writer's hands, has invariably given excellent results, and allowed of considerable latitude in exposure.

Having exposed the plate—and it may be stated that with the ordinary run of English commercial plates the exposure will be nearly right if, with an aperture of $\frac{1}{6}$, an exposure of one second in sunlight, or two in shade, be given—it should be taken into a ruby lighted room, the light—about three square feet—being situated about four feet above the head, and flooded with the following solution, which should have been made up at least twenty-four hours, and exposed to sunlight in the interim :—

Saturated solution of ferrous sulphate	1 ounce
" " " potassium oxalate	3 ounces
Tartaric acid	2 grains
Potassium bromide	2 "
White sugar	60 "

The picture should be kept rocking during development, as the image will by this means be much more brilliant than if allowed to remain motionless.

The image should appear slowly. A quickly-developed image is almost invariably "flat, stale, and unprofitable;" whereas a picture which takes from five to ten minutes to bring out is almost always a good one. For this reason it is well to have at hand an ounce bottle containing a saturated solution of potassium bromide, a few drops of which may be cautiously added to the developer if the image shows a tendency of appearing too quickly. When the image shows fairly on the surface, look at the back of the plate; if the high-lights show through distinctly, and the half-tones slightly, the picture is sufficiently developed. Now remove it from the developer, and place it at once in a dish or bath containing clean water, which must be changed after each plate.

Having washed the plate well, examine it carefully before a yellow light for density. If it appear sufficiently dense to give a satisfactory print, immerse at once into the fixing bath—consisting of a saturated solution of sodium thiosulphite in water, and when cleared from the haloid salts, plunge for a few minutes into a solution of chrome alum (strength about 1 ounce to the pint); then wash thoroughly. Should the picture appear altogether too slowly while under the influence of the developer, add to this latter a little fresh ferrous oxalate, made by mixing 3 parts of the saturated potassic oxalate solution with 1 part of saturated ferrous sulphate solution. This should be added, about a drachm at a time, to the mixed developer, until the image is satisfactorily developed.

The developer, when used, must not be thrown away, but placed in a glass bottle furnished with a tightly-fitting cork, along with 1 grain of tartaric acid to each ounce of solution. The bottle should then be placed where it can get the direct rays of the sun. This sunned developer is excellent for starting the development, and yields pictures of extraordinary density and delicacy of detail.

Should the pictures, before fixing, show a lack of density, though full of detail, the following method of intensification will be found to yield excellent results.

Prepare a solution of chlorine by shaking up 1 ounce of fresh dry chloride of lime with 1 pint of water. Allow the solution to clear itself in a stoppered bottle, which must be kept in the dark. Pour out about half-an-ounce of this solution in a measure glass, and add to it 2 or 3 drops of tincture of iodine. Flood the plate with the sherry-coloured fluid, and pour off and on, for at least one minute. Wash thoroughly, until no smell of iodine or chlorine is perceptible. Now flow over the plate a couple of drachms of the following intensifier :—

Pyrogallol	1 grain
Citric acid	1 "
Water (distilled)	1 ounce

To which must be added, after the solution has permeated the plate, and returned to the measure glass, a few drops of the following solution :—

Argentic nitrate	20 grains
Water (distilled)	1 ounce
Glacial acetic acid	1 drachm

Plates may be intensified to complete opacity by this means,

without any tendency to green or red fog, the shadows remaining as clear and bright as in a good collodion negative.

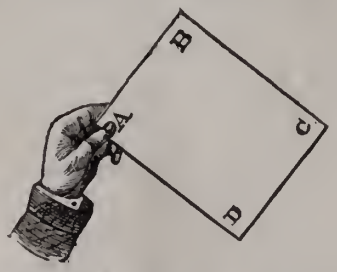
Should the picture have been fixed before the want of density has become apparent, intensification may be performed with the same solutions, and with results which are at least equally good; but then it is a *sine quâ non* that the fixed plate should have been soaked for at least five minutes in chrome alum water, and fifteen minutes in chloride of lime water. The use of chloride of lime water is absolutely essential to success, as it removes (by decomposition) every trace of sodium thiosulphate, which otherwise causes re-development to be a failure, by causing browning, stains, and reversals.

It must be remembered that no amount of intensification can bring out details which are not impressed; but given a plate, let it be ever so much over-exposed, short of reversal, it is possible, by slowing the development as above advised, to get an image, faint in proportion as the exposure has been prolonged, but full of detail, and fairly balanced; which image, by entirely checking the action of light by means of the mixed chlorinated iodine water, may then be built up to any desired degree of intensity by an acid pyrogallol intensifier.

Practical Papers for Beginners.

No. 7.—PRINTING FROM THE NEGATIVE.

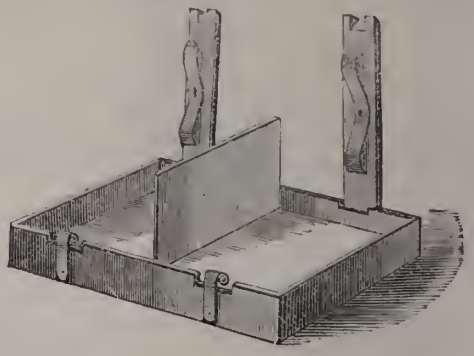
The negative having been thoroughly washed and dried, should be varnished before any prints are made from it, as otherwise the film may absorb silver from the sensitive paper used in printing, and become stained beyond remedy. Even although the negative may appear quite dry, it is as well to allow it to remain in a warm place for an hour or two before varnishing, as a trace of moisture may cause the varnish to break up, and may lead to the premature destruction of the negative. Having now made the plate so warm as to feel pleasant to the hand, by holding it before a fire, or over a gas flame, it is held horizontally by one corner, as shown in the subjoined diagram, and a



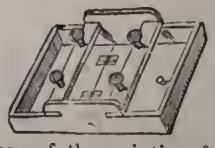
quantity of varnish is poured over the central portion; a very slight inclination of the plate now serving to make the pool of liquid flow successively to each corner. The next step is to drain off all excess of the varnish at one corner, and when no more varnish drips from the plate, it is again warmed, preferably by holding it before a fire. It is now allowed to become so hot as to be uncomfortable to the back of the hand; and, when, cool it is ready for printing from. It may be noted that the mere warming before a fire or over a gas flame, immediately before varnishing, cannot be relied upon for removing the last traces of moisture from the film, as damp gelatine parts with its water very slowly.

Special varnishes for use in protecting negatives are sold by the dealers in photographic materials; but those who prefer to make their own may obtain a very excellent varnish by dissolving two ounces of white shellac, two ounces of sandarac, and one drachm of Canada balsam in sixteen ounces of methylated spirit.

The positive print is made by placing a piece of paper so prepared that it will darken one xposure, behind the negative, and allowing the light to shine through the negative until a sufficiently vigorous image is the result. We may suppose that the beginner obtains the sensitive paper already prepared, as it is now kept in stock by all dealers; but those who wish to prepare their own need only refer to the comprehensive "Lessons on Silver Printing" which appeared in the Photographic News during 1883. Exposure to light is managed in a printing frame, the essential parts of which are a rebated frame in which a thick sheet of plate glass is usually set, a hinged back and bars provided with springs or screws for keeping the negative and the sensitized paper in close contact. The following diagrams will give an idea of some usual patterns of



printing frame, that provided with screws being generally preferable to that in which the pressure is regulated by springs.



See that the glass of the printing frame is clean, and lay the negative, face upwards, upon it. Next cover with a sheet of sensitive albumenized paper, cut to the proper size, care being taken that the sheet is placed smooth side downwards. A few thicknesses of blotting-paper are now laid over, the hinged back of the frame is placed in position, and the bars are brought down so as to keep all in its place, an adjustment being made with the screws if required. Exposure is generally best made in bright diffused daylight, although the printing can be performed much more rapidly in sunlight. In order to watch the progress of the printing, one bar of the frame is undone, so that half of the print can be examined; and it is always necessary to print a few shades darker than the finished print is intended to be, as the subsequent operations of printing and toning lighten the photograph considerably, the exact extent to which the over-printing must be carried being only learned by experience. It is convenient in practice to expose a number of prints before proceeding to tone and to fix, the impressions being stored in a dark box as they are taken from the frame. The work of cutting up the paper, changing the frames, examination of the prints on their removal from the frame, need not be carried out in the usual developing room, an apartment illuminated by a small window or by gaslight answering well.

The first step towards toning is to rinse the prints in three changes of clean water, allowing about five minutes each time; after which they are immersed in the so-called toning bath, which may be compounded as follows:—

Water	...	...	...	16 ounces
Acetate of soda	...	...	...	40 grains
Chloride of gold	...	...	...	2 ,,

The chloride of gold is sold in tubes containing 15 grains,

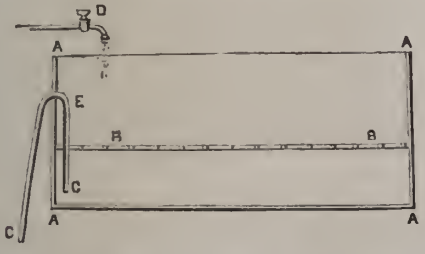
and it is convenient to dissolve the contents of one of these tubes in 15 drachms of water, so that instead of weighing out two grains of the salt, the more convenient plan of measuring out two drachms of the solution may be resorted to. It is generally well to make up the toning bath two or three hours before it is required for use.

While in the toning bath, the more or less reddish prints will gradually change in colour, and when a black-purple is arrived at, the toning may be brought to an end by removing the prints from the bath and placing them in clean water. The exact tone or tint to be produced is entirely a matter of taste, and the beginner will soon find that he can control the tint within very wide limits by allowing the gold solution to act for a longer or a shorter time, the lessons on silver printing already referred to dealing thoroughly with this matter; but in order to ensure uniform action of the toning solution, the prints should be kept in motion during the whole time.

Before proceeding to the next operation, that of fixing or dissolving out the unchanged sensitive compound which is contained in the paper, it is well for the beginner to put away his toning solution, and also the dish in which it was used, as the compound used in fixing is especially mischievous if it should find its way into the toning bath.

The fixing solution is made up by dissolving four ounces of hyposulphite of soda in a pint of water, and adding thirty drops of liquid ammonia. Cold is produced by dissolving of the hyposulphite in the water, and it is well not to use the solution until it has acquired the temperature of the surroundings. The fixing bath or solution having been poured out into a suitable dish, the prints are immersed, and are kept gently moving in the solution for fifteen minutes or so. After this they are several times rinsed in water.

Now comes one of the most important operations—that of soaking out every trace of the hyposulphite of soda, as rapid fading is likely to result if any of this salt remain behind in the prints. Half-a-dozen changes of water, with an interval of two hours between each change, may be sufficient in ordinary cases; and it is a very common thing to provide an automatic arrangement for making the requisite washings. A good apparatus of this kind is shown below,



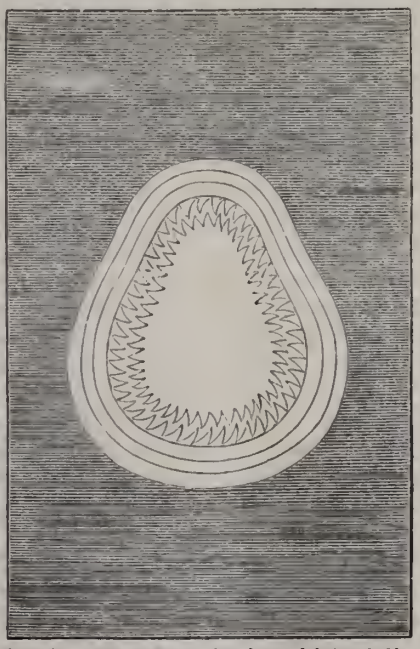
and it scarcely requires explanation. The prints are placed on the perforated plate, B B, and the water is allowed to flow slowly in. When it reaches the bend E in the syphon, the trough is emptied rapidly, again to be filled by the drip or slow stream from the tap. If such an apparatus as this is set in action at night, with the tap adjusted to the correct flow, the prints may be considered washed in the morning.

The prints are taken from the water, and the surface water is removed by means of clean white blotting-paper, after which the prints are pinned up by one corner to dry.

The mounting of the prints on cardboard is a very simple affair; but before mounting it is usual to trim them so that a neat edge shall be shown. A sharp penknife, guided by a rule or a glass cutting shape, answers well for trimming the photographs, the print being laid down on a plate of glass or a sheet of zinc, the latter being preferable, as it does not so rapidly take the edge off the knife. Thick and freshly-prepared mucilage of gum-arabic is one of the best mountants, and no special instructions are required for its use, excepting that as little as possible should be used. The mounted prints, when nearly or quite dry, are much improved by being rolled or burnished, and a fairly satisfactory result can be obtained by using a moderately warm laundress' iron with a sheet of paper interposed between it and the photograph. A rolling apparatus like that represented below is, however

more convenient and effective, and does not cost very much if the size is small. Other pressing and burnishing arrangements are described in the place already referred to.

It often happens that the vignette style of printing is preferred, and although this is most frequently the case with portraits, it often happens that a little bit of scenery, such as a country church, or a group of trees, may be vignetted with advantage. A graduator or vignetting plate, of which one kind is represented below, is fixed in



the printing-frame, as shown in the subjoined diagram, so as to shade the edges of the paper and keep them white.

The vignetting plates are sometimes made of glass, being orange at the edges and white in the centre; while in other

cases they are built up of layers of tissue paper, as is the case with that shown in our diagram. Openings of various patterns may be had, but some judgment is always required to obtain a good vignette picture, and the vignetting plate should not be placed too close to the glass of the printing-frame. Many persons make very excellent vignette pictures by placing a border of cotton-wool outside the printing-frame.

Notes.

Dr. Lohse's photograph of the sun, which we publish this week, is one out of a series of more than 600 which have been taken at Potsdam since 1881. No records of sun-spots can be of such exactness and value as photographic records; and the particulars given on page 545 will be read with interest.

It is the intention of the Trustees of the National Gallery, as soon as the photographic reproduction of their masterpieces is completed, to publish officially a selection of the photographs, with critical and descriptive letter press. What has long since been done for the great art galleries of Paris, Madrid, the Hague, Munich, Rome, and other capitals, is, in fact, at length to be done for England's national collection, though it is only very sanguine individuals who anticipate that it will be done as well.

If it be indeed true that the Government inclines favourably to the notion of ere long supplying London with a building worthy of the rapidly increasing importance of our collection of national portraits, the country has good reason to congratulate itself. The proposed site of the new gallery—viz., the ground on which Lord Carington's town house now stands in Whitehall—is an excellent one, and should the suggested plan be carried out, Mr. George Scharf will have ample room at his disposal for the carrying out of those photographic precautions which, as a discreet curator, he fully appreciates.

The immediate cause of the unexpected consent of the Treasury to take this matter into consideration is to be found in what is taking place at Edinburgh, where two successive and munificent gifts of £10,000 have been placed at the disposal of the Government towards building a Scotch National Portrait Gallery. It is only since the new building was actually commenced that the provision of a suitable gallery for England's national portraits has become a burning question.

A distinctive feature in all English photographic Associations is the good feeling which exists between the two classes of members—professionals and amateurs. This is not quite the case in America. The amateur photographers of Chicago, for instance, want to start a new society, as they are not satisfied with the way in which the present one "seems mixed up with the professionals." On the other hand, the society of professionals is not pleased because it has become "mixed up" with the amateurs. We should be inclined to think that the more they are "mixed up" the better for both.

"In answer to yours of the 25th inst., I shall be pleased to meet you at the place and time you propose, and the enclosed photograph will assist you in recognizing me."

Arranging to be recognized by allowing one's handkerchief to hang out of a pocket, by flourishing a rolled-up newspaper with the right hand, or by committing some other act of eccentricity, is certainly less satisfactory than sending one's photographic carte-de-visite. Of course we sent our photograph in return, and the recognition was immediate and mutual.

The photographic carte-de-visite has always been an album portrait rather than a visiting card in the ordinary sense; but why, indeed, should not an actual photographic card for every-day use become common? It would merely be necessary to attach a postage stamp portrait to the back or front of the usual visiting card.

Although very popular just now in the United States, the stamp portraits are not often seen here; in America they are sent out in sheets, ready perforated and gummed.

Supposing that postage stamp portraits were generally to be found in a card-case or the pocket-book, no inconvenience would arise from a railway company insisting on a portrait being supplied for attaching to every season ticket issued; or from a similar requirement being made as regards passes to exhibitions. Although all can appreciate the obvious value of the adhesive portrait when attached to a letter of credit, passport, or other certificate of identity, it is perhaps not generally known that some fourteen years ago a patent covering such uses of a photographic portrait was applied for, but not proceeded with (Baylis, "A means of preventing impersonation," 1870, No. 385).

About eight hundred English were present at the meeting of the British Association in Montreal on Wednesday, and Lord Rayleigh, in his presidential address, touched on the great scientific problem of the day—a correct estimation and representation of energy in its various manifestations. As regards the quantitative estimation of the dynamic equivalent of light but little has been done; but Lord Rayleigh spoke highly of the labours of Abney in mapping out the peculiarities of the spectral region beyond the red—where, indeed, it is difficult to know whether we should term the radiant energy light or heat.

Langley's investigations—based upon the influence which radiant energy exercises upon the conducting power of selenium—prove that the atmosphere cuts off an enormous proportion of the more refrangible rays, so that the sun appears far less blue than it would to an observer placed outside our atmosphere.

A new power having been placed in the hands of the spectroscopist by the diffraction gratings of Professor Rowland, one may, according to the President of the British Association, expect fresh results of importance; and Becquerel's investigations upon the remarkable action of the ultra-red rays in enfeebling the light emitted by phosphorescent bodies are likely to open up new paths for scientific exploration.

The publication of the Claimant's protest in the papers has had the effect of overwhelming those of his friends supposed to be much in his confidence with applications from photographic artists, all of whom are eager, on various conditions, to become his photographer-in-chief. One of the first matters of moment he will have to decide, on emerging from durance vile, will be as to the disposal of his photographic patronage. He will, in fact, have to arrange for the necessary sitting in this case, even before he discusses the details of that seat in Parliament which, it is again asserted, he intends to obtain.

Two million copies of a photograph is something like an order. This is the number of portraits of Mr. Blaine, the Republican candidate for the Presidency of the United States, which one firm has to turn out at the rate of some 67,000 per day.

Mr. Cecil V. Shadbolt's steady progress as regards photography from a balloon leads us to hope for useful applications of this branch of the art; but until some progress is made in the steering or controlling the movement of a balloon, all work with the camera must of necessity be very uncertain.

As to steering, no advance has been made, and yet the conditions under which a balloon can be steered are perfectly understood. A motor is required which will drive the balloon so forcibly through the air, that it shall be able to outstrip the strongest wind. It requires very little mathematical knowlege to prove the utter inability of any motor now known to direct a balloon, unless when the atmosphere is practically still, and if those newspaper *canardists* who so frequently and so persistently announce the practical solution of the problem would get someone else to calculate out the horse-power required to drive a balloon of given magitude at a determinate speed through the air, we should hear less about the the steering of balloons being an accomplished fact. It is, indeed, demonstrable that less motive power would be required to drive a flying machine against a strong wind, than to so drive a balloon; but both operations are far beyond the power of our existing motor engines. Still we may hope; but the first step is the invention of a sufficiently light and powerful motor engine, and other applications of such a motor as is required would almost revolutionize the world.

A comic contemporary has been finding in photography the matter for a "humorous narrative." A much married husband is photographed by a peripatetic artist at the seaside in the absence of his wife. On being subsequently shown the "proof," he finds that the rascally photographer has contrived to introduce the likeness of a bold, bad female into the picture—has, in fact, placed her in the innocent husband's arms. On the strength of this the r. p. demands and obtains hush money. And in his renewed applications for black mail and the much married man's consequent victimizing, the fun of the sketch may be supposed to exist.

The idea of all this is, of course, not a new one; the moral, "Don't be photographed by peripatetic artists" ought not to require further enforcement. It is interesting to note, however, how frequently, and appropriately some would say, photograpy is brought into our light literature. Mr. Malloch's use of it in his "Nineteenth Century Romance" is fortunately as exceptional as it is ill-advised. But those who have read Mr. Thomas Hardy's "Laodicean" will remember that the love-suit of the hero is hopelessly checked by the use of manipulated photographs of her rival.

This rival, by means of a well-known device which Mr. Hardy found out to be possible before he used it, manages to produce some cartes in which the sober and unexceptionable hero is represented with a face bespeaking seemingly an idiotic stage of inebriety. He takes care that one of these portraits shall come into the heroine's possession, the result being the postponement of the happy climax of the story for two volumes.

But this exordium deals with the past, and the item of more immediate interest we have to allude to is the announcement that a dramatic satire, in which the camera will play an important part, has been written, if not on fact, yet passed by the "Licencer of Plays." One scene—in which a professional beauty is chased by a horde of photographers, each armed with his apparatus, and, in spite of her protests, is photographed in every passing position she assumes, and which concludes with a kind of *Camera Ballet*, with novel effects—ought to be a success.

Another scene is a shop-window which will occupy the whole back of the stage, and on this enlarged photographs will be displayed in novel combinations which will themselves have a satirical interest. It is proposed, too, that the "Auditorium" shall be actually photographed from the stage in the course of the piece each evening.

The argument which publishers of engravings use against photography, that it destroys the value of an engraving by being able to produce copies of a picture at a much cheaper rate, has recently been shown by Mr. Seymour Haden, the well-known etcher, to be a most disingenuous one. Mr. Haden brings a serious charge against publishers of prints, to the effect that they systematically disregard the obligation to destroy a plate after so many proofs have been produced, and go on printing even after

the plate is worn. The artist's "stamp," which many people suppose is a guarantee that the print is one of a limited number, is no guarantee at all when the number of prints is unlimited. Mr. Haden mentions as examples, "The Allied Generals before Sebastopol," "The Derby Day," "The Relief of Lucknow," and others, the plates of which were in every case to be destroyed, and yet are printing at the present day. If this be so, what the print publishers are afraid of is the dangerous rivalry which photography sets up against the cheap and inferior "pulls" from a worn-out plate. It is clear, however, that this admission will never, in the present state of things, be made, since to do so would disclose the secrets of the prison house.

A lady of the "Dora Copperfield" type, who lately noticed in an advertisement the term "gelatine plates," opined that they must be what people used with "jelly glasses!"

The Chinese Government has initiated a new era in diplomatic negotiations. It has had the Fournier Treaty, in which the terms for the evacuation of Bac-Nin are cancelled, to be photographed, and has sent copies to the Powers. The Chinese assert that the date of the evacuation is not mentioned in the Treaty, and to prove they are right, the document has been photographed.

Our anticipation of a popular title for next year's Exhibition in the term "Inventories," has led to several suggestions being forwarded to us. One is that a shorter and more easily pronounced name for the exhibition of patents would be the "Patentries;" whilst a second, *apropos* of the fact that "Musical Instruments" will also form a prominent feature in next season's show, proposes, after discarding "Instrumentories" as too long, that the chosen name shall be the "Musicries!"

Meissonier uses photography largely. His practice is, after designing a picture, to have the figures forming the group photographed first as a group, and afterwards singly. Perhaps no painter is so scrupulously careful in the preparation of his work. His outlay to models is something enormous, on one occasion paying a man as much as two pounds the hour to lie half covered with snow. It is not every artist who could afford to do this, but then it is not every artist who is paid so well as Meissonier.

A writer in our contemporary, *La Production*, points out that great international exhibitions are by no means to be regarded as belonging exclusively to modern times, for the Book of Esther records that the exhibition which King Ahasuerus held in his palace of Shushan was kept open for no less than six months; while the exhibition organised at Venice in the thirteenth century by the Doge Tiépolo was by no means a small affair. More recent exhibitions are mentioned, as those organised under the patronage of the Society of Arts in 1756 and 1761; also the exhibition held in Paris during 1797. In the first year of the present century, a greater exhibition than that previously held in Paris was organised by Napoleon—then first Consul. On this occasion gold and silver medals were awarded by a jury of experts.

Patent Intelligence.

Applications for Letters Patent.

11,556. EUGEN HIMLY, 28, Southampton Buildings, Chancery Lane, W.C., for "Improved method of and apparatus for taking photographs by artificial light."—(Complete Specification).—Dated 22nd August, 1884.

Specification Published during the Week.

4989. JAMES STURROCK, Bank Street, Dundee, in the County of Forfar, North Britain, for "Changing sensitized plates in photographic cameras."—Dated 17th March, 1884. *Complete Specification).*

The first part of my invention relates to cameras of the ordinary well-known kind in which pictures are obtained by exposure in the camera of glass plates properly sensitized. It has for its object a novel method of constructing such cameras, or slides for cameras, so that the sensitized plates can be readily changed when required. I make at the back of the camera a space to hold a sensitized plate; this space is open above, and is provided with a flange or other similar device, to which can be readily attached by an elastic band or other convenient means the open mouth of a bag made of paper, cloth, india-rubber, or other suitable material impervious to light; or it may be made of tin, cardboard, or other rigid substance, with a flexible neck or mouth of rubber or cloth suitable for attachment to the camera. I fill the bag in a dark place with a sensitized plate, and then close or fold the mouth to exclude the light, and secure it by a spring, clip, elastic band, gum, or their equivalents; and having fixed its mouth to the camera, as already described, I remove or undo the fastening, invert the bag, and deposit the sensitized plate in the camera. After exposure, the plate is again slipped from the camera into the bag, and the fastening again put on, and the bag, with the plate, removed from the camera, when another bag containing a plate can be attached. The plates can be stored away in the bags both before and after exposure.

In the second part I make a separate holder or slide, having a space to hold one or two sensitized plates, as in the ordinary dark slides, but having a flange, or other similar device, to which the bag can be attached, and a plate or plates put in, as already described, and which can be inserted in the back of the camera in the usual way. The accompanying drawing shows bag folded

so as to exclude the light and attached to camera.

Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is:—

First. The arrangement in cameras or slides for cameras for enabling flexible bags to be attached substantially as described.

Second. Flexible bags for conveying plates to or from th

camera or slide, made so as to fold or close at the mouth, and secured by a spring, clip, elastic band, gum, or their equivalents.

Third. Bags, by means of which sensitized plates can be placed into or taken from the camera or slide, without introducing the hand or other agency into the inside of the bag.

FRENCH CORRESPONDENCE.

INSTANTANEOUS PHOTOGRAPHY—MACDOUGALD'S DEVELOPER TUBES—CHAMBRE SYNDICALE OF PHOTOGRAPHY.

Instantaneous Photography.—Photographic doings are difficult to relate at this time of the year, when everyone is taking holiday: scientific meetings are suspended, and amateurs are scouring the country, taking instantaneous photographs as reminiscences of their visits. Nothing is more delightful than to go about and thus reproduce the scenery around. Although not difficult of attainment with practice, instantaneous photography requires thoroughly good apparatus; the lens must be of the best on account of working with full aperture, and the calculation of varied exposures with a shutter takes some time to learn. During a stay on the coast of the Mediterranean, my leisure time has been taken up in photographing vessels in motion. The most delicate focussing is required in this exercise, and in the case of a ship sailing swiftly it is difficult to focus carefully the zone of sea through which it will pass, without having any point to aim at directly. No rule can be given as a guide in such cases. When boats are taken sailing on rivers or canals, objects on the banks guide one as to the focussing point; but on the sea, at a distance of from one hundred to two hundred metres, how can one measure the point exactly? An indicator of some sort may be arranged by using a little lens, having its course graduated in such a manner that a given point can be made to correspond with the same in the large lens. For instance, the indicator marking a certain point or notch (No. 10), by placing the lens in focus of the same number the object to be taken is in view. This is how I use the indicator, which really constitutes a kind of telescope having the same focus as the lens. The operator, standing by the camera, views the ship through the indicator a short time before it passes across the camera, then, when clearly defined, the lens is focussed to coincide with it. I cannot find any more expeditious way of obtaining the desired result. Time does not permit of employing the camera itself to focus on the ground glass.

Macdougald's Developer Tubes.—The idea of preparing the developer in tubes, so as to carry them about easily without risk, is excellent. To tourist-photographers and others obliged to carry photographic apparatus in as small compass as possible, I highly recommend this invention as possessing the qualities of solidity, permanence, and compactness.

Photography at Lyons.—The photographers of Lyons have just organized a syndical chamber, under the presidency of M. Bernaud. The fact tends to show how photography follows in the steps of all other industries. It does not number many professional photographers yet.

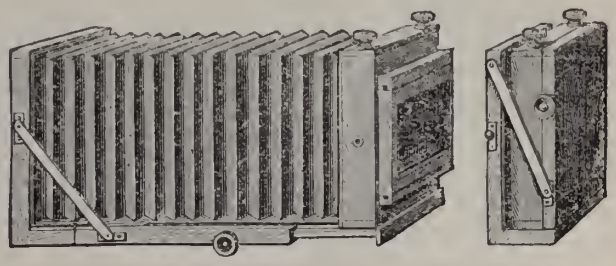
LEON VIDAL.

HOW TO PHOTOGRAPH MICROSCOPIC OBJECTS.

BY I. H. JENNINGS.

LESSON II.—PHOTOGRAPHIC APPARATUS.

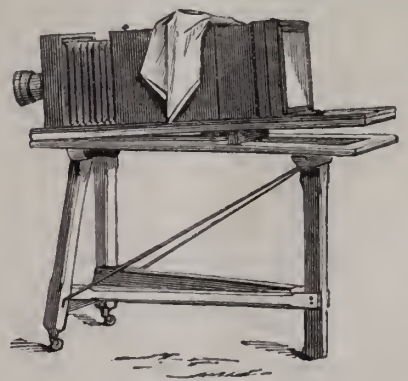
FOR simple photo-micrographic operations, any ordinary camera may be employed. A quarter-plate camera will answer, but the student is advised to obtain a half-plate, or even a whole-plate camera, for, as he advances in skill, he will, perhaps, wish to photograph sections of rocks, or woods, or whole insects, on a larger scale than the smaller camera will allow. A good lens will make a half or whole-plate enlargement of an object without loss of definition. Using the eye-piece, and working with low powers, a camera expanding to eighteen inches or two feet will suffice, but for the higher powers, which cannot well be used in conjunction with the eye-piece, a camera expanding to four feet, or even six feet, is recommended. The eye-piece cuts off so much light when working with high-power lenses, that focussing becomes difficult, if not impossible; while without it, focussing with a $\frac{1}{12}$th inch or $\frac{1}{15}$th inch is an easy matter, even when a condenser is not employed.



LONG FOCUS CAMERA, SUITABLE FOR PHOTO-MICROGRAPHY.

If an ordinary camera be employed, there are none better than those sold under the name of "long focus" cameras. The half-plate size expands from three inches to eighteen inches or twenty inches, which is ample for low powers, especially when working with the eye-piece. The above illustration shows a capital "long focus" camera, introduced by Hare, which will answer both for landscape and microscopic work, and form an excellent companion for the summer holidays, when the microscope will be, or ought to be, laid aside. Even the expert photo-micrographer will find the occasional practice of landscape photography a very good way of "keeping his hand in."

A long copying-camera, provided with focussing arrangements back and front, makes a very excellent camera for photo-micrography. It is very desirable that the front should not be fixed to the base-board, but be capable of either sliding back or moving back by screw, for frequently it may be necessary, after all is ready for taking a photograph, either to change the position of the object, or alter the illumination, which can be satisfactorily performed only by looking down the microscope tube. If the camera has to be removed for this purpose, there will be some difficulty in getting everything square again; while if the camera-front can slide back along the base-board, the relative position of microscope and screen remains unaltered. Copying cameras suitable for photo-micrography are to be met with in the lists of most dealers in second-hand apparatus.



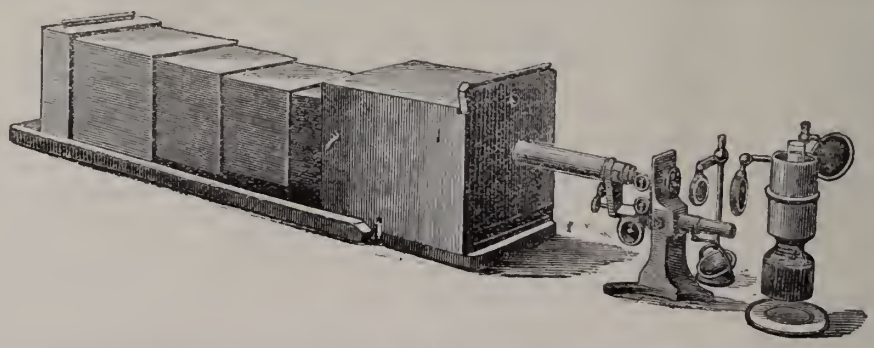
COPYING CAMERA.

If the student cannot procure one of these cameras, he may very easily construct one for himself. Procure four boards nicely planed, $\frac{1}{4}$-inch thick, some inches longer than the proposed camera, and $\frac{1}{2}$-inch less in width than the bellows are required. Make a long box with the boards, fastening them together at the ends only with screws.

Cover this box with thin black calico or book-binder's cloth, pasting the edges together where they lap over. Next cut some slips of thin cardboard $\frac{1}{2}$-inch or $\frac{3}{4}$-inch wide, and $\frac{1}{8}$-inch shorter than the width of the box. Cut the corners off each slip at an angle more acute than 45°, thus:—

When sufficient have been cut, paste the slips exactly parallel on the four sides of the box, about $\frac{1}{8}$-inch or $\frac{3}{16}$-inch apart. Each slip must be pasted on with the cut-off ends facing in the same direction. When the paste is dry, put on an outer cover of better material; twilled calico will do, but is somewhat thick for the purpose; good book-binder's cloth is best. The edges should be pasted together as neatly as possible. When the whole is dry, unfasten the end screws, when the boards will collapse, and the bellows can be drawn off. Now proceed to fold it up carefully, by pinching it into shape at the edges of the slips of cardboard, and put the bellows in a copying press, or under heavy weights, for a day or two. The base-board for this bellows should extend in front about 3 feet, so that the microscope and lamp may stand upon it. As the bellows will require no protection, the camera-front may consist of a plain vertical board, of the right size, constructed to slide back on the base-board about 15 or 18 inches. The dark slide should be purchased, preferably a single one, and the back of the camera made to fit it. The camera may be opened or closed by hand alone, the back moving in guides screwed along each side of the base-board; or by endless screw, cut with rather a coarse thread. When the endless screw is not used, a screw and butterfly-nut must be employed, to clamp the camera in any desired position.

If the student has not sufficient hand-skill to construct a bellows camera, he may make, or have made, the simpler arrangement represented below. As will be seen, it consists of a series of boxes, fitting into each other after the fashion of a sliding-body camera. It can easily



be lengthened or shortened by the addition or removal of one or more boxes. Any joiner could easily construct such a camera on seeing the illustration.

Double dark-slides may be employed, if well made, but a single slide is better, as the focussing-glass can be placed in it, and when replaced by the sensitive plate, the latter will lie in exactly the same place, which is of vital importance. For low powers, very fine ground glass will answer, but for higher powers, plain glass is best. In this case the image must be examined by means of a focussing eye-piece. The following excellent mode of performing the difficult operation of focussing is given by Mr. G. E. Davis, in "Practical Microscopy":—"Removing the ground glass slide, another is substituted of mahogany, but pierced with a series of seven holes, into each of which the ordinary A-eye-piece may be fixed. The thickness of the slide is such, that when the eye-piece is pushed in as far as it will go, the diaphragm lies in the same plane as the ground surface of the glass slide. To anyone accustomed to focus by the old method, the present system will be found a considerable improvement, it being easy under these conditions to obtain a sharp focus with an ordinary paraffin lamp when using the $\frac{1}{16}$ objective."

When the camera is extended only a short distance, the hand will be able to reach the coarse or fine adjustments of the microscope; but when drawn out to three feet or four feet, this will be impossible. It then becomes necessary to provide some method by which focussing can be easily and exactly performed while viewing the image on the screen, the camera being extended. Procure a hollow brass rod, $\frac{1}{2}$-inch in diameter, and the length of the base-board. Fix it to the side of the board by metal "eyes," so that the rod may revolve somewhat stiffly; if the camera be supported on trestles, the rod may be fixed under the base-board, which is more convenient. Make a grooved wooden wheel, two inches diameter, and fasten it to the rod, so that it will be opposite the fine adjustment of the microscope when the latter is placed horizontally, with the eye-piece end fitted to the camera-front. Make an endless band of narrow tape, of such a length that it will pass over the grooved wheel and the fine adjustment rather tightly. On turning the extremity of the rod, the fine adjustment will be moved with sufficient slowness and accuracy to allow of correct focussing with a lens of high power. The writer has long used an arrangement of this sort when photographing diatoms, and found it answer admirably.

The remaining photographic apparatus will be as follows:—A macintosh focussing-cloth; ebonite or glass dishes for developing and fixing negatives; glass measures, say, 2-oz., 4-oz., and 6-oz. capacity; basins for washing negatives; a porcelain dish for toning prints, and another for fixing them. Racks may be used for drying the negatives, but in winter, standing them up on a warm mantelpiece is as good a plan as any, unless the plates be made with very soft gelatine, when catastrophes may be expected in the shape of distortion of the image, or even melting of the gelatine.

ON THE BUSINESS MANAGEMENT OF PHOTOGRAPHY.

BY J. RYDER.*

The first necessary requirement—the foundation stone—is a thorough knowledge of every department of the work. An intelligent understanding of one's business is solid capital. The more of that element a man carries the greater is his strength. As we have no established system of apprenticeship, no regular course of study or practice of our young art, the learner is dependent upon a haphazard chance, his aptness at catching an idea, with a natural handiness in taking to new work, a taste for art, and even in a small way prove his good friends in grasping photography.

Then we could expect intelligent skill in our employés, and the public could feel assured they were being served in a proper manner.

Truly knowledge is power. It is recognized and respected by the learned and ignorant alike.

The coloured servant of a surgeon, explaining why his master

* Abstract of a communication read before the recent Cincinnati Convention.

charged twenty-five dollars for the performance of an operation in surgery which took but ten minutes to do, said he charged five dollars for the work, and twenty dollars for the know how.

To fit ourselves in the best way for the pursuit of our art, which is becoming yearly more an art, and more closely allied to science, buy books, subscribe for journals, magazines, and papers upon the subject; make your collection of photographic literature a special library, then make its acquaintance—the more intimate the better. In this way you become master of the requirements of your business, which is a rock-bottom foundation upon which you may build with all confidence and security.

Educate your assistants, teach them in the little points and in the greater ones, train them to your ways, give them your idea, and listen fairly to theirs—you may sometimes get the best end of the bargain in such exchange.

Next in value to superior quality in your productions is a safe and careful system in all the various departments, from writing an order for a sitting to delivering the finished picture into the hands of your customer. Such system should be observed. The soul of that system should be order and cleanliness.

There may be to some an affectionate interest in collections of antiquated relics of good old days, whose dust-coated and deep-stained fronts attest to long years of service, and certify to the claim of old stager. Many a well-meant operating room harbours in its corners and along its side-walls collections of crippled head-rests, rickety camera-stands, faded chairs with long-fringed upholstery, broken balustrades, old camera-boxes, &c., which are in no sense ornamental or advantageous.

It is a mistake to make a museum or a junk-shop of the operating room. Remove the old trash, give the scrub brush, the paint pot, and the whitewash tub a chance. If there be a worse smell than the atmosphere of a justice's office, it is the musty odour sometimes encountered in a slovenly-kept photograph gallery.

The man who satisfies his conscience that he cannot afford to expend money in thoroughly renovating as often as once a year, and refurnishing when needful, is a poor manager, and works against his own interest. Nothing commands more prompt respect than tidyness. A seeming of prosperity soon brings the reality; people like to patronize a prosperous man, and naturally avoid a poor unfortunate one; all which shows an air of thrift and systematic order should be practised and enforced.

Keep your show of specimen pictures fresh by frequent changes. Your customers will visit you oftener if you have new attractions. They will take pride in you and make your establishment one of the places to be visited by strangers and their visiting friends, among whom you will find good customers.

How to treat with customers. Here comes the place for exercise of judgment, for real generalship. To be polite, attentive, genial, and at the same time firm in adhering to safe rules for your own protection, is a difficult thing to do; yet it can be done. A correct start saves often misunderstandings, which are to be avoided by all means. It is a great mistake to have serious differences with your patrons; you must remember that great consideration is due to your sitter. Perhaps you sometimes sit yourself and find you are whimsical and exacting; you like to try again for some reason you can't quite explain. Perhaps when you go to your tailor you are not at once suited with the fit or hang of your coat; his telling you it is all right does not quite convince. Remember these things and be patient; you can make another sitting as quickly as you can make an argument. The sitting would perhaps convince them, your argument would not. Make your prices sufficiently high to justify the use of a number of plates, and a half hour's time if necessary. You can afford this occasionally. If the exactions of your sitter be too great, you are entitled to charge for extra service; state it pleasantly but firmly; sugar-coat your words where the subject is disagreeable.

It is the good-natured fellows who can't say no, and who, in their anxiety to please the dear ladies, get most imposed upon.

It is not an uncommon thing for a lady to have a dozen dresses and as many toilettes photographed before an order is given to finish. She gratifies her curiosity as to how they will take, and the more sittings she has, the more undecided she is which to order. Is the lady to blame? By no means; the man has helped her to impose upon him, and is helping to establish the custom of having his neighbours imposed upon also.

I believe it entirely fair to make for all sitters two good negatives, differing in position, that they may have a choice. If they desire more plates used, it is very proper they be required to pay extra for them; particularly should sitters be made to understand a change of dress or toilette means an extra charge for new sittings.

Never put off the securing of an order for another time; clinch it on the spot. It is never too late in the day to make a sitting—that is, to take a man's order for a sitting. Many a time have I written orders for sittings by gaslight, and given my client into the hands of the operator. With his money in the till he is sure to come for his proof in the morning, and well satisfied to try again on learning last night's effort was not entirely a success. Had I told him it was too late in the day, and advised his coming again, I should probably not have seen him more. With a desire for sitting while his mind was upon it he would probably try my next door neighbour, who, with more enterprise than I had shown, would gobble him.

The time to take money is before the sitter goes into the operating room; particularly should this apply to strangers and parties regarded doubtful. All photographers who fail in this important rule are practising an injustice upon themselves Prices for photographs have become greatly demoralized. Many of our prominent and good men have been led or driven—I might say "clubbed"—into this great wrong. I will venture to assert that four in every five who have fallen into low prices are ashamed of it, and would be glad to get back to more respectable figures and a more respectable standing among their fellows. Low prices are in every way degrading, the work is carelessly made, the standard of excellence is lowered—in fact, is lost; ambition sinks to indifference, enthusiasm is killed. The work becomes drudgery, devoid of interest or pleasure.

SHORT *VERSUS* LONG WASHING FOR PRINTS.

BY H. T. ANTHONY.

Extract from the Proceedings of the London and Provincial Photographic Association.—A short discussion took place as to the very divergent opinions that had recently been expressed with regard to a long washing of prints as an element of permanency.

Mr. Debenham believed that a long stay in the water was apt to cause fading—probably induced by the partial decomposition of the sizing of the paper. He had observed that prints left washing from Saturday to Monday commonly looked weaker than those which had only been in the water for a few hours.

The experience of the writer has been such as to confirm him in the belief that long washing after fixing is very injurious to the prints in every way. He was at one time in the habit of washing his prints all night in running water. Upon changing to a shorter washing (viz., three hours in running water), he found not only that the hypo was entirely eliminated, but that the brilliancy was much greater, and the prints when mounted had an entirely different appearance. Subsequent experiments led to the understanding of the cause of this trouble, and the writer would recommend the soaking of the prints, before toning, in a very weak solution of hydrochloric acid as a specific against his troubles as well as against blisters. In all cases, however, it is presupposed that the paper has been fumed with ammonia before printing.

Subjecting silver prints not fumed to the action of muriatic acid would only interfere very materially with the toning. In such cases muriatic acid should be applied after toning, and the acidity thoroughly neutralized before fixing.—*Anthony's Bulletin.*

PHOTOGRAPHING ON WOOD.

Prepare the surface of the block by rubbing thoroughly with pumice stone. Then whiten it with flake white, rubbing it on evenly with the ball of the hand or a fine brush. Let it dry thoroughly. Now coat the block with salted albumen according to the formula given below, flowing it like collodion. Use a glass stirring rod to distribute the albumen evenly on the block, being careful not to let the rod touch the block. When evenly coated, stand the block on edge on a piece of blotting-paper to drain and dry. Repeat this coating operation two or three times, letting the block dry thoroughly between each. (This part of the process may be conducted in full daylight.) Silver the block (when quite dry after last coating) in the dark room with plain nitrate of silver solution, forty grains to the ounce. This should be done in the same manner as the albumenizing, viz., by flowing and using glass stirring rod. When dry, fume with liq. ammonia ten minutes.

Now place the negative on the block, either in a printing-frame made for the purpose, or by clamping it with wooden clamps. Expose to light from five to thirty minutes according to density of negative and intensity of light. Print rather fully, as it bleaches a little in fixing. If you use clamps, scratch the negative in some unimportant place, so that you may watch the progress of the print. (The special frames made for this purpose permit of opening for examination as in ordinary printing on paper.) When sufficiently printed, it is ready for toning and fixing; toning, however, is entirely unnecessary. Wash the block, and fix in hypo about ten minutes. Wash again thoroughly, stand on edge to dry, and block is ready for engraving.

Albumen Solution.—White of an egg beaten to a froth; let settle; then pour liquid part into a bottle, add double the quantity of water, also fifteen grains chloride of sodium and two drops liq. ammonia.

Silver Solution.

Crystallized nitrate of silver ...	... 1 ounce
Water	... 12 ounces

Fixing Solution.

Hyposulphite of soda	... 1 ounce
Water	... 6 ounces

—*Photography.*

Correspondence.

PHOTO-MICROGRAPHY, AND THE POTASH DEVELOPER.

Sir,—No. 1,355 of the Photographic News contains, under the signature J. H. Jennings, articles on the above subjects.

The former process, although little practised by the professional photographer, is of extreme value to the scientist, and pictures thus produced must ultimately displace all hand-drawn representations of microscopic objects.

For this reason the article in question is of interest to all photographers, since many who are slack during the winter months might find plenty of employment if they were able to produce good photo-micrographs for histologists, botanists, and others to be exhibited with the lantern, &c. Mr. Jennings' observations on the subject are so good, generally, that I am delighted to be able to testify to the correctness of his remarks with reference to the necessity of a choice in the nature of mounts, and a knowledge both of microscopy and of photography. Mr. Jennings' reference to oblique lighting and dark ground illumination, as giving unsatisfactory results generally, is quite in accordance with my experience; nay, I will go further, and say that pictures produced by the oblique lighting are generally illusory in proportion as the obliquity of the light increases.

There is one point, however, at which I must take exception—and that is, the strong condemnation of the French lenses, properly known as "triplets." Now, apart from the question of price (and this *is* a consideration to many a beginner), there is no doubt that very many of the French triplet quarter-inch objectives, which are to be had retail for 9s., are far better, for general photo-micrographic work, than objectives by English makers at ten times the price. I say this fearlessly, having had over twenty years' practical experience in the subject.* The reason for this is not that the English lenses are *worse* for microscopic work, but because English lenses, as a rule, have such very short working distances, and such very limited *penetration.*

Per contra, these French triplets have a very fair working distance. For example, the ¼ o. g. gives really about a quarter of an inch space between the object and the lens itself, and this is of the highest importance in focussing on the screen. The magnifying power of these quarters is generally about 200 diameters with the A eye-piece, and the penetrative qualities are very great. Comparing this with a ¼ o. g. by a leading English maker, I find that this latter comes down to within $\frac{1}{16}$ inch of the covering glass, and that $\frac{1}{100}$ of a revolution of the fine adjustment throws the image perceptibly out of focus. Hence, while with the former I can get a really good photograph of a fly's proboscis, showing both the upper and the under surface of the spiral tubes, with the latter I cannot get a decent picture of this object at all, stop it down as I may; though this objective resolves *P. angulatum* quite easily, which the French o. b. will not do at all.

I say this not for the sake of finding fault with Mr. Jennings' article, but because I would not have the beginner checked in his attempts by supposing that an expensive objective is at all necessary, or even desirable. It is, however, necessary to notice that the French objectives are generally sent out with their own eye-pieces; and the corrections, both for chromatic and spherical aberration, are best corrected when they are used together.

A short paper on the best mode of using a cheap French microscope (such as can be bought retail for about 30s.) will be found in the Year-Book for 1876, page 54, *et seq.*

I now pass on to the article headed "The Potash Developer," and would ask Mr. Jennings:—1. Why he discarded the oxalate developer? 2. In what way did the ammonia affect his health?

This latter question I look upon as most important, as so many are using (in England, at least) the ammoniacal pyro developer.

Personally, I have never found any inconvenience from its use. I have, however, discarded the use of pyro developer, as I found it much less under control than the ferrous oxalate, and for my special purpose—viz., photo-micography—very much less suited, as the grain of the deposit is much coarser in the case of pyro than in that of the ferrous salt.

Collodion, however, is far superior to gelatine for the production of such pictures, the structure being much less visible.

S. Bottone.

* I enclose specimen photographs taken with a French triplet, and shall be glad to photograph any microscopic object, with the said lens, in Mr. Jennings' presence, if he will honour me with a call.

Proceedings of Societies.

Photographic Society of Great Britain.

A meeting was held in the Committee Room attached to the Gallery, 5a, Pall Mall East, on Tuesday evening last, Mr. W. England in the chair.

Mr. Cowan exhibited his arrangement for making an adjustable diaphragm to any required standard; but as this apparatus was shown some weeks previously at a meeting of the London and Provincial Association, we need do no more than refer to our report of that meeting (p. 510), where a drawing of the apparatus will be found.

Our readers will remember that the apertures in Mr. Cowan's shutter are rectangular, and when it was first exhibited, Mr. Debenham contended that it was very desirable they should be round; and at this meeting he again raised the question as to the effect of the rectangular shape.

Mr. Cowan, however, thought that better definition in the corners might result from the use of the square openings.

The conversation then drifted into flare spots and their cause, and—

Mr. Snow mentioned an instance in which a doublet that gave a decided flare spot had been found to work satisfactorily when a black patch was placed on the central portion of the front combination.

The Chairman pointed out that secondary images formed by minute apertures in the front of the camera were frequently mistaken for true flare images.

Mr. Debenham now suggested that it would be an excellent plan to fully elucidate the question as to whether the exposures usually given to gelatine plates (something approximating to the minimum) were in reality best; and he pointed out that on a

recent occasion the Baron de Kousoff had exhibited an exceptionally fine series of interiors, representing the Czar's Palace at Moscow, and it was stated that at first it was thought the plates had been extremely over-exposed; but by pre-treatment with a strong solution of bromide of potassium, unusually well graduated pictures had been obtained; indeed, pictures with much of what is known as a "wet plate character." These results led Mr. Debenham to ask whether a long exposure and restrained or slow development might not be desirable in many cases.

Mr. Ashman said that such a course would involve much expenditure of time in development.

Mr. F. Cobb said that in his hands a plate which had been very much over-exposed by accident gave a good result when restrained.

The Chairman remarked that dilution of the developer with water gave a considerable power of control in dealing with over-exposed plates.

Mr. Ashman now called attention to the value of isochromatic plates, and referred to the experiments he had described at the last meeting of the London and Provincial Association (see p. 542.) He had used an alcoholic extract of turmeric (according to the instructions of Dr. Lohse), and had obtained good results; the blue being subdued, the yellow and red prominent. Extract of marigold flowers also answers well.

Mr. Shew exhibited a folding bracket, to be placed between camera and stand, and so arranged as to enable the camera to be readily shifted from a horizontal to a vertical position.

London and Provincial Photographic Association.

A meeting of this Society was held on Thursday, the 21st inst., Mr. G. Waltenberg in the chair.

The Secretary read a communication received from Mr. F. H. Davis, editor of *Photography*, requesting detailed notes of the Society's proceedings; it was also mentioned that Mr. A. L. Henderson had demonstrated the cold emulsification process before the Chicago Society.

The question-box was then opened, and the following read and discussed:—"Where can silver, or electro-silver wire gauze, suitable for threading gelatine emulsion, be obtained?"

Mr. W. E. Debenham had tried several times to purchase some, but was unable to get it.

The Secretary remembered Mr. Henderson exhibiting some, sent by Prof. Stebbing from Paris.

Mr. A. Cowan recommended the querist to weave some on pins; there would be no difficulty in making a mesh from one-eighth to one-sixteenth of an inch.

Mr. J. Barker had experienced great difficulty in trying to weave a piece, and had given it up.

Mr. A. Haddon did not think weaving necessary; if a number of wires were secured on pins driven into pieces of wood crossing each other, it would be found to answer. He used a brass tube, closed at one end, and pierced with a number of holes; by means of a piston he could force the emulsion through without any difficulty. Several spoke in favour of mosquito netting, and some preferred the ordinary copper wire gauze.

Reference was then made to a recent communication recommending the employment of sulphite of soda in conjunction with mercurial intensification for gelatine plates.

Mr. Ashman said the printing quality obtained was excellent, and well worthy an extended trial. A similar effect could be obtained with ordinary washing soda if a little sulphurous acid were added.

Mr. A. Cowan had tried sulphite of soda after the mercury, and was well satisfied with the result. They required very little washing afterwards, which was a matter of some importance.

Mr. Debenham wished to know if these intensified negatives altered by exposure to light.

Mr. Ashman replied that he had exposed negatives so treated to sunlight for two days, without perceptible change.

In reference to Mr. Debenham's suggestion for testing transparencies from the same negative by various processes, examples by the following were promised:—Carbon, gelatino-bromide, gelatino-chloride, gelatino-citro-chloride, uranium (Col. Stuart Wortley's formula), wet collodion, and a modification of wet collodion. The negatives to be selected by the Curator, and three transparencies of varying depth to be produced by each member with his particular process.

Another question being found in the box, was read as follows:—"What is an optician's horse; has it a saddle: if so, when you get a lens in it how is it to be tested?"

Mr. Debenham said an optician's horse was a contrivance of wood, made of two upright boards notched, and sliding in grooves on a horizontal board; being V-shaped, whatever sized lens was dropped into it, always took a vertical plane.

A conversation then took place on the value of various colouring matters incorporated with bromide of silver, as suggested by Vogel and others, for obtaining photographs of colours in their true value.

Mr. Ashman had made some experiments with alcoholic extracts of marigold flowers, turmeric root, &c., and spoke favourably of the former. He preferred flooding the dry plate with the tincture without the addition of ammonia, and exposing in the moist state. This in no way interfered with the developer, but slightly slowed the plate. It was thought that a suitable addition of some such substance to an emulsion would prove valuable.

Talk in the Studio.

Instantaneous Views on the Hudson River.—Mr. F. C. Beach, of New York, has been successful in producing some remarkably fine views of river scenery on the Hudson with no other exposing apparatus than the ordinary lens cap. One picture, including a schooner off West Point, is of especial interest, as showing a very remarkable effect of light on the ripple of the water.

Heliograph Signalling between London and Portsmouth.—Arrangements have been made by Major Thrupp, Inspecter of Army Signalling, to place London and Wimbledom in communication with the Spithead forts by day and night for three days this week; the general idea on which the experiments are to be carried out being, that an enemy having landed on the South Coast and intercepted telegraphic communication between Portsmouth, London, and Aldershot, communication has to be maintained by signalling, by means of flags and the heliograph by day, and by night with the flashing-lamp. The stations will be Wimbledon to Epsom Downs, eight miles; Epsom Downs to Merrow Downs, near Guildford, thirteen miles; Merrow Downs to Hungry-hill, twelve miles; Hungry-hill to Hind Head, ten miles; Hind Head to Butser-hill, near Petersfield, fourteen miles; and Butser-hill to the Spithead Forts, fourteen miles. To enable practice to be made at longer distances, Merrow Down and Hind Head will be cut out for a time, so that the messages will go from Wimbledon to Epsom, Epsom to Hungry-hill, Hungry-hill to Butser-hill, and Butser-hill to the Spithead Forts, thus giving two distances of over twenty miles. During the experiments, the new Aldershot pattern lime-light will be tested.

Respiration of Leaves in the Dark. By G. Bonnier and L. Mangin (*Compt. Rend.*, 98, 1064—1067).—Comparative experiments respecting the oxygen absorbed and the carbonic anhydride evolved in the dark by the leaves of various species of plants show that the ratio between these two quantities is constant, whatever the temperature; and although the amount of carbonic anhydride evolved increases rapidly with the temperature, the amount of oxygen absorbed increases in exactly the same proportion. The ratio is approximately unity for certain species, *e.g.*, *Euonymus japonicus*, *Æsculus hippocastanum*, whilst for other species, *e.g.*, *Pinus pinaster*, it is considerably less than unity. The authors have previously shown that the ratio between the carbonic anhydride evolved and the oxygen absorbed is independent of the pressure of the oxygen, and of the proportion of carbonic anhydride in the surrounding atmosphere, and it is evident that these two processes of absorption and evolution are most intimately connected.—*Journal of the Chemical Society.*

Removal of Silver Stains from the Liebig Memorial Statue at Munich.—On November 6th, 1883, it was found that the marble statue of Liebig was covered with a number of black spots and stripes. Further examination showed these stains to consist of a mixture of silver and a little hydrated manganese dioxide. From this it is very probable that the liquid employed to deface the statue was a solution of silver nitrate and potassium permanganate. The method employed for the removal of the stains was founded on the conversion of the metals into sulphides, and subsequent solution of the sulphides by means of potassium cyanide. Each stain was covered with a paste made of yellow ammonium sulphide and porcelain clay. This was renewed after 24 hours, and after the lapse of another day carefully washed off,

and each stain then treated twice in succession with a paste of porcelain clay and concentrated solution of potassium cyanide. In most cases this was sufficient to remove all stain, but some few of the very deep stripes had to be treated in this way several times to effect complete removal. The success of the operation was so complete, that no sign of the stains can be seen now.—*Journal of the Chemical Society.*

Tempered Glass.—It is not very long since the discovery of M. Alfred de la Bastie filled all our newspapers with paragraphs, more or less ridiculous, about the properties of this glass. Some claimed it was malleable; others that it could not be broken. In fact, tempered glass was called upon to supersede all other materials. The excitement being over, tempered glass may now take its rank among valuable inventions, subject, however, to many defects in its present state. The process of tempering glass, as is well known, consists in heating a piece of glass, say a window pane, to such a degree as to approach malleability, but not hot enough to lose its shape; the glass in this state is instantly plunged into a bath composed of fatty and resinous matter, which is heated and maintained liquid at a temperature ranging from 300° to 600°, according to the quality of the glass. M. Siemens, of Dresden, says that the strength of glass is increased fifty times by being tempered. Tempered glass seems to be less dense than ordinary glass; it is harder, however, and is more difficult to cut by the diamond and tempered tools; it also possesses a much superior elasticity over the ordinary glass. Since tempered glass, however, cannot be cut with the diamond without flying to pieces, its use must necessarily be limited to definite sizes not requiring to be modified; this is quite a drawback to its use. It would seem, however, that some of the defects have already been overcome, for at the Paris Exposition quite a display of tempered goods was made by the *Société Anonyme du Verre Trempé*, of Paris. Among other things was quite a display of druggist's and chemical glassware, mortars, pestles, beakers, covered bowls, funnels; also a variety of plain and cut glass tumblers, goblets, decanters, globes, and chimneys; opal plates; a depolished bowl with cut facets; coloured glass, engraved, cut, &c. It is said that the making of articles varying in thickness is hazardous, as many of them are apt to fly to pieces either in the making or cutting.—*Scientific American.*

Photographic Club.—At the meeting on September 3rd, the subject for Discussion will be on "The Effect of Different Alkalines in the development of Gelatine Plates," with demonstration. Saturday afternoon outing at Hale End, leaving Liverpool Street at 2.2.

To Correspondents.

*** We cannot undertake to return rejected communications.

F. A. K.—1. You will find the rates for advertisements at the end of each number. 2. The pictures you send are very good, and if they represent your ordinary work, you should have no difficulty in getting such a situation as you desire.

Camera.—You can certainly register the designs, and so thoroughly protect any artistic merits they may possess; but your notion of securing to yourself the sole right of using a photograph in the way proposed would be untenable, even if the idea were original. It is a curious circumstance that we have many letters from persons who have a desire to protect the same "idea."

C. E. G.—Nothing is equal to the asphaltum mixture for backing plates, this method of working having been suggested in the Photographic News, July 2, 1880, and since almost universally adopted for astronomical work. The best way is to use ordinary Brunswick black, or the so-called Bates' black, and to scrape it off when the negative is finished, or, if preferred, before development. If you prepare a varnish yourself, dissolve bitumen in benzole, so as to obtain a varnish of a syrupy consistency. Fol's backing sheets (see Formulary) are very useful, but not so effectual as the bitumen varnish.

J. Holme.—The following formula is excellent, and you will find it easy to apply the mixture with a broad camel's hair brush, if the paper is very slightly damped and laid evenly on a slab of plate glass:—

Gum-arabic	2½ ounces
Water	12 ,,

dissolve, and add—

Bichromate of ammonia	1 ounce
Water	10 ounces

A highly sized and hard paper, like hank-post, is best.

E. H Rhodes.—Write to the gentleman named, care of Messrs. Ross and Co., Opticians, 112, New Bond Street.

Blundering Amateur.—The largest opening, or that when there is no stop, is $\frac{f}{8}$, or No. 4 according to the standard of the Photographic Society. A stop half-an-inch in diameter will be No. 16, one a quarter-of-inch in diameter will be No. 64, and one an eighth-of-an-inch will be No. 256.

J. and A. G. Hopkins.—The apparatus is very ingenious, and we are pleased to have had an opportunity of seeing it. It has been returned by Parcels' Post.

G. S.—Use will be made of your communication in the course of a few weeks. Thanks.

George Fuller.—The minute black specks are due, in our opinion, to careless straining of the emulsion; but we can trace a few spots which appear to arise from the settling of dust on the moist film.

G. Chiriet.—We will communicate with you by post.

E. Dickinson.—There are several firms who undertake such work, and the addresses can be gathered from our advertising columns.

Sulphurous.—Sulphurous acid is a gaseous body, and but slightly soluble in water. In the directions given, the aqueous solution is intended; and although this can be obtained from the operative chemists in London, it seems scarcely worth buying, as it is nearly all water, and soon deteriorates by keeping. Next week we will describe an easy way of preparing the aqueous solution.

Ardent Amateur.—Although your picture has merits, it has also faults; and as you request us to say the worst possible about it, we will proceed. In the first place, the definition is bad all over, this being, perhaps, due to fault in the lens, but more likely to careless focussing, or to the fact of the ground glass and the sensitive film not registering into the same plane (see page 470 of the present volume for a means of testing). Another serious fault is the fact that the building appears to be tumbling over, a result of the camera not being level. You might also be more careful as regards handling the plates, for finger-marks appear in several places.

Beginner.—Our "Practical Papers for Beginners" were commenced in our issue of July 18th, and all the numbers are in print at present.

N. B. B.—We have never worked with the lens you mention, but it is spoken well of in the country where it is manufactured; still we do not think it has any advantage over the instruments made in this country.

W. A. Schofield.—We have no means whatever of knowing whether the photograph is copyright, or, indeed, of finding out whose production it is, and it is therefore impossible for us to advise you as to whether you can safely reproduce it.

Paris.—Dilute albumen with ten times its bulk of water, taking care to beat or agitate the mixture very thoroughly, and use this as a substratum.

Inquirer.—Considering it is a subject upon which good authorities hold different opinions, you are unreasonable in asking us to "say definitely."

G. L. B.—An alcoholic solution of aurine—about fifty grains to the ounce.

The Photographic News Registry.

Employment Wanted.

General Assistant.—B. W., 52, Victoria-st., Wolverhampton.
Retoucher & Colourist.—Miss Harding, 45, Ceylon-place, Eastbourne.
Operator & Retoucher, &c.—Tax, *Photo. News* Office.
Operator, Printer, & Toner.—J. S., *Photo. News* Office.
Reception Room (Learner).—A B., 6, Duke-st., Manchester-sq., W.
Recep.-room, Spotting, &c.—Miss T., 126, The Grove, Stratford, Essex.
Recep.-room, Colourist, &c.—F. G., Florence House, P. of Wales-rd.
Assistant Operator.—G. N., 45, Ladbroke-grove, Notting Hill Gate.

Employment Offered.

Heliotype Printer for Australia.—Publishers, *Photo. News* Office.
Printer & Assistant.—A. B. C., 217, Brecknock-rd., Junction-rd., London.
Lady, to learn Spotting.—E. Smith, 3, Cheapside, E.C.
Reception-Room, Mounting, & Spotting.—W. J. Suter, Cheltenham.
Operator & Retoucher.—R. Cox, 37, White Ladies'-rd., Clifton.
Printer, at once.—S. Ayers, Regent-road, Great Yarmouth.

HELIO-CHROMIC TYPOGRAPHY BY THE METHOD OF IVES.

MR. IVES forwards us an interesting reproduction of a chromo-lithograph, printed in three colours from three blocks, and the result is such as to indicate that the method may ultimately become one of commercial importance.

The specimen is, it appears, the result of some early experiments, and is dated August, 1881. We can best describe the method of production by quoting Mr. Ives' own words. He says:—"This is printed from three plates, produced entirely by photography. One is printed with red ink, one with yellow, and the other with blue, each putting down the colour exactly where it belongs, and in almost exactly the correct proportion. If the lining of the plates had been finer, and the inks of purer and more transparent colour, the result would have been almost perfect. The negatives were made with bromide emulsion, treated with chlorophyl, eosine, and tannin, and exposed through coloured screens to distinguish the colours. The theory is not new, but the details of working are; and the result is remarkable, as being the first practical demonstration of the possibility of securing photo-mechanical reproductions in natural colour for the printing press."

We have seen chromo-typographic prints from photo-type blocks; the colours were not, as far as we know, mapped out, or distinguished by an automatic agency as in Mr. Ives' production; but a number of identical plates were made, one for each colour, and those parts which were not required to print were cut away by the tools of the engraver. Another method—which, in reality, amounts to the same thing—consists in making several identical negatives, and blocking or masking them out, so that each one shall correspond to one particular colour. A series of blocks is then prepared from the negatives so treated, and the colours are then printed in succession from the blocks.

Mr. Ives has, by his method of translating the Woodbury relief into a grain or stipple, adapted for the making of typographic blocks, made a decided step in advance, and his method bids fair to become of considerable commercial importance. Our supplement this week may be fairly taken as representing the point of perfection to which photo-block printing has arrived at present. May we hope that some future development of Mr. Ives' process may one day render it possible to produce equally good reproductions in colour?

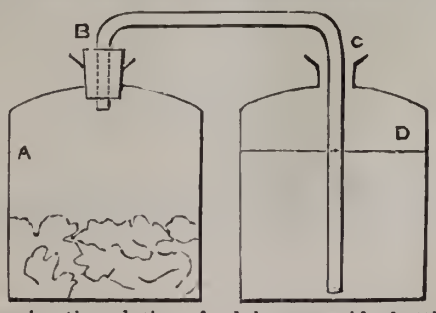
PREPARATION OF A SOLUTION OF SULPHUROUS ACID FOR PHOTOGRAPHIC PURPOSES.

ALTHOUGH an aqueous solution of sulphurous acid gas can be obtained under exceptional circumstances from the operative chemist, it is far more convenient to prepare it oneself just as it is required for use, for, once made, it is very liable to become weaker, not only on account of its tendency to absorb oxygen, and so become sulphuric acid, but also from the escape of the dissolved gas. Now that it has been recommended to use sulphurous acid in the composition of the developer, we have had several enquiries as to the best means of obtaining it, and we therefore propose now to explain how an aqueous solution of the gas may readily be prepared.

We may remind our readers that the pungent gas which is evolved when sulphur burns in the air is sulphurous acid (or rather, as it should be more systematically called, sulphurous anhydride). Still it is by no means convenient to prepare the gas by burning sulphur in the air; neither are the methods usually adopted in the laboratory those best adapted to the needs of the photographer in ordinary cases. It is, indeed, possible to purchase the pure acid condensed to a liquid in strong glass vessels like the so-called syphons used for aërated waters, Messrs. Boake, of Mile End, having introduced it into commerce in this form for the convenience of manufactures; but it is scarcely necessary to say a word as to the risk which would be incurred from inexperienced persons handling such vessels of the condensed gas.

When sulphuric acid—best diluted with twice its bulk of water—is made to react on the so-called sodium hyposulphite (or more correctly, thio-sulphate), sulphurous acid gas is evolved in abundance, and if the decomposition be effected in a suitable bottle provided with a cork and delivering tube, the gas may be easily passed into water, so as to produce a saturated solution.

Two bottles fitted up as represented below serve very well



for preparing the solution of sulphurous acid; bottles containing about one pint being a convenient size. To one of the bottles, A, is adapted a well-fitting cork, and a hole large enough to fit the glass tube, B C, is made by means of a rats-tail file; the hole being made rather too small in the first instance, and filed out to the exact size afterwards. The glass tube is cut off to the required length by making

a deep scratch with the edge of a three-cornered file, and straining it at the scratched part, when it will generally break off with a clean edge. Bending the tube is very easy, as if held in the upper part of an ordinary fish-tail gas burner, it will become sufficiently soft to yield to a very moderate pressure. Having fitted up the apparatus, about two ounces of hypo are placed in the bottle A, while the bottle B is about three-fourths filled with water—distilled water is perhaps to be preferred. Some sulphuric acid is now diluted with about twice its bulk of water, by first putting the water in an earthenware basin, and pouring in the acid as a steady stream, stirring meanwhile. If the basin is placed in the sink, no harm will be done should the heat produced by the dilution be sufficient to break it; and when cold, the diluted acid may be stored in a bottle.

The cork which serves to adapt the bent tube to the bottle, A is now just removed for an instant, the other end remaining in the water contained in D, and about two or three ounces of the dilute acid are poured in upon the hyposulphite, after which the cork is immediately replaced. Sulphurous acid is now evolved by the action of the acid on the hypo, and as the gas is generated it is led, as a series of bubbles, through the water in the second bottle. The upper part of the vessel—that is to say, the portion not occupied by the water—soon becomes filled by displacement with sulphurous acid gas, which is a little over twice as heavy as air; so in order to expedite the complete saturation of the water, it is convenient to remove the bottle A, with its tube, from the bottle D, and after having closed this latter by its cork or stopper, to agitate it thoroughly. As the sulphurous acid gas accumulated in the upper space dissolves, a partial vacuum is created, and when the stopper is eased an inrush of air may be noted. When, after passing fresh gas through the liquid for some minutes, no further inrush of air is noted on easing the stopper after closing the bottle and agitating as above, it may be concluded that the water is completely saturated with sulphurous acid. It is scarcely necessary to say that fresh additions of the diluted sulphuric acid may be made to the hyposulphite in the bottle A in order to obtain a fresh supply of gas, until the whole of the hyposulphite is decomposed; after which one must of course start with a fresh charge of materials.

The solution of sulphurous acid, if preserved at all, ought to be kept in small bottles, completely filled and perfectly closed; but as it is very easy to saturate a considerable quantity of water with sulphurous acid gas in a short time, there is but little inducement to use a solution which may possibly have become weakened by keeping.

Care should be taken not to add so much sulphuric acid at a time to the hyposulphite as to occasion any risk of the contents of the vessel A partially frothing over by the violence of the effervescence.

In preparing the sulphurous acid solution, it is well to locate the apparatus on the ouside ledge of a window, or in some other situation where no inconvenience will result from the escape of the excess of sulphurous gas as it bubbles through the water.

THE NEW STUDIO AT THE NATIONAL GALLERY.

THE above phototype engraving represents the new galvanized iron building with which the frontage of the National Gallery has recently been disfigured; but so vehement has been the outcry against such a shed being erected in Trafalgar Square, that the new structure will shortly be removed; the authorities making the somewhat shallow profession that they only intended to photograph a very few pictures. The negative—a quarter-plate—was taken by Mr. G. F. Williams, and the block was made by etching one of Messrs. Sprague and Co's. *ink photo.* transfers into relief by the chemigraphic method.

ON EXPOSURES IN THE STUDIO.

The importance attached to the correct timing of an exposure in the camera is such that its influence can hardly be over-estimated, and anything which tends to secure that desirable end must necessarily prove advantageous. What is really needed is a reliable instrument which shall be capable of registering, under any conditions of light, the actinic value of the particular light employed, irrespective of its illuminating powers. It may be said that the photographic plate is in itself as good a photometer as could be desired. In a measure, this is true; but if it were admitted to be practicable to expose and develop a test negative, a serious difficulty might be presented during the period which must elapse between exposing the test negative and the exposure proper. The difficulty to which we allude is to be found in the great changeability or alteration in the photographic power of daylight, the illuminating agent we are now dealing with. The fact is well known to those on whom devolves the duty of making exposures, and it is only by long practice interspersed with many failures, that the eye becomes so trained as to enable exposures of almost any duration to be made with a fairly close approximation to correctness. Probably the day is not distant when we shall have a reliable instrument which shall quickly indicate the actinic value of the light employed; in the meantime we must be content with such adjuncts as can be found available.

For practical reasons it has been found advantageous to employ some kind of mechanism wherewith to bring about the exposure, and we have seen many devices of simple and also complicated construction to accomplish this object; but into the respective merits of each we do not now propose to enter, as many of them have already been fully described in these pages. One thing is quite certain, and that is, any shutter which is intended to be worked on the front of a studio camera—that is, in front of the objective like an ordinary cap—must be looked upon as a mistake, and for this reason: it permits the sitter to watch the whole proceedings with more or less discomfort, and when the actual exposure takes place, a certain degree of nervous excitedness is often produced which is in every way detrimental. The resulting picture suffers, and the photograper, whose aim should be to make his clients as comfortable as they would be under ordinary conditions, has not scored a success.

We noticed a convenient form of shutter recently, which appeared to us to entirely overcome any inconvenience on this score. We were informed by the photographer that it had been in use some few years, several thousand portrait negatives in wet collodion having been made with it, the sitters being unaware of the precise moment when exposure really took place. The value of such an arrangement must have been considerable, and is of a still greater importance now that gelatine plates have entirely superseded wet collodion, because, as everyone knows perfectly well, slight movements during an exposure on a slow plate do not register at all in many cases, whereas the same degree of motion recorded on a rapid plate is very apparent; therefore a shutter which is certain in its action, noiseless, and capable of performing its work in one-quarter of a second, or any longer period, is a suitable adjuct in portraiture. Much could be said on this part of the subject if space permitted, but sufficient has been indicated for the purposes of this article, and we may rest assured that business men will utilize any means tending to give pleasure to their patrons, and commercial prosperity for themselves.

The shutter just mentioned was probably one of the earliest, if not the earliest, made on the principle of two folding doors opening from and closing at the centre of the objective. It takes up little more room inside the camera than the diameter of the objective, and can be worked by a pinion or electricity.

It is as important to become acquainted with the speed of the plates to be used, as it is to have a convenient arrangement for giving the requsite exposure; and lack of such information, or the assiduous application of it, often mars what might otherwise have been a good result. Those who make their own plates have no doubt experienced a difficulty in obtaining successive batches of uniform speed, and others who use various samples of commercial plates are not always intelligently informed: such a designation as thirty, sixty, or a hundred times as rapid as wet collodion is not by any means a useful guide. There are photographers to-day having little more than a vague notion of the capabilities of a wet plate under favourable conditions, and to whom the term is at least confusing. It follows, therefore, that a ready means of ascertaining relative comparisons between plates from different batches and various sources becomes a matter of necessity. Such a means we have in the sensitometer of Mr. Leon Warnerke, which we will describe for the benefit of our younger readers.

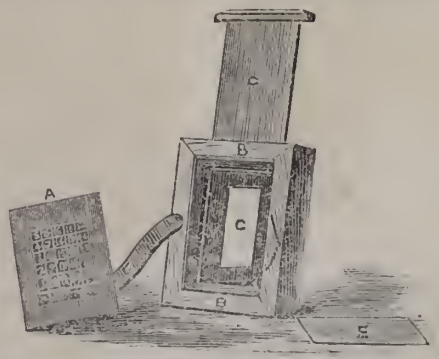
This instrument (a sketch of which is shown below) is

1	2	3	4	5
10	9	8	7	6
11	12	13	14	15
20	19	18	17	16
21	22	23	24	25

practically a series of negatives having densities varying from clear glass to the greatest opacity likely to be met with under ordinary circumstances. It is a Woodburytype print produced from several thicknesses of a semi-opaque substance, such as tissue paper or coloured gelatine of a square pattern; the number of thicknesses being progressive, a scale is thus obtained varying in opacity from one to twenty-five degrees. In the diagram, however, the gradations of tint are not shown, but only the number; still the following sketch will give an idea of the grada-

tions of the scale. Upon each square is printed in opaque pigment a number corresponding to the number of squares employed. It will be seen that plates exposed under this scale will be acted upon inversely as the number progresses; number twenty-five being the most obstructive, and therefore a reading indicative of very high sensitiveness.

In our sketch, A is the sensitometer, suitably mounted;



B the dark slide grooved; C is a phosphorescent tablet, the luminous side, when in use, being next, but not touching the sensitometer by a distance equal to about three-eighths of an inch; D is the shutter of the dark slide, which is withdrawn as in making an exposure; E is an ordinary back to exclude light from the plate from any outside

sources; F, spring, to ensure contact. The shutter being closed, the sensitometer is placed in the groove prepared for its reception (numbers upwards); the plate to be tested is placed, in contact with these numbers, in the dark-room; E is replaced, and pressure exerted by means of the spring F. The phosphorescent tablet, C, which, after being made luminous, as we shall presently describe, is placed in its receptacle, when all is ready for testing the plate.

To render the phosphorescent tablet luminous, one inch of magnesium ribbon is burnt as close as possible to the surface; the tablet is then placed in its position, and at the expiration of one minute the shutter is withdrawn, and an exposure of thirty seconds given. The plate is then developed, when certain numbers of a straw colour on a darkened ground will be seen; the highest number seen is said to be the speed of the plate. Especial care should be exercised in excluding any unsafe light from the plate previous to testing, as a non-observance of this precaution would render the test unsatisfactory.

The question of what is a correctly exposed negative has lately been brought forward as matter for consideration by the Photographic Society of Great Britain. Should it receive the attention it deserves, some tangible good will come of it; at present, opinions are somewhat divergent, which makes it invidious for us to lay down any strict lines for observance. Briefly, we may say that a correct exposure is judged by the relative degree of density existing in the opaque parts of a negative, compared with detail in the shadows. In the days of wet collodion the difficulty was to obtain sufficient detail with a reasonable exposure; but with gelatine plates it is quite the reverse. Failure is far more frequent from too much than too little exposure, and this is more often attributable to the want of uniformity in the speed of the plates than insufficient knowledge of the quality of the light. Still, it seldom happens that commercial plates from the same packet vary; thinly-coated plates are sometimes met with, which give halation and a flat-looking negative, devoid of contrast. When plates of this kind are met with, they can be made serviceable for transparencies by backing them up, previous to exposure, with a piece of carbon tissue of the same dimensions as the plate; contact is best insured by moistening the tissue with water, to which a fourth part of glycerine has been added.

It is convenient to have some kind of test for the thickness and evenness of the coating of emulsion. A tablet of printed matter answers as well as anything for the purpose, and if it be placed near the dark-room window or lamp, all plates may be examined before putting them in the dark slide. Should the printing be distinctly visible, then the plate should be put aside for use with the backing of carbon tissue.

By-the-Bye.

PHOTOGRAPHY IN SPITE OF ONESELF.

To compress Saturday morning's work into Friday is the order of things when one intends to take an over-Sunday run to a port on the other side of the Channel; while if Monday can be added to the holiday by making a little extra effort on the Tuesday and Wednesday, so much the better.

As the train which takes one from Liverpool Street for Rotterdam and Antwerp does not leave till eight o'clock, there is a good chance of doing a full day's work, with, perhaps, an extra hour or two on account of Saturday. Luggage one does not want unless a hand-bag containing a piece of soap, a tooth brush, and "Baedeker" can be called luggage. Photographic apparatus? No, indeed, not even the most portable of portable cameras, nor anything relating directly or indirectly to the dry plate; for is it not a flight from the memory of the studio and the dark room, and an attempt to forget their existence until next week's labour shall commence?

But here is Parkeston, after a two hours' ride in the train; and hesitating for a moment whether to turn off to the right in response to the invitation "this way for Rotterdam," or to go to the left on board the Antwerp boat, the latter is decided on; the fact of tickets being available to or from either place having caused a moment of hesitation. It is not long after ten when the steamer glides out of Harwich Harbour, and as it is by no means satisfactory to do without a night's rest, it is desirable to turn in and sleep until the grey of the morning stretches out from over the dimly outlined Dutch coast, as if to give a matitudinal greeting to the ship. Gradually the little red-bricked town of Flushing assumes shape in the mist, the tower giving one the idea of a pile of variously shaped beads threaded on a wire; while the old two-sailed windmill, mounted on its ancient and massive cone of masonry, seems to be labouring hard to drive away the last traces of haze and mist with its gigantic arms.

"How castaway it looks, and how out of the world!" remarks a passenger, as the steamer comes to a sudden halt, while a gleam of early morning sunshine makes the little town figure out as brightly and clearly as a lantern picture just freed from the obscuring influence of the dissolver.

Yon small boat, painted on the bows with the legend "*Pilotage d'Anvers*," has just glided away from our side, and we are now once more on the move, but this time under the charge of the Belgian pilot, who, at present, is responsible for our safety through the sixty miles or so we have to steam along the Scheldt.

The lazy and broad stream, with its dim mud-coloured banks, gradually narrows, and the banks become green, while now and then a little village of chequered red and white looks out from a break in a row of toy-like trees; but now the spire of Antwerp Cathedral, with its half-finished companion, is dimly seen.

Now it is on our right, now to the left, as each bend in the river turns our direction; but when round the final bend by the old Northern Citadel, we see the extent of the magnificent quays along the whole frontage of the city, and can notice how much this frontage has extended during the last ten years or so. Some minutes later we are on land, and trotting along nimbly in the morning sunshine towards the centre of the city, uncertain whether to stay in Antwerp, or to go to some inland town by rail; for he who neither carries photographic apparatus nor other luggage may leave such questions to be determined by the impulses of the moment. But here, at any rate, is an establishment which it is desirable to visit, as it holds out a promise of a good breakfast. A touch on the shoulder at this moment, followed by a "Hollo there!" and a turn, serves to reveal the portly form of Bridgeman, who carries a tripod stand and leather case. "You here!" he exclaims; "I am so glad, come along, and we will expose a plate on the new Scheldt Monument. How fortunate you have no luggage."

"I always like to get a few houses in with the picture of a monument," said Bridgeman, "and it will do very well if taken a little way from the corner of the square, and you may as well go and tell that policeman not to stare straight into the lens." "Ah!" he remarked, as he unfastened the camera, after having exposed, "you see that I run no risk of losing the screw, for it is fixed to the top of the stand by a few links of chain; but the last ring fits in a groove on the head, so that the screw turns easily."

Excellent and genial a fellow as Bridgeman may be under ordinary circumstances, he and his photographic apparatus are not exactly to the taste of one who is seeking to forget everything photographic for two or three days, and Bridgeman is intensely photographic just now; still, considering that he has a stock of some five or six dozen plates, which he will expose before Monday evening, it seems useless to

think of seeing the end of them and getting Bridgeman to drop the photographer and become an ordinary mortal; so after some three or four plates have been exposed, we explain that our inclinations lead us to go on to Brussels, and, perhaps, take a run to the old ruined Abbey of Villiers-la-Ville. "How very fortunate!" exclaimed our companion; "I had just concluded to go there myself, only there are a few pictures I must take at the Plantin Museum; so Brussels this evening, and Villiers in the morning!"

The fine old building which formed the printing establishment of the Plantin family does not date from the time the business was first established in 1555, but was erected by the first Plantin about twenty-five years after this time. For nearly two centuries this printing house was one of the most important in Europe.

"Screw your lens in very tight, and see that every part of the apparatus is specially rigid, when your cap may be taken off and put on several times during the exposure of one plate," said Bridgeman, as he set up his camera for a ten minutes' exposure in the dark oak-timbered gallery where many of the original designs supplied to the Plantin Printing House by Rubens are displayed in cases, and portraits by the same master hang round the walls. Many interruptions of the exposure were necessary, as whenever anyone carrying a guide-book halted in his course, it became necessary to cap the lens, as otherwise the white paper would have been tolerably certain to make an impression on the plate.

It was in the old Printing Office, or composing and press room, that Bridgeman spent most time, and, it may be added, taxed our patience to the utmost. We have here the main apartment of the establishment, one side being occupied by a row of frames and type cases, and the other by some eight of the old wooden presses, with their accompaniments of inking balls and slabs. If it had not been for a prominently-displayed notice in French and Flemish, cautioning the public not to touch anything, one might have thought that the workmen of two hundred years ago had but just left for their dinner, and would return in half-an-hour: partly set type being on the galleys and in composing sticks; while copy was on the frame, and proof-sheets on the reader's desk. "That notice must come down," said Bridgeman decidedly, pointing to the prominent caution not to touch; "it would utterly ruin everything; and do be good enough to see to it while I set the camera." This was not an easy matter, as the attendant, when first consulted, was quite sure that nothing could be done, especially as he had no screw-driver; but a little quiet conversation, during which a slight metallic jingle might have been distinguished by an attentive listener, served to convince him that there might be a possibility—in fact, that it was just possible to remove the obnoxious notice.

The extensive collection of engraved blocks and plates, together with impressions from them, are in great part displayed in vertical cases, so as to render it possible to take effective photographs of the rooms containing them.

The type foundry, with its extensive collections of original steel punches, copper matrixes, and body moulds, is arranged as if ready for work, and an inspection gives an excellent idea of the old method of casting types. The view taken of the principal work bench, with a range of melting furnaces towards the left, should make an effective picture. The magnificent library, containing, in all probability, the finest existing collection of the works of the celebrated printers of the sixteenth, seventeenth, and eighteenth centuries, was not photographed; several very learned looking personages being apparently engaged in a profound study—accompanied with occasional earnest discussion—of some of the venerable tomes; indeed, the general public are not admitted to more than a narrow strip of the great library apartment, this strip having been fenced off by wirework trellis. No one going to Antwerp should fail to visit the extensive printing house of the Plantin family, long closed, still preserved from the hands of auctioneer and salesman by a strange combination of circumstances quite romantic, but now State property, and constituted a public museum.

Bridgeman, in response to our suggestion that it was now quite time to direct our steps Brusselswards, talked of going to his hotel to change plates, and after he had recharged his slides, he must go and secure a quaint old house here, or an image of a "Virgin and Child" in a bye-street there, or try a view of the Cathedral from the far corner of the old market-place. It is only fair to admit that Bridgeman's arrangement for changing plates is ingenious, very portable, and convenient; when closed, it is somewhat like an umbrella of about half the usual length, but on unrolling the black covering, some splints or laths of wood are found, which make up a light frame, and on this is stretched the black cover, two arm-holes provided with elastic wristbands being provided. "No," said Bridgeman, "it is not safe for changing plates in full sunshine, simply because there is no necessity whatever to make it so; even now I shall pull down the blinds and cover it with my focussing-cloth."

At last we were in the train for Brussels; but Bridgeman would look at everything from a photographic point of view; and a remark of ours about Malines, as we halted there, led to our being told that the children there are remarkably troublesome to the photographer, and we learned how Bridgeman had sold them. His camera was adjusted, but he could not expose because of the troop surrounding him, so he turned his back to it, put his hands behind him in an attitude of unconcern, and asked his companion to take the leather case to a little distance, and do nothing with such an air as would convey the idea of important work. Of course, the little ones ran off to see what was being done, and the exposure was made. On another occasion, he adjusted his camera, marked the place occupied by each leg of the tripod, and retired into a neighbouring beer-house, and it was only the work of a few seconds to replace the camera and to expose when the young folks had distributed. The little station of Vieux-Dieu reminded him of a plate he had accidentally over-exposed there; but he managed to bring it round by diluting the developer very much; in fact, Bridgeman says that few persons realise the extent to which development can be controlled by simply adding water to the normal developer. When a plate shows signs of very much over-exposure, he simply pours the developer back in the glass, and fills up the dish with water, a few drops of the original developer being added as required.

Brussels at last; but the rain is falling in torrents, and of course the photographic apparatus must be left behind at the station, or the leather case will be soaked through and through; and besides, what is the use of carrying a camera about in the rain? Bridgeman, however, says nothing, but takes out his focussing-cloth—which, by-the-bye, is of mackintosh cloth with tapes fastened to it—folds this up so as to make a trough like a bread-tin, inverts it over the leather case, and ties with the tapes; a stout strap round the whole now serving to hold the shoulder straps in position. No photographing this evening, but a visit to the Eden instead; and even here Bridgeman will talk photography; he talks of exposures by the electric light, and it seems as if he muttered something about "no water required in the developer."

Next morning it rains; but despite of this, Bridgeman will take the camera; he can depend on his waterproof focussing-cloth to protect the camera, and he will be content to wait for a gleam of sunshine to make the exposure; and he does wait so patiently for his exposures that it is late in the afternoon before we leave the ruins of the grand old Cistercian Abbey—perhaps the finest of its kind in Europe—and take the footpath leading over a wooded hill to Bousval, so that we may return to Brussels by another line of railway. The rain is so heavy as to take away the enjoyment of what would otherwise be one of the most

delightful country walks in Belgium; for although one misses the ruggedness of the Ardennes districts, there is instead, the soft leafiness one is accustomed to associate with Devonshire; the bright grassy banks, lanes shaded over with light, graceful boughs, which meet at about the level of one's head; and glistening rivulets. At Bousval station the camera is brought out again; but Bridgeman has planted it right in the midst of the shunting ground, and as he sees the station-master rapidly approaching, he leaves the camera, and politely invites that functionary to stand near his office, to "give grace to the picture he is about to make." This stroke of diplomacy having converted a probable enemy into a friend, the exposure is made; but other "friends" appear and want to be immortalised, so a second exposure is made—this time with the shutter not drawn! But here is the train. Nivelles is reached—a walk from the northern station towards the eastern station, with a flying shot at the Romanesque Church on the way—another trespass on railway property, and ignominious imprisonment in a waiting room despite the blandishments of Bridgeman—Braine l'alleud, with a glance at the Waterloo Lion when the train has passed the station.—Brussels.

There has been a grand liberal demonstration (Aug. 31), and the people are as with one voice—and that is neither remarkably steady nor exceptionally tuneful—singing a dirge on an unpopular minister. The little hand-bills which are being handed round are adorned with the coffin of the unpopular Vanderpeercoom, the words and music of the dirge being printed underneath; but the little bands of soldiers who parade the streets with fixed bayonets look good-temperedly on. Curiously enough, no police are to be seen—perhaps they are in plain clothes: at anyrate, it seemed to us that the individual who started a *vive le roi* has worn a uniform and a sword. He, however, has struck a resonant chord, for the people cease singing "*O! monstre terrible*," and cheer for their king.

It is not easy to cross the city so as to reach the station from which the train for Antwerp leaves, nor is it easy either to get in the train, or to get out at Antwerp; but when out, we find ourselves to be part of a procession, marching in slow time and chanting, "*Oh! monstre terrible.*" Bridgeman, by virtue of his commanding figure and his tripod—carried like a wand of office—is, with common consent, allowed to take a prominent position.

Next morning, Bridgeman discovers that he has no more plates, so the camera is left at home—for the inn of the cosmopolitan is always his home—and we have a jovial day in the commercial capital of Belgium before boarding the steamer at 4.30 p.m. Liverpool Street Station is reached at seven the next morning, and the day's work is commenced with new spirits and energy.

Press of matter compels us to allow our "Practical Paper" (No. 6.—Taking a Portrait) to stand over until next week.

ISOCHROMATIC PLATES BY MEANS OF CHLOROPHYL.

BY FRED. E. IVES.

My method of preparing chlorophyl solution and using it for increasing the colour-sensitiveness of silver bromide plates, was published nearly five years ago in the *Philadelphia Photographer*, December, 1879; but in answer to your request, I furnish the following particulars for publication in the News.

Take fresh blue-myrtle leaves, cut them up into very small bits, and place in a florence flask. Cover with alcohol, and warm over a spirit lamp for about twenty minutes, stirring constantly, and taking care not to heat too hot, which might destroy some of the chlorophyl. The solution will be of a deep rich green colour, and will keep some weeks if tightly corked, and not exposed to light. It may also be prepared from the dried leaves by first soaking them in distilled water, but is not so good as that from the fresh leaves, and in either case a fresh solution will give the best results. I have been told that the addition of a little powdered zinc to the solution will cause it to retain its strength indefinitely, but I have not yet tried the experiment.

I believe that any good collodio-bromide emulsion will answer, but I have always used one made with a slight excess of silver, which was afterwards converted into chloride.

The plates were prepared by first flowing with the emulsion, then, as soon as it is set, covering with the chlorophyl solution for one minute. They are then washed thoroughly with pure water, and exposed in the camera while still wet, using a coloured screen in front of the lens to filter out light which would otherwise produce too much effect. As long exposures are necessary, it is often an advantage to flow the plate with glycerine, and the object to be photographed should be placed in direct sunlight when practicable.

The best screen for filtering the light is a small plate-glass tank containing a solution of bichromate of potash. If the tank is three-eighths inch between the glass, the bichromate solution may be of the strength of one grain of bichromate of potash to two ounces of water. If stronger, blues will photograph too dark, and yellow and red too light; if weaker, blues will be too light, and yellow and red too dark. If a solution of aniline red is used as a screen, the red and yellow or a highly coloured chromo-lithograph can be made to photograph almost like white, while the blue comes out black. With a green screen of a certain shade and intensity, I have made bright chromo-lithographs photograph as if almost all of the colour had been bleached out of it.

Something depends also upon the developer, some developers bringing out the colour sensitiveness more than others, or in different proportions; but so far as my experience goes, this difference is not nearly so marked with chlorophyl as with eosine plates.

It has been stated that isochromatic plates do not give a sensibly different effect from others in photographing landscapes, but this is true only when no coloured screen is employed. Some of the most striking results I have obtained were landscape photographs made with the chlorophyl plates. The effect is not only different, but so very different that everyone who sees them is astonished. I will send you prints from three landscape negatives which were made *simultaneously*—one with chlorophyl and a red screen, one with eosine and a yellow screen, and one with plain emulsion and no screen. Had I used the chlorophyl plate with a yellow screen, it would have given nearly the same result as the eosine, except that the reds would have developed stronger; but had I used the eosine plate with the red screen, it would have given no image whatever.

I have experimented with the addition of both chlorophyl and eosine to the emulsion, but have not been able to secure one-half as good results in that way as by applying them in the manner which I have described.

PS.—In the photographs which I send, note (1) the difference in foreground as compared with distance, (2) the difference in blue sky as compared with house, and (3) the difference in haystacks as compared with barns. Both of the isochromatic plates bring out a great deal more detail in the green foliage.

INCANDESCENT LAMPS AND ACCUMULATORS IN PHOTO-MICROGRAPHY.

BY FREDERICK W. MERCER, M.D., F.R.M.S.

It is but a short time since small incandescent lamps were applied to the microscope, and during this somewhat brief period the matter has received attention at the hands of a few investigators. Dr. Van Heurck, of Antwerp, was probably the first to employ incandescent lamps in this way, but they were of large size and required elaborate battery power. Mr. C. H.

Stearn, F.R.M.S., of London, originated small lamps especially adapted for this purpose, and which required a low battery power for their service. Dr. Theo. Stein, of Germany, has, in an article just published, described lamps and apparatus similar to those by Mr. Stearn, in the Journal of the Royal Microscopical Society, 1883.

Next to sunlight, the electric light is the best illuminator for photo-micrography; this assertion can be made upon the mere character of the light; but when we consider that it can be utilized day or night, in cloudy or clear weather, it gives advantages placing it nearly upon a par with sunlight itself. There are of course certain difficulties in the way of its general use, chiefly trouble and expense. Those, however, having some time and mechanical aptitude, may construct a good part of the necessary apparatus for the production of the light.

The lamps are not impossible of construction by an amateur, but as they may now be obtained at reasonable cost, it would not be well to attempt their manufacture from considerations of economy.

In the figures 2 and 3 are shown lamps made by Mawson and Swan, at Newcastle-on-Tyne. The drawing has been made nearly to exact size. The stems are of vulcanite, and contact for current is made by two slips of brass fastened to two sides of the

Fig. 1

Fig. 2.

Fig. 3.

stem; these metal strips make contact with the poles of the battery when the lamp has been pressed into its socket, which is simple in form and easily applied as an adapter to the sub-stage, or in place of the mirror, at the extremity of the mirror-bar. Fig. 3 is intended for use in the sub-stage, and may be carried close up, almost to contact, with the under surface of the object-slide. This lamp is of about $\frac{3}{4}$-candle power. The lamp at fig. 2, pressed to full incandescence, gives a light equal to nearly two candles. These lamps have a low resistance, and can be fully lighted by three large Bunsen cells. Four Leclanche cells fail to give as good results. The lamp shown in fig. 1 was made by the Edison Company, is a little larger than the Swan, has a higher resistance, and therefore requires more battery power; it is, however, very satisfactory in work, and gives a little more light than that indicated at fig. 2. The best means of illuminating these lamps is by a small and very portable accumulator made on the Faure principle. It consists of a

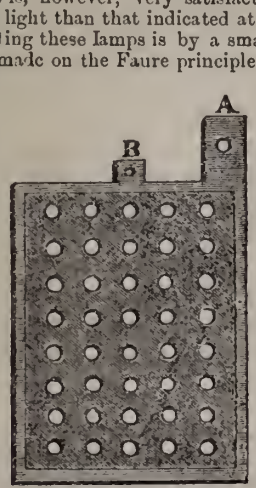


Fig. 4.

$\frac{3}{4}$-inch thick wooden box 12 inches long, 6 inches wide, and 7 inches deep, outside measure. A partition divides it in the centre, forming two cells. The joints of the box should be halved into each other, and well smeared with Canada balsam in benzol, before closing. When completed, the interior of the cells should receive four or five coats of thick asphaltum varnish, each coat being allowed to dry before applying another.

The lead plates for use in these cells should be 6 by 4½ inches, of the form shown in fig. 4, which has proved, after trying a variety of patterns, the best. The plate is made by casting in a mould, a pattern of wood having been made for that purpose. The edges and ears, A B, should be about $\frac{3}{16}$ inch thick; the surface of the plate, excepting a quarter-inch of the edge all around, should be less than $\frac{1}{8}$-inch thick; this surface is pierced by holes $\frac{5}{16}$-inch in diameter, and about the same distance apart. The ear or tag A is for connecting the plates electrically by means of a metal rod passed through the hole, a boss of lead $\frac{3}{8}$-inch, formed of small lead plate, inserted between to keep each plate apart, the whole, say eight negative or positive plates, being thus secured by means of a nut at the end of the rod. The smaller ear, B, is to secure the plate to the battery cover, through which it passes, the weight being carried by a small wooden peg passed through the hole.

The sixteen plates, eight for each cell, four —, four +, are in this way secured to the cover $\frac{3}{8}$-inch apart, and held half-an-inch clear of the bottom of the cell, to prevent short circuit through deposits formed. Plates that rest upon any portion of the bottom of the cell, or which may be connected up by means of copper wire, no matter how well protected, must prove unsatisfactory, and at last fail. The plate and its connection should be in one piece, as shown in the ear A. The holes in the lead plates, excepting those in the ears, are to be filled with a paste made of the best red lead and dilute sulphuric acid, two to five. As soon as this paste has set in the holes, the battery is ready for forming, which is done by passing reversed currents from a dynamo machine for a few days, reversing the current two or three times each day. The solution for immersing the plates should be about one of sulphuric acid to ten or twelve of water. This storage battery, once formed, can be charged or reinforced from four large Bunsen cells. Such an accumulator has positive advantages over any form of primary battery. It is small and portable, can be carried by one hand, may be taken from point to point by any conveyance. The escape of formed gas is slight and non-irritating; no offensive odours; its current is absolutely steady. The capacity for work may be stated to be a good white light from the larger lamp for a period of about three consecutive hours. This does not exhaust the charge, for the lamp can be kept at a red heat for four hours more.

In charging the battery it should not be pushed to its utmost capacity; when the plates become heated and much gas is evolved, the charge should be more slowly passed in, and the battery tested by one of the lamps for charge. In charging more than one cell they should be arranged in series and in arc, on the same principle as ordinary primary cells.

The battery should be kept clean by occasionally washing the plates under a gentle stream from the tap, the cells being thoroughly washed out. If out of use for a week or longer, the cells should be emptied and the parts washed.

In photo-micrography the lamp may be used direct—that is, without the intervention of condensers of any kind. Indeed, this may be considered a rule for all powers below $\frac{1}{6}$-inch. When used direct, the lamp should be carried pretty close to the object, a diaphragm being necessary to cut off all extraneous light. Unless the lamp has been so constructed as to bring the arch of the carbon loop at about the centre of convexity of the glass enclosing it, its direct use will not prove satisfactory; or the globe of the lamp may be flattened on two sides and aberration thus avoided. When using higher powers, the interposition of achromatic condensers will be desirable.

In photography the incandescence must be pushed to a clear white light, otherwise failure must attend every effort. The time required is a little longer than that for sunlight, the actinic power of the electric light not being as high, though the latter may give just as bright and sharp an image upon the focussing-screen. In using the lamp it is well to insert resistance in some form between the lamp and the source of energy, as the lamp may be at once destroyed through carelessly connecting it up with an unknown amount of energy. I have seen a lamp instantly burnt out by two Stöhrer medical cells, though a moment after these same two cells were so exhausted as to be unable to give sufficient current to heat the carbon film to dull redness.

The form of resistance may be either that afforded by a few feet of fine insulated wire, or by the very portable adjustable resistance coil made by Mawson and Swan. Compared with lamplight, electricity gives an intense white light having greater actinic power, consequently much shorter exposures are required.

The light can be carried close up to the object or condensers, giving advantages in sharpness of image and resolution of detail not possible by means of lamplight.

In conclusion. The accumulator will be found useful in many directions, as by means of a coil of small copper wire the stage of the microscope can be kept at an even temperature for many hours—ten or more; and it will, with fig. 1, give excellent results in printing transparencies.

Notes.

It was by the especial permission of the Czar that the Baron de Koussoff produced the photograph of the State Dining Hall of the Czar Alexis Michajlowitch, in the old palace at Moscow. This picture, which is one of our supplements this week, forms one of the first series of photographs taken in the old palace of the Czars.

Through the portal, and in the next apartment, may be seen the casket containing the original Charter of the Romanoff family; and the two large porcelain stoves, together with the double windows, serve to remind one of the coldness of the climate in winter. It was in this palace that Peter the Great was born.

How far the industrial importance of photography may become developed now that it is easy and practicable to transform photographs into types or blocks which, like ordinary wood engravings, can be printed along with the letterpress of an ordinary newspaper or magazine, it is not easy to predict; but it is not difficult to see that great results must follow the production of such photo-engravings as those by the Ives' process, which form our second supplement this week..

The Ives prints are impressions from a type block, and the production of this block depends upon the translation of the gradations in thickness of a Woodbury relief into a grain by pressure against a stippled surface, the stippled image being transferred to zinc and etched into relief by the ordinary chemigraphic method. (See PHOTOGRAPHIC NEWS 1883, p. 498-677; 1884, p. 222-324; and for details of chemigraphic engraving, a series of articles commencing on p. 673 of our volume for 1882.)

The time may come when the Ives process for translating a relief into a grain may be regarded as being a definite step in advance comparable to that made by Talbot when he introduced the system of multiplying photographs by means of a negative.

There have been few more ingenious modes of setting a fashion than that adopted by the patentees of a new shape in "masher" collars. The plan has been to take all the well known society "heads"—in a photographic as well as in a social sense—and having "fitted on" the collar pictorially, and added a coat and shirt-front, to photograph the whole. When the "masher" sees photographs in the hosiers' windows of Lord Randolph Churchill, Colonel Burnaby, Lord Charles Beresford, Mr. Henry Irving, and any number of other well known celebrities wearing this particular collar, the inference is irresistible. He musn't be behind the times, and so he immediately arrays himself in the new shape.

The general International Exhibition at Antwerp, which opens in May next, will probably comprise an extensive collection of photographic exhibits, and space must be applied for before the fifteenth of next month.

A waxed paper negative may be retouched with water-colours, if the surface be treated with ox-gall, or if the colours are rubbed up with the same material. Waxed-paper negatives are very useful for printing-in borders or clouds, and there is no need to make them by the old wax paper process, as an impression from a transparency taken on ordinary albumenized paper answers well; but before waxing, it is as well to soak the sheet in hot water, so as to remove as much of the sizing as possible.

It is satisfactory to know that the "Antients" of Barnard's Inn, who lately presented half-a-dozen portraits of legal luminaries, including a capital likeness of the great Lord Burleigh, to the National Portrait Gallery, had photographs of the interior of their Hall taken with the said pictures on the walls before sending them off to Mr. George Scharf.

Few people, probably, have ever been inside the quaint old oak wainscoted room in question; there are not many, indeed, who even know where Barnard's Inn is; and as the "Antients'" action in getting rid of their artistic portable property points apparently to a not very distant day when Barnard (as Mr. H. J. Byron once put it) will be "Inn" no longer, it is well that photographic record should remain of the "Hall" where, for several centuries past, the "Antients" have dined together at monthly intervals, and hob-nobbed over that fine old port to which they have consistently stuck. Come what may, "Barnard's Inn" will not be forgotten whilst "Great Expectations" is read; but it is nevertheless just as well to have some reminiscences of it more tangible than those which, thanks to Dickens's art, will always be associated with the Inn in which "Pip" had chambers with Herbert Pocket, and whither the weird "Convict" came in the darkness to endow him with his mysterious wealth.

As regards the British Association at Montreal, nothing of special interest to our readers transpired excepting what we recorded last week. The session closed last Wednesday.

A correspondent, writing with reference to our recent remarks on the "scissorgraphic" art, assures us that at Portsmouth, at all events, there is no immediate chance of its dying out. A local "silhouettist," rejoicing in the somewhat familiar appellation of "Snips," is said to be great with the scissors, his facility in equestrian portraits especially being most marked. Officers and men of the Royal Navy, it is said, are his frequent patrons, "Jack

ashore" being particularly fond of being cut out "on board" a jabbed charger. "Snips" would seem, indeed, like many other anachronisms, to be the source of considerable interest, though we still fail to see that his local survival is a proof that the state of "scissorgraphy" is not as black as we painted it.

A society journal announces the welcome intelligence that the hideous iron shed in front of the National Gallery will be shortly removed, as the work for which it was erected will soon be completed. The journal in question says that a "German photographer" has been in occupation. A phototype print of the structure will be found on page 562.

A filter which consists merely of a strainer so fine as to remove the minutest microbes appears to be regarded by M. Pasteur as likely to prove of more value for domestic purposes than a charcoal filter; and he has constructed one in which the filtering medium is ordinary porous earthenware, such as that used for battery cells. The extreme slowness with which filtration takes place, and the high pressure required to drive water through the earthenware, are, however, practical objections to the apparatus.

The itinerant photographer doesn't always display tact. He has a notion that everybody who rides a bicycle or tricycle wants to be photographed; and though this notion may be well founded, common prudence should have warned the photographer who, on Clapham Common, went up to a tricyclist who had just had a spill, and was covered with mud and bruises, not to beseech him to be taken "Just as you are, sir!" We forbear printing the tricyclist's reply.

A Photographic Art Exhibition is to be held at Leeuwarden, in Holland, during the early part of next year; the opening day being fixed for February 1st, and application for space must be made to Mr. G. H. Matthijssen, Ruiters-kwartier G. 95, Leeuwarden, before the 20th of October.

It is a pity the stereoscope has gone out of fame. With the rapidity of gelatine plates, effects could now be easily secured which would look marvellously well in the stereoscope. It may be questioned, owing to the unaccommodating way in which the earlier stereoscopes were made, whether half the people who looked through them realized the stereoscopic effect. The variation in the length of focus needed to suit all eyesights would surprise anybody who had not studied the subject. In this respect the old stereoscopes were singularly deficient.

What coustitutes "fair wear and tear" of photographic apparatus? We ask the question because of a dispute between two photographers which has come to our knowledge. A certain quantity of apparatus was let on hire, the hirer being responsible for its return in good condition, "fair wear and tear" excepted. In this case one of the legs of a tripod stand has been broken, a background damaged by water dripping through the roof; and the cross-piece of the head-rest has come unsoldered. One side maintains that these were all preventible accidents, and the result of carelessness; while the other holds that they were entirely unavoidable. Common sense would seem to say that injury resulting from the legitimate use of apparatus can only be claimed as "fair wear and tear." Thus a dark slide used in the wet process must in course of time become damaged by silver; the screws of the head-rest used constantly may fail to bite; and printing-frames, through exposure, and through the rough handling of boys, are liable to be rendered useless. But even taking this as a guiding principle, the question seems a difficult one to decide.

A nearly colourless cement for glass may be with advantage kept ready to hand in the photographic laboratory, and the following has proved to be useful. Seventy parts of finely-cut unvulcanised india-rubber are dissolved in one hundred parts of chloroform, after which fifteen parts of mastic are added. It takes some days for the mastic to thoroughly dissolve, and care should be taken that the cement is made and kept in a well stoppered bottle.

An artist who has been spending his holidays abroad, showed us recently a number of photographs which he had bought, in the usual way, unmounted. These he has mounted himself on boards of different tints, observing that he had endeavoured to provide each photograph with the tint best suited to the subject and tone. This may seem a small matter, but it is wonderful how much a photograph may gain or lose according to the tint by which it is surrounded. The sending of a number of prints to a professional mounter, and having all of them mounted precisely alike, must produce, in many cases, an unsatisfactory result.

Apropos of the discussion of green *versus* ruby glass: has the experiment ever been tried of a person who is colour blind in respect to either, going into a room lighted by the colour to which he is blind? His sensations would certainly be worth describing.

Patent Intelligence.

Applications for Letters Patent.

11,623. John Tirebuck, 6, Lord Street, Liverpool, for "Improvements in albums or apparatus for holding and displaying photographs."—Dated 26th August, 1884.

11,803. Frank Bishop, 53, Chancery Lane, London, W.C., for "An improved washing trough for photographic negatives."—Dated 30th August, 1884.

Specification Published during the Week.

9899. Lorentz Albert Groth, K.G.V., Civil Engineer and Managing Director of the Universal Inventors and Patentees Financial Company Limited, 30, Finsbury Pavement, London, E.C., for "A new or improved photograph and picture stand."—Dated 8th July, 1884. *Complete Specification.*

The stand is intended for the reception of photographs, lithographs, prints, drawings, pictures, or any other flat object, and differs from other similar apparatuses principally, by enabling the objects to be be seen at the same time from different sides.

The photographs, drawings, &c., are placed one behiud the other slantingly or vertically.

In both cases, the apparatus consists of a stand and a number of picture holders or frames. The stand is made of brass, tin, or any other convenient metal, and rests on feet of any angular or any other shape that may be desired, with crosspieces answering to the shape. The picture holders or frames may also be made of brass, tin, or any other metal, or of hard wood, and each frame may be divided into two or more compartments, each to contain a picture. On each side of the framc knobs or screws are provided, acting as horizontal axles, on which the frames hang and turn. What I claim is—

1st. The arrangement of any number of frames counected to one stand for the purpose of carrying photographs and such like articles as above described.

2nd. The frames placed easelwise ouc over the other, either slantingly or vertically, each revolving separately round a horizontal axle, with pictures on both sides, which can be seen by one or more persons at the same time from different positions.

3rd. The side-bearers are fastened to the foot piecc at the middle, but the other parts, being frec, are springy, or slightly flexible, and hollow cuts, in which the framcs catch, are thereby held iu a vertical position.

Patent Granted in America.

303,857. STELLA A. JACKSON, New York, N.Y. "Plaquc."—Filed April 16, 1884. (No model.)

Claim.—1. The glass plaque A, having the plain transparent spot *a* in the centre, and the frosted surface *c* on one of its facces surrounding the said trauspareut spot, substantially as shown and described.

2. The plaque A, having an aunular frosted or ground space *c*, and central transparent spot *a*, upon which the picture B is mounted, the back of the plaquc being coated with paint or other substance to the edge of the picture, aud coveriug the frosted portiou, substantially as shown and described.

HOW TO PHOTOGRAPH MICROSCOPIC OBJECTS.

BY I. H. JENNINGS.

LESSON III.—ILLUMINATING APPARATUS.

IN this country photo-mierography by daylight is troublesome and unsatisfactory. The suu shines brightly during so few months of the year, and is so fiekle when he makes his appearauce, that the photo-micrographer is compelled to fall back on artificial light to do his work. In many respects sunlight would be preferable, were it only always at the command of the photo-mierographer; it costs nothing, is rapid in its action, is more powerful than auy other light, and exhibits objcets illumined by it as we arc accustomed to sce them. The chief disadvantagc of using the sun as a source of light is, that, owing to the earth's motion, the direction of the light is eontinually altering, uccessitating the use of an expensive reflecting instrument, called a heliostat, to keep the rays constantly in any required direction.

The use of artificial light has been condemned by many. One photo-micrographer even goes so far as to say "artificial light is a delusion;" but on comparing results we shall find that, at least since the advent of rapid dry plates, photo-micrographs have been taken by many workers fully equal to any produced by daylight. In fact, certain photo-micrographers who have most strongly advocated the use of sunlight, have uot produeed work even equal to that which may be done by any manipulator of moderate ability with artificial light after a few months' praetice. Artificial light is mueh more easy to manage than daylight, and does not vary so much in actinic quality; hence exposures are easy to calculate, and the illumination is more completely under control.

The light given by burning magnesium is the richest in aetinic rays. If the stu lent possesses a Solomon's magnesium lamp, he will find no difficulty in working with this light, the only objection to the lamp being that it eonsumes the magnesium rather rapidly, and thus becomes too expensive to be used constantly. It may, however, be used with great advantage when photographing very minute objects with high powers. The most economical mode of using magnesium ribbon is to burn it in a holder made of tin or brass tube, the bore being just large enough to admit the easy passage of the ribbon. The tube should be about six inches long, and mounted on a stand similar to that of the bull's-eye eondenser, with joints to admit of proper adjustment.

NAVICULA LYRA, × 900.
Taken with a Siebert's $\frac{1}{12}$ immersion. Exposure about fifteen seconds to magnesium ribbon in a holder.

When using the holder, a spirit lamp should be placed opposite the aehromatie or other condenser, and the magnesium holder placed in sueh a position that when the ribbon is thrust through the tube, it may enter the flame of the spirit lamp. Some difficulty may be experieneed in getting the ribbon to properly illuminate the screen, but a few experiments will render the matter easy. The writer has made considerable use of the above simple apparatus, and very satisfactorily; but as it necessitates two manipulators—one to attend to the light while focussing and arranging the correct position of the light, and another to superintend the screen and focus—he much prefers, for all purposes, a good paraffin lamp.

A well-made lamp is necessary, but good paraffin still more so. Avoid all low-priced, strong-smelling oils. Paraffin sold at 8d. per gallon is not only unfit for photo-micrography, but absolutely dangerous. When burnt in any lamp with a large wick, it begins to evaporate rapidly as the lamp gets warm, and after a while the flame will rush up the chimney, blackening it, perhaps cracking it, and frightening the operator, if doing nothing worse. Reliable paraffin may be had at 1s. 6d. per gallon, and this will give more satisfaction in every way. Duplex lamps may be used, but they present no advantages for photo-micrography. They give out much heat, consume a large quantity of oil, and the double wick is troublesome when using high powers. A single wick is far preferable, but it should be the broadest possible to obtain.

The lamp devised by Mr. Dallinger specially for working with high powers, is, perhaps, the very best yet made; but photographs can be taken with any paraffin lamp; For some time the writer used a tiny microscope lamp, and took some very successful photographs with lenses varying from 2 inches to $\frac{1}{8}$th inch, but the exposure was necessarily long with all of them. The object of the photo-micrographer should be to make his exposures as short as possible, and this can only be done by using a powerful lamp and a vigorous developer.

The light from a broad-wick paraffin lamp will be found sufficient for even high powers, but the brilliancy of the light may be much increased by putting a lump of camphor in the bowl of the lamp. Gaslight and candle-light are far too unsteady to be used for photo-micrography.

WIND.

BY H. P. ROBINSON.

THE photographer, almost as much as the sailor, is at the mercy of the winds. Nobody knows how the wind blows till he becomes a landscape photographer. Everybody knows how the east wind searches, pierces, and cuts the body, but it takes a portrait photographer to perfectly appreciate the wreck it makes of the appearance of poor humanity, and a landscape photographer to discover the irritating qualities of a gentle breeze. Yet, on the other hand, how long has the unfortunate marine photographer sometimes to whistle for a wind before he can get those magnificent storm effects he so much desires, and to which he has devoted his holiday!

The effect of the east wind on the sitter is so destructive to good looks that none but the most case-hardened to biting cold should face the camera in a March east wind. It is not the intensity of the cold that does it, but the horrible blighting bitterness of the wind that causes the mischief, that turns the nose blue, shrivels up the face, and sets the teeth chattering. The pleasant author of "Tiny Travels" has a great abhorrence of the east wind. He says:—"It is totally different to other breezes; it has not a blustering honesty about it. It is a nasty, sneaking, insidious, underhand, unprincipled kind of a wind. It appears to open the pores of your skin till it is like a colander; it riddles your bones with fine pinholes, and then blows through them till you seem to have neuralgia all over your body. It penetrates the thickest of cloths, and the most formidable of friezes. You may fortify yourself with flannel waistcoats, you may don double-breasted sealskin waistcoats, you may wear three or four pairs of trousers, but the east wind will penetrate everything, and make you as miserable, as hoplessly wretched, as man can possibly be." And when a man looks hopelessly wretched it is not fair to take a photographic advantage of him and perpetuate his miseries. An ancient distich used to run something like this:—

> "When the wind is in the north,
> Take not the wretched sitter forth."

That was in the pre-studio days, when portraits were taken in the open air; but it is impossible to keep the east wind out of even the most comfortable studio; no amount of hot-water pipes and firing will do it; and there are some people so sensitive to the "ill wind" that they easily feel it in bed, and it would almost search them out in a Turkish bath.

The printer also has his complaint against the wind when in this obnoxious quarter, as it is said to crack the surface of albumenized paper; but it has not such an injurious effect on our negative process as it once had.

It was a well-known fact in the collodion days that cold retarded the exposure, but I have not noticed that it has that effect on gelatine plates. Indeed, some of my best sea pictures have been taken in intensely cold weather. I shall never forget being frozen nearly stiff in a North East gale at Deal, although it was the end of March and the sun was shining brightly. When I had exposed my last plate—I had waited a long time to press the button of the drop-shutter—I found myself so frozen that I could not return the slide of the shutter, and had to be gradually thawed.

The wind that gives the landscape photographer most trouble is not, at a first glance, an unmerciful one. It is the moderate, constant breeze that almost laughs the landscapist out of his life. The photographer knows what to do with a gale, or even a moderately high wind; he can postpone his excursion until another day. It is always satisfactory when the weather decides for you authoritatively. When the wind blows until it "cracks its cheeks," or the rain descends in water-spouts, the photographer can, with a good conscience, put away his traps and wait for better times; but it is the day that is *almost* good enough that tempts the photographer forth—to do bad work.

Given a day suitable for the work intended to be done in every respect except wind, it becomes a question whether the photographer should take his chance and run the risk of getting his exposures between the gusts. There are cases when necessity, the mother of invention, becomes the parent of expedition; and the operator, having only a single opportunity, is compelled to do the best he can to secure a view, if not under the best conditions, then as good as he can get them. It is my experience that in these cases fortune often favours the brave, and the view comes off. I am always inclined to "take the chance" if there is one, but if, after waiting for some time, there is obviously no likelihood of getting good light or reasonable freedom from motion, I give it up, and do not allow myself to waste a plate.

These are occasions when it is well not to be too critical. It sometimes happens that a photographer has gone a long distance to secure some pictures, and has a limited time to do them in; he must then be satisfied to get the best the weather will allow. It is possible, however, to dodge even the wind.

In a photographic fortnight which I enjoyed this summer, I was very much bothered by wind. It blew with a moderate to full strength all the time, but did not prevent me exposing my usual number of plates, although it gave me a great deal of trouble and waiting to do so, and perhaps deprived me altogether of one or two subjects—the best, of course, as usual—but they are possibly not lost, only saved for a future time. There are some districts in which the wind never ceases to trouble, and the leaves are never at rest. Tunbridge Wells is one of these restless places. It stands high above the sea-level, and appears to have never less than a continuous gentle breeze playing over it. Yet, such is the perversity of the wind that, now I have written it is never still here, I look up from my writing, and notice that there is not a leaf moving! This is a very rare occurrence. In other parts of the kingdom I never fail to notice that even on windy days there are occasional intervals of perfect peace; that when the wind is troublesome in the valley, it is quiet on the hills; when it is blowing on one side of a wood, there is a lull on the opposite side.

When there is no life in the subject, it is possible, in nearly all cases, by waiting patiently, to secure an exposure without the disfigurement caused by moving foliage. An exposure may be got piecemeal, so to say. When the branch of a tree is blown about ever so violently, it nearly always returns to its place, thus enabling the photographer to snatch his exposure a bit at a time. I have known an hour expended in getting an exposure of twenty seconds, a few seconds at a time as the wind would permit. But it is when you have figures in your view that wind torture comes in. The best models tire in time: I never knew one that could stand for ten minutes or a quarter of an hour without becoming limp and exhausted, necessitating a rest or a refreshing run. Now it is during this rest, however short, that the wind finds its opportunity to torment you, and dies away when you are unprepared. At other times it will leave everything at rest except some small but very conspicuous branch. You persuade yourself that a trifle like this will have no material effect on the picture, and you uncap your lens, but this moving branch annoys you for ever afterwards; it is the first thing you see in the picture, although it may not be seriously visible to anybody else.

One of the worst forms of wind torture occurs when the gentle breezes seem to take a fiendish delight in humbugging you. You come to a beautiful view, with a good deal of foliage, and when you first see it it is perfectly still, and looks photographically lovely. You unpack quickly, and are soon ready to make an exposure. As you put your hand on the cap of the lens, and, thinking to yourself "I have got it this time, anyhow," gleefully counting your chicken before it is hatched, a gust of wind comes and upsets all your calculations. You call to your models to take a rest, and let the wind blow itself out. In a few minutes it again tempts you to get ready. It very nearly dies away, but not quite, and you determine you will not miss perfection for want of a little patience, and decline the invitation. Then the breeze increases and continues, and you sit down to wait, but soon find that the sun is moving on, and your light and shade is not so good as it was, and you get fidgety about your models, and fear you are tiring them. Then you begin to feel sorry you did not take that almost good chance that occurred twenty minutes ago. Then you determine to snatch the next opportunity that has any promise in it, and get ready. The breeze is dying, with occasional short puffs; there is only a slight, general movement, with here and there a wagging branch. You shout to your models to get ready; then the breeze slightly increases, and you, fearing the wind is about to come on in full force, uncap your lens—the picture is done, for better or worse. You unship your camera, and then take another look at the view. What a change! That puff of wind during which you exposed your plate was the last flicker for a time, and all is peace—not a leaf stirring, not a ripple on the placid water. But you have exposed your last plate, and the serene calm is but a mockery!

When the wind is welcome to the photographer is when he wants to get some of the grand effects that are presented by the sea lashed into fury by the storm. It may be true of photographing the sea that "Peace hath her victories no less renowned than war," but to me the sea when calm has few attractions. There is nothing to me more enjoyable and exhilarating than having a fight with such a refractory sitter as a storm-driven wave. The difficulties which ought to drive you to despair only add to the enjoyment. If the wind is inshore and blows anything like a gale, your lens is fogged with spray as soon as it is uncapped; you have therefore to have an elaborate cleaning up after every time you endeavour to get focus or to see how the subject looks on the ground glass; you have to take careful precautions not only that your camera is steady during exposure, but that it "stays put," as the Americans say, and does not fly away. Nothing is better for ensuring stability than bags of stones suspended from the top of the tripod. A focussing cloth is quite unmanageable on these occasions, and must be done without as much as possible. The elaborate wrapping up of the camera, so much affected by some photographers, is a great tempting of the wind, and is not necessary if the camera is properly made. What can be more exciting than, with finger on trigger, watching wave after wave as it thunders on the shore, trying to determine on the instant if the arrangement is picturesque or otherwise? Truly the successful photographer, in this kind of work especially, is like the most successful general, the one who makes the least mistakes.

A PHOTOGRAPHER'S METHOD OF MAKING HIS OWN EMULSION PLATES.

BY RANALD DOUGLASS.*

BELOW is given a good way for making one's own plates, which, if carefully and exactly followed, will give absolutely reliable results. Extreme care and cleanliness are necessary at all stages of the process.

In the first place, select the glass—use the flattest lights for larger plates, and cut down the curved or irregular one to be used for smaller plates. The edges are to be roughened as usual. The plates are then laid, one by one, in a porcelain or stoneware dish, which holds the acid—1 part acid to 5 to 10 parts water. Pure acid allows more water to be used than does the common article. I use a mixture of nitric and sulphuric acids. After several hours' soaking take them out, and wash and albumenize as for wet.

Below is an excellent formula, I believe Brooks's:—

Albumen of one egg	
Water	20 ounces

Shake or beat to a froth, then add 20 drops of carbolic acid in 1 ounce of alcohol; add this mixture to the albumen, and filter through cotton or paper. In coating with albumen, let the first application run off into the sink, then give the glass a second coat, and rack up to dry.

No. 1. Weigh out 200 grains of Simeon's Swiss gelatine, put it in a pitcher or any convenient vessel, and cover it with cold water—tap-water is good—and allow the gelatine to soak till swollen, which takes fifteen minutes or so; pour off the water and drain, then add to it the following: 360 grains of bromide of potassium dissolved in 4 ounces of pure water, to which is added enough dilute hydrobromic acid to turn blue litmus paper fairly red—not too red. The hydrobromic acid is diluted 1 to 5. Now dissolve in a water-bath the gelatine and the bromide, and pour it into a bean pot, which can be found in any grocery or cookery shop; it has a loosely-fitting lid.

No. 2. Dissolve 450 grains of nitrate of silver in 7 ounces of warm water, which should be pure; tap-water is good.

No. 3. 25 grains of iodide of potassium dissolved in a drachm of water. Now carry Nos. 1, 2, and 3 into your dark-room and close the door; allow orange-red or ruby light in it. Add No. 2 slowly and a little by little into No. 1, which is dissolved in the bean pot. Now, with a strip of glass, keep stirring briskly while the silver is being added. This prevents coarse particles from being formed. After all the silver is added, add lastly No. 3; stir for a little while longer, then put on the cover of the bean pot, tie over the top several thicknesses of orange or red cloth or paper, which will allow steam to escape, and at the same time keep out the light. By this time I suppose your water-bath is boiling. Put in your bean pot, but not to quite touch the bottom of the water-bath; something must be arranged to hold it an inch or so above the bottom. If you want ordinary rapid plates, say as rapid as those marked six times as rapid as wet (if you are a novice in plate-making, you should begin with this grade), let it boil for half an hour, taking the bean pot out once in a while and shake it and replace. One hour's boiling will give as rapid plates as the best commercial plates—at least, it has been my experience.

Suppose the time of boiling is now up, take the bean pot out and set it where it can cool down gradually. In the meanwhile, soak 400 grains of Swiss gelatine in enough water to cover it, and when it is swollen, drain, and dissolve carefully and gently in six ounces of water. The heat must be just enough to slowly dissolve it with stirring at, say, 110° F. to 120° F. Too much

* Communicated to the *Philadelphia Photographer*.

heat will spoil it, and your plates will frill. Here use the greatest of caution. When it is dissolved, in the dark-room, add it gradually, with constant stirring, to the contents of the bean pot, which latter should first be cooled down to 90°, or lower. Stir a while longer; then put on cover, place the bean pot in cold water (in summer, ice is necessary); in two hours the gelatine will be set firm. It should be firm. If it is not, add more ice to the water by which the bean pot is surrounded. Now cut up the solid jelly with a strip of glass, take some of it and put it on some open-meshed cloth. I use linen having meshes of about one-sixteenth of an inch. Strain the jelly through the cloth into a one-gallon stone jar half filled with cold water; do so till all your emulsion, has been strained through the cloth. In straining the emulsion your hands must be clean and kept cold. If they are dirty, your plates will be dirty also; if they are warm, part of your emulsion will re-dissolve and be lost. When all your emulsion has passed through the cloth into the one-gallon jar, tie the cloth over the mouth of another jar, which should be two gallons capacity or more, stir the contents of jar No. 1, and pour it on the cloth; put a gallon of water into the jar, and pour it on the cloth again. The water will run through the cloth and leave the emulsion in the form of a cluster or bunch of strings behind. If any passes through it can be caught in the second jar.

If you have any reason to suppose light has got in your emulsion in any part of the process since you mixed it with the silver, you can put two or three ounces of saturated solution of bichromate of potassium in the first jar, fill it three-fourths with water, and return you emulsion to it, and stir and leave it there half-an-hour, then wash it. Fog will be removed, but the sensitiveness will be considerably reduced.

Return your emulsion to jar No. 1, fill it two-thirds with water, stir it, cover it, and leave it ten minutes; then pour it back on the cloth over jar No. 2, which, of course, is first emptied of slops. Repeat this operation six times or so, and your emulsion is well washed. Now allow your emulsion to drain over the cloth till it is free from sloppiness, when it can be now re-melted in the bean pot, which has been well washed in warm water to free it from scraps of old emulsion. Again, here, great caution is necessary with the heat. Use no more than will slowly dissolve it, or it will make your plates frill—110° to 120° F. is about right with stirring. Add to it 1 ounce of alcohol to which have been added 25 drops of carbolic acid. You can now coat a few trial plates, but I would advise to reset the emulsion and let it stand in a cool place, not less than three days, by which means it becomes ripe and more rapid for being kept. The carbolic acid makes it keep well for months; alcohol facilitates ripening and flowing. When wanted for use, take out of the jelly, with a strip of glass, as much as you want, and re-melt at a gentle heat; filter through cauton flannel into any convenient vessel, the bottom of which must come very near to the nozzle of the funnel to avoid air-bubbles. I coat with an ordinary Anthony's 8-ounce bottle. Pour, to avoid air-bubbles, a little on one corner of the plate, which must be slightly warm, or the gelatine will chill on it and produce markings of uneven coating. Spread it with a glass rod, or, better, with your little finger, then rock it to equalise the coating, slip cautiously on a slab of glass or stone previously levelled, wash your finger, and proceed till your slab is full. Take up your plates and put them in a rack as soon as they are set. If the coating-room is too hot, plates will not set; the room should be kept below 90°, or, better, below 80° F.

In summer, you should coat early in the morning, at or before sunrise. Your plates should be set inside of five minutes, or they are prepared wrong, or too much heat has been used somewhere, supposing your slab is quite cold. In such a case, dissolve a sheet of gelatine in as much water as it will absorb, and add it to the emulsion, and it will correct the emulsion, and make it set better. But if you have followed out the above directions carefully, you will have no trouble anywhere. Leave the plates alone in any well-ventilated dark-room for twenty-four hours. In the absence of such, you can get a light air-tight box, large enough to hold a batch of plates, put in a saucer of chloride of calcium, then your plates, and close down the lid and do not disturb them for two days. The calcium salt absorbs the moisture from the air and becomes wet; the air in its turn takes up the moisture from the plates and they become dry, when they can then be used at once, or packed for future use. The chloride of calcium can be dried over a stove and used over and over. It is, indeed, very convenient and very effectual.

Plates made by the above formula can be developed by any of the published formulæ. I prefer pyro and carbonate of potassium. I have given the way that I do, and I do not see any reason why it cannot be followed by others with equal success.

MAKING ENAMEL PHOTOGRAPHS.

BY T. INGLIS.

A SHEET of any smooth-surfaced glass (plate is best) is cleaned by any of the usual photographic methods; now rub over the plate a solution of alcohol containing about five drops of nitric acid to the ounce; rub over the glass and polish with a dry piece of Canton flannel; finally dust a little soapstone or French chalk from a small muslin-covered box containing the chalk; brush it off lightly with a clean piece of Canton flannel; be careful not to rub hard, as in that case the chalk would deaden the polish of the glass plate. This done, the glass is now coated with plain collodion, five grs. cotton to the ounce of equal parts alcohol and ether. The plate is now allowed to dry, and can be kept in this state any reasonable length of time. When dry lay the plate upon some level place and cover with a solution of plain gelatine about the consistency of cream, at a temperature of 90 or 100 degrees; allow the plate to lie flat until the gelatine sets, which will depend on the temperature of the room.

When dry, stand the plate (or plates) up to dry, and store them away; in this state they will keep indefinitely, and it is well to keep a stock on hand in this condition, as pictures can be mounted in a few moments.

To mount the picture, lay one or more of these plates upon some level place over the sink, so that the water to be used will have free escape to the waste pipe. Cover the plates fully with water, allowing as much to remain upon the surface as possible, lift the pictures from the water they have been washed in, and lay them face down upon the prepared surface of the plate, filling it with as many prints as it will hold, arranging them according to their sizes; pay no attention whatever to the bubbles. Have a piece of thin rubber cloth and a squeegee; lay the rubber cloth over the plates, and with the squeegee press the pictures into contact with the glass, at the same time take out all air-bells by passing it back and forth over the plate. This done, run around the edge of the plate with a knife to take off the gelatine and collodion, ½ inch; this is to allow the paper that is mounted on the back of the picture to adhere to the glass, which will thus bind the whole thing down until liberated by being cut inside of this safety edge, otherwise the pictures would be apt to leave the glass before they are thoroughly dry, and thereby lose the brilliancy they would have if properly dried. After the pictures have got surface dry, give them a coat of thin gelatine, and cover them with a wet sheet of Manilla paper or any common paper same size as the plate; now mount them with cardboard, known as printers' card-board, because it is cheap and answers every purpose; finally cover the whole with an enamel sheet of paper of any tint desired, thus having an enamelled mount, when the picture is finished, as well as an enamelled photograph. After they are thoroughly dry, cut inside the safety edge, when the prints will come off with all the beautiful finish possible. The prints may now be stamped out with a round or square cornered die, or cut with a knife any desired shape; the edges may be bevelled and bronzed with a little gum-arabic and bronze applied with a camel-hair brush.

The whole operation is simple, and not nearly so complicated in its working as it appears from the description of how to do it,

Correspondence.

THE POTASH DEVLLOPER.

SIR,—Like your correspondent Mr. J. H. Jennings, in your issue of the 22nd ult., I desire to avoid the, to me, most unpleasant fumes of ammonia. I likewise have tried the soda developer, but without encouraging success.

I read of the potash developer in your issue of the 1st inst., and actually got the ingredients, but hesitated to make them up, fearing only another disappointment.

Mr. Jennings' letter decided me to try the potash, and with my first attempt, I thought I had "struck ile." The development was beautifully gradual, and, so far as I could judge from most of the usual signs, it was perfect within a

reasonable time, though not within five minutes; but I did not mind that, as I prefer a "slow but sure" development. My delay seemed to arise from the fact that I could not obtain that density of the negative, when viewed by transmitted light, which I have been accustomed to see and depend upon. Moreover, by reflected light, the picture did not darken nearly so much as I have been generally used to see, but, on the other hand, my development was continued so long that the picture was almost as clear on the back as, on the front of the glass; so as all detail seemed to be perfectly out, I decided to wash off, when immediately the plate, like Mr. Jennings', frilled most horribly, though I practically saved it by prompt transference to the alum bath. Here let me say that I have avoided subsequent frilling, to any great extent, by not soaking the plates in water previous to development; while, on the other hand, the non-soaking in water before applying the developer has seemed to give rise to "marbling."

But the point I wish to make is, that when I finally took my negative into daylight and looked through it, I found it weak, although beautifully clear and soft. In every subsequent plate developed with potash my experience has been the same. The negatives have all been weak, although as good as I can hope for in all other respects. Intensification has improved all of them; but then I do not care to have to always intensify. I may say that in my efforts to get density I have used twice and thrice the quantity of the pyro that would usually suffice.

I should be extremely glad to know how Mr. Jennings manages to make this potash developer (as he says) far more powerful than the ordinary pyro and ammonia.

As I am unaccustomed to write to the fourth estate, perhaps I had better put my enquiries more definitely for brevity in reply.

1. How to obtain sufficient density by potash developer?

2. How to know when sufficient density is obtained, inasmuch as the usual signs (all save the image seen through the back of the plate) seem to fail with the potash?

3. As a matter of fact, does the potash developer require twice to four times the amount of pyro which would suffice if working with ammonia, and for normal development?

4. Has the ordinary alum bath any reducing effect on a negative developed by the potash formula, and put in said bath after fixing, having been in a chrome alum bath before fixing?

Since writing the foregoing I have again tried the potash developer on two negatives, one with one-third longer exposure than the other. I took the longer first, and it came up and developed as well as I could wish, finally giving evidence of density by both transmitted and reflected light, as well as by showing the image very plainly on the back. I then developed the shorter exposure, giving a little added strength to the developer. It also came up, and developed as well as one could wish. To all appearance, both were a little inclined to frill; so, after a very gentle wash, they went successively into the chrome bath, thence into the fixing bath, and thence—the first developed negative—into the plain alum bath, as in usual practice. By the time the second negative was fixed, the first had been in the plain alum bath between five and ten minutes. Looking at both by daylight, I was surprised to find the first negative markedly the weaker, while the second is decidedly the strongest I have yet had with the potash. It was only in and out again of the plain alum. Query: Did the alum reduce?

J. G. R.

DEAR SIR,—In your number for the 22nd inst., a letter from Mr. J. H. Jennings commences:—"Having lately been compelled to abandon the use of pyro and ammonia for considerations of health," &c.

I am a little surprised to hear (and somewhat startled, too) that this most usual method of development can be injurious to the health, and should feel much obliged if you will kindly tell me whether there really is much or any danger; and if so, in what way, and where is the injury likely to arise.

I imagine the fumes of ammonia are what Mr. Jennings alluded to.—I am, obediently yours, SURREY.

FRENCH TRIPLETS AND THE POTASH DEVVELOPER.

DEAR SIR,—Mr. Bottone's assertion that French triplets, costing 9s., are far better for general photo-micrographic work than English lenses costing ten times the price, will not, I think, be endorsed by the experience of the majority of workers, English or foreign. Were this the case, it is strange that Dr. Maddox and Mr. G. E. Davis, in England, Dr. Woodward and Dr. Sternberg, in America, and Dr. Koch, in Germany, should all agree in using for their work the very best lenses that opticians can manufacture. The inimitable photographs taken by Dr. Woodward could not have been produced if he had not had at his command the most perfect apparatus that money could purchase; while Dr. Maddox, who has had more experience in photo-micrography than any other man in this country, has, I know from what he has told me, no very high opinion of cheap French lenses, and has pointed out defects in lenses which my smaller experience had thought nearly perfect for photo-micrography. In this I thought photographers and microscopists were one, viz., that the best lenses were necessary for the best work. I think this is the general opinion. My own experience of microscopic work extends over twenty years, and although at first I was satisfied with the cheaper lenses, my advice now to all purchasing apparatus is, *have none but the very best English work, if it can be afforded.*

I write only for beginners, and I know the annoyance of being hampered with apparatus which more mature experience finds out to be unsatisfactory. Mr. Bottone has, no doubt, enough knowledge of landscape photography to know the difference between a photograph taken with a cheap French doublet, and one taken with such a lens as a Ross' symmetrical. For the beginner, the former may answer well, but the expert will only be satisfied with the latter; yet even the beginner had better use the Ross' lens in preference.

A $\frac{1}{4}$-inch is certainly rather a high power to use on such a large object as a fly's tongue. A good English $\frac{1}{10}$-inch, $\frac{1}{2}$-inch, or even a wide-angle $\frac{3}{4}$-inch, will give far better definition than the French $\frac{1}{4}$-inch triplet, and all the necessary penetration, besides giving more light, and allow of great amplification, without spoiling the definition.

I do not quite understand about Mr. Bottone's French $\frac{1}{4}$-inch triplet, which has a working distance of a quarter of an inch. I suppose a microscopic $\frac{1}{4}$-inch objective is so called because it has a magnifying power equal to that of a single lens of $\frac{1}{4}$-inch focal length; thus I cannot see how a compound lens like a triplet, in conjunction with the eye-piece, can have a working distance equal to that of a single lens of the same magnifying power. I have handled at different times nearly all the lenses of our English makers, besides many French and German lenses, and all had a working distance considerably shorter than their nominal focal length.

As to "penetration," Mr. Bottone must know that this is not a quality peculiar to any particular lens, but dependent, like "depth of focus" in a photographic lens, entirely on the diaphragm used. If penetration be chiefly desired, then the cheap low-angle lenses now supplied by all our best makers will fully answer all requirements, and, at the same time, define better than any cheap French lenses. I have a $\frac{1}{2}$-inch of 60°, by Swift, with which I have often exhibited opaque objects at a *conversazione*, which will yet easily resolve *P. angulatum*. This test, when dry, I consider a very easy one. I once had a $\frac{1}{10}$-inch by the same maker, which also resolved this test well. Both are cheap lenses.

Short working-distance I do not consider a defect.

Sixteenths and twenty-fifths come rather close to the glass: but even when working with the former power at a distance of 5 feet from the focussing-screen, I never found this any disadvantage.

If more penetration be desired from good lenses of wide or even moderate angle, it can easily be gained by using the Davis "aperture shutter." This point is, I think, conclusively settled by a series of experiments made by Mr. G. E. Davis, the results of which were published in the September number of the *Northern Microscopist* for 1882, to which I would refer Mr. Bottone. If he does not see this magazine, I shall be happy to lend him my copy.

As to the relative value of different developers, no fixed rule can be laid down. That some people *do* find the pyrogallic developer beyond control, I know well, but *why* I can't say. For my own part, I find ferrous oxalate too mechanical and "inelastic." Pyro can be easily modified to suit the varying requirements of subject and exposure. In photo-micrography, in particular, some subjects with high powers require the minimum exposure, and here I have found ferrous oxalate fail. I have, perhaps, worked more with a 1-16th inch than with any other power, and for such work I found I could never get a sufficiently vigorous image with this developer.

Regarding the ill-effects of pyro and ammonia, I need only quote Mr. V. Elsden in the YEAR-BOOK for 1881:—"Vapour of ammonia may produce inflammation of the lungs." Dr. Geo. Herschell has also warned photographers against the use of ammonia. All persons, therefore, who may have delicate chests, should avoid the use of a developer containing ammonia.

If Mr. Bottone will write to me privately, I shall be most happy to answer this or any other question more fully.—I am, sir, yours faithfully, J. H. JENNINGS.

Proceedings of Societies.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

A MEETING of this Society was held on Thursday, the 28th ult., Mr. W. M. ASHMAN in the chair.

Mr. J. J. BRIGINSHAW (Hon. Sec.) passed round an application form for the "Exhibition of Recent Inventions," 1885, and said the authorities had extended the time for filling them up by two weeks; he hoped their Society would be well represented. He further said that besides the transparencies already promised at a former meeting for comparison by different processes, the Taupenot process would be illustrated, and Messrs. C. and F. Darker had promised to furnish a suitable lantern for the occasion.

Mr. A. HADDON (Curator) suggested that this display of transparencies should take place shortly, to enable members to select the most suitable process for their own use before the season advanced; and he hoped that each contributor would give a concise resumé of the method adopted.

The subject of density becoming greater by keeping negatives was next discussed, and a Member passed round some very fine gelatine negatives which were rather dense. These had been developed with Newton's soda developer more than a year ago, and the exhibitor was certain the density had increased since then. The temperature was above 90° F. when they were developed, and there was no frilling, chrome alum not being used in preparing the plates.

Mr. W. E. DEBENHAM was quite certain that some wet collodion negatives increased in density by keeping; although formerly he very slightly intensified all his wet plates, he never made them approach chalkiness, yet they appeared to do so now.

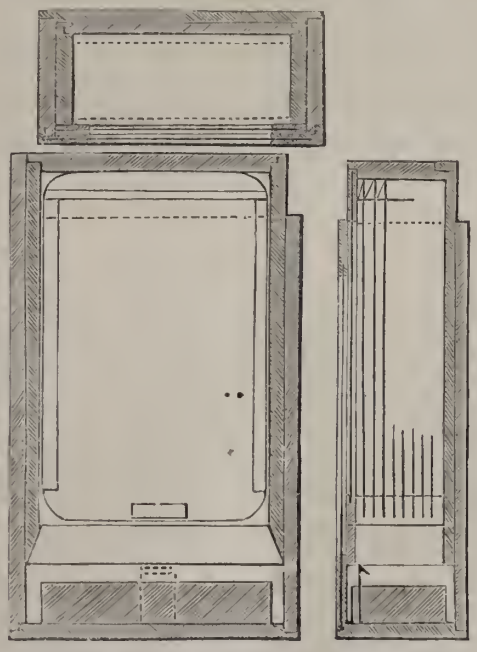
The CHAIRMAN had not discovered any change in his collodion negatives, very few of which had been intensified, and considered the slight intensification resorted to by Mr. Debenham to have set up the action. He thought the change spoken of in the gelatine plates shown was more apparent than real, and elicited the reply that fumed paper was employed when the negatives were first printed from, but not in the case of those prints made recently.

A Member said that some years ago Blanquart Evrard described a means of obtaining results of a more artistic character by exposing wet plate negatives to daylight after developing and washing, but before fixing; portions could be so lighted if suitable masks were laid over the negative, an exposure ranging from five to ten minutes being usually sufficient for the purpose. The negative was kept wet, and fixed and washed afterwards. The artistic effect being often unmistakably improved, it would be interesting to know what change is brought about—whether it is a change in the colour of the silver atoms, or an agglomeration of them might with advantage be studied under the microscope.

Mr. W. COBB recollected Mr. Valentine Blanchard recommending a similar proceeding in the case of under-exposed negatives.

The CHAIRMAN observed that when negatives were much under-exposed, the darkening action was not sufficient to gain much in printing quality; if the plates were flooded with dilute solution of bichloride of mercury, and after exposure to light were dried and printed without fixing, better results would be obtained.

Mr. J. B. B. WELLINGTON exhibited a new changing-box and dark slide combined. It was composed of two rectangular boxes, the inner one containing ten plates fitted in metallic frames, being arranged to slide within the outer case, which was fitted with an automatic metal catch arm to fall into a socket in the frames, thus securing the front plate during exposure, and releasing it upon changing the position of the box. It was necessary to withdraw the inner case upon each exposure,



as will be gathered from the sketch, wherein the outer case is shown partially drawn up.

Mr. F. W. HART exhibited a flap shutter capable of working in either direction at any desired speed, and arranged to act as a sky-shade adjustable in proportion to the requirements of the picture. After a very rapid exposure the shutter required re-setting before exposing again, but not so when the action was slow.

Mr. COBB said its special value was in being able to give a prolonged exposure when required.

Mr. HADDON passed round a frame on which he had woven copper gauze with a mesh $\frac{1}{6}$ of an inch; this was merely to show the ease by which it could be done. He had seen some paper baskets made of wire, which might answer the purpose. Other articles were also mentioned which were considered suitable.

In reply to a question from Mr. Debenham, concerning the effect metallic portions of apparatus may cause on an emulsion,

Mr. COWAN said that heads of screws in wooden vessels had no effect, so far as he could find, in any of his emulsions.

Talk in the Studio.

THE MANUFACTURE OF OXYGEN ON A LARGE SCALE.—The method of Boussingault, in which caustic baryta is heated so that it absorbs oxygen from the air, and is then made to give up the absorbed oxygen by the application of increased heat, with or without the use of steam, has long been regarded as impracticable; but the recent experiments made by the brothers Brim at Passy seem to prove that such a process can be carried on profitably as a means of obtaining oxygen for industrial purposes. Two sets of iron retorts, like those used for the manufacture of coal gas, are mounted horizontally in furnaces, charged with sufficient baryta to about half fill them, and heated to between 500 and 600 degrees Centigrade. Air is now pumped into one set of retorts, when it is found that each kilogramme of baryta absorbs from twenty-five to sixty-eight litres of oxygen. The baryta being now saturated with oxygen, the retorts are exhausted, and the temperature is raised to 800° Centigrade, when the oxygen is evolved and pumped out. By having two sets of retorts the operation is rendered continuous, as, while the baryta in one set is absorbing oxygen, the baryta in the other is evolving that which it previously absorbed. The brothers Brim propose to aërate water with oxygen and sell it as a drink; but it seems that this proposal was made some years ago by M. Maumené, who also suggested the use of nitrous oxide in the same way. Water saturated with nitrous oxide (laughing gas) is said to possess the power of producing the same kind of hilarity which results from inhaling the gas.

BALLOON SOCIETY.—The Centenary of the first aërial voyage in England will be celebrated on September 13th, in the Honourable Artillery Company's grounds, Finsbury. Photographers (members of the Balloon Society) can obtain tickets from the Society.

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting, September 10th, will be "On the Effect of Different Alkalies in the Development of Gelatine Plates." Saturday outing at Hale End. Train leaves Liverpool Street at 2.2 p.m.

To Correspondents.

*** We cannot undertake to return rejected communications.

A. B.—1. Soak the emulsion, previously broken up in small pieces, in some old fixing solution; next filter, and add a solution of sulphide of potassium until no more precipitate is thrown down. Collect this precipitate, and reduce it by fusion with about twice its weight of sodium carbonate. 2. Probably fifteen or twenty pounds.

E. J. LOVEJOY.—Next week.

J. AND A. G. H.—Thank you, but we shall not require the model again, having made note of all the points of importance.

T. STEVENSON.—Very good indeed; is quite suitable for the kind of work you refer to.

T. W. O.—No. 5 will be most suitable if you only take one lens, but it would be desirsble for you also to have one of shorter focus.

AMICUS.—We do not know the address, but believe that the person referred to is still alive.

A. G.—1. You are quite right as to the necessity of a longer exposure. 2. It may be a useful medicine, and yet injurious to a healthy person. 3. A bag made of two thicknesses of black cloth, and provided with short sleeves and elastic bands for the wrists, will answer very well.

E. Y. E. N.—It would probably liberate sulphur, and might cause rapid fading to set in. There is less objection to the use of alum, the following being the usual way:—Soak the partially-washed prints in a mixture of four ounces of a saturated solution of alum and a gallon of water. Several rinsings are required to remove the alum (see page 283 of our volume for 1883). 2. It will not do, as the contractile quality of gelatine will cause it to scale. 3. The ordinary process on albumenized paper; but you will find some useful remarks on page 429 of the present volume. 4. No book now in print gives working details; your only way will be to obtain an old edition of some handbook, such as "Hunt," or "Hardwich," at a second-hand book shop. 5. We do not quite understand the question in the way you put it, but imagine that the above answers also give you the information you require under this head.

ARTHUR T. D. BERRINGTON.—Gum a strip of paper about three-sixteenths of an inch wide on the edge, so that it makes a kind of dish, of which the film forms the bottom. Of course, in working, this "dish" is held upside down.

CAMBRIAN.—Although the word "gramme" is, we believe, spelled without the final "me" in the Act of Parliament legalizing it as a standard in this country, the longer form is more usual. A gramme is equal to nearly 15 ½ grains, and a cubic centimetre is the volume occupied by a gramme of water at 4 deg. Centigrade. You may take it that a cubic centimetre is 1-28th of an ounce. 2. Moisten the tip of the finger with a trace of turpentine, and rub gently over the surface of the varnish until dry. 3. Glass.

J. B. A.—No. 2 is insufficiently fixed, and the spots on No. 1 appear to arise from original defects of the plate. On No. 3 we can see no stains; but there was some dirt on the reverse side of the plate. The slight tint all over the plate may perhaps arise from over-exposure or, from unduly forcing the development.

J. A.—Sandarac 18 parts, mastic 4 parts, ether 200 parts, benzole 80 to 100 parts.

JOHN B—.—1. It is scarcely worth while to take the trouble to make up a solution of potassium iodide and to add to it separately, as the first plate immersed will saturate the bath with iodide of silver. 2. For such purposes you will require to have the bath in very good order, and we are inclined to think it would be better to make up a fresh solution. Of course you will recover the silver from the old bath.

LUX.—1. Pulp made from wood is largely used by paper makers at the present time, and unless the wood fibre is very carefully freed from all traces of the incrusting matter which naturally covers the fibres, the paper is subject to become yellow on exposure to light.

COMMON SENSE.—We have obtained good results with a solution containing 40 grains of the former and 2 of the latter to an ounce of water; but certainly it would be unreasonable to conclude that the usual practice of making up the solution by weight and measure is bad, because the strength may be varied within wide limits without much vitiating the result. 2. Obtain as perfect transparency as possible before treating the negative as you propose.

ARTIZAN.—1. Doubtless from the use of dirty glasses. 2. Over-exposure is probably the cause—try about one-fourth. 3. It consists of gold in a fine state of division.

B. T. OSMOND.—You have evidently had no practical experience in lens grinding, or you would not ask such a question, so you had better send the instrument to the maker. It is, however, doubtfull whether the spare thickness will be sufficient.

SIGMA.—The so-called magic photographs are made by soaking fixed but untoned silver prints in a saturated solution of mercuric chloride until the image disappears, and then drying the whitened prints. A solution of sodium hyposulphite revives the latent image; but the usual way of applying it is to lay a piece of blotting-paper, which has been moistened with a saturated solution of "hypo." and dried, on the bleached print, and to damp the blotting paper.

CHARLES.—It does not keep well in solution, so you had better dissolve it as required for use.

Employment Wanted.

Learner, Mounting, &c.—F. G., Kew Bazaar, Kew.
Printer and Toner.—H. Lane, Margaret-rd., New Barnet, Herts.
Operator and Retoucher, at £3 10s.—X., 43, Pier-st., Ryde, I.W.
Assistant Operator (general).—Chloride, *Photo. News* Office.

Employment Offered.

Experienced Photographer in City office.—Z. Y., *Photo. News* Office.
Dry-plate Maker.—Z., 6, Cranborne-st., Brighton.
Operator for India.—G. W. L., 11, Strathearn-pl., Glasgow.
Silver Printer at 39s.—F. Guy, 70, Patrick-st., Cork.
Retoucher, first-class.—F. Guy, 70, Patrick-st., Cork.
Articled Pupil.—Messrs. Downey, Ebury-st.
Retoucher, Colourist, &c.—Mr. Chapman, Clapham Common.

VOL. XXVIII. No. 1358.—*September* 12, 1884.

CONTENTS.

THE POTASH DEVELOPER.

THE worker with gelatino-bromide plates cannot complain of a lack of developers. Pyrogallic acid, ferrous oxalate, ferrous borate, ferrous sulphite, ferrous phosphate, various ferrous tartrates, hydrokinone, sodic hydrosulphite, &c., have all been used by different workers at various times. Only two, however, from this long list have really found favour, and have come into general use. These are pyrogallic acid and ferrous oxalate; but the latter, spite of its many advantages, has not found many advocates in this country, although it is extensively used by our continental brethren. When the atmosphere is clear, and the actinic value of the light can be correctly estimated, there is no doubt that ferrous oxalate is a most valuable developer; but in a climate like ours, where the light is so variable, and where the atmosphere is so frequently obscured by mist, it will hardly give general satisfaction. It gives off no noxious fumes, does not stain the plates nor the fingers, produces bright, sparkling negatives, which print quickly, and have a good "tooth" for the retouching pencil; and, in short, answers well for correctly-exposed and even over-exposed plates; but has the great defect of being inelastic—that is, it cannot be modified sufficiently to meet all the demands of the landscape photographer, who has frequently not only to give his plates the minimum exposure, but to photograph very difficult subjects often indifferently lighted. Here a more vigorous developer is required—one that that can be modified at will to suit plates that have received very varying exposures, and yet give good negatives. Such a developer we have in alkaline pyrogallic. Ferrous oxalate has, and perhaps always will have, its admirers; but the fact that the great bulk of photographers, both amateur and professional, use the pyrogallic developer in some of its many modifications, proves that for general work it is most emphatically *the* developer for gelatino-bromide plates.

Yet pyrogallic acid, as generally used, has some serious disadvantages. Prolonged development stains the negatives a sickly yellow, which injures their printing qualities. It is true, the use of an acid alum bath will generally remove this stain; but this takes time—often a long time in the case of a negative badly stained—and time is precious. Then, if made up in solution, the pyrogallic acid rapidly absorbs oxygen, and becomes useless, so that stock solutions, made up in bulk, convenient as they are, cannot be used. To remedy this defect, citric acid and sodic sulphite dissolved in the pyrogallic solution have been proposed, and they doubtless have great power in preventing its rapid oxidation, and thus keeping the solution clear during development. In fact, by the use of sodic sulphite and citric acid, a solution of pyrogallic acid will keep good for months in a well-stoppered bottle. The use of solutions made up to some definite standard is to be recommended, while the practice of some operators of using the pyrogallic acid dry, and "guessing" at a quantity of two grains or three grains, is to be condemned as both slovenly and inexact. Could grains be weighed by guessing—especially with such a substance as pyrogallic acid—there would be little use for a chemical balance in the photographer's laboratory.

The introduction of sodic sulphite in the pyrogallic developer was a great advance, and did much to oust ferrous oxalate and restore pyrogallic acid its good name, which it had well-nigh lost through its staining qualities. Still, the use of ammonia, necessary to render the pyrogallic alkaline, was objectionable. The fumes of ammonia are most injurious to delicate lungs, and have perhaps, in many cases, done much to induce an attack of pneumonia. Then, strong solutions or prolonged development frequently will fog the plates, and it is always more or less uncertain how much bromide should be used as a restrainer. Too much or too little will equally spoil the plate. Again, some plates will stand almost any amount of ammonia, but when an excess has been used, as in developing a plate that has received an "instantaneous" exposure, the negative is sometimes rendered so thin that no developer will bring it up to printing density. Again, when a solution of ammonia is made up in bulk, it soon loses strength by the evaporation of the volatile alkali, while the use of the dropping tube in the dark-room is decidedly a nuisance.

Solutions of the fixed alkalies, such as potash and soda, are free from these objections; they can be made up in bulk to any standard, and do not deteriorate by keeping. Common washing soda has been advocated by many, and certainly has advantages, not the least being its cheapness, and the fact that it is found in every household; but as it cannot be made up as a very concentrated solution, it is inferior to carbonate of potash, which is far more soluble, and, at the same time, possesses other advantages over carbonate of soda.

In the PHOTOGRAPHIC NEWS for 1883, page 385, we gave Dr. Stolze's formula for a potash developer, which was found in practice to give good results. Since then, on August 1st last, we published a formula as used by Mr. Beach, which, judging from certain experiments, appears to present some advantages over that of Dr. Stolze. We here repeat it for the benefit of those among our readers who may not yet have tried it:—

No. 1.—Pyro Solution.

Warm water	2 ounces
Sulphite of soda (chem. pure) 437 grains to the ounce	2 ,,
When cold, add—	
Sulphurous acid	2 ounces
Pyrogallic acid	½ oz. of 218 grs.

No. 2.—*Potash Solution*

A.—Water...	4 ounces
Chem. pure carb. of potash (437 grs. to oz.)	3 ,,
B.—Water	3 ,,
Chem. pure sulphite of soda (437 grs. to oz.)	2 ,,

Combine A and B in one solution. Both the pyro and potash solutions should be kept in well-stoppered bottles. To develop a whole plate that has had an "instantaneous" exposure, take 3 ounces of water, and add to it ½ ounce of No. 1, and 3 drachms of No. 2. This will usually bring out the image rapidly, and with full density. If necessary, more of No. 2 may be added, 1 drachm at a time, until the image appears. It will be noticed that the percentage of pyro is very large—about 44 grains per ounce—and this proportion may, with most plates, be reduced with advantage, or the negatives will often be too dense for printing. In fact, when using a "10 times" plate for rapid work, we found that half, or even less than half, the pyrogallic acid prescribed above was ample.

To give the developer a fair trial, we exposed a certain number of plates by means of a rapid shutter, and others by the lens cap, on different subjects, and under different conditions of lighting. All the plates used were those marked "5 to 10 times collodion;" none of the more rapid type were tried. On developing the plates exposed instantaneously, in each case the image made its appearance in a few seconds, and with plenty of detail in the shadows. Development was complete in about five minutes; in fact, in the case of the plates exposed in full sunshine, development had to be stopped sooner, to prevent the high-lights becoming hopelessly dense. The negatives were next placed in the hyposulphite without washing; when fixed, they were slightly washed, and examined in a good light. No spots nor stains were visible; each negative was of a clear bluish-black colour, perfectly clear in the deeper shadows, and very vigorous.

For plates which had received exposure by hand, we used the developer as recommended by Mr. Beach:—3 drachms No. 1, and 1 drachm No. 2 in 3 ounces of water. For subjects in strong sunshine, we found this too vigorous unless diluted with twice the volume of water recommended in the formula; otherwise plates that had received an exposure of one second with No. 5 stop of a rectilinear lens appeared somewhat over-exposed. Those that were exposed more rapidly, "cap off and on," gave far more satisfactory negatives, using the same stop; but even in the case of plates exposed on subjects in moderate shade, or on a dull day, all came out more vigorously by using the developer in a more dilute form.

One plate was exposed on a dull, drizzly day—subject, a canal lock; exposure rather less than a second with No. 4 stop. With the ordinary pyro and ammonia developer, this plate would probably have shown some signs of under-exposure; as it was, it developed sharply and well, showing all the detail in the dark shadows of the lock gate.

The last plates, tried with the potash developer, were exposed on a dull but clear day—subjects, pretty "bits" in a rustic village. A single lens was used with $\frac{f}{45}$ stop, and in each case an exposure of less than a second was given, as a high wind was blowing. All, on development, gave fully-exposed negatives.

It would appear from these trials that plates developed with potash require somewhat less exposure than when ammonia is used, which is an advantage in instantaneous photography, and in landscape work generally, where it is often difficult to get satisfactory negatives on a windy day, owing to the movement of the foliage. The entire absence of spots and stains on the negative is a quality that cannot be too highly valued, not only on account of the improved appearance of the negatives, but also because they print so much quicker.

It is possible to develop several negatives in the same solution, but our experiments lead us to think that not more than two can be developed thus; for although the solution does not become turbid, it becomes much less vigorous after being exposed to the air for several minutes. Care should be taken to obtain absolutely pure chemicals, otherwise the developer may not give satisfaction.

Briefly, the results of our experiments would appear to be these:—The potash developer can be prepared in a highly concentrated solution, which only needs dilution with water to various degrees of strength to suit any kind of exposure. It is clean, very vigorous, needs no restrainer, gives no fog, and the colour and printing quality of the negatives developed by it are all that can be desired.

HOW DR. E. ALBERT TREATS HIS NEGATIVES OF PAINTINGS.

IT is generally known that Dr. E. Albert is engaged at Munich in photographing oil paintings by the electric light, isochromatized collodio-bromide plates being used; and the following particulars as to the after-treatment of the negatives will be read with interest.

The negative varnish used consists of:—

White shellac	100 parts
White resin (colophony) ...	70 ,,
Sandarac	80 ,,
Venice turpentine	60 ,,
Alcohol	2,000 ,,

On the back of the plate a matt varnish compounded as follows is used:—

Matt Varnish.

Ether	450 parts
Benzole	250 ,,
Sandarac	50 ,,
Chloroform	50 ,,
White resin (colophony)... ...	5 ,,
Canada balsam	5 ,,

The resinous materials are first dissolved in the ether, and the solution is filtered, after which the benzole and the chloroform are added.

The above is a very excellent receipt for matt varnish—indeed, better than many which we have tried—but it is necessary to use the genuine benzole, not the light petroleum sold under the designation "benzoline."

On the surface given by the matt varnish the necessary work is done by means of the lead pencil and the stump, after which the matt varnish may be removed from those parts where it is not required by scraping, or it may be rendered transparent by being painted over with a solution of shellac in aqueous borax solution (this solution is made by boiling a saturated solution of borax in water, with as much bleached shellac as it will dissolve).

The matt varnish is covered with a protective coating or final varnish made as follows:—

Gutta-percha	15 parts
Purified oil of turpentine ...	300 ,,

This protective varnish does not destroy the effect of the matt coating, whereas most other varnishes would render it transparent and dissolve it.

The above details will not only prove of value to those who may have occasion to work upon negatives of oil paintings, but also to photographers who may find it necessary to do much retouching upon their plates.

MOUNTING AND COLOURING PHOTOGRAPHS IN IMITATION OF OIL PAINTINGS.

THE hundred-and-one methods of endeavouring to obtain artistic results in colouring photographs without the possession of artistic skill seem to depend in the main on similar principles; and putting aside the general fact that a coloured photograph is almost of necessity very im-

perfect, fairly satisfactory results may be obtained by the method termed "canvasine," of which the following description is extracted from a recent number of *Household Words*. The prints should be made from fully-exposed (and not over-dense) negatives, and on thin paper not too highly albumenized. As it appears that the main object of the article, which we quote, is to call attention to secret preparations such as *canvasine solution*, *adhesive medium*, and *canvasine medium*, it may be mentioned that for mounting the paper print, which has been reduced in thickness by glass-paper, a hot ten per cent. solution of gelatine answers admirably, the print being soaked in the gelatine solution. Before proceeding to lay a second sheet of canvas on the face, or to colour, it is necessary to clear away all gelatine from the face of the print by means of a sponge charged with warm water. Ox-gall may be used instead of the preparation termed canvasine medium, and ordinary water colours are suitable.

Anyone familiar with photographic work will diverge somewhat from the subjoined directions, which we, as before stated, quote from *Household Words*:—

"To those who are fond of colouring and painting, and yet how are not gifted with a talent for drawing or designing, or with any large amount of knowledge of the art of producing a pleasing picture, canvasine will be an agreeable amusement. This work does not claim any high place among the pursuits that require a lifetime of labour to bring to perfection; it is simply known as a process whereby an ordinary photograph, taken upon paper, can be coloured and mounted so as to resemble an oil-painting. The way to transform a mere black-and-white design into a coloured picture is very simple, and requires no knowledge of drawing or even of painting; the photograph supplies the outlines, and the impression is not obliterated by the introduction of colour, as paints are so prepared that they amalgamate with the chemicals used in producing the photograph, and sink into, and become incorporated with, the paper. By this arrangement, the shadows, half-tints, and lights of the black-and-white original design are still prominent, and appear like natural shadows in the colouring.

"The system employed in thus painting and allowing the colour to sink into the photograph consists of laying on coats of colour, and wiping them off before more than a tint has become absorbed, the colours being so strong that, if allowed to sink at once into the paper, a crude, hard colouring would be produced. The only art the student has to acquire is the art of patiently laying on successive washes of colour, and wiping them away, until the tint that has sunk in, and been retained by the photograph, is a soft, natural colouring, resembling in its smoothness ivory-painting. In order to transform the photograph into an oil-painting, it is stretched on picture-canvas and rolled with a ruler, so that the coarse thread lines of the canvas show through the photograph in the same way that canvas appears through an oil-painting, and, after the amalgamated tints have been obtained, rough strokes of opaque colour are worked on, and allowed to remain on the surface to imitate the rough lines of oil colouring.

"The manner of painting is as follows:—Choose a clear photograph of one figure only, or of some very distinct group, and match it as to size with the canvas and wooden frame; cut the photograph a little smaller than the wooden frame. Lay the photograph, face downwards, on a drawing-board, and rub it with fine glass-paper, just to take away a little of the thickness, but not so as to remove it unevenly. Drop the photograph into a soup plate, into which pour canvasine solution, so as to cover the picture; let it soak five minutes in the solution, then pour the solution back into the bottle; lay the photograph face downwards on the table, and dab off any of the solution remaining on the surface. Well wet the canvas to be used (which must be larger than the photograph, with a margin of an inch and a-half all round), and stretch it on a drawing-board, holding it down with drawing-pins. Cover the back of the photograph with a good coating of adhesive medium, and lay it on the canvas, so that it is placed in the centre of the latter, and the lines and threads of the canvas run straight with the lines of the photograph. Over the photograph place a piece of spare and dry canvas, arranging its lines in the same direction as those on the wet canvas. Take the roller and firmly roll it backwards and forwards over the canvasses and the picture, until all the creases and air-bubbles on the latter are pressed out; it firmly adheres to the first canvas, and the thread lines are brought out upon it. The spare piece of canvas should be lifted from time to time to see the progress made, and extra pressure applied to any parts of the picture that require it. Extra adhesive can be used, so that the edges of the photograph stick firmly to the canvas. Leave the picture stretched on the board for three hours or more, and until it has perfectly dried; then commence the colouring.

"Before painting, lay over the picture, with a sponge, a little canvasine medium, then put a little of the medium into a tumbler of water, and use that to mix the colours with. Prepare a wash of flesh No. 1, fill a brush with it, and pass it quickly over the complexion, then with a clean sponge wipe the wash off. Some of the colour will have sunk into the photograph, and will look rather spotty; repeat the washes and the wiping them away, until all the greasiness of the surface has been overcome, and a pure colour obtained. Apply flesh No. 2 in the same way to warm the cheeks, and flesh shadows to the sides of the face, putting these over the first washes. Tint round the eyes and nose, the temples, under the chin, and other parts of the face, and when all these places are coloured, amalgamate the whole together with washes of flesh No. 1 laid over the whole complexion. Mark out the features, the lips, the eyes, and eyebrows, with more decided colours, and do not wash these last touches off unless they have been laid on too strongly. The draperies, backgrounds, and other details are all obtained and coloured in the same way—full, clear washes of the desired tint laid on and taken off, and final touches put on with pure colour.

"The picture painted and dry, it requires fixing to the wooden stretcher. Neatly fit it to the frame, and take hold of the margin of clean canvas, and nail this to the back of the frame, so that the canvas is quite stretched out and smooth. When this is accomplished, take the eight small wedges given with each frame, and hammer these firmly into their proper apertures. All canvasine pictures are much improved by being framed in deeply-sunk and wide gold frames, as by the use of these frames the picture does not come close to the surface, and the simulated effect of an oil-painting is much enhanced."

Practical Papers for Beginners.

No. 8.—TAKING A PORTRAIT.

It is easy to see that the number of amateur landscape photographers is very much greater than that of the unprofessional portraitists who work with the camera; but considering that good portraits may be taken without in any way involving an expenditure of much time in arranging backgrounds or screens, it is a little surprising that portraiture is not more generally practised by amateur photographers. We hope, however, that the brief instructions which we shall now give will serve to enable any person who has overcome the essentially technical difficulties incidental to the production of a properly-exposed and developed negative, to make a passable portrait.

Supposing a person to be standing quite in the foreground when a view of a brightly-illuminated landscape is taken, and the face of the person is directed towards the camera, it will generally be found that the result is anything but satisfactory as far as the portrait of the individual is concerned, even although the landscape may be excellently represented in the photograph. One reason of this is, that far more exposure would generally be required to do justice to the face than is necessary for the bright landscape background; and, moreover, the flood of light from the general view quite overpowers that from the figure, and makes it feeble and dark in comparison. Let us suppose now that the camera and the individual remain in the same position, only the flood of light coming from the landscape is cut off by a large screen of a dull neutral tint, placed behind the person, this screen being large enough to shield the lens from all rays coming directly from the landscape behind. An exposure being now made

—but a longer one than before—it will be found that the result is far nearer what one requires in a portrait; the modelling and expression of the face coming out with a perfection hardly to be realized when a landscape forms the background of the picture. Still the portrait will have faults, it being very probable that the top of the head may be so brightly illuminated as to give the appearance of grey hair, and that delicate shading of one side of the face which forms so admirable a feature of the best portraits is likely to be altogether wanting.

The first necessity in portraiture is, then, some kind of a shading surface, or opaque background; and the next is some kind of a shade to go overhead, in order to screen off the more vertical rays; while the fact of a good portrait being occasionally—indeed, very occasionally—taken without these adjuncts does not affect the general statement.

The amateur may use a background made of cloth stretched on a frame, or he can often use with advantage an outside wall, especially if smooth and plastered, or overgrown with a climbing plant. Still we are inclined to recommend that the first attempts at amateur photography should be made in a room, it being possible to very nearly imitate the conditions which obtain in an ordinary photographic studio by carefully arranging matters in an ordinary sitting room having a large window and receiving its light from the north.

The subjoined cut represents one of the studios in which the late M. Adam-Salomon made some of his best pictures, and it will be seen that the principal light enters through

the side window, which is of clear glass, and has a northern aspect, while some illumination is afforded by the half roof of frosted or partially obscured glass. A background of fabric stretched on a wooden frame is behind the sitter, and the wall to right of the camera is not so dark in tint as to prevent the reflection of enough light to ensure full detail in the shaded side of the face.

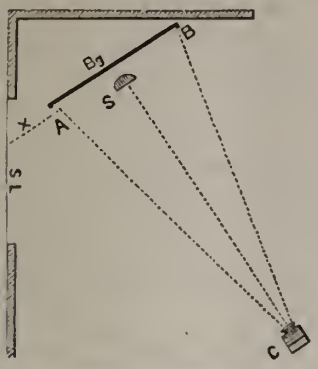
Here, then, we have the most ordinary type of glass house or portrait studio, reduced to its simplest expression, and all the essential conditions can be easily ensured in an ordinary siting room, lighted by a large window; the white ceiling throwing down quite sufficient top light in most cases.

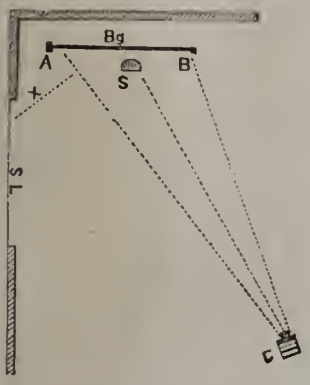
A word as to the background. We may suppose that the beginner in portraiture does not wish to use painted backgrounds, and it may also be supposed that, for the present at least, he will prefer using a plain flat sheet rather than such concave or set backgrounds as are so successfully employed by many of our best photographic portraitists, especially as for the plain background no permanently rigid frame is required. Thick brown paper may be obtained in the roll up to about sixty inches wide, and the material known as Empire cloth, and manufactured by Messrs. Avery, of Great Portland Street, is made up to a width of nearly nine feet. To make a portable background a rectangle of either of these materials may have a stout wooden roller fastened to one edge, and a strip of wood to the opposite edge, so that the whole can be rolled up map fashion, and carried about without inconvenience. Two wooden uprights provided with feet may serve very conveniently for supporting the background by its top lath, and with the exercise of a little ingenuity a very convenient and portable arrangement may be constructed; but it is often possible to extemporize a fairly satisfactory background by tacking a blanket to a large kitchen-horse. Those who prefer to make a background by distempering unbleached calico must mix whiting, water, and size to a convenient consistency, and tint the mixture with some finely-ground pigment, such as burnt sienna; the calico must be stretched on a frame, and not removed until dry. Five feet by seven feet is a convenient size for a background intended for indoor use.

The subjoined diagrams may be given as examples of the way in which the background and camera may be placed in relation to the light, and it may be mentioned that it is by no means essential that the background should be set at right angles to the axis of the camera.

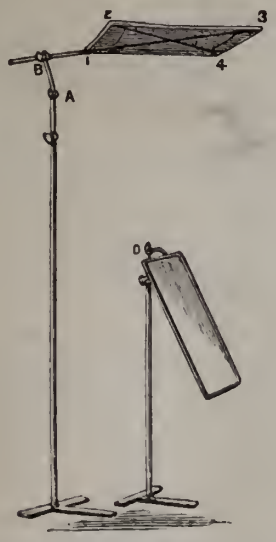
It must not be forgotten that a reflector will often be required to lessen the contrast between the lighted side of the face and the shaded side. This reflector must be so placed on the side opposite the light as to throw just the required illumination on the face of the sitter, and yet must be so arranged as not to show in the picture. A white sheet placed over a kitchen horse often makes the

most convenient reflector, but a large cheval glass on a swing frame is frequently to be preferred. Portable



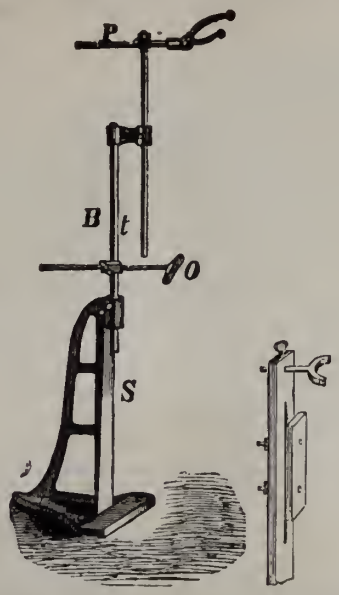


screens or white reflectors, mounted as shown below, are frequently of much value for shading or lighting up any part of the face that may be improved by such treatment.

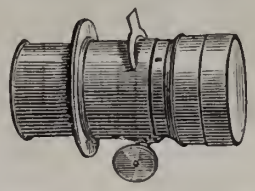


For portraiture, a head-rest is frequently required by the sitter, and he should be told rather to use it as a means of knowing whether he has moved from his position, than as an actual support for the head, and care must be taken so that no portion of the rest or its mounting shows in the picture. Such a head-rest as that shown below—provided also with a support for the hips—is almost an essential to the professional photographer; but the amateur will generally prefer to use a simpler and cheaper arrangement, which can be fastened to the back of a chair.

We have said nothing as to the lens best suited for portraiture. Indeed, we have said but little as to lenses at



all up to the present time. The lens known especially as the portrait combination, or Petzval lens, is familiar, as to the external configuration of the brass work, to almost



everyone. It consists of two lens-combinations, and generally has a working aperture of about $\frac{f}{4}$ when the stops are removed. For a head-and-shoulders portrait taken in a room as now suggested, a stop corresponding to about $\frac{f}{8}$ or $\frac{f}{10}$ is most suitable, as when the fuller aperture is used there is a difficulty in getting the whole of the subject well in focus. The lens used should not have a focus too short (see p. 515) in relation to the size of the portrait taken, it being a good rule to employ an objective having a focal length equal to about double the longest dimension of the portrait; and if this precaution be observed, any photographic lens may be used successfully for portraiture. Still, if a lens having a very small working aperture be used for portraiture in a room as now treated of, the exposure required may be inconveniently long, and for this reason it is desirable to have a special portrait lens.

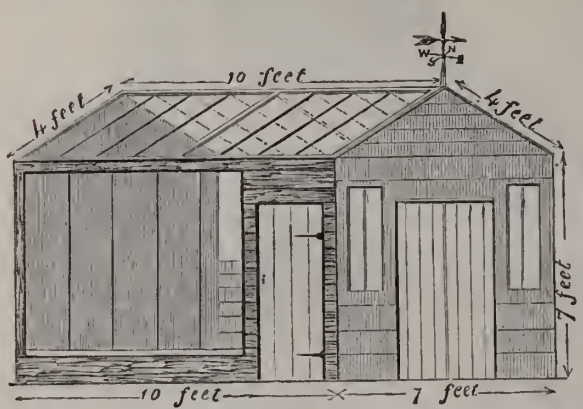
It is not necessary to say more in this place regarding the taking of a portrait, as when the beginner has carried into practice the elementary principles here laid down, he may study with profit the various comprehensive articles on lighting and posing which have appeared from time to time in the Photographic News; but we will merely quote Mr. Bockett's description of his experience in making such a simple glass house or studio as any active and ingenious amateur may easily construct for himself at a small cost.

Mr. Bockett says:—

"Now the chief end in view was to make some erection that could be easily removed, not take up too much space, be watertight, and give a range of, say, twenty feet. The first was obtained by having the place built up of sashes, there being four in the roof (which stands due east and

west); two in the north side, which is close to a low wall, so that none are required below them, and one large sash on the south side; the remainder of the house being composed, for the most part, of feather-edge boarding, the skeleton to which all the foregoing is attached being simple 2×2 inch quartering; the joints are covered with canvas, and painted, which has, hitherto, as to keeping out the wet, answered very well. To enable me to get my range, at the eastern side (in which two small windows are placed), I have two folding doors, simply made of beaded boards nailed to some cross-pieces, which, opening outwards, give me any distance I may require, and effectually protect the sitter, accessories, &c., from the weather. Next to the larger sash before alluded to, and near to the folding doors, is another door, in order that access may be obtained to the interior without disturbing the camera or anything else that may, for the time being, occupy the space between the folding doors.

"Some battens, laid edgewise upon the ground, receive the flooring planks, which would have been all the better if closer together and attached at each end to the bottom frame of the skeleton. The folding doors bolt top and bottom, from the inside, and the side door is locked from without, so that all within is properly secured.



"The shaded part represents wood, mostly feather-edge.

"To equalize the light from the south the whole of the large sash is covered with thin calico blinds, and the same with the roof, except that portion over the head of the sitter, which is covered with paper."

In order to effectually control the light in such a miniature glass house, it would be necessary to provide movable blinds in addition to those referred to by Mr. Bockett; and the beginner must remember that the most complete success in portraiture is only attained by patient study and careful observation.

PHOTO-ASTRONOMY AT THE RIFFEL.

BY C. RAY WOODS.

No. III.

I PROMISED in my last to give readers of the NEWS an account of a photographic excursion here, and hence I am afraid that the title at the head of this article is to some extent a misnomer. Photographic excursions are for me rather rare here, for I am placed in a little difficulty. Successful photographs of the mountains require a clear atmosphere, but on clear days it must be pretty obvious to all that my scientific work requires all my attention. How do I manage? Well—to make a clean breast of it—I take my views, as well as my holiday, on Sunday. Frown not, gentle reader; if you were here, even here in this earthly paradise of English clergymen, you would do the same if you came for work rather than pleasure. Besides, have I not a good precedent in the example set by an English clergyman I met coming from the Gorner Grat one Sunday morning, and who, when I jocosely threatened to tell his parishoners, gravely replied that he had been up to worship?

I think it necessary to vindicate myself thus far; for without some explanation the captious critic might enquire where the corona was, if I told him that one clear fine morning I went to the "Cima di Jazi." I did not take my camera on that occasion, contrary to the advice of a gentleman who said that the panorama was very fine. That was the very reason I did not take the camera, having had no experience in taking panoramas, and being fearful that I might have all my trouble for nothing. What few mountain views I had taken up to that time had turned out unsuccessful, for reasons I shall presently enumerate. Again, negatives forming a panorama must be alike in density; if this is not the case, the results have little artistic value, few plates being complete in themselves, and simply forming part and parcel of the whole. I started out, therefore, in company with Captain Abney's assistant, Mr. Jackson, and a guide, neither Mr. Jackson nor myself taking any apparatus.

Up towards the Gorner Grat, past the Riffelhorn, and along a narrow path three hundred feet above the Gorner Glacier. We had to go carefully at first, for it was three o'clock in the morning, and we had only the stars to light us on our way. Presently, dawn began to break, and revealed the glacier below. Looking behind us we saw the Riffelhorn, and the Matterhorn a little to its left, but away in the background, yet great and majestic as it always looks. Here was the subject of one picture which I hope to take at the first convenient opportunity. Then we soon got down to the glacier, and commenced a walk over the slippery ice till we reached a little halting place sheltered by the Stockhorn, where we stopped for breakfast. Then commenced a long tramp of three hours' duration over the crisp crackling snow. It is a monotonous walk, say most people. We did not find it so. The scene of our daily labour far behind us, we walked briskly on, rejoicing in our day's freedom. Crunch! crunch!—no soft wet snow causing one to sink in at every step; we had started too early for that. Each white particle of snow glistened like a diamond as soon as the sun rose above the great white plain, and in the early morning the mountains looked as they never look when seen from grassy slopes or rocky heights. One has no idea of distance here, and the mountains that towered around us might have seemed close at hand, instead of a mile or two away, had we not known better. To the mountaineer, the trip to the Cima di Jazi is but a mere walk, but this mere walk gives one no bad idea of the grandeur of the Alpine heights. The busy tourist who rushes from place to place, and looks at the mountains from a distance, has no better conception of them than he who only crosses the Channel has of the sea.

Had the walk been monotonous, which it was not, the view from the summit, over 12,000 feet high, would have rewarded us—Macugnaga at our feet, Monte Rosa, the Lyskamm, Castor and Pollux, the Breithorn, the Matterhorn, and other peaks around us. The Italian side presented a number of small peaks projecting above a smooth sea of green haze interspersed with fragments of cloud. But the most interesting sight to me, and but for which I should not have said so much concerning this little trip, was the remarkable haze round the sun. A pink glow extended for some twenty degrees around the sun, and at the extremity of this glow was a vivid and well-defined red ring. If ever I admired my deadliest enemy, I did then; and it is my deadly enemy. This phenomenon seems not to have been seen in Switzerland till this year, and has been put down to the volcanic dust emitted during the Krakatoa eruption, the same cause put forward (with something more than mere plausibility) for the sunsets of last year. That it is due to suspended particles of some character is certain, but further than this

W. GRIGGS, PHOTO-LITH.

C. PURDON CLARKE, COPYRIGHT.

JEYPORE PALACE. THE TOWER OF THE WINDS.

PATENT OFFICE LIBRARY

I will not venture to express an opinion. On every clear day we have had here, this peculiar haze has been more or less apparent; and the more strongly it has appeared, the more difficult has it been for me to get on my plates anything that one could say with positive certainty is truly coronal. The less of this haze round the sun, the better have been my results. M. Loppé, a well-known painter of glaciers, and a member of the Alpine Club, told my friend, the German artist, here, that his "effect" of the sun behind the Matterhorn would be considered false by those most capable of expressing an opinion, if it was not carefully labelled "The Matterhorn, in 1884."

I can generally find an hour, sometimes two hours, to spare before dinner, and several times have I had shots at the mountains, or, by walking up to the Gugel, only forty minutes' distance, taken a picture of the Findelen Glacier. As I have already said, most of my first attempts were failures. It is very provoking to take out half-a-dozen plates and not obtain one passable negative. The mountains are so bright compared with the foreground, that it was some time before I could decide what exposure to give. "Expose for the shadows, and let the high lights take care of themselves," says the good old advice, which I followed faithfully in England, with very fair results last year. I tried to follow the same advice out here, but the high lights would not take care of themselves. I could not prevent reversal of the high lights, and consequently obtained very thin negatives. I gave quicker exposures, and then obtained better results. Mr. Donkin, whom I met here, says that he cannot expose too quickly for the snow mountains, and I can fully endorse his experience. Now I expose for the high lights and let the shadows take care of themselves; and they take care of themselves very well. When the sun is shining, the foreground is well enough exposed to yield sufficient detail and ample sparkle.

I have had some very amusing experiences in attempting to photograph the goats and other livestock here. The goats were rather shy at first, and we had to spend some time, trouble, and salt to tame them. They are too tame now, and one old goat comes rubbing round my tent when he is least wanted. A little salt strewn on the rocks at the base of the Riffelhorn after we have coaxed the goats to the desired spot, and we soon get their portraits. One day I walked up to some cows that were standing in a good position, and planted my camera. Instead of moving off as cattle generally do in England, their curiosity induced them to examine the camera, and I had to beat a retreat. This happened several times, till at last they got used to it, and then came my chance. With the aid of Mr. Jackson and the artist, a cow was actually posed on one occasion, and successfully taken when a hand was held up to induce her to look in the right direction for two seconds.

As I stated in my last, we went for a little excursion on the glacier one afternoon. The "we" consisted of Mr. Jackson, who was helping me here for a few weeks, myself, and the Junior Partner; the Junior Partner carrying the apparatus. The Junior Partner, I may mention, is a young lad engaged by the German artist already mentioned, to carry his apparatus, and as the day was not only dull, but even drizzling, his services were not required for his legitimate duty. He is a sharp, intelligent boy, willing and good-humoured. When he marches along with easel and canvas on his shoulders, and comes to a picturesque spot, he turns to the owner of the paraphernalia he is carrying, and says, "Let *us* paint this," or "Let *us* paint that," like the Irish organ-blower who told the organist, "How well *we* played to-day." Hence arose the nickname of "The Junior Partner," a title he is rather proud of. The Junior Partner soon took us down to the glacier, and brought us to some good crevasses, which I proceeded to take stereoscopically. The dull day softened down the contrasts of light and shadow, and some very successful negatives were the result. We soon found that the Junior Partner was a very important individual, for not one photograph was complete without him. It is true that we did not always think so, but there was no misunderstanding the Junior Partner's opinion on the subject. No sooner was a camera pointed, than he proceeded to the place himself in a direct line with the lens, unless he was directed to some other spot, or else he proceeded to climb on to the topmost pinnacle overhanging a dangerous crevasse. On several occasions we expected to see him fall down and hurt himself, but I now know that to be impossible. He said that he could take us back to the hotel by another way than that by which we came, and he kept his word.

I have solemnly sworn never to go that way again with less than ten guides and a thousand feet of rope. Climbing the Riffelhorn was child's play compared with it. We had the satisfaction afterwards, though, of showing the bunch of Edelweiss that we had plucked in plenty from the places where few save natives cared to look for it. But to do the Junior Partner justice, so far as his desire for being photographed is concerned, there is very little hardship in having to introduce an intelligent boy into a picture, and one of my little stereos, representing a pool of water in front of a cave in the ice, derives what little merit it may possess, to the presence of the boy sitting on the rocks in the foreground.

Of course I have climbed the Riffelhorn; it furnishes a nice little constitutional before dinner. On the first occasion I went with a guide and rope, and I have an elegant—well, perhaps, *not so very* elegant—*souvenir* of that event in the shape of a bad photograph of myself and the other venturous spirits who made up the party. I have not been up the Matterhorn; I intend to wait till they run a carriage road or railway up it, blow off the top to make it flat, and put a railing round.

"All work and no play makes Jack a dull boy." I have now told you all about my play—play which has not been obtained at the expense of my work. The work is going on as satisfactorily as cloud and haze will permit, and I hope to tell my readers something about it shortly.

Notes.

When Mr. C. Purdon Clarke read his paper on the "Street Architecture of India," before the Society of Arts, he showed a series of characteristic photographs upon the screen, and of these photographs, which have already been alluded to in our columns, two are presented this week as a supplement to the PHOTOGRAPHIC NEWS, Mr. Griggs, of Peckham, having made the prints by photo-lithography.

"The Tower of the Winds at Jeypore," says Mr. Clarke, "is placed at one angle of the great palace, and almost entirely constructed of stone, has open lattice work in its multitude of projecting windows, affording, in the interior, the combined open air and shade so necessary in such a climate. The shops on either side are built against the palace wall, and where they and the other buildings occur the monotony is relieved. Similar shops extend along the whole front of the palace, which, except at the large gates, would otherwise present a frontage of bare walls, of great height."

The second picture—"A Merchant's Dwelling over a Shop, Amritzar"—shows strikingly the elaborate architectural detail which is sometimes lavished upon buildings erected for trading purposes.

It must not be forgotten that the latest time for sending in pictures to the Pall Mall Exhibition is nine o'clock on next Thursday week, the 25th instant.

Painting portraits on silvered glass—in fact, on an ordinary mirror—is a Royalty-honoured fad of the present day; but few photographers know how well a carbon print looks if developed upon the surface of a looking-glass.

In making the carbon print it is advisable to avoid wetting the back of the glass—a very easy matter to arrange, if care be taken. As, however, it is necessary to cover a picture of this kind with a plain glass, it is an excellent plan to make the carbon print on the plain glass, and then to mount this glass over the mirror; the picture being between the two. This mode of working does not necessitate the use of a reversed negative.

Artemus Ward had a curious theory that a comic paper should sometimes contain a joke; but his countrymen of the present day do not seem to think with the genial showman, if we may judge by a parallel case. The late meeting of the American Photographers' Convention at Cincinnati, at which, to quote the president of the Chicago Association, "*not one word was spoken about photography*," must have been a curiosity in its way. Photographers travelled hundreds of miles to be present—there was one even from far-away England—to see a vast store of photographic sundries, and attend solemn meetings to discuss—not the art and science of photography, but—prices.

Nevertheless they were nearly let in for a bit of knowledge from an unexpected source. The English photographer, Mr. A. L. Henderson, in the innocency of his heart, offered to give a demonstration of emulsion making. This would never do. Why, photographers would be making their own plates next: then what would become of the stock-dealers?

Even the exhibition of pictures was not unadulterated with trade. The chief exhibits were there only for the purpose of showing the merits of various makers' dry plates, and the greatest attraction in the whole bazaar was a model—a very beautiful young lady draped in Greek costume—who was hired to pose before a manufacturer's stock of backgrounds—to teach the modest citizenesses of the States how to conduct themselves when they go to a photographer's, we suppose.

How different all this is to what is done in England! How slow we are! how behind the times! We are so jealous of introducing anything like "shop" into our exhibitions that, although new designs in apparatus are allowed to be shown, nothing like a display of tools is tolerated, and anything in the shape of an advertisement is removed by the ruthless hand of the Secretary; while the wildest imagination would never suggest the exhibition of a real live young lady, however beautiful, with or without a Greek dress.

It is proposed to raise a fund to defray the cost of a memorial to the late Rev. F. F. Statham, vicar of St. Peter's, Walworth, and well known to photographers as the President of the South London Photographic Society. It is not yet decided what form the memorial—which will be placed in St. Peter's Church—is to take.

Those who have been troubled by the deterioration of plates where in contact with the packing paper, or even near it, will be interested in knowing that Mr. H. J Newton, of New York, has found sodium hyposulphite in samples of cardboard and paper which damaged plates. A grooved box made of cardboard containing hypo, ruined plates in the course of eight months. It is clearly the duty of plate makers to give attention to these matters, as original packages of plates are often kept for months before being used.

How, then, should plates be packed? Mr. Newton not only asks this question, but endeavours to answer it; his own recommendation being either to use grooved tin boxes, or to keep the plates separate by means of cord or string, after the fashion of Mr. Harrison.

Curiously enough, those who devise clever methods of keeping dry plates from contact with each other, assume the need of separating the plates. If, however, they are simply laid on each other, so as to form a solid block, and tightly wrapped up so as to preclude all possiblity of any grinding action taking place, it is a very rare thing for the films to be damaged during a journey, and the probability of mischief from impurities in the packing material is reduced to a minimum.

If the Czar of all the Russias is fond of collecting photographs, he must be in possession of a most comprehensive assortment of the portraits of his loyal Polish lieges, for no one, it seems, was admitted to the enclosed ground on which the grand review was held at Warsaw who could not produce at the barriers a ticket of admission endorsed, so to speak, by the photographic presentment of its bearer. The Warsaw photographers, it is said, highly approve of this precautionary regulation; but the loyal lieges aforesaid, according to the feeble joke of an English correspondent, regard it as a new tax on their devotion, or, at all events, as a new kind of municipal rate—a "port-rate," that is to say.

Messrs. Benque and Kinderman, of Hamburg, and Fritz Eilender, of Cologne, take the gold medals of the Berlin Society this season, and silver medals are awarded to Haufstängl of Dresden, Dreesen of Flensburg, Möller of Barth, Wettern of Hamberg, Schüren of Hamburg, and Gaillard of Berlin.

A correspondent writes: "In last week's PHOTOGRAPHIC NEWS Mr. J. H. Jennings commences his letter to you with the statement 'French triplets cost 9s.' If this be so, sir, triplets are evidently one of the things they do *not*

manage better in France, for in this country, need I remind you, any well authenticated 'English Triplets' are worth £3.—Yours, &c., A mother who has received the Queen's Bounty."

Occasionally the surface of a gelatino-bromide negative is so smooth as not to be marked by the retouching pencil. In such a case it suffices to dip the plate in a solution of sodium silicate and to allow it to dry. One part of the dry silicate in thirty of water, or one of the thick syrupy silicate and twenty-five of water, gives a solution of a convenient strength.

The secretary of a well-known London Charity has taken time by the forelock, and announces for next season a Fancy Fête, for which the Albert Hall is to be turned into the semblance of the beach of a fashionable watering place. There are to be bathing machines, "pools" in the rocks, donkey-riding, nigger minstrels, a special brand of seaweeds, &c., &c.; and last, but not least, a number of active peripatetic photographers, who, from the way they will pounce on the visitors and compel them to be photographed for the good of the cause, will be doubtless well up in the use of the "instantaneous drop."

A Paris photographer offers a year's subscription to a comic weekly as an inducement to sitters; but the prize is only given to those who take at least twelve portraits and pay cash.

Sculptors should always have their work photographed. Owing to the late closing of the Grosvenor Gallery, Mr. Robert Barrett Browning found it impossible to send his statue of Dryope and her Serpent to the Brussels Exhibition within the period fixed. The Brussels authorities, however, happened to see a photograph of the statue, and were so struck by the merits of the latter, that they unanimously resolved to grant exceptional leave, and let the original in after other works were stopped.

According to the *California News*, it is only when Mrs. Langtry's face is mobile that its beauty is apparent. "It is," adds the critic, "a face wholly out of the domain of photographic art." We should prefer the opinion of the thousand and one photographers to whom the lady has sat

The mention of the popular actress reminds us that photography has certainly something to do with the prevailing tendency of actresses to change their costumes so repeatedly during a performance. Every different dress means a new photograph, and each new photograph an additional advertisement both for the actress and her *modeste*. Many ladies now go to a new play merely to see the heroine's series of elaborate costumes. A modern comedy might be appropriately announced, in fact, as being "in four acts and nine dresses!"

A photographer, staying at a watering-place on the East Coast, was much struck with the picturesque costumes of the fishermen, and arranged with a couple to make a series of studies. But he omitted to lay especial stress on the fact that they were to come in their work-a-day dress, and he was aghast to see two brawny fellows appear with clean faces, well-oiled hair brushed neatly into the corners of their eyes, flaunting blue and red satin neckerchiefs, and ordinary—very ordinary—coats and trousers. The worst of it was, the poor men were quite disappointed to find they were not to be photographed in their Sunday clothes! Why anybody should want pictures of them in their fishy jerseys and oilskin sou'westers they couldn't understand.

Patent Intelligence.

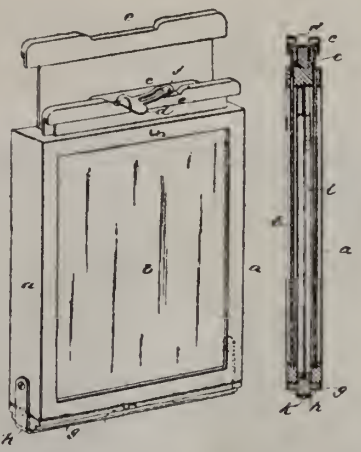
Patent Granted in America.

304,112. WILLIAM H. LEWIS, New York, N. Y., assignor to E. and H. T. Anthony and Co., same place, "Plate-holder for cameras."—Filed May 2, 1884. (No model.)

Claim.—1. The fastening for double-plate holders consisting of a clip arranged to fasten both shutters, and having a side movement sufficient to release either shutter while retaining the other in place, substantially as described.

2. The fastening for shutters of plate-holders, consisting of a clip fitted to slide on the frame of the holder, and pivoted to turn at either side for releasing one shutter, substantially as described.

3. In a plate-holder, the slotted T-shape clip *d*, combined with the shutters *b*, having recessed ends substantially as described.



4. In a plate-holder, the pivoted plate *h*, combined with the cap *g* of the holder, substantially as and for the purpose specified.

5. The pivoted fastening-plate *h*, apertured at *i*, combined with frame *a* and cap *g*, having a pin, *k*, as specified.

HOW TO PHOTOGRAPH MICROSCOPIC OBJECTS.

BY I. H. JENNINGS.

LESSON IV.—EXPOSING THE PLATE.

No rule can be laid down as to the duration of the exposure. It depends (1st) on the focal length of the lens used; (2nd) its aperture, wide-angle lenses being far quicker than those of low-angle; (3rd) the nature of the light used; (4th) the nature of the object, yellow and brown objects always requiring a prolonged exposure; (5th) the development. An operator who uses a weak developer will always expose his plates for an unnecessarily long time. The beginner will perhaps think the exposure the most difficult part of photo-micrography, but as he progresses he will alter his mind, and think the proper illumination of the object far more difficult.

Using a good paraffin lamp, and lenses of from 5 inches to $\frac{1}{16}$-inch, the exposures may vary from a fraction of a second to half an-hour. For instance, the larva of a flea, a very transparent object when properly illuminated, will not require more than half a second with the 2-inch objective; while with the same lens, a section of coal may require twenty minutes. The section of Alveolina lime-

SECTION OF ALVEOLINA LIMESTONE, HERAULT, BELGIUM.

stone figured below, although of a white colour, and apparently very transparent, had an exposure of fifteen minutes. As a rule, all rock sections will require a rather long exposure, as they stop a large amount of light. All sections

WING OF MIDGE (PSYCHODA).

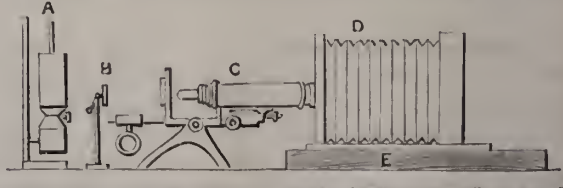
should be as thin as possible; yet a good colour is of more importance than thinness. The writer has a section of a tertiary limstone from Bengal, of a strong yellow colour, which he has often vainly tried to photograph satisfactorily, although the section is most admirably cut, and very thin.

The wing of a midge, here shown, will serve as a good example of a very transparent object, which yet has plenty of detail. This object had an exposure of one second: less would have sufficed with a more powerful lamp.

High powers, being used chiefly with very transparent objects, do not require the tremendous exposures that people generally imagine. A $\frac{1}{16}$-inch, when properly illuminated, will give a good clear image on the focussing screen five feet away from the object. When the writer first began using high powers, he heard such exaggerated statements about the difficulty attending their use, and the long exposures they required, that on first trying *P. angulatum*, he gave an exposure of an hour to this transparent object. On developing, the plate came out almost clear glass; only a faint ghost of the object could be seen on the plate. A subsequent exposure of fifteen minutes, under the same conditions, gave a fair negative. All objects are not fitted for photography, therefore it may be taken as a rule that if any object bears an exposure of half-an-hour with any lens, without being fully exposed, it is simply useless to attempt it. There is a little scarlet mite common in gardens, the scarlet Trombidium, which, owing to its colour, may be exposed for almost any period without getting any better photograph than a blank outline. Such objects should, if possible, be bleached before attempting to photograph them.

When magnesium ribbon is used as the source of light, the exposures become very rapid. The writer has never used this light with low powers, but he has found ten seconds to fifteen seconds ample for diatoms with the $\frac{1}{16}$-inch objective.

The dry plates recommended for photo-micrography are the most rapid in the market. The writer has used Swan's ten times collodion, and thirty times collodion; and while the ten times are excellent for low powers, he still prefers the thirty times plate for every purpose. He has also used plates still more rapid, and found them satisfactory in every way. Very rapid plates are often difficult to manipulate when used for landscape work, but when used for photo-micrography they become as easy to develop as any slow plate, while they have the great advantage of increased rapidity. The writer is not alone in advising the use of rapid plates, for the author of "Practical Microscopy" has obtained good results on Swan's fifteen times plate, while Dr. Sternberg, one of the most experienced and accomplished of living photo-micrographers, uses Eastman's instantaneous dry plates. The maker of the plates is of little importance. The writer has tried most of the makes in the market, and has got good results with all. The chief thing is that the plates be made of good hard gelatine. If a sample of plate be found to be prepared with soft gelatine, reject it at once. Frilling may be laughed at, but shrinkage of the film is simply ruin to all good work.

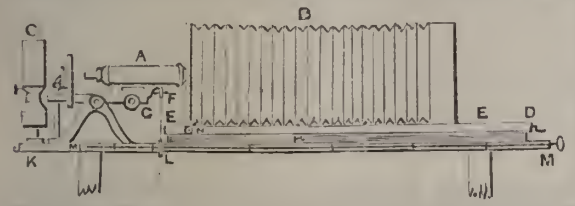


ARRANGEMENT OF MICROSCOPE WITH SHORT CAMERA FOR USE WITH EYE-PIECE.

A, lamp; B, condenser; C, microscope; D, short camera; E, block to support camera.

We come now to the actual exposure of the plate in the camera. First place the object on the stage of the microscope, choose your lens, and bring the object into focus. Notice carefully the chief points that you wish to be shown clearly in the photograph, that special attention may be paid to them in focussing and exposing. Then lay the microscope in the horizontal position, place the lamp in

front, and adjust the illuminating apparatus in the best position. The object may be seen best with oblique light: in this case be very careful, or the plate may not be fully illuminated, when the negative would be rendered worthless. When the illumination has been satisfactorily adjusted, draw the front of the camera up until the eye-piece of the microscope fits in the hole made for its reception. A hood of black velvet will probably be necessary to render the connection of camera and microscope light-tight. This done, view the object on the screen, which will be very indistinct. If the adjustments of the microscope are within reach, by their means slightly withdraw the lens from the object until the latter is in good focus. If the eye-piece be removed, and the adjustments are, therefore, out of reach, by reason of the length of the camera, turn the focussing rod until a satisfactory focus be obtained. When this is accomplished, leave the apparatus for a few minutes to allow of its expansion from the heat of the lamp. With



ARRANGEMENT OF MICROSCOPE WITH LONG CAMERA WHEN THE EYE-PIECE IS NOT USED.

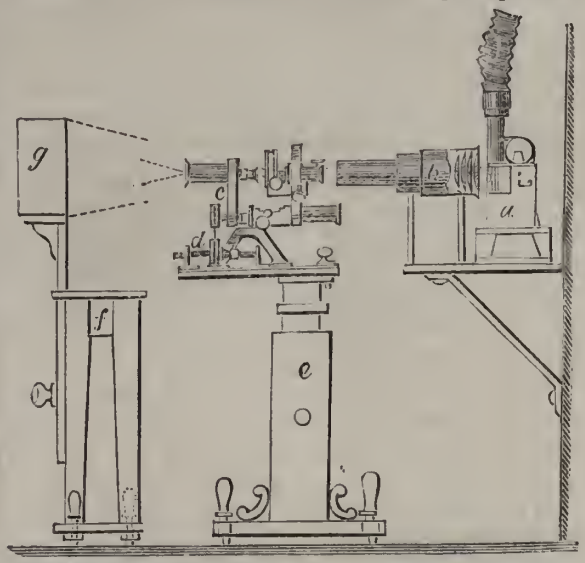
A, microscope; B, camera; C, lamp; D, winch screw; E, base-board; F, fine adjustment; G, band connecting F with wheel of rod, L; H, block supporting camera; K, table; L, wheel of focussing rod; M, focussing rod; N, rack-and-pinion for moving camera front.

low powers, this expansion is hardly likely to affect the results, but with high powers is very injurious.

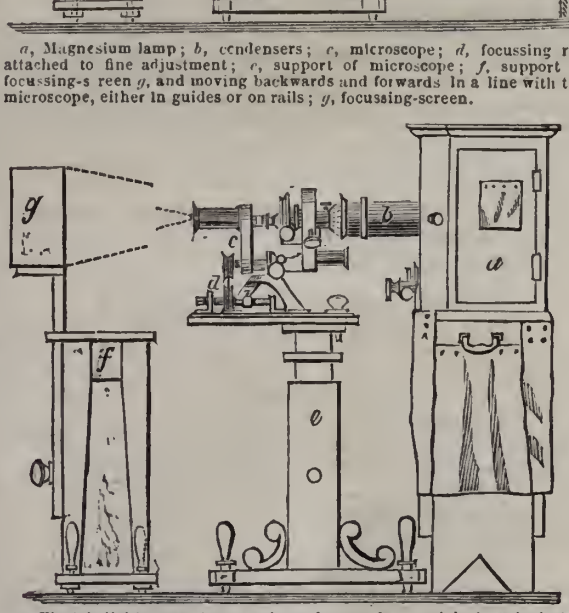
Sometimes, in fact, when using a high power, the expansion of the metal parts of the apparatus during a long exposure may be so great as to throw the object quite out of focus. It is thus advisable to place the lamp as far away from the microscope as possible, consistent with suitable illumination. The writer frequently uses a card-board screen between the lamp and microscope, with an aperture to allow the rays to pass through. By this means the microscope is kept cool, and possible injury to the lens and object averted. The alum cell, used with the heliostat to stop the heat rays, can hardly be used successfully with lamp-light. Sometimes, however, a thin cell, containing ammonio-sulphate of copper, may be employed when photographing very transparent diatoms, and answers the double object of keeping off the heat from the lamp, and giving a more diffused light. For the latter purpose, with low powers only, a strip of fine ground glass or oiled paper may be placed beneath the object. A slide of blue glass, 3 inches by 1 inch, is also used by some operators for softening the light.

All being ready for an exposure, a blackened card must be placed opposite the lens, or below the stage, to cut off the light. With a low power, the card should be in front of the lens. The dark slide may then be inserted, and the shutter drawn up. After waiting for a few moments to allow all vibration to cease, the card in front of the lens must be rapidly removed. During the exposure, the operator must abstain from walking about the room, for the vibration so produced would injure the sharpness of the picture, more especially with low powers and short exposures. When the exposure is deemed sufficient, the blackened card must be replaced in front of the lens, and the shutter pushed down. If other exposures are to be given, do not turn the lamp down, but leave the flame the full height, until the next plate can be inserted in the camera. In this way the alternate expansion and contraction of the microscope, &c., is avoided. If, on developing, the first negative be found either over- or under-exposed, try again, without disturbing the apparatus.

The two following figures illustrate the method adopted by some workers of using the microscope in a dark room, and thus dispensing with a camera. If the student have sufficient room at his disposal, and can fit up an apartment



a, Magnesium lamp; *b*, condensers; *c*, microscope; *d*, focussing rod attached to fine adjustment; *e*, support of microscope; *f*, support of focussing-screen *g*, and moving backwards and forwards in a line with the microscope, either in guides or on rails; *g*, focussing-screen.



a, Electric light apparatus: an incandescent lamp might be substituted with advantage. The other letters same as in the figure above.

specially for his work, perhaps this arrangement is the very best that can be used; it is, however, hardly suited to beginners. The references to each figure will suffice to explain the general arrangement of the apparatus.

NOTES FROM NEW YORK.

KEEPING QUALITIES OF GELATINE PLATES — REDUCING INTENSE NEGATIVES—AN EASY METHOD OF PREPARING NON-ACTINIC GLASS FOR THE DARK-ROOM.

THE keeping qualities of gelatine plates as they are at present packed in packages by manufacturers was recently discussed at the Society of Amateur Photographers by Mr. H. J. Newton, and some of the results explained by him will doubtless enlighten many who have been troubled with unaccountable fogginess in plates. He showed several specimens which supported his discovery. One plate had been kept in a cardboard box for over a year with straw-board paper frames about ¼-inch in width laid between it and the

other plates. On development, a rim of fog appeared where the paper frame was in immediate contact with the film, and extended inwards nearly an inch towards the centre. A year ago, when the same plates were first obtained from the manufacturer, clear and brilliant negatives were obtained. The effect thus shown proved conclusively to Mr. Newton's mind that there was something in the paper frame which exerted some injurious action upon the sensitive film. After two or three careful experiments, he found the frames completely loaded with hyposulphite of soda. Other specimens were exhibited where the plates had been packed in grooved cardboard boxes. The box was found to contain hypo, and in the course of six or eight months the plates were so badly affected as to be worthless. In another case the sensitive film had been made insensitive to the action of light by the action of the cardboard frame. The developer would not turn that portion of the film after exposure to light, and it was transparent after fixing in the hypo. Another curious effect was the precipitation of metallic silver over portions of the plate in streaks, and in a rim half-an-inch wide around the plate. To the amateur who might wish to take an extended trip, covering one or two years' time, the discovery of the probable deterioration of his plates due to want of care on the part of the manufacturer was demoralizing. Even packing plates with strips of white wood laid between them at their ends Mr. Newton claimed was not safe, as in the making of collodio-bromide dry plates, white wood was proved to have exerted a deleterious effect. Two methods of packing were recommended: first, to use grooved tin boxes; and second, the separation of the plates by a cotton cord running alternately at each end between each plate, and known as Wheeler's Patent Method. A collodio-bromide plate had been kept in a tin box by Mr. Newton for three and a-half years without any deterioration whatever.

Several formulas for reducing over-intense negatives were given at the same meeting. Mr. Beach recommended the following, which had been sent him:—

Water	5 drachms
Chloride of gold	15 grains

The plate is soaked in water, and then flowed over with the gold solution; it is then well washed, and laid in a bath of cyanide of potassium (water 8 ounces, cyanide 20 grains). The action proceeds gradually, and the reduction is under perfect control, one advantage being that the details in the shadows are not obliterated. Mr. Newton recommended the following as being much cheaper:—

Water	10 ounces
Sulphate of copper	100 grains

After this is dissolved, add

Bromide of potassium... ...	100 grains

Lay the negative in a bath composed of one ounce of the above in six ounces of water, watch closely, then wash, and finish with a weak solution of hypo. Another formula was to substitute a perchloride of iron solution very weak (5 minims of iron solution to 10 ounces of water) for the bromide of copper solution, and finish with a weak hypo bath. Dr. John Janeway had had much success with the following:—

Ferridcyanide of potash (red prussiate)	9 grains
5 per cent. solution hyposulphite soda	3 ounces

Dissolve the potash by stirring with a glass rod. This amount will cover a 5 by 8 plate, and can be used for three or four plates, but only on the day it is mixed. The action of the solution is quick, and it should be watched carefully. When reduced to the desired degree, the negative is simply washed and dried. Intense portions of a dry negative may be reduced by touching them over with a camel's hair brush previously dipped in the solution. After each application the plate should be washed.

A simple yet perfect method of making a non-actinic glass for the dark room was explained by Mr. Newton, and specimens were shown which attracted attention for the brilliancy and clearness of the colours.

He took a pane of deep orange (pot orange) glass, and coated it with negative varnish in which was dissolved an aniline green, called "new green;" the resulting colour, when viewed by transmitted light, was a deep clear olive green, which was perfectly non-actinic, and made a very pleasant light to work by. A clear pane of glass, coated on one side with an orange-coloured varnish, and on the other with "new green," would accomplish the same result. Any desired opaqueness or transparency could be obtained by varying the amount of colour added to the varnish, or by coating the plate with one or more films.

The annual Field Day Excursion of the Photographic Section of the American Institute occurs on the 28th inst., and Coney Island is the objective point; the day's work to end in the afternoon with a dinner and addresses, at Hotel, Brighton.

The second Field Excursion of the Society of Amateur Photographers is projected for September 10th, to Mauck Church and Ornoco Glen, Penn., locations noted for fine scenery. Mr. A. L. Henderson, of London, is expected to speak before the Society at their regular meeting on September 9th. The event is looked forward to with much interest. THE AMATEUR PHOTOGRAPHER.

New York, Aug. 23, 1884.

PROFESSOR VOGEL'S AZALINE PLATES, AND THE ISOCHROMATIC PLATES OF ATTOUT AND CLAYTON.

BY DR. J. M. EDER.

On the occasion of Professor Vogel's recent visit to Vienna, some experiments with azaline plates were made in his presence. The trials were carried out with plates from the factory of Perutz, in Munich, and from that of Sachs, in Berlin; and it is of interest to note that Löwy and Plener were present during the experiments.

Oil paintings, chromo-lithographs, and colour scales were photographed, and in front of the objective was a yellow screen or pane. The development was with ferrous oxalate.

The azaline plates, when examined before development, showed a reddish colour, but this tint became less intense during the development and fixing.

The finished negatives showed the yellow, the yellowish-green, and the green of the original as more intense than the blue and the violet; indeed, the negatives were obtained with all the gradations of the originals correctly reproduced.

The Attout and Clayton plates were exposed under similar conditions; and although they appeared to be more sensitive, there was a tendency to fog, while the azaline plates gave perfectly clear negatives.

QUICK AND SLOW DEVELOPMENT.

BY DR. C. STURENBURG.*

Very many persons who have attentively studied the various points relating to photographic operations have recognized the fact that slow development has very decided advantages over rapid development, although the stronger, and therefore more rapidly acting, developer may require a somewhat shorter exposure than is the case when a weaker developer is used; and these remarks may be considered as applicable not only to the dry process, but also to the wet.

More especially is it to be noted that a weak developer works much more cleanly and uniformly than a strong one; indeed, to use a strong developer successfully requires a very experienced hand when it is essential to obtain good clear skies in large landscapes; but with a weak developer this is quite easy. Moreover, in the case of a slowly-developed picture there is greater harmony as regards the gradations of the tones, this being especially notable in the case of

* Translated from the *Deutsche Photographen-Zeitung*.

interiors. This is probably the case because (assuming the exposure to have been correct) the dark parts have more time to develop, and it is easy to frequently pour on a fresh developer, and one need have no fear that the lights will become too intense and hard.

For all this, cases may arise in which a slow development is required in order to obtain hard images, as, for example, in the case of line subjects; but in such instances the developer must possess a special constitution; that is to say, it must be far more acid than when portrait or landscape photography is concerned (wet plate). A weak developer, constituted with excess of acid as above, gives a much finer deposit of silver than a strong developer; this being a consequence of the slowness with which the metal is precipitated. For this reason transparent positives which are intended for enlargement are much better when developed slowly.

In the modern dry process the same appears to hold good, although the conditions of development are widely different.

THE CAMERA AS A SURVEYOR.

OUT-DOOR photography, as formerly practised, was exceedingly cumbersome, and was only used by the professional or by the amateur who had plenty of time and money. The work of sensitizing, exposing, and developing the plate was of necessity done in the field. This made a dark-room on wheels of some sort and a considerable assortment of chemicals and apparatus a necessity. The cameras were heavy and burdensome. To the mass of people the whole subject was a black art, which some were inclined to class with necromancy.

The introduction of the various forms of dry plate, of which the "gelatine" now takes the lead, has wrought a complete revolution in the whole practice of out-door photography. Excellent plates of a known degree of sensitiveness can now be purchased. The methods for developing and fixing the image have been so simplified that a person of ordinary intelligence, "by following directions," can, after a few trials, make a fair negative. These improvements have stimulated instrument makers, both of cameras and lenses, to produce an apparatus which shall be at once cheap, light, substantial, and efficient.

There are other features worthy of mention, one of the most important of which is that there may be an interval of months between the exposure and the development of a gelatine dry plate. A couple of years ago Mr. Edward L. Wilson exposed some thousands of gelatine plates in Egypt and the Holy Land, which were brought to this city, and developed and fixed by appropriate chemical treatment. The resulting pictures were as clean and bright as if the process had all been continuous.

As is generally known, the photograph or positive picture on paper is printed by placing it under the finished negative and exposing to the light. The usual processes are "the silver," "the platinum," "the carbon," "the argentic gelatino-bromide," and "cyanotype." The first four are somewhat complicated, but the last, the cyanotype or the blue print, is exceedingly simple. The cyanotype paper is placed in a frame over the negative. After a proper exposure, which can be determined by a little experience, the paper is floated upon a dish of water, sensitive side down, for fifteen or twenty minutes, after which it is washed in repeated changes of water and then dried. The resulting print is in a deep blue, and is very durable. A picture can thus, on a bright, sunny day, be produced inside of an hour and a half.

The "argentic gelatino-bromide" printing process, although more complicated than that just named, is the most rapid of all. The time required for the exposure of the sensitized paper under the negative is in daylight from one to two seconds, and in lamplight from ten to twenty. The image is developed and fixed by chemical means. This can be done in five minutes. The resulting picture is clear, permanent, and brilliant. This process is the only one for the production of paper positives, which can be satisfactorily used in the night time.

The great improvements to which we have referred have enlarged the scope of photography and rendered it an important auxiliary in many and diverse enterprises. Indeed there is scarcely a branch of history, whether it be in art, in science, in mechanics, in business, or agriculture, where the camera cannot serve some practical end. It is our purpose to call attention to some of the ways in which photography can be made to serve the fire underwriter.

It will give the general appearance of many large risks, showing clearly the relation of one portion of the property to another or to contiguous buildings. The various approaches can be shown, as well as details in the buildings. A very fair notion may be got of the construction and arrangement of machinery and of boilers, furnaces, and accessory apparatus, which will aid in determining the character of the risk. The extent and value of the property, from views taken inside and outside, can be estimated, and over-insurance guarded against. The fire extinguishing appliances, such as force-pumps, stand-pipes, hose, &c., can be shown if desired. Through information thus obtained the managers at the home office can determine as to whether or not a proper rate has been charged. If changes are made in the building, in the stock, or storage of goods, photographs will aid in showing the effects such changes have upon the risk. In cities and large towns bird's-eye views from elevated points will give a pretty good idea in regard to the situation and location of the properties which are specially hazardous by reason of the material employed in, or the manner of their construction, or the uses to which they are put. In case of a claim where the proofs are not satisfactory, the camera will aid in indicating the extent of damage done to the buildings and possibly to the contents. When fraud is suspected, the place where the fire originated, and perhaps the manner, can sometimes be shown. In the event of litigation, photographs might be extremely valuable They are mute, but exceedingly veracious witnesses.

The suggestion that every inspector, adjuster, and agent doing a considerable amount of business should have a camera and be able to take views, is worthy of consideration. An ordinarily intelligent man can be taught in a few hours to do this. After exposure the plates can be sent to the home office, or to a photographer, if need be, for development and prints.

The camera, which would probably be most useful for this purpose, is one in which a picture can be taken 5 inches by 7, 5 by 8, or 6½ by 8½. Probably the smallest size would fill nearly every practical need. The cost of the apparatus would be from £12 to ten times that amount. If the scheme we have suggested should take practical shape, companies could secure instruments and prepared plates of excellent quality, uniform in size and finish, at very reasonable rates. In uniformity there would be the practical advantage that, if one dimension in any view was given, a pretty fair estimate could be made of all the sizes and distances in the picture.—*The United States Review.*

Correspondence.

PHOTOTYPE BLOCKS BY THE IVES' PROCESS.

DEAR SIR,—In justice to ourselves, I beg of you to point out to your readers that the beautiful supplement to your last issue from a photograph by Ives' process *has been printed from the stone*, where it is very easy to put in all those lights in the trees, &c.; whereas you print our plates with the letter-press on your ordinary paper, which makes all the difference. It would also be interesting to know how long it took to produce the plates, and at what price they can be supplied.—Yours faithfully, E. PICK.

Meisenbach Co., Limited, 31, *Farringdon Street*, *Sept. 6th.*

[The supplement by the Ives process which we issued last week was not printed from stone, as our correspondent appears to think, but from a typographic block; and as regards the suggestion of Dr. Pick that the excellence of the print is partly due to something of the nature of retouching, we may quote from Mr. Ives' letter to us of August 1st. He says:—"The subjects are not of a 'showy' character, and were turned out in the regular course of business, and *finished without* any retouching. They are *fair* samples of our commercial work, not better than we average from equally good copy." It is but just to Mr. Ives to mention that some few weeks before he sent us the supplement, we received from him a considerable number of subjects of equal excellence. On previous occasions, Ives' blocks have been printed along with letterpress in the PHOTOGRAPHIC NEWS (the first in 1882), and on one occasion a Meisenbach block-print was issued as a separate supplement; so each process has been presented to our readers under the two several conditions. It is curious to

note that when our separate supplement by the Meisenbach method was issued (Nov. 23rd, 1883), certain persons loudly asserted it to be a lithograph; but their mistake, like that of our correspondent, doubtless arose from the fact of the grain of the highly-rolled paper being somewhat raised by contact with the damp sheets of the recently printed reading matter. Any person who is familiar with printing, and who inspects prints which have not been laid in the damp copies of the PHOTOGRAPHIC NEWS, can see at a glance that our Meisenbach Supplement (Nov. 23rd, 1883) and our Ives' supplement of last week are actually block-prints.—ED. P.N.]

A SODA AND POTASH DEVELOPER.

SIR,—It seems from correspondence that there is much discussion as to the best developer. I have one that I love so much that any gelatine plate that would not behave in a most becoming manner towards it, I would at once condemn and discard.

The way I proceed to develop this developer is as follows. I make saturated solutions of potash (carbonate), soda (sulphite), and soda (washing).

These I name 1, 2, 3, which means, take—

Sat. sol. of carbonate of potash...	... ...	1 ounce
,, sulphite of soda ...	... ...	2 ounces
,, washing soda ...	... ...	3 ,,

To these I add 48 grains of bromide of potassium, dissolved in 18 ounces of water, and label this—"Soda Solution."

Now dissolve a ¼-ounce of citric acid in 30 ounces of water, and add 1 ounce of pyro, and label this—"Pyro Solution."

To develop a half-plate, take—

Pyro solution	2 dr.
Soda solution	*quant. suf.*

Never soak the plate in water previous to development, as it is one cause of frilling.

Anyone who tries this developer I feel sure will value it as I do; it has every virtue, and none of the faults, of the soda or potash used alone.—I am, sir, yours truly,

HENRY LAW.

THEORETICAL STUDY OF PHOTOGRAPHY.

SIR,—The City and Guilds of London Technical Institute is the only body in London, as far as I know, which offers any incentive for the study of theoretical photography for assistants. There could be but little doubt as to the advantage it would be to the photographic world generally, should those who are assistants now—but who will in the course of time be principals—have a thorough theoretical as well as practical knowledge of their business. Some of the city companies, seeing the importance to their trade of such a knowledge, offer medals and certificates to stimulate efforts which, perhaps, would otherwise lie dormant.

Photography is not guarded by a great city company, but there is the Photographic Society of Great Britain, and many others, who might do much by interesting themselves in the matter, and take some steps to second the work the City Guilds have so well begun. Exhibitions are well to a certain extent, but offer but little inducement to assistants who, with but little spare time, and less money, are hardly likely to stand much chance when principals with leisure, and every convenience, compete at the same time.

I can say that those who, like myself, studied up for the City Guilds Examination derived great benefit from doing so; but the number was quite inadequate to what it should have been. Should the societies not see their way to do anything in the matter, I would suggest that the PHOTOGRAPHIC NEWS should offer prizes, or in some way help to advance the theoretical study of photography.—Yours obediently, WILLIAM EDWARD GRAY.

THE POTASH DEVELOPER.

DEAR SIR,—I am at a loss to know how your correspondent "J. G. R." failed to obtain satisfactory results with the potash developer, unless he did not take the precaution to obtain chemicals of absolute purity. So much impure sodic sulphite is in the market, sold at a low price, that I should imagine any developer would prove a failure if made up with such rubbish. I have used sulphite in the developer almost ever since it was recommended by Mr. Berkeley, and have found it a very excellent addition; yet only a short time ago I failed completely to satisfactorily develop several negatives, simply through using a cheap sample of sulphite, which was largely contaminated with carbonate. Formerly I had paid a good price for this salt, and had always got pure samples; so for the future I mean to eschew cheap chemicals. Then, if "J. G. R." used, instead of a strong solution of sulphurous acid, water merely scented slightly with this gas, no further factors need be found to explain the failure of the developer.

As to frilling, this occurred with the plates of only one maker, which were quite new to me. Plates by three or four other makers showed no sign of this trouble, even when alum was not used.

As regards density, I have found this quality very easy to obtain; but care must be taken not to employ too much No. 2 or potash solution, or very thin negatives will be the result. If a negative requires a little strengthening, Dr. Eder's alum and ferrous sulphate intensifier answers well. In the PHOTOGRAPHIC NEWS, June 22, 1883, page 388, Dr. Eder, in speaking of Dr. Stolze's potash developer, says that very vigorous negatives result from its use: "if, however, it is wished to obtain thin negatives, the quantity of water must be doubled." Mr. Richard Parr, in writing to the PHOTOGRAPHIC NEWS, June 13, 1884, page 379, to give his experience of Newton's "potash-soda-sulphite" developer, says:—"I find it to compare very favourably with "alkaline pyro" of the old form, giving a denser negative, with more of the old wet-plate characteristics, and takes a somewhat less exposure." He complains, however, like "J. G. R.," that this form of developer induced frilling. Apart from this, what Mr. Parr says of Newton's formula applies equally well to that of Beach.

As an example of how much density can be obtained, one day I exposed a plate with $\frac{f}{6}$ stop for one second on a small cottage with foliage up the front and trees on either side. The day was clear, with little sun. Directly the developer was poured over the plate, the image flashed out. The solution was immediately poured off, and diluted with water to twice the original volume, and a few more drops of pyro solution added. Development then proceeded more slowly, but on examining the negative before the lamp, the high lights were found to be so dense that the lamp-flame was hardly visible. This negative takes two hours to print in a good light. I have not reduced it, but keep it as evidence of how dense an over-exposed negative may become in the potash developer. Since then, I dilute the developer rather more than recommended in the formula, reduce my exposures to less than a second on all well-lighted subjects, and use a smaller stop. The lens I have chiefly used has been a small 7½ inch single landscape lens, by no means a rapid one.

I consider the potash developer more vigorous than the ordinary pyro and ammonia, simply because I have been able to make quicker exposures and use smaller stops, even on dull days, than I have ever done before; and find instantaneous pictures as easy to develop as those that have received the "full" exposure, which I could'nt say when using the old developer.

Answering "J. G. R's." queries *seriatim*, I would say:—

1. Density may easily be obtained by making up the formula with good chemicals, and using the solutions strong or dilute according to the exposure of the plates.

2. The usual method of looking through the negative at a red light will show if sufficient density has been gained. If the plate *looks* thin, it *is* thin, and must be developed out more, or more pyro be added. Thin negatives will always occur with an excess of potash.

3. The amount of pyro named in the formula is, perhaps, excessive. I always use less for an instantaneous exposure in sunshine, and get ample density. For an ordinary exposure, the usual proportion of three grains or four grains per ounce is sufficient.

4. The alum bath appears to have no reducing action. My own plan is to use alum both after development, and after the fixed plate has been finally washed. The negative is left in each alum bath about five minutes. Most of my negatives are thin, but yield vigorous prints. I have intensified only in the case of a few plates that were thinly coated, but never when using Swan's "Studio" plates. Any other good plate would give equally satisfactory results.

New developers are not always satisfactory on the first trial. When I first used the soda developer, I fancy I made a far greater failure than "J. G. R." has done with the potash. His negatives were only thin; mine were simply useless.

"Surrey's" query as to the unwholesome nature of the fumes of ammonia is answered in my last letter. Still, I may, perhaps, quote from Mr. Ashman's excellent article on "Ammonia," which appeared in the PHOTOGRAPHIC NEWS, No. 1342, page 322:—"Ammonia, when taken in quantity, is fatal to life, producing inflammation of the lungs, and stricture of the throat; frequent inhalation renders susceptible persons liable to suffer periodically from cold in the head. Such persons should not inhale the fumes from the alkaline developer more than is absolutely necessary, and whenever they feel an indication of an attack, should freely inhale the fumes of glacial acetic acid."—I am, sir, yours faithfully, J. H. JENNINGS.

Proceedings of Societies.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

A MEETING of this Society was held on Thursday, the 4th inst., Mr. W. K. BURTON in the chair.

Mr. A. COWAN showed a series of eight negatives developed by means of the carbonates of soda, potash, and ammonia, separately, and mixtures of these alkalies; he found a yellow colour pervaded all those where soda was employed, although sulphite of soda was used in each case. When he first used soda, he obtained yellow negatives; but as so much had been said lately in favour of this alkali alone, and with potash, he was induced to make these trials, and found that the plates were more yellow than ever. He then tried the addition of restraining bromide, which prevented his getting an image; and he said it was astonishing how little influenced the result, a fact which might be taken advantage of in cases of over-exposure.

Mr. W. E. DEBENHAM: Can the image be developed with ammonia and pyro after being checked with soda and bromide?

Mr. COWAN replied that it could.

Mr. DEBENHAM: Then that goes a long way towards solving the difficulties of over-exposure.

Mr. COWAN: Among the experiments will be found plates developed with the mixed carbonates of potash and ammonia restrained with one-tenth of a grain of bromide; these are entirely free from yellowness.

Mr. W. M. ASHMAN used soda continuously with great success, and said it was most important that an understanding should be arrived at on this question, which may rest with the difference in the plates. He suggested that Mr. Cowan should develop some of his (Mr. Ashman's) plates, and he some of Mr. Cowan's, each exposing his own. This was agreed to, and Mr. Haddon, whose soda-developed negatives were of a yellow colour, promised to take part in the trials.

The CHAIRMAN had tried caustic potash, and found, when used with ammonia, there was greater detail. He agreed with Mr. Cowan that the smallest quantity of restrainer in the soda developer stopped the developing action. He thought Mr. Derham could tell them something about soda developers.

Mr. DERHAM (Boston, Mass.) said he brought some plates over with him which he had used; they were developed with the following developer:—Carbonate of soda, 1 ounce in 10 ounces of water; oxalic acid, 30 grains; and pyro, 20 grains in 10 ounces of water. Equal portions of these were taken. Here the negatives developed intensely yellow; in America they were black, but with more pyro he could get them black here also.

Mr. J. BARKER found the shadows of the negatives developed with sulphite of soda always possessed a grey veil or fog. He obtained the best results with carbonate of ammonia, pyro, and potassium bromide.

Mr. COWAN enquired if any change had been noticed in negatives bleached with mercury; also if anyone had experience with mercury alone as an intensifier?

Mr. W. COBB had given his gelatine negatives a slight wash with a very dilute solution of mercuric chloride for some months past, and thought, besides the improved character conferred, they would be permanent.

Mr. DEBENHAM used to change the colour of wet plate negatives in that manner, and found no ill effects—an experience borne out by others present.

Mr. G. WALTENBERG found that gelatine negatives bleached with mercury were not permanent; he had several hopelessly spoiled.

Mr. BARKER said as far as the treatment of collodion with mercury was concerned, it depended on the amount of action; if the stain went through the film, then it was permanent. Referring to a recent controversy in one of the journals regarding colour in bromide plates, he said one gentleman seemed to claim it as his own property. In 1873 he produced many bromide negatives of a red colour, and now passed round two examples. In reply to the Chairman, Mr. Barker said that the method of developing affected the colour; the plates were collodio-bromide.

The CHAIRMAN had seen a variety of colours produced on those plates.

Mr. DERHAM exhibited a 5 by 4 tourist's camera, designed for taking objects in motion, and arranged to hold against the shoulder. It consisted of two bellows bodies fixed vertically to one base, and mounted with twin lenses; the upper portion was intended for focussing and watching the object by means of a bellows extension, and the lower portion, fitted with a spring shutter on the Noton principle, was used for making an exposure. Half-a-dozen double slides in zinc case to fit back of camera completed this compact arrangement.

The CHAIRMAN, in thanking Mr. Derham for showing this camera, said it would be interesting to hear something about American lenses mostly in vogue.

Mr. DERHAM then described most of the lenses used in America, and said that the English lenses were held in high favour.

Mr. TURNER was then elected a member of the Association.

Talk in the Studio.

APPOINTMENT CARDS.—Messrs. Marion and Co. forward us some appointment cards, of which the designs are exceptionally elegant. To give a sitter a written memorandum as to the time of appointment is an excellent plan; and, moreover, on the reverse of the card may be printed suggestions as to enlargements and finishing of copies in colour, together with other matter calculated to induce the sitter to go beyond his original intentions.

CENTENARY OF THE FIRST BALLOON ASCENT IN ENGLAND.—On Monday next, exactly one hundred years will have elapsed since the first balloon ascent was made from English soil. This was effected by an Italian named Vincent Lunardi, who, on the 15th of September, 1784, rose from the grounds of the Honourable Artillery Company at Finsbury, in the city of London, in the presence of a vast multitude of spectators. Since that date no balloon has been launched into space from the same spot, but arrangements have been made by the Hon. Artillery Co., in connection with the Balloon Society of Great Britain, for holding a centenary celebration of the event on Monday next, when, weather permitting, Mr. Dale and Mr. Cecil V. Shadbolt hope to go aloft in the "Sunbeam" balloon from the identical starting point from which exactly one hundred years ago Vincent Lunardi made the first ascent in England. Whether or not the trip will be a photographic one will depend upon the weather and light.

HARDENING WOOD.— Rubennick's process for metallising wood consists in steeping the wood in caustic alkali for two or three days, at 104° to 197° F. The wood is then placed in a second bath of hydro-sulphate of calcium, to which sulphur is added, after twenty-four or thirty-eight hours. After forty-eight hours the wood is immersed in a third bath of acetate of lead at a temperature between 95° and 122° F., where it remains from thirty to fifty hours. After a complete drying, the wood thus treated is susceptible of a very fine polish, especially if its surface is rubbed with a piece of lead, tin, or zinc, and finally finished with a burnisher of glass or porcelain. It then looks like a metallic mirror, and is completely sheltered from all the deteriorating effects of moisture.—*Science.*

FLEXIBLE TUBING IMPERVIOUS TO GAS.—Ordinary rubber tube is by no means gas-tight; in fact, the gas not only filters slowly through it, but the rubber absorbs and stores up several of the denser hydrocarbons which form the most valuable illuminating constituents of the gas. To lessen the infiltration through the walls of the tube, Mr. Fletcher, of Warrington, now makes tubing consistiug of two layers of rubber separated by a fold of tinfoil.

MANUFACTURE OF ETCHING INK. (*Dingl. Polyt. J.*, 250, 555.)—According to Müller, a liquid for etching on glass has recently been introduced into commerce, and can be used with an ordinary pen. It cousists of hydrofluoric acid, ammonium fluoride, and oxalic acid, and is thickeued with bariuni sulphate. A better ink is obtained as follows:—Equal parts of the double hydrogen ammonium fluoride and dried precipitated barium sulphate are ground together in a porcelain mortar. The mixture is then treated in a platinum, lead, or gutta-percha dish with fuming hydrofluoric acid, until the latter ceases to react. D. B.

PHOTOGRAPHIC CLUB.—At the next meeting, on September 17, the subject for discussion will be "On Mountants." Saturday outing at Hale End; train leaves Liverpool Street at 2.22 and 2.15 p.m.

To Correspondents.

*** We cannot undertake to return rejected communications.

TRANSPARENT.—1. The same developer will answer quite well, and you must modify it according to the exposure given, just as in making a negative. 2. The best varnish for prints on gelatino-bromide paper is a solution of gum dammar in benzole, about forty grains to the ounce being a convenient strength. You must take care to obtain genuine benzole, and not the so-called benzoline or light petroleum; and do not forget that the vapour is extremely inflammable, so you must not work near a flame.

N. M.—We believe that a block six inches square costs about 50s. The address given on the print is sufficient.

AN INDIAN AMATEUR.—1. One part of bichromate of potassium and six of glue will answer well. Soak the glue in cold water for some hours, and melt in a water-bath, after which add the bichromate, this having been previously dissolved in the smallest possible quantity of hot water. 2. It is made by mixing the phosphorescent sulphide of calcium with a spirit varnish, and it can be obtained at 5A, Aldermanbury Postern.

W. W. H.—There are several such processes, and accounts of them will be found in recent volumes of the PHOTOGRAPHIC NEWS. You can gather much information from an article which appeared on page 258 of our volume for 1883.

S. W. WINSER.—1. It would certainly not be fit for use after having been kept so long; but under ordinary circumstances it will keep well for a few weeks. 2. Probably four or five. 3. Add a few drops of tincture of iodine to ten grains of starch boiled in an ounce of water, so as to obtain an intensely blue solution. This will be decolourised when a few drops are added to the water if hypo is present; but several washings should be given after the washings have ceased to give any indication with this test.

J. W.—1. Cover the dabber with the thinnest india-rubber, obtained by blowing out a toy air-ball until it bursts. 2. Oil of lavender (the cheaper kind sold as oil of spike). 3. About 200 deg. Fahrenheit, and for three or four hours. 4. The method of working does not appear to us to be practicable, and, moreover, danger is likely to arise.

T. W. O.—You are right as to the order in the previous case. As an additional lens, we should recommend you to obtain one having an equivalent focus of three inches, and capable of including a sufficiently wide angle to cover the quarter-plate.

G. C.—1. A light blue tint is generally preferred, and, if you object to white, you cannot do better than to adopt this colour. 2. Nothing better than thick and fresh gum.

TAFFY.—Some of them would certainly be amusing; but to put all in full would occupy about two pages of NEWS.

GIL BLAS.—1. You can best obtain it by writing to the maker: Philadelphia, Pa., U. S. A., will he sufficient address. We do not know the cost. 2. The books you mention are decidedly the best works on the subject.

H. G. P.—We should recommend you not to make a trough, but to purchase an old paraffin oil cask. Still, if you resolve to make one, you had better put it together with sides over-sailing at the ends, and the over-sailing ends should be fastened with long screw bolts. The bottom ought to be matched into the side and end pieces, so that the end bolts keep all the parts together. Notice how a slate cistern is ordinarily made.

FORESTER.—1. Quite so; it will only require one-fifth of the exposure.

X. X. X.—In such a case it would be well to fume the paper, and we should recommend you to use a bicarbonate toning bath. Chloride of gold 1 grain, bicarbonate of soda 3 grains, water 8 ounces.

S. W. WINTER.—It is quite incomprehensible to us, and we should like to see the negative.

NOVICE.—1. You do not say whether you use ready sensitized paper or not; if you use it, try another sample, or sensitize your own. 2. Try the bicarbonate toning bath recommended to X. X. X. It would be well for you to obtain Abney and Robinson's comprehensive manual of "Silver Printing."

O. T. C.—There is no satisfactory remedy; but the best plan is to make as perfect a transparency as possible, and then to soak the negative in a dilute solution of potassium cyanide—say about fifteen grains to the ounce. Wash well before drying.

PAPIER MINERAL.—You can obtain it from Werge, of Berners Street, or from the Autotype Company.

F. CARSTON.—1. Considering the result is doubtful, and the number of plates so small, you had better reject them, unless you have spare time on your hands. 2. The main point is to very thoroughly wash away the whole of the bichromate. 3. We can see no reason why there should be any advantage in so doing; but do not let that prevent you from making the experiment.

PRINTER.—Positive prints are made in the usual way, and fixed, but not toned; they are then immersed in a saturated solution of bichloride of mercury, and allowed to remain in the liquid until all traces of the image have disappeared. If now washed and dried, they may be kept without deterioration, and the impression may be revived at any time by immersion in a hypo bath. The developing paper ordinarily sold with the so-called magic photographs is merely thick blotting-paper which has been immersed in a saturated solution of "hypo," and dried; it is moistened and laid on the bleached print.

Employment Wanted.

Operator (Frenchman).—J. C., Rue Neuve, Brussels.
Operator (Stannotype, Carbon, &c.).—W. E. Sclater, Brussels.
Operator and Retoucher.—A. B., 36, Jewin-st., E.C.
Improver (age 16).—V. Y., Dudley-villa, Witton, Droitwich.
Improver (age 21).—X. Y. Z., 69, Palace-garden-ter, Notting-hill-gate.
Printer and Toner.—F. M., 15, Story-st., Caledonian-rd., N.
Assistant Operator or Printer.—A. D., 34, Sussex-st., Pimlico.
Retouching & Reception-Room.—H. G., 185, Albany-st., Regent's-pk.

Employment Offered.

Operator and Manager.—Mr. Rosenberg, 8, Euston-sq., N.W.
Reception Room Lady in provinces.—Mr. Rosenberg, 8, Euston-sq. N.W.
Printer for Sunderland.—A. & G. Taylor, 70, Queen Victoria-st.
Operator (temporarily).—Maull & Fox, 187A, Piccadilly.
Operator and Retoucher.—R. Cox, 37, White Ladies-rd., Clifton.
Printer at once.—W. D. Brigham, Scarboro'
Assistant Operator and Enameller.—W. D. Brigham, Scarboro'
Operator & Printer.—J. R., 79, Wood-st., Cheapside.

VOL. XXVIII. No. 1359.—*September* 19, 1884.

CONTENTS.

ENLARGED NEGATIVES FOR AMATEURS.

THE increased use of the pocket camera has led to the amateur photographer applying himself greatly to a branch of the photographic art which was, until lately, practised but little, except by the professional. We refer to that of enlarging.

It is pleasant to be able to carry all the requirements for taking half-a-dozen negatives in a parcel so small that if it is, as a matter of fact, somewhat bulky for the pocket, it is at any rate no heavy impediment to the pedestrian, the tricyclist, or even the bicyclist; but to get the full advantage of the small negatives which are produced, it is necessary to enlarge afterwards; and to get the very best results, it is necessary to produce enlarged negatives.

It is true that since the general introduction of gelatino-bromide paper a great power has been put in the hands of the photographic amateur. He can with comparative ease produce single enlargements of any size. Still, if the pocket camera is to take the place of the larger ones which many carry, it becomes necessary to have enlarged negatives from which prints may be taken in the ordinary way, which, in fact, take the precise place of large negatives which might be produced in the field.

Of the many processes used for producing enlarged negatives, probably the one which still holds its own is the wet collodion process. Few amateurs, however—at any rate, of those who have commenced photography within the last few years—are willing to add to their dry plate impedimenta a wet plate kit for the mere purpose of making enlargements, especially as the size required would naturally be considerable. The amateur must get his enlarged negatives by the same process that he produces his small ones, or do without. The question therefore naturally arises, whether gelatine plates will afford enlargements as good as those got by the wet process, and, if so, what is the best course to pursue in securing them.

Our own experience is that enlargements as good as any can be produced by the use of suitable gelatine plates, and that for the sizes that the amateur is likely to use, not larger than 15 by 12, or even 12 by 10, there is no great drawback in the process.

Concerning the plates to be used, we may say that whilst the most rapid ought not to be employed, there is no necessity to get very slow plates. Those of moderate rapidity, especially such as give very clean shadows, will do excellently.

All are aware that, for the production of an enlarged negative, it is usual first to produce a transparency, and from that to get a negative. Two courses may be pursued. A transparency of the size of the original negative may be taken, and from that there may be produced an enlarged negative by the lantern or other optical arrangement; or an enlarged transparency may be produced by an optical arrangement, from which may be got a negative of the same size by contact.

The latter arrangement involves the use of two large plates; the former of only one large plate and one small. There is, therefore, decided economy in the first-mentioned method. There are, however, such decided advantages in the less economical method, that we recommend its adoption.

There is, in the first place, a disadvantage in the cheaper process which is due to the inferior glass which is usually coated with gelatine emulsion. The unevenness of the glass makes perfect contact throughout impossible, and at the juncture where the contact exposure is made, there is certain to be a loss of definition in some parts. If this loss of definition is due to the large plates, it will probably not be noticeable at all; but if it is produced in the small plates, and is subsequently *enlarged*, it will become very noticeable indeed.

Another great advantage in the use of two large plates will be found if it be desired to do any retouching. The retouching of a negative can only be so done as to increase the density of parts. It would often be most desirable to *de*crease the density of a part, and thus avoid performing a separate operation on each print taken from the negative. The equivalent of this may be done on the transparency used for enlarging; but were it done on the small sized transparency, the pencil marks being enlarged afterwards would appear very conspicuous.

The apparatus most suitable for enlarging is that of the nature of the optical lantern, or, as it used to be termed, the magic lantern. Arrangements, both finished and makeshift, have been so often illustrated and described in our columns that we need say little about the matter here. The lens must not be one specially constructed for lantern exhibitions, but must be a photographic lens. One of the "rapid" landscape type is the best. The focal length should be at least one and a-half times that of the plate to be enlarged from.

The quality of negative from which the best enlargement can be got is pretty well known. It should be a soft negative with ample detail, but having a little very quite clear shadow. The sort of negative which will print quickly, and which will just give a bold silver print when the printing frame is exposed in a dull light, is the kind required.

The transparency got from this, especially if it be enlarged, must be somewhat dense. The density may be such that a very brilliant print—which would be a negative, of course—would result from it. The exposure must be so long that no part of the glass of the transparency is left quite clear. If this be not attended to, the detail in the shadows of the final enlarged negative will be lost, or

at least so weakened as to give an impression of under-exposure.

It is quite possible to get a good enlarged negative from a small one so much over-exposed that it will give but a miserably weak direct print, and this especially if development has been stopped before the shadows are much veiled.

The exposure is always a great difficulty in enlarging—it varies so enormously with the density of the negative and the amount of enlargement required. It is well, where very large negatives are being produced, to make a trial exposure on a small plate of the same sensitiveness as the large one. The length of exposure required for the contact printing can be judged with very fair accuracy after a little practice.

The developer used need not in anything materially differ from that used to produce a negative. Either the alkaline or the iron developer may be used.

Those who have a large camera, one of the size up to which they wish to enlarge, will find the most convenient method of getting an enlarged transparency to be that in which daylight is used. A hole is made in a shutter to hold the small negative; a reflector is fixed behind this at an angle of 45°, and the large camera is simply placed opposite the negative, the lens from the *small* camera being uesd, and the dark slide being manipulated in the ordinary way. It is by no means necessary absolutely to darken the room. All that is necessary is to ensure that no very bright light streams in nearly in front of the lens.

A NEW LENS.

THE specification has recently been issued by the German Imperial Printing Office of a patent granted in March of last year, to Herr Moritz Mittenzwey, of Zwickau, for a new form of lens intended for the production of photogaphs.

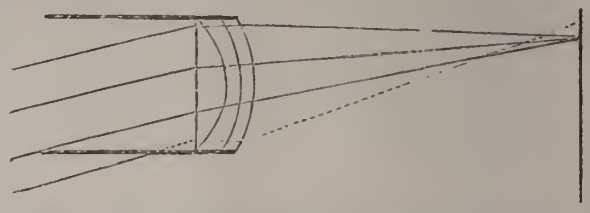
The striking novelty in this lens is, that although of the single form, it is constructed to work with an aperture of nearly $\frac{f}{3\frac{1}{2}}$, (larger, that is, than that which is generally given to lenses of the rapid portrait type). Single lenses have hitherto possessed so much spherical aberration that they have not commonly been used with a much larger aperture than one of about one-twentieth ot the focal length. Efforts have not been wanting to obtain a larger aperture with fair definition in single lenses, but, so far, it has not been attempted or thought practicable to make the aperture *much* larger than that mentioned. The late Mr. T. Grubb, more than twenty years ago, introduced a single lens in which he succeeded in so far reducing spherical aberratiou as to obtain fair definition with an aperture of about one-fourteenth of the focal length. This step, which was considered a great one at the time, will, it is evident, bear no comparison with what Herr Mittenzwey proposes to do.

The standard of rapidity adopted by the Photographic Society of Great Britain is a lens the aperture of which is one-fourth of its focal length, or $\frac{f}{4}$, aud is about the same as that of an ordinary rapid portrait lens. If the aperture of the various lenses that have been referred to be set down in a tabular form, aud compared with this standard of rapidity, it will be easy to recognize what an important claim is made for the new lens.

	Aperture.	No. on the Universal or Standard System.
Single, or landscape lens	$\frac{f}{25}$	25
Grubb's aplauatic lens (so-called)	$\frac{f}{14}$	12
Portrait lens	$\frac{f}{4}$	1
Mittenzwey's new lens	$\frac{f}{3\frac{1}{2}}$	$\frac{3}{4}$ nearly.

The numbers in the last column represent the comparative exposures. It follows that, although a single lens, the latest introduction will work with a rapidity requiring an exposure of about two-thirds that of the portrait lens, or be equal to those which are known as extra rapid. It is a generally accepted rule that the fewer parts and the less complexity (without sacrificing the perfection of the result) there is in construction, the better. In the case of lenses, every additional surface to be ground involves not only expeuse, but the liability to error from imperfection of workmanship; and if Herr Mittenzwey has really succeeded in doing with a single objective, what Petzval could only accomplish with a doublet, of which even then the components of one of the lenses had to be separated, he has indeed achieved a great thing.

In the specification three variations are described, of one of which we give a drawing. In all three the lens consists



of three cemented components; the back and fronts are of the same glass; the front lens is convergent, and the back divergent. In the figure the frout and back lens are of crown, and the middle one of flint; but in one of the variations this is reversed, and the middle lens is a strongly convergent crown, whilst the front is a very slightly convergent meniscus, and the back is powerfully divergent, both of flint.

In the leus illustrated the curves are given as follows:—

First surface	plane
Radius of the second aud third surfaces ...	36·66 mm.
,, fourth and fifth surfaces ...	64·00 mm.
,, sixth surface	73·00 mm.

This is for a lens of 168 mm. focal length, and 50 mm. diameter.

The indices of the glass are—

	Crown.	Flint.
Index of refraction for optical rays ...	1·52000	1·62500
,, ,, chemical rays ...	1·53400	1·65300

It will be noticed that the lens is set back in a tube, and the effect of this is—for all rays excepting those which form the centre of the picture—to act to a certain exteut as a diaphragm. The lens will not, therefore, when used with its full aperture, work at its calculated speed auywhere but in the centre of the field. It must be remembered, however, that this is also necessarily characteristic of the present ordinary portrait lens, the components of which are separated by being mounted at the two ends of a tube. The object in the present iustauce of using the tube which acts as diaphragm is to cut off those rays the spherical aberration of which it has not been found possible to remedy. The dotted line shows the aberration that would exist with oblique rays if there were uo tube or stop.

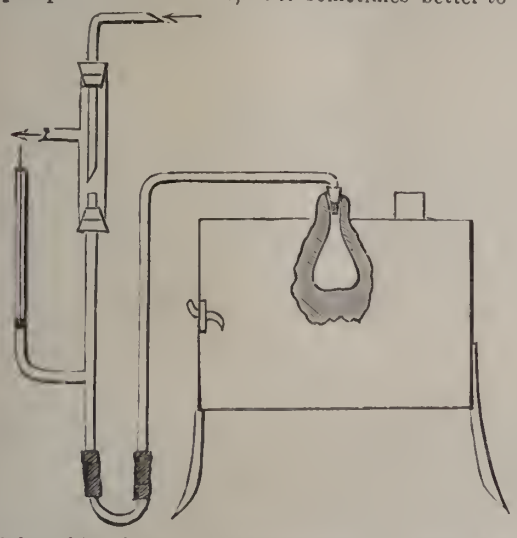
The lens figured is, as a whole, plano-convex. One of the other forms described is a rather flat meniscus, and the other, which is called a group lens, a tolerably deep one. This latter instrument is constructed to work with an opening of $\frac{f}{6}$, or about at the same speed as the most rapid of leuses of the Steinheil rapid symmetrical type.

We have not yet had an opportunity of examining aud testing the lens itself to ascertaiu how far the inventor has succeeded iu solving the problem which he set himself, and for the present must content ourselves with laying before our readers a description of the characteristics of the lens, as set forth by Herr Mittenzwey, the patentee.

A SIMPLE THERMO-REGULATOR.

To maintain a coustant temperature is a problem that has often to be solved in manufacturing technical operations, and an automatic arrangement for this purpose is almost a necessity in drying-cupboard or drying-rooms when

much work is to be done. The arrangement here illustrated, which, though not new in principle, at least has the merit of requiring only ordinary laboratory fittings, is due to Mr. H. B. Wilson. The empty flask, which is placed inside the drying-cupboard or room, must vary in size according as a higher or lower temperature is to be maintained, and it may have a capacity of a few ounces or several gallons. It is connected, air-tight, with a U-tube, the larger portion of which is filled with mercury. Instead of using a continuous glass tube bent at the proper place in the flame, it is sometimes better to use



straight tubing for the longer pieces, and to attach a short U-piece with stout rubber joints.

When the air inside of the flask becomes expanded, it depresses the mercury in the inner, and raises it in the outer limb, until it more or less completely cuts off the supply of gas, which passes in the direction of the arrows.

The outer tube bears a lateral branch, into which a piston, made of a knitting-needle and a disc of leather, fits. By pushing this down a certain distance, or by raising it up, so as to draw some of the mercury over into the branch, the temperature at which the mercury would otherwise cut off the gas may be varied at any time.

The arrangement shown is very easy to adjust to the required temperature, and is only subject to variation by the fluctuations of barometric pressure; but this may be disregarded in most instances.

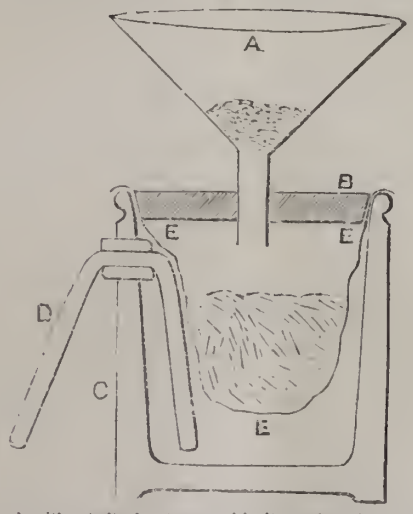
Practical Papers for Beginners.

No. 9.—MAKING GELATINO-BROMIDE PLATES.

AT the present day the commercial manufacture of dry plates is brought to such a degree of perfection as regards quality, that there is but little inducement for the photographer, whether amateur or professional, to make his own emulsion and coat his own glasses; but it is very desirable that every photographer should be able to prepare plates if he have occasion so to do. We therefore now propose to give directions which will enable any careful person to make an emulsion of the highest degree of sensitiveness, and we may confidently state that success is certain if the directions are carefully followed. The method about to be described is that of Dr. Eder.

Pure and dry bromide of potassium is taken, and 24 grammes (370 grains) are dissolved in 300 cubic centimetres (10½ fluid ounces) of distilled water,* a perfectly clean glass bottle being used. In the solution of bromide thus obtained, 40 grammes (617 grains) of a suitable gelatine are soaked—the gelatine manufactured by Simeon, of Winterthur, answers very well—and as soon as the gelatine has thoroughly swelled, the bottle is placed in water maintained at a temperature of 35° to 45° Centigrade,* and the contents are agitated until the solution of the gelatine is complete.

A solution of ammonia-nitrate of silver is now prepared by dissolving 30 grammes (463 grains) of silver nitrate in 300 cubic centimetres (10½ ounces) of distilled water, a clean glass beaker being used, and strong pure ammonia solution is added drop by drop, with constant stirring with a glass rod, until the precipitate which is first formed disappears, and the solution becomes clear. Up to this point the work may be done in daylight; but the next operation, which consists of the gradual addition of the ammonia nitrate solution to the gelatine and bromide solution, must be performed in as feeble a dark-room light as practicable. Care must be taken that the temperature of the gelatine and bromide solution is not above 35° Centigrade when the silver solution is added, and after each addition the bottle must be thoroughly agitated. The bottle containing the emulsion is now replaced in the hot-water bath, care being taken that the temperature of the water contained in the bath is not above 32° Centigrade, and it should be maintained at this temperature—let us suppose by the occasional addition of boiling water—for three-quarters of an hour. The whole is allowed to slowly cool down until a temperature of about 25° Centigrade is reached, when the emulsion is poured out into a perfectly clean glass dish, and allowed to set. The set emulsion is now divided into threads by being squeezed through canvas (such as is used for Berlin wool work) having a mesh of not less than an



A, Funnel, with a tuft of cotton wool in its neck, this wool serving to filter the inflowing water; B, Bung made of gutta-percha; C, The jam-pot, provided with a hole to carry a cork, which holds—D, India-rubber tube; E, Muslin bag, held in postion by the bung, and containing the fragments of emulsion.

eighth of an inch, so that the jelly is cut up into strips like vermicelli. But before this canvas is used it should be thoroughly cleansed by being first boiled in a dilute solution of washing soda—say one ounce to the pint—and then by several boilings in plain water. In squeezing the emulsion through the canvas, care should be taken that the hands are thoroughly clean, this being ensured by several washings in clean warm water, after the use of

* For information as to the purification of water by distillation see page 530. In London and most large towns distilled water of a satisfactory purity can be purchased in carboys.

* For use in emulsion making, a thermometer either completely enclosed in an outer tube of glass, or with the graduations marked on the stem, should be obtained. As some of the cheap thermometers occasionally give readings which are erroneous to the extent of nearly ten degrees, a second-class instrument of guaranteed accuracy should be obtained from a reputable firm. It is needless to go to the expense of a thermometer of the most accurate and expensive kind.

soap. It is well, more especially in warm weather, to perform the operation of squeezing the emulsion through the canvas under cold water.

The shreds of emulsion are now soaked in several changes of water in order to remove soluble matters; or preferably they are washed in a stream of running water for a period of from two to four hours.

A very excellent apparatus is that already described in the PHOTOGRAPHIC NEWS by Mr. Birrell, the arrangement in question being represented by the cut on preceding page.

This apparatus is placed under a tap, the water being allowed to flow in at about the same rate as it will flow through the filtering medium in the funnel, A. Instead, however, of using cotton-wool for the purpose of filtering the inflow water, it is more convenient to tie a piece of muslin over the stem of the funnel as shown in the subjoined diagram, this method of arranging a filter having

been recommended by Colonel Dawson in a another case. All string and muslin used should be cleansed before use by boiling in soda, and subsequent washing, as recommended in respect to the canvas: and it is undesirable to use either of such materials a second time when one is making a highly sensitive emulsion. The washing being completed, the muslin strainer is removed from the jar, and the edges being gathered together, the whole is swung round a few times to drive off the loosely held water; but notwithstanding this, it is extremely probable that the fine shreds of emulsion will have absorbed so much water as to make the preparation inconveniently weak when melted, and the test of this is to weigh the product. A clean beaker of suitable size is balanced on the scale-pan, and a piece of wet muslin corresponding to that used for retaining the emulsion is placed in the weight-pan. The square of muslin containing the emulsion should now be tied up blue-bag fashion, placed in the beaker, and weighed. If it weighs more than 750 grammes (26½ ounces), it is well to remove some of the water—a very easy matter if the bag be dipped in alcohol*—and moved about for a few minutes, after which it is once more swung round to drive off the redundant water, and again weighed.

The washed emulsion is now put into a clean beaker and melted by the heat of warm water, and the following solution is stirred in:—Alcohol, 28 grammes (1 ounce); carbolic acid, 1 gramme (15 grains).

The emulsion is now ready to be strained or filtered, and one of the best arrangements to use for the purpose consists of a small French porcelain coffee pot, fitted with a perforated strainer, a thickness of fine cambric (cleaned as described above) being tied securely over the bottom of the strainer. Instead of this contrivance, a short-necked funnel, tied over the end with a bag of muslin (see preceding figure) may be used in conjunction with an ordinary teapot; but in any case the teapot should be of true porcelain vitrified throughout; ordinary earthenware, consisting of a porous body covered by a glaze, being quite unsuitable. The special advantage of the teapot, provided with a strainer as described, is that all excess of emulsion

which may be poured on a plate in coating, can be at once drained off into the strainer.

The glass plates used for emulsion work should be of good quality, and they can now be bought all ready polished or cleaned at a very small advance on the cost of the rough glass; still it is wise to give a final polish in order to ensure that the plates are clean.

A plate-vice, such as that represented below, is useful;

and in order to gain the greatest advantage from its use, one of the wooden strips should be fastened down to the work-bench by a couple of screws; also care should be taken to so pack up the plate-holding rebates that the upper surface of the glass is well over the level of the wooden strips. A plate having been set in the vice with the best side upwards (generally marked by a diamond scratch in one corner), a few drops of the following mixture are poured on it:—

Alcohol	4 ounces
Water	3 ,,
Ammonia (liquid)...	1 ounce
Jeweller's rouge	½ ounce

The mixture is now quickly rubbed over the face of the glass by means of a tuft of cotton-wool or a scrap of muslin, after which the excess of rouge is polished off with a clean cloth—an old silk handkerchief answers admirably. The usual method of testing the cleanliness of a plate is to hold it obliquely against some source of light, as a window, and to gently breathe on it. If the moisture of the breath settles evenly on the glass, no streaks or patches being visible, the plate may be considered clean. As the plates are cleaned, they should be carefully piled with their best faces all in one direction; and if the weather is very cold, it is as well that they should be the least bit warm: in fact, just about as warm as they would become by being allowed to remain for an hour or so in a warm sitting-room.

A levelling-stand of a size suited for supporting the plates is now placed on the work-table immediately before

the dark-room light, and a plate, of which the sides appear to be parallel, is carefully adjusted to a horizontal position.

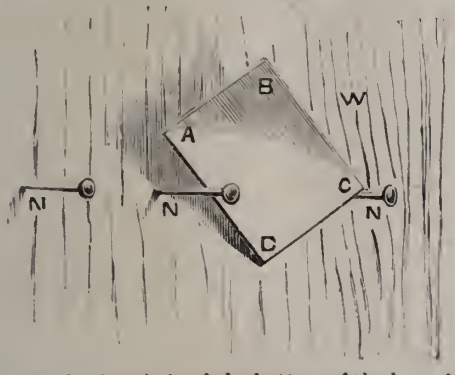
A second requisite is a flat slab upon which the plates can be laid down to set, and for this purpose nothing is better than a thick slab of plate glass set truly level on a firm table.

The final and more important requisite for plate making

* The so-called methylated alcohol may be used if pure and of good quality. It consists of alcohol mixed ten per cent. of wood spirit, and is allowed by the Excise to come into trade duty free, as this addition is supposed to make it so unpalateable as to ensure its not being used in compounding drinks. Still, as it is the custom to use the most impure spirit for methylating, and the practice is to send out the commercial methylated spirit in tins which may or may not be clean, it is necessary to obtain the article from reliable sources, and in clear glass bottles. If it shows the least tint, it ought to be rejected or purified by re-distillation. The material sold in the oil shops as methylated "finish" consists of methylated spirit in which a certain proportion of resinous matter is dissolved, and is quite unfit for photographic uses—unless, indeed, for making varnish.

is the drying cupboard or box : but if the beginner merely wishes to coat some plates occasionally, he can dry his plates very well in a large box containing a dish of chloride of calcium.

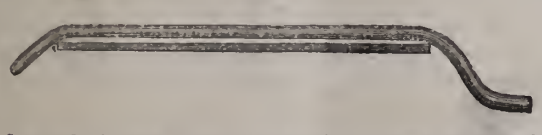
A large wooden trunk is procured, and this is made perfectly light-tight by means which may be left to the ingenuity of the worker to devise ; and, moreover, the lid should shut down as closely as practicable, so as to prevent the circulation of air at the joint. Copper nails are now driven into the insides of the trunk at regular intervals, so that the plates may be supported as shown in the subjoined diagram ; also provide a sheet-iron tray large enough



to cover nearly the whole of the bottom of the box, this tray being intended to contain chloride of calcium, one of the most useful absorbents of water known to the chemist. Before giving details as to the manipulations incidental to coating the plates, we will describe the management of the chloride of calcium and the drying-box. The trunk itself, when out of use, should be kept in a warm and dry place—if possible, in the kitchen, as if the wood be at all damp, the operation of drying the plates will naturally be slower than otherwise ; but when it is used, it is scarcely necessary to say that the dark-room is the place for it. Although chloride of calcium may be bought in bulk at something like £2 or £3 a ton, one has to pay at the rate of about a shilling a pound for quantities of 7lbs. in London. The chloride is broken into lumps about the size of a walnut, turned into any iron saucepan, and heated over a clear fire or a large gas burner until it ceases to give off vapours ; after which it is again broken up into lumps of about the original size (if necessary), and the lumps are turned into the iron tray. About a pound of the chloride to each square foot of tray-surface is a convenient quantity to use.

When the plates are dry, the chloride is returned to the stock jar, and again dried when required for use ; while the iron tray should be well rinsed from every trace of chloride before being put away, or the adhering salt will deliquesce and make the tray continually damp.

Having the emulsion ready to hand in the teapot on one side, a pile of plates on the other side, and the levelling stand before one, all is ready for coating. A plate is set on the levelling stand, and sufficient emulsion is poured on it to form a pool about equal in diameter to two-thirds of the width of the plate, and this emulsion is spread evenly over the surface of the glass by means of a clean glass rod, any excess being drained back into the teapot through the filter. The plate is now laid on the slab and allowed to remain here until the film has set, after which it is transferred to the chloride of calcium box.



Instead of using a plain glass rod to spread the emulsion upon the glass plates, it is a very excellent plan to use the bent guage-rod suggested by Colonel Dawson, and figured below. No special explanation is necessary, and the rod may easily be bent when heated in an ordinary gas flame.

Now a few words as to certain sources of failure which may trouble the maker of plates by the above-described method.

Frilling or Blistering.—Should this occur, it is best to make use of a substratum, the best being made as follows :—

Soluble silicate of soda	...	...	1 part
White of egg	...	...	5 parts
Water	...	...	60 ,,

Agitate well together by shaking up in a bottle containing some broken glass, and filter. The clean surface of the plates is flooded with the preparation, after which they are allowed to dry in a vertical position ; and when dry, they are rinsed with water, and once more dried. When a tendency to frilling shows itself, it is often sufficient to put the developed plate, but yet unfixed, in a saturated solution of alum, and leave it here for a quarter of an hour.

A Greenish Fog on the Negative.—This often arises from the application of too high a degree of heat during the preparation of the emulsion ; but more frequently from want of attention to that extreme cleanliness which is essential in the preparation of an ammoniacal emulsion. Vessels of porous earthenware should never be used, glass being most suitable ; and all vessels should be most rigorously cleaned after use. The use of impure ammonia will occasionally cause green fog.

General or Ordinary Fog may be due to the use of an unsafe light during the preparation of the plates, or from an unnecessarily long exposure to the light of the dark room.

Faults arising from imperfect straining of the emulsion, from uneven coating, or from pimples or rough places on the plate, are generally easy to trace to their source.

Transparent or Insensitive Markings, generally round, and graduating off towards the edges, may arise from some of the dust of the dry chloride of calcium coming in contact with the sensitive surface. If, however, the dish containing the chloride is placed in position before the plates are put into the drying-box, and care is taken not to shift the box during the time of drying, there will be no risk of plates being spoiled by particles from the chloride.

PHOTOGRAPHIC FESTIVAL AND EXHIBITION AT FRANKFURT-ON-MAIN.

On Wednesday, the 10th inst., the Frankfurt Society for the Advancement of Photography opened the exhibition and festive gathering which is to commemorate their first decennial anniversary. The gathering took place in the spacious apartments attached to the Palm Gardens, the first solemnity of the day being a well-served breakfast *à la carte*. At one o'clock the formal opening of the Exhibition took place, and after a somewhat rapid survey of the excellent collection of pictures, the greater part of those present took a walk through the leafy groves and the various conservatories of the Palm Gardens ; this walk through the favourite resort of the Frankfurters being a part of the pre-arranged programme. In the gardens Herr Maas took a photograph of those present, and at four o'clock a special concert took place in the Chapel. The festival supper in the great saloon was, however, the most striking feature of the occasion.

Early on Thursday morning the photographers gathered together, and at 11 o'clock they went to view the grand panorama representing the Battle of Sedan. A dinner, a visit to the Zoological Gardens, and an evening at the Opera, formed the remaining items in the programme for Thursday. For Friday a trip to Rüdesheim was arranged. Altogether about 150 persons were present.

The Committee who have the credit of arranging the programme consisted of Herrn Ayx, Borntrager, Geld-

macher, Haake, Hartman, Hetzer, Luer, Maas, and Reutlinger.

Amidst all the festivities, technical and scientific matters were not neglected, Dr. Eder having read an important paper on the preparation of isochromatic plates; and he showed a number of examples illustrating their application to the photographing of paintings.

The collection of apparatus shown was extremely interesting and instructive.

Dr. Eder's paper, which will be published in detail in the PHOTOGRAPHIC NEWS, brought out a discussion on "sensitizers in the developer for emulsion plates;" and Herr Haake, of Frankfurt, remarked that he had known good results to follow the use of the following bath after exposure and before development:—

Hyposulphite of soda	1 part
Water	1000 parts
Citric acid	3 ,,

The solution is allowed to stand at rest for some days, and then it is filtered. An immersion of one second proved sufficient in ordinary cases, and the iron developer was used. It was estimated that the sensitiveness was three times more than in the case of plates that had not been treated. Dr. Schleussner spoke of the value of an additon of hyposulphite to the oxalate developer, and Dr. Eder said that Scolik, of Vienna, had treated some under-exposed plates very successfully by dipping them in extremely dilute hypo solution (without citric acid) previously to development. Reference was also made to a secret preparation sold for adding to the developer; still this proved to contain no hyposulphite, but formic acid and other substances.

The question was then raised as to why plates which have been kept a long time, show signs of fogging round the edges; and Herr Geldmacher said that the quality of the gelatine used had no bearing on the point. It was the opinion of Herr Müller, of Munich, that mischief arose mainly from the action of damp; in fact, he found it advantageous to keep the boxes and packing materials in a warm room until required for use; but Herr Kiudermann attributed the mischief to the presence of hyposulphite in the paper and card.

It was then announced that the prizes in the competition of various makes of dry plates had been awarded as follows:—

1st Prize (silver medal)—Dr. Schleussner (22° W.)
2nd Prize—Matter, of Mannheim (19° W.)
3rd Prize—Dr. Stiefel (20° W.)
4th Prize—Engel and Feilknecht (17° W.)

The Jury for adjudicating on the photographs and apparatus consisted of Professor Samhaber, Herr Eilander, Herr Pollot, Herr Maas, and Dr. Eder; and the awards were as follows:—

Silver Medals.—1st Prize to Dr. Albert, of Munich, for his platinotype prints, and for reproduction of paintings on isochromatic plates. 2nd Prize to Van Bosch, of Frankfurt, for portraits. 3rd Prize to Braun, of Berlin, for novelties and improvements in photographic apparatus. 4th Prize, Jungmann, of Baden-Baden, for portraits. 5th Prize, Lindt, of Melhourne, for landscapes. 6th Prize, Müller, of Munich, for portraits. 7th Prize, Reutlinger, of Paris, for portraits. 8th Prize, Ruf, of Mannheim, for portraits. 9th Prize, Augerer and Szekely, of Vienna (disqualified by late arrival). 10th Prize, David and Scolik, of Vienna. 11th Prize, Lugardon, of Geneva.

Bronze Medals.—Fraulein Cullic, of Frankfurt, for portraits; Deigelmeyer and Fuhrmann, of Munich, for collotypes; Dreesen, of Flensburg, for instantaneous subjects; Haake and Albers, for collection of photographic requisites; Roch, of Neuwied, for enlargements and carbon prints; Naumann and Schröder, of Leipzig, for collotypes; Schmidt, of Frankfurt, for portraits; Strater, of Crefeld, for large portraits.

Certificates.—Engel, of Twann; Fraulein Flinkelmeyer, of Frankfurt, for retouching; Geldmacher, of Frankfurt; Grainer, of Reichenhall; Reimer, of Wilhelmshafen; Eichiegler, of Frankfurt, and Eckhorst, of Paris.

Among the exhibits there were many life-size pictures, taken direct on galatino-bromide, and a good show of instantaneous subjects; and the importance of isochromatic plates for picture reproduction was fully illustrated.

An historical collection, exemplifying the progress of photography from the time of Daguerre, was examined with lively interest.

HOW TO PHOTOGRAPH MICROSCOPIC OBJECTS.

BY I. H. JENNINGS.

LESSON V.—DEVELOPMENT.

THE development of a photo-micrograph does not differ much from that of other negatives, but requires somewhat more patience, as the image on a properly exposed plate is usually very slow in appearing, and must not be "forced" in any way. Any ordinary dry-plate developer may be used, but the writer has found that known as the sulphite developer answer best.

Ferrous oxalate is recommended by some photo-micrographers, notably by Dr. Sternberg, but is hardly sufficiently "elastic" to satisfy all requirements. It has the great merit of being clean and simple, while it never stains the negatives, as some preparations of pyrogallic acid do; but the operator will find that with this developer he has very little control over the development. In fact, the development is so mechanical, that some operators, like Dr. Sternberg, are content to place the plate in the solution and let it take its chance. No one who has become used to pyrogallic acid will ever care to use ferrous oxalate, and the writer would not advise the beginner to use it, but at once to master the difficulties of pyrogallic acid and ammonia.

However, as some may prefer to try what can be done with ferrous oxalate, the formula for this developer is given here:—

Saturated solution of ferrous sulphate ...	1 part
Saturated solution of potassic oxalate ...	3 parts

The potassic oxalate should be neutral, but as it frequently is alkaline, a few crystals of oxalic acid may be added, until the solution is neutral to test paper. The ferrous sulphate should be added to the potassic oxalate, not *vice versa*. A solution of potassic bromide, 20 grains per ounce, should be kept at hand. A few drops of this will be useful to add to the developer in case of over-exposure.

The developer which the writer prefers, and which he has used successfully for all sorts of work for some years, is the following:—

A.—Pyrogallic acid	¼ ounce
Sodic sulphite	1 ,,
Water	40 ounces
Citric acid	1 dr.
B.—Liquor ammoniæ	½ ounce
Potassic bromide	40 grains
Water	40 ounces

These form stock solutions, and will keep indefinitely. Both had better be kept in stoppered bottles. The sodic sulphite must be good; otherwise, good results need not be expected. Some writers have stated that sodic sulphite produces green fog, but this is hardly correct. The writer had used the sulphite developer for over two years before he saw anything of green fog. He had been accustomed to buy his chemicals from a good chemist, and had always paid 1s. 6d. per pound for sodic sulphite. Happening once to require some immediately, he purchased a sample from the nearest shop, and paid 6d. per pound for it. It was wretched looking stuff, but he made it up. On developing, every plate was covered with a glorious sheen of green fog. Happily, this was completely got rid of by applying Mr. H. Farmer's solution, which will be described further on. *Moral:* Buy the best chemicals from a good chemist, and do not grudge the price paid for them.

Another modification of the pyrogallic developer is given by Mr. S. Fry, as follows :—

A.—Acid pyro	1 ounce
Saturated acid solution of sodic sulphite	12 ounces
B.—Ammonium bromide	300 grains
Ammonia liquor	2 ounces
Water	12 ounces

Take 1 ounce of A; put it in a 20-ounce bottle, pouring on it 15 ounces of water. Do the same with B. Use equal parts for developing.

To develop a plate, proceed as follows :—Have a good-sized lamp glazed with pale red glass, not with the black abomination generally called "ruby," which is almost opaque to light. A good lamp may be made from any kind of box, by fitting to it a sliding pane of red glass in place of the lid, and putting a small paraffin lamp therein. A chimney should be made at the top, to ventilate the box. This arrangement will give a flood of light without endangering the plate. The writer always develops close up to the lamp, and has never yet fogged a plate. If the operator cannot see what he is doing, he need not expect good negatives, but may reasonably look for indications of failing eyesight after a few months' work. So, to get good negatives, and save temper and eyesight, have plenty of light of the right sort. No light is really non-actinic, and much of the "ruby" glass in use is quite as unsafe to use as the yellow glass used in developing wet collodion plates. Yet, once in the developer, even yellow glass may be used with complete safety. It is only while the plate is dry that exposure to a strong light is likely to act injuriously. Thus, in changing plates, or in taking them from the slides to develop, let the lamp be shaded or turned down; but while developing, every detail must be clearly seen.

PARASITE OF OX. 2-inch obj.

To proceed. Place the developing dish near the lamp; pour into the developing cup, for a half-plate, 1 ounce of the pyrogallic solution, and ½-ounce of the ammonia and bromide. Place the plate in the dish, and pour over it the mixed solutions. If the image runs out rapidly, pour the developer off, and make up a fresh developer of 1 ounce pyro and 1 drachm ammonia and bromide. If, after this, the detail does not come out satisfactorily, pour the developer back in the cup, and add more ammonia. By varying this mode, plates that have received thirty times the correct exposure may be satisfactorily developed. They will hardly have the brilliance and "pluck" of a properly-exposed negative, but will yield fair prints.

If the image does not make its appearance after it has been in the developer about a minute, add the remaining ½ ounce of the ammonia solution. The image will then slowly appear, if the plate has been properly exposed; but if under-exposed, only further doses of ammonia will bring it out. In the latter case, take no further trouble with the plate, but at once expose another, for an under-exposed plate is simply useless.

It will be found in developing some negatives that one part will develop more readily than another, and become so dense as to be quite unprintable. The photograph given below (parasite of ox) is an example of this. On developing, the body appeared first, and became of an alarming blackness before the legs had got little more than their outline. The developer was at once thrown off, and the negative well rinsed in water. Fresh developer was made up, and the tray tilted up, so that when the negative was again placed in the dish the developer would cover the parts only partially developed, which in this case were the head and legs. The dish was gently rocked all the time, and the negative, when finished, was of uniform density. By this means the after reduction of the negative was avoided.

If the development proceed satisfactorily, don't be in any hurry to take the plate from the developer; over-development will not do much harm, while the contrary would ruin it. When all the details are well out, examine the plate, by holding it up before the lamp. Should it prove sufficiently dense, rinse it in water, and place it for a minute in a solution of alum and citric acid; wash again, and put it in another dish containing hyposulphite of soda made up thus :—

Hyposulphite	4 ounces
Water	20 ,,

When the creamy bromide of silver is dissolved, which may be known by the plate becoming quite clear and transparent, place the negative in fresh hyposulphite for a few minutes; no fear need be entertained of the hyposulphite solution *weakening* the negative. Then put the plate in running water for half-an-hour. This will be sufficient, but any trace of hypo will be got rid of in the next bath :—

Alum	2 ounces
Citric acid...	1 ounce
Water	20 ounces

This solution will also harden the film, and render it less liable to injury from scratches or wet. The final immersion in alum should be regarded as absolutely necessary. It will brighten up the negative, removing any stains which the developer may have left, and make it "quicker printing."

The negative should not be dried too rapidly. In fine dry weather it can be best dried by placing it out of doors. In winter time, the writer stands his negatives on a warm mantel-piece, where they dry in one or two hours. The only precaution to observe is, that the plate should have previously been soaked in the alum bath for at least five minutes; otherwise, if the film be composed of soft gelatine, the heat of the mantel-piece is apt to melt it.

Notes.

Apart from value as a striking example of group-posing by Rejlander, our supplement of this week possesses a melancholy interest; for no less than five out of the nineteen who were photographed in 1869 are now no more. The photograph was taken in Rejlander's studio in Victoria

Street, and although the photographer himself figures in the group, he arranged everything, an assistant having made the exposure.

Those new to the study of photography are likely to gain much by a careful perusal of the series of "Practical Papers for Beginners" (commenced in our issue of July 18th), as many matters hardly touched on in the comprehensive handbooks are minutely dealt with. One method of performing each operation is described, and that method the one which we believe best for the beginner.

Not only had the fire which broke out at the Stores in Chandos Street been extinguished within an hour of its commencement, but by the expiration of that time the floor had been re-covered with kamptulicon, and workmen were busily engaged in repairing the damage done to the roof. On the principle of giving honour where honour is due, it ought to be known, we think, that but for photography this marked expedition could not have been displayed, for before anything could be moved or repaired, a photograph of the *locus in quo* had to be taken for the use of the Fire Insurance Companies concerned. Once again, then, do we find what positive assistance a negative can render.

An epoch in the application of photography to journalism may be marked by our illustration on page 562. Not only is the engraved block made entirely by photographic agency, but it represents current news; and what is of perhaps more importance, it was printed satisfactorily along with the rapidly-machined letterpress of the PHOTOGRAPHIC NEWS.

"How quickly can such a block be produced?" is an important question. We think it reasonable to hope for, and look forward to, the time when such auto-engraved blocks may be produced with certainty in five or six hours after the exposure of the sensitive plate in the camera; doubtless our daily papers will then be regularly illustrated by photography.

Persons who live by their wits should have good memories. Some time ago a tall, gaunt, shabby, slightly-rubicund-nosed individual called upon a well-known photographer, and told a long tale, how he was a colourer of photographs, and how, through a long illness, he had lost his connection. It wasn't money he wanted so much as work, although he threw out a hint that he hadn't tasted food that day. The photographer, willing to lend a helping hand, gave him sixpence and a carte to colour, telling him that if he did the work well, he could have constant employment. The man was overwhelmed with gratitude, and promised to bring the carte back the next day. A month went by before the "colourist" made his appearance, and when he did, it was to go on the same yarn about his destitution and inability to get work. "But," said the photographer, "where is the photograph I gave you to colour a month ago?" "Did you give me one to colour, sir?" "Of course I did." "Oh, I beg your pardon, I'm sure. *I quite forgot I've been here before, or I wouldn't have called!*" And he walked out quite undisturbed.

The latest novelty in photographic albums—if album it can be called—is a series of plush-covered frames, fixed on one side to a common centre, and opening like the leaves of a book. This is made to hang on a wall, and forms a very effective and novel drawing-room ornament.

Photography supplies one of the best tests of popularity. The sale of Mr. Gladstone's photographs in Scotland during his recent campaign has been enormous. It is said that in Edinburgh the street hawkers have sold over £300 worth of penny photographs.

Whether it is that infirm artists are employed we cannot say, but the attempt to paint up to a photograph generally results in a failure. A picture issued by a French house has just made its appearance in the print shops. It represents two children lying in each other's arms in a basket. The children have been beautifully photographed, and are charmingly posed; but the basket has been put in by the brush, and while the figures are round, solid, and full of light and shade, the basket is as flat—to use a homely simile—as a pancake. A more incongruous effect we have not seen for some time. Why the children could not have been photographed in the basket is puzzling.

Thursday next is the last day to send in pictures for the London Exhibition; if packed, to be sent to Mr. James Bourlet, 17, Nassau Street, Middlesex Hospital; but if unpacked, they may be delivered at the Gallery, 5A Pall Mall East. In any case, a letter containing a brief description must accompany them.

A "Special Notice," stated to be "*by order of the Council*," is printed in blue ink prominently across the official circular. It runs thus:—"*The rules and regulations respecting the Exhibition are to be strictly adhered to, therefore no picture will be received after nine o'clock on Thursday, September 25th.*

To thus make it appear that the rules are only to be observed in an exceptional case is injudicious, apart from the ludicrousness of a ruling body making an order to the effect that its own rules shall be observed. The "Special Notice" at once raise a doubt in the mind.

A case in which plaintiff and defendant were both photographic artists lately came before the Supreme Court at Baltimore, Mass. The object of the suit was to settle a dispute as to the profits of a photographic business that had been sold, and the prosecuting counsel caused considerable amusement by applying, with all apparent seriousness, that the case should be heard *in camerâ*.

Some twenty portraits of the leading men of the British

Association are given in those numbers of the *Montreal Star* which were issued during the session; but we do not find that the photographer is accredited with any of the honour involved in their production. The making of engraved portraits from photographs by illustrated newspapers is a recognised thing; but the photographer should have his due. On the whole, the series of portraits issued by the *Montreal Star* is good, one of the worst being that of the President of the Photographic Society of Great Britain.

A lady correspondent cannot make out why there should be such seeming difficulty in photographers keeping their dry plates separate. "Surely," she writes, "if they have not a plate-rack, they have a kitchen dresser!"

The *San Francisco Examiner* quotes a pretty tall photographic story from the *Independant*. The *Independant* says there has been purchased from an Indian a pair of field glasses, supposed to have belonged to Hahn, a lost guide of Wheeler's Expedition. The instrument was found in a desert near what is known as Death Valley, and printed on the object glass is a photograph of every object within range of where they had been lying. Every leaf and stalk are distinctly marked, and the pictures occupy a position about the centre of each of the object glasses, but a little nearer the plane than the convex side. We should be inclined to think that this tale will have to be taken with a very large grain of salt.

The New York photographers are busy just now in photographing lap-dogs, a fashion in this direction having set in. Their terms for the operation are the same as for babies.

Mr. Jennings' series of exceptionally practical articles on photographing microscopic objects is by far the most practical monograph on the subject yet produced. The series, which commenced a month ago, is now about half through.

The clause in a recent Act of Parliament, making it illegal for a tradesman to use the Royal arms without special authority, was doubtless intended to remain a dead letter; and indeed it has remained a dead letter. Our readers will therefore be somewhat surprised to hear that a summons under the clause in question has been applied for against Messrs. A. and G. Taylor, photographers, of Regent Street, and we are sure that all readers of the NEWS will be pained to learn that the prosecution is at the instance of another photographer. It is said that the case will be heard at the Marlborough Street Police Court on Tuesday, the 30th instant, at 2 p.m.

Here is an instance of touching modesty. A nursemaid with an infant of about six months old in her arms called at a studio a few weeks ago, and asked to see the photographer. "I am the photographer," replied the proprietor. "Oh!" said the young person, in some confusion, "I understood it was a lady who took the portraits." "No, it is not a lady; but does that make any difference?" naturally enquired the photographer. "Oh! yes; the baby's mamma particularly wants his legs photographed—but—but she thought it was a lady who did them." And the young person precipitately retired, whether to seek out a lady photographer cannot be said; but she never came back.

A society journal writes thus enthusiastically of a well-known West End studio:—"The visitor to the studio can at once see, when the light is cast on the face of one of the attendants in the studio in order to exemplify the process, how the shades are expunged, and a marble-like clear physiognomy is exposed to the lens." An "expunged shade" is good.

The fact that a number of street hawkers at Edinburgh realised so much by selling penny photographs of the Premier during the week in which he delivered his Midlothian speeches is not only a significant political fact, but is another instance of the development of the photographic art. At the last general election there were at least two cases in which a candidate issued a copy of his carte-de-visite to every elector. At the next general struggle their example will probably be followed by many of the better-looking of the candidates, who will doubtless argue that if they wish to obtain the countenance of the constituencies, a suitable preliminary step is for them to present these constituencies with theirs.

In France the use of photography as a means of helping on a political propaganda is by no means new; but the plan adopted by Paul Cassagnac and the other friends of Prince Victor, to promote his cause, is so novel that it has taken the French police authorities a considerable time to discover the *modus operandi*. An enthusiastic Victorite, it seems, furnished the funds required. Many thousands of cartes of Prince Victor in his uniform as an artillery soldier having been taken, they were placed for distribution in the middle of cheap packs of playing cards, which were re-sealed and distributed in the country districts by reliable colporteurs or book-hawkers. Some thousands of these prepared packs have been prepared at Rouen and Orleans, and the new game, for the present, at all events, is played out.

Patent Intelligence.

Applications for Letters Patent.

12,329. Joseph Lyons, 34, Southampton Buildings, Chancery Lane, W.C., for "Improvements in stereoscopes, and in combining a lamp therewith."—Dated 12th September, 1884.

12,389. Josiah Thomas Chapman and Thomas Scott, 41, John Dalton Street, Manchester, for "Improvements in folding-cameras."—Dated 15th September, 1884.

Patent Sealed.

7746. Thomas Furnell, 1, Matlock Villas, Lordship Lane, East Dulwich, London, Surrey, Civil Engineer, for "An adjustable instantaneous shutter for photographic purposes."—Dated 15th May, 1884.

Specification Published during the Week.

5947. George Rydill, of 52, Chancery Lane, in the county of Middlesex, "Improvements in the preparation of photographs, or the treatment of drawings or designs printed on paper, or

other suitable material, for the purpose of imitating stained, ground, cut, or embossed glass, or to be employed for other useful or ornamental purposes."—Dated 30th June, 1884.

This invention consists in producing, treating, and applying photographs, printed drawings, or designs, either upon sensitized white, tinted, or coloured paper, satin, cotton, linen, parchment, glass, wood, or other suitable material, printed or produced from glass negatives, wood blocks, stone, metal, glass, engraved or etched metal plate, or by any of the known methods of printing in one or more colours.

The claiming clauses of the specification, which itself is very long, are as follows:—

1. The treatment of photographic or other prints or paper in a vessel with piue or other oil, or varnish, as described, under hydraulic, vacuum, or air pressure, to make the same translucent and preserve the colour.

2. Printing photographs or other printings on the back, either before or after they are made translucent, and on another paper, to finish the picture, is printed on the face side a background, or the background may be printed on the face side of the photograph.

3. Placing photographs betwixt two sheets of glass, and cementing the edges together.

4. Placing a printed design on the back of a photograph mount.

5. Printing photographs on both sides of sensitized paper at one time by the use of two photographic negatives.

6. Cutting out photographs to be placed on a background, or cutting out coloured paper or material to be placed behind translucent photographs.

7. Placing material or designs on the back of looking-glasses, also placing a border on the front or back side, and enclosing the same betwixt sheets of glass, and cementing the edges together as described.

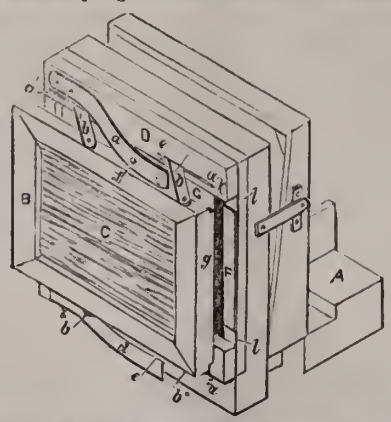
8. Placing transfer borders in imitation of stained glass, or placing designs on glass to imitate stained glass, so as to be cut with a diamond as described, and for the ornamentation of glass shades.

Patents Granted in America.

304,406. THOMAS HENRY BLAIR, Boston, Mass., "Camera-box." Filed April 14, 1884. (No model.)

Claim.—1. The combination of the box A, spring-actuated frame B, with the pivotted links *b b' b² b³*, springs *d d*, pins *c c*, and stud *f*, all substantially as and for purposes stated.

2. In camera-box, the combination, with rear frame, D, and packing, *g*, of the spring-actuated movable focussing-frame D,



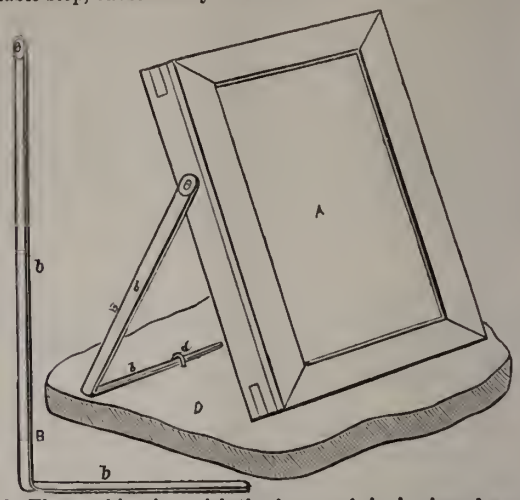
and plate-holder E, substantially as described, whereby light is entirely excluded when exposure is made, as stated.

3. The combination, with a camera-box, as herein described, of the plate-holder E, with its flap *i* and depressions *j j*, as and for purposes set forth.

4. The plate-holder E, constructed with the parts as described, consisting of the ears *q q* and flap *i*, with the spring *r*, as and for purposes herein set forth.

304,421. FRANK FRENCH, Lawrence, Kans., "Photographic printing-frame."—Filed May 7, 1884. (No model.)

Claim.—1. A support for photographic printing-frames, composed of the side arm pivoted at one end to the frame, and the base-arm extended at right angles from the opposite end of the side arm, and adapted to be inserted through a staple or other suitable stop, substantially as set forth.



2. The combination, with the frame, of the L-shaped support having its side arm pivoted at one end to the frame, and its base-arm extended at right angles from the opposite end of said arm, and adapted to be inserted through a staple or eye, substantially as and for the purposes specified.

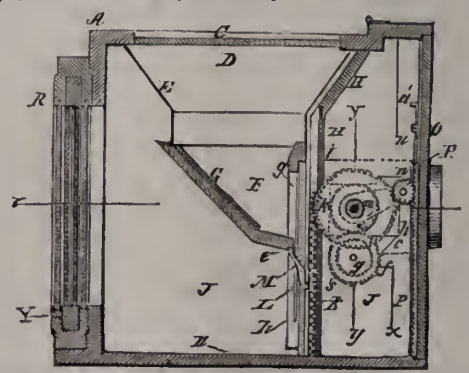
304,503. WALTER CLARK, New York, N.Y., "Photographic camera." Filed Jan. 17, 1884. (No model).

Claim.—1. In a photographic camera in which are combined an adjustable lens, a device for holding and exposing the sensitive plate at the back of the lens, a focussing glass in the side or top of the camera-box, and a reflector for throwing the image upon the focussing-glass, the camera-box constructed with a stationary partition in advance of the reflector dividing the box into front and rear compartments, and serving to carry the lens tube or case, substantially as specified.

2. The camera-box provided with a partition dividing it into front and rear compartments, and having a lens-opening through it, in combination with a movable mirror-case arranged at the back of said partition, and a focussing-glass in the top or side of the box, essentially as and for the purposes herein set forth.

3. The camera-box constructed with front and rear compartments, J J', and having a lens-opening between them, in combination with the movable inclined mirror-case F, arranged at the back of the front one, J', of said compartments, and provided with an opening and closing diaphragm, L, in its front, substantially as specified.

4. The combination, with the movable mirror-case F and its opening and closing diaphragm L, constructed to lift said case after closing it, of the sliding rack K, connected with said diaphragm, and the catch M, essentially as described.



5. The combination, with the camera-box compartments J J', the movable mirror-case F, having an opening and closing diaphragm, L, and the drop-shutter of the camera, of mechanism arranged within the forward compartment, J', for operating said case, diaphragm, and shutter, substantially as specified.

6. The combination, with the partition H, dividing the camera-box into front and rear compartments, J J', of the rack

K, fitted to slide in or on said position, the gear-wheel *k*, operating said rack, and the mirror-case F and its opening and closing diaphragm L, moved by said rack, essentially as described.

7. The sleeve *m* and spindle *c'*, arranged for operation from the exterior of the box, in combination with the gears *k n e' f' g'* and the racks K, P, and *h'* within the box, the movable mirror-case F, its opening and closing diaphragm L, the shutter N, and the adjustable lens of the camera, substantially as specified.

8. The circularly-shaped vibratory shutter N, having a notch, *r*, in combination with the spring-catch *u*, the spring-catch or lifter *t*, and the rack P, with its finger *s*, substantially as described.

9. The vibratory drop-shutter N, in combination with its controlling-spring *i*, spring-arm *l'*, and bracket or plate *k'*, essentially as and for the purpose described.

A SHORT PHOTOGRAPHIC TRIP IN INDIA.

BY CHAS. R. PANCOAST.

Having occasion last winter to visit India in connection with some exhibits at the Calcutta International Exhibition, I considered the opportunity of indulging my favourite pastime too good a one to be overlooked. Past experience having given me little or no confidence in our gelatine plates, and never having attempted their manufacture myself, I decided to "pin my faith" on those of some first-class English maker. As a last resort, in case gelatine should fail, I took a quantity of washed collodion emulsion; this I knew would work well, and be less liable to trouble from the great heat. Upon arriving in London, I did the "correct thing" in the eyes of most American amateurs—namely, order one of Mr. George Hare's improved cameras, and much credit is due to that gentleman for the promptness with which he executed the order. My outfit, therefore, including what I brought from home, consisted of a "Hare" 6½ by 4¾ camera and changing-box, one 5-inch Ross portable symmetrical, one 7½-inch Ross rapid symmetrical, and one 11-inch Dallmeyer rapid rectilinear lens; the latter lenses being fitted with shutters for instantaneous work. Of plates, I purchased those of Wratten and Wainwright, of the "Instantaneous" and "Ordinary" brands. Apparatus and chemicals for developing completed the list. As India was to me a terra incognita, I felt uncertain as to the working of gelatine, but as others had done so successfully, I felt disposed to give it a thorough trial.

The outward voyage on the P. and O. steamer *Ganges* afforded a few opportunities for work; the first of these was at Malta, where a stop of five hours enabled me to make a few pictures of the prominent objects of interest in Valetta. There are a number of professional photographers here who make fairly good work, but, I fear, cannot do so to any profit at the rate of 8d. for 12 by 10 unmounted prints. On leaving Malta Harbour, some excellent instantaneous work can be made from the steamer with Fort St. Elmo as a principal feature. Port Said, our next stop, afforded more opportunities, and some picturesque groups of Arabs rewarded my efforts. After this, little or no work was done save one or two "drop" pictures in the Suez Canal, and an occasional group of passengers or officers. As soon as possible, after establishing myself at the Great Eastern Hotel in Calcutta, I set about developing the plates exposed on the outward voyage. In order to obtain moderately cold water without using ice, I purchased a few porous earthen jars, the evaporation from which kept the contents sufficiently cool for all practical purposes. In fact, I did not experience the least "frill" even when the thermometer registered over 85°. By means of a rubber tube and clip, the water could be syphoned from the jars as readily as drawn from a tap. My formula for development, though nothing new, has the merit of simplicity and ease of manipulation:—

Pyro	2 grs. to 1 oz.	water
Citric acid	¼-gr. to 1 oz.	,,

Mixed fresh just before use.

Strong aqua ammonia	1 ounce
Water	1 ,,
Bromide potas.	60 grains
Water	1 ounce

I usually immerse the plate in the "pyro" for two or three minutes, then the addition of ten drops each of the ammonia and bromide suffice to complete development. Any variation of time can be compensated by increasing or decreasing the proportions of ammonia and bromide. Previous to fixing, I always allow the plate to remain at least five minutes in a strong solution of alum, containing five per cent. of oxalic acid. This tends not only to harden the film, but removes any of the stain occasioned by the pyro. Subsequent to fixing, a second alum bath removes any traces of "bypo" that may be left. This formula in my hands gives entire satisfaction, and seems to be equally well adapted to the various makes of plates. I always developed at night, partly from the lessened liability to danger from light, and from the fact that it was much cooler. M. Joubert, the director-general of the Exhibition, through his secretary, Mr. Walpole, kindly gave me the needed permission to make pictures in the Exhibition, and as the Indian building teemed with rare and beautiful subjects, I was not slow in availing myself of every opportunity. As many of the courts were but dimly lighted, I experienced at first a great difficulty in focussing, until a plan suggested itself which answered admirably. By taking the camera outside, and placing it at a distance from some object (preferably one having fine lines) equal to the average distance of the objects required in the picture, and focussing carefully with a large stop. Then, taking the instrument back in the building, and being careful not to disturb the focus, I was enabled to secure pictures of great sharpness, and without the severe strain on the eyes occasioned by working in a dimly-lighted interior. With the "Instantaneous" plates, I found one half-hour to be about the correct time, working the 4 stop of the 5-inch portable symmetrical.

The exhibits embraced collections from all the provinces of the Indian Empire, many of them of rare beauty and great value; those from Burmah, Punjab, Bombay and the North-West Provinces, and Oudh, making the most artistic and attractive pictures. The private exhibits of a firm of Chinese merchants in Calcutta, and that of a firm in Yokohama, were indeed beautiful, and afforded some rare and interesting bits; notably in the latter exhibit, a remarkable carved figure of the so-called wild man of Japan. This was considered by critics to be the finest specimen of wood carving of the modern Japanese workers, and was purchased by a noted connoisseur (the "Mr. Isaacs," of book fame) at a price approximating £1,600.

The government exhibits were large and varied, showing the high state of perfection to which the various details had been carried by native workmen under intelligent European supervision. While in Calcutta, I made the acquaintance of Major J. Waterhouse, to whose kindness and courtesy much of the pleasure of my stay was due. Having charge of the photographic branch of the Survey of India, he has brought the reproduction of maps and drawings by photo-zincography to a perfection I hardly deemed possible. I greatly enjoyed inspecting his establishment, and was everywhere impressed by the completeness of the details. He has lately been experimenting in the manufacture of gelatine plates, and, judging from the results shown, should say he was on the high road to success.

When not engaged in the Exhibition, I did considerable photographic work in and around the city, especially some street and river views. In these, I was greatly assisted by a "brother amateur," whose acquaintance I made in the Exhibition. His knowledge of the vernacular enabled me to secure a large number of studies that would otherwise have been impossible. A trip to the Royal Botanical Gardens at Seebpore well repaid the time and trouble, as there are many beautiful foliage effects. The great banyan tree, one of the largest of its kind in the world, is an interesting and curious subject. Eden Gardens, the Hyde Park of Calcutta, afford a few fine bits for the camera,

notably a Burmese pagoda, and a stone arch bridge overhung by beautiful trees. From the top of the Ochterlong Monument in the Maidan, a good panoramic view of the city can be obtained. To the south the Exhibition grounds, with the Museum building in the background: to the west the long stretch of the Maidan, with Eden Gardens and the Hoogly River in the distance; to the north, the business portion of the city, with the government building in the foreground, and the high dome of the post office in the distance; to the east, a portion of the native quarter, and Chowinghee Road in the foreground. From Calcutta I made a short excursion to Darjeeling. A succession of cloudy days prevented any photographic work, a fact I greatly regretted, as the scenery in the Himalaya Mountains is grand beyond description. The narrow guage railroad up the mountains is a grand piece of engineering work; in many cases the road is located close to the edge of a precipice, where a broken rail might precipitate the whole train a distance of over one thousand feet. Upon my return to Calcutta, and the Exhibition on the eve of closing, I turned homewards, intending to stop in Agra and Delci *en route* Bombay. So far I had been greatly pleased with the working of the gelatine plates; there was a softness, uniformity, and freedom form halation, that was especially satisfactory. Some few washed collodion emulsion plates I prepared did not give as satifactory results as I had hoped, owing to the dust, the great annoyance of an Indian winter. The absence of high winds, and the prevalence of bright clear skies, rendered out-door work a pleasure.

While on the subject of plates, I might remark that the English makers would do well to pay more attention to the packing of their plates shipped to India, as it is by no means uncommon to find a package containing several broken or damaged ones. Having occasion to purchase plates, I was disgusted to find a large number broken and damaged. One gentleman informed me that in getting a lot of five dozen from a prominent maker he found every plate more or less damaged from the cause named. A very slight additional care on the part of the packers would obviate the difficulty.

To return. Upon reaching Agra I set to work industriously to capture as many of the beautiful subjects as my limited time would permit. Secundra, the tomb of the Emperor Akbar, first claimed attention. Situated in a large and well kept garden, it forms an attractive subject. Thanks to the government, these beautiful buildings are kept in perfect order, and free to all, save perhaps a small gratuity to the durwau, whose smiling face and profound salaam are indicative of "backsheesh." From Secundra I next visited Agra Fort, of which the Elephant Gate forms the most interesting subject. The material used in the construction of these buildings are a red sandstone and white marble; the effects when used separately or combined are very pleasing. Inside the spacious walls is a marvel of ancient architecture, the Moti Musjib, or Pearl Mosque. Nothing can exceed the wondrous beauty of the arches and carvings, the more so when we consider that it was constructed by a race of men we are wont to compare with savages. From an archway in the private audience hall a magnificent view of the valley of the River Jumna with the Taj is obtained. It is indeed a trying subject for lenses and plates.

On the following day, in company with an intelligent guide, I drove to the Taj Mahal. This vast mausolcum was built by the Emperor Shah Jaban as a resting place for his favourite wife, Mumtaz Mahal, and, though some 230 years old, is, I feel safe in saying, the handsomest edifice in the world constructed of white marble. It has suffered little or no decay, the elements only tending to bleach the stone to a greater whiteness. Again the wisdom of the Government is apparent in the careful restorations where needed, and the great pains taken to preserve the grounds and buildings in their original beauty. The exquisite carvings of the screen surrounding the tombs, and the inlaid work on the tombs themselves, challenge comparison with the best work of modern times. It may be equalled, but I doubt excelled. From the Taj I next visited the tomb of Itmad-ud-Dowlah; this, like the Taj, although much smaller and far less imposing, is constructed of marble, covered with elaborate carvings and costly inlaid work. The carved screen surrounding the cenotaph is a marvel of the stone-cutters' art, and second in beauty only to that in the Taj. The Jumma Musjid, or Great Mosque, is a picturesque subject, were it not that the great civilizers, the railway and the telegraph, conspire to spoil its beauty by placing their rails and wires in such a position as to render a satisfactory picture impossible. Delhi is but a few hours' ride from Agra, and, like it, abounds in photographic subjects. On the way to the celebrated Kutub Minar, I examined a curious monolith known as Feroze Shah's Pillar. It is some 30 feet in height and 30 inches in diameter, and from the inscriptions we were informed that it is over 2,000 years old. It is an interesting and curious subject. The tombs of Humayun and Sofdar Jung were in turn inspected and photographed. Although in point of architecture they are inferior to Secundra (Akbar's tomb), yet they are fine specimens of the buildings of the sixteenth century. The exquisite little marble tomb of Nizam-ud-Deen well repaid me for a tramp through the dirty passages of one of the old Delhi Forts. It seemed like a jewel in the midst of a heap of rubbish. The Kutub Minar is, indeed, a wonderful and beautiful monument, constructed, as are all the tombs and forts, of red sandstone and marble; it has stood the ravages of time to the extent of nearly six centuries, and apparently unscathed. Its designer, by so proportioning the height of the various stories, has given the effect of exaggerated perspective, so that it looks much higher than it really is. Its dimensions are—height 242 feet, diameter at base 50 feet, and tapering to 13 feet at the top. Close by are the ruins of an ancient mosque in which is located the world-famous Iron Pillar. Opinions regarding this are at such variance that I refrain from making any comments; suffice to say it, together with the ruins, afford some highly picturesque photographic studies. As a trip to the Kutub consumes one day, the next I devoted to objects of interest in the city proper, prominent among these being the Cashmere Gate, famous as being the point of final attack in the Sepoy Mutiny. Delhi Fort, like its counterpart at Agra, has many points of interest. The Diwan-i-Am, or Private Audience Hall, recently restored at great expense, is perhaps the finest building of its kind in India. Near by is the Pearl Mosque, especially constructed for the ladies of the Court, having private passages to the Zenana, so that the worshippers could enter without being observed by masculine eyes. It is smaller, but scarcely less beautiful, than the similar building at Agra. Being very desirous of photographing the interior of a Jcin temple, my guide volunteered to conduct me. On arriving, those in charge objected to the leather case containing my camera. After some discussion and promise of "backsheesh," I was permitted to take the camera in, although the case kept a solitary vigil outside. It might be well to note, in cases of this kind, that the leather bellows in a camera does not count. The Jumma Musjid, or Great Mosque, is, perhaps, the most imposing building of its kind in the world, and in capacity for worshippers is said to be second only to the great mosque at Cairo, Egypt.

Leaving Delhi, my next point was Bombay. Here, having a few days prior to the departure of the steamer, I employed them in making a few pictures of the principal buildings. Few American or European cities can boast of as fine public buildings as Bombay. They are large, airy, and especially well adapted to the wants of the Government, combined with great architectural beauty. The Elephanta Caves, on an island in Bombay Harbour, are wonderful evidences of the skill displayed by the ancient workmen. With the modern appliances for mining and blasting, the work would be by no means insignificant. Much of their

pictorial beauty has been marred by the partial destruction of the statues and images. With Bombay I closed the photographic work of the trip, and packed my plates for development on reaching home. The method I adopted was to cut narrow frames from thin cardboard the exact size of the plates, and placing one between each film surface. By cutting these in one piece, although wasteful, an even bearing is obtained for each plate, and a much firmer package made than when these frames are made of narrow strips pasted together at the corners. After wrapping several thicknesses of non-actinic paper around the plates, I put them in cardboard boxes, giving these several folds of heavy wrapping paper. By giving care and attention to the packing, I was able, despite the rough handling incident to ocean travel, to take all my plates to America without a single fracture. Soon after arrival, I developed the plates exposed on my tour across India, and of the seventy plates exposed, only one proved a failure (a dark interior, from under-timing), and I could see no difference between them and those exposed and developed on the spot. It is, indeed, satisfactory to know that sensitive plates can be made in England, exposed in India, and developed in America, without the slightest deterioration.

Much has been said concerning the Indian climate, but in the winter months it is simply delightful, and closely resembling in temperature a cool American summer. On the whole, I greatly enjoyed my visit, and especially so as my photographic work proved so successful.

VOYAGE OF THE "MONARCH" BALLOON.

BY CECIL V. SHADBOLT.

We left the Artillery Grounds at about 4·15 p.m., the "Colonel" balloon having been despatched some ten minutes previously. As we gradually rose above the bricks and mortar of Finsbury, the extraordinary interest manifested in the afternoon's proceedings became very evident. Dense masses of people thronged not only the grounds from which we ascended, but every point of vantage in the neighbourhood appeared to be occupied; windows were crowded, housetops thickly packed, and the streets below on all sides literally teemed with thousands and thousands of human beings, the sight of whom, as we slowly and steadily mounted upwards, was one not easily to be forgotten.

The view was simply superb. Below us lay the whole of London stretched out in maplike beauty, with its grand and mighty buildings dwarfed into mere toys. There was the noble Cathedral of St. Paul, with its dome resembling the proportions of the thick end of a gigantic egg: further on, the Victoria Tower of the Houses of Parliament stood out boldly like an ornamental match box, and a little square-sided set of buildings with an open space in the centre, the whole appearing of dimensions almost suitable for the waistcoat pocket, was soon recognized as Somerset House.

Thus our eyes wandered from point to point as we glided upwards and onwards, now puzzled as to the individuality of this or that building which appeared to stand out more prominently than the rest, and now gratified by the recognition by one or other of us of the various places of interest which we were able from time to time to identify, as the vast pile of outstretched metropolis of the world gradually passed in panoramic procession beneath us.

At 4.25 we were directly over Regent's Park at an altitude of 2,500 feet, and at 4.44 we sighted the "Robin Hood," which had just risen, and for which we had for some time been watching; while in the opposite direction the "Colonel" could readily be distinguished in the far-off distance, both balloons appearing about the size of peas. Our course then lay almost straight over the picturesque suburb of Harrow-on-the-Hill, and thus we sped onwards on our aerial journey. Somewhat later, on again looking round for the "Robin Hood," that balloon was no more to be seen, its aeronauts having effected a descent near Sudbury, over which district we had ourselves passed some time previously.

On nearing Harefield, our supply of ballast having become reduced to one and a half bags only, it became necessary to terminate our journey, which we did at 5.15, after a run of 18½ miles, by bringing down the "Monarch" in a field close to that village.

A PHOTOGRAPHIC WALKING TOUR IN WALES.

BY CHARLES E. ABNEY, B.A.*

Having been requested to write a paper for this Society, and only having a short time for this purpose, I have decided to write on the subject of my holiday. It may interest at least some of my amateur brethren, and perhaps give them a wrinkle for the future when they are meditating on what to do with themselves during their holidays. Last Easter, a friend and I were talking over our coming holidays, and it struck us that nothing would be better than to have a short walking tour in Wales, and the matter was then and there decided. As the time drew near for our holiday, I confess to feeling a considerable amount of pleasurable excitement in getting my traps ready. I may as well at once describe the photographic kit which I took with me. In the first place, I took a 5 by 4 camera, by Watson and Sons, fitted with three double backs. The lens was of the rectilinear type, of foreign make, I believe, and having a back focus of 7½ inches; it is a most excellent lens, although it wants the maker's name. The camera, lens, and back were fitted into a case of American cloth, and the legs were of a light folding pattern. The camera, legs, &c., weighed about eight pounds. For changing plates, I took with me a folding lantern which I obtained from Mr. Werge, of Berners Street, London. I consider the lantern is so excellent both for changing plates and developing by, and so very portable, that I have brought it for the inspection of the Society. Besides the plates which I took with me, I took a few empty boxes, and paper for packing exposed plates in. And here let me give a word of advice to those who wish to carry plates safely when travelling, viz., let them pack them in their portmanteaus between articles of clothing. I did this, and although our luggage frequently had very rough treatment, I did not have one plate broken.

At last the eventful day (the 4th of August) arrived, and we started from Derby for Conway. As you all know what the weather was at that time, I need not tell you what our journey was like. We arrived at Conway a little after three o'clock, and after making arrangements for dinner and beds, I, the impatient photographer, felt bound to rush off and photograph the well-known Castle. I first went inside, as I wished to have a shot at the interior of Banquetting Hall, or whatever they call it, but unfortunately I found my lens was too long in focus to get what I wanted. After trying every position, I reluctantly left the interior to try my luck outside. I took two views of the Castle; one from near the entrance, the other from the shore. These two views are shown in the prints (Nos. 1 and 2.) The next morning we started off to walk from Conway to Bettws-y-Coed, by the right bank of the river Conway; the walk is a very beautiful one, but for the first few miles I did not light upon any subject for my camera. After we had gone about six miles, we came upon a man with a cart going to Llanrwst with empty soda water bottles. This good Samaritan offered us a lift, which we thankfully accepted, as we were nearly melted; and seated on boxes full of empty soda water bottles, we made a triumphant entry into Llanrwst; there I had my first shot for the day, and secured a good photograph of Llanrwst Bridge from the river; this is print No. 3.

Resuming our journey, in about three and a-half miles more we reached the old bridge called Pont-y-pair, at Bettws-y-Coed. I at once attacked the bridge, and then took a shot from the bridge looking up the stream, the Llugwy; the results are shown in prints 4 and 5. The next view I took (No. 6) was of the stream in front of the "Royal Oak Inn," while my companion went on to secure rooms, and see after the luggage. After luncheon, we determined that we would go and see the well-known Miners' Bridge. This bridge I consider a decided fraud. In former days it was a strong ladder reared from one edge of the stream to the top of the bank on the opposite side, and there might have been something curious, if not picturesque, about it;

* Read before the Derby Photographic Society.

but at the present date it is merely a wooden bridge with a hand-rail at each side, and is neither curious nor picturesque. However, I got two nice views (Nos. 7 and 8) of the stream near the bridge. The next morning we were up early and started for the Fairy Glen. Unfortunately, the light came the wrong way for getting the best photographs of the upper part of the glen—an afternoon light would have been better. However, I got two pictures of that part (Nos. 9 and 10), which were good, considering that the sunlight was almost coming full into the lens. I got three pictures of the lower part of the Glen (Nos. 11, 12, and 13), for which the light was better. We then returned to our hotel, and on the way back I got a view from a field just below the Waterloo Bridge (No. 14). When we got back to our hotel, I made enquiries as to a cellar in which I could change my plates. They took me to the so-called cellar, but, when I got there, I found that it was not underground, and that floods of white light kept streaming in from different parts. This looked bad. However, my friend and I took off our coats, and, after a great deal of trouble, we managed therewith to block out the greater part of the light, and then proceeded to change my plates in fear and trembling. If any plates ran a chance of being fogged, mine certainly did on that occasion. However, "all's well that ends well," and the negatives developed as brilliantly as one could desire. After lunch we started for Pandy Mill. I took duplicate photographs of the mill, and show a print from one of the negatives (No. 15); and I then took a picture (No. 16) of the bridge below the mill, which would have been improved if the sun would have kindly got under a cloud for a few seconds. We then went on to Conway Fall, of which I also took duplicate negatives; both negatives were fair, and I show a print from one (No. 17). On our way back to the hotel we came across a lovely pool of water, where we could get a plunge into fifteen or twenty feet of water. We made a mental note of this place. Next morning we were up early, and started off for our pool; there we had a most luxurious bathe before anyone was about. You may fancy the luxury of such a bath during the tropical weather we were having. After breakfast we started by coach, intending to drive to Pen-y-gwred; but at Capel Curig we were so charmed with the scenery that we determined to leave the coach, and photograph. Here I got two photographs (Nos. 18 and 19), one of the stream with rustic bridge, and the other of the stream and trees, with Moel Siabod in the distance. After this we began the hottest walk we had during the whole of our tour. During the whole of our walk from Capel Curig to Pen-y-gwred there was not an atom of shade, and the heat was intense. How grateful was the shandy-gaff when we reached our hotel! I took one photograph only (No. 20) on this part of our walk.

I had wished to get a good view of Snowdon from this part of the road, but there was a heat haze over the mountain which foiled my intentions. After luncheon we started down the Pass of Llanberis, and here I took three photographs, two of which I show, Nos. 21 and 22. The third, which was very good, I unfortunately managed to scratch after it was finished, and it is utterly spoilt. After spending that night at Pen-y-gwred, we started off on our way to Beddgelert, through the lovely vale of Gwynant, past the Lakes of Gwynant and Dinas; this I consider to be the loveliest part of our whole tour. I show three views of the Lake of Gwynant, Nos. 23, 24, and 25, and one of Lake Dinas, No. 26. When close to Beddgelert I had another shot. I hardly know what to name the view, so I have called it a view near Beddgelert, No. 27. We put up at the well-known Goat Hotel. After a short rest, we explored Beddgelert and its surroundings, but I did not take any more photographs, as I did not care again to risk changing my plates in the daytime. The next day we started off to walk over the mountains to Pan-y-Butch. I had two shots at the Pass of Aberglaslyn, before we struck off into the mountain path. I show one of these views, No. 28; the other was much over-exposed.

The walk over the mountains is exceedingly beautiful, and I cannot speak too highly of the charms of a certain mountain stream which we came across. There was a lovely deep pool under a bridge, and I should think we amused ourselves for over an hour bathing in this said pool. I show one photograph taken on this walk, No. 29, taken from a place called Croesor. At the end of this walk we came to the Oakley Arms at Tan-y-Bwtch, which is a quaint old inn, and is well worth a visit.

Next day was Sunday, and intensely hot, so the only exercise we took in the daytime was to stroll about the beautiful grounds of the Oakley family. In the evening we took the mail car to Festiniog, and thence went by rail to Dolwyd Ielan; from this place we walked by Pont-y-Pant to Betts-y-Coed, and I only regretted that it was late in the evening, for the scenery was beautiful. The next morning, after a bathe in our favourite pool, we set off for the Swallow Falls; but, alas! on our arrival there, just as I was setting up the camera, down I fell with it on to the rocks; the camera was an utter wreck, and one of my legs was damaged. However, I cared more for the camera than I did about my leg, for I was just about to attempt some lovely pictures.

This ended our tour, and we came back. In conclusion, I may say that my exposures ranged between one second and two minutes, and that the quantity of soda and milk which we swallowed would have floated a good sized fishing smack.

Correspondence.

EXHIBITION OF THE PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

DEAR SIR,—Will you kindly permit me to remind intending exhibitors that packing-cases from the country must reach our agent, Mr. Bourlet, at 17, Nassau Street, Middlesex Hospital, London, not later than Thursday next, September 25th; but it would be better if they could be despatched so as to arrive in London a day or two before that date; also that pictures delivered by hand must be left at the Gallery, 5A, Pall Mall East, on Thursday, September 25th (open until 9 p.m.)

Any information respecting the Exhibition, as also slides for the Monday evenings with the optical lantern, may be obtained from yours truly,

EDWIN COCKING, Assistant Secretary,

57, *Queen's Road, Peckham, S.E.*

Proceedings of Societies.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

A MEETING of this Society was held on Thursday, the 11th inst., Mr. W. COBB in the chair.

Mr. A. COWAN opened a discussion on developers by showing plates treated with the mixed carbonates of potash and soda. These were somewhat yellow, and he said that Mr. Ashman had developed some of the same batch with soda, and obtained black images.

Mr. W. E. DEBENHAM preferred clearer shadows than these negatives presented, and thought the veil was an objection.

The CHAIRMAN differed in this respect; he thought a slight deposit all over the plate was an advantage to be sought after; an opinion supported also by Mr. Cowan.

Mr. W. M. ASHMAN then passed round the plates which had been sent for development, and explained that for a powerful developer, such as the one used (Monroe formulæ, page 477 of the present volume), the plates had been over-exposed; they were certainly not yellow. He also showed several negatives on Mr. Henderson's plates, as examples of what the developer was capable of; in no case was there any discolouration.

The CHAIRMAN said there appeared a very distinct difference of opinion on the subject; it was plain that soda could be used without getting yellow negatives. Perhaps it might turn out that there was some difference in the samples of soda employed.

Mr. COWAN used the proportions recommended in the original formulæ, and obtained the crystallized carbonates from a well-known house.

Mr. ASHMAN employed ordinary household washing soda. Before using, it was crushed, and exposed a few days to the air.

Mr. DEBENHAM thought it probable that this treatment might change its composition into a sesquicarbonate. But Mr. Haddon held that efflorescence only took place, thus giving a more constant quantity of alkali.

Mr. DEBENHAM could see no advantage in driving off the water of crystallization in this case.

Mr. ASHMAN said that there was a certain proportion of sulphite of soda mixed with the alkali, as well as the portion added to the pyro and acidified with sulphurous acid, and thought it important to use the relative proportions recommended.

Mr. Cowan then showed the results of experiments with lactic acid in the ordinary ammouia developer (see page 542), and could not find any advantage by the addition. The sample had been put into his hands by the chairman, and it was said to be an accelerator, but he could show that it was not. Four plates were exposed the same time, and developed as follows: No. 1. Ordinary pyro, ammonia, and bromide; No. 2. Similar developer with one-half as much lactic acid as pyro added; No. 3. Lactic acid doubled; No. 4. Lactic acid, equal to double the quantity of pyro used. No. 1 developed in forty seconds; No. 4 in two minutes, the others intermediary. It acted very similar to bromide in restraining full exposure, No. 4 being very dense, but no gain in detail.

The Chairman had not found lactic acid to be an accelerator as claimed, but it conferred a quality on the plates which he liked very much. A professional friend, to whom he sent a sample, had expressed similar sentiments to those of Mr. Cowan regarding it.

Mr. Debenham would expect the developer to be slowed, owing to lactate of ammonia formiug.

Mr. Haddon said the fairest way to test its real value would be to form it into lactate of ammonia before use.

Mr. G. Waltenberg enquired the cause and remedy for a number of blisters in a sample of plates he had been using lately. When dry, they resembled small rings in relief.

Mr. Debenham said that it was a case of frilling in the incipient stage, which could be avoided by soaking the plate in alcohol before drying.

Mr. Waltenberg had tried that, but it did not have the desired effect.

The Chairman and others had met with the same kind of markings, and Mr. Monle could discern the marks after transferring the film to another plate.

Mr. Cowan recommended soaking the plate in a saturated solution of chrome alum before fixing.

In reply to Mr. Haddon, regarding the best proportion of chrome alum to add to an emulsion,

Mr. Cowan said $\frac{1}{8}$th of a grain was ample; a quarter of a grain would render an emulsion almost insoluble. He also showed a sample of fine silver wire gauze suitable for filtering emulsions, sent by M. Stebbing (Paris).

Derby Photographic Society.

On Wednesday, September 3rd, a meeting was held at the London Restaurant, Derby, the President, Captain Abney, R.E., F.R.S., in the chair.

The minutes of the previous meeting were read and confirmed.

Captain Abney then gave a short address on photography generally, and proposed that subjects for study be instituted, the results to be produced at the next quarterly meeting.

The subjects chosen were:—

1. "An Autumn Evening."
2. "Still Life."
3. "Animal Study."
4. "Rest," Life Study.

A sub-committee consisting of Messrs. R. Keene, J. Merry, A. J. Cox, and the Hon. Secretary, were appointed to consider the conditions.

Mr. Charles E. Abney, B.A., Vice-President, then read a paper on "A Photographic Walking Tour in Wales" (see page 605).

A conversation next ensued as to arrangements for technical meetings for practical demonstrations, the matter being referred to the committee of management.

A cordial vote of thanks to Captain Abney for presiding, and for his address, and also to Mr. Charles E. Abney for his paper, brought the proceedings to a close.

Talk in the Studio.

Photographic Society of Great Britain.—The next meeting of this Society will take place on Tuesday next, September 23rd, at the Gallery, 5a, Pall Mall East, at eight p.m.

The Centenary Balloon Ascent.—In accordance with the arrangements referred to last week, the ascents took place on Monday last from the ground of the Honourable Artillery Company. Three balloons rose. The first to ascend was the "Colonel," celebrated for having made four voyages across the Channel. Accompanying General Brine in his ascent were Captain Bayliss, H.A.C., and Mons. Lhoste, Secretaire de L'Academie d'Aérostation Météreologique of Paris. The last-named gentleman was announced to ascend in his balloon the "Ville de Boulogne," which has twice crossed the Channel; but, as his balloon had not arrived, he consented to go with General Brine. At a few minutes after four o'clock the "Colonel" ascended, amid the cheers of the assembled crowd, and, as the balloon rose majestically in the air, M. Lhoste stood on one foot on the edge of the car, and, holding with one hand by the ring above, with the other hand waved his hat and hurrahed. The balloon, rising rapidly the while, travelled away in a north-westerly direction, and again, at a great height, M. Lhoste could be seen repeating his venturesome performance. Shortly afterwards the "Monarch" went up, Mr. Dale being accompanied by Mr. Shadbolt and Mr. Hammet. When let go, the balloon for a moment seemed too heavily weighted to rise quickly, but some sand being thrown out, the machine soon shot up into the air, and sailed away in the wake of the "Colonel," the latter then appearing at a great distance mere speck in the air. It was a quarter to five o'clock when the "Robin Hood" ascended with Mr. Youens and Sergeant Louch, and a quarter of an hour later all the balloons were lost to the sight of the assemblage on the grounds. There was afterwards a fire-extinguishing experiment with a hand-grenade fire-extinguisher, consisting of a glass flask containing a pint of fire-extinguishing fluid. The "Monarch" came down at Harefield, in Middlesex, at a quarter past five p.m., all well, and an account of the trip will be found on page 605. On the previous Saturday Mr. Shadbolt and Mr. Dale ascended in the "Monarch" from Ramsgate.

At the *Exposition Regionale de Rouen*, a silver medal has been awarded to the "Compagnie Anglaise Tebbit" for the excellence of their manufacture of dry plates, and special mention is made in the award of the splendid display of English landscapes and portraits by Messrs. McLeish, Slingsby, Marsh Bros., and Renwick.

Effects of Light on the Respiration of Oxygen by Plants. By J. Reinke (*Bied. Centr.*, 1884, 37—39).—The author's experiments were limited to the observation of the amount of gas exhaled during varying amounts of sunshine: the evolution of gas begins when the light is fairly strong, and increases as the light becomes more intense, until the maximum is reached. This corresponds with the moment of direct sunlight; further intensification of light prolongs the evolution of gas, but does not increase its rapidity; and when the rays are concentrated by a lens, the process proceeds in this way until the chlorophyll is destroyed.—*Journal of the Chemical Society.*

Sharp Practice.—*Walzl's Monthly* says:—"We learn from the *N. Y. Tribune* that a photographer of Berlin has been sent to the penitentiary for a fraud which would probably entitle him to be called a smart man in this country. He pretended that he could make photographs of gentlemen so life-like, that their dogs would be able to recognise them. When the photographs were held up before the dogs of the owners, the dogs would wag their tails and lick the pictures. The other photographers grew jealous. They watched their colleague, and finally discovered that he put a thin layer of lard over the picture, which the dogs, of course, smelled, and then licked off. We know not a few photographers in this country who might take a hint from this, for it is certain that the likeness in nine cases out of ten could be established in no other way. And lard is cheap. The new style of pictures might be called 'dog-uerreotpyes.'"

Photographic Club.—On September 24th the subject for discussion will be "The Development of Plates known to be Over-exposed." *A Special General Meeting* will be held on October 1st. Saturday out-door meeting at Kew; afterwards at Hotel on Kew Green nearest bridge.

To Correspondents.

*** We cannot undertake to return rejected communications.

H. Spink.—1. There is no reliable table in any cheap work, but we will do our best to supply the want. 2. See our volume for 1880, p. 344.

F. Francis.—The so-called "Marine glue" is best. Make the parts warm before applying it, and bind them tightly together with wire. When thoroughly cool, remove the wire. 2. It will answer very well indeed.

FORRESTER.—1. Both would require precisely the same exposure, as the $\frac{f}{16}$ diaphragm of the sixteen inch lens will have four times the area, or double the diameter of the $\frac{f}{16}$ diaphragm of the eight inch lens. 2. Any specifications that are not out of print can be purchased at the Sale Office in Cursitor Street, the prices ranging from twopence upwards, according to the amount of matter, and the number of drawings. 3. We do not think that such a lantern is an article of commerce, but any dealer in photographic apparatus will get it made for you. 4. This query will be answered by post.

FRED S. SEED.—If packed, send them, together with a short letter of description, to Photographic Society of Great Britain, care of Mr. James Bourlet, 17, Nassau Street, Middlesex Hospital, London. They must arrive not later than Thursday next, September 25th.

K. LLOYD.—All the materials can be obtained from the Autotype Company, Oxford Street; but we should recommend you not to obtain the carbon tissue ready-sensitised.

THOS. S. (Derby).—We will write. See notice as to latest time.

H. M.—It has been sent to you.

C. A. M. W.—As you put the case, it is rather difficult to deal satisfactorily with the problem; but we think that under the circumstances it might be well to cut a narrow strip off each plate, and put these side by side in a normal developer.

G. M. WINTER.—The gelatine film appears to be more or less completely dissolved away in parts, and this may arise from the heat of the weather. You might try soaking in a saturated solution of alum before applying the intensifying liquid.

J. S. S.—We certainly cannot judge as to the cause by merely inspecting a print: even if we had the negative, it would be very difficult to form an opinion.

K. H. E.—Information on the subject may be found scattered through the last six volumes of the NEWS, but nothing of real importance has been done as regards the application of the process to photography.

R. J. H.—We are under the impression that most of the large stock-houses keep it; if not, either one would doubtless obtain it for you.

B. JACOBS.—1. The process is far older than you suppose, and was fully described in the PHOTOGRAPHIC NEWS a quarter of a century ago. 2. Yes, while it is wet. 3. Glass is far better. 4. The double sulphate of iron and ammonia is sometimes preferred, but does not seem to possess very decided advantages over the simple iron salt. 5. Once having become insoluble, there is no means known by which it can be restored to its original condition.

ALARMED.—The registration should have been secured before any copies were sold; but if, as we gather from your letter, the photograph was made to the order of a customer, you never had any right to register it in your own name.

The Every-day Formulary.

THE GELATINO-BROMIDE PROCESS.

Emulsion.—A—Nit. silver 100 grains, dist. water 2 oz. B—Bromide potassium 85 grains, Nelson's No. 1 gelatine 20 grains, dist. water 1½ oz., a one per cent. mixture of hydrochloric acid and water 50 minims. C—Iodide potassium 8 grains, dist. water ½ oz. D—Hard gelatine 120 grains, water several oz. When the gelatine is thoroughly soaked, let all possible water be poured off D. A and B are now heated to about 120° Fahr., after which B is gradually added to A with constant agitation; C is then added. Heat in water bath for half an hour, and stir in D. After washing add ½ oz. alcohol.

Pyro. Developer.—No. 1—Strong liq. ammonia 1½ oz., bromide potassium 240 grains, water 80 oz. No. 2—Pyro. 30 grains, water 10 oz. In case of an ordinary exposure mix equal vol.

Iron Developer.—Potassium oxalate sol. (1 and 4) 80 parts, ferrous sulphate sol. (1 and 4) 20 parts, dist. water 20 parts. To each 4 oz. of the mixed developer add from 5 to 30 drops ten per cent. sol. potassium bromide, and 30 drops sol. sodium hyposulphite (1 and 200).

Substratum or Preliminary Preparation.—Soluble silicate of soda 1 part, white of egg 5 parts, water 60 parts. Beat to froth and filter.

Fixing.—Sat. sol. of sod. hypo. 1 pint, sat. sol. of alum 2 pints, mixed.

Cowell's Clearing Solution.—Alum 1 part, citric acid 2 parts, water 10 parts. Edwards makes this sherry coloured with perchloride iron.

Eder's Method of Intensification.—The negative is whitened by soaking in sat. sol. of mercuric chloride, and after thorough rinsing immersed in potass. cyan. 10 parts, potass. iod. 5 parts, mercuric chloride 5 parts, water 2,000 parts. As film becomes dark brown, the actinic opacity is increased; but prolonged action causes brown tint to become lighter, until at last the negative is no denser than at first.

Fol's Backing Sheets.—A chromographic paste is prepared with gelatine 1 part, water 2 parts, glycerine 1 part, and a very small addition of Indian ink. Strong paper or shirting is coated, and the sheets are laid, face downward, on waxed glass to set. Press to back of glass plate.

THE WET COLLODION PROCESS.

The Nitrate Bath.—Water 14 oz., nit. silver 1 oz., nitric acid 1 drop Before using coat a small plate, and immerse it for 20 minutes.

Cleaning Preparation for New Plates.—Alcohol 4 oz., Jeweller's rouge ½ oz., liquid ammonia ½ oz.

Film-removing Pickle for Old Plates.—Water 1 pint, sulphuric acid 4 fluid oz., bichromate potassium 4 oz.

Substratum.—Whites of 2 eggs well beaten, 6 pints of water, and 1 dr liq. amuion.

Negative Collodion for Iron Development.—Alcohol 1 pint, pyroxyline of suitable quality 250 grains, shake well and add ether 2 pints, *Iodize this by mixing with* one-third of its volume of alcohol ½ pint, iod. ammon. 80 grains, iod. cadm. 80 grains, brom. ammon. 40 grains.

Normal Iron Developer.—Water 10 oz., proto-sulphate iron ½ oz., glacial acetic acid ½ oz., alcohol ½ oz. The amount of proto-sulphate iron may be diminished to ¼ oz. when full contrasts are desired, or increased to 1 oz. when contrasts are unduly marked. With new bath quantity of acohol may be reduced to ¼ oz.; but when bath is old more is wanted.

Intensifying Solution.—Water 6 oz., citric acid 75 grains, pyro. 30 grains. When used, add a few drops of the silver bath to each ounce.

Lead Intensification.—After neg. washing, immerse in dist. water 100 parts, red prussiate potash 6 parts, and nit. lead 4 parts. When it is yellowish white wash and immerse in liquid sulphide ammon. 1 part, water 4 parts.

Fixing Solution.—1. Potass. cyanide 200 grains, water 10 oz. 2. Sat. sol. of sod. hypo.

Varnish.—Shellac 2 oz., sandarac 2 oz., Canada balsam 1 dr., oil of lavender 1 oz., alcohol 16 oz.

PAINTING PROCESSES.

Albumen Mixture for Paper.—White of egg 18 oz., 500 grs. ammon. chlor. in 2 oz. of water. Beat to a froth, stand, and filter.

Sensitizing Solution.—Nit. silver 50 grs., water 1 oz., sod. carb. ½ gr.

Acetate Toning Bath.—Cbl. gold 1 gr., acet. soda 20 grs., water 8 oz.

Lime do.—Chl. gold 1 gr., whiting 30 grs., boiling water 8 oz., sat. sol. chl. lime 1 drop. Filter cold.

Bicarbonate do.—Chl. gold 1 gr., bicarb. soda 3 grs., water 8 oz.

Fixing Bath.—Sodium hypo. 4 oz., water 1 pint, liq. ammon. 30 drops.

Reducer for Deep Prints.—Cyan. potass. 5 grs., liq. ammon. 5 drops, water 1 pint.

Sensitizing Bath for Carbon Tissue.—Bichromate potash 1½ oz., water 30 oz., ammonia 1 dr., methylated spirit 4 oz.

Enamel Collodion.—Tough pyroxyline 120 grs., methylated alcohol 10 oz., ether 10 oz., castor oil 20 drops.

Mountant.—1. Fresh solution of best white gum. 2. Fresh starch.

Collotypic Substratum.—Soluble glass 3 parts, white of egg 7 parts, water 10 parts.

Collotypic Sensitive Coating.—Bichromate potash ½ oz., gelatine 2½ oz., water 22 oz.

Collotypic Etching Fluid.—Glycerine 150 parts, ammonia 50 parts, saltpetre 5 parts, water 25 parts.

Printing on Fabric.—Remove all dressing from fabric by boiling in water containing a little potash, dry, and albumenize with ammonium chloride 2 grammes, water 250 cubic cents., and the white of 2 eggs, all being well beaten together. A 70-grain silver bath is used, and the remaining operations are as for paper.

Cyanotype Printing.—Water 1 oz., red prussiate of potash (ferricyanide) 1 dr., ammonio citrate of iron 1 dr. Prepare and preserve in the dark. Float the paper and dry. Fixation by mere soaking in water.

VARIOUS.

Luckardt's Retouching Varnish.—Alcohol 300 parts, sandarac 50 parts, camphor 5 parts, castor oil 10 parts, Venice turpentine 5 parts.

Matt Varnish.—Sandarac 18 parts, mastic 4 parts, ether 200 parts, benzole 80 to 100 parts.

Encaustic Paste.—Best white wax, in shreds, 1 oz., turpentine 5 oz. dissolve in gentle heat, and apply cold with piece of flannel.

FERROTYPES.

Collodion.—Ammonium iodide 35 grains, cadmium iodide 25 grains cadmium bromide 20 grains, pyroxyline 70 grains, alcohol 5 oz., ether 5 oz.

Bath.—Silver nitrate 1 oz., water 10 oz., nitric acid 1 drop.

Developer.—Ferrous sulphate 1 oz., glac. acetic acid 1 oz., water 16 oz.

Fixing and Varnish.—Same as wet collodion process.

The Photographic News Registry.

Employment Wanted.

Reception Room, & to learn mounting.—Miss Cook, *Photo. News* Office.
Printer & Operator, experienced.—J. E. M., 2, West-st, Osney, Oxford.
Operator, good copyist, &c.—C. O., 25, Duke-st., Bloomsbury.
Operator, good at posing, electric light.—G. S. M, 50, Green-st., Hyde-pk.
Improver, &c.—X. Y. Z., 69, Palace-garden-ter., Notting-hill-gate.

Employment Offered.

Printer, &c., winter engagement, 21 -.—J. Inskip, Scarboro'.
Printer, used to carbons.—M. Boucher, 15, King's-rd., Brighton.
Recep.-Room, & Retouch or Colour.—Mr. Stuart, 47, Brompton-rd., S.W.
Operator, good Retoucher (indoors).—C.D.V., *Photo. News* Office.
Apprentice or Improver, indoors.—T. Vipond, Grantham.
Youth as Improver.—2, The Pavement, Clapham Common.
Retoucher & Colourist.—F. R. Chapman, Clapham Common.
Assistant Operator (Dry-plate).—Barnes & Son, 422, Mile End-rd., E.

THE APPLIANCES USED IN WASHING GELATINE EMULSION.

AT more than one recent meeting of the London and Provincial Photographic Association there has been discussed the subject of the various materials suitable for making the gauze which is generally used for cutting emulsion into small fragments for washing.

The first improvement on the old method of scraping the emulsion into somewhat large fragments with a piece of glass consisted of the introduction of coarse canvas through which the emulsion was squeezed, and this method of operating remains a favourite one with many—both amateur and commercial plate makers—at the present day. Others find the canvas arrangement a rather "messy" one, and use a squeezer of one kind or another, the appliance always consisting of a plunger, which presses the emulsion against a piece of wire gauze, or against a series of thin metal bars. When first this arrangement was proposed, there appeared to be no doubt that it would be necessary to use silver or silver-coated wire to prevent there being any action on the emulsion. It is, however, to say the least of it, somewhat doubtful whether any such precaution is necessary.

Silver wire of sufficient thickness is expensive, and there is often difficulty in getting silver-coated wire. A member of the Association just mentioned, however, pointed out that the wire with which violincello strings are covered is silver-coated, that a "cello" string can be got for a few pence in almost any town, and that if the wire be unwound from it, there will be found to be a great length of the very thing which is considered by many to be so great a desideratum.

When the matter of this silver-coated wire was brought up, a member asked the somewhat pertinent question, "Had any one found any harm to result from the use of copper wire for pressing emulsion through, and if not, what was the object of all this searching after the silver-coated wire?" He himself had used copper wire for years, and had found no harm to result from it, although he had noticed that a gelatine emulsion with much free ammonia in it turned deep green if it remained in contact with copper for only a few seconds."

Several members had used copper wire, but none of them could say that they had discovered any evil results to arise from the use of it.

We may give our own experience of the results of copper wire gauze used as a material through which to press emulsion, and also of the results of the contact of another material —namely, wood—with a long succession of emulsions.

The squeezers for emulsion are themselves usually made of either silvered copper or vulcanite, the piston being of the same material as the cylinder. We were struck, however, some time ago with the simplicity of an arrangement which we saw in the hands of an amateur plate-maker. It was made entirely of wood. In place of the cylinder there was a square wooden tube, made by simply "sprigging" together four bits of board. The plunger was of solid wood in sections about an inch and a quarter square. On to the end of the square tube there was tacked a piece of copper wire gauze, through which to squeeze the emulsions.

We made a piece of apparatus of the kind we have described, and were very well pleased with the performance of it for more than a year. The copper appeared to have no deleterious action on the emulsion. After we had, however, used our squeezer repeatedly during the time mentioned—a year or so—we commenced to get green and red fog, working by a formula which had given us no such defects before. After casting about in various directions in search of a solution of the mystery, we bethought ourselves of the squeezer. It was not likely that the defect came from the copper wire, as if the copper had any deleterious action, it surely would not have waited for more than a year before showing it. To make certain, however, a new squeezer was constructed—that is to say, the wooden portion was made anew, but the old copper wire gauze was tacked on to the end of the new machine. When this was used the green and red fog immediately disappeared. There seemed to be little doubt as to the cause of it.

We sawed the old squeezer across near the end where the copper wire gauze had been, and perceived that the wood was stained with decomposed emulsion to a depth of about an eighth of an inch from the inside surface. It is not likely that the emulsion was absorbed whilst the actual squeezing was going on. The wood might absorb the soluble salts of the emulsion, and free ammonia if there were very much of it at these times, but probably not emulsion itself. It is likely that the emulsion was absorbed during the process of washing the arrangement with hot water after using it, to wash it being of course quite necessary. The wood was not varnished, and yet it took a year to become contaminated to such an extent as to do any damage.

We believe that we could safely recommend the use of such a piece of apparatus as we have described, with this difference only, that it be thoroughly varnished with three or four coats of shellac varnish.

We have noticed the change of colour which emulsion containing free ammonia undergoes if it remains for any time in contact with copper, and have, moreover, observed that before leaving the emulsion in contact for long with the copper wire gauge, the gelatine becomes insoluble in hot water. For this reason, should emulsions made by the ammonia method be squeezed through copper wire gauze, the apparatus should be washed in hot water immediately afterwards. When an hour or so has elapsed there will

be great difficulty in washing out those small particles of emulsion which remain entangled in the meshes of the gauze.

We have seen a brawn-presser used for dividing up emulsions. This piece of apparatus is made of iron, and is simply japanned inside and outside. We believe that ordinary photographic black varnish would be found a quite sufficient coating for most metallic vessels were it desired to manipulate melted emulsions in them. Certainly those who have scruples about using unsophisticated copper wire might try the effects of giving it a coating of black varnish.

Concerning the vessel to receive the finely-divided emulsions, we may say that in our opinion nothing is better than the ordinary kitchen hair-sieve; but it must be borne in mind that this utensil being of wood, and requiring, like the squeezer, to be washed in hot water after it is used, is liable through time to become contaminated like the latter. It is not nearly so liable, however, to give up to the emulsion any contamination of which it may be the recipient, as the emulsion is never squeezed against the sides of it. Moreover, a hair-sieve is a very cheap piece of apparatus, and it is no great hardship if the plate-maker has to purchase a new one now and again.

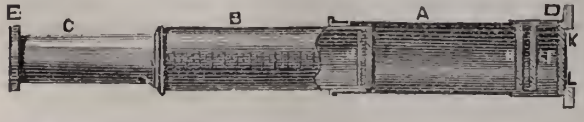
The sieve should stand in a vessel of water, and its upper edge should stand, perhaps, an inch above the outlet of the vessel; thus the emulsion is squeezed into water, and the particles are kept separate *if the water be kept cold enough*. It is necessary to use ice in winter to cool the water into which the emulsion is squeezed, otherwise it (the emulsion) will form a sloppy mass lying on the hair bottom of the sieve; water will not pass through it, and the washing will be very imperfect. If the emulsion be once squeezed into very cold water, so that the particles of it stand out distinctly from one another, comparatively warm water may be used through the rest of the washing process without any harm arising.

Mr. A. L. Henderson has devised a very neat and handy arrangement for holding a sieve whilst the emulsion is being washed. It has been already described in our columns, and has the great advantage that, being light-tight, it may, when once closed, be taken into daylight, so that it need not be an encumbrance in the dark-room.

THE SIMONOFF PHOTOMETER.

THIS instrument, which has already been briefly described in our present volume, is by no means complex in construction, and is always ready for use, while the readings are obtained directly and without calculation. It has the external form of a telescope, and is directed towards the source of light. At the end farthest from the eye are a series of diaphragms which can be shifted by the hands of the observer, and as soon as the light in the interior of the instrument is so far reduced that certain figures cannot be read, the number of the stop used is noted, and this gives the intensity of the light.

The apparatus is represented by the subjoined figure.



At the end, D, will be seen two grooves (K and L) in which slide the strip of metal containing the holes of determinate size serving as diaphragms, one of these strips being represented below.

Immediately behind the diaphragm are situated three discs of opal glass (F, G, and H), these serving to soften and diffuse the light entering the instrument; and it may be advisable, in some cases, to replace one or two of them by discs of ground glass. At one extremity of the sliding-tube, B, is fitted a transparent screen, J, on which are inscribed some figures, and the tube, C, should be so adjusted that the observer can see these figures quite distinctly; indeed, if the observer is in the habit of wearing spectacles, he should use a lens at E, corresponding to those of his spectacles.

For the use of photographers the diaphragms are marked

so as to make them indicate directly the relative times of exposure, the No. 1 stop corresponding with an exposure 1, and so with 2, 3, 4, &c., up to 36, this arrangement serving to make the apparatus very simple in working. Let us take an example. If, with a light corresponding to No. 4 on the photometer, an exposure of two seconds is required, it will be necessary to give an exposure of

$$\frac{6}{4\times 2},$$ or three seconds

if the photometer indicates 6. Or if the photometer indicates 8, the exposures will be

$$\frac{8}{4\times 2} = 4 \text{ seconds};$$

while No. 2 on the photometer will indicate an exposure of one second; and an exposure of half a second will be given if the indication of the photometer is 1. In fact, all through these numbers the unit of exposure corresponding to each degree of the photometer is half a second; and to find what is the unit of exposures corresponding to 1 on the photometer is a matter for experiment in each case. Instead of a series of fixed diaphragms, a single adjustable aperture made on the Noton principle, of two square openings sliding diagonally across each other, may be used, and, in this instance, the reading is taken from a graduated scale.

From a photographic point of view, the Simonoff photometer is subject to two important drawbacks. In the first place the actinic or photographic energy is by no means always proportionate to its intensity, and all photographers know how much a yellow cast in the atmospheric tint necessitates an altogether disproportionate increase of exposure; and, indeed, a yellowness which would scarcely affect the readings of the Simonoff instrument might be sufficient to render double or treble the normal exposure necessary. Possibly, however, the indications of the instrument for photographic purposes might be made more certain by making the diffusing screens, F, G, H, of coloured glass, so selected as to cut off those parts of the spectrum which are least active in affecting the photographic plate.

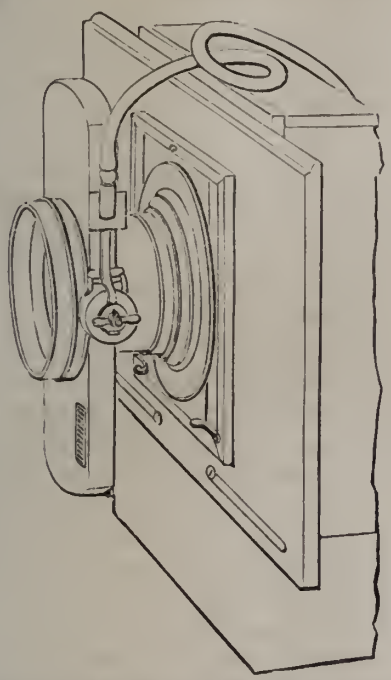
Another drawback, especially when the instrument is used in the open air, is the circumstance that the eye of the observer may not always be in the same condition of sensitiveness to light; the iris being more or less expanded according to the brilliancy of the general illumination. This latter difficulty may, however, be overcome to some extent by well shading the head during the observation, and allowing sufficient time for the eye to become accustomed to the illumination.

INSTANTANEOUS PICTURES BY DAVID AND SCOLIK.

IN a recent number of the NEWS (page 447) we referred to a series of instantaneous pictures of the Corpus Christi procession at Vienna, taken by Lieutenant David and Herr Scolik, and this week one of the series forms our supplement, while possibly another may be issued next week.

The pictures of this series were taken on plates prepared by the photographers themselves, in accordance with the older directions given by Monckhoven; that is to say, the emulsion was mixed neutral at a temperature of 50° to 60° Centigrade, after which ammonia was added,

the emulsion being next digested and washed. Iodide was present in the emulsion to the extent of about $\frac{1}{2}$ to 1 per cent., and the plates indicated 20° Warnerke. The objective used was an antiplanat of Steinheil, having an aperture of 64 mm., and a focal length of 360 mm.; while the shutter employed was that of Thury and Amey, of Geneva—the same shutter, it will be remembered, that Lugardron used for his celebrated instantaneous studies. The shutter, which is adapted to work between the lenses, is provided with a pneumatic release, and by means of a very delicately-adjusted brake arrangement the exposure, which at the quickest is $\frac{1}{2000}$th of a second, may be retarded to $\frac{1}{10}$th of a second; but the series now referred to were taken with an exposure of $\frac{1}{50}$th of a second, and the subjoined diagram shows the general appearance of the apparatus.



The internal parts consist of two sliding plates of metal which travel in contrary directions, as in the well-known shutter of Noton; but the driving arrangement consists of a pinion placed between the moving plates and gearing into two racks, one on each of the moving plates. The pinion is driven by a coiled spring.

Oxalate developer was used; but in order to produce the effect of a more prolonged exposure, the plates were immersed for some seconds in a weak solution of sodium hyposulphite ($\frac{1}{1000}$), and rinsed before development; this method of working seeming to give more details in the shadows than when no hyposulphite is used.

To return to the pictures themselves. The Corpus Christi procession is a high festival in Vienna; the Kaiser, the Crown Prince Rudolf, and the other members of the Imperial family, being in the habit of walking in the procession with uncovered heads, while horse and foot guards accompany. The "holiest" is carried by the Archbishop under a Baldichino, and immediately behind walks the Kaiser.

Lieutenant David has made an excellent series of views representing military life—soldiers with powder waggons, gun practice, and various evolutions being depicted with a wonderful realism; while Scolik has produced some fine instantaneous views on the Prater at Vienna during the month of May this year, and the active life of this favourite resort is well illustrated. An exposure equal to about $\frac{1}{50}$th of a second was ordinarily given.

AN ELECTRICAL EXHIBITION AT PHILADELPHIA.

NOT far from the spot where Benjamin Franklin drew lightning from the clouds, and satisfied himself of the identity of the grand flashings of Nature's laboratory and the tiny sparklets of his own, stands the Electrical Exhibition. Absolute novelties there are few—perhaps none—but there is a good collection of exhibits, which fairly represent the extent to which man has at present brought electricity into his service.

No awards or prizes are to be given, a feature of novelty as regards the present Exhibition; indeed, exhibition awards are not highly estimated, as a rule, especially by those who know the conditions under which awards are often made.

Official examinations and quantitative determinations as to the efficiency of the apparatus shown, will be made by a special committee, and all persons allowing quantitative tests of their machines must consent to the unconditional publication of the results.

An exceptionally large dynamo on the gramme principle, and capable of actuating no less than 2,500 incandescent lights, is shown; and it is said that many a visitor who has incautiously stood near this monster may remember it with good reason, from the fact that his watch has seemed to be under some uncanny influence ever since—sometimes going at high speed, and at other times merely crawling. Attractive to the general public is the electrical fountain, in which the streams of water are brightly illuminated by internal electric lights, as they issue from the jets, the appearance of streams of fire being produced.

Gas engines produce a large proportion of the motive force used in the Exhibition, and it is evidently the opinion of many competent judges that the gas engine is the motor of the future—at any rate, for driving dynamo-machines. Thirty-seven cubic feet per hour may be taken as the average consumption of gas per horse power; while each horse power of motive force will give a light about equal to one hundred and fifty standard candles when the incandescence system is adopted; but the return of light per h. p. amounts to 2,000 candles when small arc lights are used, or more than double this in the case of large arcs.

PHOTO-ASTRONOMY AT THE RIFFEL.

BY C. RAY WOODS.

No. IV.

POSSIBLY, by this time, many of the readers of the NEWS will have wondered why they have heard so little from me as to the work I came out here to perform. To such I may answer that my difficulties have been so many that, in spite of the promising results I got even from the first, I could not be sure that the negatives I had obtained were to be relied on, even as a partial success; that much was false I knew. It is not pleasing to find oneself in the predicament of having said anything that later work has proved to be incorrect, even if the circumstances at the time of so offending justified such a statement. Now, however, that my photographs promise some small return, in addition to proving the accuracy of the process by which they were obtained, I am able to enter more into detail than I have hitherto done.

One very important objection to the results which Dr. Huggins first produced was that the blue glass or the permanganate cell might itself be the cause of the corona-like appearances which he produced on his plates. No matter how well a surface may be polished, there is sure to be some amount of scattering of light from its surface, in addition to the reflection which is the natural accompaniment of refraction. The image of the sun being so very brilliant, all scattering of light and reflection from one surface to another must produce an appreciable effect. Dr.

Huggins, therefore, sought to do away entirely with any absorbing medium in front of the plate, and he succeeded. Why?

During the Eclipse of 1882, a plate which was exposed for three seconds only, showed the corona extending for some distance from the sun's limb, and, in addition, also reproduced the comet that caused such astonishment in the minds of the spectators. In 1883, on Caroline Island, this result was improved upon, and an exposure of only one second produced a result which, for extent, far exceeded our expectations, and showed good detail. During an eclipse, everything is favourable. There may be atmospheric glare, but such glare is due to the corona, the sun's light being cut off; one has simply to reproduce the effect not only visible to the naked eye, but reinforced by light—or to express it more correctly, by vibrations, which produce no effect on the retina. In attempting to reproduce the corona without an eclipse one has to bear in mind that there are three gradations of light to be dealt with: firstly, the light of the sun; secondly, the light from the corona *plus* atmospheric glare; thirdly, atmospheric glare alone. Now it is the second of these which has to be brought into prominence to the disparagement of the other two.

The practical photographer will bear in mind how short an exposure is required to bring out the sky, even when it is perfectly free from clouds. The exposure, for instance, is very much shorter than is required to produce a photograph of the corona during an eclipse. Taking the exposure of the average dry-shutter as one-tenth to one-eighth of a second, the sky is usually brought out *fully exposed*. It is obvious, therefore, that nothing short of what is called an "instantaneous exposure" is likely to be useful in taking the corona *plus* the light of the sky, or, in other words, *plus* the atmospheric glare. The difference between the light of corona, and the light of corona *plus* glare, is, in England at least, very slight. When two objects approach each other very closely, in the intensity of their light it is not very easy to discriminate between them. Photography, however, is better able to do this than the eye. To take a familiar illustration. Forgeries and erasures have been detected by means of photography, simply through the fact that a slight difference in texture has produced a corresponding difference in illumination; and when this slight difference in illumination has been encouraged and intensified, the fraud has been made apparent. Again, those who have made positives (I refer more particularly to lantern slides) from thin negatives must be aware that they have the power of bringing out more detail than can be obtained in a silver print, simply because, by a rapid exposure, they can just reproduce the detail, and then intensify it. Applying these examples, therefore, to the question under consideration, it *should be*, and, as Dr. Huggins has found, it *is*, possible to get the corona distinct from the atmospheric glare, and make its presence more marked by intensification. Dr. Huggins' best results were obtained by developing the plate so slowly that the action could be stopped when the corona appeared, and then intensifying it.

So far, however, one of the most important matters, the brilliancy of the sunlight, has been allowed to drop out of sight; and it certainly might be ignored altogether, did it simply stand by itself, for the bringing out the difference between corona, and corona *plus* glare, is the most important point. In photographing upon glass, however, where one portion of the film is acted on by light of greater intensity than that which acts on another portion, an action is set up by light reflected from the back of the plate, and is known as halation. In addition to this, the action of development carries the effect of reduction from one particle to other particles in its immediate neighbourhood. This latter action is not sufficient to account for the results obtained by Dr. Huggins or by myself, and has been guarded against in a way to be mentioned shortly.

The main difficulty from the first was to guard against halation, and this was done in a manner that has been mentioned in previous articles. It would appear that when asphaltum is thickly laid on the back of a plate with a spatula, all that could be done was done. But one of the objections raised against Dr. Huggins' method was, that the corona-like appearance he obtained might be due to inequalities in this asphaltum backing. I am happy to say that this point I have set at rest. By putting on the asphaltum too thinly in parts I obtained results which would not tally at all with the appearances set down to the corona; and again, when a series of photographs obtained on the same day showed the same form, it is evident enough that if they are not genuinely coronal, they must be due to some other cause than one which would vary with each plate used. It is absurd to suppose that two plates could be insufficiently backed in exactly the same manner.

It was pointed out at the time when the process was first brought forward that the results would be of greater value if the sun's image had first been cut off. I was not able to try this when first I arrived here, but on a suitable disc being sent me, I put it into requisition. It served another purpose in addition, before detailing which I must draw attention to another difficulty that arose.

It is necessary to use the shutter in front of the plate after the image has already been formed. When the shutter is placed elsewhere, the final photograph is built up of a succession of images. This matters little in landscape photography, but in solar work many errors might creep in. In photographing the sun, the shutter is placed at the focus of the first image—that formed by the object glass—and though this image is subsequently enlarged, the result is practically the same as if the shutter were close to the secondary image in front of the plate, and it is far more convenient. With such a delicate piece of work as photographing the corona, the precautions that have to be taken must be more efficient than in photographing the sun; and the shutter in front of the plate is not without its objections. I found, for instance, that my results were marred by rays which glanced off the edges of the shutter as it crossed the sun's image, and this inspired the fear that most of my corona might be due to the same cause. By carefully repainting the edges with lamp-black, however, I was able to modify this very disagreeable objection.

But when I received the disc, three difficulties vanished; possibility of insufficient backing, communication of action to surrounding particles, and defects through the shutter. The disc was larger than the sun's image, and might therefore be safely placed behind the shutter—that is to say, it was so mounted that the shutter passed between disc and plate. The results then obtained were more delicate and more trustworthy than formerly, and, in spite of the evil influence of the haze that has prevailed, may yet throw some light on the nature of the corona when a searching examination has been made of them. I cannot refrain, however, from expressing some little disappointment at not having met with any of the clear blue-black skies that up to the present year have frequently been met with at this height in Switzerland. Yet the atmosphere here is far and away superior to that which we have in England, even at the best of times. Of ærial perspective, there is none except when one glances down the valley; mountains stand out as if close at hand, and far-away peaks, taller than some at a much smaller distance, appear diminutive because the eye has nothing to guide it in estimating distance.

In this connection I cannot refrain from concluding with a story told here by a gentleman whose inventive faculties are in advance of his love of truth.

"I was coming," said he, "from St. Niklaus to Zermatt with a friend who had never been here before, and he told me that he was very much disappointed with the mountains, which did not seem so very big, after all."

"Indeed! How high do you think that peak is?" pointing to the Weisshorn.

"About a thousand feet."

"No, nearly fifteen thousand."

"We walked on," continued the narrator, "till we came to a pool of water across the road, and my friend stopped with a look of perplexity on his face."

"Why don't you jump across it?"

"No, thank you, I know better now. That puddle only looks three feet wide, but it cannot be less than forty."

A NEW DEVELOPER.

BY CARL EGLI AND ARNOLD SPILLER.

In a recent issue of the News, the fact was referred to that although the gelatino-bromide worker had a good choice of compounds for developing, only two were practically used, viz., ferrous oxalate, and pyrogallol. That the former is used abroad, while the latter is almost exclusively in vogue in this country, can be easily explained, we think, when the properties of the various developers, and the style of work carried out in the different countries, are considered.

The ferrous oxalate yields negatives of an agreeable black tone, free from stain, but generally covered with an objectionable white deposit of calcium oxalate. The films to be treated with this developer must receive approximately the correct exposure, for there is no practical means of *forcing* an under-exposed image, while the restraining of an over-exposed film is attended with a good deal of uncertainty. Pyrogallol developed negatives are of a brown tone, often dreadfully stained of a non-actinic colour; but from the nature of the developer a good deal, the exposure of the films can vary between wide limits of what is considered normal. It must be remembered that Continental photographers work with a delightfully clear and constant light, and are chiefly engaged in the studio. Thus it is much easier to determine the correct exposure; so, not being troubled with the latter difficulty, our *confrères* prefer a ferrous oxalate developed negative, with its clear, black, and unstained image.

From the foregoing it may be inferred that an ideal developer would be one capable of yielding a clear, black, wet-plate tone, free from stains and deposits, and at the same time possessing ample means for forcing and restraining. We believe that such a power is possessed by *hydroxylamine* when in the presence of an alkali.

Hydroxylamine, NH_3O, was obtained by Lossen when examining the intermediary products in the reduction of nitric acid to ammonia by means of metals. It is generally considered as ammonia in which one atom of hydrogen is replaced by the radical OH.

Ammonia	Hydroxylamine
$N\begin{cases} H \\ H \\ H \end{cases}$	$N\begin{cases} OH \\ H \\ H \end{cases}$

The process adopted for its manufacture is the same as that originally described by the discoverer, viz., the reduction of nitric ether by tin and hydrochloric acid. Hydroxylamine does not exist in the free state except in solution; but, like ammonia, it forms several permanent salts, and it is in the latter form that it will be found most useful for photographic purposes. The salt used is the hydrochloride, a substance analagous to sal-ammoniac, and already in the market. As neither the base nor its salts alone have any effect on silver bromide, it is found necessary to add a fixed alkali such as soda or potash.

For the development of gelatino-bromide plates, we recommend the following solutions:—

A.—Hydroxylamine hydrochloride...	... 32 grains
Citric acid	... 15 ,,
Potassium bromide	... 20 ,,
Water	... 1 ounce
B.—Caustic soda	... 1 dram
Water	... 1 ounce
C.—Potassium bromide	... 20 grains
Water	... 1 ounce

For a $7\frac{1}{2}$ by 5 plate the film is first soaked for about one minute in three and and a half ounces of water containing one drachm of A, about 20 drops of B is then added, and, if necessary, an extra 10 or so. Should the image show signs of over-exposure, or if the plate is one of the specially sensitive kind, a few drops of C must be used to restrain the action still more. The advantages resulting from the use of this developer are the following:—

1. The image is of a *wet-plate* tone, perfectly free from stain or deposits.
2. A great variation of exposure is permissible.
3. The solution is not acted on by the atmosphere, and therefore does not deteriorate during development from external causes.

In conclusion, we beg to state that experiments are now being carried out with a view to the application of hydroxylamine for the development of gelatino-chloride films, and gelatino-bromide paper; also for the substitution of the carbonates for the caustic alkalies.

A NEW METHOD OF PRODUCING NEGATIVES FROM ALBUMEN PRINTS.

BY W. T. WILKINSON.

Most photographers are aware of the importance of securing a transparency from any negative which is at all likely to be required for a long order, but on account of the difficulty there is usually to get a successful result upon a dry plate, or the trouble and bother of the carbon process when only used occasionally, this is usually shirked, and, may-be, the negative is subjected to the hardships and danger of printing, until at last, and long before half the order is finished, the negative is ruined, either by a crack (across the face, of course), or else by silver stains gathered from the sensitive paper.

It is now too late to get a transparency, and to make a copy in the camera will not yield the same result as the copies from the original negative; but if the plan now to be described be followed, there will be no falling-off in quality, whilst as many negatives as may be required may be secured, all being alike.

First of all, the transparency. This is furnished by selecting the deepest silver print made whilst the negative was in its pristine condition.

This print—unmounted and with a clean back—is smoothed so as to lie quite flat, when it is placed face downwards upon a piece of clean blotting-paper, and the back well rubbed with a rag saturated with olive oil until the whole of the print is evenly saturated; now clear away all superfluous oil from both back and front; finally ensuring this by warming in front of the fire, and placing between sheets of blotting-paper.

Now a word of warning: Don't, after reading this, think that waxing will be better, because it will not; a waxed silver print for this purpose will be simply useless, therefore stick to the oil.

We have now an oiled silver print, which is placed in the printing-frame *face downwards*, then surrounded by a mask or safe edge, when a piece of sensitive carbon tissue is placed in position; the frame is now closed, and exposed to light for from three to six tints.

The carbon print is developed upon a collodionised glass, and, after being dried, a print is taken from it to see if the negative is sufficiently dense; if not, a dose of a moderately strong solution of permanganate of potash will at once supply any deficiency on this score.

There are many ways in which this method of reproduction will commend itself to photographers; for instance, in cases where double printing has to be resorted to, directly a perfect print has been secured, let it be oiled, and a carbon negative or negatives made, and instead of

the trouble of double printing each and every print, the same result is got by the one printing.

Again, after being in print for some time, the pictures from a favourite negative are not so clean as the earlier ones; but with this process, as soon as a negative begins to show signs of wear, there need be no compunction in consigning it to the waste pan, as another can be made as good as new.

Those photographers who do not use the carbon process should know that a negative can be made quite as well from the oiled silver print upon a gelatino-chloride plate, using a good duplex or round wick paraffin lamp to impress the image, the only precaution needed being not to over-expose, but at the same time to get all detail out in the negative that is in the silver print.

I have tried to make a negative from the oiled silver print upon albumenized paper, but cannot get anything like a good result; there is always a want of pluck in the resulting silver print.

For the information of those not familiar with carbon manipulations, I will describe an easy and simple method of sensitizing and drying carbon tissue.

Suppose it is desired to reproduce some negatives 8½ by 6½; clean a few plates 11 by 9, and give them a final polish with French chalk; then coat with collodion (any old iodised will do), and place in clean cold water until required.

Now cut a few pieces of carbon tissue (Autotype No. 100, or Monckhoven's chocolate red), 9½ by 7½; immerse in a solution of—

Bichromate of potash ...	... 1 ounce
Water	... 20 ounces
Ammonia	... 10 drops

for three minutes.

Then remove one of the collodionised plates from the water, and immerse in the bichromate solution; place the surface of carbon tissue in contact with the collodionised surface of glass plate (taking care not to abrade the surface of collodion); adjust the tissue in the centre of plate, and lift the two from the solution. Now place a piece of American cloth over the plate, and apply the squeegee gently; remove the American cloth, and stand the plate in a rack to dry in the dark-room.

When dry, the tissue will strip off the plate with a splendid surface for getting contact with the oiled transparency.

THE INFLUENCE OF CIVILISATION UPON EYESIGHT.

BY R. BRUDENELL CARTER, F.R.C.S.

It is recorded by Humboldt that he was travelling in South America under conditions which rendered it necessary for the party to divide, and to reach their destination by different routes. As he and those who remained with him approached the appointed meeting place, he said to the Indian guide that he wondered what had become of the others. The guide looked at him with some surprise, and pointing across a wide mountain gorge, one side of which they were traversing, replied, "There they are." Humboldt himself could see nothing but rocks and verdure; but ultimately, being assisted by the guide as to the position of the other party, succeeded in discovering them by the aid of a telescope; and then, by making the guide describe the order of march and the relative positions of the several individuals, obtained proof that he actually saw them plainly with his unaided eyes. An experience of equal significance, if of less striking character, may be had in any Highland deer forest, where deer which are conspicuous to the eyes of the keeper can only be seen with difficulty and uncertainty, and after much pointing out of neighbouring landmarks, by visitors who are habitual dwellers in towns. In other words, the acuteness of sight of the average citizen is much inferior to that of the average Scotch forester; while the acuteness of sight of the forester is probably much inferior to that of the savage. People are too prone to accept this as something necessary or inevitable, and to think of the forester or the savage as the possessor of some special acuteness which has been conferred upon him by training and practice, instead of thinking of the citizen as a person who by reason of unfavourable circumstance falls short of the acuteness of vision which he ought to possess. The view thus taken is the more remarkable, since the average citizen of the better classes—say, the average member of a volunteer corps—would be fully equal to the forester or the savage in other points of physical efficiency; and the selected English citizen might be confidently expected to hold his own against any athlete in the world. In running, in jumping, in rowing, in every game which requires skill, strength, and endurance, the young urban Englishman excels; but his sight has been suffered to decline in acuteness by sheer neglect; and the conditions of his life have also produced two kinds of deformity of the eye-ball, the short-sighted eye, and the flat or hypermetropic eye, each of which constitutes a serious deterioration in the organs of the visual sense.

In order to understand the practical bearing of the subject, it is not necessary to have any minute knowledge of either optics or anatomy, but it is necessary to have a general notion of the way in which seeing is accomplished. The essential parts of the eye have their analogues in a photographic camera. They consist of a lens which produces a diminished image or picture of external objects, and of a screen on which this picture is received. In the camera, the glass lens being of invariable strength, provision for obtaining clear pictures of either near or distant objects is made by arranging that this lens may be moved nearer to or farther from the screen; but in the eye, the lens being of elastic living tissue, the same provision is made by a muscle which increases the degree of its convexity, and thus increases its optical strength. In the normal or ideal eye, with which at first we are concerned, the proportions are of such a kind that the screen receives a perfect picture of distant objects when the eye is passive, and a perfect picture of near objects when the lens is rendered more convex by its muscle. The muscle is called the muscle of accommodation, and its effect, the placing the eye in a state to see near objects acutely, is called the act of accommodation.

In the eye the screen which receives the picture is composed of a delicate layer of nerve tissue; and the perceptive portion of this layer consists of a fine mosaic, so to speak, formed by the terminations of nerve fibres. The finer the mosaic—or, in other words, the smaller the terminations of the fibres, and hence the greater the number of such terminations which fall within a given area—the greater will be the acuteness of sight. In a general way, it may be said that the size of the nerve terminations which form the mosaic bear a definite relation to the smallness of the smallest point or object which can be seen; so that a person in whom these terminations were of a given magnitude would see a smaller object than would be visible to one in whom the terminations were larger. Besides form, however, objects are rendered visible by colour; and the power to discover slight differences of tint between objects and their surroundings implies a corresponding development of the colour-sense, which appears to be a special endowment of a particular group of nerve-fibres. The importance of this endowment in relation to acuteness of vision will be perceived when it is remembered how much some animals are defended by their power to assimilate themselves to the colour of the objects amongst which they move—fish to the colour of the bed of the stream, birds and insects to the colour of foliage and other surroundings, and so forth. In the human eye, the nerve terminations upon the screen—or, as it is technically called, the retina—are of two kinds, distinguished by their shape as "rods" and "cones," and the cones are more sensitive to colour than the rods, besides possessing a more delicate susceptibility to other sensory impressions. The cones are most abundant in the central part of the retina, and are comparatively sparingly distributed over its lateral portions; with the result that vision with the central part is much more acute, both as regards form and colour, than vision with the lateral parts. The portion of the retina in which vision is most acute differs from the surrounding portions in tint and in thickness; and hence is called, almost indifferently, the "central depression," or the "yellow spot." The size of the yellow spot probably varies in different persons; but the limit of acute vision is about sufficiently large to include the width of the nail of the forefinger when the hand is held as far as possible from the eye. The image formed upon the retina by the optical apparatus of the eye is complete in all its parts, and embraces an area of about 160° from side to side, and of about 120° from above downwards; but of this comprehensive image only the small central portion is in reality actually seen. The mobility of the eye almost neutralises, so to speak, the narrowness of the field of exact vision;

insomuch that the fact of this narrowness is unknown to the majority of persons, and becomes a matter of surprise when shown by observation or experiment. In technical language, the acute vision with which we see the objects to which the gaze is directed is called direct vision; and the imperfect vision, which renders us conscious of the main outlines of lateral objects, is distinguished as indirect. The former is the function of the region of the yellow spot only, the latter of the whole of the lateral portions of the retina.

Assuming the eye to be of proper shape and proportion, the degree of acuteness of vision in the central part depends mainly upon two elements—namely, the size (or rather, the smallness) of the nerve terminations, and the acuteness of the sense of colour. There is reason to believe that a nerve termination is not stimulated or impressed by an image smaller than itself; and that therefore the finer the mosaic of the terminations, the smaller will be the images of which they can take cognizance. The influence of the colour sense needs no demonstration. A person who was colour-blind would be unable to see any indication, at a comparatively short distance, of soldiers clothed in red who were standing among foliage, or to discover ripe cherries among the leaves around them; and it is obvious that, when the colour sense is unusually acute, objects may be distinguished by its help when they would be undiscoverable by mere outline.

Not only has the acuteness of vision of civilized man fallen below the standard common among savage nations, but, at the same time, the eyes of civilized man often depart from the normal or approximately spherical formation. They depart from it in two opposite directions; either becoming flattened from front to back, so as to bring the retina too near the surface, or elongated from front to back, so as to remove the retina too far from the surface. The former condition, technically called "hypermetropia," demands the exercise of accommodation even for distant objects, thus becoming a source of fatigue to the eyes; and it is also a common cause of squint. The latter, technically called "myopia," is the cause of short sight. These two malformations may be said to have come into existence within historic time, and into prevalence almost within living memory.

Hypermetropia, or "flat-eye," may be regarded as a matter of arrested development. The eye is flat because it has not attained its fullest proportions. It is stunted, and the imperfection is seldom limited to the shape of the organ as a whole, but usually extends also to its component parts. The retina of a flat eye is commonly defective, so that vision, even when assisted by glasses which correct the fault of shape, falls short of the normal standard. It goes without saying that hypermetropia is favoured by all circumstances which interfere with complete bodily development, and that it is most common among a population living in unwholesome condition.

The original cause of myopia, on the other hand, seems to be the application of the eyes to near objects; in other words, the poring over books and handicrafts. When the eyes are directed to a near object they are turned in, or rendered convergent, so that the axis of vision meets upon it, and this position is maintained by a muscular effort which, if continued, alters the shape of the eye in the direction of elongation. Manifestly, the alteration will be most easily effected during youth, when the tissues of the body, including those of the eye, are comparatively lax and distensible, and it will also be most easily effected among those young people whose tissues are exceptionally weak, by reason of inadequate food, or of unhealthy descent or surroundings. Badly-lighted schools are the great manufactories of myopia, the bad light compelling approximation of the books or other materials of study. There is yet another defect of shape, called astigmatism, which merely means that the surface of the eye is differently curved in different directions. All three, flat-eye, myopia, and astigmatism, however produced originally, are peculiarities of shape which are constantly handed down by parents to their offspring.

An examination into the state of colour vision in England was carried out a year or two since by a committee of the Ophthalmological Society, and it was found that the percentage of defect, say among Eton boys, was decidedly smaller than in the labouring population. The same would probably hold good as regards acuteness of vision and the shape of the eye; but, at the same time, the amount of defective sight in some of the great public schools is a matter which is beginning seriously to engage the attention of masters. Unfortunately, it is often overlooked in all schools, and the children who suffer from it are liable to be treated with injustice.

The defects of shape of the eyeball, whether flatness, elongation, or astigmatism, may to a greater or less extent be corrected by optical appliances, and when so corrected the mischief which the defects produce may almost be said to be limited to the trouble and cost incidental to procuring and using such appliances. For sub-normal vision, which is independent of faulty shape, optical appliances can do nothing, but a remedy may sometimes be found in diligent exercise of the defective organs. The question remains whether a civilised community should acquiesce in the prevalence of sub-normal vision, and in the increase and perpetuation, as well as in the prevalence, of defective shapes of the eyeball, without any effort to bring about a better state of things? I think not; and I think also that the first step towards improvement must be the recognition of the nature and extent of the evil.

Is there any reason why perfection of sight should not be made a point of physical excellence in all athletic contests? The example might be fitly set by the Volunteers, who might thereafter in time diminish the diameters of the bull's-eyes of their targets; and it would soon be followed by public schools and by athletic clubs. The tests would be easy of application, the value and uses of superiority would be unquestionable. A first effect would be to make people understand what they ought to be able to see, and a powerful counteracting influence would be brought to bear against those conditions which at present render it difficult for the dwellers in large towns ever to look at a distant object. Important good results would not be immediate, nor could they be fully attained except in more than one generation; but I think it cannot be doubted that they would ultimately follow.

Notes.

The opening or Exhibition soirée of the Photographic Society, which takes place to-morrow week, is to be accompanied by a total eclipse of the moon: first contact at 8·15, commencement of totality at 9·16, end of totality at 10·48, last contact with the shadow at 11·49.

One may predict that the Photographic Exhibition of this year will not be below the average, probably above it, as the pictures are in reality a selection from a much larger number than it would be possible to place, and the average of the whole seems quite up to the standard.

We have frequently alluded to the photo-micrographical researches of the recently deceased Dr. J. J. Woodward, of the United States army; and, indeed, this distinguished investigator has done much towards securing a general recognition of the importance of photography as an aid to medical science. Dr. Noriss's photographic observations, which lead him to believe in the existence of a third kind of corpuscle—practically invisible to the eye—indicate a direction in which much work may be done.

Photography is made good use of at Scotland Yard, under the directorate of Mr. J. Monro, the Assistant Commissioner of the Metropolitan Police. Attached to a circular dated the 8th instant, we find a Woodburytype print 6 by 4½, on which are closely grouped together the heads of thirty-six well-known offenders who are now wanted, each portrait having a reference number impressed; while the body of the circular gives a carefully tabulated previous history of the thirty-six, and such clues to their probable whereabouts as may be gathered from past records.

"Don't do that any longer, but purchase one of my posing chairs!" says a New-Jersey advertiser; and the

portraitist who cannot make the above burlesque representation of the too-much-rested sitter furnish him with a hint must be dull indeed.

From the bad to the good is a desirable transition; so let us glance at a well-designed posing chair made on the other side of the Atlantic (De Voe, Springfield, Ohio). The general frame-work is of cast iron, and numerous alterations can be made in a few seconds, as, for example, by changing the seat, removing the foot-stool, or putting

a back and arms in place of the body rest. The cast-iron framing need cost but very little, and photographers could then purchase the interchangeable extras as required. What British manufacturer will be enterprising enough to put something of this kind on the English market?

It would be interesting to have more exact information about that wonderful photograph, which report states was taken by a son of Mr. Rowland Winn, from the roof of Nostell Priory during the recent Franchise demonstration. If it is indeed possible, as rumour further asserts, to count 100,000 heads in this sensational picture, practical photographers would very much like to know "how it is done." A negative that thus appreciably helps the political statesman ought to be widely proclaimed from the house-top, on which it was taken. Young Mr. Winn's success suggests, indeed, a very simple way in which even the census can be "taken by photography" in future.

But, as we have said, a few additional details would be very welcome, and a "demonstration"—mathematical rather than political—of how the "heads of the people" are thus comprehensively numbered. Meanwhile sceptical critics will not be content with what may be called the *a priori*, or rather "Nostell Priory," line of argument.

Among the evils which Mr. Cocking attributes to inhaling the fumes of ammonia, may be mentioned severe catarrh and deafness!

That an edging of varnish—effectual enough in securing a collodion film to the glass plate—should be useless when applied to a gelatine film, is to be expected, for the gelatine swells and breaks up the varnish; while the varnish penetrates a collodion film and prevents it being wetted. "Merely paint the border of the gelatine plate with a saturated solution of chrome alum," says Mr. Sebastian Davis, "and the film will never frill from the edges.

How much chrome alum is it well to add to an emulsion? Here, again, we quote Mr. Davis: "Less than one-eighth of a grain to the ounce is seldom much use, and more than a quarter of a grain generally serves to make the gelatine too insoluble for easy re-melting; but of course something depends on the quality of the gelatine itself."

Truth calls attention to a singular decree on the part of the Watch Committee of the borough of Portsmouth. According to this decree, all the police inspectors, sergeants, and constables had to march down to a local photographer's, where each man had his likeness taken in a set attitude with his helmet beside him. The good people of Portsmouth have been much puzzled to know what this means, and *Truth* unkindly, and it may be untruthfully, suggests that the photographer in question has valuable influence on the Watch Committee, or that there is a surplus of the borough rates which the Corporation are anxious to dispose of quietly. There is also another theory which we are surprised has escaped our quick-witted contemporary. As our thieves are photographed for the benefit of the police, why should not the police be photographed for the benefit of the thieves? The thieves would certainly appreciate this little act of attention, especially in the case of detectives and plain-clothes men.

New developers for gelatine bromide plates may be multiplied almost indefinitely, as almost any sufficiently powerful reducing reagent which can act in a neutral or alkaline solution may be made to bring out the latent image; but, if we mistake not, the hydroxylamine developer of Egli and Spiller, described on page 613, will be found to possess notable advantages. Although the hydrochlorate of hydroxylamine now costs about ten shillings an ounce, there is every reason to suppose it can be manufactured at a low price, should a demand for it arise. It seems that the most promising and easiest mode of preparation known at present is by the action of sulphuric acid on nitromethane, and if it should be possible to use chloro-picrin (trichlor-nitro-methane) instead, hydroxylamine should become cheap, as chloro-picrin can be made very easily, and at a small cost.

Photographs of an instalment of the National Gallery pictures, presumably the outcome of the iron excrescence, are now to be seen in the London shop windows. The work in many instances, no doubt, was extremely difficult, but, taken as a whole, the specimens exhibited are not of supreme excellence. The colours of some of the pictures appear to have been very unfavourable for photographic reproduction, notably a picture by Grwze, which is now reproduced with every marking and imperfection, and really presents a mass of scratches and smudges.

Is there a duty on photographs of works of art when admitted to the United States? A correspondent who wishes to export a considerable number is anxious to be certain on the point. Perhaps some reader can tell him. So far as pictures are concerned, the duty is enormously high, so much so that, to avoid the payment of the tax, some Americans made a proposition to Mr. Herkomer, that instead of sitting to him here, he should go over to America, where they would guarantee him a profitable engagement. The offer was accepted, and last year the artist went over to the States, and was at work there several months. As Mr. Herkomer's prices are high, and as the duty amounts to nearly a third of the value, the shrewd sitters saved considerably.

Balloon photography is becoming a distinct branch of the profession. The Balloon Society in connection with L'Academie d'Aerostation Meteorologique of Paris intend next year to hold an exhibition in London, and at which a special exhibit will be apparatus for balloon photography.

If rumour is reliable, a well-known "professional beauty" celebrated last week the taking of her thousand and first photograph by a private entertainment to a few chosen friends. One of the chief subjects of conversation was a screen, on which had been most artistically arranged a copy of each of the thousand and one photographic portraits.

By noting the thermic results obtained with his sun motor (see present volume, page 19), Captain Ericsson has come to the conclusion that the heat of the solar surface cannot be less than 3,060,727° Fahrenheit; and it may be mentioned that the highest temperatures which have been yet realized in the laboratory are so trifling, as compared with this, as in no measure to support the mind in attempting to grasp the idea of such a degree of heat. There appears to be no reason to doubt the general accuracy of Captain Ericsson's conclusions.

Some illustrated "Hints on Posing, and the Management of the Sitter," will shortly appear as a series of ten or twelve papers. To mention that these will come from the pen and the pencil of Mr. H. P. Robinson is to say the utmost in praise of them.

"If you have occasion to look much at incandescent electric lights, you had best wear blue spectacles." This is the advice of Dr. W. H. Stone to Electrical Engineers, as he finds that the excess of the red rays in the light referred to injures the eyes; but when the arc light is concerned, this order of things is reversed, the violet rays being in excess. Here again we have conditions bad for the eyesight, so red side glasses or blinkers are provided on Dr. Stone's blue spectacles, and when the wearer has to work with the arc light, he simply turns these red glasses round so that they fold over the blue front glasses. Through the joint media it is said that the arc light may be looked at with safety.

The dark room window having been allowed a short period of rest after the recent discussions, we may mention that Obernetter colours a two per cent. collodion with turmeric and Jalap resin, and pours this on plain glass. Another way of making a medium is to make up a mixture of gelatine and turmeric, and to coat glass with it. The above are recommended for use with Vogel's azaline plates.

To accurately map out the very small stars by the aid of the eye and hand has proved to be only a step from the impossible; but M. Mouchez, of the Paris Observatory, finds photography to satisfactorily solve the difficulty. Now, in the course of an hour, an accurate map covering an area of 2° by 3°, and including all the stars of the twelfth magnitude, is obtained. To produce a chart covering the same area, on the old system required many months' hard work. An objective six inches in diameter, and having a focal length of eighty inches, is used.

Applications for Letters Patent.

12,482. Ernest Daniel Adcock, 53, Chancery Lane, London, W.C., for "An improved vignetting apparatus for photographic printing frames."—Dated 16th September, 1884.

Patent Sealed.

7678. Abel McDonald, Penrith, and Thomas Williamson Kendall, Cockermouth, both in Cumberland, Photographers, for "Improvements in apparatus for washing unmounted photographs and the like."—Dated 14th May, 1884.

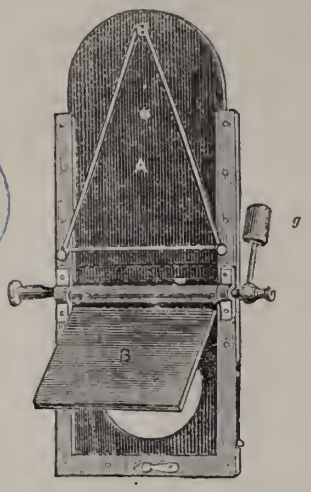
Specification Published during the Week.

2767. Frederick Woodward Branson, of Leeds, in the County of York, Pharmaceutical Chemist, for "Improvements in photographic shutters."

My invention has reference to improvements in photographic shutters, for which Letters Patent were granted to Richard Reynolds and myself dated 2nd April, 1883, No. 1650. According to my present invention, on the end of the spindle which carries the flap I mount a lever, having thereon a suitable adjustable weight; by altering the position of the weight upon the lever the flap may be actuated at different velocities, and the time of exposure be thereby varied. The lever may be moved and fixed at any desired angle or position on the flap spindle, so that it may be applied in some cases for opening the flap to allow the drop to fall; or, when required, by throwing the lever over to the opposite side of the centre of the flap spindle, and fixing it there to retain the flap closed, until it is raised by a movement imparted to the flap spindle by the attendant. Instead of the weight being placed on the adjustable lever, in some cases it may be found preferable to attach a cord or its equivalent to such lever at any suitable point; such cord or its equivalent being passed over a pulley on the upper part of the shutter, the required weight being suspended to the other end. Other parts of the photographic shutter are similar to those described in the specification of the above-named Letters Patent.

The claiming clauses are as follows:—

1. The arrangement and application of the lever, having thereon the adjustable weight *g*, and attached to the spindle, substantially as and for purposes herein set forth.



PATENT OFFICE LIBRARY

2. The general arrangement and combination of the various parts forming my improved photographic shutter, substantially as herein described.

HOW TO PHOTOGRAPH MICROSCOPIC OBJECTS.

BY I. H. JENNINGS.

LESSON 6.—DEFECTS IN THE NEGATIVE.

As the defects in photo-micrographic negatives are very numerous, it may be well to mention the chief, and their remedies, when such exist.

1. *Unequal Illumination.*—This is very apt to occur when using very oblique light, but may happen also with central light, from improper arrangement of condensers, &c. This defect may be known by the negative being dense on one side of the plate, and thin on the other. Do not blame the plate maker for improperly levelling his plates; this defect sometimes occurs, but very rarely. If the difference of density on each side is not very marked, it may be remedied by using matt varnish on the thin side of the plate, to diffuse the light when printing. Adding a little yellow dye to the varnish often improves the result, but in all cases the rough edge of the varnish should be softened by the use of a little alcohol or ether, or a nasty mark will be left on the print, just under the boundary line of the varnish.

2. *Too Powerful Illumination.*—In this case the object is "drowned in light," and the picture comes out flat and degraded. Remedy: take another negative.

3. *Reflection from the Apparatus.*—When the tube of the microscope is not lined with cloth or velvet, a bright central spot may often be seen on the screen while focussing, and a corresponding black patch will be found on the negative, which will be worthless. When using the eye-piece, this defect will not be met with. Reflection from the camera will also ruin the negative, also using the eye-piece without the cap. Let the inside of the camera and microscope tube be a dead black.

4. *Access of Stray Light to the Plate.*—Probably through the connection of camera and microscope not being light-tight. Result—general fog. Use a thick black velvet hood to connect the microscope with the camera, and keep it in place with elastic bands.

5. *Green Fog.*—This may arise from the use of impure sodic sulphite, or, in the plain pyro developer, from using too much ammonia. Green fog appears to be a silver deposit, from the fact that certain silver solvents get rid of it at once. Bichromate of potash, or peroxide of hydrogen, may be used, but the writer recommends the following, which is given by Mr. Howard Farmer in the YEAR-BOOK or 1884:—

A.—Potassium ferricyanide	...	1 ounce
Water	...	20 ounces
B.—Sodium hyposulphite ...	...	1 ounce
Water	...	20 ounces

First wet the negative if it has been dried. Pour a little of the hypo solution in a cup, and add a few drops of the ferricyanide solution. Dip a plug of cotton-wool in this mixture, and sponge the negative rapidly with it; then plunge it in water, and wash well. All trace of green fog will have disappeared.

6. *Over-exposure.*—This should be controlled in the development. After-intensification rarely produces even tolerable negatives from over-exposed plates. If much over-exposed, don't waste time in trying to patch up the negative, but expose another plate.

7. *Under-exposure.*—There is no cure for this evil: destroy the negative and take another.

8. *Under-development.*—An under-developed plate is useless. Don't hurry the development, but be sure all possible detail has been worked out, and examine the negative for density before the lamp.

9. *Thinness.*—The negative appears fully exposed and developed, but is too thin to give good prints. In this case try the effect of covering the back with matt-varnish, and print in the shade. Never intensify a negative before trying how it will print. Many a negative that appears too thin will give perfect prints. The negative from which the accompanying illustration of "Palpi of Male Spider" was taken furnishes a good example of this. This negative

PALPI OF MALE GARDEN SPIDER.

appears a mere "ghost," but prints well and strongly. Had it been intensified it would probably have been ruined. If the matt-varnish does not mend matters, the negative must be intensified. There is a choice of intensifiers, but the mercury and silver intensifiers are most generally used. The mercury intensifier is made as follows:—

A.—Saturated solution of mercuric chloride.

B.—Liquor ammoniæ ... ... 10 drops per oz.

After soaking the negative in water, it is placed in the bichloride solution until it becomes uniformly white. If requiring only slight intensification, it must be left in only a few seconds, or it will become too dense. Then wash well for five minutes, when the negative must be placed in B, which will turn the plate to a dark colour. With a little experience, this intensifier will be found very useful, but all intensification should be avoided if possible. Look for good results to the development alone, and let intensification be merely a last resource.

Other intensifiers are potassium sulphide and ammonium sulphide; either salt may be made up to the strength of 1 drachm to 20 ounces of water.

One of the best silver intensifiers is that given by Mr. W. Brooks, and is as follows:—"After the plate has been well washed from the hypo, place it in a weak solution of alum and citric acid solution:—

Stock Solution.

Saturated solution of alum	... 10 ounces
Citric acid	... 1 ounce

For the solution above named, I dilute one part to four of water, allow the plate to remain in it about five or six minutes; in the meantime, place in a developing cup about (say for a small plate) two drachms of the stock solution of alum and citric, and place in it about four grains of pyro; when dissolved, add a few drops of about a twenty-grain nitrate of silver solution."

This solution is to be applied to the plate until sufficient density be obtained; when the plate is washed, it is placed in the hypo bath for a few minutes, again washed, and finally treated with alum and citric acid solution to clear it. Plates thus intensified should not first be dried.

10. *Too Great Density.*—This is more frequently met with when using the plain pyro developer. Perhaps the simplest agent for removing it is Mr. Howard Farmer's ferri-cyanide reducer given above in speaking of green fog. The plate, if dry, is soaked in water for a few minutes, then placed in the solution, and examined from time to time until sufficiently thin. Only a few drops of ferri-cyanide must be added, or the action will be too rapid. Then wash well in running water, and dry.

11. *Shrinking of the Gelatine.*—This may arise from the gelatine being too soft, or from heat being employed to hasten the drying, which is a great mistake. The shrinking may be slight, spoiling the fine microscopic detail, or may amount to actual distortion of the image. Either way, the negative is ruined; the photo-micrographer is therfore advised to use only plates prepared with hard gelatine. Since the use of the alum bath has become more general, frilling is not so common as formerly, and the photo-micrographer need hardly be cautioned against it. Still, to avoid this, as well as the more serious evil of shrinking of the film, any plates found to be prepared with soft gelatine should be rejected for microscopic work.

Practical Papers for Beginners.

No. 10.—MAKING AN ENLARGEMENT.

How best to make an enlargement is one of those points which may be discussed again and again without any conclusion being arrived at, and the by-stander who listens to the arguments, and sees the specimens shown, may be excused if he comes to the conclusion that there is no best method; but that any person who excels in one particular method is very apt to conclude that his own way of working is indubitably the best. Simplicity and ease of working is a matter of special consideration for the beginner, and we will therefore choose for him, and describe how to make enlargements on paper with a gelatino-bromide emulsion similar to that used for the negative plates.

Now-a-days excellent gelatino-bromide paper can be obtained commercially, and we are inclined to think that the beginner will often do well to obtain it ready made; but, notwithstanding this, it is well to give directions for preparing it.

A good quality of paper is desirable, moderately stout Saxe or Rives being most suitable; but in order to fill in the inequalities of the paper, and to keep the picture well to the surface, a preliminary coating or substratum is required, and if this substratum is made partially opaque by means of a white pigment, the clearness and brilliancy of the pictures are much greater than otherwise would be. A suitable substratum or enamel is made as follows:—

No. 1.—Nitrate of barium ...	... 3 ounces
Hot water	... 1 pint
No. 2.—Sulphate of soda ...	... 4 ounces
Hot water	... 1 pint

Filter the above solutions through closely-woven muslin, and mix them, after which the deposit which forms must be allowed to settle down, and the clear liquor is poured off as closely as possible. Sufficient hot water is now added to fill up the vessel, and the precipitate or deposit is again allowed to settle down. This process of washing the precipitate should be repeated five or six times, and then the liquor containing the precipitate should be adjusted (by pouring off more or less of the water) to thirty fluid ounces, and four ounces of white gelatine are added, sufficient heat being applied to ensure its solution. When all is dissolved and the preparation is uniformly mixed, a solution of fifteen grains of chrome alum in an ounce of water is stirred in, and a quarter of an ounce of glacial acetic acid is added.

To coat paper with this preparation, the sheets are moistened, and one having been laid quite level on a slab of plate glass of corresponding size, the edges of the paper are secured by means of a bordering of thin slips of wood, laid frame-fashion on the edges of the sheet, and held in position with American clips. We thus obtain a kind of paper-bottomed dish, into which some of the enamel composition is poured, and the excess having been rapidly drained off, the glass is allowed to remain in a horizontal position until the gelatine is set—this generally happening in about half-a-minute or so—then the sheet is removed, and hung up to dry.

The emulsion is applied over the enamel in precisely the same way as the preliminary coating was applied, the sheets of enamelled paper being damped and clamped down to the glass just as already described; only it is not advisable to use an extremely sensitive emulsion like that referred to in the last lesson; a preparation well adapted for coating paper being made by the following formula, it being understood that the beginner has mastered the general details of emulsion making by carrying into practice the directions contained in our previous lesson:—

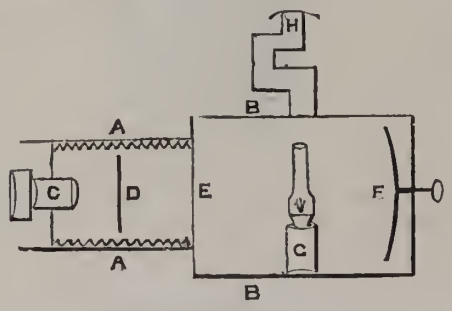
A.—Nitrate of silver	... 100 grains
Distilled water	... 2 ounces
B.—Bromide potassium ...	... 85 grains
Gelatine (as previously used)	... 20 ,,
Distilled water	... 1½ ounces
Hydrochloric acid ...	... 1 drop
C.—Iodide potassium... ...	... 8 grains
Distilled water	... ½ ounce

A and B are heated to 140° Fahrenheit, and A is gradually added to B with constant agitation. C is next stirred in, and finally 120 grains gelatine, which has been soaked in water until it has become quite soft, is added. When the whole is thoroughly melted and incorporated, it is poured out to set, and cut up into strips about a quarter of an inch square, the handle of a silver spoon being used for this purpose. These strips are washed by being soaked in some four or five changes of water, allowing (say) half-an-hour each time; but too much washing is not to be recommended in the present instance.

For drying the paper which has been coated with sensi-

tive emulsion, a tolerably warm room, from which every trace of light has been excluded, is best, and unless conditions are very unfavourable indeed, one may depend on the material drying in the course of four or five hours. As a means of enlarging, some form of magic lantern is to be recommended, and but little special instruction need be given. The negative is placed in the carrier of the lantern, and the image is adjusted as to size and focus on a sheet of white paper attached to the wall. The adjustments being completed, one caps the lens and pins up a sheet of the sensitive paper so that it occupies the required position, when the exposure is made by removing the cap. A preliminary trial as to exposure is easily made by exposing a small strip of the paper, and developing.

It is by no means essential to make use of an expensively constructed lantern with complex adjustments, and a careful worker may obtain excellent results with such a lantern as is represented below.



BUTINET'S ENLARGING LANTERN.
A, camera-front; B, tin case; C, lens; D, support for negatives; E, ground glass or diffusing screen; F, silvered reflector; G, paraffin lamp; H, chimney.

To make an apparatus like that represented above is a very easy affair, especially if the aid of a tinman be invoked. The camera originally used may slide into the front extension of the apparatus; and, as a general rule, it may be considered that the lens originally used to take a picture is a convenient one to employ for enlarging it. If one thickness of ground glass does not diffuse the light sufficiently, another may be placed at some little distance from it; or in other cases it may be well to place a piece of fluted plate glass on the lamp side of the ground glass screen.

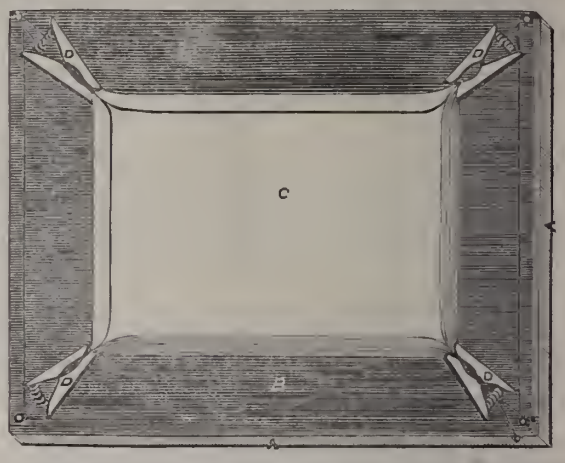
Should any difficulty be experienced in keeping the gelatino-bromide paper sufficiently flat during the exposure, it may be exposed in a printing-frame; the same frame, or a similar one, being used to contain the white sheet upon which the image is focussed.

A form of lantern very similar in general features to that above represented is shown, the main difference being that a condenser is provided, this serving to ensure a more complete illumination of the negative; and we may mention that those lanterns sold as the "Sciopticon Model," and constructed in the main as represented, are generally well adapted for making enlargements on gelatino-bromide paper.

Excellent results may be obtained with the developing solution already recommended (page 532), the paper being treated just as the glass plate was treated; but some persons prefer the ferrous oxalate developer for paper prints, and we therefore give the following directions:—

Prepare a saturated solution of protosulphate of iron by putting some of the crystals along with water in a bottle, and agitating occasionally, adding more crystals until a portion remains undissolved; and in a similar way prepare a saturated solution of potassium oxalate. One part of the iron solution and four parts of the oxalate solution, with the addition of one-fifth of a grain of bromide of potassium to each ounce of the mixed liquids, will be a good working proportion for the iron developer; and as the exact exposure may always be determined by means of trial strips, one need not vary the composition of the developing fluid. After development, the prints should be washed for a few minutes, and then allowed to remain for ten minutes in a fixing bath similar to that used for ordinary prints on albumenized paper (one and five). The final series of washings intended to remove the hyposulphite should be thoroughly performed (see p. 551).

In working with large sheets of paper it is a great convenience to be able to extemporise a large dish, and this is quite easy if a sheet of stout brown paper be waterproofed by the application of boiled linseed oil, and



allowed to dry; the sheet being then laid on a board and the corners held together by American clips, as shown above.

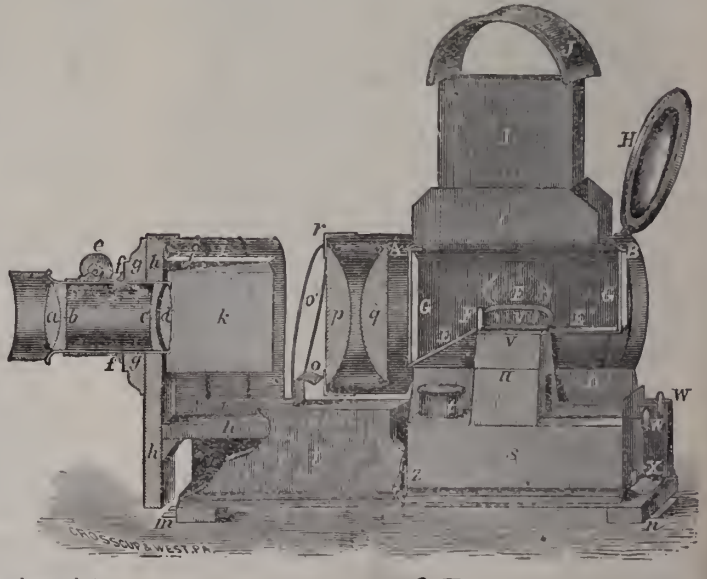


PHOTO-LITHOGRAPHY AND PHOTO-ZINCOGRAPHY.

BY MAJOR J. WATERHOUSE, B.S.C.,
Assistant Surveyor-General of India.

CHAPTER XVII.—MISCELLANEOUS PROCESSES.

WE now come to the consideration of sundry photo-lithographic processes which have been introduced from time to time, but do not come within the categories of the transfer and direct methods already described.

They may be divided under the following heads :—

1. Processes based on the uses of metallic salts other than those of chromium.
2. Oleate Processes.
3. Dusting Processes.
4. Other Processes.

1. *Processes based on the use of silver, iron, and other metallic salts.*—The earliest of these processes is Halleur's. According to Martin, he covered a thin grained stone with a strongish but perfectly neutral solution of sesqui-oxalate of iron, and by repeated washings with the solution, caused it to penetrate tolerably deeply into the stone. The stone was exposed in the camera, not wet, but just moist. The image produced appears in dull brown, and is immediately and perfectly fixed by washing over with a solution of carbonate of ammonia. A good washing with water removes all the salts, after which the stone is slightly etched with a weak solution of oxalic acid, and rolled up with printing ink as usual. The process never seems to have come into practical use.

Jobard, of Brussels, who claims to have been the first to invent a process of photo-lithography, covered a stone or zinc plate with iodine, and exposed it to the sun. Then, instead of treating it with mercury to develop the image, he covered it with a thick solution of gum-arabic blackened with lampblack, protecting it from the light until the coating of gum was dry. The stone was then plunged into water to wash away and dissolve the gum. It was then placed in the press, and rolled up with ink, which took only on the parts of the stone or plate where the iodide had not been decomposed by light. The whites remained quite pure, and perfect proofs could be obtained ; but the operation was a delicate one, and required some skill. The main point seems to have been in charging the roller very slightly with ink.

A somewhat similar process was brought forward by Messrs. Salmon and Garnier, who exposed a brass plate to the fumes of iodine, exposed to light under a photographic cliché, then applied mercury with a tuft of cotton, the mercury attaching itself only to the parts protected from the light. Ink was now applied with a lithographic roller, and attached itself only to the parts where the light acted, left untouched by the mercury. If a positive cliché were used, an image was obtained which could be bitten by acids ; if a negative, the image could be printed from in the lithographic press. This process also seems never to have come into any practical use.

Mr. Joseph Lewis, of Dublin, has described (NEWS, vol. vii.) several ingenious methods of obtaining photo-lithographic transfers with resists in silver, produced by modifications of the Daguerreotype and wet collodion processes.

In his first process he coated the surface of a card with hard plate ink, brushed it over with very fine pure silver powder, and then passed the card through a press on a highly polished steel plate. The picture was produced by the ordinary Daguerreotype process just as with a silver plate. It was then etched by the galvanic influence, which dissolved away the shadows, consisting of pure silver, and exposed the transfer ink in deep contrast with the mercurial deposit forming the lights of the image. It was then treated with a solution of cyanide of potassium, washed and dried, and then laid face downwards on a clean heated lithographic stone or metal plate, and passed through the press. The ink in the exposed parts attached itself to the stone or plate, while in the lights the film of undissolved silver and mercury prevented the ink from coming into contact with the stone. The images so produced are said to be sharp, and to stand printing very well.

In a second process Mr. Lewis treated an unvarnished collodion negative with acid and alcohol, and transferred the film to the surface of a card inked as before with greasy transfer ink. The card was then treated with ether and alcohol to dissolve off the collodion covering the shadows of the picture, thereby exposing the greasy ink surface, which may be at once transferred to stone or zinc by pressure. The difficulty in this method is to dissolve the collodion film off properly—some samples dissolving easily, others not at all, or with great difficulty.

In a third process Mr. Lewis formed upon the surface of a collodion negative a thick deposit of the mercurial salt and oxide used in intensifying, choosing for this purpose a collodion suitable for giving an image entirely upon the surface, and easily wiped off it. By pressing the inked card upon such a film the image is taken up as a dusty deposit, which prevents the ink from penetrating the stone when passed through the press. A very delicate transfer can be obtained in this way, but care is necessary to avoid stripping the collodion film along with the dusty deposit.

In a fourth process Mr. Lewis dispensed with the collodion film by precipitating a layer of chloride and iodide of silver on a glass plate. Before the plates were completely dry, a mixture of dextrine, glycerine, and nitrate of silver was applied to them. When dry, they were exposed under a positive, and when properly fixed, the deposit could be applied to the ink card and transferred as before.

In 1867, M. Morvan took out a patent for a process in which permanganate of potash was the sensitive agent. He dipped Saxe or Rive paper into a bath of sour milk, lactine, or whey, and allowed it to dry. It was then coated with a preparation made by dissolving half-a-pound of French gelatine or glue in a pint of water, and adding to it a solution of 160 grains of permanganate of potash in a quart of water. This was allowed to cool, and was then ready to coat the paper, which was allowed to dry in the dark. After exposure under a negative it was coated on the prepared side very evenly with a composition made by dissolving equal parts of bitumen, white wax, and Burgundy pitch in oil of lavender. The proof was then placed, coated side upwards, in a dish of cold water, which dissolved the permanganate in those parts not acted on by light, taking with it the coating of bitumen, &c. The proof was cleaned with a few strokes of the sponge, and was then ready for transfer to zinc or stone in the ordinary manner. M. Morvan claims for this process that it gives sharper results than the ordinary processes with bichromate and transfer ink.

(To be continued.)

PHOTOGRAPHING A TIGER ATTACKING HIS PREY.

THE *Daily Telegraph*, in a leader published yesterday, describes the photographing of a tiger in the act of attacking his prey ; but the following is the original account as given by a correspondent of the *Madras Mail*, who writes:—"So far as I can ascertain, a photograph of a tiger in the act of striking down a large animal was never taken until last week, when I secured a negative of a tiger killing a buffalo. I had focussed on the buffalo, which was tied to the stump of a tree in the middle of a field, and had just put a dry plate into the camera, when the tiger came up and struck down the buffalo with a single blow of his paw. My camera was not ten yards from the buffalo, and the tiger might just as well have come at me if he had chosen to do so, but fortunately he selected the buffalo instead, and then I took advantage of my position, and released the spring shutter just as he had given the buffalo his knock-down blow. The negative, I am sorry to say, is not a good one, but it is nevertheless interesting, because it throws some light on that vexed question—"How does a tiger kill his prey?" In the picture, which I have before me as I write, the tiger is seen standing on his hind legs, which are bent ; his body is inclined to the ground at an angle of about 45° ; his tail is straight, except the tip, which is curled upwards, and the right fore-paw is seen above, and the left below, the buffalo's neck. The head of the buffalo covers the shoulders and heart of the tiger, whose head appears above his horns ; his back is nearly level, but his front legs are doubled up under him, and he is just in the act of falling. The head is drooping and lifeless, and the whole appearance of the buffalo tends to confirm the generally accepted opinion that the tiger, with his knock-down blow, dislocates the neck of his victim.

"Lest any of your readers should be sceptical regarding the genuineness of the photograph, and also to prevent any rival running unnecessary risk when endeavouring to take a tiger in a similar position, I should explain that the tiger I photographed was not altogether a wild tiger, though he was quite loose and free at the time the picture was taken. A few days before, I had been told that a tiger was being led about by some Mahommedans, and had killed a buffalo that had been provided for it near Guntakal. I at once said that I was willing to offer another buffalo in the cause of science, and I took an early opportunity of bringing down my camera. The buffalo was tied to a stump in the open field by a rope, about twenty feet long, fastened to one hind leg. It was brought to the west side of the stump as far as the rope would allow it to go, and I took up my position with the camera about seven or eight yards to the north. The tiger was then led up to the west side of the field, and, when opposite the buffalo, was turned towards it. The buffalo, on seeing him, did not attempt to turn, or back away the dozen yards the heel rope would have allowed, but simply stood and looked at the tiger, apparently fascinated by him, as he approached. At that time there were three ropes to the collar round the tiger's neck, and a man holding each rope. When they came to within about fifty yards of the buffalo, one rope was slipped off, and soon after, the tiger, having by that time fixed his eyes on his prey, the other two ropes were let go, and he was perfectly free. It was an exciting moment for all concerned, including the photographer. The tiger came on, walking slowly, not crouching. When within two or three yards, he paused for an instant, then made one spring and gave a pat to the buffalo's neck with its right paw. Immediately after this I touched the trigger of my spring shutter, and in one-twentieth part of a second got the picture I have already described. As the buffalo fell, the tiger put his head over its neck, slipped his mouth down to his throat, and then lay across it, sucking its life-blood. As I was changing the slide for another picture, one of the Mahommedans with the tiger asked to be allowed to "Hala" the buffalo; unless this ceremony was performed, they would have been unable to eat any of the flesh. On getting permission he went behind the buffalo, which was lying on its side with its feet towards the camera, and struck his knife into its throat just above the place where the tiger had its hold. The tiger did not snarl or show any sign of annoyance; but it seemed a risky thing for a man to put his hand so near a tiger's mouth when the beast was excited with the taste of blood.

"I took some other photographs as the tiger was lying on the carcase of the buffalo; these have come out clearly, but do not possess much scientific interest. After some time the men drew away the tiger with a rope, but by that time he had eaten as much as he wanted, and was not unwilling to go. The men stated that they got him as a cub, and had had him for seven years. He was a very fine specimen, and the ease with which he knocked down the buffalo, and afterwards lifted the carcase and dragged it about, gave me an impression of his strength which will not easily fade from my memory."

Correspondence.

FELLOWS OF THE ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

DEAR SIR,—As anyone, by payment of a certain fee, can become a member of the above Society, it is a question whether it is not desirable that some distinction should be made between ordinary members, and masters, in the art of photography. I therefore humbly suggest as a plan, that all the recipients of medals at the annual exhibition become *ipso facto* Fellows. There should be some reward for merit beyond the medal, and some more lasting distinction. The Judges could be elected from the Fellows, and other benefits given to the Fellows which would make the title both desirable and honourable, as are the titles of A.R.A. and R.A. at the Royal Academy. If the annual exhibition at Pall Mall is to do for photography what the Royal Academy does for painting (and this should be the case), it is only to be done by a just but more rigid weeding of pictures. For many years some very second-rate work has been hung that should not be, for there are smaller exhibitions where such work can be received; in fact, it is to be hoped that soon it will come to pass that it is considered an honour to get a picture hung, let alone getting a medal.

There are complaints of the smallness of the Gallery, but it seems to me the Gallery is at present quite large enough to hold all the really good work sent up, and such alone is wanted at Pall Mall. Again, the question of limiting the number of pictures sent by each exhibitor may produce a better show.

I write this briefly in hope that my suggestions may be read, and, if considered worthy, acted upon. My only desire is to see the art of which I am so fond advanced by an exhibition of masters in it, and not degraded by mediocre work.—Yours truly, P. H. EMERSON.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

A MEETING was held in the small room attached to the Gallery, 5A, Pall Mall East, on Tuesday, 23rd inst., Mr. T. SEBASTIAN DAVIS, F.C.S., in the chair.

Mr. W. ENGLAND exhibited a new form of plate-box for use with a changing bag. The ordinary grooves are replaced by small frames containing two plates with a sheet of stout black card between. In connection with the box is a double dark slide fitted with a spring lid at one end, and just large enough to permit the insertion of the afore-described frames, each containing two plates.

Mr DEBENHAM remarked that the apparatus was very practical; in changing-boxes the cases are generally made too small, the result being that the plates often stick in their slides while in process of transfer. One plan of avoiding this difficulty, and at the same time the presence of pinholes in the resulting negatives, is to dust out the case each time previous to use.

The CHAIRMAN passed round a negative developed according to a slight modification of a recently-published formula containing washing soda, sulphite, citric acid, bromide, and pyro. It was claimed that very brilliant results were obtainable by the published method. He, however, only succeeded in developing up the high lights; but on adding to the formula 1 minim of ammonia and 1 grain of bromide per ounce, a developer yielding very vigorous results was produced. Unfortunately, the large proportion of alkali, although partially neutralized by citric acid, caused frilling, so he would be glad to know of a good substratum adapted to the requirements of gelatine plates.

Mr. COWAN believed that if the citric acid had been left out, frilling would not have set in, and much less exposure would have been required. Most commercial plates will stand the alkali.

Mr. DEBENHAM remarked that citrate of soda—formed from the action of citric acid on sodium carbonate—no doubt served to give intensity, but a much longer exposure was required.

The CHAIRMAN remarked that the use of sulphite of soda in hot weather causes red and green fog.

Mr. W. BROOKS said that while recently photographing paintings, he had developed twenty-eight plates with the same solution, and the translation of colour and general effect in the resulting negatives was better than if a new solution had been used each time.

The discussion then turned to the necessary quantity of chrome alum used in emulsion.

The CHAIRMAN was of opinion that not more than one-fourth, and not less than one-eighth, of a grain per ounce should be used, and he had tried the effect of adding one grain to the ounce, but found that the whole of the gelatine was coagulated, and that during the recent hot weather he had experienced frilling in films containing a quarter of a grain.

Mr. ENGLAND, Jun., said that probably in the latter case the emulsion had not received sufficient washing, and that frilling often results from the presence of decomposed gelatine and soluble salts. He also remarked that he had kept an emulsion at least a month during the hot weather, previous to coating, without any decomposition taking place; but then he had added thymol in the proportion of half a grain to the ounce.

The question was then put from the chair: "Has anyone ex-

perimented with Mr. Law's developer containing a mixture of potassium and sodium carbonates in place of ammonia?"

Mr. COCKING said that he had, and was well satisfied. He considered the subject before the meeting was of very great importance, as he had suffered lately very much from the effects of ammonia. The symptoms were a catarrh in the nose, deafness, and general nervousness. He would be glad to know of a remedy.

Mr. ASHMAN advised the use of a smelling bottle containing glacial acetic acid.

Mr. COCKING had used the acetic, and was temporarily relieved.

The meeting was then adjourned.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

A MEETING of this Society was held on Thursday, the 18th inst., Mr. W. ACKLAND in the chair.

The colour of gelatine negatives developed with soda and other carbonates again formed a subject for discussion, and the three plates sent by Mr. Ashman to Mr. Cowan for development were shown, which were developed as follows:—No. 1, carbonate of potash (crystals); No. 2, carbonate of ammonia; No. 3, carbonate of soda and potash (crystals). Nos. 1 and 3 were intensely yellow, and took a longer time in printing, the time required being:—No. 2, 12 minutes; No. 1, 19 minutes; No. 3, 22 minutes.

Mr. COWAN held that the majority of those who employed soda or potash obtained yellow negatives, and gave preference to carbonate of ammonia; in each case where he obtained yellow images, Mr. Ashman had, with similar plates, produced black films.

The CHAIRMAN observed that the difference between common washing soda and recrystallized carbonate of soda might account for that result; washing soda frequently contained caustic soda, a powerful alkali, whereas pure recrystallized carbonate of soda was almost neutral.

Mr. W. M. ASHMAN passed round some plates handed to him by a member at the previous meeting, which were said to give yellow films with the soda developer; in his hands they were not in the least yellow, although they were the most rapid plates he had yet met with.

Mr. W. TURNER exhibited a series of paper negatives and prints, both on albumenized and plain paper; also examples of blue printing, most of which were of large size, and similar to those described on page 526. The method adopted was that of rendering the picture or drawing to be copied translucent by means of lard diluted with turpentine, one part of the former to three parts of the latter. Mr. Turner preferred boiling these for three minutes, which he said killed the grease; the mixture is then rubbed over the drawing, and when surface-dry, is placed in a printing frame with sensitized paper, and a negative obtained; this negative is fixed in an old hypo bath, rich in silver, and washed in the usual way, after which a positive is taken from the paper negative. The plain paper was prepared by floating Saxe paper on the following:—

Sodium chloride	200	grains
Gelatine	30	,,
Water	20	ounces

Dissolve the gelatine and chloride separately, and mix; float three minutes. When dry, sensitize on—

Silver nitrate	1	ounce
Citric acid	1	drachm
Water	14	ounces

The paper will keep good for six weeks.

Mr. H. L. STARNES directed attention to a sample of silver-coated wire which he thought suitable for making a mesh for cutting up emulsion-jelly before washing; he said it was very cheap, as it was used for winding around violincello strings, and could be obtained at any musical instrument shop.

Mr. W. K. BURTON enquired if anyone had found harm to result from the use of ordinary copper gauze.

Mr. J. B. B. WELLINGTON used it even with ammonia emulsions, but did not allow the emulsion to remain long enough to attack the copper.

Mr. BURTON'S experience was that the ammonia acted very rapidly on copper gauze.

Mr. STARNES passed round an emulsion-coater made of pine in the form of a developing tray; a slit beneath, somewhat similar to Mr. T. G. Whaite's, permits the escapement of sufficient

emulsion to coat half-a-dozen plates, arrayed on a levelling table at one sweep.

Mr. DEBENHAM: Does the emulsion get between the plates?

Mr. STARNES had not found it do so; he took the precaution of securing the plates at each end of the levelling table by means of carriage pins. He then passed round a negative which presented a broad opaque band around two sides of the plate, and enquired the cause.

Mr. BURTON attributed the marks to a defect in drying, an opinion held by Mr. Debenham and several others.

Mr. HADDON thought the marks were due to insufficient washing; soluble salts being left in the film would cause parts of a plate to be more sensitive than others, so that a partial reversal might occur.

Talk in the Studio.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—A special meeting of the members will be held (in accordance with a resolution passed at the June meeting) at the House of the Society of Arts on Thursday next, October 2nd, at eight o'clock, to consider the future of the Society, after which Mr. W. Ackland will read a paper on "Furuell's Lens."

THE BIRMINGHAM AND MIDLAND INSTITUTE.—A Photographic Section has been established, and we note that on November 12th next, Mr. A. J. Ball will read a paper on the Photo-Filigraine process. The following extract of the last annual report will give some notion of the activity of the Photographic Section:—"The Photographic Section has continued to do useful work in spreading the knowledge of that interesting art, now rendered so easy by the invention of dry plates. The number of members has increased to 39. Several papers have been read by different members, and the exhibitions of landscape photographs in the lantern have afforded much interest even to the non-photographer. The excursions have, however, been but poorly attended, which is to be regretted, as the beginner would profit by the advice of the more experienced—even in the taking of the picture. Rules have been adopted for the exchange of prints and for the sale at a nominal price to non-photographers, who have been glad of the opportunity of obtaining momentos of places visited by the Society. Arrangements have been made for the albums of the Postal Photo. Society to be exhibited at the meeting, whereby the members will be able to compare their work with other amateurs. The surplus funds of the Section have been devoted to the purchase of a number of books likely to be useful to the members of the Section."

THE PROPOSED AMERICAN EXHIBITION IN LONDON.—A novelty in exhibitions is proposed for 1886: a comprehensive collection of all the numerous things that the United States can show us. Should the proposal be carried out on a sufficiently large scale to make the Exhibition a thorough success, much will be accomplished towards building up a more complete unity of feeling between the one people which now form two great nations. It is proposed that the Exhibition shall open on the 1st of May, 1886, and it is intended that a complete representation of the arts, manufactures, employments, and productions of the United States shall be given. The characteristic amusements of the American people are not to be forgotten. At an American theatre performances will be given by American actors, and by the negro singers. A number of the best-known Americans artists, in Europe and America, have undertaken to furnish the Fine Art Galleries, and amongst many other works will be portraits of the most prominent personages of the United States. There will be in connection with the Exhibition such sports as may be practicable, including roller-skating, base-ball playing, la-crosse, trotting matches, bicycling tournaments, billiards, and the American variations of every sport which is popular in the old country. The principal phases of American life will be represented in the Exhibition, from a broker's office in Wall Street, to the camp fires in Nevada. A Californian wine-shop; Florida fruit stores; Indian canoe-makers and mat-weavers; ice drink pavilions and bars; restaurants, with the products of

the Eastern and Pacific coast, and of the Northern and Southern States, characteristically prepared, and served by white and coloured male and female cooks and waiters, will help to mark the peculiarities and variety of American social development. There will be a press pavilion; an Atlantic Cable Office; an electrical elevated railway, and reproductions of the façades and interiors of remarkable hotels and public buildings. Influential people in London are in favour of the scheme, and passing over the names of two dukes, four marquesses, fifteen earls, and thirty-three lords, we find the names of very many illustrious men as supporters on this side of the Atlantic. The London agent is General Norton, 7, Poultry, E. C.

THE dead season in town is generally a busy season at Trafalgar Square, and one of the first changes a Londoner looks out for on his return home he finds within the walls of the National Gallery. This year the authorities have been busy with the building rather than with the pictures. One of the galleries has been closed for renovation, but will be opened again in the course of the week, and the whole series of rooms will thus be gradually put to rights. Indeed, the abundance and the pervasiveness of the soot, smoke, and dust which collect each year on these walls show beyond doubt the central character of the situation. They explain also the need for glazing so many of the pictures. Many gaps will also be found upon the walls, and some very favourite canvasses are withdrawn; but the visitor may take confidence when he learns the cause. These are not pictures that have been lent to provincial exhibitions, and their absence will be of short duration. The more important works are being photographed in the studio outside the building. London fogs may come upon us at any moment, and these bright September days are being prudently utilised.—*Daily News.*

SUBSTITUTE FOR A GROUND GLASS.—While out viewing the other morning I was so unfortunate as to break the ground glass of my camera. As a substitute I stretched my white handkerchief across the back of the camera, closing the empty frame over it, and found no difficulty in securing a good focus. The fact may be of use to others.—F. A. JACKSON, in the *Photographic Times.*

PHOTOGRAPHIC CLUB.—The subject for discussion on Oct. 1st will be on "Artificial Lighting." At nine o'clock the meeting will be resolved into a special general meeting. Saturday outing at Blackwall by first train after two o'clock.

To Correspondents.

*** We cannot undertake to return rejected communications.

PALMAM QUI MERUIT FERAT.—Your enclosure touches on points of considerable importance, and we hope you will continue to give attention to the subject.

ETA.—The method of filling up the form is made sufficiently clear by the information given thereon. We have posted you one.

WILLIAM WOOD AND CO.—There must have been some mistake; let us know if anything of the kind should occur again.

DAMAGES.—No doubt you are entitled to compensation, but we do not think that any sum you are likely to obtain will cover the expense and trouble involved in getting it. The fact of your having had no written or stamped agreement is likely to make proceedings difficult. At any rate, you should go to the house of the person and demand the return of the negative.

LIONEL.—The exact method employed by the firm using the title quoted is a trade secret; but during the past two years methods of obtaining similar results have been described in the PHOTOGRAPHIC NEWS.

ASPIRING AMATEUR.—As soon as space will allow, we will publish a series of articles on the subject.

A. BROWN.—Our "Practical Paper" this week embodies all the information you ask for.

J. G.—1. As a rule they are not so fitted on both sides. 2. Plain white screens. 3. A so-called whole-plate lens, having an equivalent focus of about ten or twelve inches.

R. D. B.—Put the black varnish on the glass before mounting the picture, and let it dry thoroughly.

WM. M.—We are inclined to attribute the markings to imperfect fixation. But it seems that the gelatine is hard in parts, so that some portions will require a longer time than others. Allow the plates to remain longer in the hyposulphite bath.

L. NORMAN.—Excellent as it may be, you cannot reasonably expect such an interchangeable set to be equal to the separate instruments which it is intended to replace.

C. M. EBSWORTH.—1. The glass is not sufficiently good in quality, as the pimple-like projections and the rough places will be certain to cause defects in the films. A rough test of the general quality of glass is afforded by the compactness and solidity of a pile of the plates, any inequalities of surface naturally preventing close contact. 2. Surely chloride must be intended: at any rate, you would do well to make up a trial batch on this supposition. 3. Remove the varnish by means of alcohol before proceeding. Abundance of spirit should be used, its action being assisted by gentle friction with a soft camel's-hair brush, and when all seems to be dissolved, the plate should be well rinsed with abundance of spirit.

E. EDWARDS.—Received.

W. T. D.—1. It will decompose rapidly after mixing, and you cannot depend on it after the first day. 2. Apply to the manufacturer. 3. They are printed on an ordinary lithographic machine.

B. CHASE.—The collodion should be of a tough and elastic kind, and, although there is no need whatever to have it iodized, it is sometimes convenient to use an iodized sample rather than to search for or prepare plain collodion. The iodizing salts are dissolved out by the water, and do no harm.

H. C.—1. Such an excess of acid will serve to make the plates extremely slow, and this without any compensating advantage. 2. Yes, very good, but subject to the fault referred to. 3. A lens having a focus of between 7 and 8 inches will prove most suitable. 4. One part of bichromate of potassium to six of gelatine. 5. It would be almost certain to cause mischief; the products of combustion into the open air by means of a chimney.

T. WESTON.—Soak the prints in hot water so as to remove as much as possible of the size from the paper, after which, dry them and wax them. The most convenient method of waxing is to make a slab of slate hot, and, after having covered it with a sheet of plain paper, to lay the print on it and rub with a cake of white wax. When the whole of the paper is saturated, remove the excess by means of blotting-paper.

Photographs Registered.

VOL. XXVIII. No. 1361.—*October* 3, 1884.

CONTENTS.

ENLARGEMENTS UPON CANVAS.

A SPECIFICATION of a continental patent applied for by Messrs. Winter, of Prague, and dealing with a method of enlarging on canvas which does not differ very much from that already detailed in the "Studios of Europe," has been published. As Messrs. Winter's method of enlargement is that which has proved most practical and easy in the hands of those who have not been accustomed to work of this character, details will now be given embodying the points of importance to be found in both places.

A fine compact and closely-woven artist's canvas—not too dark in tint—must be used, but such a material as is sold already painted or primed is not suitable. This must be thoroughly washed in hot water, then rinsed with cold water, after which it is stretched so as to remove folds, and allowed to dry.

The salting solution may be made up with bromide alone, or with bromide and iodide, the latter being, perhaps, preferable on the whole.

1.—*Bromide Salting Solution.*

Bromide of potassium	4 parts
Bromide of cadmium	1 part
Water	240 parts

2.—*Bromo-iodide Salting Solution.*

Bromide of potassium	3 parts
Iodide of potassium	1 part
Bromide of cadmium	1 ,,
Water	240 parts

Whichever salting solution is used, the mode of application is the same. A horizontal bath, considerably larger than the sheet of canvas to be dealt with, is tilted, and the salting solution is poured in; but care must be taken to leave so much space uncovered as corresponds to the size of the canvas to be sensitized. The sheet of canvas is now held by two assistants, so as to correspond to the portion of the bath in which there is no liquid, and a stout glass rod is next lowered so as to bring down one end of the canvas, after which the sheet of material is drawn steadily under the rod. The canvas is in this way thoroughly and uniformly saturated with liquid, and the next step is to hang it up in a warm room to dry. It need scarcely be remarked that there is no need to exactly follow the above directions for salting the canvas, it being sufficient to draw the material through the liquid in any way which may be convenient; but it is advisable to draw over a glass rod if practicable, so as to strike off the excess of fluid; the above described method is, however, convenient when a sufficient number of persons are at hand, four being required when a large sheet—say, three feet by four feet—is being treated.

When dry, the material is sensitized with an acid solution of silver nitrate, prepared as follows:—

Sensitizing Bath.

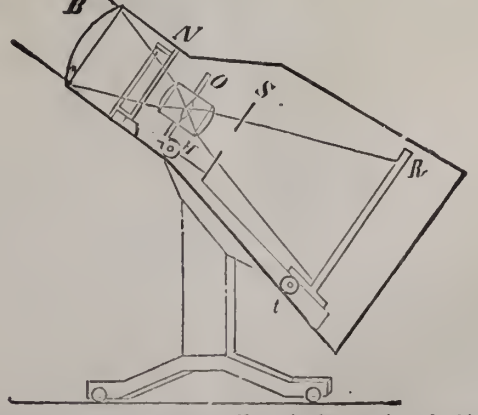
Nitrate of silver	4 parts
Citric acid or nitric acid ...	1 part
Water	140 parts

The citric acid will be preferred in most cases, but something depends on the canvas used, and the sensitizing is conducted precisely in the same way as the salting. In drying, it is necessary to take care that the canvas is in no way rumpled or creased.

Exposure may be made either in the solar camera, or by artificial illumination; Messrs. Winter preferring the electric light, and employing a six horse-power engine, and a Siemens dynamo machine. The optical arrangement is a simple one, a condensing lens being set in front of the arc light, and immediately the other side of the condenser is a camera with the negative in the position usually occupied by the focussing screen; all that is now required being a screen on which the image can be projected for focussing. The chief point in arranging such an apparatus is to take care that the image of the arc as formed by the condensing lens is formed exactly in the position occupied by the diaphragm of the objective.

Messrs. Winter make the enlarging arrangement multiple, so as to economise the light as much as possible; three enlarging systems being made to converge towards the electric lamp.

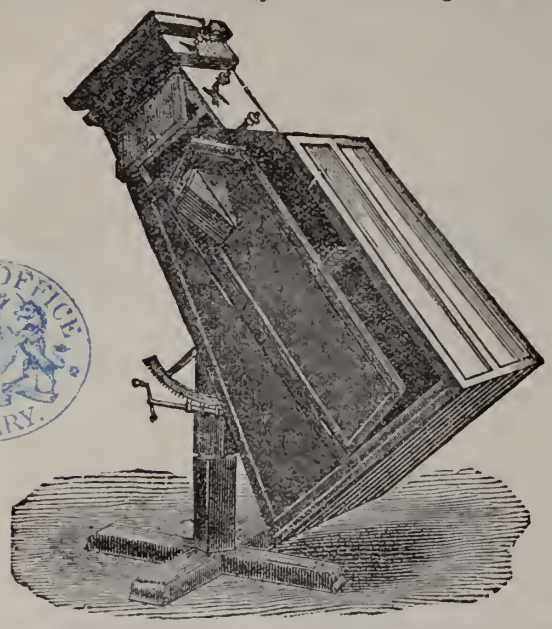
A convenient arrangement of the solar camera is exemplified by the following sectional sketch, and it is by no



B, condenser directed towards sun; N, carrier for negative; O, objective actuated by a rack-work, given by the milled head, H; S, screen to cut off superfluous light; R, adjustable screen to take canvas or paper.

means difficult to fit up such an apparatus in an extemporised form, and from the subjoined diagram some idea of

the external aspect of the apparatus may be gathered; the worm and arc-rack, by which the direction is kept, being shown to the left of the figure. When a vignette effect



PATENT OFFICE LIBRARY.

is to be produced, the screen, S, is serrated like a paper vignetter.

For very large sizes, the solar camera is by no means convenient; and if it be not desirable to fit up a room with the electric light, an arrangement like that devised by Solomon for use with the magnesium light may be used. Explanation is scarcely required, and it is obvious that such an apparatus will serve equally well, whether the magnesium light is employed as represented, or whether the electric light is used.

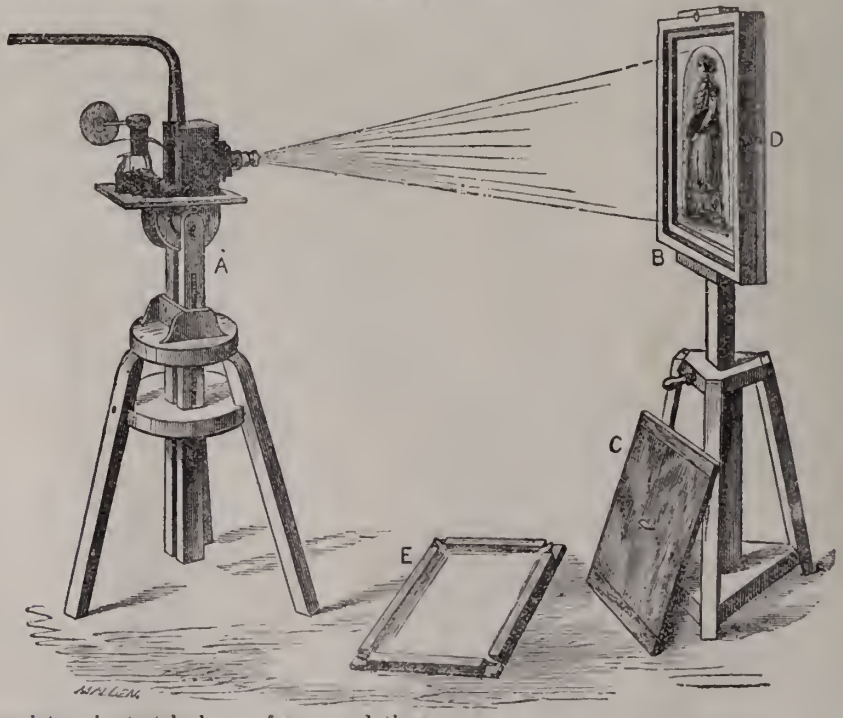
As in all photographic operations, the exposure must be learned by experience, but something over ten minutes may be required with the electric light when the scale of enlargement is considerable; still, with good sunlight and a properly-arranged solar camera, a much shorter exposure will suffice. In any case, there should be a distinct outline on the canvas before development.

The exposed canvas is immersed into the developing bath, this being made up as follows:—

Pyrogallic acid	...	...	...	10 parts
Citric acid	...	...	...	45 ,,
Water	...	...	...	410 ,,

The developer should be used slightly warm, and about ten minutes is required to bring the picture properly out. A thorough washing is required after development, and the next step is to tone the image, this being done with such a toning bath as is employed for prints on albumenized paper—as, for example, the ordinary acetate of soda and gold bath.

Fixing, again, requires no special comment, the usual hyposulphite solution, consisting of one part of the salt in five of water, being used, and immersion for ten minutes being ample, as the canvas is very permeable to the liquid. A very thorough washing should be given—let us say a dozen changes of water—extending over a period of twelve or sixteen hours.



When dry, the picture is stretched on a frame, and the surface is slightly waxed in order to smooth down the rough fibres which stand up, and to give a brilliancy to the resulting picture. A waxing paste similar to the so-called "encaustic paste" used for silver prints may be used:—White wax in shreds, 1 ounce; oil of turpentine, 5 ounces. Such enlargements as those described are sometimes sold as finished pictures, and at other times are painted upon by an artist.

GLASS.*

Tenth Article.

Visitors to the Health Exhibition at South Kensington may there see in the French Court a complete set of tools and appliances for blowing glass by mechanically compressed air. There is a full-sized model of the blowing-

* Reference to previous articles, vol. xxvi., pages 675 and 737; vol. xxvii., pages 3, 93, 226, 419, and 757; vol. xxviii., pages 338 and 356.

hole in the furnace, together with the pipes and connexions to the air reservoirs. It is called the "Système Appert Frères," constructed by Count Delamarre, 24, Rue Godot de Mauroi, Paris. An inspection of the models and plans will give a clearer idea than any written description can convey. The "system" is by no means new, for a dozen years ago compressed air was employed in glass-blowing by one English manufacturer, the apparatus being nicknamed "the iron man." By its aid it was expected that very large sizes could be blown, such as were beyond the power of a man's lungs to produce; and this was so far realized, but it was found that the process was not so handy, nor so completely under the control of the blower, probably because of the inconvenience of the flexible pipe or hose, which prevented that extreme freedom which the blower appears to enjoy when not so fettered. Hence the system was abandoned in favour of the ordinary process of forcing air into the pipe by the mouth and lungs. Glass-blowing is classed among the unhealthy trades, and it is, perhaps, to be regretted that some kind of mechanical arrangement cannot be perfected so as to prolong the men's lives, and diminish the distress occasioned by reason of the injury to the lungs and chest which frequently terminates the blower's existence.

The methods of blowing and flattening sheet glass, described on pages 338 and 386, are those invariably followed in making all kinds and substances of sheet glass. Whether it be the thinnest 14 ounce Belgian, or the stoutest 42-ounce English, the process is practically the same; the only departure or variation being when making *coloured glass*.

Glass can be tinted or coloured of every conceivable hue to suit the taste of the most fantastic and the critical; therefore, we find that coloured glasses have played an important part in history for ages past. At the present day, the employment and consumption of coloured glass is simply enormous. Without venturing into figures, it may safely be asserted that never in the world's history has coloured glass become so much the rage as at present. Leaving aside the church restoration mania which convulsed Great Britain some twenty years ago, and looking at matters of to-day, wherever we glance we see coloured glass. In churches, chapels, schools, and convents; in palaces, mansions, villas, and cottages; in clubs, institutions, shops, restaurants, and public-houses; in railway stations, on lamp-posts, and, in fact, in every conceivable place, there we find some employment for coloured glass. We are not speaking particularly of coloured glass as it concerns the photographer, because there is only one colour that really concerns him—viz., *ruby* or red. We beg pardon; of late the photographer has affected the *green*. However, not to be exclusive, it may interest the reader to know that colours in glass are produced by the oxides of metals, and by a few other substances; the following list showing that different colours are obtainable according to the state of oxidation of the metal:—

Blue.—Oxide of cobalt, deutoxide of copper, perchloride of gold.

Yellow.—Oxide of silver, oxide of antimony, protoxide of iron, ferrous oxide of manganese, carbon, protoxide of copper.

Green.—Deutoxide of copper, deutoxide of iron, oxide of uranium, and by mixing the colouring agents employed in making blue and yellow.

Violet.—Manganese, oxide of gold, and by mixing red and blue agents.

Red.—Oxide of gold, manganese, oxide of silver, protoxide of copper, and peroxide of iron mixed.

White (opal).—Deutoxide of tin, phosphate of lime from mutton bones, arsenic.

Black.—Oxide of iridium, manganese in excess, oxides of cobalt, copper and iron in excess.

And so on. It will be apparent to the most casual reader that the mixture in various proportions of the colouring agents aforesaid enables the glass maker to produce every colour in the rainbow—or out of it. Further, that the proportion of the colouring agents determines the depth or strength of colour in the resulting glass, so that it is quite competent for the mixer to produce the palest tint or the deepest colour at will.

Coloured glass is made in two ways—either as "flashed," when the colour is really a thin skin on a basis of clear glass, or as "pot-metal," or solid (*massif—French*), in which the colour pervades the whole of the substance of the glass.

Suppose we follow the process in the fabrication of a sheet of coloured glass; let it be ruby, and let it be understood that it is photographic ruby that is desired.

In the furnace, almost side by side, there must be two pots of metal ready for blowing; one must be ordinary window glass metal, and the other must be ruby for "flashing" or "casing." The composition of this ruby metal varies according to the formula of different makers, but it may safely be stated as being composed of about one part of protoxide of copper to one hundred parts of ordinary window glass metal, and sometimes there is added about one per cent. of protoxide of iron (iron scales) or oxide of tin. This mixture gives a glass sufficiently dense in colour for flashing.

The blower dips his clean pipe into the ruby pot and gathers thereon a certain weight of the ruby metal; he then gathers over it the white metal, and he forthwith proceeds to blow the cylinder, the inside of which has the thin skin of ruby. If the blower wants to produce a full, rich, dark tone of ruby, he would gather, perhaps, one pound of ruby and twenty pounds of white; but on the other hand, if he wished to produce a pink, or rosy kind of glass, he would gather very sparingly out of the ruby pot, so as to keep the flash as thin as possible. The thicker the flash the darker the ruby; the thinner the flash, the paler will be the glass—always supposing the same ruby pot is being blown from. There is a vast difference in ruby or red glass. Some is made from materials which make it utterly valueless for photographic use; it transmits blue rays when examined by the spectroscope, and this probably has given rise to some of the confusion, and misunderstandings, and bickerings among photographers who, perhaps, do not know that there is a difference, and that there is a pale ruby glass and a rich red, all going under the one designation of ruby. Ruby can be flashed upon any other colour; it can be flashed upon yellow, or blue, or green, or, in fact, upon any base that may be desired. Ruby cannot be made solid (*massif*); it would be no longer ruby—it would be black, quite opaque.

So-called ruby can be made solid if it is composed with perchloride of gold (purple of Cassius), but it is certainly not a red, but more correctly a deep pink. This is the colour employed in making chimnies for use in lighthouses, where great translucency is required.

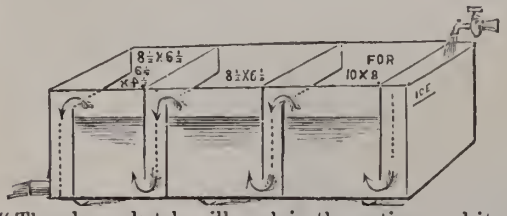
Green glass is also made by the employment of copper and iron; but the metal in this instance is in a different state of oxidation than when used to make ruby. In making green glass the copper is usually employed in the form of the sulphate, which is mixed with the batch by being dissolved in water, and poured over the sand, &c., and then dried before being shovelled into the pots. The tone of the green can be varied by the proportion of iron to copper, but such glass as that known as cathedral green is made by about ten per cent. of copper sulphate and five per cent. of sulphate of iron, added to the ordinary mixture for window-glass. Frequently a small percentage of blue mixture is added to get a blue-green, or yellow mixture to get a yellow-green. Green is seldom blown except as pot metal, in which the colour pervades the whole substance of the glass, the use for flashed green being very limited. In all pot colours the metal is gathered and blown just in the same manner as ordinary window-glass, the chief care being to obtain uniformity of substance in

the sheet, otherwise the colour or tint may be very pale in one part, and very dense in another. The same remark applies to flashed colours; if the flash is unequal, the colour varies considerably in depth. When cylinders of coloured glass are blown, they are split and flattened just in the same way as ordinary window-glass.

The production of coloured glass calls for considerable skill on the part of the glass maker. He must be a chemist, and understand thoroughly the effect produced by every addition of an ingredient; rule-of-thumb is all very well in its way, but it often happens that whole pots of glass go wrong, the colour will not "come," or turns out to be a different one to what was expected. The skilled glass maker sees what is wrong, and by altering his heat, or by the addition of a substance either rich in oxygen or an absorbent of oxygen, he can speedily turn the metal to the correct colour sought. The tints and colours are so manifold, that it is really surprising to know that a skilled man can compose a batch, and hit the tint or colour of a given sample; indeed, the experienced glass-maker can, on looking at a sample of coloured glass of even a peculiar tint, sit down and write a formula, which, when compounded and founded with care, will come out an exact match, even although he may never have made that identical colour before.

A WASHING APPARATUS FOR NEGATIVES.

Mr. Germanus Shaw is good enough to send us the following description of a washing trough, constructed by Mr. Charles Stortz. Mr. Shaw says:—



"The above sketch will explain the action, and its complete success may be proved by putting a small quantity of any colouring matter (Judson's dye picture) into the first compartment, and watching the result. The hypo-sulphite, as it is dissolved off the plate, sinks to the bottom of the tank, and as it is the bottom water from each compartment that is forced to flow into the next, and thence to the outside, it will be readily seen that all the plates are thus subjected to a continually changing stream of fresh water. Nor is this all: during the hot weather the troubles of frilling may be effectually avoided by a small supply of ice in the first compartment, without any danger of scratching the films, which it cannot touch.

"Although the tank is not a syphon, it will never overflow (if ordinary care is used to regulate the supply), and should the supply of water suddenly fail, this invention has the advantage over syphon washers, as it does not slowly drain off the water, leaving the films to dry in irregular lines, but the tank still retains sufficient water to quite cover all the plates that are in it. This feature is invaluable where a cistern sometimes empties without any previous warning.

"The comparatively small cost of an apparatus of this kind is more than repaid by the sense of security, and satisfaction of feeling that one's negatives are thoroughly freed from the destroying angel—hypo. I strongly advise all who value the permanency of their work to try it."

A DIVIDING PRESS FOR EMULSION WORK.

BY L. DAVID.*

The apparatus about to be described is especially available for those who may wish to work on a large scale, and the arrangement consists essentially of a cylinder of strong glass, which should be as uniform in the bore as possible. This cylinder is set over a sieve of stout plated brass wire, having a mesh of 2 m.m. (about one-twelfth of an inch). By means of a stout framework of wood, the cylinder is held in position, and by undoing two thumb-screws, the cross-head of the framing can be removed easily, so as to liberate the cylinder. A wooden piston, provided with an

india-rubber packing-ring, is forced down into the glass cylinder by a screw, as shown in the drawing. With the apparatus in question, the work of dividing the emulsion is easy, and the cut threads or strips are allowed to drop into a porcelain vessel placed below the base-board of the apparatus.

* Abstracted from the *Photographische Correspondenz*.

By-the-Bye.

PHOTOGRAPHING ON THE BLOCK OF THE WOOD ENGRAVER.

The wood engraver is not always a draughtsman, and as a consequence very many skilful wood-engravers are entirely dependent upon others for the drawing or sketch which is invariably made on the wood block before the actual cutting or engraving is commenced. Still, on the other hand, it is not difficult to find those who unite in themselves the artist, the draughtsman, and the engraver.

The artist or draughtsman, when he makes his drawing upon the boxwood block—this block having been previously whitened by being rubbed over with a white pigment, such as white lead—does not trouble himself to draw every line by which degrees of shading are represented in the finished engraving, but he merely endeavours to show the required degrees of light and shade; indeed, it is generally considered better that the artist should make the picture in gradated tints or washes, and leave the engraver to exercise his own judgment as to the best means of translating these tints into lines or cross-hatching.

A drawing in tints or washes, and very nearly resembling a photograph, answers very well indeed; and as the engraver works upon it, he has merely to translate each gradation of tone into a system of lines or dots, more or less closely packed together, and of appropriate width. This being the case, the engraver was not slow to call in the aid of the photographer; but the result was not altogether satisfactory to the wood-engraver, as he sometimes found that the block had been so far saturated with aqueous liquids as to become rotten and unsound when printed from; while at other times a more or less tough film covered the wood, and the consequence was that it became very difficult—indeed, almost impracticable—to cut clean and sharp lines.

In order to produce something which shall be acceptable

to the wood-engraver, not only must the picture be made directly on the wood without the intervention of any film, and the free use of aqueous liquids must be avoided; but it must be easy to add to or take from the photographic picture. All these conditions appear to be satisfactorily fulfilled by the method of making a transfer in fatty ink by a photo-lithographic process, and then transferring this to the previously whitened block by pressure, as already described in the PHOTOGRAPHIC NEWS 1880, page 409, and 1883, page 402. Still, notwithstanding the fact that many persons are now working these fatty transfer methods with perfect success on a considerable scale, experience shows that the general photographer seldom works a bichromate method with success if he only practises it occasionally, as the behaviour of bichromated organic bodies is very dependent upon atmospheric conditions, and the influence of varying conditions is very difficult to control unless a very vigilant watch be kept on all variations.

When talking over this matter the other day with Mr. Werge—who is an old wood-engraver—some surprise was expressed that among the more or less novel methods of making photographic pictures on the wood block which are being so frequently brought forward, so little attention should be given to one of the earliest modes of procedure, and one which is completely free from the objections that have been mentioned. The method referred to is one which was suggested in our editorial columns in 1858*—over twenty-five years ago, and it consists in rubbing the face of the wood block with a pasty mixture composed of oxalate of silver and water, a trace of gum being added if required. Supposing that the block is four inches square, it is sufficient to take as much of the oxalate as will lie on a threepenny-piece; and after having sprinkled this on the surface of the wood, to rub it well in with the tip of the finger; a trace of pure water or thin gum being applied to the finger from time to time.

The amount of moisture communicated to the block during this process need not be more than is involved in the usual process of facing with white pigment, and is altogether insignificant. As soon as the coating with the oxalate has been finished, the block may be exposed at once under a reversed negative, and the prepared block may be stored away in a dark place for future use. In order to increase the sensitiveness of the oxalate, it is well to slightly fume the block with ammonia, just in the same way that albumenized paper is fumed (see present volume, page 346). If both negative and block are carefully registered into one corner of a deep printing-frame, it becomes practicable to remove the block from time to time, so as to watch the progress of the exposure.

If the engraver is to work by lamp-light, no fixing or further preparation of the block is required, as the oxalate of silver does not darken to any notable extent under these circumstances; and even if the engraver does his work by daylight it is quite practicable to cover the block with a mask of yellow paper, and just to tear this away piecemeal as the work progresses. At any rate, this is the experience of Mr. Werge, who has worked practically with the process.

Some recent experiences of our own show, however, that it is quite easy to so far de-sensitize the adherent oxalate of silver as to render it unnecessary to take any special precautions for screening the block from the light while the engraving is in progress.

On removal from the printing-frame, the block is fumed with hydrochloric acid for a few seconds, the most convenient method of doing this being to pour a little of the strong commercial acid into a flat dish, and to support the block over it—face downwards, of course—by means of a couple of glass rods, or in any way which may be convenient.

Another, and perhaps more complete mode of de-sensitizing the oxalate, is to slightly moisten a sheet of blotting-paper with a saturated solution of common salt, and to lay this paper on the face of the printed block; contact being established by a pad and weight. Ten minutes are generally sufficient, and the block need not be damped nearly so much as it would be if a drawing were made upon it with washes of India ink.

The negative required is a reversed one—that is to say, one which will give a print having the sides interchanged against each other, and a very convenient method of making such a negative is to direct the uncoated side of the plate towards the lens when the exposure is made in the camera. Of course the back of the plate must be clean, and in focussing allowance must be made for the thickness of the glass.

* PHOTOGRAPHIC NEWS, vol. i., page 193.

Press of matter compels us to allow our "Practical Paper" (No. 11, "Making Lantern Slides") to stand over until next week.

HOW TO PHOTOGRAPH MICROSCOPIC OBJECTS.

BY I. H. JENNINGS.

LESSON 7.—PRINTING.

The advice given in the introduction is here repeated: let the photo-micrographer make all his own silver prints, as in no other way can he hope for results of a satisfactory nature. The process is not difficult, and, when once mastered, the microscopist will have the pleasure of seeing his pictures *real* representations of the originals, instead of being little else than caricatures, which is often the case when the negatives are entrusted to another to print. A professional photographer may be able to produce perfect specimens of art from portrait or landscape negatives, yet fail entirely when he tries to print a photo-micrograph, simply from not understanding the nature of the object represented.

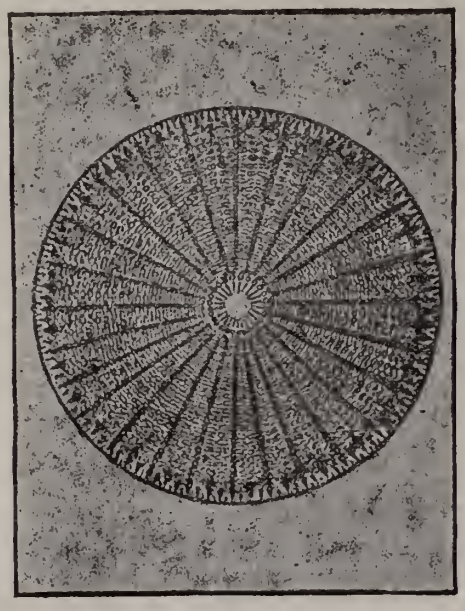
Ready-sensitized paper may now be procured of great excellence at a moderate price. The photo-micrographer should purchase the best obtainable, for the best costs at first very little more than the worst, and in the end costs really less, as there will be no defective sheets to reject, to say nothing of the superior quality of prints to be produced on good paper.

Frequently a photo-micrographic negative may require some little preparation before it is ready to print. For instance, diatoms being, as a rule, very transparent objects, require a short exposure. This exposure, though sufficient to bring out the detail in the diatom, is not long enough to give proper density to the background, which should appear white in the finished print. In this case the best plan is to "paint out" the background, at the back of the negative, with Bates' or Fallowfield's black varnish. It will be easy to follow with the brush the regular outlines of the diatom; but should any varnish trespass on the edges, don't wipe it off, but let the whole dry. When dry, hold the negative up to the light, and go round the edges of the image with a fine-pointed penknife, cutting away in an even manner any varnish that intrudes on the edge of the picture. The varnish should come exactly up to the edge of the image; there should be no intervening space, or failure will ensue. The negatives treated thus should always be printed in the shade—a powerful light would produce an objectionable black halo round the object. All objects which have regular outlines should be thus treated, if necessary.

The *Arachnoisdiscus* figured above had an exposure of fifteen minutes, with Swift's low-angle $\frac{1}{5}$-inch eye-piece and small microscope lamp. This exposure brought out the diatom sharply and with due printing density, but the background was weak, and would have printed in with a most objectionable blackness had not the plan of "painting out" been practised.

Parts which come out insufficiently dense, may be

strengthened on the film side of the negative with a soft blacklead pencil. This is best done after the negative has been varnished, using a little turpentine to roughen the part to which the pencil is to be applied.



ARACHNOIDISCUS INDICUS × 300.

Local reduction has often to be effected, and can easily be done by using the ferricyanide reducer given above. Wet the negative thoroughly; when the excess of water has drained off, dip a fine brush in the solution, and apply to the over-dense parts. As each dense place is reduced, dip the negative in water to stop the reducing action, and proceed with the next part.

It will often be found that, no matter what skill may be expended on the negative in strengthening weak parts and reducing dense ones, it is impossible to get a harmonious print. Some parts will print in strongly long before other parts are done, and no choice seems to be left but to underprint some portions, and over-print others. In this case, good prints may generally be obtained by the judicious application of cotton-wool. When the quick-printing portions are done, cover them with cotton-wool, place the printing-frame in the sun, and print in the denser parts as quickly as possible. In the finished print there should be no mark left by the wool, but all should appear as if printed in at the same time. The writer once photographed a section—transverse—of hazel, which was thicker one side than the other. As the negative showed splendid detail, he did not like to destroy it, but made use of cotton-wool, covering the weak part, corresponding to the thicker side of the section, with cotton-wool as soon as sufficiently printed, and leaving the dense part, which corresponded to the thinner side, to print further in a strong light. In the finished print there was not the slightest indication of the unequal density of the negative.

Very dense negatives should always be printed in strong sunlight; but as such negatives always give harsh prints, they should always be reduced to a proper density by the ferricyanide reducer. Some, however, are not injured by excessive density. The density that would ruin a portrait or landscape negative may pass unnoticed in a photo-micrograph, or, perhaps, be even an improvement. The chief objection to dense photo-micrographs is that they print very slowly, but in the majority of cases this will be no serious defect. The figure of a spider's head, given below, is from a very dense negative, which prints very slowly, but otherwise is satisfactory.

Thin, delicate negatives should be printed in the shade. The application of matt-varnish or tissue paper to the back of the negative will frequently improve the quality of the print. As a rule, all negatives should be printed somewhat deeper than is required in the finished picture.

HEAD AND JAWS, GARDEN SPIDER.

For toning prints on ready-sensitized paper, the borax or tungstate toning baths will be found the best. The formula for the borax bath is as follows:—

Solution of borax...	8 ounces
Solution of gold chloride ...	1 ounce

The borax solution is made by dissolving 1 ounce of borax in 80 ounces of water. For the gold solution, break a 15-grain tube of chloride of gold in a bottle, and add 15 ounces of water. Each ounce of water will contain 1 grain of chloride of gold.

For photo-micrographs which look best toned a black tint, the tungstate bath is very suitable. The formula is as follows:—

Chloride of gold	1 grain
Tungstate of soda	20 grains
Boiling water	8 ounces

To be used when cold.

Many other toning formulæ are used, but the writer has found those given above answer best the requirements of the photo-micrographer.

Before toning, the prints must be washed, either in running water or in several changes of water, to remove all traces of free silver nitrate. A quarter of an hour's washing is not too long. The toning dish should be a large shallow dish of ebonite or porcelain, capable of holding several prints *side by side*—not over each other in layers. Place the prints in the toning bath, and gently rock the dish. They will gradually change colour, and when they become of the exact colour required, remove them to a basin of clean water.

When all are toned, and *when all the dishes and solutions used in toning are put away*, to avoid all possible contamination by the hyposulphite of soda, the prints are transferred to the fixing bath:—

Hyposulphite of soda	4 ounces
Water	20 ,,

The fixing solution should be prepared shortly before use,

and 1 drachm of liquor ammoniæ added to each pint, to neutralise the acidity of the hyposulphite. If the ammonia be not added, the prints, after fixing, frequently appear of a sickly yellow, instead of a good purple or black.

The prints should remain in the fixing-bath from ten to fifteen minutes, and the dish should be rocked all the time to prevent the prints sticking together. They are next transferred to a basin or tub, and washed for two hours in running water. After this they may be placed between sheets of clean blotting-paper. When the excess of water has been absorbed, they should be ironed between dry blotting-paper until quite dry, when a further ironing on the face and back of the print with a very hot box-iron will improve its appearance. If the photo-micrographer have a rolling-press, the ironing may be omitted.

The writer has a frame of prints treated as above, which has been exposed to damp and strong sunlight during three years in a glass-roofed hall, yet no trace of fading can be detected in any one of the prints.

Some subjects, such as diatoms, have a far more delicate and natural appearance if enamelled either with plain collodion, or with collodion and gelatine. Full details of this simple process will be found in "Enamelling and Retouching," and "Silver Printing," published by Messrs. Piper and Carter. The photo-micrographer who wishes to excel in his art will find both works simply invaluable.

Our next three or four lessons will be devoted to the consideration of "Preparing Objects specially for Photo-micrography.

NOTES FROM NEW YORK.

Mr. Henderson in New York—Experiments with Gelatine Emulsions—An Explanation of One Cause of Transparent Spots on Gelatine Plates.

On the 9th inst. the Society of Amateur Photographers had the unexpected privilege of seeing and listening to Mr. A. L. Henderson, of London, and one of your most indefatigable workers in the chemistry of photography. Unfortunately, at the time he was here, the weather was extraordinarily hot and oppressive. Notwithstanding this drawback, his appearance attracted a large audience, including several prominent dry-plate manufacturers. Many of those present had never seen a gelatine emulsion made, and to them the demonstration was specially interesting and instructive.

Mr. Henderson's remarks were confined mostly to his process of cold emulsification and precipitation with alcohol, to show that by its ease of manipulation it was well adapted for use by the amateur. He was probably surprised to find how few amateurs there were here who made their own emulsions and plates.

On a temperature at 90° F., it was difficult to get the thermometer low enough to test the temperature of some of the solutions, and a curious part of the experiment was the necessity of rearing the thermometer on ice to make the mercury fall. I doubt whether Mr. Henderson had ever had occasion to make an emulsion in such a warm atmosphere.

One gentleman suggested the idea of injecting bromine vapour into a solution of nitrate of silver. Mr. Henderson had not heard of any experiments in that line.

Another gentleman related an experiment which involved the idea of suspending metallic silver in a finely-divided state in a warm solution of gelatine, and subjecting it to the fumes of bromine, which were made to pass through the solution. The bromine converted the exterior surface of each fine particle of silver into a bromide having a centre of pure silver.

Mr. Henderson was elected an honorary member of the Society, and a vote of thanks was passed to him for his kindness in explaining his process. A statement which he made, that he had tried not less than ten thousand experiments on making emulsions, gave authority to the conclusions which he had arrived at.

Owing to the dryness of our atmosphere at certain times during the summer months, manufacturers of dry plates have experienced difficulty in thoroughly drying their plates on a large scale. Several have gone to a large expense in constructing special apparatus, by which immense volumes of dry air are passed over several hundred plates at a time, thereby drying them completely within two hours, where it formerly took twelve to fifteen hours.

Another manufacturer, after many experiments, has discovered a new cause of pinholes in gelatine plates. He took a plate freshly coated in a wet state, and exposed it in the camera; a perfect negative resulted. He then tried another plate coated with the same emulsion, and when dried exposed it in the camera. When developed, it was full of minute pinholes. He then examined the action of the gelatine film as it dried under the microscope, and to his surprise found something from the surrounding air entered the film. His theory was, that minute spores floating in the air attached to the moist film, and when in contact, combined with the acid in the film and produced a vapour, which, during the drying, dilated the gelatine, making the transparent spot. There was no solid centre to the spot like that noticed in spots produced from some foreign substance in the film. He overcame the difficulty by surcharging the atmosphere in the drying room with some poisonous gas, poisonous to the spores, but not to human life; after that no spores occurred.

The sudden collapse of the new journal, *Photography*, published at Chicago, leaves the weekly, called *The Photographic Eye*, in full sway.

The field excursion to Manck Church of the Amateur Photographers, which was to have been held on the 10th, was postponed to the 24th inst. on account of the excessively hot weather.

I am told the manufacture and consumption of dry plates in this country has now reached enormous proportions.

New York, Sept. 17. The Amateur Photographer.

THE POTASH DEVELOPER.

BY FRANCIS COBB.

As I know you like to collate experiences, I send you mine. The first thing that struck me was, that the component salts were to be "chemically pure." I went to a well-known pharmaceutical compiler of mixtures, and said, "Can you supply me with some carbonate of potash?" "Certainly." "I want that," said I, putting the symbols before him—$K_2.CO_3$ "Oh, ah! if you require that, you had better go to ——," naming another chemist.

I went to ——'s, and the same preliminary was gone through; the production of the symbols raised the price of the carbonate just three hundred per cent., so that by the time I had collected my pure chemicals the developer looked rather an expensive one. The results of developing with the potash pleased me very much, and with proper exposures three—if not four—plates can be developed, the developer keeping clear all the time. But with instantaneous shutter work I did not find it as useful as the old ammonia process. On one occasion, with a quarter of a second exposure, it came to a stop, and I added dose after dose of the potash without moving it. I then dropped one drop of ammonia into the developer, and it started and gave density directly.

On one occasion I found myself with a potash developer that had developed three plates, and a pyro ammonia developer that had developed one plate. I had one more plate to develop, and no fresh mixture ready, so I mixed the two old developers, and the only fault that I have with that plate is, that it is too dense. I have repeated this unscientific process since, with equally good results. The one drop of ammonia works wonders; but this one

drop is the fly in the apothecary's ointment—it is a drop too much. We want to do away with ammonia, and do without "one drop." But when I have an extra sparkle in my potash developer, I think it is due to the "one drop" of our old enemy—ammonia.

Notes.

Another picture from Messrs. David and Scolik's series forms our supplement this week. The Emperor of Austria, walking bare-headed, is distinctly recognizable.

Workers with the soda developer complain of the difficulty of obtaining constant results, and they will have frequent cause of complaint as long as they use the common washing soda crystals obtained from the chandler's shop.

Washing soda should consist of the normal carbonate, Na_2CO_3, united with ten molecules of water of crystallization; or 106 parts of the carbonate and 180 of water. That is to say, the crystals should contain 37 per cent. of carbonate; but, as a matter of fact, nearly one-third of the 37 per cent. is often sulphate of soda.

The best way is to purchase the dried pure carbonate of soda, which is sold semi-wholesale by large dealers in chemicals at from 7d. to 8d. per pound; this containing about 97 per cent. of the carbonate of soda.

The salt ordinarily sold as "carbonate" by druggists, and used occasionally for making tea dark-coloured, is a sodium-hydrogen carbonate containing $NaHCO_3$, and this compound is often called bicarbonate of soda.

A contemporary is making a very strange photographic collection. It is, gradually filling an album with the cartes of men who are well-known "prowlers," a term which is defined to mean "men who make it the occupation of their lives to insult and annoy unprotected women." Already, it would seem, the likenesses of eight well-known "prowlers" have been received with accompanying "startling revelations," and in due time it is intended to publish the entire collection grouped in a cartoon. But how about the law of libel?

An honest, simple-minded photographer of our acquaintance can't make out why Alderman Nottage, the Lord Mayor-elect, should be described as "citizen and carpenter!" He says:—"Had it been cabinet maker, I shouldn't have been surprised, because making cameras and all that would come under this heading; but 'carpenter'—no, it beats me."

Very civic, indeed, were the remarks made by the Mayor-elect at the Common Hall on Monday. Doubtless he felt himself constrained to offer incense to Gog and Magog.

These are Mr. Alderman Nottage's views. The right of the Livery Companies to their property is as indubitable as that of any private person to his. Some people take a delight in calumniating the City Guilds. Civil Service stores must be endured until a remedy is found; but, in the meantime, it would be as well to exercise *an influence* on such tradesmen as affiliate themselves to these Stores; still, civil liberty must be defended to the utmost. Foreign philosophers will ruin the City if they are allowed to interfere with the practical business men now in power.

The revolving show-case forms just now a feature in the reception-rooms and windows of photographic establishments in the States. A case with three revolving cylinders, each of which supports twenty-five cabinets, costs forty-eight dollars, this price including the spring motor; while a one-cylinder case will conveniently fill up an odd corner.

A photographic novelty is announced in the shape of a new ornament for the wedding-breakfast table. This consists of the photographs of the bride and bridegroom enclosed in a block of transparent ice, one on either side. The effect is said to be very pretty; but is not the position of the portraits rather suggestive of an undoubted coolness between the newly-married pair?

That most samples of water contain traces of alcohol has been abundantly proved; and Professor W. N. Hartley, in his recent Cantor lectures on "Fermentation," gave interesting details.

Sea water, river water, and rain water are invariably alcoholic; the water of the river Seine, for example, containing one part in a million by weight, or a gramme in a cubic meter—let us say half a teaspoonful in an ordinary street watering-cart full. Spring water is often free from alcohol, but surface soils always contain it. To sum up, alcohol is a nearly constant product of the natural disintegration of organic matters.

As a test for the presence of alcohol in the distillate of any substance, Professor Hartley recommends the addition of iodine, and then sufficient caustic potash to destroy the dark colour. On gently heating the liquid, yellow shining crystals of iodoform are deposited if alcohol was present, these being easily identified by microscopic examination.

A new field is proposed for the operations of the "instantaneous photographer"—viz, the interior of a fashionable Turkish bath during the height of the season. A scene depicting the shampooing of famous statesmen, well-known dramatists, popular authors, aristocratic actors, and social celebrities, &c., would certainly be a very amusing one. Even the most severely solemn of our judges would find it difficult to appear in such a picture with dignity, and devoted adherents of Episcopism have been known to entertain altered views of the Apostolic succession of bishops after meeting a Right Reverend Father of the Church in a Hummums.

The Prince of Wales was photographed nine times last week, the greater part of the negatives having been taken in connection with the deer stalking operation in which H.R.H. engaged. Copies of all these likenesses—and, in fact, of all that are taken from time to time of any member of the Royal Family—are sent to her Majesty, one of whose personal attendants has the custody and arrangement of all such photographs. This duty, as may be imagined, is no sinecure. The accumulation of cartes, cabinets &c., is enormous; and the albums in which they are arranged form quite a library of themselves. A new album has lately been added to the list: it is to be devoted to the portraits of her Majesty's great grandchildren.

The Liverpool Amateur Association institutes a competition for the best series of six photographs taken by a non-professional photographer within a radius of ten miles of Liverpool; but instead of giving a mere certificate of honour as a prize, they offer two of their presentation prints, framed and glazed—an excellent idea, as few persons know what to do with a certificate of honour, while anyone can find wall space for a good photograph already framed.

Tannic acid, gallic acid, and pyrogallic acid may, according to Nasse, be distinguished from most analogous substances by the fact that they give a transient purple colouration with iodine in an aqueous solution.

The faint hope of picking up a long-lost treasure is doubtless the motive which actuates many a lounger in the auctionr-room. Few, however, can hope to get what Mr. T. C. Robinson says he got for a few shillings at the sale of the Fountaine collection—nothing less than an original drawing by Michel Angelo.

Mr. J. Glaisher, F.R.S., when presiding at the half-yearly meeting of Harrow District Gas Company on Wednesday last, told the shareholders that even in the United States, where gas costs from eight to ten shillings per thousand feet, it can hold its own against the electric light.

"Each letter I receive is accompanied by some four or five photographs, and these really give me far more information than the letters themselves."

This remark was made by a friend of ours who possesses an orange plantation far distant from his present abode; indeed, as far as the New World is from the Old. Still, with the eye of the camera he can see across a gap of several thousand miles, but he sees things as they were about a fortnight previously.

Who knows but what the time may come when it may be practicable to send a photographic representation by cable, a feat which, at the present state of science, is just possible, but certainly very, very far from practicable, owing to the enormous cost of the requisite apparatus, and the extreme slowness with which the transmission could be effected.

Hitherto photographs of the heavenly bodies have been held to be superior to drawings by hand. Professor Langley, however, in his interesting paper in last month's *Century* entitled "The New Astronomy," contends that in one instance at least photography fails. This is in regard to sun spots. The method adopted at Alleghany Observatory is to project the image of the sun through the 13-inch equitorial on to a sheet of paper, and increase the size of the disc by the use of various lenses. The outlines having been traced, a polarising eye-piece is fitted to the telescope, and the surface of the sun examined with the eye for the details of the spots which are drawn within the outlines already traced. Professor Langley says a photograph would give simply a black umbral space within the outline; the details being lost.

If the Society of Amateur Photographers of New York does not foster and develop the true spirit of photographic research in the United States, we shall be surprised. Experimental photography in America has up to now been much hampered by patents; and as the tendency of those reading papers before the societies has been to try how little information they could give, and how much they could learn, one cannot help feeling gratified at the success of a Society in which this business element is altogether absent.

An excellent rule of the Amateur Association is, that any office-bearer or committee-man who shall neglect his post for three months is *de facto* un-officered.

A correspondent who has been attending the meeting of the American Association at Philadelphia tells us that the most interesting matter in connection with photography brought out at the meeting had reference to Mr. Muybridge's pictures. Mr. Muybridge demonstrated the working of his apparatus in the Philadelphian Zoological Gardens, various animals being caused to walk or run (and, in the case of birds, to fly) before the battery of cameras. Our correspondent declines to express any opinion as to whether the exposures were "dummy" ones; but anyhow, the shutters were fired off, and whether or no there were any plates in the cameras is a matter for Mr. Muybridge alone. We are glad to learn that by the use of gelatine plates much finer results have been attained than the silhouettes of galloping horses now so well known. The full details of the figure, even in the shades, are given in the latest negatives obtained.

The same correspondent remarks that, as far as he can ascertain, just 38·5 per cent. of the members of the British Association took cameras with them to Montreal. Outside of Hampstead Heath on a Bank Holiday he never saw so many cameras in the field at once, but he hints that some of these enthusiastic amateurs did not quite seem to have proper control over the legs of the tripod; but this insinuation of his we attribute to ill-nature and spite, as we know he did not take his own apparatus.

In a postscript, our correspondent adds that he does not

mean to include Mr. York in his list of those who got mixed up uncomfortably with their tripods. To see the deft way in which that worthy gentleman leapt from the train during a momentary stoppage, and secured his first view of Niagara, should have taught a lesson to the rest of the company.

12,855 William Watts, 41, John Dalton Street, Manchester, for "Improvements in camera tripods or supports."—Dated 27th September, 1884.

Patent Sealed.

8643. Benjamin Joseph Edwards, 6, The Grove, Hackney, Middlesex, Photographer, for "Improved apparatus for coating photographic plates or paper with gelatine emulsion." Dated 5th June, 1884.

Specification Published during the Week.

10,950. Alexander Henry Reed, of 90, Cannon Street, in the City of London, for "Certain improvements in photographic cameras."—Dated 5th August, 1884. (*Complete Specification.*) This invention has already been described and figured in the Photographic News, present volume, page 460.

THE USE OF THE ROYAL ARMS.

On Tuesday last, the 30th ultimo, Messrs. A. and G. Taylor, photographers, of Regent Street and elsewhere, were summoned at the Great Marlborough Police Court for using the Royal Arms without authority. The summons was taken out by Mr. W. Turner, photographer, of 140, Upper Kennington Lane, and the case was based upon the 106th section of the new Patent Act, which came into force at the beginning of the present year. The clause in question makes it penal to use the Royal Arms for business purposes without authority from a member of the Royal Family or a Government Department.

Mr. Bateson, solicitor, who opened the case against Messrs. Taylor, read a letter which he had received from the Lord Chamberlain's Office, in which it was stated that Messrs. Taylor held no warrant of appointment as photographers to the Queen, but on reference to the Act it was not found that a warrant of appointment was mentioned as being necessary; and Mr. St. John Wontner, who appeared for Messrs. Taylor, contended that even if the letter from the Lord Chamberlain's Office could be regarded as evidence, it would have no bearing on the case; he also contended that his clients actually had authority to act as they had done, this authority being virtually given by repeated commissions executed for the Royal Family, and in virtue of orders given by the various members individually, one of the partners in the firm being an old retainer on the Balmoral Estate.

The only evidence called by the prosecution was that of W. Simkins, who had been for a short time in the employment of Messrs. Taylor as a traveller. The witness stated that he had circulated prospectuses for the defendants which bore the Royal Arms, and that the defendants displayed the Royal Arms in front of their premises. Mr. Wontner handed the witness a cabinet card issued by Messrs. Taylor, and asked him to state whether the Royal Arms were printed on the back, and he immediately answered in the affirmative. The magistrate, however, could not detect the Arms in question, as it appeared to him that the only device on the card consisted of a crown and coronet; and he expressed himself as by no means satisfied that the witness possessed a sufficient knowledge of heraldry to make his evidence valuable.

No more witnesses were called, and the magistrate, in commenting on the difficulty of proving that the defendants possessed no such authority as was required by the 106th clause in the new Patent Act, pointed out that the plaintiff's case could only be thoroughly made out by putting in evidence to the effect that no authority had been given by any member of the Royal Family, or any Government Department, a course altogether impracticable; he consequently felt inclined to rule that the burden of proof should rest upon the defendants.

Mr. Wontner argued against this, it being contrary to usage to throw the burden of proof upon the defendants in a penal case; notwithstanding this, he would have no difficulty in proving that his client acted under sufficient authority. He also again remarked that even under the new Act he did not see that a written warrant of appointment was by any means necessary.

The case was then adjourned until Tuesday, the 7th instant, it being understood that evidence would be given on behalf of the prosecution by someone from the Lord Chamberlain's Office, and by heraldic experts, after which Messrs. Taylor would be able to call their witnesses.

MY STUDIO.

How I Let It and How I was Let In.

He was a pale-faced sickly little man, certainly not more than four feet in height. She—from the little difference apparent in their ages, she might either have been his wife or his mother—was a shade taller, say four feet one inch. Both were shabby, decidedly shabby, and yet had the appearance of having on their Sunday clothes. They came into the room in an apologetic kind of way, and when I asked them to be seated, sat down gratefully and humbly.

"You have advertised a studio, I think," said the small man, in the meekest of voices.

Yes, I had. I had also advertised apparatus, for which I wanted £35. By their looks the—well, I will call them the Midgets—did not appear to have thirty-five pence.

"I am afraid the place will not suit you," said I, benevolently. "It needs capital to enable you to wait while you are forming your connection. Then— "

"Oh, I shouldn't think of depending on the portrait business," said the male Midget.

"Oh, dear no. You see, sir, he"—the female Midget always spoke of the male in the third person—"he's a photographic printer."

"Yes, I print for the trade," chimed in the little man.

I reflected. Yes, it did make a difference. I had never to my knowledge seen a photographic printer, and perhaps it was only in the nature of things that he should be attired in a suit of rusty seedy black.

"But what about the apparatus?" said I.

"Oh, we will buy that; we will give you a bill at three months," said the male.

"Yes, he will give you a bill at three months," said the female; "I have a little money coming in then."

What could be more satisfactory? They were shabby, it is true, but then millionnaires sometimes wear bad hats. Besides, how reassuring was their quiet, placid, respectful, almost timid manner. No blustering, no bumptiousness, no demanding this or that condition, no haggling over terms. Really I was in luck at last. Still, such guileless simplicity needed protecting, and I was not the one to take advantage of it.

"But," I objected, "you have not seen the studio yet."

"When," hesitated the male, "could I—"

"Yes, sir," added the female, "when could he see the place?"

I named a day, made an appointment, and, after many apologies for taking up my time, the Midgets withdrew.

Never were two people more delighted with anything than were the Midgets over the studio.

"Oh, ve-ry nice," said the small man to every remark of mine pointing out the best qualities of the place.

"It's in capital order; had it repainted, you see."

"Oh, ve-ry nice."

"Roof overhauled and well puttied."

"Oh, ve-ry nice."

"Pretty well a new floor laid down where the planks were rotten."

"Ve-ry nice indeed."

"Fine large garden."

"Yes, I wanted a large garden. I print for the trade, you know"—in a dreamy voice, as though conning a lesson.

They took the studio at once, and not only at once, but for three years. I had references? Certainly. I did not see the referees personally, as a prudent landlord should have done, but then I had such faith in the Midgets.

They were to pay their rent monthly, and, sure enough, at the end of the first month came a letter. "Exemplary tenants!" I murmured; "they have sent a cheque," I was about to say, but it wasn't a cheque. It was a note apologizing for not sending the rent, as they had not been able to commence business owing to workmen being in the place; but next month they would pay up the arrear.

I was not quite so comfortable, still there was reason in the excuse. I would wait till the next month.

Before the time arrived, a visitor called upon me. He was a British working man. The working man, as generally drawn, is a broad-shouldered individual in a corduroy jacket. He has a square face, a bushy fringe of whiskers, and curly hair. If artists had detective cameras and photographed the working man as he is, they would draw him undersized, with not much hair on his face, and wearing anything but corduroy. My working man was a specimen of this type.

He came in softly, shut the door mysteriously, and, in a whisper which curdled my blood, said: "Wot sort o' people have you got in your place at ——, Guv'nor?"

"What sort of people? Very decent people, of course. They're not much to look at ("They ain't that!" ejaculated the W. M.), but I believe they're thoroughly respectable."

I really felt quite indignant that any doubt should be cast upon the respectability of the Midgets, and was quite prepared to be their champion.

"Well, all I know is that I've been doing ten or twelve pounds' worth o' work for 'em, and can't get a smell o' their money. Why, they can't even pay the deposit for the gas meter, and the Company won't put the gas on."

This looked bad. Still, I clung desperately to the Midgets' respectability. There was something in their very smallness which was reassuring. Two such diminutive people could not possibly be swindlers.

I argued in their favour with the W. M., and sent him away sad, but slightly comforted.

"I will go and see the Midgets, nevertheless," I thought.

I went. The studio door was open, and I saw the male Midget reclining peacefully in the posing chair. He had on a dirty red cap of the fez pattern, and he looked sicklier than ever.

I put on a business-like air.

"Well, Mr. Midget, what about this rent coming due?"

"Oh, you shall be paid," said he, placidly.

"It looks bad, you know, not to be able to pay your first month's rent."

"Oh yes, it does look very bad," more placidly than ever.

What could be said to a man who owned his transgressions so readily? I could say nothing, and left—but not before I had peeped into his dwelling rooms. His *menage* was not inspiriting. Ten shillings at the very outside would have purchased the whole of his furniture, and I had let this microscopic mortal my studio and house for three years! No, I was not comfortable.

I was visited again by the W. M. "Guv'nor," said he, I dunno what to make o' that little lot. They're in debt all over the place. They've got credit out of a neighbour o' mine to two pounds. It's my belief they ain't got a penny to bless theirselves with. I don't say as he don't do no work, for he's always a begging my men to give him a morsel o' paint or a bit o' wood, and then he tinkers away at it; but what he does with it I don't know. I never come near sich a queer card."

I could not comfort the W. M. this time; I wanted comforting myself. The second month expired, but no cheque arrived. Again I visited the studio, and found Mr. Midget in the garden contemplating a solitary quarter-plate printing-frame.

"Well, Mr. Midget, I have not received the two months' rent as you promised. This won't do, you know."

"Oh, no," said he, more placidly than before; "it will never do. But I got an order last night, and I'm executing it"—pointing complacently to the quarter-plate printing-frame.

"Good Heavens! do you mean to tell me you are going to pay me eight pounds on the proceeds of the order?"

"Oh, I expect to get other orders. You shall be paid every farthing!" and he gazed plaintively at the chimney-pots on the house next door. I confess I lost patience then.

"Mr. Midget, if you are not a swindler, you are behaving in a manner to make me believe you are one. You call yourself a photographic printer: where is the evidence of it? Where are your printing-frames?

He was quite undisturbed.

"That is one," he remarked.

"One!" I repeated, with all the emphasis which could be placed on the word. "But if you print for the trade, you ought to have not one printing-frame, but a hundred."

"Oh, yes," said Mrs. Midget, coming up at this moment; "so he had, but he lent them to a friend."

Lent them to a friend! Lent his stock-in-trade, by which he hoped to gain his livelihood and pay his rent, to a friend! Did anyone ever hear of such self-sacrifice?

"Mr. Midget," said I, sternly, "I don't believe you. To-day is Friday: if you have not the two months' rent ready by Monday, I must put the brokers in." And with that I left him still contemplating the quarter-plate frame, perfectly undisturbed.

But it is one thing to put the brokers into a house, and another to get out a tenant to whom you have granted a three years' agreement. On reflection it occurred to me, in view of the "sticks" which Mr. Midget called his furniture, that I should get no further by putting in a broker. Had the apparatus been the tenant's the case would have been altered; but it was mine, and I couldn't seize my own property, which, by the way, he could still use, for hadn't I sold it to him for a three months' bill, and there was a month yet to run?

In a word, I was "cornered," and I went and consulted the W. M., whom I found anxiously curious as to how I had got on.

"Well," said he, "we're in a pretty mess, you with your rent, and me with my £12 worth of work. I don't see no good in putting in the brokers. I tell you what, though," he added, suddenly, "we might go and see my solicitor. He's a reglar sharp 'un, he is. I'd sooner take his opinion than a whole bench of judges. Why, he's the man who seized a tramcar on a writ of eligeit; seized her as she was running, sir."

I was overcome with this example of sharpness, and, being heartily sick of the affair, clutched at the straw. My reviving spirits were dashed somewhat when the W. M. proceeded to say that his solicitor had been "struck off the rolls," and that we should most likely find him in the public-house; but I hoped for the best.

The W. M.'s prognostigatiou was correct. We did find the solicitor in the public-house, and after a "refresher" in the shape of a pint of stout-and-bitter, the legal luminary proceeded to lay down the law. I am bound to say he took rather a gloomy view of the case when I had explained it to him, and was inclined to the opinion that Mr. Midget was "one of that class of swindlers, sir, who take houses with nothing worth seizing, and you have to pay them to go out. I can see this man's game, sir—he wants £5 to go."

This was pleasant, and the worst of it was, it seemed to describe accurately the state of affairs.

All at once a bright idea seized me.

"Look here; why shouldn't I proceed against this man for obtaining these premises under false pretences? He represented to me that he printed for the trade, and in the faith of that representation I let him the house. Now he doesn't print for the trade; at least, there's no evidence of it."

"That's a good notion," said the solicitor, approvingly. "Shall I go with you—as a friend, you know—and see what this man has to say for himself?"

I accepted the offer, and we at once set out with this arrangement, that the W. M. should drop in "promiscuslike" afterwards.

Nothing seemed to astonish Mr. Midget, and he received us quite calmly. However, when I informed him that on thinking over the matter, I had come to the conclusion that he had rendered himself liable to a criminal prosecution, he was rather startled. The solicitor held his peace while I stated my views and heard what the Midgets (the mother still kept up her character of spokeswoman) had to say in reply, which wasn't much. In fact, they could say nothing. Then stepped in the solicitor, always purely in a friendly way, as he explained, and solemnly warned the Midgets what in his opinion, after thirty years of police court practice, would happen. Having thoroughly alarmed them, he cooled down and represented that I—overflowing as I was with kindness—did not wish to do anything harsh. "Have I," said he, turning to me, "your permission to make a proposition?"

"Certainly;" and as, in walking to the house, we had agreed he should make this proposition, I was quite prepared to hear it.

"Well, my proposition is this: will you, Mr. Midget, go out at once, give up possession, and cancel the agreement, if the landlord forgives you the two months' rent?"

Most people under the circumstances would, I fancy, have closed with this offer at once; but not so the Midgets. They, on the contrary, thought it was very hard, just as they had found a place which suited them, to be obliged to go. Finally, however, they accepted the proposition, but only under a threat of my at once going before a magistrate; and it was with great reluctance they produced the agreement, which I need not say I had at once destroyed.

Even to the last they kept up the deception. In the very act of delivering up the key, Mr. Midget—as though nothing had happened—said, "Perhaps I may be able to buy the apparatus in about a month's time. I suppose you would have no objection to sell it to me?"

I forbear repeating my reply. It was not an approval of the Midget's cool unblushing effrontery.

PHOTO-LITHOGRAPHY AND PHOTO-ZINCOGRAPHY.

BY MAJOR J. WATERHOUSE, B.S.C.,
Assistant Surveyor-General of India.

Chapter XVII.—Miscellaneous Processes—(*continued*).

Various methods of working with the salts of iron dependent on Poitevin's discovery of the reactions of a mixture of perchloride of iron and tartaric acid under the influence of light are applicable to photo-lithography, but beyond the fact that the effects produced by the action of light are the exact converse of those produced in the collo-chromate processes, these methods appear to have no special advantage over the latter.

Sensitive films of gelatine prepared with the perchloride of iron and tartaric acid have the property of becoming deliquescent and soluble under the action of light. Therefore, if a roller charged with greasy ink be passed over such a film after exposure to light, the ink will only take on the parts preserved from the light, and in the proportion to the extent of the protection.

The image thus produced will be of the same character as the cliché—positive from a positive, negative from a negative. If, however, instead of the image being rolled up with transfer ink, a brush charged with a very fine resinous or lithographic ink powder be passed over it, the powder will only attach itself to the parts affected by the light, producing an image the reverse of the cliché, and capable of being transferred to stone or zinc.

The sensitive paper for the transfer process above noted may be prepared by immersing slightly gelatinized paper in a solution of

Perchloride of iron	10 parts
Tartaric acid	3 ,,
Water	100 part

and allowing it to dry.

Liebert, *Photographie en Amerique*, gives the following method, which is equally applicable to stone. Thick glasses finely ground on one side are thoroughly cleaned, then covered with a coating of gelatine at ten or fifteen per cent. of water, and dried in a warm chamber free from dust. The day before the plates are required, they are sensitized by immersing them for one or two minutes in a bath of

Water	100 parts
Perchloride of iron	3 ,,
Tartaric acid	1 ,,

They are then left to dry in the dark. The exposure to light is made under a positive on glass or transparent paper. After exposure the glasses must be well soaked in water to remove all the iron salts. They are then rolled in with printing ink, which takes only on the parts that have been protected from light and have retained their insolubility.

This process has the advantage that the underlying coat of gelatine in contact with the stone or glass, instead of being soluble, and therefore liable to be removed by the washing and wear and tear of printing, is insoluble, and no sunning at the back or preliminary coatings are required.

In 1878 M. Poiteven published another mode of working, dependent on a discovery he had made that gelatine rendered insoluble by perchloride of iron and tartaric acid became soluble again by treatment with dilute acids, and thus he was able to obtain positive prints in fatty ink from negatives, and such prints could be transferred to stone or metal to be printed or engraved.

His method of proceeding is as follows:—Paper coated on one side only with gelatine, lightly coloured to enable the operations to be better followed, is sensitized by floating both sides successively, or plunging it for some minutes into a bath of

Perchloride of iron...	10 parts
Tartaric acid	3 ,,
Water	100 ,,

and letting it dry in the dark. When dry it is exposed for some minutes in the sun under a negative. The exposed surface is then treated with warm water, which dissolves all the parts that have been acted on by light, and thus a negative print of the drawing is obtained, the transparent parts of the negative being formed by the white paper laid bare

After a sufficient washing, the sheet is left to dry, and then covered all over with fatty ink by means of a roller or pad, or better, in the press. The inked print is next plunged into water slightly acidulated with hydrochloric acid, and then into warm water, which dissolves the gelatine and takes with it the coating of greasy ink, while the ink in contact with the paper remains and forms a positive print in greasy ink, which can be transferred to stone or zinc in the usual way.

Dr. Liesegang has suggested the use of Pelouze's salt for making what may be called negative transfers, the fatty ink taking on the parts protected from the light, instead of on those exposed to the light as usual. He made a solution of bichromate of potash in hydrochloric acid, and floated albumenized paper upon it (albumenized side up-

wards) until the albumenized film became of a uniform yellow colour. The paper so prepared was not more sensitive than that prepared with biehromate of ammonia, but upon treating the exposed inked print with warm water, to remove the ink from the non-exposed parts, a negative image was obtained.

Dr. Eder has lately published the fact that a solution of ferrid-cyanide of potassium renders gelatine insoluble, the solubility being restored under the influence of light in the same manner as when treated with perchloride of iron and tartaric acid. Investigation would probably result in the discovery of similar reactions with other salts of iron, which might be turned to useful account in these processes.

AN EASY METHOD OF COLOURING CARBON TRANSPARENCIES AND PHOTOGRAPHIC CARDS.

BY E. EDWARDS.

The method which I am about to describe requires very little practice to become proficient in it, and can be used by anybody. The colours which are used in this method are excellent for colouring photographs, and also for canvasine painting, an account of which was given in No. 1358 (September 12th, p. 578) of this journal; it will, therefore, be unnecessary to give the details of canvasine as the only difference in the working is, that the print must be coloured before the canvas effect is fixed.

The first thing to be done is to prepare the paints. Get from any wholesale chemist a small quantity of different aniline colours or dyes, and dissolve them separately in spirits of wine, gradually adding the spirit until all is dissolved; dilute by about its own bulk of water, and add ox-gall until the colours flow smoothly from a camel-hair brush over glazed paper; when this has been attained, the colours are ready for use, and the painting may be commenced. It is advisable for the beginner to commence with a portion of the transparency which has the smallest surface of the same colour, as it requires a little practice to lay on an even coat on a large surface, such as the sky or sea. If the colour is piled on by degrees with dilute colour, it renders the laying on of a smoother coat much easier. It is as well to give the transparency a coat of varnish when the colouring is completed and quite dry. For colouring cards the colours should be laid on very dilute (especially the flesh colour), and should be laid on in successive washes until the desired colour has been attained. The colours most useful are—lemon-yellow, green, orange red, blue, violet.

For flesh colour—lemon-yellow and red.

For different shades of green—lemon-yellow and blue.

For lilac and purple—violet and red.

For jewellery and fair hair—orange.

The commonest water-colour brushes give as good an effect as the most expensive ones.

Correspondence.

FELLOWS OF THE ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

Dear Sir,—Excellent as is Mr. Emerson's suggestion that there should be some "distinction between ordinary members and masters in the art of photography," I beg to state that he is mistaken in stating that anyone, by payment of a certain fee, can become a member of the above Society." If Mr. Emerson will refer to the rules of the Society he will find in Law IX.: "Every candidate for admission into the Society must be proposed by two or more members, who must sign a certificate in recommendation of him, which must set forth the name, place of residence, and qualifications of the candidate, and state that he is desirous of becoming a member of the Society; and the proposer, whose name stands first upon the certificate, must have personal knowledge of the candidate." Of course, the above quotation does seriously interfere with the proposal to cast honours on the "masters in the art of photography." In addition, I would extend the proposed title to *our masters in the science of photography*, for there is no reason why those who improve and freely present the world with new powers should not be placed in the same position as those who make use of, and benefit by, their study.—Yours truly, A Member.

EXHIBITION OF THE PHOTOGRAPHIC SOCIETY OF IRELAND.

Sir,—Permit me, through the medium of your columns, to remind those who purpose sending pictures, &c., for exhibition, and who have not already intimated their intention of so doing, that the last day for receiving will be the 31st October. The form of entry, of which I shall be happy to supply copies, should be returned to me here, and the packing case addressed to care of Royal Hibernian Academy, Abbey Street, Dublin.

I may also mention that there is no charge for space; carriage of all packages for exhibition will be defrayed by the Society, the consignee paying that on return.—Yours truly, Greenwood Pim, Hon. Sec.

Monkstown, Co. Dublin, Sept. 27. Exhibition Committee.

NITRITES IN THE DEVELOPER.

Sir,—As the use of a sulphite in the developer is apparently, from the discussions at the meetings of our various societies, advocated by some, and none the less strongly condemned by others, one of the reasons for its being held in disfavour being its instability, and especially the difficulty of neutralizing an alkaline solution thereof by sulphurous acid, unless sometimes used in large quantities, would not a nitrite be free from at least the latter objection? I have not time to make the necessary experiments myself; but the following, which I tried some little time ago, led me by its results to hope for success, and encouraged me to suggest the matter to other gentlemen with more time and opportunity at their disposal.

Nitric acid was heated with a little starch, and the evolved gas passed through a saturated solution of potassic hydrate until a neutral liquid resulted. This was evaporated nearly to dryness, and a saturated solution of the salt made in water.

A drachm of this with four grains of pyro, and the usual amount of ammonia, bromide, and water, developed plates successfully free from stain, and bright, the solution meanwhile remaining as clear as when sulphite was used.—Yours &c., W. B. Allison.

USE OF SNUFF IN THE DARK-ROOM.

Sir,—Will you permit me to suggest to those who suffer from the inhalation of ammoniacal fumes a trial of my simple and, after a while, not unpleasant remedy? When first subjected (almost constantly by day) to the fumes of ammonia, I suffered much in the head and chest with frequent and severe attacks of influenza. My antidote was a well-filled snuff-box, and a frequent use of it while in the dark-room. The benefit has been marked, and one need not contract a habit of snuff-taking if the box be kept and left in the dark-room. The habit may remain a dark-room one, and no more, as it has done with me.—Yours truly, R. S. Freeman.

Proceedings of Societies.

London and Provincial Photographic Association.

A meeting of this Society was held on Thursday, the 25th ult., Mr. A. Haddon in the chair.

At the request of the Chairman, Mr. A. L. Henderson gave an interesting account of his visit to America, mentioning many details in connection with dry-plate photography there; especially the working arraugements of some of the larger factories. In the factory of Mr. J. Inglis, a slight modification of the cold emulsification process was at work, three batches each of ten gallons being precipitated with alcohol. After coating, the plates travelled by means of a twelve-horse power steam engine into a refrigerator containing two tons of ice; thence on racks capable of holding 200 12 by 10 plates, until 4,000 were coated. The steam power was also utilized for pumping filtered air into the drying-rooms, raising an elevator, and warming the establishment. The whole batch was perfectly dry in two hours. A contrivance used in packing at this factory was then shown by Mr. Henderson. It was a wooden tray sufficiently commodious to permit cardboard packing boxes 12 by 10, or any smaller sizes, to be clamped while being filled. Two parallel bars fixed on the top sides acted as guides to a horizontal bar, which travelled to and fro over the box supporting the free ends of two balls of string, which were secured to the box; adjustable clamps being used to regulate the proper distances between the two strings. The method of separating plates by string was suggested by Mr. Harrison, of London. Mr. Henderson then described a method of glass cleaning he had seen in operation, which was quick and effective. The plates, covered with whiting, were passed between two reels of paper, revolving at a high speed. In reply to questions, Mr. Hendersou said coatiug was done by hand in all the factories he visited. The gelatines employed were similar to those used in England. Regarding the general style and quality of work shown at the Cincinnati Convention, he said that, considering the short time gelatine plates have been in use in America, the results were astonishing; some large direct studies of children shown there could not be done in this country. Whether it was the superiority of the light, or the plates, he was not prepared to say. The Americans would have clear shadows; plates giving veil would immediately be rejected. Speaking of the New York Amateur Association, he said their arrangements were excellent. A room in which he demonstrated the precipitation process was capable of seating over two hundred; attached to this was a laboratory, fitted with lockers for each member, and suitably lit for photographic work during the day or evening. He also took occasion to say, in reference to the report of his remarks at the Convention, that the word "art" had been omitted, which conveyed the idea that he was not a photographer.

Mr. J. Weston (Boston, U.S.A.) passed round a series of composition pictures, including one of a numerous assembly engaged in skating at the Ice Palace built at Montreal last February; some very good exteriors of the Palace were also shown.

Mr. W. E. Craig showed some instantaneous negatives developed according to the formulæ described on page 485 of the present volume; the quality was considered excellent.

The Chairman exhibited three plates by the ammonia-nitrate process, which were of an interesting nature. The first had been exposed wet, and developed with ammonia; the negative then presented green fog by reflected light, and red by transmitted; by accident the plate was left in the hypo fixing bath for twenty-four hours, when the green fog had changed to blue. The second plate was exposed after drying, and developed with ammonia, the shadows being deep ruby. The third plate, exposed like the second, was developed with the Monroe formula (page 477 of the present volume), and resulted in a most splendid negative. From this he (the Chairman) concluded that soda was the best alkali to use with plates having a tendency to red or green fog with ammonia.

The Chairman then announced that the monthly series of lecturettes would be continued through the winter months. "Toning" would be the subject next dealt with by Mr. W. M. Ashman, on Thursday, October 9th.

Bristol and West of England Amateur Photographic Association.

The usual monthly summer excursion of this Society took place on Friday, the 29th of August. Amongst those present were Mr. T. Davey (President), Colonel Playfair (Vice-president), and the Hon. Secretary (Mr. H. A. H. Daniel).

The locality fixed upon comprised the very romantic districts of Moorend and Glen Froom, and that portion of the latter beautiful scenery enclosed in the grounds of Mr. Vassall. On arrival at Fishponds the party found that ample accommodation had been provided for carriage, and a short drive landed them at the new country residence of Mr. Daniel. After a substantial luncheon, a start was made for work. The weather, which for many weeks had been unintermittingly fine, at once began to storm at the little party; but nothing daunted, and with the shelter afforded by focussing cloths and other impromptu devices, the old mill at Moorend was reached.

Here a long and patient halt was made, for "the wind it blew, and the leaves they shivered." At last a few shots were made despite the movement of the foliage, and a move was made for Frenchay and Glen Froom, distant about two miles. Near the entrance to Oldbury Court Park, but on the wrong side of the river, stood a very enchanting-looking cottage, and all agreed that it might make a good picture, so a formal request was made to the lady in charge that we might be permitted to carry away her house—photographically speaking—a descent being made on consent. Disappointment, however, was the result, as on trying to secure a point of vantage for fixing the cameras, it was found an impossibility to get a view without standing up to one's waistcoat in the middle of the river.

Thence to the private grounds of Mr. Vassall, than which nothing can be prettier in their way. Here, in fine weather, and with better light than favoured the party, there is ample store for a good day's work; but time was passing, and light was waning, so the word was given to march onwards. Then ensued the usual and very acceptable wind up of these and similar delightful excursions—the tea and coffee, &c. Never was a pleasanter gathering, even if the result in pictures was perhaps not quite so good as upon some previous occasions.

Liverpool Amateur Photographic Association.

The ordinary meeting of the above Association was held on Thursday, the 25th ult., at the Free Library, Mr. J. H. Day, Vice-president, in the chair.

The minutes of the June, July, and August meetings having been read and confirmed, Mr. J. Eaglesfield was elected a member of the Association.

Mr. W. H. Kirkby introduced a resolution on the subject of the July and August out-door meetings, and said that he thought it would better conduce to the welfare of the Association if these meetings were held, as usual, in the city. After some discussion, Mr. Kirkby said he would propose a new rule at the next meetiug, and the subject dropped.

The Chairman announced donations to the print collection of of the Society, by Messrs. Watts, Williams, Hartley, and Whaimby.

Mr. H. N. Atkins gave some account of his success in the production of paper enlargements, and passed round some very fine specimens of his work.

Mr. J. H. Day said he had obtained good results with Morgan's paper, and showed a print from a waxed negative, which was perfectly sharp, and could not be distinguished from an ordinary glass negative.

A Member exhibited an excellent enlargement, 16 by 12, made in this way on gelatino-bromide paper from a quarter-plate.

The Rev. H. J. Palmer read an important resolution passed at the last meeting of the Executive Committee at the Associated Soirée:—That a certificate of merit be awarded by the Soirée Executive Committee to the best series of six photographs, taken by an amateur, of subjects within a radius of ten miles from Liverpool," and urged the members of the Association to join in this useful competition. Mr. Palmer further reminded those present of the number of interesting negatives of subjects connected with the Liverpool of the past, which had been taken by members of the Society. He hoped that these would all be printed afresh, that members would produce numerous other pictures of scenes which were now fast disappearing, and thus that a really useful and valuable collection of views connected with Liverpool might be available for exhibition at the coming soirée.

Mr. J. A. Forrest remarked that one wall of the old slave market of Liverpool was still standing.

The Chairman spoke in cordial approval of the competition and of its objects, and thought that the Association should assist the project by giving a prize.

It was resolved that the Association assign two of its presentation prints, properly mounted and framed, as a first prize for the best series of six prints of Liverpool, &c., and one such print, also mounted and framed, as a second prize.

Mr. H. A. Wharmby gave notice that he should, at the next meeting, move the following addition to the rules:—Each member shall send in to the Secretary, at or before the meeting following his election, his carte portrait for insertion in the Society's album.

Mr. Green gave an interesting account of his mode of collodionizing and developing 24 by 18 plates, and remarked that negatives taken by him with his large camera at Melrose, Furness, Conway, and other places, and varnished twenty-five years ago, were now just as bright and good as ever.

Mr. Forrest exhibited three views taken at Rivington, two at Tal-y-Cefu, and one at Bidston at the last excursion; Mr. Baker, a clever instantaneous picture of "A cat in the act of springing on a bird;" Mr. Day, some very fine negatives of Carnarvon and Amlwch Coast, with prints; Mr. Wharmby, views at Sefton, Walton, and Bidston; and Messrs. Hartley, Watts, and Haworth some prints from their negatives taken at Condover, Pitchford, and Wenlock.

The meeting was then adjourned.

Talk in the Studio.

Nickel Vessels.—Prof. Dittmar has recently advocated the use of nickel vessels for use in treating solutions of caustic alkalies. In its resistance to the action of soda and potash, nickel is equal to any metal, whilst for its cheapness it surpasses silver. Mr. J. Spiller (Photographic News, vol. 15, p. 462) recommended the plating of metallic surfaces with nickel, for photographic purposes. Nickel plated copper and brass bars, immersed in a silver nitrate solution, do not reduce the metallic salt. Nickel-plated copper gauze would prove valuable for breaking up emulsion jelly; and nickelled wire corners to wet plate carriers would be much cheaper than those of silver.

A Photographic Section has been formed within the Literary Club, Blackburn, Lancashire, open to all members of the Club, many of whom revel in the dark deeds of photography. During the winter, four meetings will be held at the Club for the discussion of subjects connected with the art, at 8.30 p.m., as follows:—October 20, "Lantern Slides"; November 24, "Plate Making"; (1885) January 19, "Development"; February 23, "Intensification and Reduction, &c., of Negatives." Two entertainments will also be given in the Lecture Room to members and friends, one on the 19th December, "An Exhibition of Lantern Slides," and the other on the 17th of April next, "An Exhibition of Prints." During the summer it is proposed to have a series of monthly excursions with cameras, due notice of which will be given. The Hon. Sec. would be glad to arrange, if possible, to meet other societies in the district on some of these excursions. All communications should be addressed, The Hon. Sec., Photo. Section Literary Club, Blackburn.

Photography at the Midland Railway Works, Derby.—Mr. F. J. Austin, who writes to the *Leisure Hour*, thus describes a visit to the Photographic Department, which is under the direction of Mr. T. Scottou:—One would hardly expect to find a photographic studio amid such powerful machinery as we have been describing. And yet, not far from the gas-engine house—for the Midland Company make their own gas—there is a small building occupied by an intelligent and skilful photographer, whose duty—and evidently whose delight—it is to take the portraits of the various engines when completed, old bridges before their demolition, new bridges constructed in their place, and any other work of which the Company may require memorials. One picture shows us a train which was photographed while running at a speed of thirty miles an hour; but so instantaneous was the process that there is no mistiness about it. Every line is brought out distinctly. The apparatus used for this purpose might almost be carried in a capacious pocket, the dry plates fixed ready for use in the sliding frame being carried in another, while the stand might be used as a not unwieldy walking-stick. A five-pound note, or even less, would probably cover the whole cost. Among other work accomplished here which saves an immense amount of time and labour, is the copying of tracings and drawings in a few minutes by a process known as "Pellet's process." No camera is required; the tracing is simply laid flat upon the glass under-surface of a large frame (very similar to an ordinary photographer's frame for printing from negatives), and over this is placed a sheet of prepared paper having a bluish tint. After exposure to the light for a few minutes, the paper, which has now assumed a whitish hue, is removed, and the edges having been turned up so as to form a tray three-quarters of an inch in depth, it is floated face downwards for about half-a-minute in a solution of yellow prussiate of potash, until faint blue spots appear in the background. It is then washed in a trough of clean water to check the action of the prussiate solution. This having been repeated two or three times, the print is immersed for from five to fifteen minutes in a bath of hydrochloric acid, the surface being worked all over with a brush to start and loosen the blue mucilage which originally covered it. It is then placed once more in a tray of clean water, and brushed over to remove any mucilage that may still be adhering to it, after which the lines of the print will be seen standing out blue upon a white ground. The whole operation occupies only a few minutes, for the paper is extremely sensitive, the time of exposure (which can be determined by means of test slips) varying from half-a-minute upwards, according to the intensity of the light. The writer saw a complicated tracing of the various parts of an engine, two or three feet in length, copied by this process with such clearness that the faintest lines and minutest marks were in every respect as plainly discernible as in the original drawing.

Influence of Light on the Disengagement of Oxygen by Plants.—J. Reinke has made further experiments, and describes the means adopted by him to measure the oxygen disengaged by leaves in presence of light of varying intensity, by counting the bubbles of gas which escape from a given leaf surface of an aquatic plant in measured intervals of time. *Elodea*, having very thin leaves, is especially suitable. The light of the sun is reflected from a heliostat through a convex lens into a darkened chamber. The intensity of light to which the leaf is subjected then varies according to its position in the double cone of rays formed by the lens. Working in this way the author finds that disengagement of oxygen attains its maximum with light of normal intensity (*i.e.*, at twice the focal distance of the lens, where the diameter of the cone of rays is the same as that of the lens), that it diminishes rapidly, with intensities of $\frac{1}{4}$, $\frac{1}{8}$, $\frac{1}{16}$; but on the other hand remains almost constant when the intensity is 2, 4, and 8 times the normal. The author has adopted his method of counting the number of bubbles of gas escaping from a given leaf surface of an aquatic plant (*Elodea*) in a given time to the study of the influence of light of different colours on the disengagement of oxygen by plants. The same apparatus was employed as that previously described with the interposition of a prism of known dispersive power adjusted for the minimum angle of deviation, in the path of the conical beam. The spectrum was received on a screen, composed of two vertical plates of wood, adjustable at any distance from each other. The band of coloured light passing between the wooden uprights was concentrated on the leaf by a lens, the distance between the uprights being so adjusted for each colour as to obtain an equal luminous concentration (*i.e.*, an equal number of wave-lengths) in all cases. The maximum disengagement of oxygen corresponds with the maximum absorption of chlorophyll, and is situated in the red, not far from the line B; the curve descends rapidly towards the ultra-red, more slowly towards the ultra-violet; but, contrary to the experiments of Engelmann, there is no augmentation in the disengagement of oxygen corresponding with the absorption-band, commencing between the lines *b* and F, and extending over the whole of the right side of the spectrum.—*Journal of the Chemical Society.*

The Photographer to the Greely Expedition.—The diary of Sergt. Rice (the photographer of the Greely Expedition, who died before the rescue) abounds in evidence of the attempt of the members of the Greely party to enliven each other's spirits during the long periods of desolation at Fort Conger. To judge from his notes and suggestions, Sergt. Rice was himself no small contributor to the general amusement. They had a paper which they printed on the polygraph, called *The Arctic Moon*, and some articles intended for it are found in the diary; the following being one of these:—"*A word to photographers.*—Suppose the photographing of a baby, who has been given to a couple whose motto for years has been 'hope.' Describe said babe a beautiful, innocent, dew-eyed darling—the preparation of the baby for the photographer's manipulation. The babe is gorged by the mother as the Bedouin would a camel before starting on a desert journey, so that it would be quiet and content. Results in babe's indigestion. Then the attending troop of relatives. The photographer must await the arrival of someone who is said to charm the babe. Baby gets tired, but must be photograped smiling. He must vouchsafe a smile of benevolence, while in

heart he desires to out-Herod Herod. The next subject is the beauty—or the faded beauty—who is, as are also her friends, dissatisfied with the photograph of her in the sere and yellow. Or the young old lady who resembles Mary Anderson or Adelaide Neilson. Or the ignorant lady who will not tolerate a shadow under her chin. Or the General with the battle scar, which his patriotic wife worships. Suggestions from carte-de-visite. The social equality of the arrangement of photographs in a shop-window—Henry Ward Beecher cheek by jowl with Pat Rooney. It is easy to recognise a photographer (unless he makes all his pictures by chance) by the manner in which the subject is posed, and the arrangement of the light. A photographer has negatives in number equal to the population of a country town. Quote the criticism on Walter North's garden scene. The sense of beauty and best momentary pose of the body is a gift that cannot be picked up as a mechanical art can be—instance among difficult subjects the fat woman—'like heavenly pastures, large and fair.' The trial of the jail photographers, the 'Bashful Sitter.' Custom-house officers who want to see the dry-plate.—*Photographer's Bureau.*

The Precious Metals in Mexico.—The greater portion of the gold and silver mines that are now in action were worked at the time of the Spanish conquest. While the country was under Spanish rule, that is to say from 1537 to 1821, the mines produced gold to the amount of £13,753,682, and silver to the amount of £117,253,940. Since that period, and up to 1880, the mines produced gold to the amount of £180,131,662. The total value of the gold and silver produced between 1537 and 1880 is £621,022,042, the average annual production being to the value of £1,812,000. Compared with this, California, Nevada, Colorado, Utah, Dakota, Montana, Idaho, Oregon, Washington, New Mexico, and Arizona, have produced the precious metals from 1848 to 1882, of a total average value of £13,560,000; and a large portion of this was obtained from territory which formerly belonged to Mexico. It has been found necessary to abandon mines, even when yielding more than nine troy pounds of silver to the ton of ore, on account of the difficulty of transport and want of labour; but with systematic mining and economical methods of reducing the metal, added to the necessary capital and improved means of communication, Mexico would regain the foremost position among countries producing the precious metals which she held up to 1848. The completion of the central railway, which traverses the state of Chihuahua, will contribute towards bringing about this result. It has often been said that there is no coal in Mexico, and that this want will prove an obstacle to the development of the natural resources. This, however, is not the case, as the Government has published an official list of localities where coal deposits exist. Petroleum is also found in large quantities.—*Journal of the Society of Arts.*

Photographic Club.—At the next meeting the subject for discussion will be on "Artificial Lighting."

To Correspondents.

*** We cannot undertake to return rejected communications.

Ebbw Vale.—It is quite possible that the paper you used may have been rather strongly sized, and the size would naturally prevent the thorough and uniform penetration of the fatty matter. Try the effect of soaking the prints in hot water and drying them, before treating them.

H.—Messrs. Burgoyne and Co., wholesale Druggists, of Coleman Street, City, keep it in stock.

John Smith.—Your experience is of considerable interest as confirming the experience of many others, as to the advantages resulting from the use of the potash developer.

T. S. (Derby).—Thank you.

G. A. Oldham.—We are strongly inclined to think that they arise from some deleterious ingredient in the mount. Cut a print into several pieces, and mount these on the various samples of card you may have in stock, and keep all under the same conditions. The results will probably speak for themselves.

W. G. H.—We hardly think they could be made for a few pence, unless many thousands of precisely the same pattern were required. Still you may be able to introduce them successfully into the market. Provisional protection for a year can now be had at a cost of a trifle over £1, if you will fill up the form yourself, and do not require the assistance of a patent agent. The form can be obtained through any post office. In your specification you must clearly state the novel points of your invention.

R. Percy.—1. Not many days, and in hot weather, perhaps not one day. 2. Very shortly.

Carmina.—The best thing you can do is to use the so-called encaustic paste, made by melting one ounce of white wax cut into shreds in five ounces of oil of turpentine, a gentle heat being required to effect a solution. Apply a trace of this to the surface of the print with a piece of flannel.

J. S.—Print the title from ordinary type on thin paper which has been previously coated with starch paste and dried, and then, after very slightly damping, transfer by pressure to the varnished side of the negative. The paper is now thoroughly wetted and stripped off, leaving the printing-ink behind. Dust the impression with powdered red lead to make it opaque. Full details will be found on page 517 of our volume for 1883.

Pogator.—They are quite sufficient, and of the three we should prefer Captain Abney's book. 2. Quite so, but nothing more modern in any way surpasses it. 3. Through a foreign bookseller, as, for example, Trübner, of Lugate Hill.

R. D. Barret.—You will not find it easy to deal with the actual manufacturers of the brass rims unless you require a large quantity. We believe that most of them are made in France. You had therefore better obtain through the ordinary trade channels.

F. Francis.—If you buy your carbonate at the price you mention, it will cost you more to restore the old developer than the whole thing is worth. Ask for "pearl-ash" at the oilshop; it should cost sixpence per pound.

H. C.—Unequal hardness of the paper is the cause; otherwise the quality appears to be good.

Mechanic.—That which you require can be had from Messrs. Sprague and Co., Lithographers, Martin's Lane, Cannon Street, London.

Thio.—1. A portrait combination having an equivalent focus of twelve inches will do well for both. Possibly you may have to put a block or distance piece on the front of the camera for a lens of this focal length. It will cost something over twenty pounds if you go to a first-class maker. 2. You probably had sixpenny bottles of Judson's aniline dyes, and there will be no difficulty in obtaining these. At any rate, the aniline dyes will answer your purpose very well indeed.

Lux.—1. You must place a shade over your sitter, so as to do away with the whitish glare on the front hair. 2. It is difficult to understand your difficulty, as it dissolves in twice its weight of water. Just run over the matter again, and see if you have not made some mistake.

C. W. W.—Mr. Cowan tells us that is not so.

C. Weston.—Float letter paper on a solution made by dissolving 1 drachm of red prussiate of potash and 1 drachm of ammonia citrate of iron in 1 ounce of water. When dry, expose under the tracing, and fix by mere washing in water.

THE PALL MALL EXHIBITION.

PICTURES AND APPARATUS.

THE opening soirée of the Exhibition may now be looked upon as a meeting-place for those interested in photography, and on this occasion the principal London and country photographers have an opportunity of exchanging a few hasty greetings with each other; in fact, one may say that, on the opening night, most of those present are rather looking after their friends or acquaintance than critically examining the pictures. To say that the room was crowded scarcely expresses the whole truth, as about nine o'clock so compact was the mass of visitors that the direct journeying from one end of the room to the other became a labour only to be attempted occasionally. About half-past nine locomotion became easier, and soon after this the Lord Mayor-elect, with his lady, visited the Gallery.

As regards the pictures, the general expression was one of satisfaction, although here and again one came across someone who felt sure that the show would not bear comparison with that of last year. All, however, seemed agreed that there was a remarkable absence of decidedly bad photographs; while there seemed to be a general notion that the very exceptionally good was also notable by its absence. The above views of the case are by no means in contradiction with the opinion we have formed, namely, that the Exhibition, as a whole, is above the average.

Complaints regarding the hanging committee or the judges were few, and by no means bitter: but now and again some exhibitor who had been skied condoled with one who had been abased to the lowest level; but even then it was generally allowed that in the case of all the other pictures the Committee had exercised good judgment. The disappointed exhibitor who knew that he ought to have received a medal, generally refused to be comforted by anything less than a patient listening to his views as to the partiality and blindness of the adjudicators.

It is said that a goodly portion of pictures were rejected this year, and perhaps to this circumstance we may attribute the paucity—indeed, may we say, absence—of bad photographs this year. "I would have been content and proud had they admitted but one of my frames," remarked a meek-faced little man who had vainly looked round the walls three times in the hope of finding his pictures, when a medallist comforted him by pointing out that even one out of his three frames had been rejected.

The work of Mr. Tagliaferro has been most fully honoured by the judges, for not only have they awarded him a medal for his series of four pictures, representing the interior of the Cathedral at Malta (No. 234), but they have also given a similar award to the Autotype Company for a pair of excellent enlargements, one of these enlargements (No. 217) being from Mr. Tagliaferro's prize negative, and the other (No. 135) from a negative by Mr. Sinclair.

The medal picture of Mr. Tagliaferro certainly is far more effective and striking when looked at in the shape of an enlargement than when the original (10 by 8) is viewed. The Cathedral Church of St John, at Malta, is one of exceptional beauty and grandeur, but is a little out of the usual run of the British tourist. Erected by the knights of Malta when they were in the height of their power, a trifle over three hundred years ago, the decoration and elaboration of the church was their constant care until their overthrow two hundred years later; and its magnificent frescoes, mosaics, and carved work are, like those at St. Mark's, in Venice, the result of a requisition made over the whole of the civilised world. The view of the high altar which is the subject of the enlargement is taken with the camera sufficiently out of the axial line of the church to destroy the painfully symmetrical effect which is an almost certain consequence of taking such a subject directly in face. It will be noticed that the vertical lines of the subject are a trifle out of the perpendicular in the photograph, and it is surprising to notice how many photographers are faulty in this respect—the result of haste and carelessness in adjusting the camera. Three other general views of the interior of the cathedral accompany the medal picture; one of these showing the high altar from a more distant point of view, so as to include some of the massive piers which form a main support of the structure, while the remaining photographs show two out of the twelve aisle chapels. In Mr. Tagliaferro's splendid pictures one can find none of those heavy detailless blanks and extended chalky lights which mar so many interiors; but so evenly detailed and perfectly gradated are the photographs, that one needs but the effect of colour to thoroughly realise the beauty of the frescoes on the ceiling, the arabesques, leaves, flowers, &c., which are sculptured on the walls from floor to ceiling, together with the precious stones and gilded metal work which decorate the marble of which the high altar is built Another frame exhibited by Mr. Tagliaferro shows four of the monuments erected to the memory of the most distinguished knights, that erected in honour of the Grand Master, Emanuel Pinto, being the most striking; while in a third frame we find that Mr. Tagliaferro has used his camera successfully to depict indoor life in Malta.

Mr. H. P. Robinson receives a medal for his "Mill Door" (No. 67), in which a bag of meal is being loaded on donkey-back, and among those who are ardently interested in watching this and other operations incident to the business of the mill one finds the main interest of the picture. The subject is a simple one, but it is invested with that charm and feeling which Mr. Robinson so well knows how

to infuse into his productions. Still, it rather surprises us that the judges did not prefer to award the medal to "He never told his love," a composition into which the artist-photographer has thrown much more of his especial individuality, and in which his strongest point—the telling of the story by the facial expression of the models—is most strikingly exemplified. He who can properly take advantage of circumstances is the man of true genius; at any rate, this is about the way in which Goethe states the case, and by turning back the NEWS to p. 468 of the present volume, one may find an account of the origin of what we are inclined to regard as the gem of the Exhibition—Robinson's "He never told his love." Let us quote Mr. Robinson's own account of the matter. He says:—

"One day I could not have the keeper who usually attended me, and I had to take an under-gardener. This man was a pictorial treasure. He was old, and had scarcely been further from the estate than Mold in his life. He was essentially a happy-looking old man, and full of native wit. I had been looking for a view some way off, and returning, saw my old man sitting on a rail in the hedge, surrounded by the models, who were chaffing him in Welsh and English. They made a picturesque group, and I heard one of them say, 'He never told his love.' Here was subject and title together, and was at once secured."

As in this case, good subjects for the camera may often be found ready-made and to hand by the observant and ready-witted photographer; but only one in a thousand can take advantage of what is offered to him.

Other pictures by Mr. Robinson are to be found in the gallery; (No. 53) "He loves me, he loves me not," recalling a means of divination so common among the sentimental maidens of the Fatherland; while "Come Across" just illustrates the well known fact that it is often very much easier to exhort another to do a thing, than to do it oneself. (No. 64) "The Cuckoo" shows us four children who are looking towards the place whence the always-welcome note seems to come; but holding up "The Gilly Flower" for baby to look at appealed more strongly to the maternal instincts of the fair visitors, if we may judge by the expressions which we noticed in front of the frame, and the remarks made. "A Chat with the Miller" (68) possesses some of the characteristics of "He never told his love," but the "Music of the Birds" is more akin in its nature to "The Cuckoo." "Finding the Calves" is a field scene, and would perhaps be better if the main figures were a trifle larger; and the mystic title, "Yn Cymraeg a Saesneg," will be unintelligible to those who have not made a study of the language of the Principality. "The Stream in Summer" gives a fine representation of

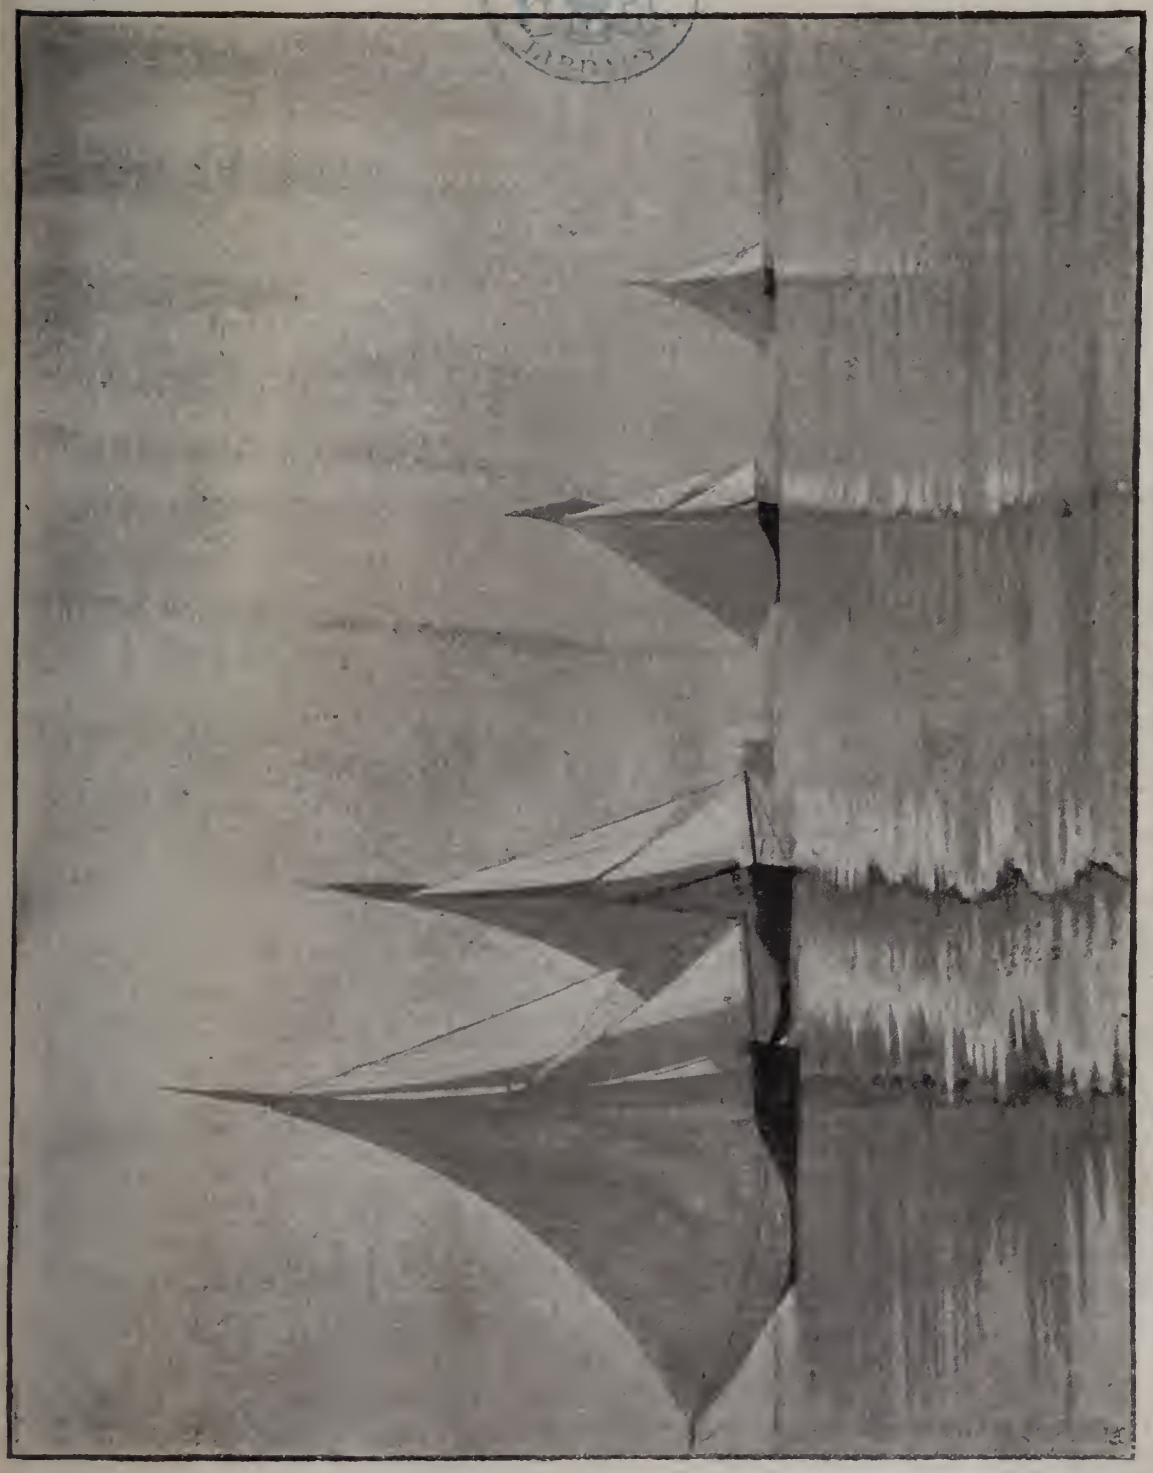
HANGING THE EXHIBITION PICTURES.
Negative by A. L. Henderson. Phototype Block by the Meissenbach Company.

that close rich foliage that crowds around our water-courses.

Mr. W. P. Marsh well deserves the medal which he has gained for his "Instantaneous Sea Studies" (No. 43), the anger and fury of the stormy sea being strikingly shown by bold clouds of foam in these pictures; indeed, in one picture the foam-cloud may be seen to rise to the full height of a large house, and an enlargement of this subject is shown on the opposite side of the gallery (No. 269).

The Swiss views of Vittorio Sella are well known to continental tourists, and it is pleasing to note that the judges have so far appreciated them as to give them an award. Four are shown: "The Lys-kamm," "Mont Blanc," "Märjelen See," and "Monte Rosa."

No. 135, which, along with 217, takes the medal for enlargements, is from a negative by Mr. J. C. Sinclair; it is called, "A Peep at Derwent Water," and affords a fine example of ærial perspective, not too much exaggerated, hill and cloud nearly blending in the extreme distance.



MARJORIE. MARGUERITE. GENESTRA. TARA.

Yachts on the Solent. Photographed by G. West and Son, Gosport. Phototype Block by the Meissenbach Company.

In our notice of the Brussels Exhibition of 1883, we referred to the magnificent examples of instantaneous photography contributed by M. Grassin, of Boulogne-sur-Mer; and it is gratifying to notice that he has come to the London show, and has conquered; the actual picture for which he is awarded a medal is his "Breaking Wave" (No. 153), a remarkable production. There seems to be a large black hollow like the entrance to a cave in the gigantic mass of spray and foam which advances. His remaining pictures, the "Folkstone Boat entering the Boulogne Harbour," his celebrated "Express Train," which we have already referred to, his "Fishing Boat" (No. 367), and "Yacht and Fishing Boat" (No. 368), are all very striking productions; but to us, the most effective as a picture is (No. 207) the "Quai Gambetta" at Boulogne," showing the active life of the pleasant French watering place.

A chill seems to pass through one on glancing at Nos. 167 and 168, two winter scenes in Mr. G. Renwick's well-known style. The cold is in the air of the pictures rather than in the solid objects, and to see the square tower of the old church faintly outlined through the frost-loaded air is to feel the intense realism of the representation. Mr. Renwick well deserves his medal. Here, it may be observed, photography is at its best; there being no colour in the original subject, the absence of it is not noticed in the photograph.

Mr. Berkeley's productions, printed in platinotype, have all the charm of good photographs, together with the peculiar beauty which accompanies a good steel plate engraving. (No. 209) "The Thames at Pangbourne," (219) "A likely place for a trout," and (220) "Aground, Pangbourne Loch," for which a medal has been given, are charming, the delicate gradations of sheen on the water, and the breaking up of the light by the trees, being rendered admirably.

In portraiture, Mr. Mendelssohn is prominent, and there is an individuality about his pictures which runs through all: notwithstanding that the lighting is bold and well-marked, those deep, heavy, and extended shades which so often mar portraits lighted on the so-called "Rembrandt" system are absent. Mr. Mendelssohn evidently believes in so exposing and developing as to secure full detail everywhere. The poses have much originality and grace; the picture of the medal series (Nos. 243, 244, 245, 246, 247, 248) which seems to us to be most happy in this respect, is the portrait of Miss Grant, in which the model is inclined slightly forward, with the eyes directed a trifle downwards. A little consciousness of the neighbourhood of the camera is obvious in No. 248, "The Misses Sandbach," those ladies being represented—one standing and the other sitting—at a work-table.

Mr. Hubbard deserves much praise for his admirable composition, "A Mother's Love." The poorly furnished cottage room contains little which the mother can value but her babe; and as she leans loving and anxiously over its cradle, one can realise the position at once.

To say much regarding the fresh and vigorous pictures of yachts, for which Messrs. West and Son have received so well-deserved a medal, is unnecessary, the class of work which they turn out in this direction being so well known. Perhaps the best of the series is that which forms our illustration on page 643. It is printed from a photo-type block made by the Meissenbach Company. Beginning at the left hand of the picture, the order of the yachts is as follows:—Marjorie, Marguerite, Genestra, and Tara.

In "Out of Sorts" (No. 330) we have a picture of the kind which has made a name for Mr. Adam Diston. The patient is an old Dutch clock, and the ancient dame who is endeavouring to infuse new vigour into it by blasts from the kitchen bellows is evidently as deeply interested in the welfare of her charge as ever Court physician was regarding the future of his Royal clients. Mr. Diston, who may be considered to be essentially the Gerard Dow among photographers of the present time, can infuse a depth of meaning and detail into the blackest holes and corners of an interior. Mr. Diston only exhibits one picture, but that one picture is a host in itself.

No. 362, a frame of small studies, by Mr. G. Hadley, must be looked well into, but will reward one for the pains. Photo-miniatures may often be overlooked among so many large pictures. Mr. Hadley has earned his medal.

Lafayette, of Dublin, exhibits excellent portraits, and for these he has been awarded a medal. The most striking is perhaps a picture of two ladies at the piano, one fingering the keys, and the other standing at her right-hand side, we will suppose, singing.

The photo-engraving process of Messrs. T. and R. Annan so completely and thoroughly renders all gradations of a negative, and, moreover, in a grain so fine as to appear like a uniform tint, that it would have been difficult for the judges to have passed over their exhibits without making an award. The charming picture of Norfolk Roads (No. 464), together with the portraits of the Duke of Buccleuch, and of Sir Daniel McNee (No. 474), are those for which the medal is given; but it is difficult to look on them as better than the rest. For high class book-illustration, the photo-engraving method of Messrs. Annan should have a good future before it.

Photography as a means of assisting in microscopic work is becoming of increasing importance each year, and it is gratifying to find that the importance of this development of photography, and the excellence of the work exhibited by Mr. Atkinson, have been recognised by an award for the frame of enlarged microscopic objects contributed by this gentleman.

The photograph of lightning shown by M. Auty differs much in character from that of Herr Haensel, which we reproduced on page 2 of our present volume, as in M. Auty's picture the discharge appears to have no definite starting and terminating points. A medal has been adjudged to M. Auty on account of the scientific value of his production.

The last medal picture to be noticed is Mr. S. G. Payne's exhibit (No. 528), "Knuckle down tight." A capital subject for the camera is a game of marbles, but how few can do it justice! The two lads who are standing in the background watching the game do so with an expression of interest and concern which is most admirably realised.

Our notice of the medalists pictures is now complete, and next week we shall commence our systematic walk round the room, and description of the pictures.

On the tables there is an extensive collection of apparatus, but very little which is novel. Indeed, there are very few contrivances which are the outcome of the past year's work, or which have not been shown in the gallery before. So crowded are the tables with what may be considered the ordinary production of the manufacturers, that the few novelties are practically lost to the bulk of the visitors. In fact, the show of apparatus has degenerated to but little else than a trade exhibition of every-day goods—excellent and well-made specimens, it is true—but still out of place in an exhibition which should represent progress during the past year. Another circumstance which cannot fail to strike the visitor as unsatisfactory is the fact that a number of trade catalogues and general price lists of photographic requisites are allowed to remain on the table for distribution. That some houses should thus be allowed to push their business is very unfair to those whose feelings of what is becoming will not allow them to so lower themselves. It might be an excellent plan for the price to be marked on every piece of apparatus which is made commercially, as the price is sometimes an essential in forming an opinion as to the merits of an invention; but that the exhibition of the Society has been made a means of distributing circulars and general lists of photographic requisites is a matter to be regretted.

Mr. Herbert S. Starnes shows a well-designed camera of the "detective" type; camera, changing-box, and plate-box, being united in one. The changing of the plate is effected by a sleeve at the back of the apparatus.

The "Camera Adapter," designed by Mr. Shew, is likely to be useful to those who may wish to avoid the expense and inconvenience of numerous cameras. The idea is to adapt a movable extension piece to the back of a small camera, so as to virtually make a larger instrument of it. The adapter has on the one end runners to fit the small camera, and on the other end grooves to take the large slides, and the idea is well worked out by Mr. Shew. Possibly the time may not be far distant when all commercial slides will be made to recognised standards, and should this be done, such adapters as we have referred to will be extremely useful.

A new model of the Cadett pneumatic shutter is exhibited by Marion and Co. It is simply a lift and return shutter neatly made of ebonite, and is likely to be useful in the studio, as it works without noise, and may be placed inside the camera.

A large number of excellently made stands are shown, it being a significant fact that all but one have adjustable or sliding legs.

Plate-boxes made of sheet metal are exhibited by Mr. T. Samuels, but there are no grooves, each plate being held by a kind of frame of tin, consisting of a sheet of the metal with the edges turned over, so as to grip the glass.

Nos. 628 and 629 are compact and well-designed cameras of the "detective" type, designed by Professor Ezutchewsky, and instead of using a focussing cloth, the required shade is obtained by a bellows-like hood, which can be extended at pleasure. In one of the apparatus, the changing of the plates is effected by reversing the arrangement. We shall say more regarding the apparatus next week.

On Monday evening an exhibition of lantern slides was held, Mr. York contributing some views of London; Mr. Moncrief and Mr. Brooks, charming views of Wales; while Mr. George Smith, of the Sciopticon Company, showed that when a Woodburytype slide is coloured with pure carbon, the tone is an agreeable warm brown. Mr. Pringle and Mr. Fineham also exhibited excellent lantern transparencies.

Practical Papers for Beginners.

No. 11.—MAKING LANTERN SLIDES.

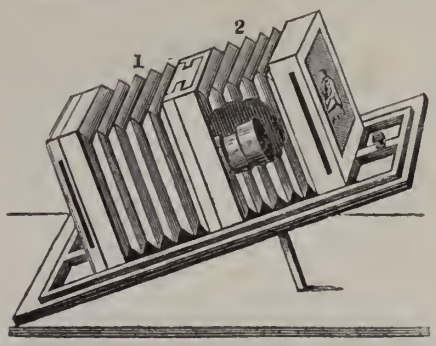
The non-professional, or amateur, will often find it much better to lay himself out for making transparencies to be exhibited by means of the magic lantern, than for the production of silver prints. For exhibition to circles of private friends, the lime-light is by no means required; a well made lantern of the Sciopticon type (p. 629) giving abundant illumination, although ordinary paraffine oil is burned.

The non-professional who makes silver prints is very much at the mercy of his friends, who think they are complimenting him by asking for copies of his pictures, and the result is that he is often without copies himself, or may be he has only a few waste impressions which he did not consider good enough to give away. When, however, the beginner boldly announces that he does not make pictures on paper, but that his productions are to be seen at such and such a time upon the screen, he avoids the inconvenience of having to be constantly at work making copies, as comparatively few persons would ask for a lantern slide. Apart from this, there is no question whatever that the very best way of fully displaying the merits of a good photograph is to project it upon the screen. Supposing that the negative is set up against the light—as, for example, in a window—and photographed on such a plate as would give a negative of an ordinary object, a transparent photograph is obtained, but the quality and tone of the resulting transparency depends very much on the process employed, and the details of manipulation.

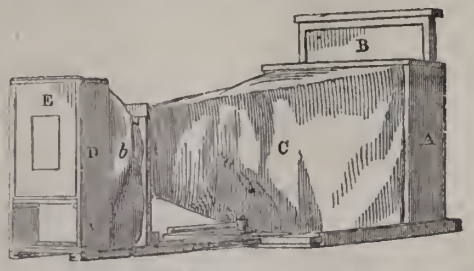
Before entering into the vexed question as to which process should be adopted for making the lantern transparencies, it may be well to say a few words about the manipulations incidental to exposure. When the reproduction is to be made from a quarter-plate negative ($3\frac{1}{4}$ by $4\frac{1}{4}$) the camera may be dispensed with, it being sufficient to place the original negative, film side upwards, in an ordinary printing frame, and to lay the sensitive plate upon it, both films being in contact. The exposure is now made, a few seconds at a distance of a foot or so from an ordinary gas flame being sufficient in many cases. It should be noted that the standard height for the photographic lantern transparencies is $3\frac{1}{4}$ inches, or the narrow dimension of a quarter plate; and although many makers of slides make the width to correspond with the height, there are a few who send them out $4\frac{1}{4}$ wide. It will thus be seen that unless the dimensions of the picture are to be altered, it is not necessary to use a camera in the production of the transparent positive. Still, in very many cases, one has to enlarge or reduce from the original negative in order to obtain just so much of the subject as is required.

Although it is quite practicable to set the negative up in a window, and to copy by adjusting the camera inside the room, it is far more convenient to set up a special copying camera if one intends to make lantern slides as a regular thing.

The subjoined drawing represents the usual type of copying or enlarging camera as used for this purpose, and it may be regarded as two adjustable cameras joined front to front,



and mounted on a hinged framing; so that the upper end, which carries the transparency, may be directed towards the sky, while the dark slide is adapted to the lower end. An arrangement which answers quite as well as a special enlarging camera can generally be extemporised from two cameras, a funnel-shaped connecting piece of black cloth being used to connect, if the cameras themselves are not adjustable; the following sketch will make all clear.



In copying with the camera, it is often advantageous to put a sheet of moderately fine ground glass behind the negative—that is to say, on the side farthest from the lens—indeed, a piece of ground glass so placed often appears to add in a remarkable way to the intensity of the illumination and the brightness of the image on the focussing screen.

If transparencies are made on the ordinary gelatino-bromide plates, and developed with pyrogallic acid and ammonia, as directed on page 531, it is an excellent plan to

brighten up the image by soaking the finished transparency for some hours—it may be as much as eighteen or twenty—in Mr. Cowell's clearing solution:

Alum	1 part
Citric acid	2 parts
Water	10 ,,

If the negative is a little clouded, or requires reduction, it is well to add enough of a strong solution of perchloride of iron to make the solution the colour of sherry.

Many persons, however, prefer to develop transparencies for the lantern with the oxalate developer prepared as described in our last Practical Paper (p. 620); but those whose ambition it is to make slides possessing the richest and most pleasing tones should undoubtedly adopt the gelatino-chloride process of Dr. Eder.

Gelatino-chloride plates are now an article of commerce, but the following directions will enable the beginner who has followed our papers to make his own.

The emulsion is prepared much after the manner generally adopted for the production of a gelatino-bromide emulsion. Twenty-five parts of gelatine are dissolved in 200 parts of distilled water, together with 7 parts of sodium chloride and 6·40 parts of ammonium chloride, it being convenient to allow the gelatine to swell for half-an-hour before applying heat. The gelatine being dissolved, and the solution at 50° C. (122° F.), a silver-nitrate solution containing 15 parts of the salt in 200 parts of water is gradually added with agitation; and it should be noted that it is advisable to warm the silver solution to the same temperature as the gelatinous liquid.

The chloride is deposited, under these circumstances, in a very fine state of division, and the mixture is at once poured out to set, a beaker or drinking-glass serving very well as a mould, and external cooling may be resorted to when it is desirable to work expeditiously. The gelatinized emulsion may now be divided and washed as directed on page 596, after which it is melted, and plates are coated according to the directions on the page referred to.

An exposure of from one to three seconds is required when the transparency is made in a printing frame, and exposure is made by diffused daylight; while thirty minutes at a distance of five feet from an ordinary bat's-wing burner may be considered an average exposure when gas light is made use of.

The developer is prepared as follows:—

A solution of 600 parts of commercial citric acid in 2,000 parts of water is prepared, a gentle heat being employed to dissolve the acid; and the liquid is next neutralized — or, rather, made very slightly alkaline — with ammonia, about 300 parts being required for this purpose. Red litmus-paper should be slowly turned blue by the solution at this stage; but if, by inadvertence, too much ammonia has been added, this excess may be readily removed by heating the liquid until the superfluous ammonia has been driven off. The solution in this condition contains, then, the neutral citrate of ammonium, or this salt with a mere trace of ammonia in excess. The next step is to dissolve 400 parts of citric acid in the solution, and to make up the volume of the liquid to double that of the water first used, about 400 parts of water serving for this purpose. The acid solution of ammonium citrate thus prepared keeps well, and, therefore, a considerable stock of it may be prepared, a trace of mouldiness on the surface being of no importance. The formation of this mould may, however, be prevented by the addition of a few drops of carbolic acid.

The standard solution of ferrous sulphate is next prepared by dissolving one part of the crystallized salt in three parts of water (about one drop of sulphuric acid being added to each four ounces, in order to prevent the deposition of a basic sulphate). It will readily be understood that this solution should be kept in a closely-stoppered bottle, as, when oxidized to a notable extent, it would obviously be unfit for use. The above solutions are mixed, when required, in the following proportions, the small proportion of chloride of sodium being added as a restrainer:—

Ammonium citrate solution	90 vols.
Ferrous sulphate solution	30 ,,
Chloride of sodium solution (1 and 30)...	6 ,,

The operation of development is conducted just as in the case of a gelatino-bromide plate, and the image should acquire the necessary intensity in five or ten minutes. Several plates may be successively developed with the same solution.

A solution of hyposulphite of soda containing one part of the salt to ten of water may be used for fixing, and after the plates have been washed and dried it is convenient to place a second glass on the film side, and to bind the two together with strips of paper gummed over the edges. The slide generally looks neater than it would otherwise do if a mask of black paper, having a suitable opening cut therein, is included between the two glass plates. These masks can be purchased ready to hand, or may be cut out with the point of a sharp penknife, a glass shape being used as a guide.

PHOTOGRAPHIC ADVENTURES IN A SAILING BOAT.

BY A. J. WEST.

Those who have been fortunate in spending their summer holidays cruising about the Solent during the sunny month of August cannot but express the feeling of delight they must have experienced in the pleasures derived from such a lovely cruising ground, and in such exceptionally fine weather. How different from last year, which can be well remembered for its wind and rain! The racing yachts at times had rather hard work to make headway, there not being sufficient wind to fill the sails; one day in particular, it was a race for the Town Cup, Cowes, and I looked forward to making some good studies of the fine yachts which were to compete in that great race. I got on board my boat about 7.30 a.m., and left Gosport with a light breeze and a fair tide, which soon carried us to where the yachts would have to pass. After I had rigged the camera up and everything was all ready for action, the wind unfortunately dropped, and we were becalmed about two miles from Ryde; it was very disappointing, as I had hoped for a stiff breeze and a rough sea, but instead of which the water was like a sheet of glass. The sky was an intense blue, not a cloud to be seen, and the sun pouring down its hot rays made the heat almost unbearable. Everything appeared to have lost life, and so strangely still was the air, that sounds which were issuing from vessels a long distance away could be heard with remarkable distinctness. About two miles on our port bow was a fishing smack, and a man could be heard singing, "Wait till the clouds roll by."

"Rather a queer song for to-day," quoth my man Williams, who is rather a dry one.

Looking for the yachts in the direction of Cowes nothing could be seen, owing to a thick brown mist caused by the intense heat.

"We're going to have a regular roaster, sir," says my captain; and he was perfectly correct.

We lay becalmed for over five hours, during which time I took a few steam yachts which happened to come past us. About 2 p.m. the tide turned, and we could just discern, looming through the mist, six magnificent yachts with their spinnakers all set, making towards us. As they came closer, I noticed four together which, I felt certain, would make a pretty picture, but unfortunately I was more than a mile on the wrong side. I asked Williams if it was possible to get the boat over to the furthermost one, and then rake them.

"If you don't mind having a pull, I think we might do it," he replied; "but we shall have to be quick, as they will soon be down upon us. We at once took to the oars and pulled our hardest. The heat was intense, and the perspiration, as it rolled down our faces, gave us a melting appearance.

"I doubt we shall do it," cries my captain. "Pull, sir, pull hard;" and I did, in a most desperate manner. It was a great relief to find that we had only a little further to go to get in position; the yachts were coming up with the tide very quickly. I suddenly remembered that I only had two plates ready; the plates in the other slides had been exposed for steam yachts, and had not been changed. I rushed into the cabin and managed to fill two more just as Williams called out, "You'll be too late; they are up to us." I flew to the camera, hurriedly placed a slide in, raised the shutter, sighted, fired, and dropped on the seat alongside nearly overcome by the heat from rowing and rushing about. As I sat and watched the yachts drifting along, I noticed what a fine effect was caused by the reflection in the water owing to the wonderful calmness. I was, however, soon roused from the reverie into which I had fallen by Williams asking if I was only going to have one shot. This sent me to the camera again, and before the yachts had all passed, I secured six different views of them, the reflection in each one being remarkable. About 200 yards astern of the yachts came a gentle breeze which soon filled our sails, and we steered in the direction of home

It had been a great wish of mine to secure the bow view of a yacht with a spinnaker set, but to do this I should have to sail across her path, which is extremely dangerous, owing to being obliged to get close to her to make a large picture, and there would hardly be sufficient time to get out of her way after the photograph was taken. However, an opportunity offered itself on the day of the Albert Regatta, and I determined to avail myself of it, much against the will of my captain. When the yachts started they had to keep tacking until they arrived at the Nab light-ship, which they rounded, and with spinnakers all set, they came tearing along in the direction of Noman's Fort, where I was hove-to waiting for them. One of them had a larger spinnaker than any of the rest, and I picked her out as my victim. The sun was shining so as to give a perfect roundness to the sail, which cannot always be obtained.

"Now, Williams," said I, "do you see that large yacht bearing down this way?"

"Yes, sir."

"Well, I intend to have her right on the bow, so mind you steer me in that position."

"But we shall be run over."

"I think not, if you use your usual seamanlike skill and judgment."

Having put him upon his mettle in this manner, he remonstrated no longer, but put the helm hard down and sailed towards her.

"It will be a very close shave, and supposing we cannot get out of her way, what shall we do then?"

"Why, be capsized, that's all," said I, laughing.

But he did not consider it quite a laughing matter, and felt anxious over it. The yacht was by this time getting rather close.

"Now mind you look out, sir, and be prepared to take the oars directly you have fired."

I had my slide and shutter quite ready, and as we got nearer and nearer an exclamation escaped me, "What a grand sight!" She looked enormous; the spinnaker was well ballooned out, and the sun shone on it and made a grand effect.

"Now, sir; now is your time!"

I waited two more seconds; then sighted—fired.

"I have got her, Williams," I exclaimed.

"Yes, and she's got us," replied he; "out with the oars sharp, or we shall be run over."

We just escaped; but only by a few inches; her mainsail boom nearly hit us; but, as I told Williams, a miss was as good as a mile. Taking the length of the booms end to end, it was over 100 feet.

Those on board stared at us, and seemed to wonder where we came from; but when they found what we were up to, they waved their hands and shouted out something about good steering, which made Williams almost blush; perhaps he did, but owing to his face being so tanned, I could not perceive it. We often speak of this as one of our dangerous experiments.

On another occasion I thought I would try and take a yacht in a similar position to the *Chittywee*; but there was not sufficient wind to make the sea rough, neither could I persuade the clouds to come and look pretty; but I obtained the position, or nearly so, as will be seen in the photograph of *Buttercup*. It is almost incredible that so small a yacht should carry such a wonderful amount of canvas. I sailed so close under her stern that I could almost shake hands with those on board. In this case I had to obtain the position, whereas with the *Chittywee* the captain on board put her in that position. I happened to see him this summer, and he explained to me that, seeing I was photographing the yachts, and wanting his little craft taken, he thought he would give me a good opportunity, and sailed very close past the stern of my boat, and then payed off. Of course I was not slow in availing myself of such a pretty picture, although sailing so close made my boat tumble about to such an extent as to make it very difficult to take it.

After we had taken the *Buttercup*, we cruised along towards Browndown, and were amazed to find a volley of musket shots come flying around us; the soldiers were practising at the ranges. Whether they mistook us for the target, or whether it was bad shooting, I can hardly say, but am rather inclined to think the latter. Three volleys were fired, and in each case the shots came flying on all sides. One we could distinctly hear with its peculiar "twing," came about two feet over our heads between the mainsail and mizen, that made us duck down, and we felt far from comfortable. We thought the best plan was to lay down at the bottom of the boat out of harm's way, until we had got out of range.

"This is reversing things," says Williams; "instead of us shooting, we are being shot at."

I did not see the joke, as there was no comparison between my harmless firing and their deadly weapons. Two fishermen were rowing in a boat, returning after a hard day's work, and when they found the shots so close, turned, and pulled most desperately. We thought they might have received some hurt, and hailed them, but found, with the exception of a splinter shot away from the gunwale, they were quite safe. They came alongside, and I was soon tempted to buy some fish, which we cooked for tea.

I have traversed over 600 miles in my cruising about the Solent this year, and the different adventures I have met with in obtaining photographs of yachts have been both exciting and amusing.

Notes.

Hanging committees or judges who expect to give satisfaction to everybody are doomed to disappointment; still, it is gratifying to be able to say that we only heard two very decided expressions of disapproval on Saturday evening. In one instance we approached an esteemed friend: he was standing with his back to the wall, and looked dejected. "How d'ye do?" we asked, extending the right hand. His breast heaved, moisture appeared to be exuding from his

eye, with his thumb he pointed over one shoulder, and with an evident effort he said: "They have skied my picture."

The other discontented one expressed himself vigorously and decidedly while standing immediately before a frame of medal pictures. This is how he instructed the by-standers: "They don't know anything about it; why don't they have judges who know something about it? I shan't send any more pictures here—— Eh! what did you say, my exhibit? Well it does, as you say, deserve a medal; but, as I said before, the judges don't understand photographs."

Towards the latter part of the evening, as the haze cleared off, a good view of the eclipse became possible, and those leaving the Exhibition Soirée had an excellent opportunity of seeing the latter phase. At Paris, the *Champs Elysees* was crowded with moon gazers, and a balloon ascent was made from La Vilette. Ma. Banjafield, of Stepney, sends a photograph which he took.

Some years ago, when one of the present Royal Academicians was made an Associate, the election took place between sending-in day and the opening of the exhibition, and the story goes that the works of the new Associate had been rejected, and had to be fished up from the cellars, to take their place of honour on the line. It is whispered that something of the sort happened to a picture in the present exhibition of the Photographic Society. The jurors, it is said, remembered a very important picture, but could not find it on the walls. It was ultimately discovered among the rejected, brought back, hung, and medalled. There is this difference between the two incidents—the paintings were rejected by the deliberate judgment of the Council of the R.A., and the photograph was sent away with the unfortunates by one of those rare accidents which prove that we are all human, and therefore not infallible. We have high authority for saying there is "good in everything," and those who have had the misfortune to find their pictures rejected, may console themselves by fancying that they were among the "outs" by accident.

Mr. T. C. Robinson's find of an original by Michel Angelo at the Fountaine Sale is followed by an account of the purchase of three original paintings by Turner. They represent views of the interior of Exeter Cathedral, and were bought from a broker for £3. Although it is not definitely determined that they are authentic, it is said that £1,500 has been offered for them, and refused.

It is pointed out in the *Papier-Zeitung*, that packing-paper which has been made from pulp treated by the sulphite (bisulphite) process is very liable to give off sulphurous acid, and this may cause injury to metallic and other articles wrapped in such paper. Although a trace of sulphurous acid may do no harm to dry plates or silver prints, we would certainly prefer to have paper free from it.

The second hearing of the summons against Messrs. A. and G. Taylor for using the Royal Arms without authority (see page 613) has been adjourned from Tuesday last, the 7th instant, to Tuesday next, the 14th. It is stated that the case will not come on before two o'clock in the afternoon.

Much that is suggestive is to be found in Mr. Robinson's picture which forms our "ink photo." supplement this week; the bantering aspect of the damsel, who is amusing herself by talking to the old agriculturist, being as much indicated by the general attitude as by facial expression, and in this harmonious unification of the general pose of the model with the main idea of the picture lies much of Mr. Robinson's strength.

Some months ago a number of persons well known in photographic circles were taken unawares by one of the party when a halt was made on the return from an out-door photographic meeting; and although every one had his back to the camera, there was no difficulty in recognizing each person; indeed, more than this, for in several cases the attitudes indicated pretty clearly the part each was taking in the discussion.

Major Serpa Pinto is an experienced explorer, and he has shown his usual good judgment in deciding to attach an experienced photographer to his Congo Expedition, which is just about leaving Mozambique. The artist chosen is an Englishman, and, as there will be 250 carriers attached to the Expedition, ample chemical stores and the most approved portable apparatus will be taken. One thing, however, the gallant Major and his photographic henchman need not trouble about, and that is a dark-room or cupboard for developing the plates. Dark cupboard, forsooth! why the enterprising photographer will have a whole "Dark Continent" at his disposal.

Mr. Braun will be allowed to obtain as good a photograph as he can of the Blenheim "Raphael" before this £70,000 picture is placed on the screen prepared for it in the National Gallery. It would not be a bad idea, indeed, for Mr. Childers to have reduced copies of the work appended to the Supplementary Estimate which members of the House of Commons will be required to vote next session, to pay for the sensational purchase in question. The beauty of the subject might thus possibly influence the votes of the most rigid economists, as well as inspire the speeches of the defenders of the outlay.

It is lucky for Mr. Freeman's suggested use of snuff in the dark-room, to counteract the effect of ammonia fumes, that gelatine plates are so much more hardy in constitution than their collodion brethren. A violent sneeze over a gelatine plate would probably not affect it much; a collodion plate would most certainly suffer. In any case, snuff-taking involves a certain amount of education. If you are unaccustomed to the titillating powder, and you feel inclined to sneeze, the best plan, supposing you to have a plate in your hand at the time, is to put the plate down and have your sneeze out. To restrain yourself to the

bursting point might result in a convulsion which would send a choice negative flying to the other side of the dark-room. We once knew an eminent microscopist who lost his time and temper for an entire evening through holding his breath. He spent an hour or so in getting some very minute sea shells into focus, and just as he succeeded he shut his mouth firmly and held his breath, so that not the least draught should shift the position of the delicate objects. Unluckily, at the very critical moment, his lungs failed him, and though he controlled his lips, he couldn't prevent a violent blast descending from his nostrils, and away went the shells to the four points of the compass. Perhaps, if Mr. Freeman's plan succeeds, we shall have some ingenious inventor advertising "dark-room nosebags for photographers!"

The promoters of the prohibited baby show at Paris have turned their attention to an exhibition likely to be quite as attractive. They contemplate an International Beauty Show for ladies between twenty and thirty years of age. The committee have established themselves at No. 11, Rue de Lille, and are ready to receive photographs of the competitors as a preliminary measure. They do not say whether the photographs are to be "untouched." This is rather an important omission, so far as freckles and wrinkles are concerned.

Miss Anderson, it seems, is a trouble to her photographers. They complain—at least, some of them do—that there is no variety in her face, since her expression never changes. Hence—so we learn on the authority of a journal of fashion—her latest photographs were taken with the actress draped all in black, so as to get an effect from the contrast of those dark garments with the whiteness of the arms, throat, and neck. It is doubtful whether in these photographs Miss Anderson has not erred in the opposite direction. If it be not treason to say so, her arms are very long, and have not statuesque proportions. These defects the method adopted to get contrast has exaggerated.

Is not the date fixed for the exhibition of the Photographic Society of Ireland likely to affect the number of works contributed by English photographers? The exhibition at Pall Mall will be in full swing on October 31st, the last day for receiving at Dublin, and it is not every photographer who cares to print and frame duplicates of his pictures for exhibition. Only those who have gone through the ordeal know what it is to prepare photographs for show purposes. One hungers after absolute perfection of printing, fastidiousness on the question of the exact tone is carried to a fault, and minute blemishes which, in the ordinary way, would be "spotted out," are considered sufficient to cause rejection of the prints. All this is bad enough in the case of single pictures, but when there are four or five in one frame the difficulties are carried to agony point. For these reasons it is a pity that the Dublin exhibition is not held a month later than the date arranged.

Photography has added a proof of the wonderful vitality of the Emperor of Germany. It was not known that he still drove until his most recent photograph, taken at Babelsberg six weeks ago, showed him in cap and overcoat seated in a cabriolet drawn by two white horses, reins in hand, and on the point of starting. Loyal Germans, probably, will not hear of the suggestion that possibly the monarch was placed in the vehicle for the purpose of being photographed. Yet such things have been.

HINTS ON POSING AND THE MANAGEMENT OF THE SITTER.

BY H. P. ROBINSON.

Chapter I.—The Head.

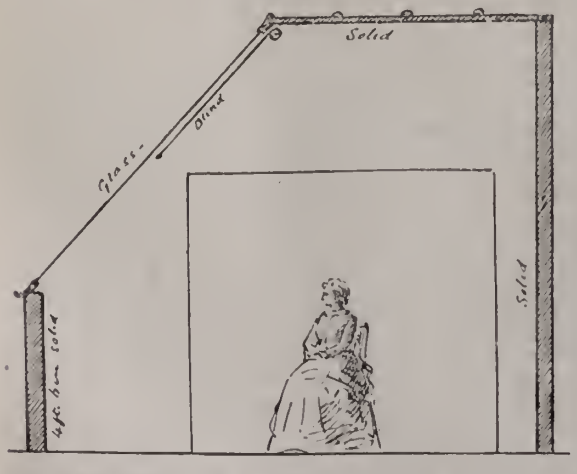
In the following papers I hope to give some general ideas on posing sitters for portraiture, suitable for the requirements of the professional photographer—not, I trust, without being of some use to the amateur. I do not intend to confine myself to the ornamental and elaborate, but shall prefer to give such simple advice as, in my opinion, is calculated to be of most use in ordinary studio practice. Much of it, perhaps, will seem too elementary for the skilled photographer, but I trust that here and there may crop up ideas worthy of the attention of even the most experienced operator. In doing this, I protest against the enervating practice of giving a set of poses for the imitation of those idle and thoughtless operators who do not try to think for themselves and adapt their ideas to their subjects, but who place their sitters, no matter how unsuitable it may be to them, in the same position day after day, as if the posing-chair was a sort of Procrustean bed on which everybody must be cut to the same size and shape and form, and brought to that state of imbecile appearance to which photography is popularly supposed to reduce its victims. A recent writer on composition has some forcible remarks on this point. He says: "Our subjects and our treatment of them must be emphatically our own; but nevertheless, every student of art owes it to himself to get what help he can from the study of the works of the great painters who have gone before. His object should be to notice not only how natural appearances have been modified—or, as it is technically called, treated—by painters of acknowledged fame, but also why this was done. No painter who has in him any spark of originality will directly repeat any effect that has already been painted; but an earnest student can only benefit himself by trying in a measure to look at nature from the point of view of the masters of his art."

For the purpose of these lessons, portraiture may be divided into different classes, such as the head, the three-quarter, the full-length, the seated, the standing, the group, &c. Of all this variety, the head is perhaps the most important, for nine-tenths of the portraits taken in ordinary studios—excluding the lower class and "the beach"—consist of heads taken under different names, such as the Vignette, the Berlin, the Medallion, the Rembrandt. Now it might be thought that nothing could be simpler or easier than to pose a head, and that there was very little to say on the subject; but if we are to judge by the majority of specimens, we see the art of setting a head properly on its shoulders is not given to all men, and the results suggest the notion that their victims were first hanged—*sus. per col.*—and then, instead of being "drawn" according to the old sentence, had been photographed. This broken-necked effect is more visible in Rembrandt's than in the other forms mentioned, although they are not absent from Vignettes and Medallions. The reason why it is more apparent in Rembrandts, probably, is, that this kind of picture is commonly taken in profile, and the strain to turn the head sufficiently makes it lean towards

the camera. Here is an illustration. You have only to add a rope to make the thing complete.

The eye, also, in these shadow portraits, nearly always seems to be afraid of looking straight—the shy, half-frightened, and wholly-deceitful glance of the eye in most of these pictures, suggesting that none but the very worst characters ever had their portraits done in this style. Both these very grave faults are easily avoided. The inclination of the head towards the camera is caused chiefly, as I have said, by the strain in turning to a side view of the face, when the body is in full front view. If the figure were turned to a three-quarter view towards the light, the strain would be lessened, and if the head still leans over too much, a very slight movement of the head by the photographer would set it upright. But I must take the opportunity that here presents itself of saying that the less the operator handles his sitter the better. It worries him, and oftener tends, except in very skilled hands, to stiffen the figure rather than add to its grace. But I still strongly advise the use of the head-rest, even for short exposures; not so much for the purpose of keeping the figure still, as for the aid it gives in posing.

The defect in the eye, just mentioned, is caused entirely by having the light too low down, so that the sitter, if he looks straight, is dazzled, and has to look aside. There is no reason whatever why there should be any light in a studio lower than five feet from the ground. A studio of the following section answers every purpose, and as the



solid walls are not less than four feet six inches high, the eye of the sitter for a Rembrandt portrait may be looking at a pleasant picture instead of a glaring light.

There is, apparently, very little glass used here, but it will be found quite enough. And if a space of clear glass measuring five feet by four feet just behind and in front of the sitter be used, the rest of the roof may be obscured, or semi-obscured, leaving the possibility, however, of letting in a little reflected light on the shadowed side of the head. The shadow pictures are very much improved if some gradation of light and shade can be obtained in the background, and fine effects can be got by turning the face from the light, and bringing it out dark against a light background.

I have incidentally mentioned the head-rest, but as an instrument of the greatest use in posing it deserves more detailed notice under the heading of these chapters.

The head-rest is chiefly famous for the unmeasured abuse it meets with from the ungrateful sitters for whose benefit it was invented. They never stop to think that it is not the instrument that is in fault, but the clumsy users of it; but I notice in my own practice that the complaints against the rest are not so frequent as they were once upon a time, and if a sitter objects to the rest, I feel certain that he has been badly treated, and had an awful experience with some other photographer, and make it a point of honour to induce him not only to submit to, but enjoy it.

The rest should not be treated as an instrument to keep the sitter still, but as a posing machine. One of the most objectonable things you can do to a sitter is to insist on his being still. You of course want him to be quiet while the exposure is going on, but this should result from your general treatment of him, rather than any preconceived notion he may have brought with him. He should be so managed that sufficient stillness is a natural result. During the few seconds' exposure that is all now necessary, a slight touch of the rest, properly applied, is enough to secure steadiness, but its great use is in making slight variations of the pose—of which, more hereafter—and the confidence it gives the sitter that he is not going to spoil your plate by moving. On the other hand, if you dispense with the rest, the sitter makes a desperate struggle to keep still, and *looks like it.* Now the portrait of a gentleman with an expression of firm determination to keep steady, as if rigidity was the one absorbing passion of his life, is not a pleasant object to contemplate.

The rest should be a comfort instead of a nuisance. It should be adjusted to the head, and not the head to the rest. It should never be applied until everything else is ready. A sitter should never have time to feel how ridiculous he looks, and the longer he is fixed to the rest, the more this feeling obtrudes itself. The plate should be exposed as quickly as possible after the rest is placed. If a slight alteration strikes you as a possible advantage, it is better to give it up than disturb the sitter at this moment; but if there is anything gravely wrong in the pose or dress, it is better to begin all over again.

The rest should be understood to be, and used as, a delicate support to the head and figure, not a rigid fixture against which the figure is to lean. The rest, as used in most studios, is a great deal too heavy. There is no occasion whatever for the cumbrous iron supports so often used. For ordinary portraiture I prefer a light simple rest without any complications—one that can be easily carried about after the sitter without trouble. I have no fixed place for the sitter in my studio, but place him in any part, just as the fancy strikes me, and it is here I find a light rest of so much use. A perfect rest has yet to be made. It must be moderately light and portable, and very simple. The complicated movements of the ordinary machines, often with chairs attached, are worse than useless, and very confusing.

ON FURNELL'S LENS.

BY W. ACKLAND.*

In addressing you this evening I intend my remarks to apply more especially to the amateur, whose equipment usually includes but one lens to reproduce all he may attempt in his photographic rambles; but I trust they will interest even the practical photographer who is armed with a whole battery of lenses.

It is well known that in order to produce pleasing results and artistic excellence in landscape photography one lens is sufficient, and even three of different focal length would be no excess. That is, a lens of short focus for buildings in close and confined situations, and another of medium focus for general views is requisite, whilst a third of much longer focal length is needed to reproduce distant objects, &c.; and any lens capable of variation in its focus so as to serve for these varied purposes would be a boon to both the amateur and professional photographer.

In April, 1883, Mr. Thomas Furnell described a photographic lens specially suitable for landscape and architectural photography, the focal length of which may be varied at will within certain limits, and which has certainly not received that attention from photographers its merits deserve.

The Furnell lens consists of a front combination of two lenses of somewhat novel construction. The outside one is of crown glass—convex on its exterior and plano on the interior; and the inner lens is of flint—plano on its inside and concave on its back surface—the plano sides of the flint and crown being cemented together by Canada balsam. Behind the front combination, and separated from it by a distance about equal to its diameter, is a double concave lens of flint glass. The most posterior lens is placed at a slight distance from the concave lens; it is of crown glass and plano-convex, and three back lenses of varied foci are supplied to complete the set. By using one or other of the back lenses, or no back lens at all, we can obtain with the half-plate lens either of the following focal lengths:—Seven, eight, nine, or fifteen inches. This lens gives a flat field, straight marginal lines, freedom from flare, covers well with stop No. 16 P. S. S. (Photographic Society's Standard), and can be made at a moderate cost.

One peculiarity of this lens is that, if the front cemented combination is well and carefully made, the posterior lenses may be of far less accurate workmanship, ordinary spectacle lenses, *if properly centred*, acting quite as well as those made with all the optician's care and skill. Moreover, the concave flint lens may be replaced by a concave spectacle lens of crown glass; and, further, the curves of the three-back plano-convex lenses may be altered to either double-convex or meniscus without injury to its working powers or disturbance of the chemical focus. In order to test its merits I have made one of these lenses with every possible care and attention in strict accordance with the author's description. In order to give an unbiassed opinion I placed it in the hands of Mr. A. Cowan, and some of the results of his trials are now before us, proving Mr. Furnell's lens to be both useful and efficient; but if you ask me if I am *entirely* satisfied with this lens, my answer would be a negative one, for its many good qualities are marred by two defects. These are—want of rapidity, and total absence of uniformity in the stops; and, to remedy these defects, I have strong hopes of shortly bringing out a lens on somewhat the same lines, under the title of compound doublet. This compound doublet will consist of one brass mount only, into which any one or two of the lenses forming the set may be screwed for use.

By varying the lenses employed we hope readily to obtain for the half-plate size either a focal length of six inches, of eight and a-half inches, or of twelve inches. These focal lengths have been selected because they are especially suitable for general use, embracing horizontal angles respectively of 65° with the six-inch, 45° with the eight and a half inch, and 31° with the twelve inch focus; and, further, with six stops it can be worked so as to give all the advantages of the Photographic Society's standard stops.

These six stops I propose to engrave as follows:—A on the largest, then B C D E and to F on the smallest. The first four, A B C D, will be 8, 16, 32, 64, when used with the twelve-inch set of lenses. The middle four, B C D and E, will be 8, 16, 32, and 64 with the eight and a half inch set of lenses; and the last four, C D E F, will be 8, 16, 32, and 64, when used with the six inch set of lenses.

Such is a rough outline of what I hope to accomplish, and all that I have hitherto done in this matter points to success at no very distant period of time. If success is gained it will be largely due to Mr. Furnell, as his writings have certainly pointed out the path by which that success can be reached.

* Abstract of a communication to the South London Photographic Society.

PRESS NOTICES OF THE PHOTOGRAPHIC EXHIBITION.

[From *The Times*.]

The annual exhibition of the Photographic Society of Great Britain will be remembered rather by reason of the generally high level of the results obtained, than for any startling novelty in the treatment of subjects or methods of work. There are, indeed, very few pictures among the thousand or more exhibited which would not have been ranked with or next to the leading productions of five or six years ago. The causes of this advance along the whole line will be found directly, to some extent, in the revolution which has taken place in the chemical processes of photography, and secondarily, and in consequence of this change, in the conditions under which the camera can now be employed, in the enrolment among the exhibitors of a largely-increased number of amateurs of cultured taste, enjoying means and leisure for the successful practice of the art. A traveller may pack in his portmanteau the whole of the apparatus he requires to photograph scenes or places he visits, and on his return home may hand the sensitive plates to a professional photographer to bring out or develop the images latent in the dry gelatine films, and to print direct from or to enlarge the pictures produced. How long the plates may be kept after exposure in the camera cannot yet be said, but, as an instance in the exhibition shows, they may safely be kept at least as long as any traveller is likely to be obliged to postpone the after processes. Dr. G. Berwick shows (481—Dumblane Cathedral) a clean, sharply-defined print from a negative exposed in July, 1880, and developed in July, 1884. Moreover, if the traveller choose his point of view well, paying due regard to the forms in which the objects before him appear to be grouped in his camera and to the position of the sun at the time—in short, to the composition and lighting of the work—he may, like Professor Donkin in his Alpine studies, return with small pictures that on enlargment are as pleasing in effect as they prove full of the most minute and instructive physical detail. While touching on the reproduction of Alpine scenery, we may conveniently direct the attention of the visitor to the set of views in Switzerland (23—The Lyskamm, Mont Blanc, Marjelen See, and Monte Rosa) by Signor Vittorio Sella, to which a medal is awarded. These large and singularly fine pictures are printed direct from the negatives taken in the Alps.

In comparison with the changes which have been made in other branches of the photographic art, the most important advance noticeable this year is in portraitnre. The greater uniformity of quality obtained by improved methods of manufacturing sensitive gelatine plates has, no doubt, something to do with this. A photographer's attention, too, is not now distracted by fears lest his prepared plate should be spoilt if he stops to improve the pose of a subject at the last moment; but with the power obtained by the use of rapidly-impressed plates of taking portraits which are more or less satisfactory, as pictures of people in their own homes, there has grown up a demand for more naturalness and ease in style. Several examples may be found in the gallery of this change, which substitutes for the plain or painted background, and the classic pillar and balustrade, or the hack table and chair, the luxury of Oriental hangings and æsthetic furniture and surroundings, with a tendency, however, it must be observed, to so fill the picture with pretty detail, that the portrait of the sitter is apt to be lost in the crowd of objects. The series of portraits of ladies (243-252), for which the judges have awarded a medal to Mr. H. S. Mendelssohn, may be cited, those of Lady Brooke and child, and of Miss Grant, as showing both the gain in freedom of treatment, and the dangers of over-elaboration of accessories. Turning to the introduction of figures into landscape and interiors, it is matter for congratulation that photographers who were tempted by the facilities new discoveries placed in their hands to essay the presentment of emotional incidents, already show a chastened ambition. Brought in as the groups of children and rustics are in Mr. H. P. Robinson's (64) "The Cuckoo," and (66) "He never told his Love"; in Mr. J. Gale's (69) "Off to Market," and (70) "The Smuggler's Cave"; and as the little girl feeding ducks is

in Mr. John G. Horsey's view of a charmingly embowered homestead (183), "The Pets," pictorial effect is heightened by the presence of the figures; and even in the cottage interior (282), "Mother's Love," a composition by Mr. J. Hubbard, which has gained a medal, the photographer is well within the bounds set him by his dependence upon the dramatic attitude of his model. When, however, he goes beyond this, and attempts the portrayal of strong feeling, as in an admirably-composed picture of a country churchyard, where a girl has thrown herself on a grave in a passion of grief, hiding her face in her sister's lap, the very realness of the scene suggests unreality and simulation, because the author of the picture has not the painter's privilege of presenting such an incident as imagined, and the mind revolts from the supposition that the camera could be turned in cold blood on a scene of such distress.

Of instantaneous photography there are many specimens, the most remarkable for artistic worth being the medal pictures (309) of yachts racing in the Solent, taken by Messrs. G. West and Son from a sailing boat, so that camera and subjects were both moving when the exposure of the plate was made. Another medal is awarded to Mr. W. P. Marsh for studies of breaking waves, and there is a well-defined and consequently apparently motionless express train, of which the picture (206) by Mr. C. Grassin was taken with an exposure of the three-hundredth part of a second. Studies of woodland, mountain, sea, and clouds are as numerous and as freshly delightful to the lover of good photographs as ever, admirable among many being (381) views at Hampstead by Mr. Edward Dunmore; (366) Rydal Water, and other views by Mr. W. Wainwright, jun.; (352) "At Home and Abroad," some Yosemite and other scenes by Mr. Andrew Pringle; (202) Bonchurch Old Church, by Mr. J. Duncan Peirce; several in a set by Captain Abney; (537) views in Surrey by Mr. C. A. Fernely; (463) North Wales by Mr. A. E. Durham; (552) The Valley of Desolation, South Africa, by Mr. R. Harris; a stormy seascape (260), "Rescued," by Mr. H. J. Godbold; and peeps into cloudland obtained by Mr. B. Wyles. Arresting attention by their delicacy of tone, the platinotype prints repay one for the close examination they invite. A medal has been deservedly awarded for a set (209 and 219-221) exhibited by Mr. H. B. Berkeley. The chilliness of a misty wintry river scene (167), by Mr. G. Renwick, is suggestively rendered by the cold bluish grays of this process, which, with quite another purpose, is no less happily suited to the copy (145) by Mr. F. Hollyer, of Mr. Burne Jones's painting, "The Six Days of Creation." Architectural work is well represented by Mr. F. Machell Smith's wondrously massive and solid-looking north portal of the cathedral at Chartres, by the marble-like brilliancy of the Rev. J. S. Knight's temples and monuments at Athens; by Mr. G. Hadley's interiors of Lincoln Cathedral; and Mr. Alfred Tagliaferro's medal picture (234) of the tombs of the Knights of Malta in St. John's Church. Mr. Henry Stevens again contributes some of his matchless studies of flowers and foliage. Of the scientific and educational uses of photography, there are examples in the microscopically small pictures on glass of Saturn's rings shown by Mr. A. Ainslie Common, F.R.A.S.; and again in the magnified photographs of sections of plant stems, parts of insects, &c., by Mr. J. Renton Dunlop, and (485) two photographs of lightning by Mr. M. Auty. Small but masterly copies of oil-paintings are shown by Mr. Edwin Cocking. Photo-engraving is illustrated by Messrs. T. and R. Annan, and the portraits of the late Duke of Buccleuch and Sir Daniel M'Nee, and the three-quarter figure of a girl, are full of promise for the future of this branch of art.

REPORT ON COMMERCIAL BROMIDE OF POTASSIUM.

BY PROF. VIRGIL COBLENTZ.*

At the suggestion of the Chairman of Papers and Queries, that samples of the same manufacturer's product should be examined at different intervals of time, samples of six American and two European manufactures were obtained in original unbroken packages in the summer of 1883; and again the same ones in the spring of 1884, this being done in order to ascertain any differences in quality of different lots issued by the same manufacturer during the year. To judge a manufacturer by the examination of a single sample would be unfair; but to examine different lots of his own make would exhibit the uniformity of his own product. Considering the quantity of material that the manufacturers turn out at a time, the two examinations within a year would no more than exhibit the variances of his products. Of the two foreign samples, one was German, the other English, both in cubes. Of the six American, two were granulated. The pharmacopœia requirements, being of first importance, are first considered; though afterwards a few unofficinal tests were also applied where it might be thought to be of some interest for comparison. The U. S. P., 1870, and Ph. Germ., 1882, tests were also applied secondarily.

Taken in this order of the Pharmacopœias, we have—

1. *Solubility.*

Soluble	1	part	in 1·6	parts of	water	U. S. P., '80 at 15° C.
,,	1	,,	200	,,	alcohol	
,,	1	,,	1	part	water	U. S. P., '80 boiling point.
,,	1	,,	1·6	,,	alcohol	
,,	1	,,	2	parts of	water	Ph. Germ. 1882.
,,	1	,,	200	,,	alcohol	

The British Ph. states it to be readily soluble in water, and less so in spirit, but does not give exact proportions.

The solubility of the samples as taken in distilled water at 212° F., and in alcohol (of 97 per cent. vol.) at 60° F. The solubility in distilled water was taken by adding the powdered salt in small portions at a time to a definite weight of water while boiling in a flask fitted with an inverted condenser, keeping the proportions of water constant; the addition was continued till the salt was in slight excess, when the saturated solution was quickly decanted from the residue, which was then thrown upon a tarred and moistened filter, dried and weighed; the insoluble residue deducted from total amount used gave quantity dissolved. The solubility in alcohol was ascertained by digesting an excess of the finely pulv. salt in 20 c.c. of alcohol (97 per cent.) contained in a closely stoppered tube, and after standing some time, during which it was frequently shaken, it was thrown on a filter moistened with alcohol, and after filtration a small portion of alcohol was added to force out any adhering solution; the filtrate evaporated to dryness and weighed.

The solubility in alcohol serves to detect only gross impurities to a certain extent, such as carbonates, iodides, free alkalies, &c. The amount of bromide itself dissolved being about 1 part in 200, the amount of impurities dissolved by the alcohol might be roughly calculated from this.

2. *Alkalinity.*—"Faintly alkaline—single crystal laid upon moistened red litmus paper should not at once produce a violet blue stain (absence of more than 1 per cent. of alkali)" (U. S. P., 1880).

"Its aqueous solution does not affect the colour of litmus or turmeric" (U. S. P., 1870).

"A few pieces placed on moist litmus should not change the colour to violet blue" (Ph. Ger., 1882).

The British Pharmacopœia mentions nothing in regard to the reaction.

The lime-water test may also be added to this, the carbonates being detected by the white turbidity occurring upon the addition of a little concentrated solution of the salt to lime-water.

Since the lime-water test does not reveal less than 1 per cent., and is sometimes less sensitive when the conditions are not closely followed, and the other tests being indefinite, a volumetric estimation of the alkali was made, viz.: 3 grammes of the dried salt having been deprived of water by ignition at a strong heat, were dissolved in about 30 c.c. of water in a beaker, solution of litmus added, and then heated to boiling, decinormal solution of H_2SO_4 was run into the liquid from a burette, until a slight excess remained after the continuance of the heat to expel the liberated CO_2, the solution being of a bright red colour. The excess of acid is then inversely titrated with standard KOH solution. From the number of cubic centimetres of acid solution, the amount of pure K_2CO_3 contained therein may be calculated, each c.c. of the normal acid solution corresponding to ·0692 grams of anhydrous K_2CO_3.

A small per cent. of alkali, though a general feature in most all the medicinal bromides, is hardly objectionable from a therapeutic point. It must, however, be remembered that the presence of any may cause incompatibilities in solutions such as contain alkaloids, iron salts, &c. In such cases, where the salt is supposed to be alkaline, it is best to be first dissolved, tested with litmus, and if the reaction be alkaline, neutralized with dilute HCl [or HBr] before adding the alkaloidal salt.

3. *Bromate.*—"If dilute H_2SO_4 be dropped upon crushed crystals of the salt, they should not at once assume a yellow colour" (U. S. P., 1880).

* A communication to the American Pharmaceutical Association.

"When its solution in water is mixed with a little chlorine, . . . chloroform agitated with it, on falling to the bottom, exhibits a red colour" (Br. P.).

"If spread in powder form on a porcelain plate, it should not be coloured yellow immediately on addition of H_2SO_4" (Ph. G., 1882).

"In aqueous solution it may also be detected by the liberation of bromine upon addition of a few drops of H_2SO_4 dil., imparting a yellow colour, which, upon subseqdent agitation of the solution with a few drops of CS_2, will be absorbed by the latter" (Hoffmann and Power, Anal.)

The U. S. P. and Ph. Germ., essentially the same, both depend on the immediate colouration of the salt on the addition of H_2SO_4; this test is practically a close one when carefully followed. Of course, the presence of this salt should always be avoided by the manufacturers, and, when present, it is there from carelessness or neglect of proper precautions in manufacture. Since the bromate is well known to be poisonous, though reducing agents do not liberate the free bromine as readily as iodine from the corresponding iodate, as might be possible in the stomach, still, as potassium bromide is generally given in much larger doses than the iodide, the presence of more than traces of bromate would render its administration inadmissible.

4. *Iodide.*—"If one gramme of the salt be dissolved in ten c.c of water, some gelatinized starch added, then a few drops of chlorine water be carefully poured on top, no blue zone should make its appearance at the line of contact of the two liquids" (U. S. P., 1880).

"A solution of the salt mixed with mucilage of starch and a drop of an aqueous solution of bromine or chlorine does not exhibit any blue colour" (B. P.).

"A solution of one gramme of salt in 100 c.c. of water should not, after the addition of a few drops of Fe_2Cl_6, impart a violet colour to chloroform" (Ph. Germ., 1882).

Bonis recommends adding a few drops of Fe_2Cl_6 to a test tube containing a sol. of KBr, and heating to a gentle ebullition, when the iodine is precipitated, while the bromine remains intact. This makes a very delicate test, even for traces. In performing the U. S. P. test, care should be taken, in adding the chlorine water, not to add too much at once, since, in the presence of the iodine, the excess of free bromine liberated may in every case mask the reaction. Advantage of this reaction has been made use of in the separation of iodine from bromide of potassium. The contaminated salt is dissolved in water, and then bromine water is added in small portions at a time to the solution heated to boiling, until it is present in excess. The solution is then evaporated to dryness, thus driving off the iodine. Iodine, though not often an impurity in bromine at present, still might occasionally occur in poor samples, and in this way enter as an iodide in the manufacture. An intentional adulteration with the iodide in any quantity is not probable, considering the difference in the market value, although some years ago the presence of iodides in bromide was of frequent occurrence in the English market—probably added for the reason that the bromide, when containing any iodide, crystallizes in much larger crystals, also enhancing the beauty and appearance of the salt.

(To be continued.)

Patent Intelligence.

Applications for Letters Patent.

13,103. Ludwig Hermann Philippi, 55, Chancery Lane, London, for "Improvements in reproducing photographs by printing, and in producing printing blocks and rollers therefor."—Dated 2nd October, 1884.

13,107. William Thomas Morgan, and Robert Leamon Kidd, 45, Southamptou Buildings, London, for "Improved means for the production of permanent or durable photographic pictures upon canvas, linen, wood, or similar substances."—Dated 2nd October, 1884.

13,156. James William Thomas Cadett, 84, Grove Lane, Camberwell, S.E., for "New or improved arrangements applicable to photographic shutters whereby the duration of exposure can be varied."—Dated 3rd October, 1884.

Patent Sealed.

4989. James Sturrock, Cashier, Dundee Advertiser Office Dundee, for "Changing sensitized plates in photographic cameras."—Dated 17th March, 1884.

Proceedings of Societies.

South London Photographic Society.

An ordinary meeting was held on Thursday, October 2nd, in the large room at the House of the Society of Arts, Mr. W. Ackland, Vice-president, in the chair.

The minutes of the previous meeting having been read and confirmed,

The Hon. Secretary stated that an engrossed memorial and a cheque for £50 had been handed to Mrs. Statham, the widow of the late president, it having been considered better to allow the family to use the amount in such a way as might seem to them best for commemorating the life and labours of the Rev. F. F. Statham. It will be remembered that the subscription originated during the lifetime of Mr. Statham, the intention being to present him with something that should serve to remind him of the regard in which he was held by the members of the Society; but on his death it was arranged to make such use of the sum as might be agreeable to the family.

A letter from Mrs. Statham, in which she expressed her appreciation of the good feeling of the Society towards Mr. Statham, was then read.

Mr. W. Brooks then took the chair, while Mr. Ackland read a paper upon "Furnell's Lens" (see page 651.)

The Chairman, in commenting upon the exceptionally interesting character of the paper, which contained much that was new to himself, remarked that the new lens was evidently one which could be made at a comparatively low price, and was probably not intended to altogether supplant the expensive instruments now manufactured by the best opticians; but the unprofessional photographer will often find the advantage of possessing the means of varying the focal length of his objective, without going to the considerable expense of a battery of good lenses.

Mr. Cowan thought the principle suggested by Mr Furnell likely to be an important one, and to illustrate the very trifling nature of the error as regards want of coincidence between the chemical focus and the actinic focus, he showed pictures of Claudet's focimeter taken at very close quarters, and it was surprising to note how little the actinic focus was affected by addition on change of the non-corrected lenses. Mr. Cowan had tried lenses built up on the Furnell system in actual work, and he was quite satisfied with the result.

Mr. J. Traill Taylor remarked that when a deeply-curved front combination is used, there is much latitude as to the back combination.

Mr. Ackland here remarked that, although his theoretical knowledge would have led him to reject the notion of making good working lenses as suggested by Mr. Furnell, he had proved by actual experiment that the arrangement possesses practical value.

Mr. Taylor pointed out that something very near to the Furnell lens was patented many years ago by Mr. Grubb; a back consisting of a positive and negative lens, the joint result of which amounted to plain glass being used in conjunction with a deep meniscus-corrected front. Morrison, of New York, also makes a lens with an uncorrected back, which may be interchanged against others.

Mr. Ackland said that flat surfaces in a photographic lens very much cheapened the cost of production, as extremely true flats are not required, a trifling convexity or concavity being unimportant; and in reply to Mr. Burton, Mr. Ackland said he did not anticipate that the Furnell system could be applied to large lenses with great advantage.

Mr. W. Cobb now observed that he had taken very great liberties with the rectilinear or symmetrical lenses of the leading makers of the present day; uniting the fronts and backs of various instruments, so as to build up a combination of the desired focus, he had found all the combinations to be good.

It was remarked that there is nothing very new in using spectacle or other lenses for modifying the focal length of a photographic objective, and that the touchstone of success in working with such extemporised instruments is the use of a small stop. With a portrait lens or other combination working at $\frac{1}{32}$ or thereabouts, very few liberties can be taken.

The meeting then adjourned until the first Thursday in November, when Mr. J. T. Taylor will give a lantern lecture on "Florida, and its Orange Groves," the illustrations consisting of some sixty photographs, which will be projected on the screen.

Some business relating to the future management of the Society was then transacted.

London and Provincial Photographic Association.

At the usual weekly meeting, Mr. A. L. Henderson occupied the chair.

The Chairman read an extract from a letter he had received from Mr. Alex. Henderson, of Montreal, in which the writer referred to a flash of pale flame following the diamond cut on a sensitive plate, which continued visible after the plate had been exposed to daylight, and again taken into the dark-room. The writer also drew attention to a part of a stereo pictures sent. The negative was taken in 1858 on a Hill Norris plate. The print had been sized with gelatine, and gum-dammar varnish passed over it.

The Chairman said he had in his possession now a print over which he had brushed gum dammar varnish, but omitted to cover it entirely. That part of the print which had not been covered with the varnish was almost entirely faded.

The Chairman showed an automatic retoucher that he had brought from America. At the end of a pointed metal cylinder of the size and shape of an ordinary pencil, was fixed a cylindrical metal box enclosing a clockwork arrangement, wound by a fixed key, which gave motion to a metal point at the tip of the pencil, forming a series of dots when held to the film of a negative. Three small buttons outside the metal case regulated the rapidity of stroke at will, or stopped the works when required.

Another American novelty referred to by the Chairman was the "Air Brush," a small machine held in the hand connected with an air pump—air from a compressed air-chamber being employed as the distributing medium, causing the liquid pigment contained in a separate receptacle to be blown in a fine spray, enabling the artist, by the angle or distance from the paper at which the machine was held, to produce the finest line or the broadest shadow with immediate effect. A specimen of the work done with the air-brush in a few minutes was passed round, showing the delicate effects and fine modelling which the machine was capable of giving in the hands of the artist (see page 370 of the present volume).

A gelatino-chloride plate developed with pyro was shown by Mr. W. A. Haddon; the developer used was the Munroe, diluted, and restrained with bromide of potassium.

Edinburgh Photographic Society.

The ninth ordinary meeting was held in 5, St. Audrew Square, on the evening of Wednesday, 1st October, Mr. W. Neilson, President, in the chair.

The minutes of last meeting having been approved,

Mr. Norman Macbeth proposed that a small committee be appointed to draw up details for a monthly competition among the members, in order to make the study of the picturesque more an object of the Society. He said:—"It would be a good arrangement for the Society if each department were kept distinct and under special committees, so that full justice be done to them respectively. For instance, I would divide the objects of the Society into three departments, viz., the chemical, the artistic, and the mechanical. I would have small committees to each, not exceeding three, and that they have no other department to occupy their mind but the one with which they were specially adapted for and appointed. In the meantime, I would press upon you the claims of the artistic department, particularly in reference to composition and effects of the pictorial. With a view to the study of this, I would propose that at each monthly meeting of the Society members bring forward some of their selected work done during the summer, that these be submitted not so much for mere criticism, but for friendly conference, that members be called upon to give their opinion as to the respective merits of each, and specially pointing out what they conceive would be an improvement. At the close of the conference, a vote by papers, numbered according to the number attached to the respective work which the members consider best, be taken. The one having the greatest number of votes to be set aside for the custody of the committee, and, at the close of the session, another vote be expressed by the Society as to the best of all that were formerly approved of, and probably some award be given."

The motion was carried, and Messrs. Norman Macbeth, Alexander Matheson, and John Simpson were appointed as a preliminary committee to consider the matter.

The President proposed that the balloting for new members be by means of tickets with the words "admit" and "reject" printed upon them, the ticket to be dropped into the ballot-box by members on entering the room. This was agreed to.

The following gentlemen were proposed as new members, to be balloted for at next meeting:—Messrs. F. W. Palmer, Edward Binning, Alfred G. Tagliaferro, and Charles Waterson.

Mr. J. M. Turnbull next communicated some notes on "Sulphite of Soda in the Developer." Having traced the history of this salt as an adjunct to the developer, he proceeded to show the reason for the contradictory evidence as to its usefulness. He pointed out the unstable character of sulphurous acid, and also of the liability of the sulphite of soda to change to sulphate. The sulphite of soda as purchased was usually strongly alkaline, and to remedy this, many people added citric acid; but this produced citrate of soda, which is a powerful restrainer, hence *sulphurous* acid should replace citric acid. By this means a reducer is formed instead of a restrainer. Sulphurous acid is, however, a feeble acid, and it required about fifty per cent. of this acid to be added to the ordinary sample of sulphite of soda to secure the desired acid reaction. It was to be remembered that the same sample of sulphurous acid was constantly getting weaker, the gas which forms the acid constantly escaping every time the bottle is opened, and therefore it is necessary to ascertain by test paper that sufficient acid has been added. When these simple directions were followed, the sulphite developer was entitled to all the praise and none of the blame that had been bestowed upon it, the development being rapid, the negatives beautifully clean and of fine colour.

In reply to a question concerning the hydrokinone developer, Mr. Hugh Brebner said he had discarded as impracticable the formula issued therewith, namely, 2 grains hydrokinone, 1 ounce water, and 5 minims liquor ammonia, as even with a full exposure he could only succeed in bringing out the very faintest of images, and that, too, after an absurdly protracted development. By increasing the proportion of hydrokinone from 0·5 per cent. to somewhat less than 2·0 per cent., he found that very great density, perfect detail, and exceptional quality could be easily produced with considerably under-exposed plates (home made). Capt. Abney, the introducer of this developing agent, claims that a 4·0 per cent. to 6·0 per cent. strength only half the exposure necessary with alkaline pyrogallol is required. Dr. Eder, again, states that "a 2·0 per cent. aqueous solution of hydrokinone, to which a few drops of ammonia have been added, is thin, but admits of silver intensification." Mr. Brebner, while regretting the limited extent of his experience, nevertheless expressed his opinion that hydrokinone promotes abnormally short exposures, great density, and exceptionally fine quality. The only drawback which he found this developer to possess was an apparently characteristic ruddy-brown colour, which, although beautiful in itself, was scarcely conducive to rapid printing. Mr. Brebner, however, deprecated the acceptance of his evidence as conclusive upon any point whatsoever.

Mr. A. B. Stewart next developed several negatives by the potash developer of Mr. Beach. He said: "For some time back considerable discussion has been going on in the columns of the Photographic News as to the merits of a developer which would seem to be, for general use, better suited to the requirements of the photographer than any other yet published. I now give a summary of that correspondence." Of the innumerable developers which have from time to time been promulgated, the principal survivors seem to be pyro and ammonia, pyro and washing soda, and ferrous oxalate. Hydrokinone I do not include, as its price, if nothing else, would probably prevent its general adoption. But to each of the developers which I have mentioned there exists some objection. The pyro and ammonia developer gives off noxious fumes, and in cases of prolonged development causes stains and fog in the negative. Of the washing soda I have had no experience, but I see from the photographic journals that complaints are largely made that the negatives produced by it are apt to be yellow. The objection to the ferrous oxalate is that it is non-elastic, there is no latitude for exposure; and, in my experience, prolonged development produces iridescence, especially round the edges of the plate. The potash developer of Mr. Beach, however, seems to be free from these objections. The published formula is:—

Pyro Solution.

Warm distilled water	2	ounces
Sulphite soda (chem. pure)	2	,,

Dissolve; and when cold add—

Sulphurous acid	2	ounces
Pyrogallic acid	½	ounce

Potash Solution.

A	Water	4	ounces
	Carb. potash (chem. pure)	3	,,
B	Water	3	,,
	Sulphite soda (chem. pure)	2	,,

Combine A and B in one solution.

For a 5 by 4 plate with instantaneous exposure, take 1½ ounces of water, 2 drachms of pyro solution, and 1½ drachms of potash solution. The advantages claimed for this developer are—that with it plates require less exposure, that it does not give off any deleterious fumes, that it does not fog or stain the negatives, it needs no restrainer, but is simply modified by dilution to meet over-exposure where necessary. Complaints have been made by some workers that this developer causes the plates to frill. I can only say that I have not found it to do so, and I do not use alum until after fixing, when I put the plates in a chrome alum bath for a few minutes. You will observe that chemical purity is strongly insisted on in the formula given, but I may tell you that in making my solutions I used the ordinary commercial qualities of the different salts, and while this may be the reason of the dark colour of my pyro solution, I do not find that the developer works any the worse. I had intended to bring plates with varied exposures, but yesterday afternoon when I began to prepare for to-night the sun had disappeared, though the air was clear, while the wind was so high that my camera would not stand without being held, and an accident to my shutter rendering it useless, I had to make the exposures as rapidly as possible with the one hand, while I held the camera with the other. My lens was an old French stereoscopic doublet, with a focus of 4 inches, and the aperture of the stop I used was ¼ of an inch in diameter for the first plate, and $\frac{1}{16}$ for the rest.

A discussion on the question, "Has the introduction of the modern gelatine dry plate been advantageous?" was to have been opened by Mr. J. Howie, who, it was understood, would have replied in the negative, but, as he failed to make an appearance, Mr. W. Crooke said that from all points of view he considered the modern gelatine plate had been of immense advantage. For landscapes and studio work they enabled subjects such as moving objects and passing expressions to be captured that could not be seized by collodion, but for reproductions of engravings and similar objects requiring strong contrasts, he believed that collodion still maintained its supremacy.

Members were reminded to send in specimens of work for the annual display which takes place at the next meeting. These should be in the hands of the Curator not later than the day before the meeting (Tuesday, Nov. 4th), so as to allow of being hung properly.

A vote of thanks to the Chair terminated the proceedings.

Dundee and East of Scotland Photographic Association.

The first monthly meeting for the session 1884-85 was held on Thursday, the 2nd inst., in Lamb's Hotel, Dundee, Mr. J. C. Cox, President, in the chair.

After the routine business had been disposed of,

The President delivered his annual address as follows:—I have no intention of giving an address; but you will expect from me a word of congratulation on this the opening night of our fifth session. Before I do so, allow me to refer—and it is with regret—to the loss our science has sustained by the death of several prominent workers, namely, the Rev. F. F. Statham, who was twenty-five years President of the South London Photographic Society; Mr. H. Baden Pritchard, editor of the Photographic News; and Mr. C. Jabez Hughes—whose names were honourably associated with the literature of photography. Of these our immediate connection lies with Mr. Pritchard, who, as you will remember, so kindly acted as one of the judges at our highly-successful Photographic Exhibition three years ago, and whose decisions gave the utmost satisfaction, and who gave a staunch support to everything tending to the advancement of photography. We cannot but lament his death. Nor can I but notice the decease of Mr. Colin Sinclair, of Edinburgh, who also kindly gave his services as judge at one exhibition. The report of this Society, which you have before you, and which I understand is to be taken as read, must, if we look back two or three years, convince us that it is thriving beyond expectation in membership, in attendance, in quality of work produced, in free offering of papers on interesting subjects, and last, but by no means least, the credit at our bankers. Not the least of our success, I may say, is due to our young Secretary, Mr. D. Ireland, Jun., who is an enthusiast himself, backed up by his friends, the Committee of Management, and the members in general. He certainly has worked well for the Society, and he means, I have no doubt, to still further increase his usefulness. I have to ask you to accord him a vote of thanks, and the same to our worthy Treasurer, Mr. J. Robertson, and to our Auditors, Mr. Baxter and Mr. Rodger. The President suggested the offer of practical lessons at a small fee, in the rudiments of photography, and closed by saying that he should also like to broach the idea of holding another exhibition.

Mr. G. D. Macdougald then read an interesting and able paper on "Chemistry and Photography," on which some discussion ensued, and for which a hearty vote of thanks was awarded.

It was remitted to the Council to make arrangements for a series of lecturettes, to be given at the monthly meetings, on different branches of photography.

An inquiry was found in the question-box as to whether better results were obtained by washing prints thoroughly before toning, and it was agreed that although the toning was quicker in the case of an imperfectly-washed print, still most of the tone was lost in fixing. A washing of about half-an-hour in the case of ready-sensitised paper was recommended.

A vote of thanks to the Chairman brought the meeting to a close.

Coventry and Midland Photographic Society.

A meeting of this Society was held on Thursday, 2nd October.

The President (Mr. Andrews) showed a very portable camera stand made out of three bamboo fishing rods, which was greatly admired by the members present on account of its lightness and simplicity of construction.

Mr. Bayntон, who had promised "Practical details on dry plate development for beginners," recommended the following developer:—

No. 1.—Citric acid	20	grains
Water	20	ounces
No. 2.—Strong liquid ammonia	1	ounce
Bromide of potassium	100	grains
Water	3	ounces

Into 2 ounces of No. 1 put 4 grains of pyro; add 1 drachm of No. 2, and immediately flow over the plate.

The meeting then adjourned to a large and well appointed dark room to witness the demonstration, which was most successful.

This Society commenced by holding its meeting in a large room at the Coventry Provident Dispensary; but, either through the meeting being too formal, or from some other cause, it was nearly on its last legs; but it is now holding its meetings at members' houses, and, with the introduction of a "pipe and glass," there is every hope of success.

Talk in the Studio.

Collodio-Chloride Emulsion and Paper.—We have received from Herr Romain Talbot, of Berlin, some samples of Risse's emulsion and paper, and find that excellent results can be obtained with no more trouble than is involved in the ordinary method of printing on albumenized paper. Enamelled paper is used, and to coat it with emulsion it is stretched on a wooden frame, and after a sufficient quantity of emulsion has been poured on, the excess is drained off at one corner. When the film is dry, a second coating is given, this time the excess being drained off at the opposite corner. The exposure required is less than that ordinarily given in the case of albumen prints, and a sulpho-cyanate bath is recommended for toning.

No. 1.—Chloride of gold	60	grains
Distilled water	3	pints
No. 2.—Pure sulphocyanate of ammonium ...	3	ounces
Distilled water	3	pints

No. 1 is added to No. 2, and the brownish precipitate which forms is allowed to remain, the solution keeping for years in this condition. To tone, one part of the above concentrated solution is mixed with ten parts of water. The fixing bath recommended is one of about half the usual strength—two ounces of hyposulphite to a pint of water.

Displacement of Chlorine by Bromine in Chloride of Silver.—In the current number of the *Berichte*, Mr. T. S. Humpidge describes a recent series of experiments relating to the displacement of chlorine by bromine in chloride of silver at various temperatures and periods of time. When using an equivalent proportion of an aqueous solution of bromine at 44·4° C. for twelve hours, fourteen and a half per cent. of chlorine was displaced.

Some Reactions of Albumen.—By E. Grimaux (*Compt. Rend.*, 98, 1336—1338).—When dilute solutions of albumen are mixed with small quantities of sodium chloride, calcium sulphate, magnesium sulphate, ammonium chloride, &c., they become coagulable by the action of heat. A similar effect is produced by passing carbonic anhydride into the solution. Albumen, as is well known, is not modified by dilution in the cold, but if the liquid is boiled, modification takes place. The author finds that if a 1 per cent. solution of albumen is heated at 90° for some minutes, the albumen undergoes complete modification. The limpid solution is not coagulated by boiling, but simply becomes opalescent. When treated with carbonic anhydride in the cold, it yields a gelatinous precipitate, which redissolves when a current of air is passed into the liquid. The precipitate also re-dissolves if the liquid is placed in a vacuum over potash, or if the precipitate is collected, washed, and placed in aerated water. Dilute acetic acid produces a gelatinous precipitate, easily soluble in excess, re-precipitated on neutralising with an alkali, but soluble in an excess of the latter. The addition of sodium phosphate prevents precipitation by carbonic anhydride, but not by acetic acid, and the solution gives all the reactions for casein. The modified albumen becomes coagulable by heat when the solution is mixed with small quantities of sodium chloride, calcium sulphate, &c. Carbonic anhydride does not completely precipitate solutions of modified albumen. The filtrate contains a peptone, and if the solution of albumen has been boiled for some hours instead of being heated at 80°, the substance precipitated by carbonic anhydride diminishes, and the amount of soluble peptone increases. It would seem that dilution dissociates albumen into free soda and an albuminoïd, which becomes hydrated and converted into an albuminate. With carbonic anhydride, this albuminate forms an unstable insoluble compound, which loses carbonic anhydride when exposed to air or in a vacuum, and re-dissolves. This last reaction is common to many colloïds.—*Journal of the Chemical Society.*

Photographic Club.—At the next meeting the subject for discussion will be, "The Collodio-Albumen Process as applied to the Production of Transparencies for the Lantern and for Enlargements." On Saturday, the 11th inst, there will be an outdoor meeting on Wimbledom Common, leaving Waterloo Station by the first train after 2 p.m. for Putney Station; to meet at the Windmill on Wimbledon Common. Visitors coming to London to view the Exhibition of the Photographic Society are invited to the Wednesday evening meetings at Anderton's Hotel, Fleet Street, at 8 o'clock.

To Correspondents.

*** We cannot undertake to return rejected communications.

Metallic.—They are due to minute particles of metal rubbed off from the paper making machinery, and reduce the nitrate of silver. We are afraid that the only thing you can do is to obtain another sample of paper.

Bromley.—Make the mucilage tolerably thick, and strain through fine muslin; then apply with a broad and flat camel's hair brush.

C. W. and S.—We think it is too late according to the regulations, but will write to you.

R. A.—We know nothing of the firm, and have no means of ascertaining, but think your fears are likely to be unfounded. The quality of the work you can do is the real point.

X. X. L.—We cannot tell you who are the makers—indeed, we have not heard of it under the name you mention; but a very good ruby lamp can be obtained for the sum you mention, at any photographic material warehouse.

F. Brown.—The simplest way is to strip it by the method of Mr. Plener (see page 122 of the present volume). 2. Remove any loosely adherent dirt by sponging the surface with water, and then copy it with a long focus lens; giving plenty of exposure.

J. M.—We understand that the manufacturer does not advertise his own address, as most stock dealers keep the goods, and he prefers to do his business through agents.

F. F. H.—(Wokington). Dammar 60 grains, benzole one ounce. Apply as quickly as possible with a broad camel's hair brush.

A. G. Levy.—1. The actual cutting down of the film is the best method in such a case, and in doing this it is often possible to improve the negative very much, when the manipulator possesses artistic skill. 2. It operates by whitening the film, and it is possible that your negative was too dense to be successfully treated by the method.

A. G. B.—It is a very excellent and well-made apparatus, and has been described in the News. We do not know of any difficulty likely to arise in using it.

H. Foss.—Write to the Meissenbach Company, Farringdon Street, London.

Constant Reader.—The chances are against it being good enough; although portrait lenses are now usually supplied with the lantern, such lenses are almost always low-priced French instruments.

C. A. M. W.—The addition of bromide is undoubtedly advantageous when the over-exposure has been considerable, but when about one and a-half times or even twice the normal exposure has been given, simple dilution is better. Of course, the proportion of bromide requires a very careful adjustment, and we shall be glad if you will send us a letter embodying the results of your experience regarding the point touched upon in the first part of your communication.

H. S.—1. It is not very well suited for portraiture, but may be a trifle better than ordinary gas light. 2. It does not appear to us that it would in any way infringe the patent. Did you notice Mr. Frewing's article on page 439? But if you gather any idea from it, be very careful to avoid accident from the arsenical fumes.

Norman May.—Thank you very much; we will refer to the matter when a suitable opportunity occurs.

Ed. V. B.—No standard of any kind is recognised, the variation being so great.

Essayist.—You will not get quite all the information you require in any one book yet published; but you might gather it all from the back volumes of the Photographic News. You had better obtain the new edition of Captain Abney's "Instruction," which will be published very shortly. Perhaps if you can get a copy of Hunt's Photography from a second-hand bookseller, it may help you.

Scotland.—The mere purchase of a negative at a sale does not vest the copyright in yourself. It is our impression that each copyright must be specially assigned, and the transfer registered.

W. W. H.—It is better, if possible, to make them of the right density in the first instance, as neither the intensification nor reduction of gelatine negatives is invariably satisfactory.

A. E.—The colours should be mixed with the varnish known as "crystal paper varnish," but they will all change under the action of light and time.

Fred. A. Bellamy.—After fixing and thoroughly washing. The proportions do not matter much within reasonable limits, as the reaction is allowed to continue until the whole of the deposit is altered.

James W. Filles.—The new edition of Captain Abney's "Instruction" will be ready in about a fortnight, and you had better wait for it.

Barton.—A mixture containing magnesium is necessarily expensive, but the following answers very well:—

Chlorate of potassium	8 parts
Sulphide of antimony	4 ,,
Sulphur	2 ,,
Magnesium dust	2 ,,

W. COTESWORTH, COPYRIGHT.

AN AWKWARD LEAD.

THE PHOTOGRAPHIC NEWS.

VOL. XXVIII. No. 1363.—*October* 17, 1884.

CONTENTS.

"THE AWKWARD LEAD," BY W. COTESWORTH.

To the non-professioual photographer, especially in England, photography owes much of its progress. To him we are indebted for the thousand and one experiments out of which the great central discoveries have grown, and, indeed, we owe not a few of the important completed processes to the indefatigable perseverance and skill of those who have taken up the art more for pleasure than profit. To the non-professional also we look for the large mass of faithful transcripts of nature that adorn our exhibitions; but we think we are right in saying that he seldom attempts what may be called the highest branches of the art, by which we mean those efforts which show the influence of imagination in choice or subject, suitable selection and arrangement of models, and the power to evoke the various shades of expressions and emotions which go to the making up of pictures in which mind, as well as skill, is displayed. It gives us all the more pleasure, therefore, to welcome pictures by an amateur in which some of these great art qualities are shown. In the present exhibition, Mr. W. Cotesworth has three pictures: "The Awkward Lead," "The Revoke," and "The Last Bit of Scandal." The first mentioned we have secured as our supplementary illustration for this week, and this admirable little picture, which might almost be called a photographic study after Meissonier, represents a party of whist players, and the costumes seem to indicate the period as that of the early part of the present century. The story is clearly told, and requires no further description; the composition is excellent, while the expressions, so difficult where various subtle shades of character are required to be shown, is perfect. The pleased, partly-triumphant, expression of the old Tabby (if we may speak of her so disrespectfully) sitting near the puzzled old gentleman, is delightful. It goes to just that point, without overstepping it, beyond which nature verges into caricature. The anxious look of the old gentleman's partner, and the calm of the lady to the left, all aid in telling the story and giving artistic variety to the group.

We understand that these pictures are Mr. Coteworth's first attempts at composition and combination photographs, and hope to see still better results from his camera.

We have one little suggestion to make which Mr. Cotesworth may find of use in making his future pictures. The nearer an object is to the eye, the clearer and more sharply defined it appears. In the "Awkward Lead" this law of nature has not been observed, as the background is in better focus than the figures. The effect would have been better if the photographer had sacrificed some definition, and kept the details of the room in subordination to the principal objects.

INTENSIFICATION WITH MERCURIC CHLORIDE AND SODIUM SULPHITE.

It is only within the last few months that it has become known that sodium sulphite (a salt which has already done good service in the pyrogallic developer) may be useful in connection with the intensification of negatives.

If a negative be bleached or whitened by being soaked in a solution of mercuric chloride, there are several reagents which may serve to blacken it; ammonia or Monckhoven's argento-cyanide of potassium solution being often preferred, because they yield delicate gradations of tint, which yield soft and brilliant prints. As a new means of darkening the whitened negative, sulphite of soda is now proposed.

Scolik, of Vienna, has made exhaustive researches with this intensifier, and he, in the *Photographische Correspondenz*, recommends the following method of working:—The fixed and well washed negative is allowed to remain in the mercuric chloride bath until the film is thoroughly whitened, the following bath being recommended:—

Mercuric chloride	1 part
Potassium bromide	1 ,,
Water...	50 parts

This solution may often be diluted with advantage, even to the extent of four times its volume of water, in order that it may not act too energetically. Still, a mercuric chloride solution made up in accordance with any other of the usual formulæ may be employed. The bleaching being complete, the mercuric solution is rinsed off, and a thorough washing at this stage is not required; indeed, the washing may be altogether dispensed with. Having now immersed the negative in a mixture of equal parts of saturated solution of sodium sulphite and water, the darkening action will be seen to take place steadily and slowly, just as when ammonia is used. No special precautions are necessary, any signs of irregularity in the action of the sulphite disappearing as the action becomes complete; and, as far as observation has extended, the negatives intensified as described are permanent.

As regards the chemical reaction which takes place, Dr. Eder gives the following particulars:—

The whitened negative contains mercurous chloride (calomel), and this is reduced to the metallic state by the sodium sulphite, just as appears to be the case when cyanide of potassium is used; thus the method now described may be regarded as analogous with Monckhoven's argento-cyanide of potassium method. Mercuric chloride is not reduced in the cold by alkaline sulphites, because stable double salts are formed; still, at a boiling temperature, reduction sets in, the mercurous chloride being first formed, and then metallic mercury. The above fact explains why it is unnecessary to wash away all traces of mercuric chloride before treating wieh sulphite of sodium.

THE DEATH OF MR. HENRY T. ANTHONY, OF NEW YORK.

On Saturday last, the 11th instant, Mr. H. T. Anthony, of New York, breathed his last, and the loss of one who has been so intimately connected with the progress of photography in the United States will be severely felt. Mr. Anthony was seventy years of age, and although he started in life as a civil engineer, he became so charmed with the Daguerreotype process on its introduction, that he finally dropped his original profession, determined to devote the whole of his energies to photographic work, and, in conjunction with his brother Edward, established the now celebrated firm of E. and H. T. Anthony and Co. In losing Mr. Henry Anthony the photographic world in the West loses one of its oldest investigators, one of its most appreciated writers, and one whose amiability of character made him beloved by all.

THE PALL MALL EXHIBITION.

Pictures and Apparatus.

second notice.

Having now noticed all the exhibits of those who have been awarded medals, perhaps the most convenient way will be to follow in the main the order of the catalogue; or, what amounts to the same thing, commence on the left as one enters the room; still, it will be convenient to go out of the regular order now and again, so as at the same time to review all the works of each exhibitor.

"Marli," a child's portrait (No. 1), by Mr. W. Slade, of New South Wales, is a pleasing study, but one cannot help feeling that it might have been better if the lens had penetrated a little more deeply into the shaded portions of the subject; and the same artist also contributes some good illustrations of Australian life, "Mending the Boat" (No. 521), and the "Pilot's Haven" (No. 532), being especially worthy of notice by the visitor. Dr. Morton had a difficult subject to deal with in taking the South Aisle and Wellington's Tomb in St. Paul's Cathedral (No. 2), but, notwithstanding this, he has obtained a very pleasing picture. No. 3, "A Portrait" by Mr. George J. Pitt, of Bethnal Green Road, is especially interesting, as showing how extremely dark the background of a portrait may sometimes be made without producing an unpleasing result. In No. 4, "On the Tyne at Bywell," by Mr. J. P. Gibson, of Hexham, we have one of those delightful combinations of cloud, water, and wood, which almost every ardent lover of his country considers to be eminently characteristic of his own native land. Nos. 5 and 6 by the same gentleman, "An Autumn Evening on the South Tyne," and "On the Allen near Staward," are productions with similar merits; but the best of Mr. Gibson's series is, to our mind, the "Blasted Oak on the Allen" (No. 7). Hartmann Koch's picture, "Schloss Hagenwyl" (No 8), would have made a more pleasing photograph had it not been taken so symetrically on the central portion of the plate; and as regards the remaining pictures by Herr Koch (Nos. 114, 115, 517, 518), it is impossible to say anything but in praise; the rich, warm, brown tone of 115, "The Roth-bach Fall," being especially well suited to the nature of the subject. Major Verney's "Studies" (No 9) is skied, so that one has to crane one's neck to look into the crowded masses of fully exposed and richly detailed foliage; and in the other exhibits of this gentleman (No. 256) "Burdunat; Roman Bridge, Bettws-y-Coed; Fairy Glen, do.; Pandy's Glen, do.; Conway;" 365, "Melrose; Penrhyn Slate Quarries," and 427, "Ripley; Wendover Manor, Chalfont," show the hand of the old practitioner, who knows how to expose for the deep shadows, and develop in accordance with the exposure. Mr. G. W. Wilson's enlarged view of the "Queen's View, Loch Tummel" (No. 10), does credit to the photographer, and to the Autotype Company as enlargers. With respect to No. 11, "Plant Studies," by Mr. B. Wyles, one can see more artistic quality than technical excellence; the backgrounds being uneven and marked in some instances. Mr. B. Wyles also contributes other pictures to the Exhibition, some exceptionally striking studies of cloud being among the number (160, 199, 229, 230, 413, 414); but the degrees of light and shade appear to us to be somewhat exaggerated, the gradations shown in the pictures extending from something very close to a jet black to a pure white. The rustic figures contributed by the same photographer also merit praise; No. 169, a woman carrying a bundle of sticks, is an effective study in red chalk; while No. 286 is a frame of pretty country views, perhaps the best being "The Minstrels."

The series of 12 by 15 views (illustrating Devonshire scenery), contributed by the School of Military Engineering (No. 12), and their "Near the Water Meet," Lyn Valley, North Devon (No. 373), show the most studiedly careful technical execution, together with much taste and judgment in the selection of good points of view. The pictures contributed by Mr. Malcolm H. Clerk tell their own tale; "The Last Bit of Scandal" (No. 13), and "A Counoisseur" (No. 14), being well worthy of mention—the facial expression of the recipient of the scandal well illustrating malicious delight in the former picture; while in the latter the attitude of the man who holds his glass up almost lovingly, is perhaps a trifle too theatrical. Mr. Clerk has other pictures: (159) "Chess," (222) "Stopped Again" (a watch), and (223) "The End of the Chapter," in which a girl is looking up a little tired, after finishing her hour's reading. No. 306 is an enlargement from No. 14. Mr. Clerk has in every case endeavoured to illustrate a sentiment or emotion by a photograph, and he deserves credit for what he has done in this very difficult branch of photography. A photographer who attempts this exceptionally difficult class of work is largely dependent on the skill of his models.

Mr. Cotesworth's "Awkward Lead," and "The Revoke" (No. 15), are so strikingly good, that we wonder their merit was not recognized by a medal. As one of these pictures forms our supplement this week, and a special article is given in reference to them, we need say no more in this place.

Mr. Arnold Spiller contributes some pleasant little pictures which he has secured during his holiday wanderings; No. 16, "The Maderaner Valley," giving a good idea of the grandeur of Swiss scenery compared with anything we can find in our island home, and indeed the same remark applies to No. 17, "Amsteg." "Luther's Window in the Wartburg, Eisenach," No. 141, has an interest for all who love to trace the springs of those revulsions of thought which have from time to time revolutionised the world. Mr. Spiller's "Misty Morning on Lake Wesen," No. 142, will hardly compare with the now celebrated photograph of McLiesh, and therefore suffers by comparison. No. 19, a quartette and three solos, is a neat little picture illustrating modern 'cycling; the quartette being a four-in-hand machine. "Where shall we go?" (No. 20) is realistic enough, and whoever has been out with a party of 'cyclists bound for nowhere in particular can appreciate the clever way in which Mr. Henry Smith makes his dumb figures speak.

Mr. J. H. Stone contributes some pictures which have more interest from a traveller's point of view than on account of their photographic merits, these being No. 21, "The Cave at Haria Lanzarote," and 254, "The Troglodyte Village of Atalaya, Cran Canaria. They appear to us to be enlargements from small and very thin originals, but we find nothing regarding this point in the catalogue, neither can we gather whether Mr. Stone is the producer of the original negative or the enlargement.

Mr. Francis Cobb only claims credit for the original negative of No. 22, "A Rustic Bridge," a charming pro-

duction, the ripple of the water and the shady nooks being admirably reproduced; while some swans and cygnets give a life to the picture which adds much to the value. The enlargement is the work of Messrs. Byrne, of Rich-

Blackheath. From an elevation of 2,700 ft. Negative by Cecil V. Shadbolt. Phototype Block by the Meisenbach Co.

"now it is done."
Negative by H. Chubb. Phototype Block by the Meisenbach Co.

mond. Mr. Cobb contributes other pictures to the show: Nos. 360 ("A Quiet Nook") and 529, the latter being a delightful series of views on the Thames.

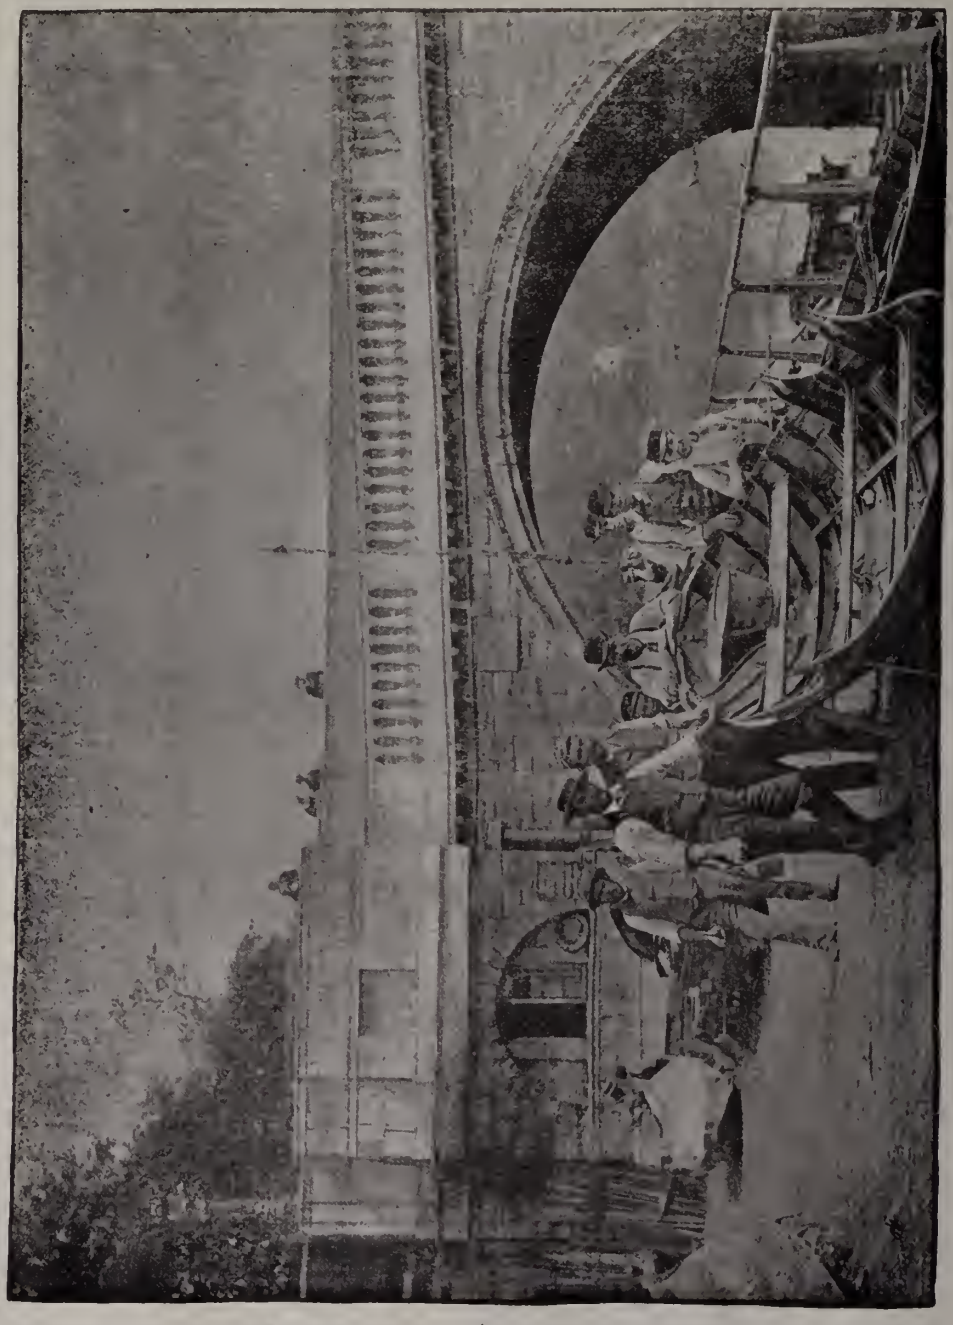
We have already referred to the Swiss views of Vittorio Sella, which have been awarded a medal; and so excellent are they in all respects, that nothing we now could say would do them justice. A picture rather than a photograph is G. Hadley's "At the Wheel," (No. 24); and the next on the list, "Dog and Cat," by Miss E. M. Cotesworth, has great merits as a composition. Puss is engaged in the agreeable occupation of drinking milk, and the dog is looking on; perhaps with a lively recollection of the scratched nose he got last time he interfered. We now come to a portrait of Miss Duppa, by H. S. Mendelssohn; but we have already noticed the works of this gentleman.

A frame of Mr. Shadbolt's photographs taken from the car of a balloon is to be found on one of the tables, and they show the decided advance which has been made by this gentleman since last year. Blackheath, from the car of the "Monarch," the elevation being 2,700 feet, is in one sense the most striking picture, the houses, streets, and gardens being shown as in a plan. The illustration which we give in no sense does justice to the original, as, curiously enough, there is an unaccountable thinness about the balloon negatives which makes reproduction by a block process very difficult. Mr. Shadbolt tells us that he cannot understand why negatives taken in cloud-land should thus differ from those made on *terra firma;* but it is a fact that they do differ.

Woolwich from a height of 500 feet, and the Royal Albert Dock from a similar elevation, are more pictorial than the plan-like representation of Blackheath, asthe

camera was only set at a small angle with the horizon. In the latter picture one can trace the windings of the Thames over many miles, while the rigging of the ships in the dock is most clearly shown.

Our illustration, "How it is done," represents the car of the "Sunbeam" with apparatus fixed in readiness, Mr. Shadbolt in the car, and Mr. Dale standing outside. The negative was taken by Mr. H. Chubb, of Chislehurst.



"WANT A BOAT, SIR? ALL READY."
Negative by Matthew Whiting. Phototype block by the Meisenbach Company.

We also illustrate, by means of a Meisenbach block, one of an excellent series of Thames views contributed to the exhibition by Mr. Matthew Whiting (No. 112). "Want a boat, sir? All ready!" said the Richmond boatman to Mr. Whiting as he approached with his camera; but Mr. Whiting did not take the boat: he took a photograph instead.

A few words more may be said with respect to the apparatus on the table, but there is really not much for us to add to our remarks of last week; the greater part of the exhibits being ordinary goods such as are sold every day in the shops, very few novelties being exhibited. We see one shutter there which has been on the table on two previous occasions, and was illustrated on p. 646 of our volume for 1882 in a notice of the exhibits of that year. This is in reality only one instance out of many in which the same apparatus is brought forward from year to year as a novelty at the Photographic Exhibition, and it is difficult to see why those whose business it is to determine what is to be admitted should not exclude everything

which is not novel, just as a picture shown in a previous exhibition would be excluded.

The *plate book* of Hunter and Sands (No. 590) is a contrivance likely to be useful, although not differing much from a plate book described over twenty years ago in the PHOTOGRAPHIC NEWS; still here we have a revival of a practically forgotten contrivance. Messrs. J. and L. Lane show slides in which the shutter is jointed in several places, so that it can be folded quite back when withdrawn—an excellent plan, which deserves to be universally adopted, as the projecting slide gets in the way of the dark cloth, and catches the wind like a sail. The flexible joint shutter is, however, not new, as Johnson adopted it in the case of the slides supplied with his pantascopic camera.

No. 602, "The Compactum Shutter," exhibited by Rouch, is a drop and flap constructed on the lines of the Reynolds and Branson shutter, which we have already fully described; but in Mr. Rouch's form the flap closes again after the drop has fallen, so that the apparatus is immediately ready for re-setting. There is also a spring permanently set for actuating the drop. This form of shutter recals an almost forgotten apparatus, the double flap, also shown by Rouch, in which two flaps are actuated by a very simple tooth gearing, as shown in the subjoined cut. The shutter of Mr. J. Furuell (No. 645) is con-

structed on an analogous principle, but with a number of complex adjustments for regulating the speed. It has already been described in the PHOTOGRAPHIC NEWS. As novelties of the year, one may mention the Godstone washing tray (625), and Marion's print washing apparatus; but as these have been already described in the NEWS one need say no more in this place. A very small metal camera made by Messrs. Marion and Co., and taking plates about an inch square, may perhaps be useful to the tourist, as it is sufficiently strongly made to stand some knocking about.

HOW TO PHOTOGRAPH MICROSCOPIC OBJECTS.

BY I. H. JENNINGS.

LESSON VIII.—PREPARING OBJECTS FOR PHOTOGRAPHY.

MANY microscopic objects are totally unfit for photo-micrography, as the beginner will soon discover if he attempt to photograph indiscriminately the objects in his collection. It does not follow, because an object looks very beautiful under the microscope, that it will yield even a passable photograph. It may look all that can be desired on the stage of the microscope; all its different parts may be defined clearly with diffused light, yet its colour, or the strong contrast of one part with another, may be such as to render a photograph of it quite impossible. Take, for instance, an object mentioned in our first lesson, the tongue or proboscis of a fly; satisfactory photographs of this object are not common, simply because they have been taken from the specimens usually met with in collections which have been prepared to give the best effect when seen through the microscope, where the strong contrast in depth of colour between the lobes of the ligula and the thick portion of the maxillae and maxillary palpi is no defect, but positively an advantage. When such a specimen is photographed, its unfituess is clearly seen; the thin, transparent lobes are usually much over-exposed long before the darker parts of the ligula have received their proper amount of light; in short, no exposure will suit this object as a whole. It is true a sort of makeshift may be employed, and fair results gained, by shading the transparent parts during exposure, keeping the shade in gentle motion all the time, during half or three-fourths of the exposure, when the whole may be exposed. It is far more satisfactory, however, either to select one of these tongues from a large number, or prepare one specially, so as to subdue these undesirable contrasts, and bring the whole object more into harmony as regards density.

The beginner in photo-micrography is strongly advised to make his own microscopic preparations. A microscope can never be much more than a pleasant toy if its possessor rely wholly on purchased slides. To own even a moderate collection of slides prepared by the professional mounter will cost a large sum of money, and when these have been examined a few times, their interest is gone, and the microscope is laid aside for want of objects to examine. But when the student prepares his own objects, his microscope becomes to him a continual source of pleasure and instruction. His slides, in the majority of cases, may not be equal to those professionally prepared, and they will certainly lack that exquisite finish which constant practice in their preparation alone can give; but for the purpose of study, and especially for photo-micrography, they may be equal to, or even better than, anything that can be purchased from the optician. Then, with practice, the student will so far improve that he will find his own preparations so much better for his special purpose, that he will rarely visit the optician's shop for slides, unless it be to purchase some object that cannot be procured elsewhere, or one which may be beyond his own powers to prepare. That there are such objects, it cannot be denied; and we may perhaps place anatomical preparations in the list of objects better left to the experience and skill of the professional preparer. As the student will not require his objects to be mounted in fancy style, he may prepare slides of such diatoms as he can find in his walks, or obtain by exchange, small as these objects are, purchasing only the rarer forms, or such as are prepared especially as test-objects. Practice in preparing and photographing minute objects, like diatoms, is not only desirable, but necessary, to give the beginner complete command over his microscope and camera.

The apparatus required in the preparation of microscopic objects is neither cumbrous nor costly. The following list includes most of what the beginner will require:—A spirit lamp; needles mounted in wooden handles; glass slides, 3 in. by 1 in. (these should be of plate-glass with ground edges); circles and squares of thin cover-glass, the thinner the better; solution of potash, commonly called liquor potassæ; methylated spirits; spirits of turpentine; some pure benzole, not benzoline; nitric, sulphuric, and hydrochloric acids; chlorate of potash; a bottle of balsam, or balsam and benzole; glycerine; gelatine; fine and coarse emery; a glass plate (preferably *plate-glass*) about a foot square, and one of cast-iron the same size, for grinding down sections of horn, bone, or rocks; a pair of scissors; a sharp knife; a pair of forceps; and a dozen brass clips for holding the covers on the slides, will also be required.

It is best to keep the balsam in a bottle fitted with a wooden stopper, through which a glass rod may be passed. The end of the rod may be kept above the balsam when not in use. When it is required to take some balsam out, the rod can easily be pushed down until it just dips below the surface, and a small quantity taken out without soiling the neck of the jar. Corks should not be used, as they are apt to stick fast, and, by crumbling away, fill the balsam with small fragments which are difficult to remove. By keeping the glass rod always in the bottle, it will remain clean, which would not be the case were it kept elsewhere; and the learner will soon find that cleanliness is absolutely necessary in microscopic work.

Newly-purchased slides and covers are always dirty. Water will not always effectually cleanse them; they should therefore be washed in a solution of caustic potash,

ammonia, or soda. This will free them from impurities; but the slides should afterwards be well rinsed in pure water, or some of the alkali will remain on the glass, and prove as great a hindrance as the dirt.

Microscopic objects are mounted in three different ways: 1. Dry. 2. In a gum, such as balsam or dammar. 3. In some fluid, such as water, glycerine, or alcohol. Dry-mounted objects being usually opaque, are not well suited for photography, unless the operator has more than common dexterity in the management of reflected light. In the case of very transparent objects, however, such as diatoms, dry-mounting is far the best, as the use of balsam or glycerine does much to obliterate fine markings, on which the interest of the object, perhaps, entirely depends. Balsam or dammar will most generally be used as the mounting medium, as these gums render an object mounted in them more transparent, and can be used in most cases where they exercise no solvent action on the preparation. Insect preparations, vegetable tissues, rock sections, crystals of various salts, are, as a rule, photographed to best advantage when mounted in balsam.

As insect preparations are of perhaps more general interest than any other, and are more easily photographed, we shall treat of preparing these objects for photography in our next lesson.

HINTS ON POSING AND THE MANAGEMENT OF THE SITTER.

BY H. P. ROBINSON.

Chapter II.—The Head Vignette.

In the last chapter I left my man hanging, while I went off into a digression on studios and head-rests, turning him, indeed—as well as my chapter—into a "subject" quite other than that intended. This is bad art. A subject should never be left suspended. Years ago there was published a series of portraits of a famous actress as she appeared reciting Tennyson's sensational "Charge of the Light Brigade," a poem utterly unworthy of the great poet's genius, but which, however, still finds listeners, if not readers. There were seven poses in all, and the last of the series left the lady with arms extended in the very ecstacy of declamation; to make the series complete, and finish artistically, the photographer should have added another picture with arms down, and left her in repose.

We will continue the consideration of how a head ought to be treated.

The first thing to decide when you see your sitter should be: "Which side of his face will make the best picture?" This consideration seldom gives an experienced operator any trouble. To one who is in the habit of observing, the sides of every face differ so much, and in such a definite manner, that a glance is all that is necessary to settle the question; but the young photographer will want to know how to select, and have some rule for the selection.

If you will look critically at a full face (or the photograph of a full face would be better, as it would enable you to measure), you will find that the eyes are not level—one is higher than the other. This is almost invariable, and is one of the peculiar instances in which nature insists on variety, even where uniformity would seem to be proper. If you take a photograph of the face in a three-quarter position, with the eye that is highest away from you, the unevenness will be still more visible; but if you take the other side of the face, and have the highest eye nearest to the camera, the lower eye will seem to fall away naturally, through the effect of perspective. The same facts apply to the nose, sometimes in a very marked degree; but it fortunately happens, in nine cases out of ten, that the eyes and nose agree as to which is the best side of the face. When they disagree, the portrait is seldom satisfactory. The two illustrations are taken from different sides of the same face, and show which side should have been taken. In the one to the right the nose looks broken, and the eyes out of line; in the other these defects are not seen.

I keep an illustrated catalogue of all the portraits I take, and on looking through several volumes, I found confirmed a very curious idea that was stated in a Note in the News. I found that about four out of five of the portraits were taken looking to the right, showing that I had in these instances chosen the left side as the best. Now, as both ends of my studio are equally well lighted, and it is no more trouble to take one side of the face than the other, it follows that, in my judgment, in four out of five cases the left side was the best. If this is correct, the knowledge of it would be of some practical use to those who have to build studios in a confined place, with only one end available, to make it that end on which the left side of the face can be best lighted.

If your sitter is not in a good state to be photographed, and if it does not endanger the loss of him (this is a purely business consideration which is out of place here), it is much better to postpone the sitting than to risk taking an indifferent portrait. The other day I saw that one of my sitters was not looking his best, and asked him if anything was the matter. "Well," he replied, "I've got a headache that ought to be good enough to split a planet into fragments, but I thought I would keep my appointment." Now it is a good thing to encourage sitters to be punctual, but I felt it right to send this one away for a day or two. My friend's description of a perfect and complete headache was as good as I had heard until another friend said he had got an effervescing mixture of sunstroke and neuralgia.

A sitter will sometimes want to be taken "naturally." His ideas of being natural—"just as I am, you know"—is to sprawl over the furniture. Perhaps he will put his hands in his pockets, sink low in the chair, and expect you to make a good head and shoulders of him. This is an awkward customer to manage. Possibly the best plan is to recommend him to go to the worst photographer he can find—one of those who advertise themselves loudly as "artists" without knowing the meaning of the word (there are plenty of them in every town)—or to the peripatetic on the sands or common, who will let him have his own way entirely, so that he pays his sixpence in advance.

But, given a decent sitter who, for the present purpose, let us say, wants a head and shoulders, what is called a vignette head, the question is, what to do with him.

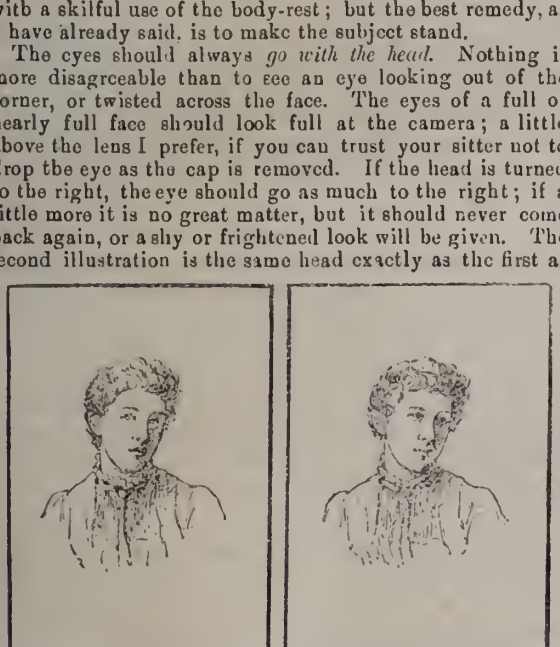
A conscientious photographer who desires to do his best, and who charges a price that will allow him to forget the cost of his materials, will in this case take at least three positions—a full, or nearly full face; a three-quarter; and, if the face will bear it, a profile, or nearly profile, showing a little of the off eyebrow; but if the side face would be too trying, then the third negative may be devoted to a variation of expression in one of the other positions.

A simple head requires to be properly composed as much as any other kind of picture, and should not be without variety of line and contrast. If with a full face the body is also turned full towards the camera, a line drawn down

the middle of the picture would divide it into two halves, as nearly corresponding as variety-loving nature will allow; but if the body is turned a little away, and the face to the camera, there will be variety of line suggesting movement and life, especially if the expression can be made to correspond. For a three-quarter face, it is better to turn the figure quite in profile, or even showing a little of the back; or the figure may be full, and the head turned away; either way will give a lively and agreeable turn to the neck. The same remarks will apply to a profile, except that there must not be too much strain in the neck, so as to pitch the head forwards, as already alluded to in the last chapter.

In a "head," the shoulders should be always nearly level, and the figure upright. It looks awkward to see one shoulder much higher than the other, when the rest of the figure is not shown to account for the position. Some sitters are obstinate about this, and will not sit upright, preferring, as they say, to feel at ease and "natural," as if it was their feelings they wanted photographed, instead of their appearance. The only remedy for a bad case of this kind is to make your subject stand. This usually improves the fall of the shadows; it is also a sovereign cure for another difficulty. Some sitters, if you ask them to sit upright, will think they are complying with your wishes if they lean back in the chair and stick their chins in the air, for some people think they are not upright until they are nearly falling backwards. This leaning back in the chair, added to too much twist to the neck, is the cause of nearly all the broken-necked effects. A good deal can be done with a skilful use of the body-rest; but the best remedy, as I have already said, is to make the subject stand.

The eyes should always *go with the head*. Nothing is more disagreeable than to see an eye looking out of the corner, or twisted across the face. The eyes of a full or nearly full face should look full at the camera; a little above the lens I prefer, if you can trust your sitter not to drop the eye as the cap is removed. If the head is turned to the right, the eye should go as much to the right; if a little more it is no great matter, but it should never come back again, or a shy or frightened look will be given. The second illustration is the same head exactly as the first as



near as I can draw it, with the position of the eyes only altered. The first is constrained and self-conscious, the other easy and natural.

Many sitters who look bright and lively when they talk, sink suddenly into the opposite extreme. As they speak the last word, their head drops, and a sort of reactionary expression comes on; this expression is as much the result of the drop of the head as the alteration in the features, and must be looked out for and counteracted. If a head-rest is used without any support to the back, this result is almost inevitable. Some photographers use a posing-chair —sometimes called a vignetting-chair—which supports the back; but I prefer to use a back rest. Indeed, I use this rest constantly, and could not do without it. The use of the rest should be a fine art.

Care should be taken to have the camera a proper height with regard to the head. If it is raised so high that the lens looks down on the sitter, the neck will be shortened, and the shoulders will appear raised. If, on the other hand, the camera is too low, the effect is perhaps still more disagreeable. The face is foreshortened from the chin to the forehead, and the nostrils are unduly visible.

The proportions of the head in a picture should have great consideration. It is too often the practice to make vignette heads much too large for the space they occupy. A carte vignette head should never be larger than $1\frac{1}{8}$ inch from the top of the hair to the chin, and a cabinet should not exceed two inches in the same dimensions.

SOME CURIOSITIES OF THE EXHIBITION.

BY YOUR OWN CYNIC.

Observing in the "Notes," in your last number, comments on the curiously narrow escape a picture had of being excluded, but which afterwards obtained a medal, perhaps you will permit me to direct attention to some further matters connected with the Exhibition that are likely to excite surprise.

First of all, it puzzles me why visitors should be troubled to look at more than one version of any one subject. I do not so much object to this when the one is the original picture, and the other is an enlargement of it, as it might show the skill of the enlarger! This is aptly illustrated by the very picture I presume you allude to in the "Notes" to which I have referred.

It is the doubles that are so annoying and puzzling to visitors. As an example: there are two pictures of a little girl sitting on the ground—about a ten by eight—one on the long wall, the other on the east wall; they are apparently identical. Both are very good, but it is possible to have too much of a good thing, and two identical pictures in one exhibition is more than the ordinary visitor understands or cares for.

Another photographer is so enamoured of a certain cathedral that, after exhibiting large pictures of it from the same point of view on two previous occasions, he sends two views of it this year, taken from the same point, or with a variation of a few yards. This year, perhaps, he wished to show the building not quite so much obscured by fog.

Yet another illustration of how an exhibitor has made the most of his negative is that shown in a picture of a man in a stagey costume drinking. To his second picture from this negative he has ingeniously given variety, not only by enlarging, but reversing it.

Then what was the meaning of the following line in the Society's circular: "Photographs coloured by hand will not be admitted"? If portrait enlargements, highly finished in water paint, are not only admitted, but hung in a place of honour on the line, after this precedent I expect to see the Exhibition inundated with highly finished water colours. Perhaps the hangers will quibble, and say monochrome is not colour.

Then, again, I am puzzled to understand the strange views that led to the selection of No. 67 for honour, whilst veritable pictures by the same masters were hung in absolute contact with it. One explanation, I have been told, is, that the majority of jurors thought more of definition than art. Is it not time that the optician's idea of a picture were given up for more valuable qualities?

Why a medal was awarded to No. 485 may prove as unanswerable a conundrum to others as it certainly did to me. Still I must confess that I am one of the unscientific: it does but demonstrate to my mind the over readiness of the jurors to assert a connection with science, however distant.

What ignorant sin must Messrs. West and Son have committed to be saddled with the awful responsibility of all the yachts scattered about the room, as one might suppose from the unrevised catalogue.

Notes.

Judging the Pall Mall pictures involves no little labour, and this is how the work is done. The pictures being all placed in position and numbered, each judge goes his rounds, and gives marks to every picture, the maximum number being ten; unless, indeed, the judge considers a picture so bad that it ought not to have been accepted, when he marks his disapproval by giving no marks; but when he is decidedly of opinion that a photograph should be awarded a medal, he of course gives it the full number—ten.

All the markings are then collated and added up by the officers of the Society, and the rest is simple, all that is required being to determine the standard, above which means success, and below, failure.

As we have already stated, the judges this year are Messrs. Glaisher, W. Bedford, Donkin, W. England, J. E. Mayall, Mayland, and Pringle.

That several of these gentlemen would have been medallists this year, had not their works been out of competition, is hardly a secret, as some of the best pictures in the room are contributed by them.

Not only do the judges thus forego all possibility of gaining distinction, but they have to brave the displeasure of such demonstrative non-medallists who write to them and enquire the reason why.

A correspondent writes:—"Have you tried the following clearing solution? It is very efficient, but do not use it over and over again, as if so it will clear so well that the image disappears altogether in ten minutes or so:—

Alum	1 ounce
Citric acid	1 ,,
Sulphate of iron	3 ounces
Water	20 ,,

When freshly made, this clearing solution has but little action on the image, but as oxygen is absorbed from the air, and the proto-salt is converted into a per-salt, the solution becomes capable of dissolving the reduced silver with tolerable rapidity. If used when old, its action must be carefully watched.

Such as may wish to figure as photographers, and yet do no photographic work, have now great facilities offered them in the United States, as plates which have been exposed at the Niagara Fall, the Yellowstone Park, and other great tourist resorts, can now be purchased to hand. He who is anxious to wear the photographic laurels in the circle of his immediate friends has now only to buy the exposed plates, take them to one of those persons who make a business of developing, and finally order the required number of prints. Even the possession of a camera is not essential; but it looks very much better to have one.

Those who are behind the scenes, however, tell us how the "ready-exposed plates" are manufactured. A number of plates, alternated with sheets of black paper, are placed on a table in the dark-room, and a transparency—say, of the Horse-shoe Fall—is laid on the top. A wax match is now struck, and allowed to burn itself out while held at a distance of about a foot from the top of the pile. The exposed plate and the underlying sheet of black paper are now removed, and the next plate is exposed.

The "Universal Column" which they talk of erecting at Lucerne is to contain relief portraits in bronze of all the illustrious men and women of the present time. In fact, the proposed column is literally the "tallest" thing in albums yet projected, the proposed height being 300 feet.

Still, if the Committee wish to be well up with the progress of the nineteenth century, the portraits should be photographs. Let us suppose photo-enamels made upon porcelain tiles. If more realistic productions are required than flat pictures, it would be quite easy to superimpose the photo-enamel picture on a relief tile cast from a Woodbury relief.

Walzl's Monthly remarks that it is not gratifying for a maternal parent to bring a squalling brat into the studio with the remark, "I guess you'll have lot of trouble; Mr. Johnson, the photographer, tried her twenty times—but, there, he was so bad tempered that I'll never go near his place again!" You feel for your rival, Johnson, as you never did before.

There seems an energetic search now after antiseptic substances, but there does not seem to be much practical gain by adding to the already long list. It is, however, interesting to note that, according to Professor Dewar, one part of peroxide of hydrogen in ten thousand of a putrescible liquid will prevent the development of bacteria. Although the peroxide, if in strong solution, is instantly reduced by most organic matter, a small trace can consist in solution along with easily reducible organic bodies.

If all be true as reported, the photographing of the Treaty of Tientsin has hoisted the Chinese on their own petard. The story of the Chinese journal, Li Hung Chang, is that certain erasures were made in the document of Captain Fournier, and were initialled by him. Now that a copy of the photograph has arrived in Paris, it is urged that the erasures and initials have been forged by Li Hung Chang. Captain Fournier has yet to make his statement, and if this statement corroborates the assertion of forgery, the Chinese Government will wish they had not employed the science of the barbarian. Probably it has also been described by Li Hung Chang, who perhaps did not think the document would be copied so exactly.

It may be that the belles of Long Branch are not photographed, since freckles, which nature imparts to blonde beauties only as a rule, are fashionable; and those who

cannot get them naturally, resort to art. The artificial freckle is produced by the application of moistened sand just after rising in the morning, and the charge is fifty cents per freckle. However charming freckles may look in real life, they are hideous when photographed. Photography must be at a low ebb at Long Branch.

To multiply the skulls of deceased celebrities, as is the case with Oliver Cromwell's, of which at least two "guaranteed" originals exist, is perhaps carrying realism rather too far; but there is certainly no reason why every provincial museum should not vary its inevitable collection of local fossils. New Zealand war-clubs, mediæval cannon balls, and British birds'-eggs, with facsimiles of "Magna Charta" (say) and the "Bill of Rights," and selections of the most generally interesting of those unique M.SS. and autograph letters which are to be found in Great Russell Street in such profusion.

To take the most recent case. A year ago the country gave £40,000 for a collection of M.SS. known as the "Stowe Papers." "Where," to parody Hans Breitmann, "are those papers now?" The irreverent wag might reply: "Stowed away!" and the irreverent wag would be about right. But if the most interesting of the M.SS. were reproducted by photography, the whole nation might soon be benefiting by its acquisition, and what is surely intended for the instructiou and edification of the people would not be persistently pigeon-holed.

It is satisfactory to learn that the trustees of the British Museum intend to strongly represent to the Treasury the desirability of establishing a photographic department in connection with their national storehouse of literary and artistic treasures. As it is, but a ridiculously inadequate sum is included annually in the British Museum vote for photographic purposes; the result being that it can only be tentatively and sparingly used. But, as Dr. Garnett pointed out in the admirable paper he read to the Library Association at Dublin the other week, the utmost facilities should be afforded for photographing literary and artistic objects, so that *facsimiles* of precious manuscripts and of priceless *chefs d'ouvre* might be produced for the education and delectation of the millions who can never hope to visit our great central libraries and museums.

There is, indeed, but little new under the sun. A correspondent writes to inform us that five or six years ago he had a number of photographic visiting cards prepared for him on the plan recently suggested in these columns. In the left-hand corner of each card was affixed a small oval photographic likeness of himself. He tells us that at the time several of his friends followed suit, but that the idea never became generally fashionable.

All the same, it is easy to see that its introduction would be in many cases most useful. What person is there that is blessed with a large circle of acquaintances who does not now and then find among the cards left during an absence, several bearing names which he is temporarily unable to associate with any actual personality? If, however, they had only had some photograph in the corner, no doubt as to the identity of their names would have arisen.

The Smiths, Browns, Joneses, and Robinsons would find the photographic visiting card especially convenient. As it is, they are driven—in order to preserve their identity—to resort to all kinds of curious expedients. Those Smiths who do not turn themselves into Smyths, or Smythes, or Smits, find it necessary to hyphen themselves on to some such high-sounding denomination as Clavering, Montgomery, or Ponsonby to prevent confusion, reckless of the extra trouble they thus inflict upon themselves for life in the shape of elongated autographs.

Patent Intelligence.

Applications for Letters Patent.

13,317. James Thomson, 21, High Park Street, Liverpool, for "Improvements in photographic cameras."—Dated 8th October, 1884.

13,318. James Thomson, 21, High Park Street, Liverpool, for "Improvements in photographic cameras."—Dated 8th October, 1884.

13,371. William Charles Hughes, Brewster House, 82, Mortimer Road, Kingsland Road, N., London, for "An improved form of lantern front for magic-lanterns."—(*Complete Specification*).—Dated 9th October, 1884.

13,372. William Charles Hughes, Brewster House, 82, Mortimer Road, Kingsland Road, N., London, for "An instantaneous mechanical frame for the rapid change of pictures in the lantern."—(*Complete Specification*).—Dated 9th Obtober, 1884.

Specification Published during the Week.

10,226. Benjamin Joseph Edwards, 6, The Grove, Hackney, in in the County of Middlesex, Photographer, for "Changing the slides or pictures in the magic-lantern, and for exhibiting dissolving views with a single lantern."—(*Complete Specification*).—Dated 16th July, 1884.

The invention relates to a method of, and apparatus for, exhibiting a series of slides or pictures in the optical instrument commonly known as the magic lantern, and has for its object the changing of the slides or pictures mechanically by one movement of a lever or handle without any movement being perceptible upon the screen.

In order to accomplish this object I first shut off the light, and consequently the picture from the screen, by gradually closing or covering the front lens or objective of the lantern, and during the momentary interval of darkness thus produced I rapidly change the slide or view, and substitute another one previously placed in position, and then by gradually uncovering the lens I allow the new picture to fall upon the screen.

In carrying out this my invention in the simplest possible manner, I fix a short rod or spindle, turning on its axis parallel to the optical axis of the lantern, and which spindle is rotated by a handle or lever. At the outer end of this rod I attach an opaque screen projecting in front of the lens so as to cover or close it, a certain portion of the screen being cut away, so that during a part of the revolution the lens is uncovered, and the light, and consequently the picture, is allowed to fall upon the screen, and by means of suitable excentric gearing I connect the rod, carrying this opaque screen to a swinging or sliding frame, carrying two slides or pictures arranged in such a position in the frame or carrier that when the lens is not covered by the opaque screen or dissolver, one or other of the pictures shall be rest in its proper position in front of the condenser, and I arrange the gearing or excentric motion so that the sliding or swinging frame shall be set in motion and the picture changed during the momentary interval of darkness caused by the passage of the opaque part of the screen or dissolver in front of the lens. In order that the darkening of the picture shall be

gradual I make the aperture in the dissolving screen with serrated edges; but I prefer, instead of this revolving screen, to close and re-open the lens by means of two thin sliding plates or diaphragms working in grooves attached in front of the lens, and I make the sliding plates with both ends concave, and I suspend these plates by means of a cord passing over and once round a drum or pulley fixed to the rod in place of the opaque screen before described. One of these plates being attached to each end of the cord, they balance each other, one rising and the other falling as the drum revolves. I make the plates of sufficient width to cover the opening of the lens, and of sufficient length to keep the light entirely shut off during the time the position of the slide carrier is being changed; and I arrange that when the upper concave edge of the rising plate comes in contact with the drum, the lower concave end of that plate is just free of the upper edge of the lens, while the upper concave end of the falling plate is just clear of the lower edge of the lens. For holding the slides or pictures in position I use a double carrier of the usual construction, but arranged by means of guides or runners to travel easily in metal grooves attached to a second frame, which is firmly fixed in the lantern immediately in front of the condenser. The slide holder or carrier, carrying the slides or views, is moved from side to side by means of a lever slotted at its lower end and working on a pin fixed to the central division of the double slide holder; the upper end of this lever is firmly fixed to a rod or spindle turning on its axis and placed parallel to the spindle carrying the drum before described.

SCRAPS FROM MY HOLIDAYS.

BY H. ARNOLD BEMROSE, M.A.*

My reason for taking up the art of photography was because I wanted lantern slides to illustrate subjects for lectures which were not to be found in any maker's catalogue. My first attempts, not of a very artistic character, were made with a rough camera composed of a wooden box, a dark slide, and the objective of my sciopticon lantern. This summer I took with me to Dolgelley, in North Wales (in addition to a half-plate camera, the negatives from which I have not yet developed), a sciopticon camera for plates 3¼-inches square, which, with lenses and four double dark slides in case, weighs about four pounds. I took also Mr. Smith's Brattice and Manx stands, each weighing about 1 pound. The former I found very useful for hill work, especially in climbing Cader Idris. In such cases the stand becomes an alpenstock, and is not an useless weight for the time, like a folding one is.

The object of my holiday—not forgetting, of course, fresh air and exercise—was geology, and not photography, and most of the photographs I took were to illustrate that science. During the fortnight I walked 250 miles, collected over a hundredweight of specimens, and exposed 25 plates. The weight of the camera was of some importance to me. Four pounds is quite enough on a hot day on rough ground, in addition to several pounds' weight of iron in the hammer and chisel, and that of any specimens brought home. I found no difficulty in the packing of plates either before or after exposure. The plates were the Manchester rapid ones, which were taken in the boxes as supplied by the maker, and after exposure were replaced in a similar way. The changing I did under the bed-clothes at night, wrapping each box up carefully in non-actinic paper, numbering each box, and taking notes of the plates replaced, so that on my return home I was able to pick out any plate required for development.

A few of my transparencies were printed on gelatine-albumen plates (Chapman's); but the majority on Edwards' gelatino-chloride plates. They were exposed by contact with the negatives to a bats-wing burner, at a distance of two and a half feet. The exposures varied from five to fifteen minutes. And here let me point out, in passing, what probably most photographers know, that light varies inversely as the square of the distance, so that an exposure of twelve seconds at a distance of four feet from the light would be equivalent to one of three seconds at a distance of two feet. A short calculation will enable us to obtain the same results from different distances with the same exposure, as we can from different exposures at the same distance from the light; so that, instead of varying the exposure, we may vary the distance, thus saving time.

The developer used was the one supplied by Edwards—a long exposure and weak developer giving reddish tones; a short exposure and strong developer rich black tones—the latter making, I think, the best pictures.

The remainder of the time was spent in showing the transparencies with the sciopticon lantern, and explaining them, and in exhibiting the camera and stands.

* Notes of an address to the Derby Photographic Society.

ON CHEMISTRY AND PHOTOGRAPHY.

BY MR. MACDOUGALD.*

The science of chemistry is that which takes cognisance of the combinations of matter. One would imagine that this science must form a most important item in the education of a photographer, as he uses chemical substances to a considerable extent. As a rule, however, it does not. Photographers, apparently, speaking of them as a body, have no inclination to understand the minutiæ of chemistry. This disinclination may be the result of a widespread opinion that a knowledge of chemistry is not necessary to the production of a good picture. A week or two ago, in one of the photographic journals, a writer gave it as his opinion that, in order to excel, photographers should not trouble over the minutiæ of formula, or about any technical part of photographic work. To strengthen his position, he remarked that the true artist never condescended to paltry matters of that kind, but rather accepted materials put to his hand, and questioned nothing. This gentleman instanced the old painters taking their painting material as they found it, their main object being to put colouring material on their canvas in a particular way.

Now, while we might all agree with this writer when he says that the main object to be kept in view by the painter or the photographer is the putting on of colours or the printing of lights and shadows in a particular way, it would manifestly be absurd to say he is not to trouble himself about the underlying technics. I doubt not, if we could get close up to the back window where Raphael or Rubens was working, we might find these gentlemen very busy with other implements than the brush and canvas. There is no reason to doubt—nay, I have good reason to believe—that these good old painters made, mixed, and ground their own colours, and paid a very great deal of attention to the medium through which they were to give to the world their thoughts and ideas. We may well imagine their fear of colours fading or darkening.

The absurdity of the position is increased when applied to photography. If photographers in past years had taken processes and material as they found them, and remained content therewith, where would our art-science be in this year of grace? A more than ordinarily enterprising man might possibly be trying to take instantaneous photographs on Daguerreotype plates; but this, perhaps, is not what our friend means. Photographers should be graded. First, there would be the great photographer himself—the idealistic and ethereal. He would be surrounded and possess large and small satellites such as the camera-maker and the plate-maker, whilst such operations as printing, toning, fixing, and mounting would be done by obscure persons. He, the great, would sit in the centre of all, not dirtying his hands in the slightest, but devoting his whole energies to the production of ideas. In fact, this gentleman wished the term "photographer" to apply only to the man who searches out good combinations, makes good grouping, or has a knowledge of what does and what does not form a good pictorial landscape—just such an individual as would get his man John to inform him what lens to screw into the camera to suit a particular view; who would get John to estimate the light and the number of seconds necessary for exposure; who would further cause John to make plates, develop plates, to print, tone, fix, and mount; and, finally, to put into a frame the finished result for the exhibition wall as photographed by his august master. It would be very wrong to say that John in this case was better than his master, unless we knew if an equal power was possessed by John of finding or making good subjects, in which case he would be distinctly better than his master.

And this leads me to the subject of the evening—"Chemistry and Photography." Should a man who essays photography know something of chemistry? Is a knowledge of the science a help or an encumbrance to him? An answer which will satisfy every case must be carefully framed, and to that end I would divide photographers into two great classes—the photographer whose

* A communication to the Dundee and East of Scotland Photographic Association.

sole object is to make and multiply pictures, who does not care very much about the means by which the pictures are made; and the photographer whose object is not only the making of pictures, but, in addition, the making of new and superior methods of operation.

To the photographer who simply makes pictures, chemistry is not of much benefit; for chemistry, although it has to do with combinations, will not enable an operator to combine a number of individuals into a good group, or to combine a tree and a mountain to form a good landscape. To the other photographer chemistry is of importance, as it enables him in some measure to intelligently examine already-known phenomena, and prevents him from making absurd blunders or advocating absurd theories, as is too frequently the case amongst his other brethren. As an instance of the little, yet aggravating mistakes sometimes made: the other day I learned from a friend that he had left for ten days some fine plate glass amongst a strong solution of caustic soda. He told me he did not know what had happened, but the glass was marked and spoilt, and had lost its polish. The real state of matters was simply that my friend had unwittingly made a partial solution of his plate glass, glass being appreciably soluble in caustic soda.

Then, again, we are all more or less troubled with the very active man who rushes into print with a new idea, and supports it with a flow of language of astonishing abundance and acrimoniousness. We do not require to go far to find instances. A writer in one of the journals not long ago asserted that light reflected from an orange surface affected a gelatine plate to a greater extent than light from a blue surface, and actually went the length of asserting that experiments supported him. Little matters of this kind are continually cropping up, showing the value of a knowledge of natural philosophy and chemistry to the photographer.

On the other hand, too much should not be expected from chemistry. When anything out of the common occurs during some of the processes connected with photography—such as some blotching, staining, or other occurrence entirely unexpected—chemistry more than points to a probable cause. The science for the moment might appear to be at fault, may be able to do very little—not because the blotching or staining is caused by something outside the domain of chemistry, but simply that the cause is so occult, so intangible, as to be difficult of approach.

Photography is an art above all others which is based upon occult or semi-occult causes. The whole art has always appeared to my mind to be a good example, in a chemical sense, of what Professor Tait, of Edinburgh, calls an incalculable machine—a machine whose motions, although following strictly the usual lines of cause and effect, are quite incalculable owing to the occult nature of the causes regulating its motion.

To illustrate more fully what I mean, we may instance an egg balanced on end near the edge of a table. This is a possible feat, especially if the egg be rough, and the place very still and free from vibration. Even if the feat were impossible, we could imagine such a state of matters. All conditions remaining the same, the egg will remain in position, and neither fall on the floor or turn over on the table. But on the slightest disturbance from without reaching the egg—if we as much as look at it, to use an expression—the egg will in all likelihood either fall to the floor or turn over on the table. We have reason to believe—nay, we know to a certainty—that the falling to the floor, or the simply turning over on the table, is the result of a specific cause; but that cause is so inappreciable in itself as to elude the most careful observation. The most careful scrutiny of the surroundings of the egg would not enable anyone to predict which way the egg would fall.

This balanced egg may be likened to some of the conditions surrounding the chemical substances used in photography. In their constitution they are so delicately constructed, and so easily, so to speak, put off their balance, that it would require almost superhuman intelligence to predict what amount of force would put them off their balance.

Some of the actions which take place are beyond prediction and calculation, and the science of chemistry is able to give explanations, the value of which only amounts to probability.

PRESS NOTICES OF THE PHOTOGRAPHIC EXHIBITION.

[From *Society*.]

A cynic has said that war has one advantage—it is a great teacher of geography. True; but we might possibly have been as happy had we never known the exact whereabouts of Isandlwhana, Majuba Hill, and the Ityosi River, were rather shaky about the boundaries of the Soudan, and given to follow the example of our nearest neighbours and put down every place outside our ken as *là bas*. But even Jacques Bonhomme is rapidly learning—possibly by the time his lesson is finished, every *pion* in France will have been so taught by the *pion-pions* that he will be able to set down China from Hong Kong to the Great Wall on the big blackboard for the benefit of the young Republic. But we would wish to learn geography without the necessity of a "big butcher's bill"—the Iron Duke used another adjective. An apt teacher is at hand in the person of the artist whose palette is a "dry plate;" who scales peaks, dives into volcanos, ascends in balloons, canoodles down strange rivers, and visits strange people who have no manners, and whose customs are nasty; to set out before the stay-at-homes the result of his travels, and expound for their benefit a royal road to geography. His armament looks warlike, but he may say in the words of the Irish photographer, when his patient thought he was taking aim with murderous intent, a natural conclusion if he had the rare good luck to be an Irish landlord, "It isn't yer life, but yer focus I want." The knight of the camera is ubiquitous; he follows our armies; he makes long journeys for himself; he establishes himself in yachts; as a merchant captain he varies the monotony of taking the meridian by taking a photograph; he is a magician who has a Djin at his command to take down a picture in less time than old-fashioned fogeyish Puck ever dreamt of. If words fly, and the writing remains, how much more durable is such a record as Mor Déchy—the Hungarian traveller has taken of the great group of the Central Caucasus; in the course of his explorings ascending such a peak as Adai Chocb, of no less a height than Mont Blanc; taking in slopes, snow-clad peaks, glaciers and moraines, by which his comrades of the Alpine Club may take notes for future ascents.

It is for this reason that we learn so much, and learn it so pleasantly, that the annual display of the Photographic Society of Great Britain, at the Gallery, 5a, Pall Mall East, is one of the most enjoyable exhibitions of the season. This year the effect of the gallery taken *en bloc* is excellent, whilst, after a close examination *en détail*, the favourable impression is maintained. Each year some new wonder of the camera is shown; instantaneous views, even though taken in the 300th part of a second—as this "Express Train," which seems to stand still, of M. C. Grassin, of Boulogne, or this Quai Gambetta, with its mixture of white-capped *poissardes* and "ditto"-suited tourists, taken on the instant—amaze us no longer. But the energetic secretary, Mr. Edwin Cocking, is a man of "reserved force," ready to spring a mine on you and surprise you at any moment. The surprise this year is, he shows you a small plate of glass, with some still smaller plates attached. You take your magnifier, and each tiny morsel resolves itself into Saturn and his ring, Jupiter and his moons, taken by what magic who can say, by A. H. Common. What would Albert Smith have thought of this when he chaffed amateur photographers in his Mont Blanc, and showed a blank piece of paper as a representation of Cologne Cathedral at midnight? I remember seeing a portrait of him and his wife, Miss Mary Keeley, taken on the Mer de Glace; it was certainly not what Mr. James Whistler would term a harmony in black and white; there were no half-tones, figures black, ice dead white. With such an idea in your mind, compare such pictures as this "Mont Blanc" and "Monte Rosa," by Vittorio Sella, the "Weisshorn" with its peak fissured with ice, from the Täsch Alp, by W. F. Donkin, or the dreaded "Matterhorn, from the Höuli," and note the delicate half-tones, the cleverly-taken foregrounds, the artistic knowledge that is brought to bear.

Another veritable surprise is two photographs of lightning which quite upset the idea of forked lightning cutting across the sky in a series of sharp angles. M. Auty sets each flash before us lighting up the darkness of the night. Each is shaped like a bow; each starts from what gardeners would call two "tap roots," and in each the angles are much smaller and much less acute than we have been accustomed to believe. So much for the surprises; and now to a section which interests all men and women in their habits as they live—the clever and the stupid, the known and the unknown, the pretty girl and the lady whose sole remnant of the days of her "gyurlhood" is a chronic simper—simper faithfully caught, not a grin, but a Mariana at the Moated Grange expression, a kind of "he cometh not," a sort of desire of the moth for the star, a facial rendering of gather ye rosebuds while ye may; but, sad to say, the flower, the gilded youth, the golden nobs, to speak pomologically, of the day, will

not stop to cull is the wallflower of the ball-room, and a decided wallflower hangs on these walls. Let the reader or visitor seek for himself, "*Cherchez le chat*," "*Où est le lapin ?*" as the backs of the tickets of the Seine *bateaux-mouches* ask us.

Firstly, amongst the portraits, one that should be hung in the place of honour, not put on one side on a screen, is that of the evergreen President of the Society, Mr. James Glaisher, seeming as if he had found the fountain of eternal youth in his recent run through Canada with the British Association, and looking "Ready, aye, ready," for another seven mile ascent with Mr. Henry Coxwell. This by Mr. J. E. Mayall. Then Mr. Bergamasco of St. Petersburgh, Abdullah Frères of Constantinople, Luckhardt of Vienna, or Sarony of New York, would surpass this lifelike portrait—a portrait which gives not only the man, but the man behind the mask, by Mr. Valentine Blanchard, of Mr. Andrew Levey, the clever *marechal du baton* of the Lyceum, or rival in delicacy the soft whites and tender fleeciness of the dress of this lady in "The Siesta." Here is a portrait enlargement by the London Stereoscopic of Sir Joseph Porter, K.C.B., beaming on us as if no oyster crossed in love had ever interfered with his digestion. Then, of course, we have that very much photographed lady, Miss Maude Branscombe, but, as Audrey said, "the gods be thanked," no professional beauties advertising the merits of some new dresses. Mr. H. S. Mendelssohn contributes a charming series of charming faces, amongst which I would note a platiuotype of the Lady Brooke and two exquisite portraits of Mrs. James. All Mr. Mendelssohn's portraits are marked with rare refiuement. "Love me, love my dog," might be said of this enlargement by the Woodbury Company of a negative by MM. W. and D. Downey, a picture in neutral tints. Mr. T. J. Dixon, who may be styled photographer to the Zoo, presents us with a regal-looking "Imperial Spanish eagle," an eagle that looks a survival of when the red and yellow flag, with the shield of Leon and Castille, floated over a New World, and when her galleons and caravels swept every sea.

If I mistake not, the gelatine process was first taken up by an amateur. How it has spread may be guessed by the fact that the catalogue tells us, "All the original negatives of photographs exhibited this year were taken on gelatine plates, the exceptions only being noted," aud the exceptions are few and far between. As Mr. Vernon Heath has shown conclusively, each enlargement of a gelatine plate displays some new beauty, some delicate half-tone, whereas the old collodion enlargements were blurred and woolly, as if Brobdignagian spiders had been weaving their webs in mockery over the work. To turn to the travelled thanes who have sent in exteriors and interiors from every part of the civilised globe. These views are naturally taken small ; how admirably they are enlarged is told on these walls. Here is the "Church of the Knights of Malta," an enlargement after the negative by Signor A. G. Tagliaferro, with its wealth of ornament, its altar with massy silver candelabra, its carved stalls, its Renaissance panels, its treasures of the silversmith's art. It is well Malta is English. Were these treasures the property of any church in Italy they would every one be marked, their weight taken in an inventory, ready to be a prey to the looter wheu Italian finance is at as low an ebb as Italian statesmanship. Here, by the same artist, is another interior of the Church of S. John, with the tombs of the bygone Knights of Malta, some of whom had gone in battle with the Paynim Turk for the defence of Rhodes. "The Knights are dust, Their swords are rust, Their souls are with the saints, I trust." Pass from this treasure of church architecture to this Troglodyte village of Atalaya, Gran Canaria, by Mr. Stone, both the works of man. This autotype enlargement of the Rheims Cathedral, that has seen the crowning of all the descendants of S. Louis, this ruin of Raglan Castle, this North Portal of Chartres Cathedral, by Mr. Machell Smith, and these Athenian views by a chaplaiu in the Royal Navy, the Rev. J. S. Knight. The temple of Æolus, the Parthenon, the Tomb of Cecrops, copied in the Vestry of S. Pancras' Church, and the Erectheum, survivals of when Grecce was the mistress of all arts, the brain-ruler of the world.

Nor is the present forgotten. The Stereoscopic Company have taken down every nook and corner of "Old Londou" in the Healtherics to survive when its six months' life is ended. One word on interiors. Why does not Signor Tagliaferro set down with his camera the church of Monreale in Sicily, the grandest Byzantine shrine in the world, to which Ravenna, and even St. Mark's, must pay homage ?

Now for a hasty flight over a wide field, that travelled by the camera. The School of Military Engineering shows marked improvement in such works as this. Lynmouth and the picturesque Lyn Valley, the old tower painted by so many an artist ; Surrey Scenery, such as John Linnell loved ; Surrey Lanes, by Mr. H. E. Moberley ; Surrey Woodland Scenery, by Mr. T. M. Brownrigg ; Bettws-y-Coed, and all the spots kuown to the tourist, to say uothing of the artists, where easels arc set as closely together as the auglers in Mr. Deney Sadler's "Pegging-down Match" ; those by Capt. Abney, R.E. ; the Cherwell and Magdalen College ; Mr. Arnold Spiller's Souvenirs of Luther, including his window in the Wartburg, Eisenach ; Shipping at Rochester, Coonish Coves, Thuringiau Forests, the Lake District, our old abbeys, Melrose, Jedburgh, and Tintern. Such a delicious glen as "Near the Waters-meet, Lyn Valley," by the School of Military Engiueering ; Views in Londou, such as these by Messrs. York and Son, which set us thinking where can they be ; and such South African scenes as this Easter Hunt at Wycombe, with the caravan setting out, the motley groups of hunters and natives, the camp fire and the trophies of springbok, elands and two-pronged deer ; finally, the surf boats of Port Elizabeth, or these Bird Islands, Algoa Bay, or this Valley of Desolation, Graaf Reinet, all by Mr. R. Harris. "The Effects of the Earthquake at Colchester, 1884," by Mr. John Spiller ; the natives—for all who live at Colchester must be "natives"—seem very proud of having had an earthquake all to themselves. Certainly, if this view is to be credited, it did no harm to the Old Castle. Finally, some instantaneous bits : "Folkestone Boat entering Boulogne Harbour," by M. C. Grassin ; and Breaking Waves at Bognor, and Giant Breakers, marvels of technique, by Mr. W. P. Marsh, and some of Mr. W. England's too seldom exhibited "Views in Switzerland," clear and bright as the air of the Higher Alps.

Amongst what may perhaps be best termed "Genre" subjects I would note Mr. Val. Blanchard's imposing and truthful "Message from the Sea," with the old salt looking at the last remains of the dinghy, the board which bears the name "Concord"—an epitaph, it is to hoped, for those who have found peace and rest beneath the waves. Mr. H. P. Robinson, the founder of this school, is naturally present in a number of studies, oue of which, "The Mill Door," two donkeys being laden, gained the medal, and another, which I prefer for its unforced humour, "He never told his love" : an old fellow with a merry twiukle in his eye, who sits on a stile chaffing some laughing girls. This "Last Bit of Scandal," with the figures in Second Georgian costumes, by Mr. Malcolm H. Clerk, and "The Awkward Lead" and "The Revoke," exceedingly humorous, and Fred. Barnardesque, by Mr. W. Cotesworth. Amongst sketches, Dorothy Vernou's Room, the Steps at Haddon Hall, and the postern from whence she eloped with handsome Robert Manners, and added Haddon to Belvoir Castle, by the Hon. Mrs. Holden Hambrugh, must uot be forgotten, or this "At Rest in the Desert," outside the Biskra oasis, enlarged from a uegative by the late H. Baden Pritchard. What would Aristophanes have said to these photographs of his Birds taken after the performance at Cambridge, November, 1883 ? Surely tho merry old Greek would have chuckled, and made Mr. R. H. Lord the subject of a new character.

But space warns me. I would but mention some artistic lily screens and daintily taken flowers, by Mr. F. Hollyer, the æsthetic photographer, who admirably reproduces in all but the glowing glory of colours, tones and tints ; "The Six Days of Creation" of Mr. Burne-Jones, and some excellent photographs of oil paintings by the indefatigable secretary, Mr. Edwiu Cocking.

[From *The Builder.*]

It is curious to observe how completely "your photographer" neglects architecture as a rule. Of the nearly 600 plates exhibited, not one represents an architectural subject properly so-called ; there are a few commonplace street views, and that is all. Yet there is no subject for which photography is more eminently suited than the reproductiou of architectural detail. In the Photographic Exhibition, takeu generally, there is doubtless much good technical achievement ; yet how dull is the interest excited by these microscopically perfect reproductions of form and detail in nature, as compared with that aroused by the imperfect works usually exhibited in the same room. In the one case we place between us and nature a chemical machine ; in the other case, a sensitive human mind and hands. In a certain way the balance is in favour of the human agency, even in regard to verisimilitude. The instantaneous photographs of breaking-waves and sea-spray, for instance, do not, somehow

look like sea. A painter would convey the idea of motion; modern photography, by its very perfection of instantaneous imprint, loses the motion, and gives us a rigid mass thrust permanently up into the air. The effect is curiously seen in a photograph of an express train, taken in the 300th part of a second. The train appears to be standing still. A photograph of lightning, which is shown, still retains the idea of motion; lightning is too quick even for the photographer. The scientific value of photography is finely shown in some photographs of magnified objects, sections of parts of plants and insects; but in regard to the representation of natural scenery, the failures of the painter are worth more than the successes of the photographer, even apart from the question of colour.

Correspondence.

MORE PLATES FOGGED BY THE LEATHER HINGE OF THE SLIDE.

Dear Sir,—Last Thursday a gentleman called on me and asked me to develop a plate for him, as he thought there was something wrong with his dark slide. I developed the plate, and found a dark band on the right hand side of the plate about 1½ inch wide. On returning it to the dark-slide, I found that the mark corresponded exactly to the leather used for hinging the shutter of the slide. The leather smelled strongly, and had imparted a slight fog to the whole plate. The plate had remained in the slide for about one month, but during that time it had not been exposed to any white light. I was informed that the plate, if only kept in the slide for a short time, was all right; but if kept for two or three days, the band of fog was sure to appear

The camera makers should be more careful in selecting the leather they use for their slides, and save plates being condemned through no fault of the plate maker.—I am, sir, yours truly, J. D. England.

[Camera makers might do well to use vellum for making the hinges of their slide shutters. The way to make a vellum hinge may be learned by inspecting the inside of a pianoforte.—Ed. P. N.

THE PHOTOGRAPHIC EXHIBITION.

Sir,—In the *Times* report of the Photographic Exhibition, there is an observation which opens up a question of some importance in the interest of fairness. In this report it is suggested that the traveller may hand his exposed plates to a professional photographer to develop and print. Possibly this is often done, but in what sense can anyone so doing lay claim to the results? If the plates are bought ready-prepared, and are afterwards developed, printed, and mounted by professional hands, the amateur has had nothing to do with them but the exposure. This may be a matter of little or no importance until such pictures are offered for competitive medals, or for the honour of a place in the Exhibition. In this case, does the Society require some distinct guarantee or declaration that the person exhibiting has had more to do with the production of the pictures than the mere exposure in the camera?—I am, your faithful servant, Sacerdos.

THE POTASH DEVELOPER.

Dear Sir,—I have just received your issue of 22nd Aug., and in it I read Mr. Jennings' letter about the potash developer. As I have lately been trying this developer (Newton's), you may perhaps care to hear what the result has been with me. I entirely agree with Mr. Jennings in all the advantages he attributes to it. It is a quick, powerful developer, and gives very bright, clean negatives. It can be used of even greater strength than that recommended for instantaneous pictures; but for ordinary exposures I find half strength, or even weaker, is an improvement. Plates at all prone to frilling seem more liable to do so with this developer than with the pyro and ammonia developer; but the alum bath between developing and fixing is a remedy for that. I have just been down to Bombay on leave, and while there, I took some instantaneous street views. I am sending you half-a-dozen prints, on which I should be glad to have your opinion. They are the first pictures of this kind I have tried, and the way I managed was as follows. I fixed the focus of my lens for an object at about a medium distance from the camera before starting, and then, getting on to the top of a cab, drove down the streets; and when I came to any spot that took my fancy, and looked as if it would make a picture, I held up the camera, looked over the top of it, and, when I thought I had got it square on the object, fired away. I developed the negative on my return here with the potash developer, full strength as recommended by Mr. Newton.

A professional printer would produce better results, as I am not great at printing; but perhaps you will be able to judge of the negatives from what I send.—I remain, yours faithfully, M. W. Hooper, Lieut.-Col.

Bangalore, India, Sept 12.

[The pictures sent by our correspondent are of the first order, well graduated, and vigorous; while the absence of any want of sharpness where pedestrians are shown in the act of crossing in the immediate foreground shows that the exposures must have been exceedingly brief.—Ed. P.N.]

THE DUBLIN EXHIBITION.

Sir,—Your remark in this week's "Notes," relating to the date fixed for the above, is a most natural one. Permit me, however, a word of explanation. In making our arrangements we were not entirely free agents, because, but for the courtesy of the Royal Hibernian Academy in lending us their rooms, we could not have held the Exhibition at all. Hence we were obliged to fix the date to suit the Academy's convenience more than our own. As a matter of fact, we have had a large measure of support from English and Scotch photographers, and scarcely anyone has objected to the date clashing with that of Pall Mall.—Yours truly, Greenwood Pim.

Monkstown, Dublin, October 13.

Proceedings of Societies.

London and Provincial Photographic Association.

At the weekly meeting of this Society, held on the 9th inst., Mr. W. Ackland occupied the chair.

The Chairman read a medical certificate he had received from Mr. Ashman, who, in consequence of a severe attack of bronchitis, was unable to be present to give his lecturette on Toning fixed for this night.

The Members, in expressing their great regret at Mr. Ashman's illness, decided that the lecturette should be postponed to Thursday, the 23rd inst.

Mr. Teasdale (a visitor) showed some transparencies he had made on bromide plates, which he had been very successful with—the developer used was the ordinary ferrous oxalate—also the results he had obtained on some chloride plates made by Mr. Cowan.

A Member, who had been recently making transparencies, asked what was the best paper and mountant to use for this work.

Mr. Henderson had found a needle paper answer the purpose.

The Chairman used a dark French paper.

Mr. G. Smith used a mountant of gum and sugar. The strips of gummed paper for binding the transparencies were cut an inch longer than required, and drawn over a postage stamp damper; by this method the fingers were not soiled or made sticky with the gum.

Mr. Barker used a mixture of flour paste and gelatine boiled to the consistency of size; the addition of ammonia improved its keeping quantities.

Mr. Teasdale remarked that he had been for some time past much interested in the making of transparencies, and referred to the difficulty he experienced in getting perfectly flat thin glass

for this purpose, and also the needle paper referred to; he had used the gum and sugar, but preferred a weak glue, this admitting of a stouter paper being used; but it had the disadvantage of requiring to be made hot on each occasion of using it. Instead of the ordinary paper biuding for transparencies, he suggested using a plain preserver, such as is used for glass positives, if a manufacturer could be induced to make them for the purpose. Mr. Teesdale also referred to a paper that had been used in 1862, similar to, but more yellow in appearance than, the present albumenized paper; this was sensitized on a 60-grain bath. After printing, the paper was immersed in cold water. A tough film floated off, which could be floated on to a glass plate. He had found this an exceedingly easy way of making transparencies. On his return from abroad the paper was no longer in the market, and he had failed to obtain it anywhere since.

Mr. Henderson agreed as to the convenience of the preservers, as the glasses could be easily separated should occasion require removal of any dust, &c., from between them.

The Secretary read a letter he had received from the Edinburgh Photographic Society, asking the members of the London and Provincial Association to act as judges in a competition of pictures fixed for the end of the month.

The Members willingly agreed to this, and the Secretary was instructed to reply to this effect.

The ordinary business of the meeting being over, Mr. A. L. Henderson invited the members present to an adjoining room, where an excellent supper was laid. After full justice had been done to the good things put before his guests, and the Chairman had proposed the usual loyal toast, Mr. W. E. Debenham proposed the health of Mr. Henderson, congratulating him on his successful tour in America, and expressing the pleasure the members of the Association felt in giving him a hearty welcome back. The toast was enthusiastically responded to by all present, Mr. Henderson replying to same. The toast of the visitors was proposed by Mr. A. Haddon, and replied to by Messrs. Teasdale and Harrison.

Songs and recitations were contributed by Messrs. Cobb, Cowan, Rymer, Harrison, and Briginshaw, some humorous original verses by Mr. W. Cobb causing much merriment.

Sheffield Photographic Society.

The annual dinner and meeting took place at the Masonic Hall, on Tuesday, the 7th inst., Councillor J. Firth in the chair, when a very good muster of members sat down to a plentiful and well-selected meal, which was followed by the usual yearly routine of discussing and passing accounts, and electing new and re-electing other officers. In the statement of account, the most notable item was a rather serious loss on the last exhibition, which was held in January of this year.

The following officers were elected for the ensuing year:—

President—Mr. W. B. Hatfield.

Vice-Presidents—Councillor Thomas Firth and Dr. T. H. Morton.

Treasurer—Mr. T. S. Yeomans.

Secretary—Mr. J. Taylor

Council—Messrs. Bacon and Turner.

On leaving the chair, Mr. Firth spoke of the prosperous condition of the Society, notwithstanding the loss on the exhibition.

Mr. Hatfield, on taking the chair, said that it would be his study to maintain the interest and improvement the Society was now making.

The subject for this month's competition was the best picture of "Clouds," and was won by Mr. Turner.

Mr. H. Rawson brought a very rich print and negative of clouds, which called forth great praise.

Mr. Turner had a number of good pictures of his summer's work on the table.

The subject for the November meeting will be "Enlargements by Artificial Light on Argentic and other Sensitive Paper," by Mr. Foxon.

Leeds Photographic Society.

At the last ordinary meeting held on Thursday, Dr. Thorpe, F.R.S., in the chair, there was a good attendance of members. The following gentlemen were elected members:—Sir Percy Radcliffe, Rev. C. Courtenay, Messrs. T. W. Harding, and R. T. McKay.

Messrs. S. Marshall and T. Dawson were elected auditors.

A large number of prints from negatives taken at the out-door meetings were exhibited by Messrs. Teasdale, Ramsden, Ward, Denham, McKay, Bothamby, and Pearson.

Dr. J. Walker exhibited a changing-bag of simple construction, but most efficient, which elicited much admiration.

Mr. Branson exhibited a number of lantern slides, to show the effect of introducing sulphite of soda into the soda developer.

Mr. Pocklington exhibited a lantern slide toned with gold, in which the foreground was a brown colour, the trees and middle distance green, while the sky was a light blue. Mr. Pocklington promised details of the process when he had made further experiments.

Messrs. Reynolds and Branson exhibited a new dark-room lantern with special features, which will meet with the approval of amateurs.

Mr. Teasdale, referring to the manner in which exposed plates were packed by some of the members previous to development—*i.e.*, face to face, without anything between—suggested that it was possible by this means some of the plates might become more or less fogged, basing his opinion on the fact that plates wrapt up in paper that had recently been exposed to a strong light exhibited traces of fog.

Dr. Thorpe was of opinion that the suggestion made by Mr. Teasdale was of great interest, and trusted some of the members would make experiments so as to thereby test it. He informed the members of the Society that a committee had recently been appointed by the Leeds Philosophical Society for considering the question of pushing the interests of meteorology in some way, and he asked the attention of the members of the Photographic Society to this subject, as he thought they might be able to derive some method of determining the amount of solar energy day by day. What was required at present was not any delicate and intricate apparatus, but, until their knowledge was more advanced, some simple rough-and-ready method would be most useful. He mentioned several actinometers that were in use, and trusted the members would interest themselves in the matter.

Several members made suggestions, and a general conversation ensued.

Derby Photographic Society.

The ordinary monthly meeting was held at the London Restaurant, Irongate, Derby, on Wednesday, Oct. 1st, Mr. Richard Keene in the chair.

The minutes of the previous meeting having been read and confirmed,

Mr. H. Arnold Bemrose, M.A., Vice-President of the Society, gave an address entitled "Scraps from my Holiday," (see page 666), which he illustrated with lantern transparencies by means of the Sciopticon lantern.

A vote of thanks was passed to Mr. Bemrose for his interesting paper.

The report of the sub-committee appointed to consider the conditions of the subjects for study was, after a few slight alterations, adopted, the last day for sending in the prints being fixed for December 10th.

Mr. W. Haslam was elected a member of the Society. A cordial vote of thanks to the Chairman brought the proceedings to a close.

Bolton Photographic Society.

The annual meeting of this Society was held at the Baths, Bridgman Street, on the 2nd inst., Mr. E. N. Ashworth in the chair.

The minutes of previous meeting having been read and confirmed, the following annual report was read:—

"In presenting their fifth annual report, your Council desire to congratulate you on the eminently satisfactory state of the Society. During the year 1883-4 there has been a large increase in the number of members, and at no time since its formation has the Society stood on a sounder basis. Your Council are happy to state that the balance in the hands of the Treasurer is steadily increasing. The following demonstrations have been given during the season:—'On toning and fixing silver prints,' by Mr. Parkinson; 'On enamelling silver prints,' by Mr. J. Taylor; and one on the "Development of platinotype prints," by Mr. C. K. Dalton.

"Lantern exhibitions have been given by Messrs. W. Banks, R. Harwood, and T. Parkinson, and have undoubtedly added to the attractiveness of the Society.

"The annual open meeting was held in April last, at the Baths, and was in every sense a success.

"Your Council have again to regret the meagre attendance at the out-door meetings; in fact, there has, strictly speaking, been only one meeting held during the summer months, although the weather has not been unfavourable. It is hoped that efforts will be made to render these meetings more attractive, and so secure a better attendance."

The Report having been accepted as read, a vote of thanks was passed to Mr. Hicks, and regrets expressed as to his retirement from the Presidency of the Society. Mr. Hawksworth having also desired to retire, the thanks of the Society were tendered for his energetic and valuable services as Honorary Secretary.

Messrs. Paitou and Taylor examined the voting papers, the following being the result:—

President—J. A. Bridson.

Vice-Presidents—Harwood, Ashworth, Parkinson, and Hawksworth.

Council—Banks, Taylor, Knowles, and Slater.

Treasurer—J. C. Sewell.

Hon. Sec.—C. K. Dalton.

On the motion of Mr. B. Abbott, a vote of thanks was passed to the retiring Council for their services during the past year.

Photographic Society of Ireland.

A meeting was held in the Royal College of Science, Stephen's Green, on Friday, the 10th inst., Mr. Greenwood Pim, M.A., in the chair.

The minutes of the last meeting having been read and confirmed,

Mr. A. G. Tagliaferro, of Malta, was elected a member of the Society.

The following names were proposed for membership:—S. Geoghan, C.E., H. Magee, and Francis S. Hall.

Messrs. Samuel Baker and Thomas Curtis were elected to audit the yearly accounts before the next meeting.

Mr. C. W. Watson gave an account of his recent trip to Derbyshire with the camera, and exhibited a large number of excellent views taken during the tour.

Mr. George Mansfield showed a series of 10 by 12 views, which he had recently taken in France and Spain, all of which were much admired for their artistic and technical merit.

Mr. J. V. Robinson showed a patent instantaneous shutter, the invention of Mr. F. W. Monsell, a member of the Society, and which formed the basis of a varied and interesting discussion on shutters in general.

Mr. Thomas Mayne exhibited a new expanding camera of great length, suitable for copying, &c.

Mr. John L. Robinson's paper, "A Week in Suffolk," was by consent postponed until that gentleman's return.

The proceedings were then adjourned until the 9th November, when the annual meeting will be held.

St. Helen's Association of Science, Literature, and Art.

Photographic Section.

A meeting of this Section was held on the 17th ult., Mr. Heather in the chair.

Mr. Bewley showed a number of views taken at Betts-y-Coed during the month; part of these were toned with platinum.

Mr. Sherlock said he preferred to use the platinum bath, as he could get as great a variety of tone with it as with gold, and the cost was only a quarter that of the latter metal.

Mr. J. F. Houghton showed a number of lantern slides of local scenery. Two (Chapman's albumen), developed by the pyro-sulphite method from a formulæ given in "Marion's Photography," were especially praised for their clearness. The rest were developed by Cowan's solutions; these tones were much admired.

Mr. Thomason showed a number of lantern slides of some very pretty views near Buxton.

Mr. Heather showed about twelve prints toned with a solution made up of perchloride of iron, nitrate of silver, and hyposulphite of soda. The tones varied very much; some, however, had a very pleasing effect.

Mr. Taylor enquired if the prints were as permanent as the ordinary ones; he did not consider they would be, especially in a town like St. Helens.

Mr. Heather said his experience was limited to the few prints he had shown; he fully endorsed Mr. Taylor's remarks. Mr. Heather then showed two negatives, one fogged, the other quite clear. He explained that while cooking the emulsion, he found a series of small holes in the can, and consequently the emulsion was fogged. Mr. Heather then placed it in a ten per cent. solution of bichromate of potash for fourteen hours; after this treatment it was quite free from fog, but was considerably slower.

After a discussion on emulsions, developers, &c., the meeting closed.

Amateur Photographic Association of Victoria.

The monthly meeting was held on Monday, 1st September, at the Royal Society's Hall, Mr. E. C. Bell, Vice-President, in the chair.

The minutes of previous meeting were read and confirmed, after the election of new members and the nomination of two others for membership.

Mr. Baker demonstrated the method of using Warnerke's sensitometer. He showed several of the sensitometers, and it was remarked by some of the members that if all those which are manufactured are equal to the samples exhibited, very little reliance can be placed upon them for comparative tests, as the density in no two of them was similar. When the development of the best plates was commenced, similar complaints were made by many of the members as to the careless coating of many of the makes of gelatine plates which reach this market, some samples issued from the factory of a well-known English maker being conspicuous for uneven coating. It was jocularly remarked by one member that gelatine emulsion must be exceedingly cheap, or the manufacturers could never afford to coat the backs of the plates as freely as they do the faces, without extra charge, which is very often the case.

The result of the tests showed that some of Mr. Baker's make of plates registered as high numbers as the best makes of English plates which were tried.

The lecturer afterwards exposed and developed several opal plates of his own make, and a great deal of information was given; after which the meeting closed.

Talk in the Studio.

The Exhibition of Inventions, 1885.—Those who may wish to exhibit will be interested in knowing that applications will be received up to November 1st, the time having been extended. As a feature is made of photographic apparatus in the classification, it is to be hoped that all important steps made since the last great exhibition will be properly represented. Pictures as pictures are not to be admitted; but as illustrating a process they will be received. Forms of application for space may be had from the Secretary, Inventions Exhibition, South Kensington.

A Journal Illustrated entirely by Photographs.—Herr Wilhelm Hoffmann, of Dresden, has issued the first number of a monthly magazine, "*Das Universum*," which is illustrated entirely by means of the collotype process. In the first issue there is an instantaneous picture by Auschütz, and four other photographs.

The Northampton Exhibition.—Notice should be given by intending exhibitors before the 1st of November. Forms of application for space may be had from Mr. H. Manfield, The Museum, Northampton. Nine silver medals and sixteen bronze medals are offered.

New Panoramic Photographs by Mr. Gutekunst, of Philadelphia.—We have received two remarkable panoramic pictures of the kind for the production of which Mr. Gutekunst has made himself so celebrated. One represents the new Susquehanna Bridge, and a train of cars ready to cross; while the other is a picture of the "Back Saddle Curve" on the same line. The pictures measure 16 by 48 inches.

The Use of the Royal Arms.—The case against Messrs. A. and G. Taylor (see p. 634), which was adjourned from the 30th ultimo to Tuesday last the 14th instant, was again adjourned, and came on for hearing on Wednesday last, and the magistrate, after some unimportant remarks, inflicted a fine of one shilling and two shillings costs. The prosecution was founded, it will be remembered, on the 106th section of the new Patent Act, which came into force on the 1st of January, 1884, and in connection

with this enactment the *Solicitor's Journal* remarks:—"It appears to us that the harassing of tradesmen who cannot produce an authority for using the royal arms is unjustifiable, for no one is, or could reasonably be, deceived by such use into believing that a shop keeper 'carries on his business by or under the authority of Her Majesty, or any of the Royal Family, or any Government department.' Everyone knows that the use of the royal arms by a shop-keeper means nothing at all. The real object of the enactment was supposed to be to prevent patent agents from using the royal arms on their offices and paper, so as to lead people to believe that their advice was given with the authority of a Government department; and if employed for this purpose only, the provision might have been valuable. But to attempt to extend its application to cases in which it is of no importance to any one, whether the arms are used or not, is absurd." It is stated that Messrs. Taylor Brothers intend to appeal on the ground that they have been actually photographers to the Queen during the past fifteen years.

Photographing an Actress.—It was manifestly unfair on the part of an American photographer to take a certain actress much appreciated in her own country by surprise, and obtain a portrait of her just as as she was stepping, dripping wet, out of the sea to regain her dressing-box. The lady of whom a mean advantage was thus taken had refused to be photographed, with a determination that baffled the endeavours of New York photographers; her reason being that she objected to see her likeness in every shop window she passed. Finding her inexorable, it was resolved to have recourse to an expedient, and one member of the profession, ascertaining that she was spending a few days for the purpose of bathing at San Francisco, followed her there with his apparatus, put it in a bathing machine, and obtained what he wanted, unknown to the *artiste*. Shortly afterwards she received a polite note containing her portrait as she emerged from the waves, and the intimation that ten thousand of the same would be put on sale the following day unless she consented to allow herself to be photographed in more becoming attire. The actress talked, in the first moment of irritation, of appealing to the police, but on reflection she considered it wiser to capitulate, although her annoyance is extreme at the unfair proceedings of her persecutors.—*Evening Standard.*

Reactions of Silver Cyanide.—Professor C. L. Bloxam describes in the *Chemical News* a series of experiments on the effect of nitric acid and the alkaline carbonates on precipitated cyanide of silver. This salt is completely dissolved by boiling in nitric acid, with the production of hydrocyanic acid and silver nitrate. If the solution be decanted off before the action is complete, minute needle-like crystals are deposited on cooling. The crystals prove by analysis to have the composition $AgCn2Ag NO_3$. Precipitated silver cyanide, when treated in the cold with a strong solution of sodium carbonate, becomes granular. Under the microscope the edges of the granules exhibit minute needles. On boiling, the salt becomes grey, and with the exception of a trace of metallic silver, all is dissolved. The solution, on cooling, deposits a mass of needle-like crystals, which prove to be pure silver cyanide. The conversion of amorphous cyanide of silver to the crystalline takes place more readily with potassium carbonate than with the sodium salt.

Photographic Club.—On the 22nd inst., the subject for discussion will be "Reversed Negatives." All notices affecting the annual general meeting must be made on or before the 22nd inst.

To Correspondents.

*** We cannot undertake to return rejected communications.

Ebbw Vale.—Until the thirteenth of November.

Enquirer.—1. The best solvent is crude benzole or light coal oil. 2. Silicate of soda 1 part, white of egg 5 parts, water 60. Beat to a froth, filter, pour on the glass, and allow the excess to drain off. Some prefer to rinse the plates with water after the substratum has dried. The syrup is not satisfactory.

Amateur Photo.—The gentleman you name has no claim to be considered an amateur, as his photographic views are sold in Regent Street and elsewhere.

James J. Walker.—1. The single lens will do, but where accurate focussing is required, it is better that both instruments should be identical. A lens of inferior quality would not be quite satisfactory, and we think that you had better call upon the maker of the instrument, and see if you can make any arrangement for him to construct what you require.

M. E. T.—1. Your work is rather too pronounced; that is to say, you have done too much on the prominent features, and not sufficiently removed the irregularities of texture in the face. Take prints from the negative occasionally as you go on, and study the general effect. The retoucher who can most adroitly flatter vain sitters is most appreciated, and if you wish to succeed you will have no alternative but to accommodate yourself to circumstances. 2. Yes, but probably not just yet.

E. and L. Lander.—There is no list kept, but each is announced in the Photographic News as particulars reach us.

F. Francis.—All depends on the style of the work, but about half-a-crown would be near the mark if well done.

Chestrian.—Nothing can be done but to clean off the films.

J. B.—We think not, unless the quantity is so great as to retain moisture.

An American.—If you will send us your address, we will forward you some of the photographic journals published in the United States, so that you can gather information from the advertising pages.

Henry Spink.—We do not know the nature of the composition "finally adopted" by the gentlemen you name, but will do our best to find out what is really best for the purpose. These particulars, together with the address of the gentleman you name, shall be posted to you.

Rev. W. A. C. A.—Thank you for your communication, which touches on an important point; but we are not sure whether we can make use of it this week.

H. J. H.—1. Yes, if you adopt the method of Mr. Pleuer. See page 465. 2. Either the first or second. 3. The old process will give much finer results in skilful hands, but much more work must be done to get the results. 4. To speak candidly, the best way is bad, and you had better make your pictures by the gelatino-chloride process, described in the Year-Book for 1882.

G. Mackie.—It makes absolutely no difference which way you mix it.

Chas. W. Brown.—As far as we know, they are not in the market at present, and we have not yet seen the instrument. The data given are, however, sufficient for enabling an optician to construct one for you.

Alpha.—1. It is to be feared that without suitable apparatus or experience, your chance of success will be small, as it is difficult work when all the appliances are ready to hand. A rolling press of the full size is essential. 2 Long soaking is not required, and any method of quickly drawing it through the solution will answer. 3. It is better to dry it, as otherwise it may contract from partial drying during the time of exposure. There is no other reason for drying it. 4. You do not quite understand the method, as there is nothing to peel off, and the waxing mixture is applied afterwards.

C. Wyrall.—Send them to the Hon. Secretary, Mr. Greenwood Pim, Royal Hibernian Academy, Abbey Street, Dublin.

H. Rendell.—Cover it with thin tissue paper, this being far better than any composition applied to the glass. When the paper becomes yellow or dirty, you can easily renew it.

A. Brown.—1. See the Notes this week. 2. Not before fixing; but a second immersion in the fixing bath is required after the treatment.

Forster Brown.—A large round hole at the back, with a piece of blackened sheet metal mounted an inch from it, is all that is required.

E. B.—You have been surprisingly successful in your work, and your Swiss views are admirable. Still, it seems to us that by giving a longer exposure, and working with a less active developer, you might perhaps get a little more detail in the shadows. It is, however, extremely difficult to obtain all gradations of tint in the case of dark objects against a background of snow and ice. You must, however, bear in mind that we are doing our best to find a fault.

THE PHOTOGRAPHIC NEWS.

VOL. XXVIII. No. 1364.—*October* 24, 1884.

CONTENTS.

COMPETITION OF PROCESSES FOR LANTERN SLIDES.

A COMPETITION of a kind which ought to lead to a useful result has been inaugurated by the London and Provincial Photographic Society. The competition, which has been instituted at the suggestion of Mr. W. E. Debenham, is between *processes* for producing lantern slides.

Photographers who are considered to be adepts at particular processes have been selected, and these have been asked to produce a certain number of slides—two or three, we forget which—from each of two different negatives. It has been made to be distinctly understood that the competition is not one between the individual photographers who have undertaken to represent particular processes, but is between these processes themselves, the object to be attained being a comparison of the merits of the processes. The negatives from which the slides are to be produced have been handed in turn to the gentlemen aforementioned, so that all the slides will represent the same pictures. The negatives are of excellent quality, and the slides are to be made by contact exposures, or are at least to be of the same size as the negatives.

A discussion on the subject of the competition took place a short time since, and waxed somewhat warm, several members apparently forgetting that the object of the competition is merely to compare *processes*, and is not in any way intended to be a trial of skill between the individuals who undertake the work. Nevertheless, several points of interest were touched upon.

Mr. A. L. Henderson had been asked to represent the wet process. He urged that the competition as instituted was such as would in no way bring out the special merits of that process as compared with others. Let the negatives, he said, be such as were faulty. Were either too thin or too dense, or had other such like defects, and he would undertake to show that the wet process would cope with the difficulties thereby introduced better than would any other; or let it be a case of enlarging or reducing, and he would guarantee a similar result. But with perfect negatives to be reproduced as transparencies of the same size, the wet process would show to no advantage. In fact, he urged that although the wet process was the best wherewith to undertake the general run of work, which included reproductions from all sorts and conditions of negatives, it would produce an effect not superior, and probably inferior, to others, with the conditions as Mr. Debenham had laid them down.

Mr. George Smith was asked to represent the Woodburytype process. This gentleman urged another objection to the method of the competition. He said that were it a case of producing a single slide from a negative, or producing even two or three, he *knew* that the Woodbury process would be beaten by others. Let it, however, be a case of producing a hundred or a thousand slides, and let clear high lights and *uniformity* be a condition, then he would guarantee a better result than could be got by any other process.

Probably Mr. A. Cowan, representing gelatino-chloride plates, might have added that if a condition was variety of tone, no process could touch that which he had undertaken to champion. The variety of beautiful tones which can be got from gelatino-chloride plates does indeed excel anything that we have seen produced by any other process. Those who have not tried the capabilities of these plates, or who have not had an opportunity of seeing what can be done by them, should inspect Mr. Cowan's exhibits at the present show of the Parent Society. There are frames containing an almost endless number of small transparencies, the colour of which ranges from a perfect black to something almost approaching crimson, and in every case the tone is a most pleasing one.

But to return to the Woodbury process. Mr. Smith stated that in producing lantern slides by means of it, it is always necessary to sacrifice somewhat of the gradations of density either at one end or at the other—that it is necessary, if we wish to retain all the detail of the highest lights, to sacrifice some of the detail in the deepest shadows. If we wish to retain all the detail of the deepest shadows, we must sacrifice some of the shadow detail. An attempt to secure the whole of the gradations from the highest lights to the deepest shadows always resulted, he said, in the production of either a flat or a heavy picture.

A theoretical reason might be given for this in the case of the Woodburytype—or still more in the case of the Stannotype—process.

It is stated by Abney, and the statement is pretty well recognised as correct, that there is no photographic process for producing a negative from a positive, or a positive from a negative, in which the correct gradation of tones—or, more strictly, densities—is retained; that in every case there is an exaggeration of the difference between one half tone and another half tone, and a diminution of the difference between various shadow tones or various high light tones, the result of continually producing a positive from a negative, a negative from this positive, a positive from this latter negative, and so on, being a tendency towards a picture in two tones only. Eventually, if the process be continued long enough, there will be nothing between transparency and a certain uniform amount of opacity, all half-tones having merged into one or the other extreme. A black and white image is got, in fact.

If any one wish to convince himself that this is the fact, let him take, for example, ordinary gelatino-bromide plates. One of these is exposed by contact under a nega-

tive. When the transparency is developed and dried, another plate is exposed under this, and the process is continued indefinitely. It will not be long—probably not a dozen plates will have been exposed in all—before we have a picture in black-and-white, with no half tone at all, and this, let the development and exposure be varied as we will.

In the fact that we have tried to explain, may lie the cause of what Mr. Smith states with regard to the Woodbury process.

In the Stannotype process, a transparency is produced from the original negative. From this transparency is taken a negative in bichromated gelatine. From this negative is produced the mould, from which finally the finished transparency is got. It is true that the last two processes are not, strictly speaking, photographic, and are not likely to—in fact, do not—produce that alteration in gradation of tone which we have spoken of; but even without them there is one more transition than there is in most processes used for producing slides.

In spite of the objections which were urged by Mr. Henderson and Mr. Smith against the competition of lantern slide processes, we will venture to say that useful results will rise from it, and will farther say that we hope that a suggestion which was made during the discussion may be given effect to. A member proposed that after the present competition was over, there should be another between the same processes, with this difference only—"that the negatives used should be typically bad ones, instead of typically good ones." A farther suggestion was made that after this second competition was over, a third might be inaugurated with the object of discovering which process would give the greatest uniformity when a number of slides were to be produced.

THE PALL MALL EXHIBITION.

Pictures and Apparatus.

third notice.

No. 27, "Winchelsea," by Mr. John Lswis, is an effective picture, and the same gentleman contributes "Bedford's Oak, Chingford" (No. 39), "A View in the New Forest, near Lyndhurst" (No. 106), and "Catford Bridge, Kent" (No. 446). Of these, the Chingford Oak perhaps possesses the most strikingly pictorial qualities, although when looked upon from a technical point of view, one cannot help thinking that the shades are somewhat too black. Mr. H. J. Godbold's "Religious Procession of Charles le Bon at Bruges" (No. 28) is a clever rendering of a difficult subject, and will recall pleasant memories to those who love to wander in the old, and now comparatively-deserted, Flemish cities. How the ordinary deserted aspect of Bruges contrasts with the stirring activity accompanying a public holiday! Indeed, it is only at the time of a Church festival or holiday that the tourist of to-day can feel himself face to face with a dim shadowing of the past history of the City of Bridges. Mr. Godbold also exhibits "Break, break, on thy cold grey stones, O sea!" (No. 40) a delightful study of beach and foam; "Wintry Garments" (No. 157), showing the trees in their mantle of frost and rime; "By the sad sea waves" (No. 158), a picture in which one can almost see the ripple moving onwards towards the shore; "Boulogne-sur-Mer" (No. 225); "To the Rescue" (No 226), an effective production, showing a ship in distress; "A Gale at Old Hastings" (No. 237), in which the fury of the raging sea is well depicted; "Rescued" (No. 260), a life-boat study; and 486, an enlargement from the "Gale at Old Hastings." All through Mr. Godbold's pictures there runs a vein of robust artistic feeling, and in several the pictorial qualities are very prominent. "Chorley Parish Church" (No. 29), by Luke Berry, is a picture taken from a well-selected point of view, and it at once suggests to the mind the idea of peace and quietness. Mr. Luke Berry contributes quite a host of other pictures. No. 128 is a view of Fountains Abbey; and here, again, the photographer has shown good judgment in selecting a point of view. Of Mr. Berry's remaining pictures, No. 170, "The Mid-day Meal," is, perhaps, one of the best. The reapers who are partaking have all the appearance of enjoying their dinner; still, we hardly know whether "The Swing" (No. 187) is not a more pleasing study. No. 197, "A Centenarian," represents the aged one sitting outside his cottage; No. 213, "An Autumn Morning," may be looked upon as a good failure, still a failure—the subject being an exceptionally difficult one; No. 294 is a frame of portraits; No. 349, "The Last Load," and No. 350, "In the Country," are good pictures of rural life, and there is the same rural air about 393, 394, and 395, "I'm ready," "Llanberis Pass," and "Daddy's Coming." 399, "Wild Flowers," is the last of Mr. Luke Berry's series, but is by no means the least as regards artistic merit.

"Studies" priuted in red carbon, by Mr. W. E. Debenham (No. 30), is placed rather too high to be seen with comfort; we have here two of the chubby-faced and curly-haired little ones which Mr. Debenham takes so much delight in photographing. We do not very much object to the term "red carbon" ourselves—although it is unscientific and inexact—because it conveys a pretty clear idea to the photographic mind. Still, it surprises us very much that Mr. Debenham should use such a phrase, considering how roundly he takes others to task for want of accuracy in expression. No. 31, "Venetian Boats," by Robinson and Thompson, is more than a photograph; it is a true picture of the lazy boats and sluggish water of the Adriatic Queen, and were it not in a photographic exhibition, one might take it for a study by Turner; we shall have more to say about this picture. Messrs. Robinson and Thompson also contribute Nos. 137, 138, and 161, the first and second of them representing the starting of the boats of the Mersey Sailing Club, while No. 161 is a frame containing eighteen half-plate pictures taken on board-ship.

Mr. T. W. Boord, M.P., has succeeded in producing a fine series of pictures from a yacht (No. 33), the sky and atmosphere being admirably rendered in most of them; these are just the photographs likely to be of real value to an artist. No. 34 is a frame containing some cabinet portraits by Mr. A. Ellis, and some good poses may be noticed. "Miss Villiers, as Fedora" (No. 35), by Adams and Scanlan, of Southampton, is a good picture, but the background is a trifle too dark for the drapery. One may be sure that any portrait taken by Mr. Valentine Blanchard will merit praise; and (No. 36) "Andrew Levy, Esq.," is no exception. Mr. Blanchard only contributes three other pictures to the Exhibition. No. 129, "A Siesta," shows a young lady who has gone to sleep over her book, while reclining in the open air. In No. 292, "A Message from the Sea," the prominent object is the name-board of the *Concord*, and this is the only relic of the good ship; but it strikes one that the edges of the wood and the lettering on the board have been remarkably preserved during all the buffeting about that it must have had. No. 302, Mr. Blanchard's remaining picture, shows "Miss Edith Powis," fan in hand.

Mr. T. M. Brownrigg is at home in the forest, and his studies of the "New Forest, near Lyndhurst—Old Oaks—Adam and Eve" (No. 37), are gems; while his remaining exhibit (No. 113), "Surrey Woodland Scenery—A Lane at Waverley—In a Wood at Cobham, and, On a Mill Stream at Waverly" show that he knows as well how to handle his camera outside the forest as when shaded by the boughs. No. 41 is a portrait of Sir Samuel Baker exhibited by the London Stereoscopic Company; while in No. 42 we have "The Dent d'Herens, from the Stockje Hut," one of those magnificent Alpine studies with

which Professor Donkin's name is now so thoroughly identified; others of the series being 63, "The Rothhorn from Lo Besso"; 92, "The Dent Blanche, from the Trift-joch"; 103, "The Weisshorn, from the Täsch Alp; 178, "The Matterhorn, from the Hörnli"; 337, a picturesque study of Swiss guides "At Work" and "At Rest"; 328, "The Weisshorn, and view from it"; 374, "Three Views near Zermatt," and 375, "Four Swiss Mountains." Mr. Donkin manages to do what is exceptionally difficult—that is, to secure all the beauty of the ice and snow, and yet do justice to the darker objects; and looking on his numerous pictures as a whole, one does not know where to look for anything comparable to the series.

In No. 44, "Studies of Cornfields, near Burgess Hill, Sussex," by S. Norman, one finds a trio of subjects; well exposed, so as to bring out the most shaded details, and yet showing no signs of the weakness or flatness which oftentimes is the result of "exposing for the deep shades." Mr. Norman has only one other exhibit, No. 94, a series of out-door studies which have all the merits of those just mentioned. "Summer Flowers," "Blackberrying," and "The After-dinner Pipe," are good titles that indicate the character of the photographs. The pictures showing the period of rest after the labour of faggot cutting are especially excellent.

Mr. A. H. Dyke Acland is particularly happy in his three studies of children (No. 45), the best of the three being "How long can you sit up, Jock?" in which the little one is severely testing the sitting-up qualities of the pet dog. Mr. Dyke Acland has other figure studies of merit (No. 95); (No. 337) "A Viva-voce Examination in the University of the Future"; and also a good study of sea and cloud (No. 492).

Mr. W. Davis, of Ripley, Derbyshire, has made pictures of the much-photographed Conway Castle, the threadbare Bridges at Bettws-y-Coed (Nos. 46, 47, 96), Bridge at Pemnacho (No. 257), Pandy Mill, Penma (No. 520), and the ever-recurring Fairy Glen at Bettws; but we do not see that he has exercised his camera upon any of the natural beauties within a couple of hours' walk of his own town.

The enlargement of a view of Constantine, Algeria, made by the Autotype Company from one of the negatives of the late Mr. Baden Pritchard (No. 48), is a striking picture, showing the town on its rocky elevation; a quaint mixture of old half-ruined buildings, intermingled with modern houses in the French style, and native huts. Another picture from the series taken by Mr. Pritchard during his recent trip is a scene in the Sahara, near Biskra, "At rest in the Desert, outside the Biskra Oasis" (No. 79). It represents an Arab encampment, and was taken in the early morning; it conveys in a singularly forcible manner the idea of rest, the wandering life of the Arab tribes serving as a foil against which the contrast becomes especially striking.

Somehow or other the yacht "Fleur de Lis," of Mr. T. Milman Brown, does not seem to convey the idea of motion, it seems to be dead and stiff; but his cattle piece, "Repose" (No. 81), makes a fine study, and his "Home Cottage" (No. 126) deserves praise. No. 204, "Church Lane, Shanklin," by the same gentleman, is somewhat marred by the exaggerated whiteness of the road; while No. 371, "An Isle-of-Wight Cottage," and No. 519, "Summer Evening," are creditable productions.

Lieut. C. E. Gladstone's "Botanical Gardens at Palermo" (No. 50) pleases us much, and one cannot fail to be struck by the almost tropical character of the vegetation—palms and aloes being most noticeable. Lieut. Gladstone has two more exhibits: No. 80, "In Moor Park," is a good picture, and also No. 439, another view in Moor Park, "Cedar Tree;" these latter being printed in platinotype.

We have already referred to Messrs. West and Son's medal exhibit, and reproduced one of the most striking of the yacht pictures, a group at comparative rest; but as a contrast to this picture, we now reproduce the central photograph of their frame — the yacht "Buttercup," scudding along like a bird under the influence of a stiff wind. Of its kind, this picture is almost unique.

Another of the medal pictures is also presented to our readers as a print from a Meisenbach block: one of Mr. Auty's remarkable photographs of lightning; and in writing about this picture he says:—

"I took on the evening of Saturday, August 9th, during a very heavy thunderstorm, when the storm was at its height; the pictures were taken from the top room of a house, with the camera pointing seaward. The focussing was done on the lightning, as the flashes followed each other so quickly. I made six exposures on rapid plates, but four out of the six plates appeared to be fogged through sheet lightning which accompanied the forked variety."

The most notable point with respect to Mr. Auty's lightning photograph is, that the discharge appears to be of the "brush" character at the extremities of the spark, and only fairly disruptive in the central portions. This may be due to the circumstance of the photographs being taken seawards, and the flashes rather striking between vaporous masses than upon a solid substance. If our readers will look at the lightning photograph of Haensel, given on page 2 of our present volume, they will be able

to detect a definite striking point where the discharge enters the ground.

Mr. Tagliaferro's picture of the Cathedral at Malta; the supplement which we present to our readers this week is, like that issued with the NEWS last week, the work of a non-professional photographer; and Mr. Tagliaferro has to be congratulated on being the only exhibitor this year who has been honoured by a double award. It is true that the Autotype Company will take the joint medal which has been given for the two enlargements—that of the picture which forms our supplement this week, and that from Mr. Sinclair's negative of Derwentwater—but Mr. Tagliaferro takes the medal awarded for the original photograph from which our supplement has been reproduced.

Few photographers make a special point of producing church and cathedral interiors, and, when done, it seldom happens that they have all the perfections which those who have not attempted this difficult class of work consider they have a right to look for in the work of others. To say that Mr. Tagliaferro's picture is without faults would be absurd; but despite of them, it is such a magnificent picture of an exceptionally difficult subject, that one can only endorse the opinions of the judges in their verdict, that it is essentially the "interior" of the 1884 Exhibition. Although there are three other photographs of the interior of the Church of St. John in the frame containing the picture which we present to our readers, it is pretty generally recognised that the medal was awarded for that which we publish this week, this being undoubtedly the finest picture of the series. In our first notice of the Exhibition we have already noticed the main points of the pictures, so we need say no more at present.

Practical Papers for Beginners.

No. 12.—INTENSIFICATION OF NEGATIVES.

IT often happens that a negative is too thin to yield a good print, even though all the details of the original subject be reproduced; and this want of vigour is very frequently a consequence of over-exposure in the camera.

The strengthening or reinforcing of the negative, so as to convert a thin plate into a vigorous picture, is known as intensification, and one must confess that there is no perfectly and uniformly satisfactory means of intensification known; but we will now describe that which we consider the best in ordinary cases.

The well-washed but unvarnished negative is immersed in the following solution:—

Mercuric chloride	1 ounce
Sal. ammoniic	1 ,,
Water	40 ounces

In this solution the image will gradually become white, and when the bleaching action is complete—no dark portions being visible when the negative is looked at on the glass side—the plate may be removed from the mercuric bath. The next step is to very thoroughly wash the plate, and this can only be effected by long soaking in several changes of water. The following may be taken as giving an idea of the amount of washing which will be sufficient. First rinse the loosely adhering solution from the plate by allowing water from the tap to flow over it for a few minutes; after which place it in water, an inclined position being preferable. If this water is changed every half hour during three or four hours, and one takes care to slightly agitate the water now and then during the periods of soaking, one may consider that the whole of the soluble mercuric salt is removed. Next place the whitened negative in a weak ammouiacal bath made as follows:—

Liquor ammonia	½ ounce
Water	20 ounces

In this liquid the image becomes rapidly darkened, and, generally speaking, the maximum darkening is attained in about five minutes, when all that is necessary is to wash the plate, and to allow it to dry.

The method just described is thoroughly satisfactory when only a moderate degree of intensification is required; and if the washing is thorough after the treatment with the mercurial solution, there seems to be but little or no probability of the negative subsequently fading; but, should the washing have been insufficient, not only do the transparent parts of the negative become veiled, but the negative is likely to become light in colour, and again weak, in the course of a few months. It is, however, curious to note that a negative of this kind which has faded may generally be restored by repeating the process of intensification. It is scarcely necessary to remark that it is useless to attempt the intensification or restoration of a negative while it is coated with a film of varnish, but the varnish may be readily removed by the following method.

Warm a stout porcelain dish by filling it with hot water, and having dried it by wiping with a towel, put the plate in (film upwards), and pour on enough methylated spirit to cover it.* Now rock the dish to and fro for four or five minutes, pour off the spirit as completely as possible, add more, and again rock for a minute or so; a couple more rinsings with spirit will now suffice to remove the resinous material; but the negative should be soaked in water for a few minutes before immersion in the mercuric bath.

When a very considerable degree of intensification is required, it is better to treat the whitened negative in another way. After it has been removed from the mercuric bath, and thoroughly washed as already directed, it is immersed in a dilute solution of sulphide of ammonium—one part of the strong solution, and about ten of water; in this liquid it becomes almost jet black.

In any case it is well to take the precaution of making a transparency from a valuable negative before intensifying it, as in case of any unforeseen circumstance causing the destruction of the picture, the negative can be reproduced from the transparency by any method which is adapted for making a transparency from a negative. Details as to the method of making transparencies will be found in our recent "Practical Paper" on making lantern slides (page 645).

* See foot-note, regarding methylated spirit, on p. 596.

HINTS ON POSING AND THE MANAGEMENT OF THE SITTER.

BY H. P. ROBINSON.

Chapter III.—The Three-Quarter Length.—Men.

In the kind of picture we have now under consideration, there is more scope for variety of pose than in those which include the head and shoulders only. Almost every variety of picturesque effect can be brought to bear, both of light and shade and line.

The three-quarter length is generally supposed to include the figure down to the knees, but in treating of it we may fairly include a proportion that takes in somewhat less, and is more nearly a half-length.

For ordinary every-day portraiture of ordinary humanity, no great variety of pose is necessary—or, indeed, admissible. This is especially so as regards the photographic presentation of men. If you will go through a modern exhibition—for example, the Royal Academy—and take a general and comparative survey of all those pictures which used to be catalogued under the title of "portrait of a gentleman," you will find that the variety in the pose is very limited. This is due in a great measure to the restraint that modern dress imposes on the artist. The masculine coat and trousers of to-day do not admit of artistic arrangement, and any attempt to alter them savours of affectation. Adam-Salomon's black velvet cloak was very picturesque as arranged by his artistic hands, but it looked out of place on a Manchester merchant or a book-maker. Some of our best portrait-painters seem to have given up all hope of varying the positions of their sitters, and seat them all, with rare exceptions, in the same chair in endless succession. I do not state this for the photographer's imitation, he had better always strive for improvement, and not give up all effort as the painters seem to do when they are elected into the Academic body, but as some little comfort for him when his efforts to become original fail.

Photography has done much to teach the painter. There can be no doubt that our art has greatly improved portrait painting. When photographers began to take portraits, portraiture in paint was at its lowest ebb; it is now at its greatest since the time of Gainsborough and Reynolds. Our art has been especially useful in teaching the painter what to avoid; it has completely abolished the column and curtain. I don't think this once inevitable background has been seen in the Academy Exhibitions for several years. It has taught him how to give individuality and character. In every portrait painter's work before the introduction of photography, one face was very like another, and it has taught him that conventionality is only to be tolerated in decorative work.

But if there is very little variety open to the operator in his portraits of men, there is one posture that I should like to see entirely discarded, and never used any more. This

pose is hallowed by tradition, and sanctified by use, for it has been the one pose of photographers since the morning twilight of the art. It is the pose with which the amateur begins; with which the professional, however capable of art knowledge, commences; and with which the incapable spends all his days. I give it here as an example of what to avoid.

Who does not know, who has not been guilty of, this pose, in which the victim appears to be laid out and trussed, little round table and all? But it is all very well, the young photographer will say, to tell me what to avoid—destructive criticism is always easy; but I want to be told what to do. I can only reply by again resorting partly to pointing out what to avoid.

Let us take a portrait. The subject is a gentleman of any age between twenty-five and fifty; he wants a standing portrait. To begin, make him stand in as easy an attitude as possible; don't dictate to him how he shall stand at first, but let him take his own position, and use his suggestion if good; alter it a little if necessary, but don't "mess the figure about." If it does not easily "come," make him walk away and try again. It is possible he may have an idea that he ought to be upright when he stands for a picture, and will stand equally on both legs. Now, however strange it may seem, human beings seldom stand on both legs at once, except in their first and second childhood. Infants and very old men *toddle* equally on both feet. Between these ages a person, when standing at ease, rests on one leg, and in walking it is one or other leg alternately that bears the burden. By this means nature gives variety of line, and avoids the uniformity it abhors. In posing a man, strive to get sufficient variety to give picturesqueness. Do not let the head be in exact line with the body: if the figure is turned full, let the face be in three-quarter view; if the figure is slightly turned away, the face may be full or in profile. See that there is variety in the figure; do not let the hands appear as two spots exactly opposite each other on both sides; do not allow uniformity in the furniture and accessories; for instance, if there is a chair on one side of him, it would be better not to have another on the other side. I do not like to speak too definitely, for fear of cramping the operator instead of helping him; and I can quite conceive cases where exactly the reverse of what I have recommended would be exactly what was wanted. If possible, avoid the leaning position—the pedestal and back-of-chair business has been thoroughly overdone. So much are some sitters, who often have their portraits taken, used to it, that they naturally ask for something to lean on.

"It makes me feel so easy and natural," a man will say; but is puzzled when asked if he can ever remember leaning on a pedestal, and looking like the monument of Shakespeare, anywhere but in a photographer's studio. I remember a studio, in the days of the carte-de-visite mania, where the pedestal and head-rest were fixed institutions, and every figure was fitted to them, all with their legs crossed, like Crusaders on their tombs, only upright.

To a seated figure the same suggestion for variety will apply. A man will sometimes think he looks easy when he feels so, and will slouch down in a chair, put his hands in his pockets, shrug up his shoulders, and, putting his foot up over the knee of the other leg, will present the sole of his boot as the principal object in the picture. But it is "not thy sole, but thy soul," as Gratiano says to the Jew, that is wanted in a portrait, and the lounger must be shaken up. Some young men think it looks easy and graceful to sit astride on a chair, and lean their elbows on the back. To me they look awkward and ungraceful in this position, and all I can say about it is that it is just allowable when it cannot be avoided.

Old men usually make admirable photographs. There is a gravity about old age that seems to suit photography. White hair may be a technical difficulty, but it is to be got over by judicious lighting and manipulation, and difficulty ought to lend a zest to all arts. Old people are usually steady without much effort, and, as a rule, they do not care so much how they look as younger people do,

and therefore are free from the self-conscious look that so sadly mars nearly all portraits, whether painted or photographed. Seated positions, in arm-chairs for preference, seem to be most suitable for age.

PHOTOGRAPHIC PROGRESS OF THE CURRENT YEAR.

BY W. LANG.*

I do not think that this year, so far as it has gone, can be said to have produced any great photographic discovery. It is more a working up of details that has been going on. Perhaps the most important fact to notice first is Dr. Vogel's method of reproducing colours in their true colour intensity. We all know how, in photographing a blue object, the print from the resulting negative brings that colour out as if it were white in the original, while yellow and red come out more or less dark. A photograph of an oil painting, for instance, does not represent the colours in what may be called their relative tone as seen by the human eye. The addition of a dye to a sensitised film, to diminish the action of the blue and violet rays, and increase that of the red yellow, is by no means a new one. Dr. Vogel himself was working in this direction as far back as 1873. It was only this spring, however, that details that would enable any one to work out the process for himself were published by Dr. Vogel. The first communication from Vogel on the subject is to be found in the number of the Photographic News of 28th March. There are further articles by him appearing in the numbers of 2nd, 9th, and 11th May. The dye used by Vogel for collodion plates is eosin, and for gelatine plates, azaline. Through the kindness of Mr. Bolas I am enabled to show specimens of the work done by these plates, and the fact that they have been prepared by Dr. Vogel himself lends an additional interest. The rather formidable term isochromatic has been applied to plates treated with the fore-mentioned or similar dyes, and already they are an article of commerce.

Passing from the work done by a continental investigator, it would have seemed an anomaly had we had nothing put forward by Capt. Abney. A short article entitled "Molecular Physics and Photographic Action," and appearing in the News of May 16, is well worthy of perusal. He proves from experimental evidence that heat causes greater sensitiveness in a gelatine plate, while cold diminishes it.

A series of six lectures on "Photography considered as the work of Radiation," were delivered at the Royal Institution last spring by Capt. Abney. Another very interesting series of lectures were delivered early in the year, under the auspices of the Society of Arts, by Mr. Bolas, the subject treated being "Recent Improvements in Photo-Mechanical Printing Methods."

It may interest members to know that a very successful method of photo-engraving is being carried on in Glasgow at the present moment. The process is one devised by an Austrian, Herr Klic, who spent several years in perfecting it. The portrait of Mungo Ponton, which appeared in the Year-Book of Photography for 1882, was produced by Klic's method. Messrs. Annan have acquired the right to work the process in this country. It is at present a secret one. Under an arrangement with Messrs. Annan, Messrs. Maclure and Macdonald are now producing work done by Herr Klic's method.

Passing from photo-engraving, let us consider for a few minutes what has been exercising a good number of minds this last few years, viz., the production of printing photo-blocks to be used in letter-press printing. I think the day is not very far off now when our illustrated magazines will avail themselves of some of the processes that have been lately brought forward. The conversion of the gradation of an ordinary photograph into a black and white grain or stipple with the lights and shades of the same intensity as the original, is perhaps more a mechanical problem than a photographic one. I would especially call your attention to two processes that have been quite recently introduced, viz. Meisenbach's of Munich, and Ives' of Philadelphia. Judging from the results obtained, it seems to me that the days of the wood engraver are considerably on the wane if they be not about numbered. The starting point of Ives' method, in his original method, is a Woodbury relief; this is covered with ink, and a peculiarly prepared paper is pressed against it. The higher portions of the relief crush down the grain of the paper forming the blacks of the picture, while the gradations, the half tones of the relief, are rendered by this crushing being not so complete. The print thus obtained can either be photographed or used as a transfer. Ives' latest improvement is to take a plater-cast from the relief picture, and by means of an elastic stamp impresses an inked stipple on its surface. Where the relief is highest and the pressure greatest, there the ink spots unite and form the blacks, while in the deeper portions of the cast the spots are exceedingly minute. The merit of the invention lies in the application of the elastic stamp. I have no details as to how the photo-blocks by Meisenbach's process are produced. Woodbury, Zuccato, and others have brought forward processes for producing phototype blocks, but Ives' and Meisenbach's are perhaps the most recent.

Passing on from the consideration of these photo-mechanical methods, let us discuss for a little what has been said and done regarding developers during the period we are considering—a subject that cannot fail to be of interest to us amateurs. Every one has a certain pet formula, and from the enormous number of formulæ published from time to time, it would be no invidious task were the amateur to tackle each one in succession. Hence, perhaps, the wisest plan, after all, is once having a formula giving good results, to stick to it. There is no doubt, however, but that the soda developer has been coming to the front. The soda developer pure and simple—or, to give it its characteristic name, the washing soda developer—is by no means the best form of this developer. The negatives produced have a green unhealthy hue, which would prejudice many against its use, accustomed, as most of us are, to the blacks of the ammonia pyro developer. The prints are, however, all that can be desired.

The formula to be recommended is that of Mr. Bassano—

Pyro	4 grains
Sod. sulphite	30 ,,
Water	1 ounce
Anhydrous sodium carbonate ...	... 40 grains
Water	1 ounce

For every ounce of pyro solution 1 dr. of soda solution to be added—best in my experience in two portions. The negatives have very much the appearance of the old collodion plate. I developed a good number of negatives this summer with the developer in question, and with the exception of some plates lost through frilling during the very hot weather, I had no reason to be dissatisfied with it. I question if at the time the plates I refer to were developed, they would have stood the ordinary ammonia developer. Solutions in the room showed a temperature of 70° F., and the water from the tap a constant temperature of 60° F. The doing away of the odour of ammonia in the developing room is certainly an improvement, while a solution of sodium carbonate is much more reliable as to its original strength being retained than a solution of the very volatile alkali ammonia. One thing members should bear in mind, when using sodium sulphite, is, that it is by no means a stable salt in solution. Fresh solutions are indispensable in order to obtain the best results. It is clear that formulæ in which sodium sulphite is employed should have neither citric acid nor a bromide present. Bassano's formula meets this requirement.

Regarding the potash developer, where potassium carbonate replaces sodium carbonate, I am informed that frilling can scarcely be prevented; this is hardly to be wondered at, seeing potassium carbonate is much more strongly alkaline in its character than the corresponding sodium salt. A mixture of the carbonates has been also recommended to be used. I fail to see when a combination of these two alkalies should have anything special in itself for it to be recommended. A hint thrown out by a contributor to the Photographic News, regarding the employment of nitrites instead of sulphites in the developer, is a suggestive one.

Hydrokinone, as a developer, will never, I think, be adopted by professionals to any large extent, its action being slow as compared with the universally used pyro. This fault—if fault it be—is one that does not affect the amateur in the same manner as the professional. Inasmuch as hydrokinone does its work without requiring the presence of a restraining bromide, it is *par excellence* the developer. Mr. Goodwin, who develops largely with hydrokinone, informs me that for some time he was troubled with thin images. This he overcame by giving a second application of fresh hydrokinone when the details were out.

With the exception of enlargement work, ferrous oxalate does not seem to be much employed either by professionals or amateurs in this country. It is, however, largely employed on the Continent, where the conditions of light are much more uniform

* Read before the Glasgow and W. of Scotland Photographic Association.

than with us. The ferrous oxalate does not allow the same latitude of exposure. The inky black tones of the image developed by ferrous oxalate are all that can be desired.

A word or two regarding our old friend "hypo." While developers increase and multiply, it remains the photographer's universal fixing agent. One thing is certain: it will be difficult to find a substance that would act better than hypo, and at such a low rate of cost. The hyposulphite of the photographer, however, is not the hyposulphite of the chemist, and already in several treatises on photography we find its true chemical name given to it, viz., sodium thiosulphate. It is therefore not at all improbable that, instead of the familiar hypo, we shall have to accustom ourselves to the use of the term "thio," that being, I take it, the natural abbreviation of thiosulphate.

We will pass on now to consider briefly two other subjects that are of interest to us in the production of good negatives, that of intensification and reduction. I know that as far as intensifying is concerned, many of us would prefer to take a fresh negative, to commencing to try to make good a negative that has not come up to a good printing density. This, however, is not always practicable. Mercurial intensification is the one most commonly used for gelatine plates, but the proneness to staining of the film has been one of its great drawbacks, prolonged washing between the application of the mercurial salt and that of the ammonia being required to prevent this. The washing after intensification must also be very thorough to ensure permanency. The method of employing a solution of sodium sulphite to the bleached image, instead of ammonia intensifying, I have tried on several negatives, and can testify to its excellent character. There are no insoluble products formed in the film, hence the washing, to eliminate the mercuric chloride that may happen to remain in it, does not require to be of the usual thorough character. The plate for that part may be taken out of the mercurial chloride solution, and plunged directly into the sodium sulphite solution without staining the film. I should mention, that a very convenient strength for the solution of the sulphite is a 10 per cent. one.

It may seem superfluous to state the fact, but for the benefit of our less experienced members it may be as well to do so, that the complete removal of the hypo is necessary before commencing this or any other method of intensification, otherwise sulphides are formed within the film, and the picture hopelessly stained.

Coming now to the counterpart of intensification, that of reduction. The method for reducing an over-dense negative that has found most favour is one devised by Mr. Howard Farmer, and published by him in the Year-Book of the present year.

TRANSPARENCIES.

BY J. PIKE.*

The subject of transparency making is a very large one, and to treat it thoroughly—that is, by a description of all the various known processes—would take up, not one evening, but three or four. However, I think we may limit ourselves to two or three processes, and consider—1st, the carbon method; 2nd, the collodion, wet and dry; and 3rd, the gelatino-chloride.

Those who have negatives small enough will find the carbon process by no means difficult. Briefly, a special transparency tissue is sensitized with bichromate of potash in the usual way; it is then squeegeed upon a piece of very clean collodionized glass. When dry (which process must take place in the dark) it is peeled off, cut into the proper sizes, and exposed under the negative. The usual circular, dome-shaped, cushion, or square masks, serve very well for the "safe edge" always used in carbon printing. The exposure is rather longer than that given for prints. The exposed tissue is then immersed in water until it softens, squeegeed on to a piece of very clear and clean glass, and developed as for prints. Plenty of time should be taken over this operation, and the water used should not be too hot. Carbon transparencies may be intensified by pouring over the still wet film a solution of pyrogallic acid, followed, after slight washing, by a solution of sulphate of iron.

Wet collodion I have not tried, but I am told that, provided the "bath" be in good condition and ordinary care used, there is nothing to prevent anyone from achieving success in this direction. A "bath" may be purchased ready made and in the best condition. The collodion rather old and high coloured is preferred, as it works cleaner. Mr. Hedley Robinson, whose paper on "Transparencies" will be remembered by most of us, recommends that the "bath" be decidedly acid, and suggests as a developer a solution containing—

Ammonio-sulphate of iron	15 grains
Glacial acetic acid	½ drachm
Lump sugar	15 grains
Water	1 ounce

The older the solution the better. Mr. Robinson also recommends as a toning solution—

Ferridcyanide of potassium	2 grains
Nitrate of uranium	2 ,,
Chloride of gold	$\frac{1}{15}$th grain
Water	1 ounce

which, he says, gives a colour nearly approaching that of a Woodbury slide.

Dry collodion plates will probably be used by some of us. In this case, doubtless, the Beechy emulsion plates will be generally preferred. Their advantages have been summed up by Mr. Robinson as follows:—"Considerable latitude of exposure, good colour of image, perfect control of density, and comfort in developing. They bear forcing with ammonia, and are not easily fogged." The emulsion can be bought ready made, all that is then necessary being to coat properly-cleaned and prepared glass plates.

Good results have been obtained on gelatino-bromide plates. I have one or two samples of work on ordinary gelatine plates, but there is great risk of veil and fog. The ferrous oxalate developer gives about the best results, and the proportion of potash solution to that of iron sulphate should be increased slightly, using bromide.

We are now able to get gelatino-chloride plates, and with these we can do all that we require without much difficulty. They are rather slow. If printing by contact, five minutes, twelve inches distant from an ordinary fishtail gas jet, is not more than enough for a negative of ordinary density. I will show later on a few negatives of varying density, and exhibit transparencies taken from these on gelatino-chloride plates. This will give some idea of the exposure requisite. The developer I succeed best with is one containing carbonate of ammonia, citric acid, and a solution of sulphate of iron. This is Cowan's second formula. The plate should be fully exposed, and the development must not be prolonged. A variety of tones are produced by varying the developers, three of which are given.

I find them very slow when taking transparencies through the camera in daylight, ten minutes being the shortest exposure with a rather thin negative. This was, however, in very dull weather. The lens used was a six-inch Ross's symmetrical, full aperture, the transparency being made from a whole-plate negative. Care must be taken in mixing the developer. The iron solution should always be added to the potash or ammonia solution. I use as a clearing solution a mixture containing one ounce of alum and one ounce of citric acid to one pint of water. The developer may be used for several plates, and the same amount of density may be had with the last plate as the first.

* A communication to the Newcastle-on-Tyne and Northern Counties' Photographic Association.

Notes.

The Year-Book of Photography, which has been the standard book of reference for more than a quarter of a century, will be published on the usual date, December 20th next; and this will enable our readers to have it in their hands before Christmas Day.

Those who have promised contributions will, we hope, send them to us promptly; and we shall be happy to receive short and practical articles from such of our friends as may be able to communicate interesting matter.

It is by no means uncommon to regard the rapidity of a lens simply as a function of aperture with focus, and to neglect the actinic transparency of the glass; but some recent

investigations of M. Chardonnet show that one cannot afford to overlook variations in the quality of glass, except in the case of very rough determinations. English optical glass is generally, according to M. Chardonnet, rather more transparent to the actinic rays than French glass.

The "Triplet" portrait, introduced by Mr. Anckorn, of Arbroath, consist of three separate portraits of the same person, vignetted into one another, the whole being carte size. M. Anckorn's idea of thus giving three positions on one carte is an excellent one.

"The Editor would feel obliged with copies of beautiful photos. for editorial purposes"; after this follows a list comprising the whole of the pictures contributed to the Exhibition by the person to whom the missive was sent. The above is a note which has been posted to several—and probably to many—of the Pall Mall exhibitors; and the letter appears to be dated from the office of a weekly newspaper; still we do not find that the paper in question is mentioned in "May's Press Guide," or "Mitchel's Directory" for the present year.

Light emitted by insects of the Pyrophore genus shows no bands when examined spectroscopically, according to MM. Aubert and Dubois, the spectrum being continuous; but when the light is very weak it only contains green and orange. We have already referred to the photographic action of the glow-worm's light.

If the Lord Mayor's show of this year is to be the last, Alderman Nottage is determined it shall not be behind its predecessors in magnificence. Rumour has it that the worthy Alderman interviewed Mr. Augustus Harris on the question of the cost of producing the procession of kings and queens which made such a sensation in the Drury Lane pantomime of 1883. Said Mr. Harris, doubtfully, "It will cost you a lot of money. The bill for boots alone will stand you in some £200." Mr. Nottage has decided to abandon the idea.

Punch is poking its fun at the Lord Mayor elect, and, at the same time, reviving a very crusted old photographic joke, when it proposes that the Mansion House Police cases shall be heard before his Lordship *in camerâ*. It was *apropos* to the same municipal dignitary, by the way, that Mrs. MeMalaprop has made her latest "derangement of epitaphs." She wants to know if his Lordship ever had his stereoscope cast to see if he was born under a civic star.

Some years ago it was a common thing for the disappointed exhibitor to air his spite against the judges by writing long and furious letters to the NEWS, and pointing out the utter and complete unfitness of the adjudicators for their office; but such exhibitions of littleness are now comparatively rare—as a matter of fact, these outbursts of spleen are too transparent. As a contrast, we may quote the following remarks from one who would have certainly taken the medal for land and riverscape had one been awarded.

"The judges at the exhibition seem to have done their difficult work better than usual, the only fault I can find being that W. Cotesworth did not get a medal for his 'Awkward' print, and the ladies whom he has represented did not have one each also."

One of the curiosities of the Pall Mall Exhibition will probably pass unnoticed, save by the sharpest and most experienced professional eye. It is a portrait, the head of which is from one negative, while the body and accessories are from another. Probably, as often happens, the most successful expression has been associated with some defect in another part of the picture, and the photographer resorted to the expedient of joining the best head to the best pose. The combination has been most cleverly effected—so clever that it would be a pity to name the picture. The curious visitor must find it out for himself.

The friends of the Claimant lay much stress on the importance of an instrument called the identiscope. The identiscope is a variation of the camera-lucida. Two portraits are placed on a couple of hinged panels, with a sheet of coloured glass between them. The panels are opened out like book covers till the images are reflected in the coloured glass, and become coincident. The inventor fixes upon the mathematical centre of the pupil of the eye as the starting point, and claims that when a line drawn through these centres in each portrait coincide, the two portraits are of one man. The portrait of the Claimant, he holds, thus coincides with the well-known portrait of young Roger Tichborne.

There are also other points of coincidence which may be summed up in a question of the inventor—"Can it be for a moment imagined," he asks, "that in the photographs of any two distinct men, there shall occur a perfect correspondence—first, in the diameter of the iris; second, in the plan and space occupied by the eye-brows; third, in the precise width from one pupil of the eye to the other; fourth, in the curve and opening of the eyelid; fifth, in the shape and the profile line of the nose; sixth, in its exact length; seventh, in the precise points at which the nostrils arise from the face; eighth, in the depth of the upper lip; ninth, in the place and size of the mouth; tenth, in the curvatures of the lower lip and chin; eleventh, in the precise place of the dimple mark of the chin." There is only one man who can answer this question, and he is Mr. Francis Galton. The problem is one which his experiments in composite portraiture should solve.

One of the chief expenses incurred in legal and criminal work is the result of the many copyings of depositions, of witnesses, of indictments, of briefs, of deeds, and documents of all kinds which are now laboriously made by copyists and law writers at so much a folio. It has been suggested—though we need scarcely add, the suggestion has not been favourably received in legal circles—that copies should be multiplied by one of the many processes with which photography is now allied, perfect accuracy and considerable economy being thereby secured.

Solicitors will, of course, oppose this, tooth and nail; but the Treasury, which repays to counties the large proportion of the expenses of criminal prosecutions, might surely initiate the reform by insisting that the copies for which the country pays should be effected in the proposed manner. "Process by law" is already a well-known legal term, and we do not see why in future we should not have as much of our law as possible done by "process."

Professor J. Miller Thompson will read before the Society of Chemical Industry, at Burlington House, a paper on "Photography for those Engaged in Industrial Purposes," the date fixed being December 1st.

The sensitive plate now records almost every natural phenomena which is visible within the range of civilisation, and among the records of the recent eclipse which have been obtained, one may mention the fine series of photographs obtained by MM. Paul and Henry at the Paris Observatory.

The old saying that "treaties are like pie-crust, made to be broken," must be altered if the custom the Chinese have introduced of interpolating initials, &c., on such documents, and then photographing the amended copy, is followed. It will be more *apropos* to say that "treaties are like negatives, to be touched up."

A common complaint against photographic portraits is, that they so rarely represent people as their friends know them. Judging from the "Answers to Correspondents" by a physiognomist in a journal which caters especially for ladies, this complaint must be ill founded. Out of a whole host of answers, we will take a few at random: "The eyes in this photograph being so close together denote astuteness which amounts to cunning;" "The curved and somewhat thin lips combined with the rather long upper lip denote eloquence;" "The eyes in this photograph show vivacity and coquetry, the eyebrows and straight long eyelashes an imaginative and poetic temperament;" "The photograph shows great sweetness and tenderness of nature, but both brows and eyebrows are wanting in force of character;" "Indicates a person of decidedly nervous temperament—the eyes are clear both as to shape and power of colour;" and so on *ad infinitum*. And yet scores of persons, especially ladies, declare that photography does not do them justice.

Patent Intelligence.

Applications for Letters Patent.

13,596. Alfred Julius Boult, 323, High Holborn, Middlesex, for "Gelatine plates, films, or tissues for use in photography, and process of manufacturing and using the same."—Communicated by George Eastman and William Hall Walker, United States.—Dated 14th October, 1884.

13,774. John Mitchell Dowling Worsnop, 4, South Street, Finsbury, London, for "An improved method of transferring the film of photographs, or a film of colour painted upon photographs, to canvas or other surfaces."—(*Complete Specification.*)—Dated 17th October, 1884.

Patents on which the Fourth Year's Renewal Fee of £10 has been Paid.

4394. Ernest de Pass, of the Office for British and Foreign Patents, 68, Fleet Street, in the city of London, Patent Agent, for an invention of "Improved processes of obtaining bas-reliefs, medals, casts, dies, matrices, and the like by photography, and means or apparatus to be employed in such processes."—A communication to him from abroad by William Henry Guilleband, of 17, Boulevard Saint-Martin, Paris, France.—Dated 10th October, 1881.

Specification Published during the Week.

11,556. Eugen Himly, late captain, No. 54, Zossener Street, City of Berlin, Kingdom of Prussia, Empire of Germany, for "Improved method of, and apparatus for, taking photographs by artificial light."—(*Complete Specification.*)—Dated August 22, 1884.

For obtaining the irregular reflection of rays from powerful sources of light, so as to produce an artificially diffused light analogous to that of daylight, it has hitherto been customary to employ, as the most perfect means attainable, intensely illuminated white surfaces, either plane or concave, not acting as mirrors, which reflect the rays divergently in the general direction of the object to be illuminated. These illuminated surfaces can also consist in dulled sheets of glass, through which the rays from a number of sources of light are caused to pass divergently. The diffusion thus obtained is, however, but little analogous to that of daylight, as the direction of the rays still remains more or less one-sided, and, consequently, the photographic pictures obtained by these means have easily discernible strongly one-sided illumination.

Another usual method of a comparatively perfect nature for obtaining an illumination analogous to that of daylight, consists in the use of several sources of light shaded by opal globes arranged round the object to be photographed, which, together with the photographic apparatus, is mounted on a revolving turn-table.

Independently of the question of the expensive nature of this arrangement, requiring specially careful attention to the several sources of light, it is not free from imperfections of illumination, due to the fact that in addition to the rays that are irregularly reflected in the desired manner by the small surfaces produced by the clouding of a glass globe, many rays pass through the glass which, in consequence of the varying absorbing or refracting powers of the glass, and also in consequence of the want of parallelism of the glass surfaces, produce light and dark spots on the object.

My present invention relates to a method of, and appliances for, producing artificial illumination as analogous as possible to the action of day-light, consisting mainly in the employment of a mechanically-moved illuminating screen which reflects the rays from one or more powerful sources of light irregularly in the direction of the object to be photographed, but which entirely diverts the direct or regularly reflected rays of such sources of light from such object, the movement of the said screen being effected during the whole time of exposure either through a certain arc round the stationary object to be photographed, or through a straight line past the same. By this method I obtain firstly, by means of the construction of the illuminating screen, an illuminating effect analogous to the action of diffused daylight, and free from shadows or excessively strong shadows; and secondly, owing to the quicker or slower advancing motion of the screen, regulated according to requirements, I obtain a moderate lateral gradation of the illumination of the object, similar to that of daylight. In particular, I am enabled by this method to prevent the too powerful illumination of one side of the object while another side has to be exposed for a longer time in order to develop deeper shadows.

The number of sources of light employed in combination with my illuminating screen is not limited; there may be only one, or two, or more arranged in an analogous manner. The adjustment of the bottom surface on a horizontal axis has for its object to distribute the light to a greater or less degree to the lower parts of the object to be illuminated.

Of the constructions that can be employed for effecting the motion of the illuminating screen during the duration of the exposal, two are more particularly suitable.

The object to be illuminated is situated near to and underneath the centre of motion of the crane, so that the illuminating screen is caused to move in a circular path round the object by means of any suitable mechanism. Or a semicircular rail is

suspended from the ceiling of the studio, on which rail the screen is made to run by means of rollers, being moved to and fro by cords.

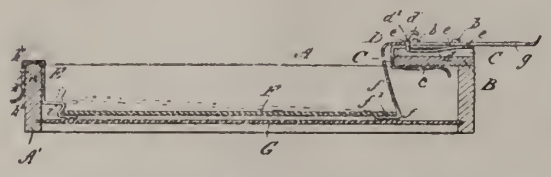
Patents Granted in America.

306,281. Samuel B. Pratt, Boston, Mass., assignor to Charles Parker, Newark, N. J. "Device for holding photographic plates in developing trays." Filed Feb. 18, 1884. (No model.)

Claim.—1. The combination, with a developing-tray, of the sliding plate E, arranged to hold one end of the photographic plate, and adapted to be raised for lifting one end of the photographic plate out of the liquid, substantially as described.

2. The combination, with the plate E, for holding one end of the photographic plate, of the foot *f f'*, for holding the other end of the photographic plate, substantially as described.

3. The combination, with a developing-tray and spring-foot *f f'*,



for holding one end of the photographic plate, of a suitable detent, *i*, for holding the opposite end of the photographic plate, substantially as described.

4. The combination, with the detent *i*, for holding one end of the photographic plate, of the adjustable plate D, formed with the spring-foot *f f'*, substantially as and for the purpose set forth.

5. The plate D, having spring-foot *f f'*, in combination with the clamp C, arranged for holding the plate D, and adapted to be attached to the tray A, substantially as and for the purposes set forth.

6. The clamp C, formed with the spring-tongue *c*, spring-catch *d*, and lips *b*, in combination with the plate D, slotted and notched, and formed with the spring-foot *f f'*, substantially as and for the purposes set forth.

7. The combination, with the developing-tray A, of the sliding, holding, and lifting plate E, clamp C, and sliding plate D, held by the clamp C and formed with the spring-foot *f f' f²*, substantially as and for the purposes set forth.

PRESS NOTICES OF THE PHOTOGRAPHIC EXHIBITION.

[From the *Morning Advertiser*.]

The Exhibition can hardly be said to be disappointing, although there is little to be noted in the way of advance, either in the artistic qualities of the exhibits, or the scientific application of photography as compared with recent years. Some progress has, however, been made in the process of photogravure, and the specimens shown by Messrs. T. and R. Annan, of Glasgow, are remarkable for delicacy and mellowness of gradations. Klic's invention seems destined to become invaluable for the production of works suitable for high-class book illustrations, and Messrs. Annan are undoubtedly working it with great success. These monochromes are printed from copper plates, which are engraved by chemical processes, the tints resembling in their flatness water-washes of Indian ink or sepia. It is difficult to distinguish between some of the specimens of photo-engraving and carefully finished drawings in black and white, the resemblance being so close. Messrs. Annan have this year, as last, been awarded a medal for the scientific application of photography. Many of the best photographs are exhibited by non-professional gentlemen, who study the subject purely *con amore*, and are able to devote to it almost any amount of time and capital. In this category may be cited the frame of instantaneous views taken from a yacht in Scotland by Mr. T. W. Boord, one of the members for Greenwich; also the effective studies of flowers in vases by Mr. Henry Stevens, of King Street, Covent Garden. Captain Abney, R.E., F.R.S., again, is an accomplished master of the art, and the diversified subjects which he exhibits, produced from gelatino-iodobromide plates of his own preparation, are equal to anything that has yet been done by means of the camera. Several other non-professional photographers contribute excellent work. The combination pictures of Mr. H. P. Robinson are interesting examples of the artistic manipulation of photography. He has been awarded a medal for "The Mill Door," a work of real merit. In some other of his pictures the figures are not quite so natural, betraying by their pose their knowledge of the photographer's presence. At the same time it must be admitted that Mr. Robinson's productions are more free from this obvious defect than are those of most of his *confrères* who attempt combinations of figures and landscape taken on separate plates. The instantaneous studies of sea waves dashing on the shore, and mountains of feathery spray, exhibited by Mr. W. P. Marsh, have gained a medal. It would be useful if in these, and similar examples, it were stated whether there had been any retouching. It is difficult to distinguish in all cases whether the pencil of the artist has been employed or not, and any intimation with respect to this matter would be welcomed. In portraiture the practice of retouching is largely adopted, and does not debar the exhibitor from the Society's awards. It should be made a *sine qua non* in all such cases that a print from the untouched negative should accompany the hand-elaborated example. The spectator would then be able to discriminate between pure photography and skilled or unskilled—and it is more often unskilled than skilled—handicraft. The Photographic Society do not seem to distinguish by their awards the one from the other; and, although the novice can easily detect retouching more or less laboured here and there, it would be a point gained if he could, by comparing the negative print with the hand-finished performance, be enabled to judge of the quantity and the quality of the artist's work. Possibly some of the sitters might object to being displayed publicly without having their angularities and blemishes toned down, and their wrinkles obliterated; but, in the interest of photography, these scruples ought to be disregarded. There are exhibits in portraiture by Mr. J. Lafayette, Mr. J. E. Mayall, Mr. H. S. Mendelssohn, Mr. W. Byrne, by the London Stereoscopic Company, enlargements by the Woodbury Company of negatives by Messrs. W. and D. Downey, and a frame of comically-treated cats and dogs by Mr. H. Pointer, all worthy of commendation. Mr. Cecil V. Shadbolt, the æronaut, contributes photographs taken from the car of the *Monarch* balloon, on the 13th of August last, in an ascent from the Crystal Palace, and, as everybody cannot go up in a balloon, these views—one of them of streets, resembling a carpet of geometrical pattern—cannot fail to interest, altogether irrespective of any scientific merit or otherwise which they may possess. On the tables will be found an assortment of cameras, shutters, plate sets, lanterns, and other photographic paraphernalia, by different makers, and of the most recent pattern and approved type.

AN INSTANTANEOUS SHUTTER OF THIRTY YEARS AGO.

BY J. S. POLLITT.*

The shutter I have brought before you to-night is probably one of the oldest and, as I think, for absolutely instantaneous work, the best form of shutter extant. It was given to me some years ago by my friend Mr. Joseph Sidebotham, but for want of time and opportunity I have never, until quite recently, put it to a practical test.

It was made by Dallmeyer about 1856-7, Mr. Sidebotham having taken part in developing the principle, which is extremely simple. It consists of two light laths of mahogany, in each of which I will say, for simplicity, is a square opening (although in this particular shutter there are two openings in each lath, because it is a double one for stereoscopic work). When the focussing is done and everything ready, the exposure is made by touching a light trigger, when the two laths are instantaneously pulled in opposite directions, one square opening passing across the other, thus giving the centre of the lens the greatest benefit, as it is there the shutter first opens and last closes.

It will thus be seen that, however quickly a shutter may be made to work simply by a movable opening passing a stationary opening fixed to the front or inside the lens tube, as in the case of the drop shutter, if the stationary opening be converted into a movable one, and in an opposite direction, the exposure in the latter case will only be half the duration of that in the former case. It is precisely analogous to the passing of two express trains in opposite directions. Any slight opening between the trains seen by a person standing on the platform of a railway station at the time will be exceedingly brief as compared with an

* Read before the Manchester Photographic Society.

opening seen between a single train and a stationary object, such as the end of a building which may happen to be on the other side of the line of railway on which the train runs.

My object is not to depreciate any other form of shutter, for there are many excellent and deservedly popular ones now in the market; but I thought it would interest many to see an efficient instantaneous shutter which was made nearly thirty years ago, and I further think it will be admitted that the results I am showing you are sufficient proofs of its efficiency for what may be called extra-rapid work.

I must, however, point out that the details of construction are bad in two important particulars. The source of motion is an india-ruber band attached to each lath, the elasticity of which, when the trigger is liberated, draws them in opposite directions; and as each elastic band works on its own account, and quite independently of the other, there is a danger, by reason of the difficulty of getting the tension in both cases equal, that one lath may travel quicker than the other, which, in fact, I found on one occasion to be the case, when one-half of the plate was better exposed than the other half.

In the first place, therefore, I would have no india-rubber; it is an untrustworthy and perishable material, and liable to break or become useless when one has no chance of renewing it. In the second place, I would connect the two laths in such a way that one source of motion only, instead of two independent ones, would be required. Both of these alterations, I believe, could be readily accomplished by connecting the laths with a strong silk cord passing over a small ivory roller, and using as the source of motion a good watch or small clock spring. The speed of the shutter could, I think, also be altered within certain limits by means of the introduction of a brake action.

THE EXPERIENCES OF A BEGINNER.

BY ARTHUR B. FROST.*

Correspondence.

THE POTASH AND SODA DEVELOPER.

Sir,—We have lately heard a good deal of the potash and soda developers, some speaking for and some against them. May I be allowed to say a few words on the same subject, since it is by no means new to me, having tried these developers at least eight years ago with collodion emulsion plates, as some of the old editions of "Instruction in Photography" can testify. When gelatine plates came to the fore I also tried them, but with no advantage, it seemed then to me, over the ammonia developer. There are complaints from some that the sodium and potassium carbonates will not develop at times, but that a "drop of ammonia" is necessary to give them a start. Now, so far as I have read some formulæ, the necessity for addition of ammonia should be no surprise when the composition of the developer is taken into theoretical consideration. First we have sulphite of soda—of that I make no complaint; but then we have sulphurous acid as another ingredient, and given in terms of liquid ounces—at least, so it is to be presumed. Now, sulphurous acid at ordinary pressures is gaseous, and it can hardly be supposed that ounces of this are really meant. It may be supposed then to be a solution of sulphurous acid. If the equivalents of the neutral sulphite be calculated, and also the amount of sulphurous acid in solution, it will be evident that the poor monocarbonates or alkalies which we are told to add, stand a very poor chance of existence in any quantity, and, consequently, the alkalinity of such a developer must be

* From the *Chicago Eye*.

small; hence the suggestion of the addition of the ammonia to it. I would ask, Why use anything beyond pyro., the carbonates of the alkalies, and perhaps a slight restrainer? It is true that such a developer is apt to give a yellow stain, but the stain instantly disappears before a weak solution of hydrochloric acid, or any of the acid alum baths. My developing formula would stand thus:—

1. Pyrogallic acid—dry.

2. Mono-carbonate of soda (common washing soda)—a saturated solution at 60° F.

3. Potassium bromide—10 grains; water, 1 ounce.

Take 1 drachm of 2 and ½ drachm of 3, and add to them 3 grains of pyrogallic acid. Make up to 2 ounces, and develop as usual. When any fear of over-exposure arises, use ½ drachm of No. 2, and 1 drachm of No. 3.

Fix and wash, and then clear away the yellow stain as indicated above. The same formula may apply, using potassium carbonate instead of the sodium carbonate. I have not found the impurities which are said to exist in the commercial carbonates any drawback, though my experience with different samples is not extensive. The sodium salt I have bought at an oil and colourman's shop.

This yellow stain, which is so much objected to by some, can be entirely obviated by using *hydrokinone instead of pyrogallic acid*; at least, such is the case with all the plates that I have tried. The colour of the negative is a grey black, without a trace of stain on the transparent parts of the negative. What I have used is as follows:—

Hydrokinone	...	...	3 grains
Water	...	...	4 ounces

the sodium or potassium carbonates being mixed as before stated. Properly exposed plates may be developed without any restraining bromide; but if over-exposure is suspected, ½ drachm of No. 3, and half the normal quantity of No. 2, should be used. In the developing dish the solution becomes slightly inky-looking, but does not stain the film. I have found that excellent density is obtained on a properly coated plate. When a film is "starved" of silver—which is the case in several different samples of plates I have tried—of course only a certain amount of density can be obtained with any developer. But a comparison of a pyrogallic acid developed plate with one developed by hydrokinone shows an equal density in both. I have been asked if I would give up the use of ammonia for these carbonates, and at present I cannot say I would, rather, perhaps, from a feeling of conservatism than from any other cause. There is one advantage in the use of the carbonates, which is, that when solid they do not change appreciably in strength of alkali, whereas a solution of ammonia is always open to suspicion. I am told that the fumes of ammonia are injurious in the mucous membrane, which I can readily believe. The carbonates are certainly free from any evil attribute of this kind when merely used in development. I have also seen it stated that there is a liability for plates developed with these alkalies to frill: so far I have not had one that has, and I do not see why they should, more than with an ammonia developer.

6th October. W. de. W. Abney.

ENGLISH CAMERA MAKERS.

Sir,—We often hear of the decadence of English trade, and it may be well to point out, from time to time, defects which may give grounds for such a conclusion. There is a general complaint abroad that English goods are not what they used to be, and that orders upon English firms are not executed with the promptitude with which they used to be executed. My acquaintance with photography, and with photographers and photographic dealers, is not of long standing; but there is one principle to which I have heard frequent reference made, and which, if it really exists and is tolerated, is surely rather alarming. When complaining to professional photographers of inattention or bad workmanship on the part of photographic dealers, I have had it said to me: "Oh, but as an amateur you cannot expect to have such attention paid to you as to us; you cannot expect to have such good things sent to you as to us; all the worst things are given to amateurs; dealers have nothing to lose in such little custom as you may give them; but if they lose ours, it is a serious thing, and they take care to be careful." How far this principle is really carried out, I know not; but at any rate some such words have been said to me over and over again.

My own present and particular grievance is a small one. I came out here two years ago, not for the first time, to study a particular subject, and to make use of photography in illustrating it. I brought out two cameras by one of the most celebrated London makers, one for plates 8½ by 6½, the other a pocket camera, so-called, for plates 5 by 4. At the end of last winter, I found, when on the point of starting for the mountains, where my studies lie, that the slides of my pocket camera were (though I had not had them two years) defective. I thought of sending them to Marseilles or Paris to have them repaired, but a photographer friend said to me, "Send them to England; they will not only be better done, but you will have them back sooner than if you sent them even to Marseilles." So to England I sent them. I sent them to the maker with a letter requesting that they might be returned to me as soon as possible, and also requesting an estimate of the probable expense. A post-card, I said, would be sufficient to let me know about their arrival. Upon the receipt of that I would, I added, forward the sum due. The slides, as I heard from the agents to whom I consigned them at Boulogne, duly arrived at that port, and were transmitted from thence to London; but from that moment I heard nothing more about them. This was in the beginning of April. I waited two months, and then, still hearing nothing, wrote another letter to the maker begging him to give me some news about the slides, and also enclosing a cheque for an amount which I thought would cover the repairs. I also took the opportunity of forwarding two other slides, belonging to the larger camera. These in their turn arrived at Boulogne, and were duly announced to me by my courteous agents there, and were by them transmitted, as before, to the maker.

This second dispatch was in the beginning of June, but I heard no more about it than about the other. As in the former case, I waited two months for an answer to my letter; and then, in the beginning of August, finding the summer slipping away, and much inconvenience arising, I wrote another letter, asking for an answer of some kind, in order that I might know whether any of the things I had sent, or any of the letters I had written, had arrived. As before, I said a post-card would be quite sufficient for me, and I should not be in any way offended thereat. But to this day—and another ten months have now elapsed—I have received no answer of any kind whatever. In fact, six months have now elapsed since my first letter and the slides, and yet no notice whatever has been taken thereof.

One is accustomed to meet such treatment in the South of Europe, but I had hardly looked for it in England, and I venture to think that had I sent my slides even to Marseilles, I should have had them back, and perhaps a letter as well, months ago.—I am, sir, your obedient servant,

Bastelica, Corsica, Oct. 2nd J. W. Barry.

THE POTASH DEVELOPER.

Dear Sir,—The results which Mr. Jennings and others have obtained with the formula for a potash developer used by me and published in the News of Aug. 1st, I am glad to see, confirms all that I had obtained with it. For some brands of plates the amount of pyro stated is too great, and the only rule I can give is to suit the pyro to the plate, which can be ascertained easily by experiment.

To illustrate the difference in plates, and the wonderful adaptability of the developer, I recently developed ten plates (a fresh solution for each plate), subjects all interiors.

By using 3 ounces of water, 50 minims of pyro (or 5 grains), and only 20 minims of the potash solution, and not a bit of bromide, I secured beautiful, soft, clear, stainless, vigorous printing negatives. I believe, if pure chemicals are used, this developer will become universally adopted. Many of my friends have tried it with uniform success, and all commended it.—Yours respectfully, F. C. Beach.

New York, Sept. 26.

THE ROYAL ARMS CASE.

Sir,—Now that the case is over, and it has been definitely settled before a magistrate that it is not lawful to assume the use of the Royal Arms without proper authority, perhaps you will allow a word or two on the subject.

There appears to be a sort of feeling with some people that it was a pity anybody should be prosecuted for using the Royal Arms, or representing himself as photographer to the Queen, the Prince of Wales, or any of the Royal family. Why this should be must puzzle all thinking persons. To use the arms without authority is not fair to the public, to the members of the profession in general, or to those who have authority to use the arms. The arms could only be used without authority for the purpose of obtaining patronage by false pretences, the photographer well knowing that the British public—who, a Society paper assures us, are "nearly all snobs"—are led away by the thinnest pretence where the Royal family is concerned, and easily believe in any photographer who has the courage to put the Lion and Unicorn, or the three feathers over his door. It is not so generally understood that it is the smallest photographers who are apparently most patronized by royalty, especially the Prince of Wales. That kindly gentleman appears to sit to any photographer who is recommended to him by his servants. I think it is a fact capable of proof that the Prince has never been photographed by any English photographer of great reputation; the reason being that he seems never to send for a photographer, but falls a victim to any one who choses to disgrace his profession by touting.

H. T. Methven.

PLATES FOGGED BY THE LEATHER HINGE OF THE SLIDE.

Sir,—In the last number of the Photographic News is a short letter from Mr. J. D. England on plates fogged by the leather hinge of the slide. I have had a good number spoiled, I must believe, in this way, and should be greatly obliged if you would kindly inform me whether there is no other remedy than to replace the leather by vellum? The slides are all by a London maker, made, I suppose, in his usual style.—Sincerely yours, A. S. Dismore.

[If our correspondent has satisfied himself that the slides have caused the mischief, his best way will be to simply return them to the maker for prompt alteration or exchange. —Ed. P.N.]

THE PHOTOGRAPHIC EXHIBITION.

CLAIMING THE HONOUR DUE TO OTHERS.

Sir,—Your correspondent "Sacerdos" has certainly raised a question of much interest to all who wish to encourage straightforward honesty in photographic matters, and although he fairly chastises the so-called amateur who has nothing worth speaking of to do with the production of the exhibited pictures, I would suggest that there is a worse type of impostor around now-a-days. This is the newly-fledged professional photographer whose knowledge of photography is little more than nothing; he takes plates out, exposes them, gets somebody else to develop, enlarge, and retouch, after which he puts the picture into the market as his own. This would be all right and square enough if the gentleman put "professional photographer" on his front door, and did not claim to have made the pictures personally; but he does not do this, he calls himself an amateur, and takes refuge under this name when anybody comments on the badness of the pictures. I thought that this type of shuffler confined his operations to the West, but I find he is over here in great force. This is the kind of Bogus amateur against whom we agitate in the States; a man who is a badly qualified professional, and calls himself an amateur. We encourage and support the genuine amateur who never sells a picture. On my return to the States, I shall have to report to my friends the existence of the sham amateur in England.

Washington B. Strood.

Sir,—Might I suggest that it was never intended that the Exhibition should be turned into a shop with regular attendants? Some dealers have taken advantage of the fact that apparatus is admitted, to send a perfect cartload of things which are practically identical, which display no particular novelty in construction, and which cause a crowd to collect round the table to the inconvenience of those who desire to see the pictures. Last Monday evening this crowd completely blocked up the centre, so as seriously to impede locomotion.—Yours obediently,

One of the Inconvenienced.

Proceedings of Societies.

London and Provincial Photographic Association.

At the weekly meeting of this Association, held on Thursday, the 16th inst., Mr. A. Mackie occupied the chair.

Dr. C. Schleussner, of Frankfort, and Mr. Bell, visitors, were introduced by the Chairman to the members.

In reply to a question from Mr. A. L. Henderson, Dr. Schleussner, referring to the plates used in Germany, said their speed was about 22 on the sensitometer, ferrous oxalate being the favourite developer. It was considered quicker than pyro developer. The developer was made up of 17 parts of iron to 45 parts of oxalate—saturated solutions—development taking from three to four minutes.

A question was asked whether all the decomposed gelatine in an emulsion could be removed by washing?

Dr. Schleussner believed it could not; the rapidity of an emulsion depended a great deal upon the gelatine, whether acid or neutral.

Mr. Henderson had soaked gelatine in sulphuric acid—1 part to 40—for a day, using it subsequently after a thorough washing to emulsify with; negatives coated with this emulsion giving excellent results and very clear shadows, proving that gelatine usually contains substances that combined with the silver, forming compounds other than bromide.

Mr. Bell found chrome alum had a tendency to slow emulsions, and in cases of frilling had used 2 drachms of a 5 per cent. solution to 10 ounces of emulsion.

Mr. A. Cowan, with a view to test how long a neutral emulsion could be boiled without getting fog, had made seven batches of emulsion, boiling the first one three quarters of an hour, increasing the time with each batch; the last receiving three hours' boiling without producing a trace of fog. The first batch showed 17 on the sensitometer, the last 23.

Mr. Henderson said in this case Mr. Cowan was boiling in the presence of chloride of calcium, which acted as a restrainer. He (Mr. Henderson) would like to bring before the members a new modified method of making an emulsion which had been the subject of experiment with him. He gave the formula:—

1.—Gelatine	... ...	5 grains
Bromide of potassium	... ...	180 „
Iodide	... ...	2 „
Water	... ...	½ ounce

When dissolved by heat, add four ounces of alcohol; this will cause a precipitation or crystallization of the fine particles of the potassium bromide.

2.—Silver	... ...	240 grains
Water	... ...	½ ounce
Alcohol	... ...	4 ounces

Divide No. 2 solution into two parts. Add strong liquor ammonia to one of the parts until the precipitate is re-dissolved. Mix the two parts together and add No. 1 solution, the whole to be heated with water at a temperature of 120°, and 240 grains of dry gelatine stirred with it. When thoroughly incorporated and allowed to cool, the emulsion will precipitate itself, and the alcohol can be poured off, which, after filtering, can be used again. Mr. Henderson believed that the alcohol was in no way reduced in strength, as the gelatine absorbed the water. The alcohol, after pouring off, would be found to measure 7½ ounces.

Mr. Bell said he had two sensitometers of different degrees of density. He asked how either could be considered a standard.

Mr. Haddon thought the fairest test was to make a transparency in the camera.

Newcastle-on-Tyne and Northern Counties' Photographic Association.

The first ordinary meeting of the session was held in the College of Physical Science, Newcastle, on Tuesday, the 14th inst., at 7.30 p.m., Mr. J. P. Gibson in the chair.

The minutes of the previous meeting were read and passed, and Messrs. T. G. Gibson and Ruddock were elected members of the Society.

Mr. J. Pike (Hon. Secretary) said, that as it had been decided to postpone the transparency competition until December or January, it had occurred to him that a discussion on the best methods of making transparencies might be profitable, and that those who had any experience of this branch of the photographic art might be induced to allow their information to circulate amongst their less favoured brethren. Mr. Pike then read a short paper on "Transparencies" (see page 679), with special reference to the forthcoming competition. Hints were given and remarks made on the preparation of carbon transparencies, and those prepared on gelatino-chloride plates, samples of which were shown, together with the negatives from which they were taken. Speaking of the wet and dry collodion methods, Mr. Pike said he had had no practical experience, but he had asked Mr. Templeton to bring a few samples of wet-plate work, and that gentleman very kindly gave his experience of this method, remarking that he used the developer and toning solution mentioned in his (Mr. Pike's) paper.

Several questions were asked and replied to.

Mr. Downey, of South Shields, showed a large number of stereoscopic pictures and slides, which were highly appreciated.

Votes of thanks were passed to Mr. Pike and to Mr. Downey.

The Society's exhibition this year, of members' work only, will be held in November, at the Art Gallery. A presentation print is to be selected, and the medal and prize, offered by Mr. Borrow and Mr. Gibson respectively, competed for.

Glasgow and West of Scotland Amateur Photographic Association.

The usual monthly meeting of the above Association was held in their Rooms, 180, West Regent Street, Glasgow, on Tuesday, the 14th inst., Mr. Hugh Reid, President, in the chair.

After the approval of the minutes, the following new members were admitted:—Messrs. Wm. Orr, Henry Leask, H. M. Fraser, Wm. Leiper, John McKissack, George W. Gray. It was agreed to hold weekly informal meetings each Tuesday during the winter for the discussion of general photographic matters, and to enable members to know each other better.

Mr. W. Lang, Jun., then read his paper, giving a short resumé of the photographic progress of the current year (see p. 678). Mr. Lang's interesting paper was illustrated by a number of specimens of the various methods of photo-mechanical printing kindly lent by Mr. J. Craig Annan and others. Mr. Lang afterwards, to demonstrate the value of some of the new methods, reduced and intensified a number of negatives in a completely successful manner.

After some general conversation, the meeting adjourned.

Manchester Photographic Society.

General Meeting.

The first meeting of the present session was held in the Manchester Technical Schools, on Thursday, September the 11th, the President, Mr. Jno. Pollitt, in the chair. The minutes of the previous meeting were read and confirmed.

The President made reference to a subject that had been under discussion at the Council meeting, viz, the scarcity of papers being read by members, and in response to his call, Mr. Brothers volunteered a paper, and to give a practical demonstration on the Daguerreotype process.

Mr. Alan Garnett exhibited a charming collection of small landscapes, taken during a recent tour in Normandy; and exhibited a mask which he introduced in his camera, enabling him to make four exposures on one plate, and also a series of four or five prints forming a panoramic picture, in which the joinings were scarcely perceptible.

Mr. Wilson exhibited some prints from negatives taken at the outdoor meetings of the Society.

Mr. McKellen showed a fine series of photographs taken on the occasion of the Society's visit to Kirkstall Abbey.

The Hon. Secretary exhibited a new lantern carrier, made by Mr. Stewart, of London, by which slides of various sizes were automatically registered.

The meeting was brought to a close by a lantern exhibition by Mr. J. A. Chadwick, consisting of a series of Parisian and other views.

The annual meeting of this Society took place in the rooms of the Society, at the Manchester Technical Schools, on Thursday, October 11th, the President, Mr. J. Pollitt, in the chair.

The minutes of the previous meeting were read and confirmed.

The Hon. Secretary read the annual report as follows:—

"This being the twenty-ninth annual meeting of the Society, your Council have to congratulate you upon the very successful year we have just passed through. It is satisfactory to be in a position to state that, notwithstanding the heavy calls which have been made upon our exchequer this year by the exhibition in December last, our funds have increased beyond all expectations, our present position being better than has ever been known since the Society first came into existence. Although we have had 32 new members added to the list, we have to record several resignations, our numerical strength being now 130, against 113 last year. It is satisfactory to find that the average attendance at our monthly meetings has increased to 59, against 51 last year. We are, however, sorry we cannot boast of the number of papers read during the present session, but it is with pleasure we reflect upon the general interest which has pervaded our gatherings. Undoubtedly, the principal event of the year was the exhibition in December last, being chiefly the work of our own members, together with the choicest work of the leading photographers in Great Britain, and supplemented by a unique collection of photographic work collected from all parts of the world by our esteemed member, Mr. Charles Harris, who also contributed to the interest of the exhibition by a short recital of his experiences of the photographic brethren in America, India, China, and Japan. Not the least interesting event of the year was the presentation of a testimonial to the Hon. Secretary, Mr. W. J. Chadwick. That gentleman having filled the office for the past seven or eight years with so much ability and tact, besides having some time previously matured and carried into effect a scheme for placing the finances of the Society on a much sounder basis than had ever before existed, it was thought by many of the members that some substantial recognition of such long-continued, active, and purely voluntary services should be made. It was not intended, however, from the first that the funds of the Society should be drained upon for the purpose; nor was it intended, beyond the mere sending out of circulars to members apprising them of what was proposed to be done, that any solicitations for subscriptions should be made, or any canvassing resorted to. The matter was entertained in a spirit of great liberality by a large proportion of the members, and the testimonial took the form of a very handsome gold watch and guard, which was presented by the President, on behalf of the subscribers, on the occasion of the soiree by which the December exhibition was inaugurated. The ceremony took place in the presence of a large and select company of visitors, and Mr. Chadwick, labouring under some emotion, made a graceful acknowledgment of the gift. On the same occasion our valued friend and old member, Mr. John Holding, artist, presented the Secretary, on his own account, with a beautifully-executed water-colour drawing from his own pencil. We must not omit mention of our old member, Mr. W. B. Woodbury, who came down from London specially to exhibit to us and demonstrate the working details and manipulations of the stannotype process. We have also to record, amongst the papers

read, one from the President, 'On the Attitude of our Society: Past, Present, and Future'; and another from the Hon. Secretary, being a series of suggestions of subjects that might be advantageously taken up by most of the members for research and demonstration at our meetings. Mr. Rishton read an interesting paper 'On Swing-Backs and Swing-Fronts,' illustrating his remarks by an ingenious model of a camera in section, which he afterwards presented to the Society. The Hon. Secretary gave another short communication on 'Landscape Lenses and Diaphragms,' with a few elementary remarks for the benefit of the younger members of the Society. Mr. Greatorex gave an interesting and highly-amusing paper, entitled 'A Summer Holiday,' consisting of notes taken during a recent tour in Switzerland. Mr. Edwards followed by a paper advocating the importance of rising-fronts, and exhibited several negatives intended to demonstrate the superiority of rising-fronts over swing-backs. The President dealt very ably with the same subject in another communication, and conclusively proved to the members that the rising-front was a more valuable addition to a camera than a swing-back. Besides the above, many other subjects of interest have been brought before the members, including a demonstration of the manipulation of gelatino-bromide paper, by Mr. McKellen. The lantern has upon more than one occasion been successfully handled by the Hon. Secretary and his brother, Mr. J. A. Chadwick, and generally the meetings have been well supplied with novelties in apparatus and members' work, amongst which may be mentioned a series of large pictures by Mr. McKellen, and some charming smaller studies by Mr. Alan Garnett. Mr. A. Brothers also exhibited some fine micro-photographs, taken by the aid of the electric light. Before closing this retrospective survey of the past year's proceedings, we must acknowledge the unprecedented success of our out-door meetings, which have been, with few exceptions, well attended and enjoyed by all present. And now, in resigning our respective offices, we again congratulate you on the satisfactory condition of the Society—not only in its financial status, but also upon the harmonious feeling which has characterised the whole proceedings."

Mr. William Watts said he thought a very important event had been omitted from the Report, viz, the presentation to the Hon. Secretary of a testimonial for his past services.

The Hon. Secretary submitted that it was omitted, but being a testimonial from the members of the Society, and not really a gift of the Society as a body, he did not mention it in the report. However, as many of the members expressed a wish that the subject should be included in the report, the Hon. Secretary, with his usual modesty, said he would prefer that the President receive the report from his hands as it now read, and that he (the President) might alter whatever he thought best. With this understanding the report was accepted.

A printed copy of the annual balance sheet was next handed round to the members; and in proposing the same be accepted, Mr. William Watts complimented the Council upon their able management of the Society's affairs during the past year.

The election of officers next took place by ballot, resulting as follows:—

President—Mr. J. S. Pollitt.

Vice Presidents—The Rev. Canon Beechey, Dr. C. P. Bahin, M. A. Brothers, F.R.A.S., John Dale, and J. W. Leigh.

Council—R. Atherton, Alan Garnett, Joseph Greatorex, Charles Harris, F.R.G., John Kershaw, S. D. McKellen, E. Openshaw, John Schofield, John Warburton, and M. Wright.

Hon. Treasurer—W. G. Coote.

Hon. Secretary—W. Chadwick.

During the scrutinizing of the voting papers, Mr. J. Greatorex exhibited a negative much fogged with patched dense markings; this was one of a batch of excellent plates, and the only one found defective. No explanation was offered, but many members said that they had met with similar experiences.

Mr. W. Blakeley exhibited a number of excellent prints, the work of a friend, who was desirous of becoming a member of the Society, and whom he would propose at the next meeting.

Mr. Livesey exhibited a number of splendid photographs, 10 by 8, very neatly mounted; they composed a series of views in Scotland.

The President (Mr. J. S. Pollitt) exhibited an instantaneous shutter, made more than thirty years ago, and read a short paper describing the same. He also exhibited some charming stereoscopic views, and lantern slides for instantaneous negatives taken by the aid of this shutter (see p. 682).

Mr. Alfred Brothers exhibited a portrait taken about 1856 or 1857, and which he supposed was the second C.-D.-V. portrait taken in Manchester.

A general discussion took place on shutters and instantaneous exposures, in which the President, Jno. Chadwick, sen., S. D. McKellen, Schofield, and others joined, resulting in the general approval of shutters of the Noton type.

Mr. Wm. Watts exhibited a walking-stick camera tripod-stand, which opened out to five feet three inches in height, and was so firm and rigid that it supported easily a weight of 30 lbs. When closed, it resembled a bamboo walking-stick, with buck-horn handle, silver mounted; its weight was one pound to one pound seven ounces.

Mr. Jos. Greatorex exhibited a number of lantern slides by the wet collodion process, Cowan's plates, and collodio-bromide process.

Owing to the lateness of the hour, the lantern was not used, but the Hon. Sec. said he would arrange to have the lantern working at the November meeting, and hoped all members who intended to send slides would confine them to the standard size—viz., $3\frac{1}{4}$ square, and accompanied by a list of number of slides, and exhibitor's name, and desired that members would send up their slides before the last minute, in order to insure their safe return, as it was extremely perplexing for a lanternist to have slides put into his hands during the exhibition by two or three different people, and ensuring each a safe return.

The next meeting will take place November 13th, at which, besides the lantern exhibition, Mr. Alfred Brothers will demonstrate the Daguerreotype process.

Talk in the Studio.

Photographic Society of Great Britain.—The next meeting of this Society will be held in the Gallery, 5A, Pall Mall East, on Tuseday next, October 28th, at eight p.m., when the apparatus now in the Exhibition will be brought forward and explained.

Yellow Light for the Dark Room.—We notice with pleasure that our German friends now recognize the advantage of illuminating the dark room with yellow light. Some few months ago, Mr. W. E. Debenham advocated the use of yellow paper in connection with pale green glass as a means of filtering the actinic rays. Quite recently, Dr. Liesegang described in the *Archiv* the results of his experience with the so-called "Golden Fabric," the material subsequently adopted by Mr. Debenham, and originally introduced at the suggestion of Mr. Zaehnsdorf. In Dr. Liesegang's dark room there are fitted two windows, the one being glazed with ruby glass and covered with one layer of yellow fabric, and the other glazed with ordinary window glass and covered with two thicknesses of the fabric. When it is only required to examine the plate from time to time during development, a bent metal screen should be placed between the window and dish. The two layers of fabric answered perfectly during the summer months, the negatives being entirely free from fog. The same material also proved equally useful to replace the ruby glass in a dark room lantern, and Dr. Liesegang quite recently developed a large batch of instantaneous plates with such a light; a piece of the material, 30 by 15 inches, was folded twice, thus giving a thickness of four layers, and placed between a burning candle and the developing dish, without taking any means to stop out the back and top light. During development, the dish was covered with a ferrotype plate, and the latter was only removed when it was necessary to observe the process as it proceeded. The plates, without exception, developed free from fog.

Purification of Methylated Spirit.—Cazeneuve and Chapuis have made experiments to discover to what extent the French methylated spirit, which is prepared by mixing wood spirit, containing about 25 per cent. of acetone, with ethyl alcohol, can be freed from its objectionable odour. By the action of nascent hydrogen from a zinc and copper couple placed in the spirit at a temperature of about 70°, the disagreeable odour is completely removed after the reaction has gone on for five or six days. The same result can be obtained by using a zinc and copper couple in the cold, but the process takes about four times as long. By distilling a mixture from a water-bath, nearly odourless spirit is obtained. The result is obviously due to the conversion of the

acetone into secondary propyl alcohol by the action of the nascent hydrogen.

A Desideratum.—Mr. A. Anson, of Balliol College, writes:—"A papier-mache tray, with deep sloping sides, the bottom of which is no longer, but slightly narrower, than the plate in use. In this tray two plates can be washed or fixed at the same time back to back. The lower one cannot touch the bottom of the tray, as it is supported by the sloping sides, whose base is narrower than the plates. It is also an advantage, in this tray, that single plates can be washed or fixed film downwards, so that the sediment falls to the bottom. I have with me a tray bought in Paris, which will hold two 5 by 4 plates, or two quarter-plates, in this manner."

The Study of Photography.—The *Magazine of Art* says:—"The application of photography is now so extended and varied, and its practice is so simplified, that it appeals to all classes and professions, as well as to those who are attracted to photography for its own sake. It is equally useful to the architect and engineer, to the archæologist and the sculptor, the painter of landscape and cattle, and the tourist who values his reminiscences of travel. With ladies, too, it is fast becoming a veritable hobby; it involves no risk of accident, of burnt and blackened hands, and injured dress."

German Photographers.—In the *Deutsche Photographen Zeitung* are given some interesting statistics concerning the proportion of employés to photographers in German towns, as also the relative number of photographers to the population in the German Empire. As might be expected, the larger the town, the greater is the number of employés in each establishment. The following table shows in the first column the number of assistants to every hundred principal photographers in different sized towns:—

38	in villages	containing	under	2,000	inhabitants.
40	in small towns	„	„	5,000	„
77	in country „	„	„	20,000	„
138	in provincial „	„	„	100,000	„
216	in large „	„	over	100,000	„

It should be noted that in villages and small towns a great many photographers combine with their business that of an optician, or something else, and thus the above numbers can only be considered as approximately correct. In Berlin, with a population of 1,156,755, there are 627 photographers and their assistants, and thus to every 1845 inhabitants there is one photographer, while in the German Empire, out of a population of 45,222,113, there are 3,284 photographers with 3,585 assistants, and thus out of every 6,584 inhabitants, one person works at photography.

A Picture for his Wife.—A man entered a photographer's and said: "I want a cabinet picture of myself?" The artist placed him in position and screwed up his machine to the proper focus. "Now look bright and cheerful," he said, "and keep your eye fastened on that hole in the wall." Instead of looking bright and cheerful, the man concaved himself forward, dropped his jaw, and assumed a look of infinite weariness. "What's the matter with you?" exclaimed the photographer. "Brace up, I say, and look pleasant." "If this position costs anything extra," was the answer, "I am willing to pay for it. My wife is up in the country visiting friends, and this picture goes to her. I know what I am about. Pull the blanket off, Mr. Artist, and begin counting."—*Detroit Free Press.*

A New Journal.—The Magyars are to have a photographic monthly in their own tongue. A Mr. F. Veresez, of Klausenburg, will be the editor.—*Anthony's Bulletin.*

Photographic Club.—The subject for discussion at the next meeting of this Club will be on "Reversed Negatives."

To Correspondents.

*** We cannot undertake to return rejected communications.

J. E. B.—It has been sent on to Mr. Brooks.

Butler Humphrys.—We are sorry to say that we do not know the address of the gentleman referred to.

G.—1. The best is a thorough washing in abundance of water, and the expedient you referred to should only be used when there is a difficulty in obtaining a good supply of water. 2. The special objection is, that it tends to make the paper rotten.

W. A. C.—1. The picture referred to has certainly been over-exposed; perhaps it has had double the best exposure. 2. We can hardly suggest the reason without knowing more. Try fuming your paper with ammonia (see page 346 of present volume). 3. One special advantage of Beach's potash developer is the circumstance that in case of over-exposure, mere dilution with water is sufficient. 4. As regards the prints, we must speak very highly of them as a whole, but No. 7 shows signs of under-exposure.

Beginner.—Obtain Captain Abney's "Instruction"; the book you mention is very elementary, and contains no information regarding the matter you refer to.

Mai-Kama.—We should advise you to call on Mr. W. Ackland, of 416, Strand, and to take his advice in the matter.

B. L.—It depends altogether on the article itself, and if the configuration of the article is novel, you can register the design at a moderate cost by applying at the Design and Trades-marks Registry. If, on the other hand, the novelty merely consists of a particular arrangement of photographs on a card, we do not think your application will be entertained, unless the prints are so placed as to themselves build up some pattern or design which can itself be registered. You doubtless know that any individual photograph can be protected at a cost of 1s. 7d., by registration at Stationers' Hall.

M. Breithardt.—Obtain the cement used for fastening tricycle tyres; several qualities are sold, but be sure to obtain the best kind, which contains a good deal of india-rubber. Make the glass hot, rub the surfaces with the cement, and clamp together, leaving the clamps on till the glass is quite cold.

J. James.—The system is applicable to plates of any sensitiveness, but in judging exposures, success will depend largely on the individual experience of the worker.

G. H.—The curious way in which you have misunderstood the remark amuses us.

A. G. B.—Your experience is interesting, and we shall ask you to be kind enough to write a short paper on the subject. 1. To allow the easy separation of the films. 2. It does, and the paper might be used a second time if it were worth while to do so. 3. The copper compound would be likely to do mischief; and we should therefore recommend ordinary paper, or the so-called vegetable parchment. 4. The gelatined paper is sold by Dr. Liesegang, of Dusseldorf. 5. Ordinary plain collodion, containing about 5 grains of pyroxyline to the ounce.

Musicus.—Your work is very much improved, and we especially congratulate you on the picture which you contribute to the Pall Mall Exhibition. This will be noticed in due course, and we shall be glad of your permission to reproduce it in our columns.

*** Several answers must stand over till next week.

THE PHOTOGRAPHIC NEWS.

VOL. XXVIII. No. 1365.—*October* 31, 1884.

CONTENTS.

M. GRASSIN'S PHOTOGRAPH OF AN EXPRESS TRAIN.

ALTHOUGH one has seen several pictures of express trains taken at full speed—or, at any rate, photographs which were said to have been taken while the trains were in rapid motion—we believe that in M. Grassin's picture, which forms our supplement this week, we have the first authentic photograph of an express train taken broadside on. Among the express train pictures which have been exhibited, may be mentioned one in which the clouds of vapour were diffused in masses round about the funnel of the engine, a condition of things by no means consistent with rapid motion; while in the case of another "express photograph," our readers will remember that the signals were shown as being against the train.

The picture which forms our supplement was taken nearly two years ago, and was exhibited at the International Exhibition of photographs held in Brussels last year. In this case it was honoured with a medal; and, as already mentioned, M. Grassin has been awarded a medal by the Pall Mall judges this year.

The train represented is the well-known international mail of the splendid service between London and Paris, and it seems to us to have been taken just opposite to the Portland Cement Works which one passes after leaving Boulogne for Paris. The exposure is estimated as being one three hundredth of a second, and the speed of the train as forty-two miles an hour. The amount of actual motion during the exposure may be judged of by an inspection of the crank-arms attached to the driving wheels, and comparing them with the comparately sharp connecting rod; and one need only look carefully at the back-stream of vapour to detect the rythmic waves which correspond to each action of a cylinder chamber, or to one-fourth of the circumference of the driving wheel. As a genuine illustration of what can be done by the camera in the present day, M. Grassin's picture possesses much interest, especially as compared with the frauds which have been put forward as "express train" pictures.

THE PALL MALL EXHIBITION.

FOURTH NOTICE.

MR. GEORGE PITT'S portrait of a lady (No. 51) does not strike us as being remarkably good, the heavy and somewhat exaggerated shades on the face being a little too pronounced, while the hand nearest the lens is magnified so much as to be very noticeable; but No. 82, a portrait by the same gentleman, is better as regards the pose and lighting. "On the Skirts of the Downs," by Mr. J. Gale (No. 52), shows us a flock of sheep on a grassy slope; but we do not like this picture quite so well as those coming afterwards under Mr. Gale's name. "Off to Market—you'll take care of Baby?" (No. 69), has an air of truth which makes it a good picture. The mother, in leaving her babe with the girl, evidently expects to find it safe on the return. No. 70 is a curious study of light and shade in the mouth of a cave; while No. 71, "Oh Rye, Oh Fie;" 72, "Spinning—a Highland Doorway;" and No. 83, "Mowing at Cowdray," are effective pictures of rural life. The "Studies of Cattle," No. 55, by J. Beasley, Jun., although small, possess much merit, and the same remark applies to his "Morning Chat," No. 73, in which the old cottager is evidently enjoying the usual half-hour of gossip. "A Folkestone Fisherman," No. 74, and "Off Brighton," No. 75, are both good; the latter being a little out of the usual run, as it is taken directly in the face of the light. In No. 84, "Etter Water," "Rydal Water," and "Brathy Bridge," we have true pictures made by the camera, the old ivy-grown bridge being particularly attractive.

Two pictures of "Ashwood Dale, near Buxton" (Nos. 56 and 57), are two of four exhibits by the Hon. Mrs. Holden-Hambrough. These are delightful bits of woodland scenery on 12 by 10 plates, fully exposed so as to well bring out all details, and possessing great technical merits, as well as artistic qualities; while the remaining two pictures (Nos. 85 and 86) show us "Dorothy Vernon's room and steps at Haddon Hall," and "The Terrace at Haddon Hall." From Mr. Clive F. Pritchard there are three exhibits at Pall Mall; (No. 58) "Clivedon-on-Thames," (No. 59) "Clare Bridge, Cambridge," and (No. 60), "Clivedon-on-Thames;" and he has been successful in making pleasing little pictures of his subjects. "Three Children of Arthur à Beckett, Esq.," by Barraud, and enlarged by the Autotype Co., is a good group, and well enlarged; but it is difficult to see any special qualities which should entitle it to a place in the Exhibition.

"Luncheon Time" (No. 76), by Mr. B. Wilkinson, jun., and its companion picture, "Early Spring" (No. 77), show us the plough at rest, and the plough at work; while in No. 90, "Fence Making," by the same gentleman, we see another phase of field work: the remaining exhibits of Mr. Wilkinson (192 and 193) are like those referred to above, country scenes.

A good picture of pussy is always attractive, and it is a pity that Mr. Pointer's excellent enlargement on opal (No. 78) is placed so low down. The long-haired white Persian cat is sitting on a newspaper, with an air of resentment for some slight indignity offered her. Who knows better than Mr. Pointer how to depict with the camera all the graces and attitudes of the cat, and to say a cat picture is by Mr. Pointer is to say it is good! In No. 380 we have a frame of cats and dogs by the same exhibitor.

The Hampshire Cottage of Mr. C. A. Fernley shows us the thatched cottage in its most pleasing aspect—that is to say, with the sunlight streaming down on the outside; while the "Views in Surrey" (Nos. 537 and 558) show us other pleasing phases of country life. Mr. Fernley's photographs are pictures, and contain none of the heavy and detailless masses of black which often spoil landscape work.

"Studies of Pampas Grass," by J. Bracebridge Hilditch, is a difficult subject well executed, and Mr. Hilditch also deserves credit for the good qualities possessed by his remaining exhibits, "Can I trust you?" (No. 102), "Feeding the Swans" (No. 454), "The Thames at Richmond" (No. 476), and "Cholmondley Walk, Richmond" (505).

It is not often that such a good opportunity occurs for obtaining a photograph of Pilatus as Dr. Plaister had when he secured No. 89, "Lucerne with Pilatus"; and a view which so well shows the mist-clothed monarch is likely to be valued by those who know the locality.

In No. 91, "G. Grossmith, Esq.," we have a commercial portrait, and nothing more; and now-a-days commercial portraits are made partly by the camera and partly by the retoucher's pencil, one hardly feels that they are quite in their proper place in a purely photographic exhibition.

An exhibit of real and permanent interest is the frame of photographs (No. 93) sent by Mr. W. J. A. Grant to illustrate the sixth cruise of the Dutch schooner *Willem Barentts*. Of these we shall say more on a future occasion.

The enlargement on gelatino-bromide paper (No. 98), sent by Messrs. Morgan and Kidd, shows conclusively the value of the process, but the large hands spoil the exhibit as a picture.

Mr. R. H. Lord, of Cambridge, has succeeded in making an admirable picture of the new Archæological Museum at Cambridge, the subject being an especially difficult one to deal with; and Mr. Lord's other exhibits (Nos. 320 and 341), consisting of eighteen pictures showing characters

from the "Birds of Aristophanes," as performed at Cambridge in November of last year, also possesses special merits. These latter are interesting as exemplifying striking phases of facial expressions, and we select two for reproduction. The first represents the adventurer Peithetairos (Mr. M. R. James) endeavouring to persuade the Hoopoe (Mr. F. R. Pryor) to establish the aërial bird-city, which should in time govern both gods and men; but the Hoopoe looks very doubtful as to the success of the enterprise, although he ultimately yields to the persuasive talents of Peithetairos.

The other photograph, which we also reproduce as a Meisenbach block, shows a scene in which Peithetairos and

Euelpides are represented as being a little embarrassed about certain details relating to the formation of the proposed new city. A book of the play, illustrated with the complete series of Mr. Lord's pictures, would form an interesting album.

THE EFFECT OF LIGHT IN RELATION TO THE SOLUBILITY AND PRESERVATION OF GELATINE EMULSION.

In a recent issue of the *Wochenblatt*, Herr Schumann describes a series of experiments on the action of light on gelatine emulsion, which may possibly have some bearing on Mr. Burke's researches as to the production of an insoluble image on an argentic gelatine film, when treated with the usual pyro developer. Herr Schumann finds, however, that the use of pyrogallic acid is not essential to the formation of insolubility; on exposing emulsion jelly to the action of the sun's rays for some days, he found that the external surface becomes completely insoluble in hot water, and is not disintegrated even after some hours' digestion in boiling water. As our readers are aware, gelatine emulsion containing no antiseptic decomposes in summer weather in four or five days, but Herr Schumann finds that when emulsion is placed in daylight for a week or so, no decomposition appears to take place, this fact being probably due to the bromine, chlorine, or iodine liberated from the silver salts

y the actinic rays, acting as preservatives; also it is possible iat the insolubility before referred to is produced by the ombination of the halogen with gelatine, for it is well nown that aqueous solutions of bromine, chlorine, and odine have a tanning effect on gelatine.

THE HYDROCHLORATE OF HYDROXYLAMINE DEVELOPER.

We have recently been making experiments in the new eveloper described in the PHOTOGRAPHIC NEWS by Messrs. arl Egli and Arnold Spiller. The substance which forms ie active constituent of the developer goes by the formidble name which we have given as a heading.

Mr. Arnold Spiller was good enough to give us the prese formulæ which he is now using, he having varied it ightly since the article on the developer appeared in the HOTOGRAPHIC NEWS. We copy out word for word his istructions:—

"A.—Hydroxyl. hydrochlor. ... ... 32 grains
Citric acid ... ... 15 ,,
Potassium bromide ... ... 20 ,,
Water ... ... 1 ounce
"B.—Caustic soda ... ... 1 drm. (60 grs)
Water ... ... 1 ounce
"C.—Potassium bromide ... ... 20 grains
Water ... ... 1 ounce

"To develop a 7½ by 5 plate, I take 1 drachm of A, 3½ unces of water, and to begin with 40 (not 20, as stated) rops of B; then, as the operation proceeds, another 20 or o is added, *if necessary*."

On analyzing these quantities, we find that the deve-per, after the addition of the first 40 drops of B, con-sts approximately of—

Hydrochlorate of hydroxylamine ...	1·08 grains
Bromide of potassium	·7 grains
Caustic soda...	1·32 grains

each ounce of developer.

To facilitate the trying of variations in the constituents, e made up the stock solutions, not as given by Mr. piller; but we made up a ten per cent. solution of each the three constituents of the developer, keeping the roportion of citric acid to hydrochlorate of hydroxylamine e same as that just given.

We then exposed a number of plates for the same length time, one set under the sensitometer, another set in the mera, to a statuette. During all experiments, we deve-ped one sensitometer-exposed plate, and one camera-xposed one, side by side.

We first of all developed a pair of plates by the ordinary ro developer, so as to be able to have a standard with hich to compare those developed by the new developer. As a sufficiently close approximation to the formula ven by Mr. Spiller, we first tried a solution containing—

Hydrochlorate of hydroxylamine ...	1 grain
Bromide of potassium...	½ grain
Caustic soda	1½ grains

each ounce.

With this it was a very long time before any image mmenced to appear—nearly quarter of an hour—and velopment progressed so slowly after something did pear, that we despaired of ever getting sufficient density detail. We therefore added caustic soda freely—too ely, apparently—because although we got detail enough er some little time, we got fog also.

On looking for a reason for the extreme slowness of the velopment, it struck us that the quantity of citric acid commended is very large, and on making the experiment found that to neutralize the solution containing one grain of hydrochlorate of hydroxylamine, required very nearly one grain of caustic soda; so that with the developer given by Mr. Spiller, there would be but very little caustic soda left to accelerate development after the acid was neutralized; besides which, there would be formed in the developer a large proportion of citrate of soda, which is a powerful restrainer.

Taking this into consideration, we next tried the following solution:—

Hydrochlorate of hydroxylamine...	1 grain
Bromide of potassium	*nil.*
Caustic soda	2½ grains

to each ounce of developer.

This gave a far more satisfactory result. The development proceeded with much greater rapidity than before, although by no means so quickly as with ordinary pyro developer. The only fault to be found with the final result was that the negative was too thin. There was no trace of fog, from which we conclude that no soluble bromide is necessary as a restrainer with the hydroxylamine developer.

We tried one more pair of plates, using twice as much hydrochlorate of hydroxylamine as before, and using also somewhat more caustic soda.

Our developer now consisted of the following:—

Hydrochlorate of hydroxylamine ...	2 grains
Caustic soda	3 ,,

to each ounce.

This gave us an excellent result. There was not a trace of fog, nor in the fixed negative the slightest trace of discolouration. The colour of the deposit was a steel blue, which left nothing to be desired. In the case of the plate exposed under the sensitometer, the same figure was got as with the pyro developer. The only fault which could be urged against the developer is, that with the particular plates used, there was a slight reticulation of the film, doubtless due to the caustic alkali. It is only fair, however, to say that the particular sample of plate used was an exceedingly rapid commercial one, in which the films are very soluble, either on account of a soft gelatine being used, or on account of long digestion of the emulsion being employed to give sensitiveness; also that the addition of 15 per cent. of methylated spirit prevented the reticulation, although the time taken for development was increased.

It should be mentioned that the solution scarcely discolours at all during development, so that it may be used repeatedly. It must be borne in mind, however, in this connection, that whenever a bromide plate is developed, bromine is liberated, and absorbed by the developing solution. Probably, with the developer just given, it will combine with the caustic soda to form bromide of sodium; but whether it does or not, a powerful restrainer will be added to this developer.

Finally, we may say that, as the first experiments with a new developer, the results have pleased us greatly.

We unfortunately mixed the whole of the hydrochlorate of hydroxylamine which we had with citric acid and water, as directed by Mr. Spiller, otherwise we should have tried the effect of using a greatly reduced quantity of citric acid, or even none; the impression conveyed to us, even during our last experiments, being that we were using a developer far too powerfully restrained.

Concerning the citric acid, Mr. Spiller says:—"Citric acid is added to A simply to prevent the precipitation of lime by the addition of caustic alkali to the ordinary water."

As regards the name of the hydroxylamine salt used, it may be noted that it may either be called hydrochlor*ate* or hydrochlor*ide*, this latter termination having recently been adopted in the journal of the Chemical Society to distinguish the salts which hydrogen acids form with ammonia and its derivatives.

NOTES FROM NEW YORK.

Death of Henry T. Anthony—The New Orleans Exhibition—Photograph Exhibits—An Improved Camera and Shutter.

The sudden death of Mr. H. T. Anthony, one of our oldest dealers in photographic goods and supplies in this country, was as unexpected as it was sad. It had been well known that for some time that he had been in ill-health, and had visited the hot springs in Arkansas, and other places, for the purpose of gaining strength and health. He had been benefitted by these trips, and on the day of the accident was especially bright and active at his office. On his return home from the office in the afternoon, he stopped at the Phœnix Club—of which he was a member—near Union Square, and from there started on his way home. On crossing Fourth Avenue to take a car, he was knocked down by a four-wheeled cab going at a high rate of speed, which ran over him, seriously bruising his head, breast, and thigh. He was picked up in an unconscious state, was carried to a neighbouring hospital and finally to his home, where, for a few minutes, he revived sufficiently to recognize a few friends. After that he relapsed into unconciousness, and died on Saturday morning, the 11th inst., surrounded by his relations and friends. At his funeral, which took place on the morning of the 14th inst., at his brother's house, there was a very full attendance, many old photographers and scientific gentlemen prominent in their various pursuits being among those present.

In the remarks made, his career, so far as it related to photography, and the part he took in advancing it, was strongly pointed out. In his place of business he was highly esteemed by all the employees, especially for his equitable dealing towards each one. To him amateurs owe much for his perseverance in manufacturing good chemicals for photographic work. He was always ready to impart information to amateurs, no matter how ignorant they were, and in the early days of photography he would go out of his way to help some troubled man beset with difficulty. He was seventy-one years old, and had been interested in photography with his brother Edward for forty-six years. It was his fortune to witness and engage in the wonderful photographic progress of our epoch, from the time when we had the slow Daguerrotype plate, to the lightning gelatine plate of the present day. At the last meeting of our Amateur Society, on the 14th inst., resolutions of respect to his memory were passed.

At the same meeting a vote was passed authorizing the Society to send a collective exhibit of photographs made by members to the great New Orleans World's Exposition to be held at New Orleans, La., between December 1st, 1884, and May 31st, 1885, and towards which Congress has appropriated $1,500,000. A committee on "Photography," of which Mr. E. L. Wilson, of the *Philadelphia Photographer*, is chairman, has been appointed, and it is probable that a very elaborate exhibit of everything in any way pertaining to photography will be made.

Several sub-committees have been appointed under the following heads:—

E. E. Wilson and S. T. Blessing, Committee on Practical Photography.

V. M. Wilcox, Committee on Photographic Apparatus and Requisites.

Charles Himes, Committee on Educational Photography and Literature.

F. C. Beach, Committee on Amateur Societies and Exhibits.

If each man succeeds in carrying out his department fully, it is likely to make the exhibit very interesting, and a source of pleasure to those visiting the exhibition. As it is to be a world's exhibition, locality is not important, and I learn that Mr. Beach is desirous of having representative exhibits from amateur associations in England and other countries.

A party of ten members of the Amateur Society made a very pleasant outing recently, on the 10th inst., to Llewellyn Park, Orange, N. J., at the invitation of O. D. Munn, of the *Scientific American*, and lunched with him at his residence.

A novel feature at the meeting on the 14th was the inauguration of the "Question Box," which elicited much discussion, and proved very useful in bringing out information of a practical character. It seems to be the endeavour of those who manage the Society to provide matters for practical discussion and demonstrations, rather than to have dry papers read.

A special committee on "gelatine plates" was appointed, whose duties were very clearly specified. They are to ascertain by experiment what are the best grades and brands of plates for the amateur's use. Mr. Beach stated that he had used the following intensifier with much success:—

No. 1.—Saturated solution bichloride mercury	1 ounce
Water	6 ounces
No. 2.—Water	1 ounce
Sulphite soda (crystals)	...120 grains

The plate is whitened a little in No. 1, then washed and immersed in No. 2. It turns a dark wine colour, and the shadows keep very clear.

Mr. C. R. Smith, the inventor, exhibited his mirror shutter and camera, patented July 1st, 1884, and described in one of the recent issues of the News. The shutter is inside of the box, between the lens and dry plate, and has a broad curved bottom with a slit in it to match the lens. In its normal position, the front towards the lens, with the mirror attached, is at an angle of 45°, and reflects the image upon the ground glass placed horizontally at the top above. A coiled flat clock-spring at the axis of rotation imparts the necessary movement, and it is wound up or loosened by an ordinary clock key from the outside. The operator sees the image plainly on the ground glass non-reversed, and when it has reached the position he desires, a spring catch is touched, which allows the coiled clock-spring to throw the front of the shutter up in a horizontal position, and brings the slit in the curved bottom in front of and past the rear of the lens, thus making an instantaneous exposure. The apparatus worked very smoothly and silently; in fact, it was noiseless, and there was not the least jar.

The inventor remarked that the partial vacuum created in the rear of the box by the sudden movement of the shutter acted as a cushion, and prevented jar. He showed specimen prints made from negatives by the shutter.

Another gentleman, Mr. Fish, showed a shutter which he claimed was an improvement on the well-known Prosch shutter. He used two springs, one a spiral, the other a flat, straight opening, one adjustable to the other, and had some new catches to regulate the tension and movement of the shutter.

Mr. Beach remarked that from his experience Mr. Fish's idea was correct, as the chief trouble with the Prosch shutter had been the liability of the flat coiled spring to break just at the time it was needed.

Some demonstrations were made with reference to the development of instantaneous plates, after which the meeting was adjourned.

A lantern exhibition is to be given on the 30th. The next regular meeting occurs on November 11.

The membership of the Society continues to increase rapidly, and the treasurer's report for the first six months showed a handsome surplus in the treasury.

At the November 11th meeting a demonstration of the platinotype process is to be given by Mr. Chas. A. Needham, of this city, who is doing good work for amateurs.

At the outing to Llewellyn Park, on the 10th inst., Mr. R. A. C. Smith carried with him an improved Hare camera, with extension back, and a perfect working changing-box, which he had recently imported. He did some splendid work.

Mr. J. B. Metcalf had a Bick camera, with folding slide

in the plate-holders for 3¼ by 4¼ plates, which was much admired for its high finish and compactness. He, also, is an expert amateur. THE NEW YORK AMATEUR.

October 18th.

PRESS NOTICES OF THE PHOTOGRAPHIC EXHIBITION.

[From the *Graphic*]

There is no startling novelty in this year's exhibition, but there is a distinct improvement shown in various directions. Firstly, photographers are better succeeding in their endeavours to make a picture complete in itself, instead of being satisfied with a mere reproduction of a portion of a scene. Such a photograph, deprived of the colour and surroundings of the original, may be excellent from a technical point of view, but will not in any way bear criticism if judged from an artistic standpoint. Now, as a brilliant exception to this, Messrs. Robinson and Thompson have sent a scene on the quays of Venice, "Venetian Boats," which is really an admirable picture in itself. Mr. H. P. Robinson also has sent some good figure studies in the open air, of which "He never told his love" has justly been awarded a medal. The boots of one of the young women, however, were a little too close to the lens, and look like banjo clogs. Mr. J. Gale also has some capital figure subjects, of which "At Rye—Oh, Fie!"—a flirtation between a fisherboy and and a girl at a cottage door—is much the best. Mr. Adam Diston, whose charming old woman spinning excited so much admiration last year, shows another industrious housewife blowing out the dust from a Dutch clock, while his Dutchlike style has been successfully followed by Mr. G. Hadley in his "Small Studies," which have duly carried off a medal. The same artist's "Business Slack," a more ambitious study of fisher life, is capital. In many other figure subjects, however, the figures still possess the stiffness of which we have before complained, and the models are manifestly uncomfortable in their unusual costumes. Indeed it is here, in such pictures, for instance, as Mr. Cotesworth's "Awkward Lead," that the painter has the advantage over the photographer, for, while the grouping is excellent, the former would have been able by a touch of his brush to soften the rigidity of the most iron-jointed model.

Of portraits proper, Mr. Valentine Blanchard shows some capital full-length figures in unconventional attitudes, of which "A Siesta" is exceptionally graceful, while those of Messrs. Lafayette and of H. S. Mendelssohn are particularly worthy of mention, the latter especially for the arrangement of the drapery. Of animal studies there are exceptionally few this year. Mr. Dixon, as usual to the fore, sends a Spanish Imperial eagle, while a splendid cat, an enlargement on porcelain, is sent by Mr. H. Pointer.

The second improvement to be noted is undoubtedly the reproduction of interiors, which, thanks to the improved lenses, or better plates, can now be clearly depicted. With a lively recollection of the difficulties in Italy of procuring any really good photographs of interiors of churches, we can award the most unhesitating praise to the really magnificent photograph, by A. G. Tagliaferro, of "The Interior of St. John's Church, Malta," in which all the abundant detail is faithfully reproduced. Nor is the improvemement any the less marked in many other interiors exhibited. And here we may express our surprise at the extreme paucity of architectural subjects, considering how far afield both amateur and professional photographers go now-a-days. There are also very few foreign subjects, but of these a melancholy interest attaches to the desert scenes in Algeria by the late Mr. Baden Pritchard, taken only a week or so before his death; while Mr. Stone sends some good reminiscences of a trip to the Canary Islands, notably "The Troglodyte Village of Atalaya, Gran Canaria," and Mr. Donkin shows some more of his studies in the High Alps. These, by the way, together with similar scenes by Mr. V. Sella, from a photographic point of view, are some of the finest things in the room. In the home landscapes, which form the majority of the photographs, there is good techical work, but little variety in artistic treatment. The School of Military Engineering send some good views of Lynmouth; Mr. Arthur H. Dyke-Ackland some good landscapes showing long distances—a difficult feat to achieve with a small camera; Mr. J. Stenning some capital views in North Wales and the Lakes; Mr. H. B. Berkeley an exquisite platinotype print of Pangbourne Lock; and Captain Abney several scenes on the Cherwell.

As usual, there is no lack of "breaking waves," though several show signs of the negatives having been over-carefully touched up. One of the best is by Mr. C. Grassin. The velvety appearance of the neck of the wave is exceedingly good. There are some capital yacht studies on the Solent by Messrs. G. West and Son, and one very singular view of a wreck, evidently taken from a height above, by Mr. W. Brooks. Of the curiosities of the Exhibition, we should mention photographs of a streak of lightning, by M. Auty; that of an express train, taken in 1-300th of a second, by Mr. C. Grassin; and some views from a balloon.

In addition to the photographs, there is a comprehensive display of apparatus, with some new instantaneous shutters, and some abnormally light cameras, especially welcome to amateurs.

TONING.

BY W. M. ASHMAN.*

As one of the many professionals who regularly practise the perfected researches of others—viz., those photo-chemical scientists, whose names have become as familiar to all students of the art as those of Galvani, Volta, or Faraday to the students of electrical science—it will be readily understood that I cannot say anything which is new. Premising this to be the case, I shall endeavour to show the *raison d'etre* of the various processes to be hereinafter described, and to whom we are indebted for their discovery.

I have already in the previous paper dealt with the means employed in preparing a suitable paper to receive a photographic image, including the methods of albumenizing, sensitizing, and fuming. Preserved papers were also spoken of, and many useful hints were gathered in the discussion which followed. As it will be necessary to refer to these papers in the remarks which are to follow, it will be found more convenient if we distinguish the preserved paper from freshly prepared by the cognomen of "preserved" and "ordinary."

Beginning with ordinary paper, printed under a negative somewhat deeper than it is desired to have the prints when finished, we should have a print which, although beautiful to look upon, possesses a charm of only a transient nature, due to the gradual decomposition that takes place when organic substances such as albumen are long in contact with free nitrate of silver; hence the necessity of the processes I have to describe.

In the case of alkaline toning with borax or acetate of soda, the first consideration is to free the paper as much as possible from the excess of silver nitrate remaining therein, over and above the quantity used in the production of the print; this is termed washing away the free silver. That operation is satisfactorily performed by soaking the prints in a few changes of clean soft water, usually four, or until the water is no longer opalescent when tested with a few grains of salt. The washing water so obtained is collected in the manner described to you by Mr. F. W. Hart, and precipitated with dilute hydrochloric acid. The vessel employed should be scrupulously clean, either earthenware, porcelain, or wood answering the purpose.

Experiment I.—The treatment of the prints is sometimes followed by passing them into a dilute solution of sodium acetate or ordinary common salt, about one per cent., such as here shown, and stirring them about for five minutes, when it will be seen they have assumed a brick-red colour, the object of which is three-fold. Firstly, the fibres become charged with a substance which acts as a chlorine absorbent, a necessary property to be mentioned further on. Secondly, a definite colour is ensured to start with, thus obviating the possibility of mistaking fresh prints in the toning bath for those which have become purple by reason of the deposited gold, an important consideration when dealing with fumed paper. Thirdly, the last trace of free nitrate of silver is removed, thereby preventing a too rapid decomposition of the toning bath.

Theoretically considered, it is proper that the last trace of silver nitrate should be removed; but those who are engaged in the daily practice of commercial work do not insist upon the strict observance of such a rule in all cases. An especial exception is permitted and advocated when dealing with prints from weak or under-exposed negatives, this class being found to yield richer tones by not washing any of the free silver out.

The plan of soaking prints in a solution of sodium acetate was originally recommended, in lieu of washing, by a member of this Society, Mr. A. L. Henderson, as long ago as 1861, the following being an outline of the method suggested by him:—

* Read before the London and Provincial Photographic Association.

Slightly over-printed proofs were soaked in a bath composed of—

Sodium acetate	240 grains
Water	10 ounces

The unwashed proofs were moved about in this solution at least ten minutes, in order to convert all the free silver nitrate into acetate of silver; after slight rinsing in clean water the proofs were toned with—

Gold terchloride	4 grains
Sodium acetate...	240 ,,
Water	10 ounces

Among the advantages claimed was an entire absence from mealiness, a defect, you will remember, we now avoid by the adoption of ammoniacal fuming.

Guide-books to the practice of printing usually recommend three rapid washings; the decomposing action thus set up by the quantity of free silver remaining in the paper materially quickens the speed of toning. To prevent a too rapid deposition of gold, some printers prefer adding a small quantity of common salt to the toning bath, which turns the prints sufficiently red, and acts in some respects equal to an intermediary bath.

Preserved papers, containing, as they generally do, a certain proportion of free acid, are liable to give some trouble in toning, owing to the retarding action of the acid present. When this occurs it is in a great measure overcome by the use of an intermediate bath of an alkaline character and sufficient strength to neutralize the acid. Either the carbonates of ammonia or soda are found useful for this purpose, and I cannot do better than quote the one mentioned by Mr. Frederick York, which, it will be remembered, is composed of—

Washing soda	1 ounce
Water	1 gallon

Prints treated in the manner described are ready for toning by the alkaline method to be dealt with later on.

This brings us to the consideration of toning baths generally. The properties of toning baths vary somewhat, according to the mode of preparation. The term toning, as we understand it, implies a certain change of colour, brought about by chemical means, such as the deposition of a stable metal upon one that is easily affected by the atmosphere—electrolysis, in fact.

Evidently Mr. W. H. Fox Talbot was the first to use the toning bath in connection with paper photography, although he does not seem to have made much headway with his process at first, for it is recorded that from January, 1839, the date when Mr. Talbot communicated his discovery to the Royal Society, until 1845, very little improvement took place. These early paper pictures, be it remembered, were designated photogenic drawings. Talbot-type was not patented for some time afterwards.

In the year 1845, however, it was found that steeping the paper in terchloride of gold, vastly improved the results. It was not until 1853 that albumen took any part in the production of prints, the honour of its introduction being ascribed to Mr. Henry Pollock, although it seems that M. Le Gray, of Paris, about that time was producing stereoscopic pictures on albumenized paper. To M. Le Gray is due the credit of introducing gold toning in lieu of sulphur. The first toning then was performed by the decomposition of hypo, and known as sulphur toning, by which fine black tones were obtained upon the addition of an acid—such as acetic, sulphuric, or other suitable oxidizing substance—to the hypo; gold taking no part in this process. Unfortunately, prints so treated are said to be the least permanent of any, but of that I can bring no actual proof, never having employed the process.

Experiment II.—Toning by Sulphur.—We have an unwashed silver print here in a 20 per cent. solution of hypo, and to that we now add a few drops of slightly dilute sulphuric acid. It will be seen that a straw-coloured substance is immediately liberated, which is sulphur in an exceedingly fine state of division, and this becomes attached to the print. Toning action goes on, through the silver image being tarnished, or, more correctly, converted into sulphide of silver. This liberation of sulphur may be expressed by the following equation:—

Hypo + Sulph. Acid = Glauber Salts + Water + Sulph. Di-oxide + Sulph.

$$Na_2S_2O_3 + H_2SO_4 = Na_2SO_4 + H_2O + SO_2 + S$$

With respect to the reaction which takes place when toning a silver image with sulphur, I will quote a few lines from the parent work of reference for nearly all recent writers, viz., "Hardwick's Photographic Chemistry," wherein we find the following paragraph:—

"It is well known that articles of silver plate become darkened by exposure to the fumes of sulphur, or to those of sulphuretted hydrogen, of which minute traces are always present in the atmosphere. If the stopper of a bottle of sulphuretted hydrogen water be removed, and a simply fixed photographic positive suspended over it, the picture will lose its characteristic red tone, and become nearly black. The black colour is even more intense than an experienced chemist would have anticipated, because analysis teaches us that the actual quantity of silver present in a photographic picture on paper is infinitesimally small; and it is well known that sulphide of silver, although of a deep brown colour, approaching to black when in mass, exhibits a pale yellow tint in thin layers, so that a mere film of silver converted into sulphide possesses very little depth of colour. To explain the difficulty, it has been suggested that the toning action of sulphur on a red print is probably due to the production of a sub-sulphide possessing an intense colorific power, like the sub-oxide and sub-chloride of silver. When the toned picture is subjected to the further action of sulphur, it is converted into the ordinary protosulphide of silver, and becomes yellow and faded."

The toning baths following the sulphur method were principally mixtures of gold terchloride and hypo. This latter substance was found to be a solvent of certain silver compounds by the Rev. J. B. Reade in 1839, Mr. Talbot having previously fixed his prints with common salt. Prints, too, were fixed first in some cases, and toned afterwards, washing away the free silver being more or less practised in the mixed hypo and gold, and the sulphur toning processes. When fixing was employed before toning, it was usual to soak washed prints in a 20 per cent. solution of hypo for a period of ten minutes, or until the soluble silver salts were removed, the resulting colour being a disagreeable yellowish-brown. To improve the result so obtained, the prints were passed into a solution of—

Gold terchloride	10 grains
Water	20 ounces

when toning action quickly followed, the yellow colour giving place to that of a dark sepia tint. From this stage to that of mixing these two substances together was only a natural sequence and effected a diminution of gold to the extent of one-fourth, as will be seen by the following recognised formula:—

Hypo	7 ounces
Water	20 ,,

When dissolved, add

Gold terchloride	5 grains
Dissolved in water	20 ounces

After mixing, a clear solution should result.

The sel d'or process followed, and was expected to give still better results. It was found, however, that the solutions would not keep, and as a considerable quantity of the gold salt was needed, it caused experimenters to search for a less expensive method. One decided point in its favour was the circumstance that prints suffered no loss of intensity during the operation, as they do in the case of all other toning methods; briefly, the prints were well washed to extract free silver, and after soaking five minutes in salt and water, they were passed into an alkaline solution composed of—

Liquid ammonia	60 minims
Water...	20 ounces

Here they became very red; after washing in clean water the surface was flooded with a toning solution composed of—

Double hyposulphite of gold and sodium

(sel d'or)	½ grain
Hypo	1 ,,
Water	1 ounce

Upon the print assuming a purple-grey colour, it was withdrawn and fixed in a 16 per cent. solution of hypo, to dissolve the unacted upon silver chloride. Gold when in a fine state of subdivision is of a rich purple colour; the layer obtained by deposition upon the silver image is very finely divided, hence the colour; and the only object in continuing toning action beyond the stage at which a good surface colour has been reached, is to obtain a deposit of sufficient density to completely neutralize the red colour of the organic silver image beneath; therefore it is preferable, in forming a judgment of toning action, to examine proofs by transmitted light rather than by reflected only.

Before dealing with the various formulæ for alkaline toning, I should like to step out of the golden track to say a few words on platinum tetra-chloride ($Pt.Cl_4$).

Experiment 3—*Platinum Toning.*—The value of a platinum salt as a toning agent for silver images has been thoroughly demonstrated before you by Mr. Henderson, when he initiated us into the secrets of ceramic photography. My trials with this salt as a toning agent for paper proofs have only been partially successful; by that I mean that toning does take place when a dilute solution is employed, but the action is too tardy for demonstration here to-night, since anything like a black tone could not be obtained under half-an-hour. You will observe that the surface becomes covered with chloride, showing the necessity for copious washing. Yellow or discoloured prints are bleached when toned in this bath, the whites becoming very pure. The formula here given is capable of producing a very good shade of brown in less time, and should be permanent, since platinum is a metal practically unaffected by the atmosphere; and I think there is good reason to suppose that if a thin coating of platinum could be deposited on the silver image, the protection offered would be more economical as well as stable. Something has already been done in this direction, but not in recent years.

The following is the composition we are now using:—

Platinum tetrachloride, syrupy solution, colour of Old East India sherry ...	5 minims
Hydrochloric acid	150 „
Water	20 ounces

Wash away the free silver thoroughly; warm the toning solution to 70° F. Fix in a 20 per cent. hypo bath.

Mr. A. Watt, in the second volume of the Photographic News, gives a formula which runs as follows:—

Solution of platinum...	30 minims
Hypo	3 grains
Hydrochloric acid	5 minims
Water	5 ounces

This bath is said to act instantly, but I have not had an opportunity to test it. The strength of the platinum solution here given is indefinite, but any of our experimental members can soon ascertain the amount of dilution necessary to obtain the most favourable results.

Alkaline Toning.—Owing to the bleaching action which occurs in toning silver prints with gold, which is slightly acid, certain experiments were made, and it was found that bleaching increased in proportion to the quantity of hydrochloric acid added. Now in the action of toning, chlorine is disengaged, and in order to render this powerful bleaching agent inert, it has been proposed to introduce a substance capable of combining with it, and thus, in absorbing it, prevent undue loss of vigour. To obtain this a slightly alkaline toning bath became a necessity, and to Mr. Waterhouse we are indebted for the introduction of the alkaline salts (Hardwich). Here is an example:—

Experiment 4.—Sodium carb. (Na_2 H. Co_3) ...	5 grains
Auric terchloride ($Au Cl_3$)	1 „
Water	10 ounces

Instead of the dry bicarbonate, we will use a saturated solution. In this, as well as the following experiments, we shall tone three prints of the same subject—viz., ordinary ditto fumed and preserved.

Mr. Maxwell Lyte has written on and investigated the properties of toning solutions a great deal more than most men, and in Vol. I., Photographic News, we find the following emanating from Mr. Lyte—

Sesquichloride of gold	15 grains
Phosphate of soda	300 „
Distilled water	1¾ pints

And in the same communication it is mentioned that 180 grs. of borax may be substituted for the phosphate with a like result; therefore it will be seen that a borax toning bath is not of recent discovery, although it does not appear to have been quoted in many formulæ for at least a dozen years after its publication.

After the publication of Mr. Lyte's formulæ it was found that other salts behaved similarly, and among the first suggested we find sodium acetate, the qualities of which, extolled by the introducer, Mr. Hannaford, have since been verified by the whole photographic world. Here is one of the ordinary formulæ—

Experiment 5.—Gold terchloride	1 grain
Sodium acetate	10 grains
„ chloride	10 „
Hot water	20 ounces

Mix twenty-four hours before use. Neutralize with chalk or whitening (carbonate of lime).

The name of M. Le Gray must be mentioned as the originator of the lime and gold toning bath; although the original formula differs somewhat from the one now used, the results are identical. The original formula consisted firstly in washing away a portion of the free silver, by soaking the proofs for a few minutes in two changes of water, then submitting them to the action of an auriferous bath, composed of—

Terchloride of gold, 1 per cent. solution ...	1 part
Hypochloride of lime (white powder) ...	3 parts
Distilled water	1000 „

The action was complete in ten to fifteen minutes, when the prints required washing in two changes of water to free them from the chloride of lime remaining in the fibres previous to fixing in 1 to 6 hypo. If the tone was satisfactory at the expiration of fifteen minutes, the ordinary washing could be proceeded with; if not, the proofs were submitted to a final bath composed of—

Gold terchloride	2 parts
Hypo	200 „
Distilled water	1,200 „

M. le Gray says, "The proof ought not to be left in this bath less than fifteen minutes, as that is the minimum time necessary to insure the permanency of the picture; but it may be allowed to remain in it for as much longer as is requisite for obtaining the desired tone." Efficient washing in warm and cold waters completed the operation. Should any of our provincial members experience a difficulty in obtaining calcium chloride for their experiments, it can be easily made by causing dilute 1—3 hydrochloric acid to re-act on common whitening, and when neutral filter, and set aside for the crystals to separate out.

Experiment 6.—The uranium and gold toning bath has many friends. The tones are said to be richer and to economise gold, whilst it is very easy to work. I am unable to give the author's name, but I can give a formula which has worked well in my hands. After washing away the free silver, tone in the following mixture—

No. 1.—1 grain acid solution of gold terchloride	1 ounce
Water	7 ounces

Neutralize with sufficient of a 20 per cent. solution of sodium carb. (Na_2 H. Co_3).

No. 2.—3 grain solution of uranium nitrate	1 ounce
Water	7 ounces

Neutralize as in No. 1. Warm each to 70° F., mix. The bath is then ready for use; it can be used repeatedly if desired by acidifying with citric acid and neutralizing before use, but nothing is gained by using it a second time.

There are methods of toning which resemble more or less those which have occupied our attention to-night; among them may be mentioned the tungstate bath, likewise citrate of soda. The vermilion bath, too, might afford sufficient matter alone for a lecturette. If some one experienced with it could be induced to bring it before us, I am sure it would prove interesting.

My experience with toning is so limited, that I find I have become exhausted, so (*nem diss*) must conclude; but before doing so allow me to express a desire that one of our able members will, when opportunity occurs, gather up my disjointed remarks, and shape them into a paper, which may also include the processes I have omitted.

Notes.

Photography in its more scientific aspect will, we are glad to learn, be represented at the Society of Arts during the coming session; Captain Abney having consented to give another course of Cantor Lectures. The special branch to be treated of is the bearing of photography on work with the spectroscope.

"That which would infringe the patent if later, anticipates if earlier," is the excellent ruling of Mr. Justice

Sage, in a United States superior court. There have been many decisions in this country by no means in accord with this principle; indeed, it is interesting to note that there are but few photographic patents in this country which have not been anticipated, so great is the inclination of photographic experimentalists to publish their results at once.

Particulars as to the sad death of Mr. H. T. Anthony, of New York, will be found in the letter of our New York correspondent. His loss is much felt among his friends.

While volumes have been written about the masters of the Italian, Flemish, and German Schools of painters, and no end of engravings in every style have been published of their works, nothing has been done to familiarise the public with the English school. This reproach will shortly be removed, as Messrs. Goupil have now in preparation about eighty reproductions in photo-gravure of the masterpieces of deceased British artists in the National Gallery, about forty from the South Kensington Museum, and others from the National Portrait Gallery. Professor Sidney Colvin, and Messrs. T. H. Ward and Stopford Brooke, will supply the explanatory text.

Among the useful applications of the phototype or chemigraphic process of block making may be mentioned the production of new editions of old books, but it may also be used with advantage for making enlarged or reduced copies of current works, especially when special difficulties would attend the re-setting of the type.

Hymn books in which music and words are printed side by side are always required in several sizes, and we are interested to see that the reduction of the small copy of the new Methodist Hymn and Tune Book intended for congregational use is a phototypic reduction of the large edition intended for the use of organists. The work has been done by Messrs. Novello, Ewer, and Co., and is a good example of one of the modern commercial uses of photography. It may be mentioned that the expense of setting up the small edition in type would have been much greater than that of phototyping, as music type is by no means so easy to set up as ordinary work. Full working details of the chemigraphic process appeared in a series of articles commencing on page 673 of our volume for 1882.

Some years ago we pointed out that a full-sized sheet of music is quite legible if reduced to the size of a carte or cabinet by the aid of photography, and it is probable that if some music publisher were to issue his music in this size, there would be a good sale for it. Those who hesitate to take out the obtrusively obvious roll of music on the chance of being asked to sing or play, would be able to carry the more convenient cartes or cabinets in the pocket without making any show of expecting to be asked.

The appearance of a new catalogue of the National Portrait Gallery suggests a question that must have occurred to more than one visitor to this very interesting collection. Why should not the Gallery contain photographic portraits of modern English celebrities? It perhaps may be said that the collection would be swamped by a rush of mediocrities, but this need not be the case if proper supervision be exercised. Admission for entrance might be confined to deceased men and women of note, so as to prevent the introduction of ephemeral notoriety.

The superb yachting pictures of Messrs. West in the Exhibition are exciting much controversy, some keen and practical examiners contending that they are enlargements, very beautifully executed, but enlargements for all that. The absolute sharpness of one particular yacht, the masthead in which reaches nearly to the top of the frame, while the hull is not far from the bottom, is cited as an argument against the possibility of vessels proceeding at a high rate of speed being photographed of so large a size.

The forthcoming New Orleans Exhibition will, it is said, be able to boast of having the largest photographs in the world. They consist of views of the public buildings in Washington, and are five feet wide by seven feet long. They have been taken by order of the Government. It is unnecessary to add that the pictures are from a combination of negatives and a combination of prints after the fashion of the gigantic picture from Berlin, exhibited some years ago at the Photographic Exhibition. If we remember rightly, the Berlin photograph was even larger than these American ones.

The paper bottles now made in Paris are built up out of sheets of paper somewhat after the fashion of rocket cases, but the cementing material is a mixture of blood-albumen, lime, and alum. Neither water, wine, nor alcohol has any action on such bottles, and it is expected that they will prove of great value to travellers, as there is but little fear of breakage.

Professor Langley continues in this month's *Century* his interesting papers on "Celestial Physics; or the New Astronomy." He deals in the present paper with solar eclipses, and especially with total eclipses, to see which, he remarks, it is worth going a journey round the world. In 1869 the camera was first used, and proved a manifest advantage, for, as Professor Langley remarks, although the camera could see far less of the corona than the man, it has no nerves, and what it sets down we may rely on. Mr. Ranyard's photographs of the 1871 eclipse are declared by Professor Langley to be the best ever taken. The value of photography in solar eclipses is self-evident when, as Professor Langley remarks, it is considered that, although total eclipses come about every other year, yet they continue (in regard to duration of totality), one with another, hardly three minutes; and an astronomer who should devote thirty years exclusively to the subject, never missing an eclipse in whatever quarter of the globe it occurred, would, in that time, have secured in all some-

thing like three-quarters of an hour only for observation!

After more delay than was expected, the new (sixth) edition of Captain Abney's "Instruction" is published; the delay being a necessary consequence of the author's resolve to considerably enlarge the work, and bring it thoroughly up to date.

We also receive the eighth edition of Dr. Liesegang's well-known and excellent "*Handbuch des practischen Photographen*," and shall say more about both these books next week.

A building to which the Society for photographing interesting portions of the metropolis should turn its attention is the Paymaster-General's Office in Whitehall, which is to be pulled down in the course of the next twelve months. Architecturally speaking, the Office is of no interest, and its interior, though old and intricate, possesses no particular attractions in the shape of carving or fittings: but the political associations of the building are many and most interesting. It used to be the residence of the Paymaster of the Forces at a time when that post was one of the most lucrative in the gift of the Crown, and Henry Fox (afterwards Lord Holland) lived there for many years. Especially should the large room now known as "No. 5," and devoted to the payment of naval pensions, be photographed. This was the dining-room of the old Paymaster, and if walls could speak they could tell us of many a protracted carouse which rarely finished while any guest was above the table. But it has more reputable associations as well. Pitt has often dined there; and, coming down to later years, Lord Macaulay, as Paymaster-General, also used it for a dining-room.

A photograph, too, should be taken of the small, otherwise ordinary looking room, on the first floor, in the chimney of which, tradition asserts, the spirit of Oliver Cromwell finds asylum.

Gossip has it that if by any chance the room in question is profaned by an oath, the Puritanic Lord Protector's ghost gives audible proof of its presence by three distinct raps! It is too much, we fear, to ask the Society to obtain a cabinet—or a dark cabinet, shall we say?—of Oliver's shade, which, by the way, will probably claim compensation of some sort for disturbance when its flue is rattled about its ears, if, indeed, shades have any. It will be necessary, by-the-bye, for psychologists to note if Oliver's spirit takes up its abode in one of the brand new chimneys of the new structure.

Why should the photograph of a Hanson cab—which is always to be seen in the windows of most of the Strand photographic print dealers—occupy such a prominent place? The Hanson is an ordinary Hanson, the driver has nothing about him different from other cab drivers, and the steed is a fair sample of the London cab horse. The reason is, that this particular picture is an especial favourite with American buyers. There are no Hanson cabs in New York, and hence the photograph of the London gondola is bought as representing something essentially typical of London life.

No wonder Miss Anderson favours photography. Apart from the splendid advertisements it has furnished her, it was the means of giving her an introduction to the aristocratic sculptor, Count Gleichen. The count was one evening dining with the Prince and Princess of Wales, and after dinner the Princess produced a number of photographs of a young lady, remarking that the subject would be an admirable one for a sculptor. The photographs were those of Miss Anderson, whom Count Gleichen had never seen before, and he asked if he might tell Miss Anderson that the Princess would be pleased if he executed a bust of her. The Princess answered in the affirmative and the bust in due time was chiselled.

Patent Intelligence.

Applications for Letters Patent.

13,906. John Veda Robinson, 39, Lower Sackville Street, Dublin, for "Improvements on his photographic camera."—Dated 21st October, 1884.

14,122. John Joly, 43, Pembroke Road, Dublin, for "The measurement and estimation of the amount of light emitted from a luminous body."—Dated 25th October, 1884.

14,156. George Percival Smith, Beechholm, Tunbridge Wells, for "Improvements in photographic apparatus."—Dated 25th October, 1884.

Patents Granted in America.

306,635. Charles A. Needham, New York, N.Y., assignor to E. P. Needham and Son, same place. "Clamp for manipulating photographic plates." Filed April 10, 1884. (No model).

Claim.—A device for manipulating a photographic plate, consisting of an approximately-straight portion, B, a portion *b*, near one end of said straight portion, extending transversely thereto, and a portion, *a*, extending from said straight portion downward toward the portion *b*, so as to nearly meet the same, and forming therewith a narrow opening through which a photographic plate may be slid sidewise or edgewise, the side edges of the device being in approximately the same plane, substantially as specified.

306,636. Charles A. Needham, New York, N. Y., assignor to E. P. Needham and Son, same place. "Photographic printing frame." Filed April 14, 1884. (No model).

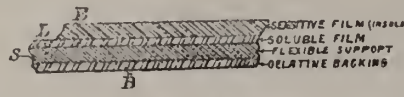
Claim.—The combination, with the back of a printing frame, made of two sections, and having a hinge connection at one side, of a covering applied to each of said sections, and turned over the meeting edges of said sections, and secured thereto by glue or other adhesive material.

306,470. George Eastman and William H. Walker, Rochester, N. Y., assignors to the Eastman Dry-Plate Company, same plate, for "Photographic film." Filed May 10th, 1884. (No model).

Claim.—1. As a new article of manufacture, the herein-described sensitive photographic film, consisting of a suitable flexible support coated on one side with a layer of gelatine, and on the other side with a layer of sensitive gelatino-argentic emulsion attached to the support by an interposed layer of relatively more soluble gelatine, substantially as described.

2. As an improvement in the art of photography, the herein-described process of making sensitive flexible photographic films,

consisting in coating a suitable flexible support on the reverse side with a solution of gelatine, in drying the said coating, in applying to the face side a coating of soluble gelatine, in drying the said coating, and in subsequently applying thereto a coating



of gelatino argentic emulsion of relative insolubility, and in drying the same, substantially as described.

3. As an improvement in the art of photography, the herein-described process of making sensitive flexible photographic films, consisting in coating a suitable flexible support on the reverse side with a solution of gelatine, in drying the said coating, in applying to the face side a coating of soluble gelatine, in drying the said coating, in calendering the coated support, and in subsequently applying to the face side of the coated and calendered support a coating of gelatino-argentic emulsion of relative insolubility, substantially as described.

4. The combination, with the flexible support S, of the gelatine backing B, and the layer of relatively-iusoluble gelatino-argentic emulsion E, attached to the support by the layer of more soluble calendered gelatine L, substantially as described.

5. The flexible support S, provided on one side with the insoluble gelatine backing B, and on the other with the soluble gelatine layer L, substantially as described.

6. The flexible support provided with a layer of soluble calendered gelatine, and having a coating of relatively-insoluble gelatino-argentic emulsion applied thereto, substantially as described.

7. The combination, with a flexible support, S, for a layer of sensitive gelatino-argentic emulsion, of the backing B, consisting of gelatine treated with chrome-alum or other chemical, and glycerine, substantially as and for the purposes set forth.

8. As a support for the film of sensitive gelatino-argentic emulsion, a flexible sheet coated with a layer of soluble translucent gelatine, and calendered on the coated surface, substantially as described.

9. As an improvement in the art of preparing sensitive photographic films, the process consisting in applying to a sheet of paper or like support a layer of soluble gelatine, and drying the same, then calendering the sheet to harden and polish its surface, and finally applying to the soluble layer of the calendered sheet a coating of relatively-insoluble gelatino-argentic emulsion.

306,594. George Eastman, Rochester, N. Y., assiguor to the Eastman Dry Plate Company, same place, "Photographic film."—Filed March 7, 1884. (No model.)

Claim.—1. As a new article of manufacture, a sensitive photographic film consisting of a coating of insoluble sensitized gelatine, a paper or equivalent support, and an interposed coating of soluble gelatine.

2. In a photographic film, the combination of the support A, the insoluble sensitive gelatino-argentic-emulsion film C, and the soluble interposed gelatine layer B, substantially as described.

3. In a film for photographic purposes, the combination of a backing sheet or support of paper or like material, a film of sensitized gelatine adapted to withstand the solvent action of water, and an intermediate film of soluble gelatine.

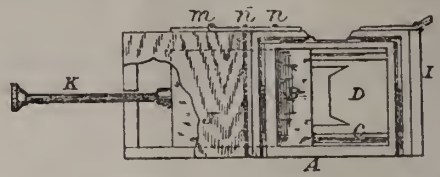
4. The herein-described sensitive flexible photographic film, consisting of the support A, having a layer of insoluble sensitized gelatine C, attached thereto by means of an interposed soluble gelatine substratum, said film being rendered flexible by means of glycerine, substantially as described.

5. As an improvement in the art of photography, the process consisting in, first, providing an insoluble sensitive gelatine film affixed by solvent material to a supporting-sheet; second, in exposing and developing said film; third, attaching the developed film to a rigid plate by means of wax or its equivalent; fourth, in detaching the support from the film by the application of heat; and, fifth, stripping the film from the waxed surface.

6. As a new article of manufacture, a sensitive photographic film composed of a paper or equivalent support, an insoluble sensitized film, and an intermediate soluble attaching film insoluble in the developing fluids, and at normal temperatures, but rendered soluble by the application of heat in watery solutions, substantially as described.

7. As a new article of manufacture, a sensitive photographic film composed, essentially, of a paper or equivalent support, a film of sensitized gelatine, and an interposed attaching film, the said sensitized film being insoluble, and the said intermediate attaching film being insoluble with respect to the developing fluids, but rendered soluble in water by the application of heat, substantially as described.

306,618. George W. Hough, Chicago, Ill., "Photographer's dry-plate holder."* Filed December 17, 1883. (No model.)



Claim.—1. As an article of manufacture, the holding-case B provided with the plate-holder C, and the cross-head G, as and for the purpose shown.

2. The auxiliary case J, in combination with an exposing case, for the purpose of affording a dark chamber for the case B to be drawn into, as and for the purpose shown.

3. The rod K, in combination with the auxiliary case J and the holding-case B, for the purpose of drawing the holding-case B into the auxiliary case J, substantially as shown.

4. The plate-holder C and spring D, both made from one and the same piece, as and for the purpose shown.

5. The exposing-case, with the light-excluding door I, at one end, and auxiliary case J at the other end, as and for the purpose shown.

6. The combination of the auxiliary case J, exposing-case A, holding-case B, and rod K, whereby the holding-case B, holding the plate, can be withdrawn from the exposing-case without exposing the dry-plate to the light, substantially as and for the purpose shown.

FRENCH CORRESPONDENCE.

Ceramic Exhibiton—Angerer and Goeschl's Phototypes—Development of the Graphic Method—Instantaneous Photography.

Ceramic Exhibition at the Palais de l'Industrie.—In this fine exhibition, organised by the Central Union of the Decorative Arts at the *Palais de l'Industrie*, I expected to find a good show of specimens showing commercial applications of photography in the decoration of china and earthenware, but as yet I have not discovered anything of a satisfactory nature. Perhaps, after a closer inspection of the various processes of decoration adopted, I may light upon that of photography. It is surprising to find how long it takes us to progress beyond the limits of our routine. However, I have be initiating a certain number of artisans, principally at Limoges, in the practice of decoration by photographic processes, whereby the accuracy and truth of the design are faithfully rendered. The processes themselves are now so improved that with a drawing on a particular kind of paper, a typographic block is made directly without further complication. Of course, these processes will have their day, but it seems a long time coming. As another example of our force of habit, may be cited the catalogue of the exhibition. It is illustrated with wood-cuts taken from photographs of the objects exhibited. With photographic negatives at one's disposal, would it not have been better, with the view of obtaining more exact and authenticated results, to have had them directly changed into typographic negatives by one of those processes so successfullly practised by Ives of Philadelphia, Meisenbach of Munich, or Angerer and Goschl of Vienna? The work thus produced would have been much more valuable than these wood-cuts can

* This apparatus appears to be similar to or identical with an arrangement previously patented in England.

possibly make it. Being absent from Paris at the time the catalogue was compiled, I was unable to take any steps towards having it illustrated in a more accurate as well as more useful way.

Angerer and Goschl's Phototypes.—While on the subject, I must say a few words on the beautiful prints issued by Angerer and Göschl, of Vienna. Until lately this firm has produced by mechanical engraving admirable typographic blocks, but direct typographic reproduction from photographs from nature had not been undertaken. The specimens which have been shown to me prove that in this line no others excel them. I am glad to notice this important fact, because it gives one the hope of a wide-spread use of this mode of photo-engraving for illustrating books and journals. The great difficulty still to be overcome is the facility of printing with the text, but it only needs more experience on the part of the printer, and proper apparatus for work of a different nature to that which is already in use.

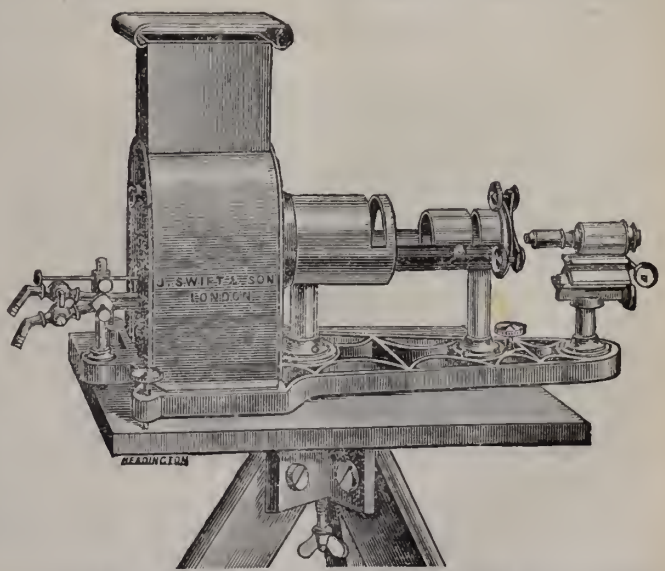
M. Marey's Book.—M. Marey, of the Institute of France, has, in his work entitled *Developpement de la Methode Graphique par l'emploie de la Photographie*, summed up the researches of several experimentalists and himself on the application of photography to the instantaneous reproduction of the movements of men and animals. The pamphlet is very interesting, and is only, to my mind, one stake planted in the track of the numerous applications promised to both science and art by instantaneous photography. M. Marey is pursuing his remarkable work, and we await new and interesting communications from him.

Instantaneous Photography.—I have devoted a considerable part of my long stay in the South of France on the shores of the Mediterranean to new experiments on instantaneous photography, and have had more than ever reason to insist upon the necessity of using a shutter giving exposures of known duration. It is useless trusting to chance. The first thing to be known is that the nearer the object or person in movement, the shorter should be the exposure; and yet most amateurs use the same, especially those employing a drop-shutter. I use a circular one made by Francais, fixed in the place of the diaphragms, and not troublesome in either weight or bulk, while the length of exposure is regulated by a spring. LEON VIDAL.

SWIFT AND SON'S OXYHYDROGEN MICROSCOPE.*

THIS apparatus is suitable for use with ordinary objectives from 4 in. to $\frac{1}{4}$ in. The gas jet can be regulated for either parallel or convergent light without the necessity of opening the lantern, it being mounted on an independent pillar 2 in. from the back, and fitted to adjust to or from the condensing lenses as occasion may require. The perforated metal base renders it very light, and also allows the passage of free current of air, so that the lantern is kept as cool as possible. There are three screws, upon which the whole is supported, to finally adjust the disc of light. The tube into which the convergent lenses, polariscope, and spot-lens fit is cut open for the purpose of easily dropping these pieces into position. This opening is covered with a revolving segment of tube, similar to the breach action of the Martini rifle.

The stage has rectangular motions by cams which are moved by the milled heads at the back of the stage, and the clip holding the object will equally clamp the thinnest slide or a thick zoophyte trough; the clip is lifted by turning the milled head. The coarse focussing is by rack and pinion, and the fine adjustment is similar in construction to that of the ordinary Hartnack microscope. The alum trough for stopping the heat rays can be used behind the condensers for convergent rays, or inserted in the opening in front when parallel light is required, the opening being covered by a revolving segment of tube when not used.



* *Journal of the Royal Microscopic Society.*

PHOTOGRAPHY AT THE SOUTH AFRICAN INDUSTRIAL EXHIBITION.

ON the 9th ult. opened the first great exhibition at Cape Town, and the following account of the photographic department is abstracted from the *Cape Times*.

In the photographic section of the Exhibition we find a collection of photographs which could be well compared with those taken anywhere else in the world. Those of O. Battenhausen, of the Vienna Photographic Studio, Port Elizabeth, are confined to portraits which are seen to advantage in a very handsome stand of colonial make, and of colonial woods. The centre portrait is that of a charming young lady in fancy costume, after the well-known picture of the Duchess of Devonshire, painted by Gainsborough. Mr. Harris contributes photographs of natives, and some magnificent views of the Valley of Desolation, in the district of Graaf-Reinet; of Algoa Bay; of sights seen on the voyage between England and the Cape; of places in the East frequented by sportsmen with gun and rod; extensive panorama of Port Elizabeth, and several large portraits. The Valley of Desolation, probably so-called because of the absence of verdure—for the photographs represent a region of stone and stunted bush—enables the photographer to picture towering masses of rock-work, which come out sharply distinct against a cloudless sky. Amongst the strange shapes which the rocks have taken there are column-like summits, in the crevices of which lurk deep shadows, bringing out in bold relief those portions on which the glare of the sunshine can positively be seen. Doré, when he was illustrating Dante's "Inferno," would have been deeply indebted to Mr. Harris for a set of these photographs of the Valley of Desolation, for they would have afforded some suggestions for the wild and the weird in the painting and imagining of which the great French artist was so consummate a master.

The view of the pier-head of the Port Elizabeth jetty is almost submerged in surf, and beyond the jetty the tugs tossing and pitching as they travel between ship and shore indicate the class of tug employed, and the skill of the sailors in charge of them. It is not necessary to say that Barnard, of Cape Town, holds his own in comparison with others. He exhibits some beautiful pictures of Cape flowers, exquisitely coloured, midget and other portraits. All the photographs of Mr. Barnard, and of other Cape Town photographers, demonstrate that the suburbs of Cape Town, for grandeur and beauty, are as unsurpassed by other parts of South Africa, as the Cape Town photographers are by their brother artists in the other towns of the colony. Mr. E. H. Allis, of Rosebank, has a most interesting set of views. That of Cape Town from the signal hill is one of the best photographic panoramas printed of the metropolis of South Africa. In the foreground is the dense bush which is found on some of the slopes of the hill. The town, with its regular blocks of buildings and straight lines of streets, would look like a chess-board if half of the blocks were painted black. The background is Table

Mountain and the Devil's Peak, and no mountain range is to be found amongst all the photographs in the Exhibition of greater grandeur.

Mr. Herman, whose oil paintings of Cape scenery have been so much admired, selects with an artistic eye the scenes which he has photographed with great skill. There is a fine panorama of Cape Town, of the breakers off Sea Point, of avenues at and near Rondebosch, of Mitchell's Pass and Bain's Kloof, of Camp's Bay, and of Cape Point Lighthouse, with the Cape of Good Hope. We are glad to see that the photographs of colonial scenery contains one of the once dreaded Cape of Storms, and Mr. Herman has been very successful. The bold headland on which the lighthouse is perched, the precipitous cliff, at the foot of which is a sandy shore, the lines of breakers, and the grandeur of the whole view, are faithfully reproduced.

There are photographs illustrative of the principal bridges constructed, or in course of construction, in the Orange Free State. They are of interest as indicating what the State is doing in the way of public works. Very singularly, with these bridge photographs is a group consisting of the late Right Hon. Sir Bartle Frere, Lady Frere, two of the Misses Frere, with the Hon. Will Littleton and Major Hallam Parr.

A NEW SENSITIVE COMPOUND.

Dr. R. B. West, of Guilford, Connecticut, writes thus to *Anthony's Bulletin*:—"Among the substances said to be sensitive to the action of light, I have never seen mentioned the so-called diazo compounds, some of which are changed by the actinic rays almost as rapidly as the chloride of silver; for example, diazo salicylic acid. This substance can be formed by dissolving salicylic acid in strong nitric acid, the vessel being kept cool by immersion in ice water. This nitro-salicylic acid has now to be reduced to amido-salicylic acid by boiling it with an appropriate reducing agent, say zinc dust and dilute sulphuric acid, the mixture first becoming brown and then colourless. It can be separated from the zinc sulphate by evaporation—solution in alcohol—which dissolves only the amido-salicylic acid sulphate, and final evaporation of the alcohol. The amido-salicylic acid sulphate—the acid being a base as well as an acid—becomes changed to diazo-salicylic acid sulphate, by saturating its aqueous solution with nitrogen-trioxide gas, evolved by the action of dilute nitric acid on starch or arsenious acid. Paper, silk, or other fabrics floated on a solution of diazo-salicylic acid or one of its salts, dried, printed, and washed in water, shows an image of a beautiful crimson colour.

Correspondence.

THE ROYAL ARMS CASE.

Sir,—Allow me to point out a few of the numerous inconsisteucies and misconceptions contained in the letter of Mr. H. T. Methven, published in your last.

The use of the Royal Arms is so general that in reality it has become to mean nothing more than that the person using it, or imprinting it upon his goods, wishes to signify that on one occasion at least he has been patronized by some member of the Royal Family of England; and those who see a deeper signification than this, view the symbol with the eyes of prejudice. Who, indeed, can suppose that the pickle manufacturer, the blacking maker, or the shoe-black, who uses the "Arms," does so with the "purpose of obtaining patronage by false pretences?" Personally, I can only look upon the free use of the "Arms" as an indication of a loyal feeling in this country, and a very cheap way of advertising royalty; but this is only an opinion. Now for matters of fact.

The firm prosecuted were actually and really photographers to the Queen personally, and also to various members of the Royal Family; but if they had held a formal warrant of appointment, they would have been in no better position as regards the law, as such a warrant does not in any way confer the privilege of using the Arms; moreover, Messrs. A. and G. Taylor were not prosecuted, as your correspondent appears to think, for representing themselves to be photographers to the Queen.

Mr. Methven seems to think that the Royal Family prefers to patronise "the smallest photographers"—a phrase a trifle vague; but one may suppose he means those doing a small amount of business. If this is his meaning, the case in point is a notable exception, as Messrs. Taylor have certainly one of the most extensive photographic businesses in the country, and one which gives employment to a host of workers.

According to the strict wording of the Act, the nature of the authority required to use the Royal Arms is a permission from some member of the Royal Family; but it is my conviction that no photographer at present holds such a permission. Still, those who are photographers to the Queen are likely to so style themselves as long as any loyal feeling (or snobbish feeling, as Mr. Methven would perhaps put it) exists in the public mind.

In conclusion, may I call attention to the following, which appeared in the *Solicitor's Journal* in reference to the carelessly worded and strange 106th Section of the New Patent Act?

"It appears to us that the harassing of tradesmen who cannot produce an authority for using the royal arms is unjustifiable, for no one is, or could reasonably be, deceived by such use into believing that a shop-keeper 'carries on his business by or under the authority of Her Majesty, or any of the Royal Family, or any Government department.' Everyone knows that the use of the royal arms by a shop-keeper means nothing at all. The real object of the enactment was supposed to be to prevent patent agents from using the royal arms on their offices and paper, so as to lead people to believe that their advice was given with the authority of a Government department; and if employed for this purpose only, the provision might have been valuable. But to attempt to extend its application to cases in which it is of no importance to any one, whether the arms are used or not, is absurd."

R. B. Halcombe.

[Our correspondent does not seem to be aware that the above quotation from the *Solicitor's Journal* has already been reprinted in the Photographic News.—Ed. P.N.]

Sir,—It is pretty generally known that soon after the New Patent Act came into operation, some business houses using the Arms were served with a caution from the Lord Chamberlain's department not to continue to do so; but many firms of this town replied to the effect that labels and price lists bearing the Arms had been registered by them in Government Departments, and fees accepted, and they were quite satisfied to rely upon this as a sufficient authority. No proceedings were taken against them. The recent action of a rival in trade against a large firm of photographers to the Queen is so mean and contemptible as to need no comment.

Redditch.

Sir,—A correspondent in your last has very properly denounced the misleading use that is made by some photographers of the Royal Arms. I can add an illustration of the very mild pretext on which they are, at times, assumed. Not very long ago, a photographer at a sea side place, which it is not necessary to indicate precisely, with an eye to future profit, as well as to vary the monotony of an off season, determined on taking a set of local views. Amongst the subjects selected was a pretty and picturesque cottage. A friend to whom the negatives were shown, exclaimed, "Why, that is where our Queen lived when she was Princess Victoria!" Here was a grand opportunity too good to be lost by so enterprising a photographer. A copy was at once forwarded to Windsor, and duly acknowledged in the usual formal manner by the official whose duty it was to attend to such things. The little local paper, of course, had its little puffing paragraph on "Our talented fellow townsman," &c., and as speedily as the necessary preparations could be completed, the Royal Arms were proudly affixed to the front of the ambitious photographer's place of business, and he called himself photographer to the Queen ever after.

J. R. Jones.

THE POTASH DEVELOPER.

Dear Sir,—Whatever Captain Abney may say concerning photographic matters must be received with the greatest respect and consideration; but judging from his words, I should imagine he speaks of Beach's developer more from theory than from any actual experience of its merits. I do not profess to be an expert in landscape, but last summer I experimented largely with the pyro-potash developer, and found it quite equal to anything in the way of instantaneous work, and far superior to the ordinary pyro and ammonia. The plates used were chiefly Swan's "10 times collodion," and they developed well and quickly, with abundant density. Nothing was needed to "start" the development, for it commenced in most cases as soon as the developer had fairly covered the plates.

Of microscopic photography I do profess to know something, and if Captain Abney has ever tried to develop with ammoniacal pyro a plate exposed with a $\frac{1}{12}$ in. or $\frac{1}{16}$ in. to a common paraffin lamp, he will know how difficult it is at times to start the development, and, when started, how still more difficult to get sufficient density. Using the potash developer, these difficulties almost entirely disappear, for the image appears readily, and proper density is easy to obtain on a properly-coated plate.

The sulphurous acid in Beach's developer is merely to correct the excessive alkalinity of the commercial sodic sulphite. That the mixed developer is sufficiently alkaline is proved by its action on the fingers when dipped in the solution, and test paper shows that No. 1 solution of pyro, sodic sulphite and sulphurous acid, to be by no means acid; blue litmus not being affected by it.

Doubtless hydrokinone or hydroxylamine would answer as well, the only objection to these developers being their high price. However, in photo-micrography, when taking negatives of scientific importance, cost would be only a minor consideration, and both developers should be given a fair trial. I hope to try them myself this winter.—I am, sir, yours faithfully, I. H. Jennings.

THE CLAIMS OF THE IDENTISCOPE.

Sir,—I perceive that in one of your useful "Notes" (of which, let me say, I am a "constant reader"), you state, *re* the identiscope, that "the inventor claims that when a line drawn through these [pupil] centres in each portrait coincides, the two portraits are of one man."

To this "statement of claim," my briefest expression is (pardon the abruptness), "No, I don't."

You proceed in your further note very fairly and fully, and without *lapsus*, to state the series of eleven points in which the two Tichborne portraits coincide; and you conclude, in effect, by suggesting Professor Galton as a referee. To this course I can have no objection. The Professor and myself will not for the first time have been brought into contact. In 1875, long before his composite portraits obtained deserved attention, Mr. Galton, in common with the other *savans* of the British Association (in that year meeting at Bristol), were furnished with printed details of the identiscopic process. Your own columns have likewise from time to time given to the public an inkling of what the inventor professes to claim.

The "Galton process" assumes, legitimately, the infinite diversity that prevails in the contour and details of the human face. The "identiscopic process" asserts, specifically, the abiding identity of the face of a given individual. No one can better be aware than Mr. Galton, that if the facts were not practically as I here state, then his multiplied arrangements for securing only the "points in common" of each of several separate identities would be mere superfluities.

In the matter of geometric nomenclature, that item which, from the first inception of the method, I have designated the "zero line," Mr. Galton has since denominated the "datum line." The signification is, of course, identical. I will conclude, under your favour, by stating, categorically, that which I really maintain.

I claim, then, to be the originator (1) of the *zero* or *datum* line; (2) Of the employment of the diameter of the iris (at its exterior rim) as the unit of an admeasurement proceeding from zero; (3) Of mathematically superposing, by the above geometric agency, photographic portraits, whether per actual negatives, or per the identiscope, the latter appliance being, after its kind, as you correctly intimate, of the nature of a *camera lucida*.

Then, as to the outcome of the method, I claim to have determined:—(1) That given photographs, if of the same person, shall, *cæteris paribus*, at all periods of adult life match mathematically at every point of the perpendicular. (2) That in such case, the units of the two admeasurements remain identical, and that the diameter-lines shall bisect the features identically at eleven specified points at the least. (3) That the exact converse of this is true, as it relates to the portraits of all other individuals: and that this is evidenced by the nature and results of the "Galton process." William Matthews.

EYES GOING WITH THE HEAD.

Sir,—Under the title of "Hints on Posing the Sitter," by Mr. H. P. Robinson, that justly-esteemed artist, speaking of the position of the head, lays down the rule that "the eyes should always go with the head."

Now Mr. Robinson cannot but know that there is no hard and fast rule laid down by any of our great teachers in relation to the direction of the eye; on the contrary, every licence is given and taken by the most eminent painters, past and present, with that most speakable of all the features. Now, if artists could, and do, make so free a use of its direction in relation to the position of the head, why should not photographers use the same liberty?

I think it is a great assistance to have certain necessary laws to guide us in the study of nature; but I also think that we can have too many. The following list will prove that our best painters acted contrary to Mr. Robinson's new theory:—Boschaert, painted by Vandyke (Vandyke painted nearly half of his celebrated heads in the pose condemned by Mr. Robinson); Raffaelle, painted by himself; Sir Josh. Reynolds, by himself; Michael Angelo, by himself.

All the above are three-quarter face, eyes full front.—I am sir, yours truly, J. Randolph.

APPARATUS AT THE EXHIBITION.

Sir,—It seems not to have occurred to your "inconvenienced correspondent" (see last week's News) that the crowd round the apparatus table which so roused his ire, is itself an evidence of the interest taken in the exhibits there shown. For myself, I am glad of the opportunity of inspecting many of the articles. Take the shutters, for example: it is not easy to form any opinion of these from the descriptions given in the papers, or from advertisements, without actual examination and handling; and it is not very pleasant to go round to the various shops and ask to be shown the articles, and then to depart without purchasing, with some lame excuse. The expression of resigned sorrow on the face of the assistant on such occasions (where it is not indignant disgust) is really too much for my nerves; besides, the better part of a day would be taken up with a much less satisfactory result than when all can be seen together and compared. The same with other pieces of apparatus. I do not even object to showing the same thing, if good, year after year. Fresh men are turning up to whom much must be new. What seems to be required is more room. The special lighting of a picture gallery is not necessary for such a purpose, and perhaps there may be rooms in other parts of the building which could be made available for a still larger display of apparatus. R. Sedgfield.

EXHIBITION AWARDS.

Sir,—Perusing the many letters of complaint and indictment which have been launched against the unfortunate heads of the judges, one cannot help feeling that the writers have in many cases been somewhat hasty in their accusations, and scarcely fair to the committee. All the letters up to the present omit to mention any fairer method of arriving at the award than that adopted by the committee, and carried out by the judges, detailed in your issue of a fortnight ago.

I am informed by the Assistant Secretary, Mr. Cocking, that these judges held no communication with each other with regard to the pictures until their numbers had been given in, and only those who cast the numbers knew at the time where the medals would fall; and as these additions were made principally by the President himself, there can be no question about the honesty of the results.

The main offender, which puts the backs of indignant correspondents up more than any other picture, appears to be No. 234, "Interior of St. John's Church, Malta," by Signor Tagliaferro. At the time the award was made this gentleman was unknown to every member of the Committee but one, and that member had nothing to do with awarding prizes; but this one member asked the signor to exhibit his photograph, instead of taking another as he had proposed. This picture, like all others, went before the judges, designated by a member only, and it is absurd to imagine that the men who examined this photograph did not see the converging lines and thoroughly comprehend the cause; but they saw something else besides the converging lines, and what they did find was merit of a high description, and allowed the perceptible merit to outweigh the faulty lines, and placed high figures as the measure of their commendation.

Correspondents should bear in mind that those gentlemen who consent to become judges must give up any chance of a medal for themselves; and if, in addition to this, the judges are to be vituperated collectively, and sneered at individually, it will deter gentlemen from accepting the onerous duties attaching to the appointment at all. No unbiassed critic can go round the room and not admit that among the exhibits by the judges there are pictures that would have carried a medal had they not been so debarred. I, for one, see no reason to complain, although I am

An Exhibitor but not a Medallist.

PHOTOGRAPHS OF THE PRINCE OF WALES.

Sir,—I think I may safely assert that all the members of the Royal family have been the best supporters that the photographic profession have had.

I quite agree with what Mr. Methven says, that "it is misleading for persons to use Royal Arms, Feathers, &c. (though perhaps it helps to feather their nest), when they have not been patronized by Royalty, and have only taken a photograph of Balmoral." But who are the English photographers of great reputation? I could mention many names of photographers who are considered to be real good hands at their work, and do it themselves, and live in fashionable thoroughfares; and, if I mistake not, it is many of these that the genial Prince has honoured with his patronage. But they are not "touters."

If Mr. M. is the English photographer of great reputation, perhaps he feels "slighted," "blighted," and would like to be "knighted," so that he could be taken to the Royal arms at once; and I can only say another person who would like to be served the same way is yours respectfully,

James Syrus Tulley.

Dear Sir,—A letter appears in your last signed "H. J. Methven," complaining that "it is a fact capable of proof that the Prince of Wales has never been photographed by any English photographer of great reputation," and that he seems to be led by servants to small touting men. I subjoin a list of about thirty photographers—English and foreign—by whom the Prince has been photographed, and your readers will see it includes the names of the most successful photographers of England and the world during the last twenty years.

Mr. Bassano; Mr. J. E. Mayall; Mr. Mayall, Jun.; Messrs. W. and D. Downey; Messrs. Southwell Bros.; Messrs. Elliot and Fry; Mr. John Watkins; Mr. Charles Watkins; Mr. W. Mayland; Messrs. Hills and Saunders; Mr. Godfrey Allen, Bristol; Mr. George Cooper, Hull; Messrs. Turner and Drinkwater; Messrs. G. W. Wilson and Co., Aberdeen; Mr. Vanderweyde; Messrs. Byrne and Co., Richmond; Mr. Jabez Hughes; Messrs. James Russell and Sons, Chichester; MM. Ghemar Frères, Brussels; M. Geruzet, Brussels; M. Levitzki, Paris; M. Nadar, Paris; M. Joliot, Paris.

No doubt there are many I have omitted.—Truly yours,

Samuel Fry.

Proceedings of Societies.

Photographic Society of Great Britain.

A meeting was held in the Gallery, Pall Mall East, on Tuesday last, Mr. Payne Jennings in the chair.

The Chairman announced that, in accordance with the notice, there would be some explanation given regarding the apparatus shown in the Exhibition.

Mr. Watson called attention to the fact that he had found it convenient to make the swing-back of the portable camera with a strong outer frame, something like the arrangement adopted in the case of an ordinary studio camera. He also showed a small Kinnear camera, with a universal or "gimbal" movement to the front.

Mr. Sands next called attention to a cradle form of attachment for the swing-back, in which all the adjustments were made from the bottom, the frame containing the back being easily detachable from the cradle for placing at a position at right angles to the first. In this case the bellows turns round with the back, the fore end of the bellows being connected with a movable ring set in the front. Mr. Sands also showed a double slide shutter.

Mr. Samuels next made some remarks on cameras, these remarks having special reference to his changing-back, which was exhibited last year (see page 649 of our volume for 1883). The use of such a back rendered it advisable to construct the camera more strongly than is usually the case, and also to adopt the old system of racking out the lens, the back being stationary; and it becomes convenient to use the swing front rather than a swing-back. All these points of construction were exemplified in the small Kinnear camera which Mr. Watson had exhibited. Mr. Samuels also said he had used an external screw thread cut on the lens tube as a means of adjustment for focussing, this being an arrangement which has never yet found general favour with the users of lenses, although often proposed. Mr. Samuels also showed a tripod top made by screwing six screw-eyes in a triangle of wood.

Mr. Starnes showed his changing-camera (see page 614), and mentioned that as each plate is set upon the same stops, absolute register is secured.

The Chairman referred to the great importance of exact register in the case of slides and other plate receptacles, and said that he had found six out of seven commercial instruments to be defective in this respect.

Mr. Rouch exhibited his new shutter (see page 645), and a portable camera. He had found it very advantageous to have a number of clamping positions on the base-board, and a comparatively short rack, this system giving greater firmness than when a very long slide is actuated by a rack of corresponding length; in the case of Mr. Rouch's camera, the back is stationary, and the front movable.

Mr. Shew exhibited the camera adapter which we described on page 645, and the bracket top for a tripod, which was exhibited at one of the previous meetings of the Society (see page 559).

Messrs. Marion and Co.'s representative then called attention to a syphon washing trough for negatives, and to the print-washing apparatus which is figured on page 207 of our present volume.

The Chairman said a word or two in favour of washing negatives in a reasonable time, as he had sometimes found holes eaten in the gelatine when the washing was very prolonged.

Mr. S. O. McKellen said that it was quite sufficient to provide grooves along the bottom of the trough and on one side, this arrangement allowing any sized plate—if within the dimensions of the trough—to be supported in a vertical position. Instead of a syphon, Mr. McKellen prefers to make a small hole in the lower part of the trough, and to allow rather more water to run from the tap than this hole will give vent to. Under these circumstances the trough is always full, and a stream is constantly flowing through it.

Mr. McKellen then exhibited a portable camera possessing some novel features. The bellows is of the Kinnear form, while both front and back fold down upon the base-board so as to form an exceptionally thin and compact package. The tripod legs are attached to a brass top, consisting of a ring let into the base-board, and this ring turns freely, so that when the camera is once mounted, it can be quickly turned to any point of the horizon, and a screw serves to clamp it at the required position. The front is provided with a circular piece let in and working like a turntable, so that by using this arrangement in conjunction with the swing-front, any required side shift can be obtained, together with the needed rise or fall. The focussing done is by means of rack work and slides contained in the base, and movable screens are provided for covering half or three-quarters of the plate in case it should be desired to take two or four pictures on one glass.

Mr Warnerke explained the ingenious changing-box cameras of Professor Ezutchewsky (see page 645), and exhibited some glass plates coated with the Balmain phosphorescent composition. These he had found very useful in printing transparencies on gelatino-bromide plates; the phosphorescent surface being exposed to light until saturated, and then laid for a fixed period over the printing-frame containing the negative and sensitive plate. From five to twenty seconds' exposure to the phosphorescent light was generally required.

Mr. Furnell's shutter, and Mr. Hopkins' new dark slide arrangement, were then exhibited, and the method of working with the latter demonstrated.

Mr. Hart then showed a shutter made by Jonniaux, of Liège. It consists of a flap, A, provided with a needle, B, placed as shown in the subjoined sectional diagram. Over the needle B is the ring F, this ring being attached to a hinged piece C. The hinged piece C is lifted by the air-ball D, which expands under the influence of air forced in through the tube E. If the flap is only lifted until it is in a horizontal position, the ring remains on the needle; but if lifted beyond this position the ring passes over the end of the needle and the flap closes immediately. If a spring is attached to the flap an exposure as short as one-twentieth of a second may be made.

London and Provincial Photographic Association.

A meeting of this Society was held on Thursday, the 23rd inst., Mr. J. Traill Taylor in the chair.

The Chairman, in a few introductory remarks, expressed his pleasure in seeing Mr. Ashman again among them, and called upon him to deliver his lecturette on toning.

Mr. W. M. Ashman, having thanked the chairman and the members for the sympathy shown him, proceeded with the lecturette (see page 693). Mr. Clemcuts undertaking the experiments. Mr. Ashman having concluded, the Chairman invited a discussion.

Mr. A. L. Henderson spoke in favour of sulphur toning; he regretted the introduction of the alkaline salts, and said they had not had stable prints since alkaline gold toning baths came into use; sulphur toning was by far the best.

The Chairman: Many years ago Mr. Shadbolt stated that sulphide of silver was the most stable of any of the silver compounds.

Mr. Henderson thought that was correct. In reference to preserved papers, he found an addition of uranium to the sensitizing bath caused paper so sensitized to become whiter by keeping. He had tried many experiments to obtain a preserved paper which acted as well as freshly prepared, but had failed. He obtained a paper which might be useful for amateurs by floating on acetate of silver and gold; upon moistening the prints, toning action commenced.

Mr. W. E. Debenham, in support of fading of sulphur-toned prints, said that some years ago he submitted designs printed with marking ink on d'oyles to the fumes of potassium sulphide, to blacken; soon afterwards, the designs faded just like a photograph. He noticed the print just toned with platinum became weak, like the acid gold toned prints which the lecturer spoke of. He had used platinum for toning transparencies, but neutralized the solution, and then made it faintly acid with nitric acid. Citrate of soda was one of the salts first employed in the alkaline method, so also was borax, a bath he still employed.

The Chairman: Reasoning from analogy, transparencies treated with potassium sulphide ought to fade, but they do not.

Mr. Henderson: They withstand the action of strong cyanide for a long time. If a faded silver print is restored by the platinum method I have suggested, the image is removed with strong cyanide. Perhaps the lecturer will explain why this occurs?

Mr. W. K. Burton considered an alkaline bath to be a mixture of gold chloride and a slightly alkaline salt; he had seen it stated that the salt added acted as a retarder. Was that an error? Is toning a galvanic or electro-gilding operation? He had seen good black tones obtained with a commercial salt of platinum, and a judicious mixture of this salt with the gold salt enabled any colour to be obtained.

Mr. A. Mackie: What is the reason prints turn red in salt and water? Why does an acetate bath require twenty-four hours to ripen when a borax bath can be used immediately?

Mr. Martin said it is an axiom in chemistry that colour is determined by the form and size of the particles; the size of the reduced particles in a weak negative would be different to the reduced particles in a strong negative. He asked the lecturer if there was any difference in the reduction of the particles in the prints.

Mr. Burton held that there was no difference in the size of reduced particles in strong and weak negatives.

Mr. Henderson wished the lecturer to state whether toning is a substitution or a gilding process.

Mr. A. Haddon said there was so little gold used that it could scarcely be substitution.

Mr. Leon Warnerke did not think acid at all necessary to the preserving of sensitized paper as mentioned by the lecturer; he (Mr. Warnerke) kept paper many months by the method published in one of Abney's books, viz., washing, and the use of potassium nitrite.

Mr. Burton had prepared paper in that manner, but single albumenized paper gave poor prints. Richer prints could be got with double albumenized.

Mr. Cobb's experience coincided with Mr. Burton's in using this preservative.

Mr. W. H. Prestwich preferred a plain gold bath without any other salts. He used preserved sensitive paper.

The Chairman then adjourned the discussion until the next meeting, and asked for a vote of thanks to the lecturer, which was accorded.

The sensitometers mentioned at the last meeting were sent by Mr. Bell to be examined; one registered 15, and the other 20, with plates from the same batch.

The meeting was then resolved into committee to adjudicate the prize pictures from a number sent by the Edinburgh Photographic Society for this Society's decision.

Cambridge University Photographic Society.

A meeting of the above was held last Wednesday for the purpose of electing officers. The following were elected:—

President—Mr. W. M. Shaw, M.A.

Vice-President—Rev. A. J. Chapman.

Secretary—Mr. C. F. Pritchard.

Committee—Messrs. L. Cobbett, H. M. Elder, M. Miley, and D. W. Samways.

Talk in the Studio.

South London Photographic Society.—On Thursday evening next, at the House of the Society of Arts, at eight o'clock, Mr. J. Traill Taylor will deliver a lecture entitled "Florida: Its

Orango Groves and Myrtle Bowers," illustrated by a series of photographs shown on the screen by the limelight.

Standard Weights and Measures.—The International Committee which has been sitting at Sèvres during the past year has just issued a voluminous report, and their investigations show that the standard metres and kilogrammes belonging to various countries are by no means identical, the Austrian standard kilogramme being, for example, 1·35 milligrammes too light. The report contains much detail likely to be of value to persons having occasion to make exact weighings or measurements.

Sham Photographic Agents.—Henry Hunt, aged 42 years, a canvasser, giving his address at a lodging-house in Kingsland Road; Edward Dudley, 37, a traveller, of 83, Cowper Road, South Hornsey; and Arthur Province, 24, a canvasser, of 5, Bruce Grove Road, Tottenham, were recently charged at the Clerkenwell Police Court on remand with having been concerned together in fraudulently obtaining a shilling from Sarah Ross, of 59, Highbury Quadrant, Islington, on the 16th inst., and also with having fraudulently obtained one shilling from three other persons in the same neighbourhood. The evidence for the prosecution was that the prisoners had obtained the money by falsely representing themselves as the agents of photographic firms, receiving the shilling payments on account, on the understanding that if they called at the photographers' their likenesses would be taken. On the prosecutors calling at the firms named by the prisoners they found they had been defrauded. The prisoners were committed for trial.

Death of Mr. A. E. Fradelle, Photographer, of Regent Street.—This gentleman, who died last week, was the son and grandson of well-known artist-painters, his grandfather's painting, "Rizzio and Mary Stuart," being one of the gems of the Duke of Norfolk's collection.

Schroeder's Universal Camera.—An ingenious universal camera was much admired at the Berlin exhibition, and one of its special features is the introduction of a musical box. Frequently as the musical box has been made use of to call the attention and to amuse juvenile sitters, we believe the incorporation of it into the construction of the camera to be a novelty to most of our readers.

Told in Camera.—The Innocent, knowing nothing of photography, was of course selected as the very best person possible to review the Photographic Exhibition in Pall Mall. This is his report:—Went to Photographic Exhibition as requested. Found walls hung with pictures. Never could make out why walls should be hung; always thought it was the pictures which, &c. Commenced at beginning of catalogue with the intention of going straight through, but as no steps were provided to enable me to see the skyed ones, gave up notion. Wanted to know the qualification of a skyed picture. Was it one when the *skyuro oscuro* was good? Secretary couldn't tell me. Pictures quite a success all along the line. Photography isn't an art, isn't it?

"But H. P.
Robinson he
Sez this kind o' thing's an exploded idee."

And H. P. Robinson proves it. His "Mill Door" takes a medal, the skill shown in it being by no means door-mant. T. M. Brownrigg has some lovely pictures. Particularly struck with the "Old Oaks, Adam and Eve, New Forest." My idea of the first-parent theory quite—always thought it a very old hoax. W. F. Donkin's collection of glacier photographs an ice one. Wanted to know, you know, why they weren't taken by Mr. Glacier, F.R.S., president of the Photographic Society. Secretary on his back again—couldn't say why. Extraordinary breaking surf at Bognor, by W. P. Marsh. "Bognor people had a surf-cit—eh?" Secretary turned the conversation and his head at the same time. "See Hester, by Valentine Blanchard," said he. Secretary wrong somewhere. V. B.'s picture is "*A Siesta*"—young lady under umbrella. Wanted to know why. Secretary ready with a *parry-plea*.—"You *must* look at Hubbard's 'Mother's Love.'" Splendid picture "Mother Hubbard's Love"—I mean "Hubbard's Cupboard Love"—hang it! "Lover's Other Cupboard." Dear me! Yes, really clever, and deserved the medal it got. Medal for H. B. Berkeley—"A Likely Place for a Trout (platinotype print)." Not likely, *I* should think—that is, not in a "platinotype print," picture *trout* to nature notwithstanding. West's yachting pictures perfect gems of the first water. Taken in a West wind, of course. "A Message from the Sea" (V. Blanchard)—capital. Tells its own story—to be taken, of course, with the usual old salts. M. Auty's photograph of lightning curious. Why wasn't it printed in Auty-type? Shadbolt's photographs from a balloon—cloudy, but odd. Not skyed, as I expected. Plenty of other splendid photographs haven't space to say anything about. My views of them very positive. Go and see 'em.—*Funny Folks*.

Photographic Club.—The next meeting of this Club, November 5th, will be the Annual General Meeting.

To Correspondents.

** We cannot undertake to return rejected communications.

Cambria.—It is rather a delicate operation, and if the paintings are valuable, you should send them to some person accustomed to the work. You will, however, run no risk in cleaning the surface with a soft rag moistened with methylated spirit, provided, of course, that you exercise reasonable care.

F. W. W. B.—We think not, as those who manufacture such productions buy the photographs for use on their own cards. Still, one may expect that there would be a good sale for them if introduced into the market; and if this were represented to the house you mention, they would probably act on the suggestion.

H. Howard.—If the central lens is a convex or magnifying glass, the focus will be shorter: but if a concave or diminishing glass, the focus will be longer. Probably two extra lenses were originally sent with the instrument—one convex and the other concave.

G. E. Bignell.—Thanks.

J. Button.—It is insufficiently washed, and no doubt enough bromide remains to make it very slow. If you emulsify longer or at a higher temperature, you must proceed with caution.

H. C. Garland.—We will obtain a copy of the rules, and post it to you.

Major M.—You must not expect to obtain quite such good results upon ready-sensitized paper as upon the freshly sensitized material. As regards the other matter, we will make enquiries and write to you.

G. E.—Turpentine will generally cause discolouration, so you had better use benzole; still, this latter dries so quickly as to occasion inconvenience.

F. H. C.—1. The lens you mention will answer very well for outdoor work, and when the light is good; but a portrait lens will be very much more suitable; one having an equivalent focus of about eight inches being best adapted to your requirements. 2. The best thing of the kind is the series of articles on "Posing and Management of the Sitter," by H. P. Robinson, which were commenced in our issue of the 10th inst.

A. G. M.—Either the first, second, or third on your list. There is, in fact, nothing to choose between them, as each is good.

H. De K.—There is no best, and if you go to one of the large houses from which professional photographers are in the habit of obtaining their apparatus, you will be well served. See our advertising columns.

A Novice.—Your pictures are good, especially that showing active life on the sands, and the sea and cloud piece.

S. S. Y.—1. You have probably come to the best decision, as one cannot judge from one example, but rather by the experience of photographers in general. 2. Thank you for your kind intentions.

Photographs Registered.

Dr. P. H. Emerson (Southwold)—5 Photos. of Figures and Scenery, &c.
Mr. J. Place (13, Bull Street, Birmingham)—Photo. of Bust of Matthew Bolton; Photo. of Statue of James Watt.
Mr. F. S. Seed (Widemarsh Street, Hereford)—Photo. entitled "The Village Corn Doctor."
Mr. H. Spink (West Brighton)—Photo. of Hove Police Force, 1884.

THE PHOTOGRAPHIC NEWS.

VOL. XXVIII. No. 1366.—*November* 7, 1884.

CONTENTS.

ESTIMATION OF SILVER NITRATE IN THE SENSITIZING BATH.

THE common method of estimating the amount of silver nitrate in the bath which the printer uses is by means of an "argentometer," which is a rough form of hydrometer, with the stem graduated for grains of silver nitrate per ounce of bath. The estimation thereby made is commonly very inaccurate; in fact, is often no estimation at all.

The instruments sold under the name of "argentometer" are, as a rule, far from accurate, but the amount of inaccuracy in them is not, as a rule, great enough to give rise to mistakes likely to prove practically hurtful.

It is in the solution itself that is to be found the chief elements of inaccuracy. So long as the solution contains nothing but silver nitrate, the argentometer is a useful enough instrument. With a bath which has the by no means uncommon addition of nitrates, &c., or which has been much used, it is useless.

As paper is sensitized, the silver of the solution combines with the chlorine of the soluble chloride in the albumen, forming silver chloride; whilst on the other hand a soluble nitrate is formed which is dissolved in the bath. An old printing bath is thus always impregnated with some soluble nitrate, and it is, therefore, impossible to estimate the silver nitrate in it by taking the specific gravity.

It is a thing of importance to the printer to have some ready means which will not be affected by foreign substances, for estimation of the amount of silver nitrate in the bath. It is, of course, easy to precipitate the silver from a certain small portion of solution, as chloride by common salt or some other soluble chloride, to collect this on a filter paper, to weigh it, and to estimate the amount of silver nitrate which has been in the portion of solution taken; but this method takes too long a time, is too troublesome, and requires too nice measurement for most photographers. A volumetric method is certainly the best to adopt, and it so happens that there is one for silver nitrate which is particularly easy to perform.

The principle of this volumetric test depends on the following fact. If silver nitrate be added to a solution containing chromate of potash, and containing also either a soluble chloride, bromide, or iodide, the silver will combine with the whole of chlorine, bromine, or iodine present, before it combines with any of the chromium. When the whole of the bromine of the bromide (we will say of potassium, for convenience sake) has gone to form silver bromide, then the chromate commences to combine with the farther silver, and chromate of silver is formed; and as this is of a brilliant red colour, it is easy to notice precisely when the whole of the soluble bromide has been gone to form bromide of silver.

A simple experiment will explain what is meant. Into an ordinary glass of water is put a few grains of bromide of (say) potassium, and two or three grains of potassium chromate. When these are dissolved, weak silver nitrate solution is added drop by drop, the first-mentioned solution being stirred this time. As each drop of silver nitrate solution falls into the glass, it will be noticed that a brilliant red precipitate is formed, but that as the liquid is stirred the colour disappears. As each succeeding drop touches the solution, a longer time of stirring is required before the red colour disappears, and soon it will be found that it does not disappear at all, but is persistent. This means that we have added enough silver to combine with all the bromine of the bromide of potassium, and just a trace more which has combined with some of the chromium of the potassium chromate to form silver chromate. This latter trace may be disregarded, and it may be considered that we have added precisely enough silver in the silver nitrate to combine with all the bromine of the potassium bromide. We may now very readily estimate the amount of silver nitrate which we have used, if we know the amount of potassium bromide, or *vice versâ*.

To make actual practical use of the principle just explained, the best method is to use a graduated burette and a pipette. With the latter, a certain amount of the bath solution is taken, and is placed in a glass of water. From the former a solution of (say) bromide of potassium, rendered yellow with a little chromate of potassium, is poured. This solution can readily be so made up that the graduation of the burette will read grains to the ounce of silver nitrate in the bath solutions.

This, we say, is the most perfect method of any, and is, in truth, very simple; yet we can explain one which, if not quite so precise, is more likely to be of practical use to the photographer. The only necessary piece of apparatus is a small graduated pipette, which costs threepence. The size of this does not matter at all, but the smaller it is the less bath solution will be wanted. As a rule, the smallest size of pipette which is sold contains two cubic centimetres. This requires the waste of some three or four grains of silver nitrate whenever we wish to test the strength of our bath. We should explain that this method is not strictly one of estimating the strength of the bath, but of testing whether it is above or below any certain strength that we have fixed upon. It is, however, quite possible to make a fairly accurate guess as to how much too weak or too strong it is.

The following is the precise manner in which we keep our own bath up to strength. A solution is prepared in the following manner:—

Chromate of potassium	2 or 3 grains
Bromide of potassium ...	quantity as to be explained
Water	up to 1 ounce

The quantity of bromide of potassium varies according to

the strength up to which we wish to keep our bath. From following table the blank in the above formula may be filled in.

For 20 grain bath		14	grains of potassium bromide
„ 25	„	17·5	„
„ 30	„	21	„
„ 35	„	24·5	„
„ 40	„	28	„
„ 45	„	31·5	„
„ 50	„	35	„
„ 55	„	38·5	„
„ 60	„	42	„
„ 70	„	49	„
„ 80	„	56	„

It will be understood that if, for example, we work with a 55 grain bath, we make a solution of bromide of potassium 38·5 grains to each ounce. The quantity of potassium chromate is of little consequence. There should be added enough to make the solution quite yellow.

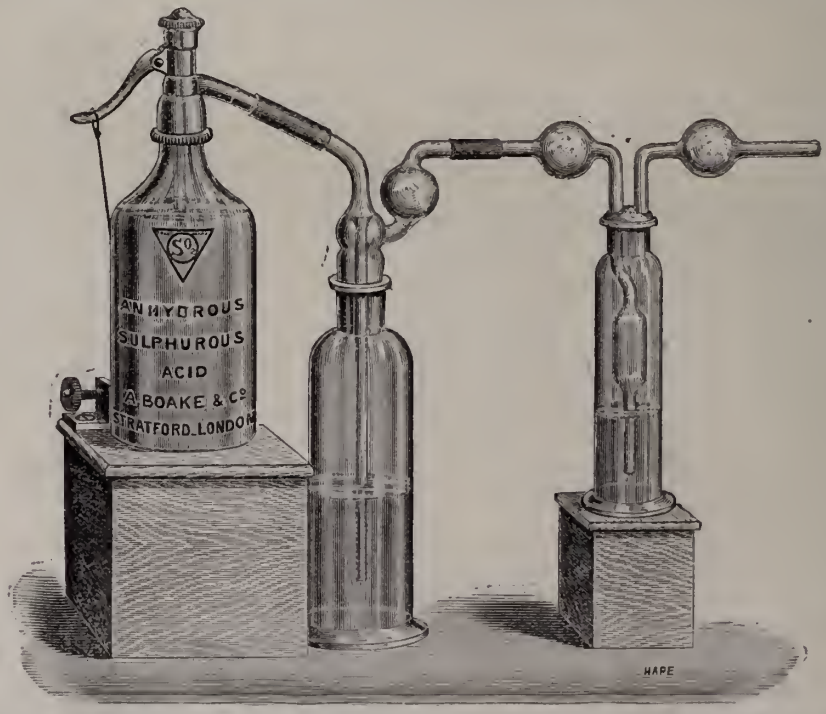
We now place in an ordinary glass three or four ounces of tap water. To this we add one pipette full of the bromide solution. The pipette is then washed, and is filled with the bath solution. This is added to the solution in the glass, drop by drop, with constant stirring. According as the amount of silver nitrate solution is just enough, is too much, or is too little to cause the red colour in the glass to be persistent, the bath is of correct strength, is too strong, or is too weak. By noticing how much silver nitrate solution is left in the pipette, or how much more has to be added to the glass of water to make the colour persistent, we may estimate about how much too strong our bath is, or how much silver nitrate must be added to it to bring it up to correct strength. The whole thing may be done in about a minute, and the estimation is correct, however much foreign matter is in the bath.

The exact quantity of water used does not matter, but very much more than that given should not be employed with a 2 c.c. pipette, because the chlorides in ordinary tap water cause a slight disturbance of the estimation. With a 2 c.c. pipette, and the ordinary run of London tap water, there is an error introduced of one grain for every three or four ounces of water used. This error is in the right direction, however, as it causes the bath to appear somewhat weaker than it in reality is. If distilled water be used, there is of course no error.

Much less than three or four ounces of water should not be used with a 2 c.c. pipette, or the precipitate will be in a spongy form, and there will be some difficulty in causing the red colour to disappear, which will make it appear to be persistent before it really is.

SULPHUROUS ACID FOR USE IN THE PHOTOGRAPHIC LABORATORY.

In our issue of September 5th, we described a simple method of preparing an aqueous solution of sulphurous acid, and pointed out the impracticability of purchasing the aqueous solution, owing to its bad keeping qualities. We also mentioned the fact that Messrs. Boake and Co., of Stratford, who are the principal manufacturers of sul-



phites and bi-sulphites, sell the anhydrous acid condensed in strong glass vessels, similar to the so-called syphon vessels used for aërated waters.

Finding that the potash developer of Mr. F. C. Beach is so universally praised by those who have tried it, but that the main objection to its use is the trouble involved in preparing the necessary solution of sulphurous acid, and the uncertainty arising from the use of sulphite of soda which has become converted into sulphate by oxidation, or was originally made with excess of alkali, we requested Messrs. Boake to give us particulars as to their system of sending out the acid in syphon-vessels, and the following description has been furnished by the firm :—

The figure shows one of the syphons connected with a very convenient form of apparatus for preparing a solution of sulphurous acid in water, or of sulphites, as may be required.

The syphons are easy to manage, the flow of gaseous acid being regulated with the greatest nicety by simply turning the milled head shown in the engraving, the liquid acid being gradually converted into gas as the pressure is relieved. There is, moreover, no danger attending the use of this simple apparatus; sulphurous acid exerting at ordinary temperatures a pressure of about 30 pounds on the square inch, while each syphon is care-

fully tested under a pressure of 200 pounds on the square inch before being sent out.

In preparing a solution, say, of sulphurous acid in water, the ground stopper carrying the tubes for passing the gas should be removed from the glass jar in immediate connection with the syphon, and two-thirds filled with distilled water; the stopper is then to be replaced, and the second glass jar half filled with caustic soda solution. The soda solution is used to absorb any sulphurous acid not dissolved by the distilled water, and so prevent the escape of this irritating gas into the air. Solution of sulphite of soda, and also of bisulphite, can be prepared in a similar way, substituting only pure caustic soda solution for the distilled water employed in the case of preparing the solution of sulphurous acid; but we must rather advise the purchase of the pure solid forms of these salts specially prepared, and put up by us in one-pound stoppered bottles for use in photography, these preparations can be obtained either direct from the manufacturers, or from any wholesale chemical firm. The syphons may be obtained either separately or already connected with the absorbing jars. It may be mentioned that these syphons contain about two-and-a-half pounds of liquified sulphurous acid, and can be refilled when required; but those requiring larger quanties can obtain the acid compound in copper drums.

In the above description it will be noticed that Messrs. Boake say there is no danger attending the use of the syphons, as the glass vessels are tested at a much greater pressure than that ordinarily exerted by the condensed sulphurous acid; but our readers must remember that a blow against a hard substance may cause the glass to become fractured, and that under these circumstances the bursting of a syphon might cause a serious injury. Still, if proper care is exercised, there need be no accident; but we would suggest that the condensed acid should always be kept in the coolest place available, as the pressure it exerts becomes much greater when the temperature is raised.

The above caution is necessary, as a bare statement that there is no danger may cause persons to handle the syphons without reasonable care. The risk is precisely analogous to that attending the use and handling of bottles containing ordinary aërated waters, only the irritating nature of the sulphurous acid must be taken into account. Instances have occurred in which serious injury has resulted from the bursting of a bottle of soda water; but few, if any, are deterred from the use of soda water or lemonade on this account.

THE PALL MALL EXHIBITION.

Fifth Notice.

Mr. P. H. Emerson's "Confessions" (No. 10) is only one of a series of admirable pictorial studies contributed by this gentleman, but of the series we much prefer three little pictures in a frame which has been terribly skied (No. 359). "After dinner rest awhile," "Tug of War," and "What's o'clock," are delightful little illustrations of child life; the "Tug of War," in which two little girls are testing their relative pulling strength, being perhaps the best. Good views on gelatino-chloride paper are contributed by Mr. S. E. Phillips (101, 471, 477); and Mr. S. H. R. Salmon has also excellent views taken in Sussex and Surrey (195), together with a charming little picture of a "Ewe and Lamb" (No. 104).

A good interior is that of "The Vyne, Bramshill" (No. 107), by Mr. Seymour Conway; and his views of North Wales (No. 326) are delightful, and will no doubt please those who care to take their holidays in the Principality. One frame only is contributed by Mr. G. T. Grammer, and this (No. 108) shows us some of the beauties of Herefordshire; but Mr. W. Muller, who comes next on our list, sends three exhibits, including Cornwall, North Devon, and Scotland (Nos. 110, 111, and 146). They are clear and bright, while the tone is a rich dark shade. The wet collodion process was employed by Mr. E. Fox in making his large and excellent picture of "Wick Hall" (No. 117); and this gentleman's interiors (293) are excellent.

Mr. John G. Horsey has no less than thirteen frames, almost an exhibition in themselves. "Early Morning" (No. 118) is good, showing us a flock of geese going to their field. It is strange that this exceptionally intelligent bird should be so slandered as it usually is. "Meeting of the Waters" (No. 121) is a striking picture, the mixing currents being wonderfully represented. Views of London Streets are shown by York and Son (124, 629), and the work of these gentlemen is so well known that it is needless to say much as to the striking way in which the active streets are represented. The "Surrey Homes" and "Thuringian Forest Scenes" of Mr. H. G. Moberley (125, 278) are wonderfully pictorial; the fact of these photographs being printed on platinotype detracts nothing from their charms.

"Thoughts far away" (No. 127), by Mr. F. Whaley, showing a young woman in a meditative mood, is by no means a bad picture, and (No. 319) "Waiting for Nursie" has much merit; but the best of Mr. Whaley's pictures is "This little pig went to market" (No. 340). Does the familiar mode of saying the nursery *paters* or *aves* on a little one's toes as a rosary require explanation? But the little girl who is being nursed, herself nurses dolly, and appears a trifle non-plussed because the latter has no toes.

Water-pieces are evidently favourite subjects with Mr. H. F. McConnell, his "Fishers a Sailing out into the West" (No. 355) being, perhaps, the most pleasing.

The shades of approaching night are very strikingly rendered in the "October Evening" of Mr. A. D. Hatford (No. 131), and this gentleman contributes good views of "Cannes and the Neighbourhood" (389, 390). Four views of the "Cheeswring, Cornwall" (No. 133), by Mr. Alfred Dismorr, deserve mention, and this gentleman contributes several other frames of Cornish scenery, among which may be especially mentioned Nos. 273 and 274. No. 134 is a splendid example of military portraiture by Teich-Haufstangl, of Dresden; and we are a little surprised that these exhibits did not receive a medal. Hollyer's "Dandelions" (136) is a photograph quite standing by itself, soft, full of detail without violent contrasts, and in every sense a picture; the delicacy with which the seed puffs are reproduced being most remarkable. His "Lily Dado" (No. 307) we do not like nearly so well. Several new series of Mr. W. Cobb's inimitable street views of London are shown (139, 218, 495), and, if possible, we note an improvement on last year's work.

Many exhibits of great excellence are sent by Mr. E. Smithells—"After a Gambol" (No. 238), representing three dogs open-mouthed and panting, being, perhaps, the best. A lady, with a guitar, forms the subject of Mr. F. Ruston's exhibit (150), and he quotes Tennyson to illustrate his picture. Mr. G. Selwyn Edwards is happy in river scenery (162, 163, 164), the best picture being one on the Cherwell. Mr. Winter, of Derby, contributes good studies, "Undecided" (No. 174) representing a young woman who does not know what to say in her letter, being, perhaps, the best. The views of Mr. W. G. Macmillan, of Cambridge (175, 176, 177), are good; the old church at Doncaster being especially noteworthy.

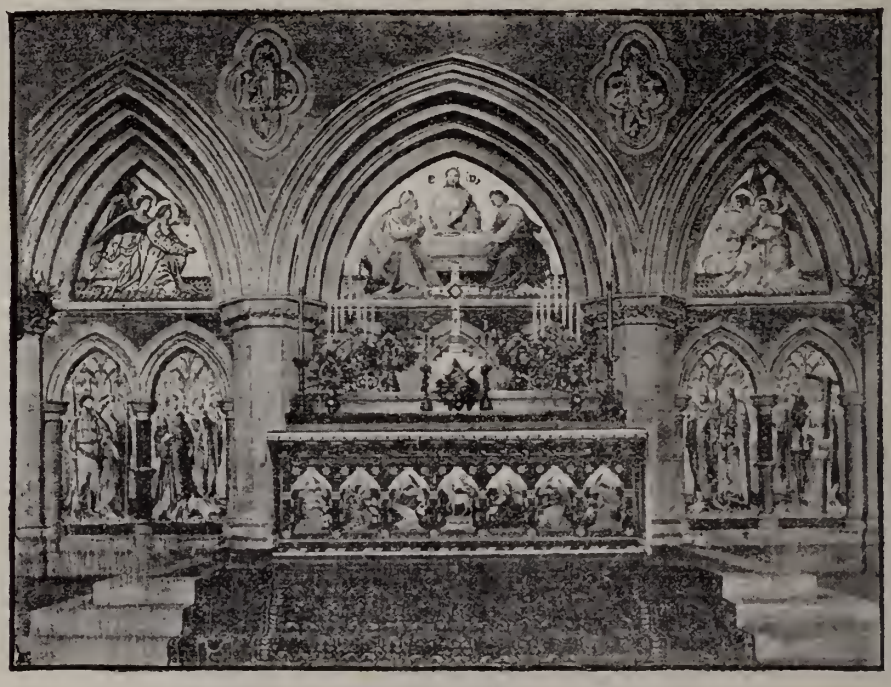
Mr. J. E. Mayall contributes magnificent specimens of photographic portraiture, not spoiled by retouching like some of the portraits which have been admitted. The most attractive is the delightful study of a little girl "Marguerite" (284); and the splendid portrait of the President of the Photographic Society, taken by the electric light (No. 546), merits exceptional praise. Mr. Frank E. Sutcliff's charming study of two fisher girls "Under the Cliff" (No. 224) should not be passed over by the visitor, and Mr. R. Keene's excellent productions (255, 384, 460, 466, 469, 547) should be noticed; the portrait of a lady taken in a private room (No. 384) being remarkably good.

A goodly collection of views from the camera of Captain Abney is to be found in the Exhibition, and the quality

of the pictures speaks loudly in favour of the iodo-bromide plates on which they were taken; it is scarcely necessary to remark that Captain Abney prepares his own plates. A series of views on the Cherwell (field club size) are especially attractive; but some larger views of Oxford and of scenery in Wales are also shown. The gem of the collection is—to our mind—a "Study of trees" (No. 272). Mr. C. E. Abney contributes but one frame (No. 280), pictures taken near Bettws-y-Coed; the gradations of tone even in the deepest shades being reproduced with a perfection not often met with.

"Tales of other Lands" (No. 281), by Mr. R. Slingsby, represents two little girls reading, and has deservedly attracted much notice.

An interior of exceptional merit is now reproduced in our columns as a Meisenbach block: (No. 562) 'Altar of



THE ALTAR AT CHRIST CHURCH, ST. LEONARDS.
Negative by the Rev. A. M. Macdona. Phototype Block by the Meisenbach Co.

Christ Church, St. Leonards-on-Sea," by the Rev. A. M. Macdona. To obtain a bad interior is easy; but few who handle the camera really make good pictures of such subjects, and on the Continent it is notoriously difficult to obtain even passable interiors of the Cathedrals and Churches.

HINTS ON POSING AND THE MANAGEMENT OF THE SITTER.

BY H. P. ROBINSON.

CHAPTER IV.—THREE-QUARTER LENGTH.—LADIES.

HITHERTO I have spoken of the sitter generically as "he," meaning, however, to include both sexes, just as women and children are included in all mankind; but as I am writing this chapter exclusively on ladies, I must alter the sitter's designation for the time being to "she." There is also the apparent absurdity, in writing on this subject, of calling all your models "sitters," although they may not want seated portraits of themselves; but the term is so generally accepted and understood to include all those who go to be represented either by the painter or photographer, that I shall continue to use it.

The female costume, when it suits those who order fashion to have it picturesque, offers greater facilities to the artist who desires variety in his poses than ugly masculine garments will admit of. Besides which, other reasons conduce to the making of more effective pictures when a lady is the subject. A greater range of expression is allowable, and the occupations and amusements of ladies afford many motives and much help to the photographer, while the occasional beauty of the subject encourages the operator by compelling him to make really fine pictures in spite of himself. There is a natural grace about some women and children that gives harmony to their slightest movements, and a fitness to their most trivial acts, so that if they only move across the room, the eye follows them with a similar kind of pleasure to which the ear listens to melodious sounds.

But it is not how to make "beauty go beautifully" that the photographer wants to know, so much as how to manage and make the best of the ordinary sitter who comes to the studio in the course of every-day practice.

Much will depend on the age of the subject, but we will take it for the present that she is neither very old nor very young, neither a young girl nor an elderly matron. Something also must be allowed for the temperament of the sitter: difficult poses should never be tried with nervous or awkward people.

A general rule might be given in very few words: Make your pose very simple, but avoid the "front elevation" or "profile section" effect, to do which you must get variety in the lines of the figure; but in doing so, avoid the twists and contortions so much affected by some photographers. Try to get the feeling of life and motion.

To accomplish this, it is sometimes necessary to make your subject walk round the studio and suddenly stop at the point where you wish to photograph her, thus getting the effect of suspended motion which is often seen in statues, and gives such an effect of animation when properly managed. The Apollo Belvidere is a well-known example of the kind of pose I mean. The figure is suddenly arrested in its action to watch the flight of the arrow, and stands for a moment in a pose that gives great variety of graceful lines without exaggeration, and could have been

easily photographed. But to come down from the classic to the real, let us try to sketch a figure photographed on this principle. And I may mention here that it would be

easy to give a set of poses for imitation, but this would be bad for the student if he did not get at the same time the principles on which the pose is based, and learn the causes which lead up to the pose, as in the present example.

A lady walking past a table slightly stoops to pick up a book or a flower, and raising herself, turns her head to speak to a friend. This action, if made by an easy and graceful figure, is full of animation, and gives great variety. Sitters almost always place both feet flat on the ground as they stand for a portrait: this often gives great stiffness. In the pose just described, if the left foot rests on the toe, as in the act of walking, the gracefulness of the action is much increased, and there is more "go" in the figure.

The changes may be rung on this idea for representing figures in suspended motion. A lady sitting at her table or desk rises as a friend enters the room; she picks up a book, or buttons her glove. These are natural actions, and anything is better than the stiff, self-conscious position so often adopted. In attempting to give life and motion to a figure, avoid going to extremes. There are those who, overstepping the modesty of nature, put too much "gush" into their poses. There are also those of what might be called the invertebrate school, who contort their figures into ridiculously strained attitudes, in their endeavour to make them graceful.

As a rule for the ordinary lady sitter, there is nothing better than the simple attitude a figure takes when standing in a room with the hands together, or, for the sake of variety, one hand may be on the table or behind the back, care being taken to avoid any ostentatious display of pose. Let the art conceal the art, and not let the figure suggest the idea that every limb and finger and fold had been adjusted by the operator. On the other hand, it must always be remembered that those portraits which appear the easiest and most natural, owe their effect, not to letting nature alone, but to the skill of the photographer in seeing at once what wants correcting, and making the alteration on the instant, before the sitter has had time to tire. The best poser is he who sees at once what he wants, and knows the readiest means of getting it. Some posers are so skilful and full of resource that they take the portrait almost without troubling the sitter, making the sitting, as it were, merely a little episode in the midst of a pleasant conversation. These are the masters of the art, and I am afraid their number is small. The majority of photographers have to painfully feel their way and (the most conscientious of them who feel they must not only earn their money, but let their customers see that they are earning it) fidget their sitter about with so many alterations and adjustments, that the resulting picture often represents a much wearied sample of humanity, with all expression of life or feeling worried out of it.

Many photographers cannot get on without the eternal chair, by which they place every standing figure. It is the abuse, rather than the use of the chair, that is so objectionable. The heavy carved oak chair and *prie-dieu* have been already laughed out of photography, but there is nothing to be said against a neatly-designed drawing-room chair; this piece of furniture is always useful when used judiciously. It is better when its lines are cut up or carried off by other furniture, such as a table behind it; or its too formal lines may be broken by throwing a shawl partly over the back. A black lace shawl is of infinite use in a studio.

Seated figures are usually more easily managed than standing ones. There seems to be so much more for a seated lady to do than when in the standing position. Reading, working, sewing, drawing, writing, a cup of tea, all lend their aid. A great deal also can be done with a fan, which lends itself admirably to a variety of change of pose.

It frequently happens that when all other devices fail, a passable portrait can be got by making the sitter look down, as in reading a book, arranging flowers, knitting or sewing, thus evading the difficulties of staring eyes and open mouths.

The mention of the looking down pose somehow reminds me that a few words may be profitably said on the hands. One of the most difficult things on the stage, I have heard an old actor say, is what to do with the hands. This is a difficulty that occurs with fuller force to the photographer. Of great pictorial importance, when properly employed, they oftener are the cause of a portrait being rejected than any other part of the picture. The one great fault that ladies find is that their hands are too large, even when it can be demonstrated that they are in proportion with the head; and they will be found to be always so if they have not been taken with a lens of too short a focus, and if they are as sharply defined as the head. This erroneous notion touching the exaggerated size is traditionary.

Before the introduction of photography, which corrected many artistic mistakes, artists used to draw the hand so absurdly small, that when the truth was seen in photographs it was not believed. Still there is some truth in the hand being too large in many photographs, and the fact that to prevent this the hands must be in the same plane as the face, cramps the operator very much in his posing. There are positions of the hand in which it looks much larger than in others, especially where the broad back of it is seen, or where the two hands are joined together in a broad light, and look, at a little distance, like one hand. When the fingers are interlaced the effect is similar; so also when a long wrist is shown without being broken by a bracelet or other means.

It is better, if possible, to let the hand take its own position, and if it does not come gracefully, to try again. To alter the fingers much is seldom very successful, and if the sitter begins to think about her hand, it never looks either graceful or natural. Care should be taken that the light does not fall too flatly or strongly on the hands, so as to increase their apparent breadth or size.

A well-formed hand is a beautiful object, and is of great use pictorially. So much was thought of it by the painters of the last century, and affectation in posing and displaying the hands was carried to such a pitch, that in some pictures they are the principal objects, and the heads are accessory. Of course, the great object in composing a portrait should be to make the head the principal object, and the hands take the second place. Care should be taken that the fingers curve gracefully, and that the hand does not look like a claw. That a very little differ-

ence in position will make a vast difference in effect, is

shown in these sketches from photographs of the same hand.

Reviews.

Handbuch des praktischen Photographen. Von Dr. Paul E. Liesegang. Eighth edition (*Dusseldorf: Publishing house of Ed. Liesegang*).

As a book for study or reference, Dr. Liesegang's "Handbook of the Practical Photographer" is well known and much appreciated in Germany, and we can heartily recommend it to those readers who can work with comfort from a German text-book. Although the work in question contains more than 900 pages, it is by no means an uncomfortably thick volume to handle, as the paper is of the thin hard kind which is coming so much into use for book printing in the present day.

Dr. Liesegang's comprehensive work consists of five divisions: I. Photographic apparatus. II. The collodion process. III. Gelatino-bromide method. IV. Silver printing. V. Carbon printing.

Photographischer Almanach und Kalender fur das Jahr 1885. (*Dusseldorf, Ed. Liesegang.*)

Here we have a neat, handy little volume of rather over a hundred small octavo pages, and it contains much useful information of a general nature. We learn from it that there is a Custom's duty of about three-halfpence a pound on dry plates imported into the German Empire; the small duty being a decided advantage to the photographic tourist, as it diminishes the probability of the packages being opened.

Instruction in Photography. By Captain W. de W. Abney. Sixth Edition. (*London: Piper and Carter.*)

So well-known and thoroughly appreciated is Captain Abney's "Instruction," that to say anything in its praise is altogether superfluous. Indeed, its position as a practical guide for the beginner, and as a reference book for the advanced photographer, is thoroughly established. It is, therefore, needless for us to do more than point out that the "Instruction" has been brought up to date, and so much new matter added as to make the present edition considerably larger than the previous one. "Do not lay the wet process entirely on one side," says Captain Abney, "for valuable as the newer gelatine process is, there are some special kinds of photographic work to which it is less suited than the older one." We are glad to see that the directions for wet collodion working are not curtailed; a matter of some importance when we remember that several of the newer hand-books ignore wet collodion altogether.

NOTE ON SOME FURTHER EXPERIMENTS WITH THE HYDROXYLAMINE DEVELOPER.

BY ARNOLD SPILLER.

In the last number of the Photographic News was a full editorial description of a series of experiments with the hydroxylamine developer, as originally published by Herr Egli and myself. It is there stated that at least two grains per ounce of the compound should be used, and in some recent experiments of my own I have fully confirmed that statement, when using the commercial product. In our original experiments the hydroxylamine was probably absolutely pure, as it was prepared by Herr Egli himself, and thus, in our description, we advised the use of a much smaller proportion of the compound. With regard to the use of citric acid in the developer, I think that when water of average purity is employed, it is hardly necessary; but when very hard water is used, the acid should certainly be added to prevent the precipitation of calcium carbonate over the film.

Since our last communication was published, I have been trying the development of gelatino-chloride with this developer, and have obtained results even more pleasing. I find, by varying the alkali used, different tones are produced. Thus with potassium or sodium carbonate, a *sepia-brown* is produced; with caustic soda or potash, a *brownish-black;* with ammonia, a brilliant *purple;* and with alkaline carbonate, containing a trace of ammonia, a *chocolate.* A very curious result was observed when using the ammonia developer—viz., by increasing the exposure six-fold, and using only one-sixth the normal proportion of alkali, a bright orange deposit was formed.

In conclusion, I may state that full details of the *modus operandi* of the development of gelatino-chloride will be given in a paper which I am about to read before the Parent Society.

RECENT RESEARCHES IN STELLAR PHOTOGRAPHY

BY T. E. ESPIN, M.A., F.R.A.S.*

The application of photography to astronomy during the last few years has been very extensive. Until last year, however, it has been used chiefly for photographing isolated objects, such as the moon, the great nebula in Orion, or the comets. Professor E. C. Pickering, the Director of the Harvard College Observatory, United States, during his European tour, showed some negatives of large fields of stars. The instrument used by him was an equatorial stellar camera with an aperture of three inches, and with this he succeeded in photographing stars down to the eighth magnitude. During his visit here to address the Astronomical Society of Liverpool he showed me these negatives. The line of research seemed to me so interesting that I at once set to work to attempt the photography of certain constellations. A camera with a lens of two and a-half inches aperture was borrowed, and an ultimuth stand was converted into an equatorial. The exposures of an hour were done entirely by hand. The first negatives were shown at the second meeting of the Astronomical Society's session, and the council at once determined to ask for subscriptions for providing a suitable instrument. We quickly discovered that the purchase of any such instrument was entirely beyond our means; but at this state of affairs came a generous offer from Mr. Howard Grubb, F.R.S., to lend us what we required. The instrument arrived in March, and was very soon in position and at work. I must now give a brief description of it.

The lens is a compound lens of four and a-half inches aperture, and focal length of fifteen feet eight inches. It is fitted into an ordinary wooden camera. Upon the camera is fixed a finder of short focus. The only form of mounting admissible was that known as the "equatorial." The principle of the equatorial, as you doubtless are aware, is an axis parallel with the earth's axis of rotation. To this is affixed another axis at right angles to the first. The first axis is called the "right ascension axis;" the second the "declination axis." The convenience of this form of mounting lies in the fact that the star can be followed with one motion only. The equatorial is of

* Read before the Liverpool Amateur Photographic Association.

massive iron. The wooden camera is attached to this by screws, while a suitable counterpoise is affixed on the other end of the declination axis, so that the camera will remain in any position. The declination and right ascension axes are fitted with circles suitably divided. The iron mounting is attached by screws to a strong wooden stand. As the exposures have often to be of considerable length, a clock motion is added, so that the camera is kept fixed on a star during the required exposure. Additional slow motions are provided in the declination and the right ascension; the right ascension one is so contrived that the camera can be moved without stopping the clock.

The work which I was especially desirous of undertaking was the determination of the actinic magnitudes of the stars. The brightness of a star to the eye is the combined effect of all the rays of the spectrum that are emitted by the star; but the impression on the photographic plate is due solely to an isolated part of the spectrum. The action of light on the plate is greatest at the violet end, and decreases as the spectrum approaches to the red. You will at once perceive we shall have on the plate a totally different scale of star brightness. The more a star abounds in rays of great refrangibility, the brighter it will appear on the plate. A star of an orange or red hue will, therefore, be diminished on the plate, while a star of blue colour will be proportionately increased. Taking, then, the eye magnitude as mean magnitude, the photographs will show a certain number of stars superior and a certain number inferior to the mean magnitude. Now, a star is white to the eye, because the rays of all refrangibilities are in their proper proportion to produce the absence of colour. In about two-thirds of the stars this proportion is maintained. Taking these as our standards for the reduction of the plates, we shall find that in the case of two-thirds of the stars the eye magnitudes and the photographic magnitudes will agree; but in one third they will differ from the mean magnitude by a quantity depending upon the refrangibility of the rays they emit. In other words, the photographic magnitude gives us one of the factors necessary for the determination of the colour of the stars.

The question, then, to be solved is how to obtain photographs of large fields of stars, and how to reduce the photographic magnitudes from them. Now, with the rapid plates at present in use, daylight photographs may be taken in an exceedingly minute fraction of a second with a lens of a very small aperture; but for photographing the stars long exposures are needed, because the starlight is so faint. An object photographed in the daytime is photographed by the light it reflects, but the stars have to be photographed directly. The most sensitive plates now made ought to have their sensitiveness increased many times for stellar photography.

The quantity of light we have to deal with is, except in the case of a few bright stars, so small that long exposures are necessary. Now, length of exposure means increase of probable error. The errors fall under—(1), the instrumental errors; (2), temporary cloudiness of one part of the field photographed; (3), unequal absorption—the last a very difficult and complex matter. In the first place, it is never a constant quantity—not even from hour to hour; hence it is impossible to reduce one plate by comparison with another, supposing them both of equal sensitiveness. Each plate must be reduced separately. The first two sources of error have been eliminated by allowing the stars to drive. In this way the stars, instead of coming out as dots, come out as lines. Supposing a cloud to intervene in any part of the field: its presence is shown on the photograph by a break in the line. Supposing the stars were photographed so as to come out as dots: it is obvious that the cloud or mists present might pass undetected, and a serious error be introduced in the resulting magnitudes. The exposures for the ordinary zone work are generally between minutes and half-an-hour. On these plates stars down to eight and a-half magnitude are photographed, and on nights when the absorption is at a minimum, stars of even smaller magnitude.

The number of stars that can be reduced on any plate is limited by a curious fact, which came out in the reductions for the catalogue of the photographic magnitudes of five hundred stars lately published. This is over-exposure in an insidious form. If a be the quantity of starlight necessary to penetrate the silver film completely in half-an-hour, it is obvious that all stars whose light is greater than a will penetrate it before half-an-hour, and the action also perpendicular to the plate will immediately cease. At first sight it would seem easy enough to tell where this has happened, for all stars whose light is greater than a would come out the same. If the rays of light passed through a medium whose refractive power was constant during the exposure this would be so; but in the case of the air the quantity is never constant nor similar in any two directions for a moment, and hence the light is spread out all round the star's image. The action on the plate thus resolves itself into a vertical and horizontal action—the vertical being due to the star's light falling directly on the plate, and the horizontal due to disturbance of the star's image by atmospherical inequality.

You will see at once, then, that if we attempt to determine the magnitudes of stars greater than a we really use a different method to that in the case of stars less than a. In the former, we use the horizontal impression, which is purely due to spurious discs caused by the lens and by atmospherical inequality of refraction; and, in the latter, we make use of the vertical impressions on the plate due solely to the star's action. The value of a is affected by three things:—(1) Length of exposure; (2), aperture of lens; and (3), the sensitiveness of the plate. From the photographs already taken I have been able to get a provisional formula for the equatorial stellar camera from Wratten and Wainwright's "drop shutter" plates. Having the aperture constant and the sensitiveness of the plates supposed to be constant, the following formula is approximately true for exposures under one hour:—

$$a=\sqrt{T}$$

When T is the length of exposure in minutes, and a the value of total penetration in magnitudes.

I may be allowed to point out that increased sensitiveness of the plates is more important than either size of aperture or lengthened exposure. If T equal the time of exposure, a the aperture of the lens employed, and S the sensitiveness of the plates, the joint results will be expressed by some relations of

$$T,\ S,\ (a)^2$$

Supposing this to be:—

$$P=\frac{(\sqrt{T}+\sqrt{S})\times(a)^2}{30}$$

—a provisional formula which fairly represents observations up to the present date—it is obvious that the increase of aperture is of more consequence than either increase of exposure or sensitiveness. But increase of aperture means increase of focal length and decrease of the field of vision; hence we are very quickly limited in this direction. Increase of T means increase of all sorts of errors, both instrumental and atmospherical. The only thing we can infinitely increase without error is S, the sensitiveness of the plates.

In conclusion: I must apologise for the incompleteness of this paper. There are several points to which I should have liked to draw the attention of the Society, namely, atmospherical actinic absorption, and to the importance of the new line of research in other respects. In the stars we have the past and future of our sun written in no uncertain hand. Intense energy is shown by the star being white, decline of energy by the yallow star, and the approach of extinction by the red star. The actinic light disappears first. Our sun has reached the second stage; each thousand years the actinic light will grow more feeble, till life will at last disappear. But the camera tells us that the universe is comparatively new, not above a third of its myriads having reached the second stage yet; and it tells also of universal slow decline. What powers of recuperation space contains we cannot say. Remove the actinic light, and we blot out life; increase it, and we have a luxuriant vegetation and contemporary prolific animal world. If it be true that our sun has reached the second stage, and it was in the first stage that animal and vegetable life appeared on the earth. With the decline of chemical light the sun's forcing power diminished, and life—vegetable and animal—adapted itself to the change by natural development, we should find, then, that in the first stage life was more prolific, but in the second more developed. An interesting path of speculation is open, but I must refrain. This age should be the age of exact observation; to the future belongs the teaching of these observations. But whatever the future discovers it will owe it in a great measure to your noble science—the science of photography.

Notes.

Who can question the excellent judgment of the arbitrators in awarding a medal to Mrs. S. G. Payne for her

charming picture, "Knuckle Down Tight," which forms our supplement this week?

It is interesting to note that such a study of every-day life is far more pleasing to the majority of people than the more lofty flights of fancy coming from the photographer who seeks to emulate the historical or the tragic painter.

As an element in the contest for the Presidential chair in the United States, the postage-stamp picture will be remembered, as many hundred thousand portraits of the rival candidates have been distributed.

M. Tonndorf, of St. Louis, makes the pictures in sheets of one hundred, ready gummed and perforated, and the charge for a single hundred of one subject is four shillings to the profession.

In giving examples of the portraits circulated—repro-

duced in the form of Meisenbach blocks—we place first the

portrait of Mr. Blaine, this being followed by that of Governor Cleveland.

It is easy to make the portraits, whether direct from life, or from an existing photograph, a camera mounted with a number of small lenses of rather ng focus being used. Let us suppose that there are ten [illegible]s in a row, and that there are ten shifts of the dark slide; one thus gets the negative of a hundred stamp pictures on one glass, a 12 by 10 plate being sufficiently large for the purpose.

The border and inscription are obtained by placing a suitable paste-board mask or foreground immediately in front of the sitter or before the original photograph.

The possibility of making printing plates or blocks for real stamps has already been suggested in our columns, and the above blocks practically illustrate the idea.

Before leaving this subject, a word or two about gumming and perforating. Before applying the gum, it is convenient to tack each print face downwards on a board, and care should be taken that the mucilage is thick and fresh. Few photographers possess a perforating machine, but the best way to extemporise a substitute is to lay the sheet in the required position on a coarse file, and to then set a straightedge against the line of required perforations, after which a smooth hard body—as the back of a knife—is drawn long the line with some pressure. This ingenious and simple method of perforating is the invention of Mr. Zuccato.

Candles and oil lamps will, it seems, have to be the principal lights at the Royal Court of Justice for the next few weeks, as the authorities (who have evidently a devout regard for the ancient traditions of circumlocution) parted with the old electrical lighting plant long before the new engines and dynamos were ready for delivering. Only the electric current is required, as conductors and lamps remain fixed ready to hand in the buildings. If a commercial company required the same supply of electricity, it would have obtained it at two days' notice by placing portable engines and dynamos on the vacant ground which is adjacent to the Courts.

Our readers will remember that not long ago, a fire destroyed the electric lighting plant at the Liverpool Street Station shed, engines and dynamos all being burned.

Before the fire was extinguished, plans for a new shed had been drawn out, and materials for its construction were being loaded on trucks at a distant station; two hours after, a new dynamo was leaving the factory of the Brush Company, and a supply of power for the next day's lighting had been arranged for. As at Liverprol Street, there is a telegraph office in the Law Courts, and the Government has resources, stores and credit at least equal to those of the Great Eastern Railway Company, but there is no directive ability. The Staff of the Law Courts could, no doubt, largely and verbosely report on a dynamite explosion, should one occur in consequence of the want of light, but men are wanted who have energy and foresight enough to see that the light is provided.

The new magnesium manufactory, which has recently been established at Charlottenburg, near Berlin, may not do all it proposes—turn out magnesium at ten shillings

a pound—but there may now be some hope of a reduction in price. Numerous uses for the wire could be found, even if the price were four times that mentioned. The Berlin Company is preparing the magnesium by electrolysis: powerful Siemens machines being used.

An American photographer (of course down West) is said to have published an advertisement offering to take a score of photographs, for nothing, of the farmer that sent him in the largest water-melon, a fruit of which he was, by the way, inordinately fond. In less than ten days he had 406 sent in, so that beside eating himself in a state of "water-meloncholia," he was able to realize fifty dollars by the sale of the surplus melons at market rates. One thinks of advertising in a similar way for his winter potatoes!

Herr Makart's death has sent up the sale of large photographic copies of his principal pictures "with leaps and bounds." Those who know the prevailing characteristics of the late Hungarian painter's work will fully appreciate the comment made on this fact by a facetious contemporary: "The present demand for Herr Markart's pictures is a 're-nude' one!"

Hyposulphite as a fixing agent is rather tolerated than loved, hence Dr. Liesegang's recent experiments on fixing with a solution of common salt or a solution of ammonium chloride, or with ammonia, possess especial interest (see p. 714).

Thus may one briefly sum up his results. Collodio-chloride prints, citro-chloride films, and gelatino-bromide plates, may be satisfactorily fixed by means of a strong solution of chloride of sodium (common salt) or chloride of ammonium, but the latter is to be preferred. A little ammonia added to the bath expedites the fixing action.

Apart from the desirability of no longer using hyposulphite, it appears that the ammonium chloride fixing bath has the advantage of requiring less exposure and giving more delicacy in the half tones, as little or no reduction takes place during fixation. It is also stated that less gold is required in toning.

Prints on albumenized paper cannot be completely fixed in Dr. Liesegang's chloride bath, as only the chloride of silver dissolves, leaving the albumenate of silver in the paper; but firm as the position of albumenized paper appears to be as a printing material, we cannot help thinking that the great advantages of the collodio-chloride and the gelatino-chloride processes will become generally appreciated before long, not the least of these advantages being much greater permanency.

The *World* this week has favoured its readers with a "Celebrity at Home," in the shape of "The Lord Mayor-Elect at South Kensington." It cannot, however, be said that we learn much about the worthy Alderman. He is described as "pacing up and down the crimson drawing-room," and we are informed that "he has a grave and thoughtful face, as befits one on whom is about to descend a dignity which dates back from some seven hundred years of English history." It is also pleasant to know that Alderman Nottage "carries his sixty years lightly enough," and that "there is a merry twinkle in his bright eye, and lines of humour play about the mouth, which manifestly confirm his reputation as one of the most genial and amusing of companions." But when the interviewer has catalogued a statuette by Magin of the Alderman's daughter, two landscapes by Unterberger, a painting "by Rebossi of a lady with a guitar, which apparently moves (which—the lady or the guitar?) with the spectator," and Cruikshank's etching of the last man on the jury at the Tichborne trial, and has given us the Alderman's opinion on the Municipal Bill, he has told us all, and it has taken him three-quarters of a page of the *World* to tell it. There is scarcely a word about photography. Why didn't the interviewer draw out the Lord Mayor-Elect on the subject? Surely he must have many interesting photographic stories to relate?

A school of photography is shortly to be established at the Franklin Institute, Philadelphia.

If M. Miquel's researches are to be relied upon, ·03 parts of silver iodide, or ·08 of silver nitrate, exercise as active an antiseptic action upon beef tea as 1 part of salicylic acid or 3·2 parts of carbolic acid.

In the *Journal of the Chemical Society* one finds an interesting study regarding the influence of light on vegetation; other conditions being favourable and equal, the growth of the plant is almost directly proportioned to the intensity of the light.

From the same source we learn that Ricciardi appears to have finally settled the question of the slow re-combination of an oxyhydrogen mixture in the dark: he finds that no re-combination takes place, and in the *Chemical News* we learn from Mr. T. D. Bruce that if silver oxide is precipited from solutions cooled to 50° F., it is obtained in the truly hydrated condition; it being then flocculent and snow white. It is necessary to dissolve the silver nitrate and caustic potash in ninety per cent. alcohol, as aqueous solutions would freeze. These observations may form the keystone for interesting photographic investigations.

A paper on the detection of a trace of iodine in bromine, by Dr. Brito, which is to be found in the same number of the *Chemical News*, shall be printed *in extenso* as soon as we can find space.

On Thursday evening, the 13th instant, the Photographic Exhibition will be specially open for the benefit of the Photographers' Benevolent Association, the price of admission being sixpence. We hope that many will be present.

We alluded last week to the paper bottles now so

numerously made in Paris. But there is a still newer and more wonderful use to which paper is now turned. Paper pulp is employed in the manufacture of the most delicate of the wheels to be found in the internal mechanism of a watch. Paper is so gladly adopted because the wheels made fron it are not affected by the changes of the temperature, but "all unchanged down the grooves of time." This is, indeed, a topsy-turvey age, though, with its paper bottles, glass dresses, unintoxicating rum, grass paper, and pulp watch wheels!

Patent Intelligence.

Applications for Letters Patent.

14,457. Cleveland Green and Louis Varley Fudge, 128, Colmore Row, Birmingham, for "A new or improved actinometer."—Dated 1st November, 1884.

14,516. Alfred Julius Boult, 323, High Holborn, Middlesex, for "Films, plates, or tissues for use in photography, and process of manufacturing and using the same."—Communicated by George Eastman and William Hall Walker, United States.—Dated 3rd November, 1884.

Patent Sealed.

2767. Frederick Woodward Branson, of Leeds, in the county of York, Pharmaceutical Chemist, for "Improvements in photographic 'shutters.'"—Dated 5th February, 1884.

Patent on which the Seventh Year's Renewal Fee of £10 has been Paid.

4244. Charles Emile Reynaud, of Paris, in the French Republic, for an invention of "An improved apparatus for the production of optical illusions, called the 'Praxinoscope.'"—Dated 13th November, 1877.

Specification Published during the Week.

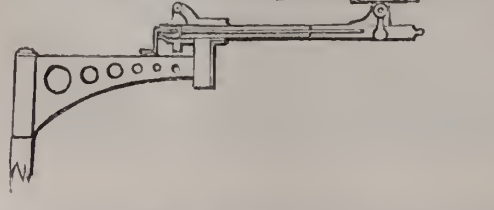
175.—William Morgan, of Cannon Street, Birmingham, in the county of Warwick, Manufacturer, for "Improvements in the production of picture and other like mounts." Dated 1st January, 1884.

Picture mounts are ordinarily produced by cutting or taking out the middle part of a sheet of cardboard or millboard, and thereby leaving an open space in the middle thereof. The part left forms a continuous frame which constitutes what is commonly called a mount.

The object of my improvements is to reduce the cost of manufacture incidental in the production of picture and such like mounts, by forming or producing such mounts from suitably prepared strips or lengths of cardboard, millboard, or other suitable material of the desired breadth, and cutting the said strips into suitable lengths with mitred ends, and afterwards uniting the said ends so as to form a frame, by means of clips and joint backings.

Patents Granted in America.

306,721. Ezra Cope, Hamilton, Ohio. Solar Printing Apparatus. Filed May 22, 1884. (No model.)



Claim.—The combination, substantially as set forth, of a main support for an exposure apparatus, a hollow arm attached at one end to said support by a journal of rotation with its axis horizontal, a lever fulcrumed at the free end of said arm upon a pivot-axis arranged at right angles to the axis of said journal of rotation, an exposure apparatus, as a printing-frame attached to one end of said lever, and an adjusting-screw housed within said arm and engaging said lever.

FIXING SILVER PRINTS AND GELATINO-BROMIDE PLATES WITHOUT HYPOSULPHITE.

BY DR. PAUL E. LIESEGANG.

It is a well-known fact that small quantities of chloride of silver are soluble in ammonia as well as in the chloride of sodium, chloride of ammonium, &c., but these solvents are not generally considered to be strong enough to be used as fixing agents for silver prints.

Being engaged in producing transparencies upon glass by the aid of the collodio-chloride process, I was struck by the thinness of the layer of chloride and citrate of silver contained in the films, and at once tried the above-mentioned solvents.

Liquid ammonia cleared the films immediately; a concentrated solution of common salt took about five minutes to dissolve the whitish film, the chloride disappearing before the citrate. I next tried to fix collodio-chloride prints on paper in the same way. Ammonia had the same effect as the usual five per cent. solution of hyposulphite of soda, but one cannot think of using it in large quantities and in open trays, because of its fumes.

Saturated solution of common salt is a little slow in its action; I therefore tried a saturated solution of chloride of ammonium, in which I left the prints for an hour. It may be that a shorter time is sufficient, or that even longer soaking is necessary, but my observations lead me to think that one hour is a safe time. The prints, not toned, come out of the bath with the same brownish yellow colour which the hyposulphite bath imparts to them. I washed the prints under the tap for a minute or so, dried them and exposed them, one half covered with black paper, to the light. They had a few hours of sunshine and two days of diffused light, and till now not a trace of difference in the protected and exposed parts is to be remarked. Of course an exposure for this time is not by any means sufficient to prove that the fixing is perfect, so I shall leave the prints in the window, and report on their behaviour.

I next toned a batch of prints in the same way as I usually tone them, in an old gold bath, with tungstate of soda, and kept there for an hour in the chloride of ammonium. After drying they had an unpleasant slatey blue colour, showing that too much gold had been deposited on them. I therefore prepared another bath of prints, which, instead of ten minutes, I left only one minute in the old gold bath. In the chloride bath they took a vigorous purplish brown colour, but were somewhat over-printed, although I had taken care to print less than for hypo fixing.

Now if this way of fixing prints proves to be safe (only time can teach us), we shall realise the advantage of doing away with hyposulphite, we shall use less gold for toning, and also shorten the time of exposing in the printing-frame.

Comparing the prints with others fixed with hyposulphite, I find that the finest half-tones in the lights, as well as in the shadows, are better preserved, and that from under-exposed negatives better results are to be obtained.

If the chloride of ammonium does not sufficiently fix the prints, I am sure we shall succeed by adding to it some ammonia. The fixing might then be done in upright vessels, the prints being hung vertically.

Since writing the above I have tried to fix gelatino-bromide plates and albumen prints with a saturated solution of chloride of ammonium, and I have experimented with plates from German and from English makers. The result is, that I find a period of two to two and a-half hours to be sufficient to completely clear the film. By adding liquid ammonia to the bath, the time may be reduced to half an hour or one hour, according to the thickness of the film.

The salt bath dissolves the chloride out of albumen silver prints, but not the albuminate of silver, so that the albumen print darkens on exposure. The collodio-chloride prints mentioned in my last letter have had a few

days more of exposure to day and sunlight; they do not show any trace of alteration.

IODO-CHLORIDE OF SILVER EMULSION.

BY V. SCHUMANN.

In a recent paper in the *Wochenblatt*, this investigator relates his experience of gelatine emulsion containing chloride and iodide of silver. Gelatine films containing pure chloride of silver can only be used in the camera in exceptional cases; if, however, iodide be added, the resulting iodo-chloride films answer most of the purposes of a gelatino-bromide plate. It may be remarked that with gelatino-chloride emulsion an image is easily developed with pyro or oxalate; but, unfortunately, fogging is very liable to set in. On strongly diluting the developing solution and adding a large proportion of bromide, it is possible to obtain a clear deposit, but the image is so thin that is is quite useless for practical purposes.

Gelatino-iodide films possess totally different properties. The development is extremely slow, without any tendency to fog; thus the addition of a restrainer should be avoided. Iodo-chloride emulsion can be prepared either by dissolving the chloride and iodide salts in the gelatine solution, and then adding by degrees the silver nitrate; or by making two separate emulsions of chloride and iodide of silver, and then mixing the two after the washing process. It should be noted that the properties of a compound or a mixture of the two haloids are very different. A negative of the spectrum impressed on an iodo-chloride film, prepared by mixing the two emulsions, shows two coloured deposits. The red end of the spectrum as far as the G line is reproduced in the negative as a red tone, while that part of the spectrum from G extending to the violet appears as a greyish violet deposit. When using Stolze's potash developer, the difference of the two tones on the negative appears even more marked.

Experiments were instituted to determine the most suitable proportion of the silver haloids to be suspended in the emulsion. For this purpose three emulsions were prepared according to the following formulæ.

No. 1.—*Iodo-Chloride Emulsion.*

A.—Ammonium chloride	...	...	·64 gram
Potassium iodide ...	...	...	·05 ,,
Gelatine	...	...	1·5 ,,
Water	...	...	15 c.c.
B.—Silver nitrate	...	...	1·55 gram
Water ...	...	...	15 c.c.

No. 2.—Same as No. 1, but with ·15 potassium iodide instead of ·05; and 1·65 silver nitrate instead of 1·55.

No. 3.—Same as No. 1, but with ·64 potassium iodide instead of ·05; and 2·14 silver nitrate instead of 1·55.

To prepare the emulsion, A and B were heated in a water bath, and then mixed slowly, with thorough shaking. The mixture, after an hour's cooking, was allowed to stand over night; the emulsion was next washed for seventy-two hours, and after slightly diluting, at once poured over the plates. The emulsions prepared according to formulæ 1 and 2 transmit blue light, which, however, is much brighter than that exhibited by gelatino-bromide emulsion. No. 3 emulsion transmits an orange light.

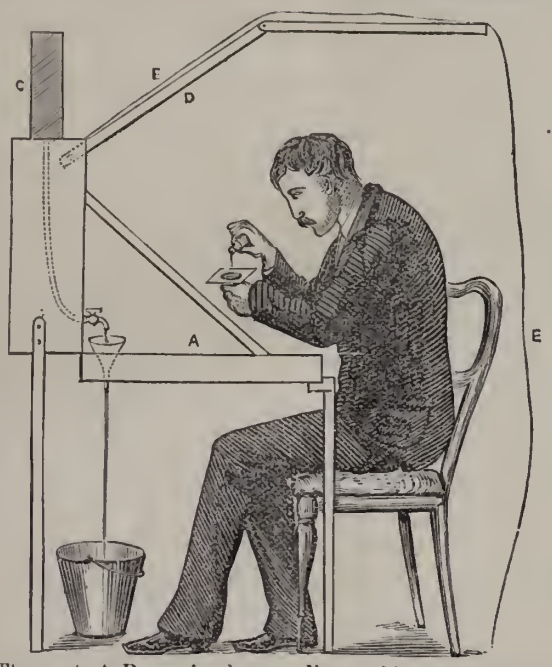
Previous to cooking the emulsion, a small quantity from each sample was spread on a glass plate, and, with the films prepared from the fully digested emulsion, were placed in sunlight. The unripe emulsion darkened much more quickly than that which had been digested. The colours of the exposed films prepared according to Nos. 1 and 2 were chocolate, and there was very little difference between the tones of the ripe and unripe emulsion. With the plates made by No. 3 formula there was, however, a great difference of colour noticeable; thus, while the unripe emulsion yielded a deposit not unlike that of Nos. 1 and 2, the films prepared from the ripe emulsion assumed a greyish-green colour, which did not alter even after some weeks' exposure to daylight.

PHOTOGRAPHY IN LLEYN.

BY J. VINCENT ELSDEN, B.Sc. (LOND.), F.C.S.

Perhaps no part of the British Isles is less frequented by the tourist than that part of Carnarvonshire which has received the name of the Lleyn promontory; and a description of a photographic tour in this district, as yet but little overrun by the camera, may be of interest to those who are in search of "fresh fields and pastures new," within easy reach of London.

To begin with, I will say a few words about a dark tent which was found extremely portable and convenient. The outside dimensions, when packed for travelling, were 24 by 12 by 6 inches, and the general appearance, when opened for use, will be seen in the subjoined rough sketch;



The parts A B are simply an ordinary oblong box and its lid. C is a small tin cistern, whence a small india-rubber tube conducts the water to a small tap inside the tent, the waste escaping by a funnel into a pail beneath. The legs are fixed by means of wooden screws. D is a jointed lath for the purpose of holding up the hood, E. The front part of this hood is made of cherry fabric; the back part may be of any cheap black material. The whole may be readily made, and the cost is but trifling. One point, however, deserves notice with respect to the cherry fabric. After the hood had been folded up several times, and packed in the box along with the apparatus, it was found that where the cherry fabric was creased, small pinholes were formed, and some red glazed lining had to be procured to lay over the front to obviate any risk of fog. Evidently, therefore, the cherry fabric is unsuited for rough usage. With this single exception, the home-made tent was all that could be desired.

One great feature of the Lleyn district is its total want of railway accommodation. We were, therefore, compelled to make a stay at Pwllheli, the termination of the Cambrian railway in this direction. Pwllheli is a quaint old town, and one or two interesting street views may be found; but there is nothing of any special attraction in the immediate neighbourhood. About four miles along the coast we came to Llanbedrog, charmingly situated amidst all the conditions necessary for a picture—wooded

glens, a rocky coast, quaint old cottages, and a fine hill rising from the beach. Along our route to this place we were able to secure a negative of a most interesting geological section, boulder clay lying in a hollow in a mass of igneous rock, and our thoughts were momentarily transferred to the times, far separated from one another, when the Lleyn promontory was a centre of volcanic action, and again, when huge glaciers conveyed their freights of rocky débris down the valleys. An easy excursion from Pwllheli is to Nevin, a small town situated on the North coast of the promontory. Here some charming subjects may be found. Along the beach are plenty of small vessels lying in all sorts of picturesque positions; innumerable remains of wrecks and shattered hulks break up the foreground; while in the background the fine old Eifl mountains give a grandeur to the scene which is rarely to be surpassed. Half-way between Pwllheli and Nevin is Boduan, the seat of Lord Newborough, where several excellent subjects may be obtained.

At Porth Abersoch we were fortunate in finding the tide out, and several coaling vessels in the process of being unladen by carts across the sands, giving a general appearance of activity and life to this picturesque bay, which contrasted strangely with the loneliness and inaccessibility of the spot. A good negative was secured here, without the necessity of either rapid plates or drop-shutter; and although a dozen horses figured in the scene, no movement can be detected.

No visit to Lleyn would be complete without seeing Aberdaron, situated almost at the extremity of the promontory, twenty miles from the nearest railway station. The village is scarcely seen until it bursts suddenly into view, reposing in a valley by the seashore, and hemmed in by hills which, from their close proximity, afford good positions for securing views. On descending to the shore a curious old church is seen, and we were again fortunate in being able to secure a view of a large wrecked steamer, a too common occurrence on this rocky and difficult coast.

A striking feature of the Lleyn district is, that although thinly populated, and without easy means of communication, there are many good hotels, and the country inns are often exceptionally large and clean. The pedestrian would do well, however, to provide himself with a good Ordnance map and pocket compass, as few of the inhabitants understand sufficient English to give intelligible directions.

THE CARBON PROCESS FOR AMATEURS.

BY T. B. ALLISON.*

THE carbon or Autotype process is one of the most beautiful of all printing processes, and having, as one of its principal attributes, the advantage of permanency, especially recommends itself to the amateur photographer, who, as a rule, only requires one or two prints from each of the negatives.

The tissue, having been immersed in the sensitizing bath three minutes, or until completely flaccid, it is withdrawn, and laid, face downwards, upon a piece of plate glass. A squeegee [one shown] made by screwing a strip of thick india-rubber between two laths, is passed over it, thus removing all excess of moisture.

Drying the tissue is, with most amateurs, somewhat of a trouble, but I have found no method so easy and satisfactory as the following:—Sensitize at night; let the room used be freed from deleterious gas or other fumes by passing a draught of air through it for a few minutes; the kitchen is preferable, as it is usually warm in the evening, and not too hot after all the household have retired to rest. Suspend the tissue by American clips to a line stretched across the apartment; come down early in the morning before daybreak, when you will find all the tissue dry and curled up. A door, or doors, of the drying room should be if possible left open, as the object is not so much to dry by heat as by a current of dry air. When dry, the tissue is, of course, ready for printing, before which operation, however, the negative must be prepared by making a "safe edge to it." This I do by drawing round the reverse side of the glass for about a quarter of an inch depth a margin of Brunswick black; this depth for 11 by 9, and proportionally less margin for smaller negatives. Now expose in a printing-frame, and as it is, of course, impossible to judge by appearance of the progress in printing, an actinometer [one shown] must be used.

For the remaining operations no chemicals are required, only plenty of warm water; and as we will say that we wish to imitate a silver print as much as possible, we will take a piece of plate glass, free from scratches, and which has been rubbed and polished with bees'-wax and turpentine, so that a slight film of that compound still adheres to it. Place this in cold water with the piece of exposed tissue; this latter will begin to curl up; then go quite flat again. At this moment bring both glass and tissue, face downwards, upon it, out of the water. Apply the squeegee so that all air-bubbles are expelled, and place aside to drain for a few minutes. Of course several pieces of tissue and glass may be similarly treated at the same time.

Now place the glass and adherent tissue in warm water at about 100° F. Agitate a little until you see the dark pigment begin to ooze from beneath the edges of the paper; lift up one corner, and the whole may be lifted from the glass, leaving behind an apparently slimy mass. Dash the warm water over this until you see the image distinctly, and the water comes off colourless.

At this stage it will be seen whether the exposure has been approximately correct. Should it have been too long, a little warmer water may probably reduce the image; if too short, use cooler water containing a little blue; but, as in other processes, a correct exposure always gives the best results. After an immersion in alum and water, place the glass plate with the developed image aside to dry; when dry, take a piece of "transfer paper" which has previously been soaked in cold water until flaccid; then in warm water until just slimy. Flood the glass plate with cold water, apply the transfer paper, "squeegee," and again set aside to dry. This time the image will, if left to itself, adhere to the transfer paper, and leave the glass, giving a highly polished picture.

For more detailed information, I refer you to Captain Abney's "Instruction in Photography." In practice, the carbon process is not a bit more difficult than silver printing, and although my description thereof has been somewhat lengthy, I hope my demonstration has been none the less interesting, and that some of you, after surmounting the principal difficulty of correct exposure, will adopt what, although having been called "blind process," is none the less a beautifully scientific and, from the variety of its applications, an exquisite adaptation of a simple phenomenon to photographic purposes.

* Abstract of a paper communicated to the North Staffordshire Photographic Association.

Correspondence.

APPARATUS AT THE EXHIBITION.

SIR,—Your correspondent, R. Sedgwick, has strange ideas with regard to the annual exhibition of the Photographic Society, as it appears that he would like always to see it as it is now, a kind of show-room where the stock goods of all the manufacturers can be inspected by customers too modest to look in the shop windows, or to ask to see the articles in the ordinary way. Of course, a kind of joint stock photographic goods show-room would be a convenience to buyers, and might be a source of profit to sellers; but to convert the Exhibition into a concern of this kind, and to allow it to be a centre for the distribution of price lists and circulars, must ultimately cause serious injury to the Society. A few years ago only genuine novelties of the year were admitted, and a mere variation in form was not considered a sufficient ground for admission. Now we see the same stock goods exhibited several years in succession. J. R. JONES.

DEAR SIR,—A great deal has lately been said and written as to the incongruity of mixing up an exhibition of pictures, and a trade exhibition of apparatus, with its accompanying price lists, cameras, instantaneous shutters, &c. Could not this be avoided in future exhibitions having by a separate room devoted to this, where the general public (those who get

pulling delicate pieces of apparatus about, and so ruining them before the Exhibition has been opened a week) would not care to enter, and where only those interested, and who knew how to handle such apparatus carefully, would find their way? An attendant possessing a little scientific knowledge, at a very small expense could easily be coached up in a day or two previous to the opening, and could explain the different pieces of apparatus. Walter B. Woodbury.

THE PHOTOGRAPHIC EXHIBITION.

Sir,—There appears to be much discussion respecting the awards to pictures hanging on the walls of the Exhibition, which those pictures sent in as glass transparencies have entirely escaped, and the press have not noticed, although they have written in detail about the paper photographs and apparatus.

If those pictures which have gained medals had been sent in only as lantern slides, judging by past experience, they would have obtained no notice whatever; as it is, they have not been quite ignored, as the transparencies have, notwithstanding that a medal was offered for them.

Transparencies on glass may be, and often are, equal as pictures to anything that hang around the walls; but being only photos on glass, they do not seem to be considered as pictures; and as they cannot be classed with tripod legs and apparatus, they are passed over in silence.—Yours truly, P. Fincham.

EXHIBITION AWARDS.

Sir,—Your correspondent signing himself "An Exhibitor but not a Medallist," says that no one has yet suggested any fairer method of arriving at the solution of the problem of awards than that now used by the Committee. Feeling deeply for them in their thankless task, I would suggest, for their relief, that the Photographic Society might take a higher and grander position than hitherto, and abolish medals altogether. The Committee cannot be infallible. The difference of opinion among the mass of photographers is most notable, and how often errors are made. One instance on the moment: "A Misty Morning on the Weir," to the astonishment of everybody, escaped a medal.

But if their abolition is not thought desirable, I have another idea which I think would disarm all grumblers. It is this: the Society should place a book in the Gallery for all the exhibitors and photographers generally to put numbers or marks, so as to indicate which picture each visitor thinks fittest for the award, his name and address being appended, and at the end of the Exhibition the book could be easily added up, and the medals awarded.

I do not wonder at the dissatisfaction expressed at giving a medal to a—well, a still subject. Surely, architectural things cannot rank with nature, sea, land, or living creatures, and the perpendicular being a little fanciful makes it worse.—Very faithfully yours,

Harry Pointer.

MESSRS. WEST'S YACHT STUDIES.

Dear Sir,—In the "Notes" of last week's Photographic News we see it is stated that our yacht studies in the Exhibition are exciting much controversy, and that some keen and practical examiners are contending that they are enlargements. It seems singular that our pictures are picked out for controversy; last year they were *elaborately retouched*, and when it was found they were not, another cry was raised that they were *flukes*; and now this year they are *enlargements*.

These accusations call to mind an anecdote we have read of a keen and practical examiner of stuffed birds, who, whilst passing a second-hand shop, was attracted by an owl perched on some goods. He immediately commenced pointing out various faults in the bird to a friend who was with him. "Look at his head," said he; "it is much too small, and the body is all out of shape; besides, who ever saw an owl sitting in that absurd way? and his eye—only look at it—it's much too large!" Presently the bird winked, and ruffled his feathers, much to the astonishment of the examiner, who very quietly walked away.

We certainly have had our yacht studies enlarged—some up to 48 by 36 inches—and they have been enlarged from the direct negatives, as the Autotype Company will testify; but the size of the direct negatives is exactly the same as the photographs now exhibiting.—Yours truly,

G. West and Son.

[Messrs. West and Son are to be congratulated on having made pictures which have so many good qualities as to excite the wonder and inventive faculties of ingenuous persons.—Ed. P.N.]

EYES GOING WITH THE HEAD.

Sir,—Perhaps I did not explain quite clearly what I meant when I said the eyes should go with the head; it would have been better if I had exaggerated the effect I intended to condemn in my illustration. The pose I deprecated is that seen in the portraits by Lely and Kneller, and the painters of their time, who seem to have supposed that the more a figure was twisted, the more graceful it became. In these portraits the figure would be turned to the right, the face to the left, and the eyes back again to the right. Now, if in this pose the eyes had looked in the same direction as the head—or, in other words, to the point to which the head is turning—instead of looking back again, the effect would be natural and graceful, instead of fantastic and artificial. A variation of this twisted posing is presented when the figure and eyes are full, and the face turned away. Mr. Randolph will see that I am not giving advice contrary to the practice of the painters he mentions, when I say that nothing can be more natural, simple, and easy than the pose of many of the portraits by these artists in which the figure is turned slightly away, the face three-quarter or nearly full, and the eyes quite full. In this case I hold that *the eyes go with the head*, because they are both going towards the same point. H. P. Robinson.

PLATES DAMAGED BY PACKING MATERIALS.

Sir,—The question of the deleterious effects of separating frames and boxes themselves on gelatine plates is important, and I hope to make some experiments on it. I have developed two or three plates lately which have been kept some time, and show distinctly that they have been injured by the chemicals in paper boxes or frames. It ought to be investigated, for as it is now, amateurs are just as likely to get hold of a damaged lot of plates ruined by chemicals in paper boxes or frames, as a good lot.

New York, Oct. 24. F. C. Beach.

[Now that the President of the Amateur Association of New York is about to take up the important subject referred to in the above communication, it is to be hoped that our readers will assist him by bringing forward such facts as may tend to elucidate the matter. Amateurs are, doubtless, the greatest sufferers, as they are more likely than professionals to allow their plates to remain for a long time in the packages.—Ed. P. N.]

EXPERIENCE IN LETTING A STUDIO.

Sir,—A friend of mine has had the misfortune to make the acquaintance of the "Midgets" so graphically described in a recent number (p. 634). His case would make an admirable pendant to that of your correspondent, under the title of "How I sold my photographic business, and was myself sold." Unfortunately, my friend is a foreigner, and does not feel up to placing the matter before your readers thus; but he thinks with me that an outline of his case may be a useful lesson to others in a like position, and I have volunteered to send you one.

My friend, whom I will call Signor G., advertised his

business for sale, and in the first instance had a correspondence with them. But though they were quite ready to buy at his price, *without seeing the business*, yet, as they offered a series of bills in payment, my friend declined. He advertised again, and then the female "Midget" came on the scene. She reopened the matter, assured my friend and his wife that their bills would be met, told them that she herself had private property, and talked of her rich relatives. At last, after some weeks' delay, her son appeared on the scene; and finally an agreement was come to, by which they were to buy the business. They were to give an acceptance for £100 at a month, backed by a responsible party, and the remainder of the purchase money was to be paid in cash within this month, they taking immediate possession. The responsible backer of this acceptance was to be a certain clergyman who had married the female Midget's daughter. Upon this Sig. G. permitted them to come in and take possession, but, fortunately, he determined to remain on the premises until he had the money, and his bill was met. They came on a Saturday night, and the next day, Sunday, and Monday they took possession of the studio, and took the orders *and the money*. On the Tuesday, Signor G., perceiving the sort of pictures they were taking, was convinced that he was no photographer, and that less than a month would ruin his business beyond recall. He therefore insisted on taking the pictures and the money, though he permitted them to remain in the house. And they were all this time asserting that they had the money lying at the bank. However, day after day one plausible excuse after another was made, but no money made its appearance. This went on for seven weeks; their bill, of course, was not met, the clergyman was not to be found, and the Midgets themselves would have absolutely starved but for the money with which Mrs. G. supplied them out of pure charity. At the end of the seven weeks, with no small difficulty, my friend contrived to get them out of his place. Their belongings—such as they are—they left behind, but such is their value that I think it is more likely to cost him a half-sovereign to get rid of them, than that they would realise him a shilling, so he has had a rather expensive lesson in business selling.

As these people are still in the flesh, and probably trying their plausible tales on fresh victims, my friend and I thought it might be well that your readers should be put upon their guard.—I am, sir, yours faithfully, S. S.

Proceedings of Societies.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

A MEETING of this Society was held on Thursday, the 30th ult., Mr. W. K. BURTON in the chair.

Mr. J. TRAILL TAYLOR showed examples of Lewis's "Incandescent Gas-burners," similar to the kind used at certain railway stations. In speaking of its illuminating power, he did not contrast it with the lime light; but as a substitute in lantern work for any of the numerous petroleum burners, he could speak from experience as to its superiority. Having explained the principle of causing a small jet of gas to impinge on a cone of platinum guaze and become incandescent, Mr. Taylor showed how the proportion of air consumed is determined by pressure. Within certain limits, the greater the pressure, so is the light increased in brilliancy. The advantages of this light for the dissolving lantern were pointed out, and Mr. Taylor concluded his remarks by introducing Mr. Lewis to the meeting.

In reply to questions by the chairman,

Mr. LEWIS said the ordinary ratio of air consumed was eight parts to one part of gas. The light was equal to four candles per foot. After six months' use the platinum was not oxidized, the weight remaining the same.

Mr. W. E. DEBENHAM enquired whether it was necessary to increase the pressure of gas with higher preasure of air?

Mr. LEWIS: No, the burner can be worked with gas at three-tenths pressure.

Mr. A. L. HENDERSON had seen the light exhibited by Professor Tyndall, who spoke highly of it.

A vote of thanks having been accorded to Messrs. Taylor and Lewis, the adjourned discussion on Mr. Ashman's Lecturette was resumed.

The CHAIRMAN, in re-opening the discussion, read an extract from Abney and Robinson's book on printing, wherein it states that salts added to gold are retarders. He (the chairman) found toning took place much quicker when borax was added, than with gold alone, and the tone was far better.

Mr. W. H. PRESTWICH obtained satisfactory tones with preserved paper and a plain gold solution. He washed the prints in three waters, the second containing washing soda. In reply to Mr. Debenham's query repecting Mr. Cowan's suggestion to try distilled water, he said he used one grain of gold to eight ounces of distilled water, and obtained very satisfactory results; there was no difficulty about it.

The CHAIRMAN used ordinary sensitized paper, and neutralized the gold bath in his experiment.

Mr. HENDERSON: In that case, the gold being just neutralized, free carbonic acid would be present.

Mr. HART said the advantages of toning with or without the salts usually added was largely influenced by the method of preparing the gold salt. It would be noticed, with some samples of commercial chloride of gold, that soon after breaking the tube, the crystals fall to the bottom in a wet mass, owing to insufficient re-crystallization. If the salt is re-crystallized a number of times, it remains practically dry in the air. Such a sample may be used with a minimum of added salts.

Mr. HENDERSON had tried a double salt of gold and tin, and thought at the time it showed some advantages. He could add a good deal of tin without throwing down the gold, and enquired if anyone had tried this double salt?

Mr. HART thought that a good deal depended on the condition of the tin. Stannous chloride soon became stannic. He had been engaged on some experiments with gold quite recently, in which tin was present.

The CHAIRMAN: Does Mr. Hart consider added salts to be retarders or otherwise?

Mr. HART replied that opinions differ widely on that subject, much depending on the sample of gold salt used. Some recommend washing out every trace of free silver; if this is done, then toning is slow. On the other hand, if the silver is left in, then decomposition of the gold takes place. In his own practice he gave prints three waters, allowing one pint of solution to each sheet all through the process, including toning, fixing, &c.

Mr. J. B. B. WELLINGTON: What would be the result of leaving a larger proportion of silver in?

Mr. HART replied that it would result in spotty prints, and the toning would be unmanageable.

Mr. A. MACKIE found ready-sensitized papers required a long washing before toning; half an hour was not too much.

The CHAIRMAN thoroughly washed some prints before toning, and others very slightly. These were mounted side by side; the latter have faded, but not the former.

Some further remarks on the theory of gilding *versus* substitution, in which Messrs. Debenham, Hart, and Henderson took part, brought the discussion to a close.

The LECTURER, in reply, said Mr. Henderson spoke in favour of sulphur toning being better than the alkaline method. Will he adopt it in the future? The Chairman (Mr. J. T. Taylor) bore witness to the stability of sulphide of silver; but it is generally admitted that sulphur-toned prints, if permanent, are less pleasing to the eye than those toned by the alkaline method. Is toning a substitution process? No. His impression was that toning action is similar to the well known experiment of coating a knife blade with copper, by plunging it in a solution of cupric sulphate; but with this difference—the latter is a direct action, whilst in toning, we deposit gold by double decomposition. It cannot be a substitution process, as the metallic layer beneath is not removed. With reference to strong cyanide removing a platinum deposit obtained in restoring a silver print, he said any other metal would be removed in the same way, strong cyanide having a solvent action on most of the compounds of the noble metals. Replying to Mr. Debenham, he said he was unable to tone a silver print with the platinum bath which that gentleman had mentioned, although it toned transparencies well enough. Replying to Mr. Burton, he said any salt added to the gold becomes a restrainer, but not in proportion to the quantity added. The following simple experiment would prove this:—Two grains of borax to one grain of gold tones a print in less than one-third

the time required when eighty grains of borax are used. Toning certainly is a galvanic process. In reply to Mr. Mackie's question, why do prints turn red in salt and water? he assumed that a layer of silver chloride printed in combination with an organic acid is of a red colour, and certain substances, such as acetic acid or common salt, act upon the free silver, and augment the colour of the organic image. Why does the acetate bath require time to ripen, &c.? Bi-borate of soda is an alkaline salt, and quickly neutralizes any free acid, converting it into common salt, which tends in a great measure to prevent mealiness. Acetate of soda, on the contrary, is a neutral salt, and liable to give up its feeble organic acid in favour of the more powerful mineral acid; as the action is slow, it has been found advisable to make the bath with hot water, shaking it up with a feeble alkali such as chalk, and thus, in allowing the fine particles of alkali to settle, obtain neutrality. In reply to Mr. Martin, there is reason to believe that the kind of bath used determines the size and form of the particles of deposited gold. Rapid toning, as advocated by Mr. Prestwich, will give a coarser deposit than a bath such as the acetate or borate. Mr. Hart's remarks on different samples of chloride of gold coincided with the lecturer's experience. Re-crystallising six times was not too many if it were desired to keep the salt some time.

Mr. T. O. McKellan then exhibited and explained his new patent camera, a description of which appeared on page 703. A cordial vote of thanks was accorded.

Mr. Debenham considered it a most excellent camera, and thought it was an advantage having the plane of the plate parallel to the lens.

Mr. Henderson showed plates badly fogged through keeping them in the slides a couple of months, and suggested that Mr. McKellan should devise a perfectly light-tight dark slide, as such was needed.

A discussion then ensued on the probabilities of leather hinges causing fog, several members taking part; but nothing new was elicited.

Mr. Henderson had a communication from Mr. Birrell (Scotland) in reference to a safe light; but owing to the lateness of the hour, it was decided to adjourn discussing it until the next meeting.

Mr. W. H. Harrison was elected a member of the Association.

The Hon. Secretary announced that Thursday, the 13th inst., will be devoted to the exhibition of lantern slides, illustrating the processes suggested by Mr. Debenham.

Postal Photographic Society.

A committee meeting of this Society was held at the address of the Hon. Secretary, 3, Plowden Buildings, on October 29th, Dr. Horace Day in the chair.

The minutes of the previous meeting were read and confirmed.

The Committee having inspected specimens of photographic work sent in by candidates for membership, elected the following gentlemen (some of whom had been provisionally admitted):—Hugh Heal, Hayward's Heath; C. J. Watson, Birmingham; S. H. R. Salmon, Croydon; C. F. Pritchard, London; Rev. W. Miles Barnes, Dorchester; Charles Yeomans, Sheffield; and Charles Baker, London.

Dr. Day then proposed that in future albums, where a member exhibits more than one print, the votes which are given him in respect of each exhibit shall be added together, and the member so gaining the highest number of votes shall take the prize. The motion was carried.

The prints in album 14 were considered, and it was found that Mr. J. W. Leigh's picture, No. 830, had the greatest number of votes; Mr. Mathewson being second for one of his pictures. The prize was accordingly awarded to Mr. Leigh.

Dr. Day was unanimously elected as President for the current year, and after several letters from various members had been read, and other business transacted, the meeting dissolved.

Liverpool Amateur Photographic Association.

The monthly meeting was held at the Free Library, on Thursday, the 30th ult., Dr. Kenyon in the chair.

The minutes of the September meeting having been read and confirmed, Mr. F. P. Paul, F.R.C.S., was elected a member.

The Chairman announced the donation of twelve prints to the album by Mr. W. H. Atkins, and also to the library of guide-books to Carnarvon and Ruthin, by Mr. Maurice Jones.

The Rev. T. E. Espin read a paper on "Stellar Photography" (see page 710), and passed round some negatives and prints in illustration of his remarks.

The Chairman, after complimenting Mr. Espin on the ability and scientific interest of his paper, asked if he considered that the sun had entered upon its yellow stage of existence.

The Rev. T. E. Espin said that spectroscopic observation tended to confirm this theory. He further adverted to recent experiments on the power of actinic rays in promoting vegetation and developing life.

The Rev. H. J. Palmer mentioned the case of a schoolmaster friend of his, who, under the conviction that the blue rays were conducive of brain power, had the walls of his school and class rooms coloured blue.

The Rev. T. E. Espin, in replying to a vote of thanks, said that he should be most happy to show his apparatus to any photographer who would visit the Observatory of the Liverpool Astronomical Society at West Kirby.

Mr. W. H. Atkins then gave a demonstration of his mode of making enlarged negatives with gelatino-bromide paper, and used an ordinary triplex paraffin lantern, with a Steinheil half-plate lens. The sensitive sheet was placed in an ordinary printing-frame, and the enlargement was one of five diameters, from a very good transparency from one of Mr. Atkins' own negatives. After exposure for some three minutes Mr. Atkins placed some non-actinic glass in front of his lantern, and proceeded to develop his picture with the pyrogallic acid and washing soda developer. After applying a citric acid and iron clearing solution, the enlargement was fixed in hypo and washed, and passed round for the inspection of the meeting. The result was a brilliant success, and great interest was manifested by a crowded meeting in all Mr. Atkins' manipulations.

Mr. Kirkby gave some account of his recent experiences with the platinotype process.

Mr. W. H. Atkins complained of the degraded whites of some of the prints he had recently made by this process.

Mr. Twigge showed some specimens of his work with the sepia toned paper, and detailed his difficulties in working it satisfactorily.

The exhibits of the evening were:—Prints coloured by the new Cundall process; a number of 15 by 12 enlargements, and a volume of views in England, Ireland, and Wales, by Mr. Beer; views in Wales, by Mr. Ellerbeck; stellar negatives and prints, by the Rev. T. E. Espin; a series of enlargements, by Mr. Cornish; and some home-portraits on opal, by Mr. Twigge.

The meeting, which was a very crowded one, was then adjourned.

Amateur Photographic Association.

The annual meeting of the Council was held on Tuesday, the 28th of October, at York Place, Portman Square; Dr. Arthur Farre, M.A., in the chair.

The minutes of the last meeting having been read and confirmed, the following members were elected:—Professor Butler, M.A., Sir H. Hussey Vivian, Bart., H. H. Williamson, F.R.A.S., J. J. Brown, Miss Mary Egerton, Miss Maude Sullivan, John Hanmer, F. Trimmer, M.R.C.S., J. E. Dumont, F. Grant, Mrs. Hobson, W. E. Pickels, F.R.M.S., &c., D. B. Fraser, and F. J. Double.

The Secretary then laid before the meeting the pictures for the current year, and Mr. Glaisher having carefully examined every picture, read his report.

The following prizes were awarded:—The 1st prize to R. Leventhorpe (107, 111, and 114), a large silver goblet; 2nd prize to R. B. White (2, 7, and 15), a silver goblet; W. Muller (1005-1019, and 1020), a water-colour drawing in frame; R. O. Milne (8 and 9), a silver goblet; H. E. White (1 and 2), a silver goblet; F. S. Schwabe (3 and 5), an oil painting in frame; W. S. Hobson (305 and 310), an elegantly bound album; C. Stephens (59, 60, and 65), an elegantly bound album; S. Norman (6-9 and 11), a silver goblet; W. Adcock (2 and 4), an elegantly bound album; W. D. James (14 and 15), a water-colour drawing in frame; W. Vanner (74-77, and 80), a water-colour drawing in frame.

Certificates of Honourable Mention were awarded to Lord de Ros, A. D. Halford, T. Brownrigg, General Sladen, A. Hill, Rev. H. Palmer, F. Beasley, G. Brook, A. Tagliaferro, G. R. Fludder, P. H. Emerson, and H. R. Moiser.

North Staffordshire Amateur Photographic Association.—A meeting was held on Wednesday, 31st ult., at the Mechanics' Institute, Hanley; Mr. Charles Alfieri occupying the chair.

It was resolved that a presentation print (10 by 8) should be given to each member of the Society, at the annual meeting, held in November, the Secretary being instructed to advertise for the same. A paper (with demonstration) on the "Carbon Process for Amateurs," was read by Mr. W. B. Allison. After some interesting discussion thereon, and the election of Mr. G. C. Bradford as a member, the meeting was adjourned.

Talk in the Studio.

Photographic Society of Great Britain.—The first ordinary meeting of this Society for the session will take place on Tuesday next, November 11th, in the Exhibition Gallery, 5a, Pall Mall East, when the medals awarded will be presented; and short papers read by Arnold Spiller, on "Hydroxylamine used as a developing agent," and by Captain Abney, R.E., F.R.S., on "The Siemens' Unit Lamp applied to photography."

The Ferrocyanide Developer.—Mr. F. C. Beach, of New York, writes as follows:—"For gelatine plates Mr. Newton has just given me a formula which was used on collodio-bromide plates. He finds it is excellent for instantaneous work on gelatine plates. I saw the negative to-day. *Developer*.—Water, 1 ounce; carbonate of soda, 50 grains; yellow prussiate potash, 50 grains; sulphite soda, 15 grains. To developer add 1 ounce of above, and 6 grains dry pyro to 1 ounce of water. I shall experiment with it further with sulphurous acid and with carb. of pot. in place of soda."

Northampton Museum Photographic Exhibition.—The following gentlemen will act as jurors:—Messrs. Andrew Pringle, Wm. Bedford, W. Blanchard (photographers); Mr. Joseph Clark (member of the Institute of Painters in Oil Colours); and Mr. G. W. H. Brogden (the representative of the local Society). We learn that the Exhibition will be opened on Tuesday, Dec. 16th, and not 15th, as previously announced.

Canvassing for Orders.—On Saturday last a respectable-looking man, who described himself as a canvasser in the employ of the Temple Photographic Gallery, 170, Fleet Street, was charged at the Southwark Police Court with obtaining the sum of 5s. 6d. from Catherine Evans, a widow, by means of false and fraudulent pretences. The alleged false representation was that the prisoner came from the Photographic Gallery, Temple Bar, and asked prosecutrix if she wished to have her late husband's photograph enlarged, like one he showed her. She gave him a likeness of her son's to get done, and 5s. 6d. He promised to bring it back in a week. The prisoner, in defence, said he handed the portrait and money to a young man, who said he was in the employ of the Gallery, and he thought it would be done. Mr. Slade committed him for trial. On the same day William Cobbett was charged at the Borough Police Court with obtaining money by false pretences from his employer, Mr. E. Hibling. Prosecutor, who is a photographer, engaged prisoner to canvas for orders for photographs on commission. He gave in the names of several persons to his employer with fictitious orders, and received his commission. It was proved that many of the orders were false, and prisoner was committed for trial at the Borough Quarter Sessions.

An Assault with the Camera.—At the Nottingham County Court, on Thursday, the 30th ult., John Thomas Cant, a detective of the borough, was sued by James Wafer for a technical assault committed in forcing the plaintiff to be photographed against his will. Plaintiff was at the police-station on remand on a charge of embezzling, but the magistrates subsequently discharged him, and while there a portrait was taken of him, which was circulated. His Honour held that the officer had exceeded his duty, and gave judgement for the plaintiff for 20s.

Obituary.—Just as we are going to press, we learn, with regret, of the death of Mr. J. Hubbard, of Oxford Street, who has for many years maintained a well-deserved repute for his negative and retouching varnishes. Mr. Hubbard was well-known to and respected by a generation of photographers and dealers whose ranks have been much thinned during the last year or two.

Photographic Club.—The subject for discussion at the next meeting of this Club will be "On Emulsions in Collodion."

To Correspondents.

*** We cannot undertake to return rejected communications.

P. H. E.—1. The hyposulphite was not added to the developer, but before the plates were developed they were immersed for a few seconds in a solution made by dissolving one part of hyposulphite in one thousand parts of water. After this treatment, and before development, they were rinsed in water. 2. It matters very much, and it is the business of the optician to put the slit in the right place, the chances being very much against you if you attempt to make any improvement by alteration.

A. C. A.—1. The "working up" is by no means essential, and *better portraits* can be made without it than with. Still, one must admit that *better pictures* can often be made by skilful working upon the photograph. 2. This query is almost answered by our reply to the first, as any method which will faithfully reproduce the original will serve well; but unless you have an exceptionally large apparatus, the originals will have to be enlarged. 3. Here again all depends on the quality of the original picture. 4. Not always; but if any inequality of illumination is noticed, you should try if any improvement results from using the ground glass screen. To determine whether it should be used, it is generally sufficient to look at the image on the focussing screen. The most successful enlargers have no invariable rule, but are guided by circumstances.

Photo.—Your sensitizing bath is not strong enough to thoroughly coagulate the albumen; add more silver to the solution, or obtain another sample of paper.

J. Robinson.—There is too much water; make it up with half the quantity.

A. G. B.—When you have had more experience with the method, you will, we hope, let us have full particulars. Thank you for the samples of paper; the German sample has certainly a magnificent surface. It is difficult to see why a thicker layer should be required on paper than on glass. The first picture one may call a composition, as the whole of the subject was arranged and taken in the camera at one operation, but the latter is a *combination* of several compositions. It is evident that retouching has been resorted to in order to modify the contradictions of lighting which would otherwise be noticable; but this has not been carried to excess.

Henry.—A mixture of starch paste and lampblack. Apply it with a small piece of sponge attached to a stick.

Y. E.—Rub it over with a solution of bees-wax in benzole, the mixture being applied with a piece of flannel.

C. E. W.—It seems to us as if the paper itself contains some impurity capable of reducing the silver salts, and this may be due to accidental contamination after the manipulation.

H. P.—We thank you in anticipation.

Lantern.—Formulæ have been given in the News, but we shall shortly have a few special articles on the subject.

A. Sargeant.—The competition did not take place for want of entries; but we may safely say that we have not seen anything of the kind superior to the examples you send us.

J. P. T.—We have no doubt that it will be received and appreciated. Address it simply to the Secretary.

Wm. S. Honey.—It is very ingenious, and we think that tin-plate is a more suitable material than zinc.

O. P.—A very good way is to obtain a list from a Directory, and to write to them individually; but many persons would prefer to advertise in the usual channels.

J. Howson.—It will give us great pleasure to see your invention, and to give an opinion as regards the matter you refer to.

Chas. Bristow.—1. As far as our knowledge goes, the gentleman referred to still resides at the same place; that is to say, we have not heard of his removal. 2. It is rather a stain than a paint, but will not answer very well, as it fades rapidly on exposure to light. 3. There must be some mistake. We have heard of persons using it to remove acidity; but it is certainly not soluble enough for the purpose named. 4. Dissolve it in alcohol. 5. Yes, but you must not add too much; half-a-grain to each ounce is quite enough.

CONTENTS.

HYDROXYLAMINE.

Now that hydroxylamine has been suggested as a developing agent for gelatino-bromide films, it may prove interesting to our readers to describe the preparation of the compound, and some of its reactions.

Lossen discovered it when examining the reduction of nitric acid by metals. The discoverer prepared the substance by reducing nitric ether with tin in the presence of hydrochloric acid. Convenient proportions are five parts nitric ether, twelve parts tin, and fifty parts of hydrochloric acid (sp. gr. 1·14). The mixture at first becomes hot, and when the action is finished, the alcohol, produced by the reduction, is distilled off. The dissolved tin is then precipitated with sulphuretted hydrogen, the solution evaporated to dryness, and then the hydroxylamine, as hydrochlorate, is extracted with absolute alcohol. Thus the compounds actually used up in the manufacture are only hydrochloric acid, nitric acid, and tin, for the alcohol used in the preparation of the ether is regenerated in the reduction, and recovered by the process of distillation. Unfortunately, when employing the above method, a certain proportion of the hydroxylamine is converted into ammonia, and thus nothing like a theoretical yield is obtained.

In a recent issue of the *Journal of the Chemical Society*, Dr. Divers describes a series of experiments on the production of hydroxylamine from nitric acid and various metals without the presence of alcohol. In one experiment with tin, nitric acid, and hydrochloric acid, no less than 98 per cent. of the theoretical yield was obtained. Fuming hydrochloric acid 58 c.c., and nitric acid—sp. gr. 1.42—5 c.c. were mixed, and poured upon 35 grams of tin lying in a flask filled with carbonic acid gas to exclude air. The corked flask was cooled by well agitating in water. When the action had ceased the solution was poured off, the tin precipitated as described above, and the substance obtained by extraction with alcohol. Victor Meyer has proposed the use of carbonate of soda as a precipitant of tin in place of the inconvenient sulphuretted hydrogen treatment. The liquor containing the tin is treated with the carbonate solution till no further precipitate of the tin compound takes place; the solution is then evaporated and treated with alcohol as described above.

Hydroxylamine exhibits both oxidizing and reducing properties. Its power of developing, and also the production of the red-brown deposit of cuprous oxide, when treated with ammonio-tartrate of copper, may be given, as an example of its reducing properties. Quite recently, in the *Bulletin de Mulhouse*, M. Schaeffer has proposed to apply hydroxylamine for printing. On treating a manganese brown with the hydrochlorate, the manganese is at once reduced to the soluble manganese chloride. A dark indigo blue dyed on manganese is lowered to a lighter and brighter blue by the action of hydroxylamine.

In conclusion, we may remark that the *Société Industrielle de Mulhouse*, in consideration of the many uses to which hydroxylamine might be applied, has offered a silver medal for a cheap method for its preparation.

VENETIAN BOATS BY ROBINSON AND THOMPSON.

An exhibition picture which has neither been honoured with a medal, nor very much noticed by the press, forms our supplement this week; but had the judges consisted exclusively of artists, we fancy that the "Venetian Boats" of Messrs. Robinson and Thompson would have taken high honours. It neither demonstrates the speed of the plate, nor does it illustrate in a striking manner the capabilities of any one quick shutter; indeed, we hardly think that we could find about it the text for any kind of a sermon upon the technics of the photographer's art. Still it has qualities which might well serve for numerous discourses upon artistic principles as applied to the work of the photographer. The picture very forcibly recals a study by Turner, and the slight mistiness of the atmosphere at the time the exposure was made, adds much to the pictorial value of the view, this mistiness being just sufficient to prevent an undue clearness or sharpness in the middle distances. Just to the left of the principal group of sails will be noticed the bell-tower of the great Church of St. Mark, and other monuments of the city of Venice are recognizable through the mist. The photograph, Mr. Thompson informs us, was taken on the brightest and clearest day out of five dull ones, and we may confidently assert that had it been taken on the clearest day out of five fine days, its merits would have been less.

LANTERN SLIDES.

Sixth Article.*

Collodion Emulsions with Excess of Silver.—The formulæ for collodion emulsions would be incomplete if no allusion was made to the method of producing emulsions with an excess of silver. It is not necessary to go very minutely into this, further than to say that if the reader will take either of the formulæ given, and especially that upon page 402, and calculate the equivalents so as to have two or three grains of free nitrate of silver per ounce of emulsion, and proceed in every other respect as indicated in the last article, an emulsion will be produced whose properties and qualities will be considerably altered. Under ordinary circumstances, a

* Reference to previous articles, vol. xxvii., pages 129, 291, 482, and 818; vol. xxvii., page 401.

collodion emulsion made with free silver will give fog unless restrained by a free acid, preferably nitric, in the proportion of about one minim per ounce of emulsion. Such an emulsion will ripen quickly, be very sensitive, undergo rapid change, and ultimately give thin and foggy pictures. Hence it follows that when such an emulsion arrives at its best, if it cannot at once be used up in making slides, it should forthwith be poured out into an earthenware dish, and allowed to set. If the dish be placed in the drying box used for drying gelatine plates, the draught will carry away the alcohol and ether more rapidly, and the emulsion will be safe from fog by white light. The next step, after evaporating the solvents, will be to strip the cake from the dish and tear it up into small bits, or cut it up with a sharp paper or silver fruit knife, and place all the pieces in any convenient jar or washing arrangement, where either a continual stream can be left on to effect the washing, or else whereby repeated changes of water can be given. The effluent water can be tasted, or otherwise tested to ascertain when all the free silver is out. Lukewarm water may be used for washing, but not recommended except by the experienced emulsion maker. In any case the waste salts have to be thoroughly got rid of as well as the nitrate of silver, otherwise the emulsion will be very insensitive, and will not keep when redissolved. With a gentle running stream through a washing jar about twelve hours should be ample, if the cake of emulsion was evaporated down to less than an eighth of an inch in thickness. When washing is complete, the pieces may be collected by hand and drained on a clean towel, or between blotting-paper, and afterwards dried at a temperature below boiling water, until it has parted with all its moisture, when it may be put into a bottle for future use, labelled "Washed Collodion Emulsion Pellicle."

To use this pellicle, we simply weigh out quantities at the rate of 20 or 22, or at the utmost 24 grains per ounce of solvents. It is best to use absolute alcohol and best methylated ether, equal parts of each, say four ounces of each, put into a suitable bottle, and 160 grains of pellicle; the whole shaken until solution takes place, and a plate coated, which will show the substance of the film. If more density be desired, add 16 grains more, and so on. When satisfactory, the whole should be filtered through a plug of cotton-wool stuffed into the neck of a funnel.

By any of the formulæ now given for collodion emulsion, good prints can be made for the lantern from negatives to be photographed in the camera as explained at page 291 of the last volume. The procedure is essentially different whether we use an unwashed or a washed emulsion. For rapidity of working we should incline to the use of the emulsion unwashed, if it can be used up in a day or two; this obviates all the labour and cost of washing and redissolving. The method is as follows:—We use nothing but quarter-plate glasses selected thin. Out of a small tin biscuit box a washing trough was constructed by fixing some gutta-percha grooving inside, which enabled us to place nearly two dozen plates therein. A tube was fixed in bottom at one end, and an overflow near top at opposite end. A short piece of rubber tube connected the water which entered at bottom and overflowed at top of box; a tin lid made the whole safe. The water being turned on into the box, we commenced by coating our glasses with the unwashed emulsion, and taking care to coat up into each corner, by doing which a substratum may be dispensed with. As each glass is coated and set, it is dropped into a groove in the box, back of glass towards the stream of water entering. We pour from one bottle of emulsion, and drain off into another—this avoids dust being poured off and on. When the draining bottle is replete, we filter its contents, and use it next time as the pouring-on bottle. There is a certain knack in coating plates with collodion emulsion, differing from either collodion simply, or gelatine. In order to avoid lines and unequal thickness, a pool has to be poured on, and then dexterously off, the exact manner of which comes by practice.

By the time the last glass for the washing-box is coated, and the bottles put safely aside, the first plate will be ready for exposure if the water has been left gently flowing through the box the while. Take out the first plate, and rinse it with fresh water, stand up to drain for a minute, and wipe off the back all moisture; then place it in the dark slide, and take to the copying camera. Make the exposure—which is a matter only determinable by experiment—return to the dark room, and proceed to develop with alkaline pyro, as per the formula in the last article. Carbonate of ammonia is preferable to liquor ammonia in developing collodion emulsion plates. The image should appear directly, and if the exposure has been right, the requisite density and vigour will be attained before any surface fog has time to set in. It is very important to see to this, because if once the plate is fogged, all further chance of making a good slide of it is lost. The exposure is bound to be sufficient in order to get vigour enough in the shadows, without which the resulting slide will be poor and thin when put on the screen. Under-exposure upon a plate not prone to fog will give a harsh black-and-white picture. Over-exposure is liable to result in a veil if the shadows are not rendered thin also. There is one correct exposure which the experimenter should find out, not overlooking the fact that a normal exposure with a good light will give a better result than an abnormal exposure with a poor light, and a lens which will work with a tolerably wide aperture is preferable to one which needs to be closely stopped down.

The foregoing refers to the use of an unwashed emulsion, the plates treated wet. To employ a washed emulsion, and also work the plates wet, we have merely to coat our glasses, preferably using a substratum, immerse them in the washing-box, in this case only to free them from the alcohol and ether, and proceed exactly as above directed for exposure and development.

To use plates for contact printing, we are compelled to employ dry films, and even in camera printing there are some reasons why dried films should be preferred. One person could be preparing the plates, and racking them when dry in grooved plate-boxes for use immediately by another operator, or for use at some future time by the person who prepares them. The amateur could clean, and coat, and dry a batch of plates—in fact, use up that particular lot of emulsion—say, one evening or on a wet day, and keep them until the first bright day or other convenient opportunity presented itself. To dry the plates some little care is required to avoid the wavy surface marks which appear whenever and as often as the drying is stopped. Perhaps the most certain way is to dry upon a tin or zinc box containing hot water; they then dry off at once, and can be put into plate-boxes out of the way.

To expose these dried plates, one is taken from the plate-box and put in the dark slide and exposed dry. Then before development the plate must be soaked in a weak alcoholic wash—alcohol 1, water 2 parts; this is necessary to penetrate the film, otherwise the development will be very slow, and the result weak and thin. Development is the same as for the undried plates.

Fixing can be done with weak cyanide, but is usually effected by hypo, followed by plentiful washing.

We have purposely avoided introducing any organifiers or preservatives in the compounding of these emulsions, for the certain reason that such are almost sure to lead to spots and other blemishes on the films sooner or later. From one point of view, organic or preservative agents are of value, inasmuch as they tend rather towards the development of a reddish image, and this is desirable; but we should prefer to obtain a reddish image without the preservative by the introduction of chloride into the emulsion, or altering the exposure and developer to bring about that object.

We have likewise abstained from introducing iron as a developer, because it tends rather towards a cold grey class

of image, whereas the same plate if developed by pyro will probably give a warm-toned image.

If we can develop a red image, we can afterwards tone it by platinum to any tone we like up to actual blue, but the medium, purple, a compound of the red and blue, will be found most liked. The method of toning by platinum was given under the head of wet plates.

With all kinds of collodion emulsion plates there is frequently a very slight surface deposit which can be removed by very weak nitric acid, a few drops per ounce of water, without fear of injuring the image or the tone.

The production of lantern slides by means of collodion emulsion, either wet or dry, is a really enjoyable occupation, which we commend to our readers whilst the present fine weather lasts.

THE NEWCASTLE-ON-TYNE PHOTOGRAPHIC EXHIBITION.

This exhibition of photographs by members was opened on Tuesday last in the Central Exchange Art Gallery, and an excellent show of work is on view. The Judges are Col. Sheppee, Mr. W. Cozens Way, and Mr. P. M. Laws. The silver medal for the best series of three pictures taken by a member at the Society's out-door meetings was awarded to Mr. Gibson, of Hexham, while the prize for the best two pictures taken at the out-door meetings was given to Mr. Goold. The exhibition will remain open until the 18th instant.

The Society's presentation print is to be selected by the whole body of members voting for the picture or pictures most pleasing to themselves; and on the last night of the exhibition scrutineers will be appointed to examine the voting papers.

Among the pictures especially worthy of mention are the medal photographs of Mr. Gibson, No. 8, "Blasted Oak, Staward," and No. 11, "On the Allen Staward;" both fine examples of out-door work. Mr. Goold's prize views of Dilston and Bywell (Nos. 19 and 20) are also exceptionally meritorious. Platinotype printing is well represented by Mr. Dodd, and such workers as this gentlemen will do much to make the process popular; but one must not omit to mention that Mr. W. J. Robinson, jun., also sends an admirable collection of platinotype pictures. Mr. Proctor (who shows a view taken without a lens), Mr. Templeton, Mr. Galloway, Mr. Stevenson, Mr. Borrow, Mr. Balsdon, Mr. Anty, and Mr. Pike, all deserve honourable mention; and the views on the Allen by the last named gentleman were much admired.

THE PALL MALL EXHIBITION.

Final Notice.

Some pictures not hitherto mentioned call for notice, and prominent among these may be mentioned Mr. W. England's unrivalled views of Switzerland (No. 297). Mr. T. Scotton, of Derby, sends a good example of the kind of work he habitually does for the Midland Railway Company, the picture in question (No. 298) being a side view of an express engine. One cannot help thinking that the company should have all such subjects printed in carbon or platinotype. The best picture of several contributed by Mr. Lyddell Sawyer is, undoubtedly, No. 345, "The Three Fishers," which shows three lads fishing from a large trunk placed bridge-fashion across the stream. "The Unfamiliar Tune" of Mr. Edwin Smithlls shows us a violinist who is, evidently not quite used to playing at sight, and the somewhat embarrassed expression is admirably caught. A magnificient sea study (No. 470) by W. P. Marsh is, to our mind, a little marred by the cold inky tone in which the enlargement is printed. Mr. E. Cocking, the Assistant Secretary of the Society, shows some admirable reproductions of oil paintings, and he is to be complimented on his success in this exceptionally difficult branch of photography. We now give a Meisenbach block of a picture in the "medal" frame of Mr. Taglia-

ferro; it shows the monument erected to the memory o Emanuel Pinto, the celebrated Grand Master of the Knights of Malta. The monument is in a side chapel of the great Church of St. John, and is built of marble and mosaic. Even in the present day the coins of Pinto are occasionally met with in Maltese currency, and they all bear the arms shown on the base of the monument.

COLOURING MATTERS AS OPTICAL SENSITIZERS.

BY DR. J. M. EDER.

I have made experiments with a great number of red, green, and yellow colouring matters, in order to determine their action on gelatino-bromide films as optical sensitizers. Each of the following colouring matters was found to exercise a sensitizing action quite in accordance with the absorbtion spectrum obtained by the transmission of light through a dry film of gelatine coloured with the dye, and

all of those mentioned are sensitizers for the extreme red rays of the solar spectrum. Iodine green, bromeosine, iodeosine, erythrosin, pyrosin, aureosine, ethyleosine, methyleosine, phloxin, rose-Bengal, gyanosin, hydrochlorate of rosaniline, acetate of rosaniline, Coupier's tolnidine-red, bitter-almond-oil green, brilliant green, methyl green, picrate of methyl-green, aldehyde green, Hoffman's violet, dahlia, methyl violet, Paris violet, benzyl-rosaniline violet, gentian violet B, gentian violet B R, resorcin blue, fluorescin, iodcyanine, chlor-cyanine, cyanine sulphate, cyanine nitrate, Coupier's blue, red corailine, naphthaline red.

The following gave no absorption bands, but a gradual action towards the red (often, however, scarcely recognizable):—Carthamine, turmeric, hematoxyline, the same with ammonia, soluble Prussian blue, hydrochlorate of monophenylrosaniline.

Coloured gelatino-chloride of silver films gave the maximum of action in the yellow, and in the same place as with a gelatino-bromide film.

I have taken photographs of oil paintings (under yellow glass) on plates prepared with the above colouring matters, and have found the colour-scale of the paintings to be correctly reproduced. Such plates I call "orthochromatic" plates, as the term "isochromatic" is used to designate the special plates of Clayton, in Paris; and, moreover, the term "isochromatic" is used in quite a different sense in optics.

At Home.

WITH MR. H. N. WHITE: MAKING VITRIFIED PHOTOGRAPHS.

MR. RANDS, the manager of the Ceramic Stained Glass and Vitrified Stained Glass Company, looks rather surprised when we call at 19, Finsbury Circus, and tell him we have come to see how the enamel photographs are made. "The works," he says, "are at Chingford—we have only show rooms and offices here; and I really don't know anything at all about your seeing the factory; but let me show you what we have here."

Almost every branch of photography executed in vitrifiable colours was represented in the show rooms, as the bulk of the work is done to order from the negatives or prints of customers, and the greater part of the pictures were either made on glass, or on articles of crockery, such as plates or dishes. There were, it is true, a good many photographs which had been vitrified on square earthern quarries, like the well-known Dutch tiles, but, as far as we could gather, the public taste does not run so much on these as on ordinary plates and dishes decorated with photographs, or on transparencies for the window. Vitrified pictures are, Mr. Rands told us, coming much into use for placing on graves and mounting in tombstones, an application of them which has been common on the Continent for some years.

Our inspection of the show-rooms is soon over, and notwithstanding the fact that the manager is by no means certain that we can be admitted to the works, he is good enough to accompany us to Chingford by the next train.

The clean bright little village—or, maybe, it is a town—being reached, we turn down a private road with a row of cottages on one side and a meadow on the other, the last two cottages forming part of the works. Mr. White, whom we had never seen before, receives us with a hearty welcome, and at once promises to show everything; also to tell everything with two exceptions.

The establishment hardly corresponds to the general notion of a "works" or factory, as the cottages are comfortably-fitted up in the ordinary house fashion, and are principally occupied by young ladies who are engaged in retouching, painting diapers or borders, and colouring the ceramic pictures. At the back of the cottages is a field, of which a part is laid out as a garden, and beyond the garden beds are three studio-like buildings of wood and glass, while on one side, and as much out of the way as possible, is the stove or furnace where the firing is done.

It is the dusting-on process which Mr. White adopts, and he first took us into the studio-like building where the sensitive plates are prepared, upon which the enamel colour is dusted; and it does not follow by any means that the glass or porcelain first coated with the sensitive mixture is that upon which the enamel is finally vitrified, as it is quite easy to transfer the dusted image to a new glass or tile. If, however, the image is to be transferred, the glass should be collodionized and allowed to dry before the application of the sensitive mixture. The exact composition of the sensitive preparation used by Mr. White is one of those two things which he keeps to himself, but we know that the mixture recommended for this purpose in Dr. Liesegang's "Handbook of Photographic Enamelling"* answers very well, so we will give it here:—

Water	...	...	...	100 parts
Moist sugar	...	...	...	10 ,,
Gum-arabic	...	...	...	10 ,,
Bichromate of ammonium			...	4 ,,

The glass, very carefully cleaned and (collodionized if the image is to be transferred), is now placed on a levelling-stand, flooded with the sensitive mixture, and after the composition has been allowed to remain on for a few seconds, the excess is drained off, the plate being now dried in an inclined position. The drying cupboard is contained in the "dark"—or rather, yellow-lighted—portion of the building; but no doors separate the dark-room from the rest, the entry of white light being prevented by hangings of haize arranged on the baffle-plate principle, so that one can walk in or out of the yellow room without touching or disturbing the hangings. The warm cupboard stands on a tin water vessel, scarcely two inches deep, and about two feet wide by five feet long, the whole being closed, excepting that a pipe is provided, by which any vapour may escape. The wooden bottom of the drying-box stands directly upon the top of the hot-plate or water-bath, and the front of the box is merely closed by means of a curtain. As the plates are coated, they are reared up on edge in the cupboard, and allowed to remain until quite dry, when they are ready for exposure in the printing-frame. Mr. White tells us that much depends upon care in drying, and that many fail in the working of the dusting-on process through drying the plates at too high a temperature; indeed, he tells us that in warm weather he very often uses no artificial heat at all. "What is the temperature in the cupboard now?" we ask; but Mr. White confesses that he has no idea of the temperature in degrees. To the hand the interior of the drying-box seems only a trifle warmer than the external air, and one may perhaps estimate it at about 85° Fahrenheit. The large flat water-bath or hot plate upon which the cupboard stands is kept sufficiently warm by one paraffin heater with a four-inch wick, and turned down very low. "The special advantage of the hot water plate is that it ensures a uniform heat all through the bath," says Mr. White; and once more he takes the opportunity of impressing upon us the fact that very little overheating is fatal, as it bakes the mixture, and renders it incapable of again absorbing moisture.

The exposure is made under a transparent positive, and the greatest care is exercised to see that printing frames and transparencies are perfectly dry; indeed, it is generally considered advisable even to slightly warm them before use. More than this, Mr. White called our attention to an apparatus somewhat resembling a gardener's forcing frame, and provided with a heating arrangement consisting of a battery of paraffin lamps. "This is where the printing frames are placed during damp weather," Mr. White said; "and without some such arrangement for keeping them

* *Photographische Schmelzfarbenbilder.* Ed. Liesegang, Dusseldorf.

perfectly dry, our work would be very uncertain." The exposure required is not a very prolonged one, a single minute in bright sunshine being often sufficient, while in dull daylight half-an-hour or more may be required. No actinometer is used, it being easy for one who is constantly at the work to judge the exposures with sufficient accuracy. The effect of exposure to light is to destroy the power of absorbing moisture which the sugar and gum ordinarily possess, consequently when the plate is withdrawn from the printing frame and exposed to damp air for a few minutes, those portions which have been protected from the action of the light will hold the vitrifiable pigment which is now dusted over the plate, while the most exposed parts refuse to take up any pigment, because they do not become adhesive by the absorption of water. For dusting with the vitrifiable pigment—which is just such a powder colour as potters use in decorating their goods—the plate is laid in a tin dish, and the powder is dusted over with a broad camel's-hair brush. If the image is very slow to appear, one may venture to breathe very cautiously on the plate, after which the enamel colour is again applied. A little consideration will show that in this process over-exposure results in a hard image, while fog or general tinting is a consequence of under-exposure. When a perfect picture, having all the gradations of the original, is obtained, the excess of pigment is brushed off, and the powder colour is fixed by flowing collodion over the plate. If the plate were now fired, the chromium compounds in the film would become vitrified, and would give a disagreeable green tint to the picture, so some means of ensuring their removal must be adopted.

One of Mr. White's secrets is the composition of the fluid in which he soaks the plates at this stage to remove the chromium; but Dr. Liesegang recommends soaking for half-an-hour or so in a two per cent. solution of caustic potash. The preparation used by Mr. White for the removal of the chromium is contained in the largest collection of glass dipping baths which we ever before saw in one place; we counted eighty all placed in a compact row one behind the other, and then gave up the task, as we observed other such rows on another part of the table. The chromium having been removed, and the plate dried, all is ready for the final operation in the furnace, if the vitrification is to take place on the original support; but if the film is to be transferred, the plate must be allowed to remain in very dilute acid (say, one part of nitric acid in sixty or eighty of water) until the film can be floated off, and placed in position on the glass or tile which is to be decorated.

As we leave the place where the dusting work is done, we meet an inventive friend of Mr. White, who has just come to tell him that he has discovered a new use for vitrified photographs. "See here," he says, as he fastens to the door of the room a tile bearing a group photograph; "let these portraits be those of the persons employed in the establishment; you mount this upon the door, and when any one goes out you cover him up with a kind of shield hinged on a wire thus." This suggestion of the "funny man" not only makes Mr. White smile, but it serves as a text for him to explain his views as to the future of ceramic photography. Mr. White, we may remark, is an enthusiast, and he looks on the burnt-in picture as the photograph of the future. He tells us that pictures on glass need not cost so much as to prevent their general use for window decoration. Not only can you make an album of your drawing-room window, but it may be an art gallery as well, decorated with reproductions of the choicest engravings and paintings; while your library windows may be adorned with portraits of all the great masters in letters.

We have now reached the furnace room, and as we enter we see a row of four cast iron muffles along the side opposite to the door and windows. No coal is visible, and for a moment we fancy that the furnace must be fed with gas made on the Seimens system; but no, Mr. White tells us that he is sorry to say that he uses coal, but in order to minimise the inconvenience from its use, he has arranged for all the feed places of the furnaces to be outside and at the back. Wood is, according to Mr. White, the only solid fuel which is quite satisfactory, as this alone is free from sulphur; and he hopes to secure a good supply when the lopping season commences in Epping Forest.

Three of the muffles are large ones, and each has runners for taking twelve iron plates, each of these plates being large enough to carry a square of glass thirteen inches square. The muffles are red hot, and Mr. White is about to fire some plates, but his first step is to draw down the blinds—which, by-the-bye, are black—and to make the room darker than many a so-called "dark room." "This is to enable me to judge of the heat," explains Mr. White; and he says that it would be quite impossible to form any notion if daylight were admitted. Each plate to be fired, whether porcelain or glass, lies on an even bed of whiting, about a quarter of an inch thick, this whiting being spread on the cast iron plates that slide into the muffles, and in every case the bed of whiting is carefully levelled by means of a thick slab of plate glass provided with a handle. To put the iron plates bearing the sheets of glass directly in the hot muffle would be quite out of the question, so Mr. White has arranged a set of paraffin stoves, one for each iron plate. All these are placed in a row, each one towards the left being turned up a little higher than its neighbour on the right. When an iron plate, with its bed of whiting and sheet of glass, has been heated to the full power of the first stove, it is moved to the next, and so on until it is sufficiently heated to be placed in the muffle without danger of fracture. When the muffle is fully charged, it is closed with a heavy iron door, upon which are two tubular pieces which project forwards and fit into corresponding openings in the outer door of the furnace. When this outer door is closed, the flames can circulate all round the muffle, but cannot reach the interior. Still, in the case of colour work, Mr. White finds mischief to result from the sulphur of the coal, so he has put himself to some pains to arrange for the ventilation of the muffles by means of tubes leading from the upper part into the open air. The firing does not take long, but the cooling is a slow process, as if the glass is rapidly cooled, it is so liable to break as to be useless; indeed, two charges a week, or at most three, are as much as can be fired if the plates are properly annealed.

Besides the three large cast-iron muffles, there is an experimental muffle, built up out of fire tiles, and in front of this hangs a framed sheet of glass, balanced sash-fashion by weights—a very necessary protection to the eyes during experimental work.

The photographic department is in one of the three glass-houses already referred to, and the first thing to attract our attention is one of Ottewell's old cameras for making large portraits direct, the lens being a Jamin of nearly seven inches diameter. Although the slide of this apparatus will take a 16 by 14 plate, it is in daily use for the smallest sizes. Mr. White is a little conservative in his notions: he holds strongly to the superior advantages of taking large portraits direct, and has only worked the gelatino-bromide process during the past few months: in pointing to his large bath, and the four half-gallons of solution required to charge it, he could not help expressing regret at keeping it to look at rather than to use.

The dark-room is at the other end of the glass-house, and is partitioned off by doors sliding in deep grooves, so that the whole length can be thrown into the studio if required—an excellent arrangement for those who may wish to work with lenses of long focus.

Outside the studio we find a number of ceramic pictures nailed up; and enquiring the reason why—"It is to test their power of resisting the weather," we are told; but in no case have they shown any indication of deterioration,

although they have been exposed for three years. Still, if a picture should not be sufficiently fired, or if the flux-colour contain too much lead, enamels will be liable to damage by exposure.

It should be mentioned that many of Mr. White's pictures are vitrified on opal glass, and he told us that the English flashed opal is the only material upon which he can depend, the foreign pot-opal melting completely at the temperature required for a proper vitrification of the colours.

Several medals have been awarded to Mr. White for his productions, among which may be mentioned those of the Edinburgh Art Society, and the Cornwall Polytechnic Society; while the Glass Sellers' Company has conferred upon him the honorary freedom of the Company, as well as its silver medal.

HINTS ON POSING AND THE MANAGEMENT OF THE SITTER.

BY H. P. ROBINSON.

CHAPTER 5.—FULL-LENGTH FIGURES.

THE full-length figure as a portrait has "gone out." When the carte-de-visite was introduced it assumed this well-known form, and a year or two elapsed before there was any change; then the head-vignette came in. Photographers stuck to these two forms, and resisted all attempts to add to them for a considerable time. Then the three-quarter figure was introduced, until we came to that monstrosity, the large head that nearly fills the whole space. This last form of card owed its origin to accident. A firm of photographers who possessed a very large stock of negatives of famous people—three-quarter figure, whole plate size—finding that the carte had quite spoilt the sale of their 8×6 portraits, conceived the idea of printing the heads and issuing them as cartes. The ignorant multitude, seeing that so many celebrated characters had had their portraits taken in this way, rushed to have their own done in the same style; and thus it is that even to this day we are sometimes obliged to do these out of proportion cards. Some of the earliest full-length cartes-de-visite were pictorial gems. They were done by masters of posing and picture-making. The art had not got into the hands of the trade then; prices had not fallen below the usual guinea; and photographers could afford to give a picture instead of a map. Cartes of that time by Disderi or Silvy are still beautiful in pose and effect. Then the art, as an art, fell upon evil times. It struck a photograph maker that "ten for ten shillings" would be a good cry to go to the public with; and it succeeded, commercially, for sitters followed like flocks of sheep. They were collected, after paying their money, in a room; a door was opened about every five minutes, and a sitter ordered through it into the studio, where he was fixed up against the head-rest (always ready), exposed, and shown through another door, and left to find his way down stairs. There was no thought given to variety of pose or light and shade; the only consideration was how to get the sitters through the studio fast enough. No proofs were submitted; the sitter had to be content with whatever the manufacturer chose to send him. In those days people were almost compelled against their will to carry their cartes in their pocket for the purposes of exchange, and many did not care for the quality of the portraits, so they could observe the "social custom" cheaper. This was scarcely fair to those who went to the best photographers and paid a good price; and people objected to exchange the beautiful little pictures by T. R. Williams, costing, perhaps, seven and sixpence each, for shilling failures, manufactured by a company.

But this is not a history, and I must return from this digression.

The full-length figure, then, is not so much in vogue as it was twenty-five years ago. It was never a favourite of mine for men's portraits, for I cannot be induced to take any interest in boots and trousers; but it was useful for ladies' portraits, especially when dresses were worn long; They were not so easily managed during the short-skirted period, and I am not sure that it was not the kind of dress that cheeked the full-length portraits. The declension of crinoline also was another check, for it was found difficult to fill up the cabinet form of picture with the thin figures that succeeded the monstrous balloon figures of a quarter of a century ago. The full-length is still useful, and will, I think, become more prevalent. It still affords the best way of showing gorgeous dresses, fancy costumes, and some portraits, such as those of girls between the age of nine and fifteen. There is a great difficulty in showing the age between these periods. A girl of thirteen or fourteen will often look much older in her portrait if some way is not taken to show that she is a young girl, such as showing that she is wearing a short frock, and here it is that the full-length is appropriate.

A full-length admits of a more florid treatment than any other style of picture. A more elaborate make up of the furniture and surroundings is permissible, and pictorial backgrounds may be employed. For ladies' portraits it admits of a greater variety of pose and effect, but it is not so easy to make a pleasing picture of the whole length of a gentleman; there does not appear to be enough of him to fill the picture, he is too long for his breadth, and he almost always looks stuck up to be shot at. Let us finish off the gentleman first, as he presents the greatest difficulty. The problem is, how to produce a full-length portrait of a man, so that he shall look like a gentleman at his ease, without a preposterous look of attempted dignity, self-consciousness, or defiant swagger, on the one hand, or feeble inanity on the other. This is often attempted, but seldom comes off. It is impossible to give rules and regulations in this case, and all that is left for me to do is to tell you what to avoid. If for a standing figure, get some idea of the posture you think would suit the case in hand and arrange the furniture so that it should lead, as it were, to the pose you require. Then get the model to stand in the place you have prepared for him, and instantly take advantage of all accidents. He may not go into the pose you had in your mind, but if he is not thinking intently on doing his best—which exercise of the faculties spoils half the portraits taken—he will perhaps assume a better. This you must seize at once. It will probably require some slight alterations, some slight turn of the head, or variation in the position of the arm. These are easily made, and can often be done without the model knowing much about it. For example, if you want him to raise his arm, with his hand on his hip, if you will assume this position yourself, you will find in most cases he will with unconscious imitation follow your lead. This will not occur to a blundering operator, one who does not seem to know his own mind; but the skilled operator appears to have a kind of magnetic influence on his sitter which is both curious and useful.

All I have said in the chapter on three-quarter lengths as to variety, movement, animation, &c., applies here, and need not be repeated; but in a full-length there is more scope for what may be called technical art than in any other form of portrait. There is room for the photographer to show his knowledge of composition, a subject into which I have entered fully in "Pictorial Effect" and "Picture-Making by Photography." The student has, I hope, read these little essays, and will know how to arrange his accessories so as to get balance, variety, and contrast.

To make good full-length portraits of ladies is a comparatively easy matter. They are nearly always picturesque in themselves, and, except when an insanity of ugliness seizes those who command the fashions, as it did when the order for wearing crinolettes was issued, this dress lends itself to the needs of the artist. Here again I have said,

in a former chapter, everything that is necessary regarding the arrangement of the figure, for what applies to the three-quarter will apply nearly to the full-length; but I might add here, what I think has been omitted before, that a lady should never be seated in a very low chair; however easy and natural it may look in life, it often results in the representation of a mere bundle of clothes in a photograph; and if a lady is seated in a high-backed chair it is well to avoid letting the back of the chair rise above each shoulder, which often produces the appearance of deformity.

It is difficult to say anything definite about the posing of ladies without taking the style of dress into consideration. We have just passed through a period of seven years distinguished as being the most picturesque and beautiful in regard to ladies' dress that the world has seen for centuries. Æstheticism, however it might be sneered at by the unthinking, or brought into contempt by its too enthusiastic votaries, did wonders for what is known as taste. The reaction that has come has been fortunately only partially successful. The tyrants who rule over fashion, for trade purposes, have perhaps for the first time in the world's history been partly defeated. They ordered that beauty shall be abolished for a season, and ugliness reign. The preposterous forms in which some women now appear is absurd. The curious thing is that they don't see it themselves, and laugh in each other's faces; but they don't even smile at one another. I have just photographed a short lady who, by the curious arrangement of her dress, looked so like a bantam that I almost expected her to crow!

But the reign of ugliness is only partly successful. There was a great revolt against the revolution never before known in the history of fashion. Women are now not the absolute slaves to the dictates of fashion that they have hitherto shown themselves to be throughout the ages. Some of them have been educated, and have learned that taste does not consist entirely in dressing to order to suit trade purposes. Therefore, some of them, chiefly the wives and daughters of artists, combined together and signed the pledge against crinolette! We owe it to this that there are still women to be seen who do not look ridiculous, and who can afford to stand for full-length portraits. In the old crinoline times a lady used to justify herself for her inflated appearance with the pretence, "I must not be singular." That excuse no longer holds. So many sensible women still cling to the good taste they have learnt during the interregnum of crinoline that there is no pretext for wearing it except absence of taste or a determination to blindly follow the dictates of fashion at all costs.

NOTES FROM NEW YORK.

Fall Lantern Exhibition by the New York Amateur Society.

The first fall lantern exhibition given by the Society of Amateur Photographers here occurred on the 30th inst., and, despite the inclement weather, was largely attended by many gentlemen and ladies.

Several interesting slides were exhibited, including views in the Colorado River, Candor, Arizona, mining districts, and the Cliff Dwellings in the same region, by Mr. R. Spaulding, an amateur of but two years' standing.

Other views, made on dry plates, of watering places near this city and the White Mountains, by Mr. Brush and Wright, were much admired. Slides of the World's Exhibition building, at New Orleans, La., were kindly contributed by Mr. Edward L. Wilson, of Philadelphia. Among those present was Mr. York, of Loudon, well-known for his manufacture of fine lantern slides. He promises to be present at a future meeting, and it is hoped that he will give a talk to the Society on the subject of lantern slides. I learn that he contemplates visiting Washington soon, and has thus far made some three hundred negatives, and has been as far north-west as Manitoba.

The entertainment was much enjoyed by the members and friends.—The New York Amateur.

New York, Oct. 31st, 1884.

MAKING AND DEVELOPMENT OF GELATINO-CHLORIDE PLATES.

BY T. BAYNTON.*

I must commence by stating that I am indebted to Mr. A. Cowan for the emulsion formula, and to Mr. B. J. Edwards for the developing formula, although I have made some slight alteration in them. The members will find that they can, with this kind of plate [sample transparencies from negatives taken during the summer were here passed round], make very beautiful lantern slides, and so amuse their friends and themselves at the same time on these dull winter evenings.

For the convenience of those members who wish to make their own emulsion plates, I will now give the formulæ. Those who do not care to be at this trouble, can obtain them from me if they like.

Silver	1 ounce
Water	10 ounces
Gelatine (hard)	1 ounce
Sodium chloride (pure)...	½ ,,
Water	10 ounces

Let the gelatine soak for a short time, and then dissolve by placing the vessel in water at about 110° F., and warm the silver to the same temperature. Now take into the dark-room, and mix by any of the well-known methods, so as to form a very fine emulsion. It may now be cooled by placing the containing vessel in running water, and when cold, wash, re-melt, filter, and coat in the usual way. Expose for five seconds (more or less, according to the density of the negative) to diffused daylight, and develop with—

No. 1.

Neutral oxalate of potash	2 ounces
Chloride of ammonium...	40 grains
Citric acid	2 drachms
Distilled water	20 ounces

No. 2.

Sulphate of iron	4 drachms
Alum	90 grains
Distilled water	20 ounces

Add one part of No. 2 to an equal part of No. 1, but do not reverse this by adding No. 1 to No. 2, or the result will not be so good. If the plate is properly exposed, the result will be a fine purple-black tone in the transparency. If you like a warm brown tone, expose double the time, and add an equal bulk of water to the developer. The development in this case will be much slower. Many different tones may be obtained by using the various developers given by Mr. Cowan. To fix the picture, use one part of hypo to eight parts of water. After fixing and washing, put the plates for half-a-minute in the following:—

Alum	1 ounce
Sulphuric acid	1 ,,
Water	20 ounces

This will dissolve the opalescence caused by the oxalate. The plate must now be well washed, dried, and varnished in the usual way.

Notes.

The Lord-Lieutenant of Ireland has promised to open the Exhibition of the Photographic Society of Ireland on Tuesday next, while both as regards quantity and quality the Exhibition is expected to be an exceptionally good one.

The awards are to be made by a method which is practi-

* Read before the Coventry and Midland Photographic Society.

cally identical with that suggested by Mr. Harry Pointer, in our issue of last week.

Mr. Common's labours in applying photography to astronomical research are very highly spoken of in the recently published Cantor lectures of Mr. Norman Lockyer. Speaking of the photograph which formed one of our supplements during the past year, Mr. Lockyer says:—"This photograph I consider to be one of the greatest achievements of modern astronomy, and I have taken occasion elsewhere to say what I believe to be perfectly true, that if all the human efforts which have been directed, so to speak, to this group of nebulæ in Orion for two-and-a-half centuries were put in one scale, and this photograph were put in the other, it would weigh them down; in fact, that sixty minutes of nature are worth two-and-a-half centuries of art."

The photographing of the treaty of Tientsin was announced as a novelty, but it turns out to be no novelty at all. Turning over the pages of the *Daguerreian Journal* for 1851, the other day, we came upon the following paragraph:—"We find in one of the foreign magazines for 1843 a notice of a curious application of photogenic drawing." It says, "We have just heard of a curious and interesting practical application of a recent scientific discovery, which will somewhat startle our readers. The Chinese treaty was copied by the photographic process of Mr. Fox Talbot, and the copy so made, for the sake of securing perfect accuracy, is now deposited among the State papers."

The President of the Photographic Society, speaking from the chair on Tuesday last, referred in glowing terms to the great prosperity of the Society; and as an illustration of this he mentioned the fact that there were no less than forty-three candidates for admission into the Society, a condition of things quite unprecedented.

That the Society is prospering there can be no doubt, and we heartily congratulate the President; still, the forty-three candidates must not be taken at par.

The charge of one shilling per foot for wall space at the Exhibition is not made to members of the Society, and, moreover, it is excused to those who may become members at the November meeting. In addition to this, those elected in November or December pay no subscription until the beginning of the following year. Out of the forty-three members elected on Tuesday last, twenty-five are exhibitors.

"Sixteen shillings an ounce was the price of pyrogallic acid when first I used it in photography; now it is nearer sixteen pence."

The above remark was made on Tuesday last by Mr. John Spiller in reply to a remark as to the impracticability of using hydroxylamine on account of its high price. One may not be wrong in expecting the reduction in price in hydroxylamine salts to be more rapid and more considerable than that which we have experienced in the case of pyrogallic acid.

One may expect that the Siemens unit lamp will come into general use as a working standard of light for the photographer, and from Abney's description we imagine that the cost of the apparatus need not be more than two shillings or half-a-crown. Indeed, an ordinary spirit lamp may be so adjusted as to serve very well.

Acetate of amyl (artificial essence of jargonelle pear) is not an extremely expensive fuel, considering that one is not likely to burn the lamp for a long time at a stretch. Perhaps the acetate may cost eight or ten shillings a pound.

It was hardly expected that the Pall Mall judges would make any awards for apparatus, but they did so at the eleventh hour, Mr. McKellen taking a medal for his excellently designed camera (see p. 703). This camera did not arrive till about a fortnight ago, the instrument which was originally prepared for exhibition having been inadvertently parted with.

Details given in our report on page 723, show that the Photographic Exhibition, which closed yesterday, was one of the most successful—if not the most successful—which has yet been held by the Photographic Society of Great Britain.

From Vienna we hear that isochromatic plates are being used for portraiture in the studio.

The uniform of a Captain in the Hungarian Cavalry presents such an array of bright colour as one rarely meets with, and to satisfactorily photograph one of these officers in uniform has been considered impracticable; but Herr Scolik says that when azaline plates are used, there is no difficulty, the red trousers showing lighter in the picture than the deep-blue portions of the uniform.

The Emperor of Germany has decorated Dr. H. W Vogel with the order of the Red-Eagle.

Badly as photography was represented at the Lord Mayor's Show on Monday, we are glad to say that the President of the Photographic Society and Mr. W. England were present at the banquet in the evening.

Unfavourable as the day was for instantaneous work with the camera, Mr. W. Cobb obtained a series of about half-a-dozen pictures on ten by eight plates, the exposures being made from a point near the west end of the Holborn Viaduct. Although the plates were exposed at three o'clock in the afternoon, and Mr. Cobb took them to Woolwich for development, he exhibited a transparency at the Pall Mall Gallery during the evening.

Half-a-dozen Meissenbach-block portraits, which are to

be found on p. 16 of *Cassell's Illustrated Almanack* for 1885 speak well for the future of the photographic block work as compared with wood engraving. To produce wood engravings of equal merit would certainly cost six or eight times as much as the price of the blocks. Mr. Heywood, of Manchester, also issues an almanac illustrated with Meisenbach block portraits.

The late Mr. E. Authony, of New York, encouraged photography in a very practical fashion. In 1851 he offered a prize of 500 dollars for the most important improvement in practical photography that should be effected during the year.

A novel exhibition, of which photography will form a part, is to be held in Bristol next February. It relates entirely to the industrial pursuits of women, the object of the promoters being to show the progress made by women who follow some line of work as a business. Amateurs, therefore, are ineligible. Lady photographers are not numerous, though we may expect to see the ranks extended now that ladies have begun to practise the art as amateurs; but there must be hosts of retouchers, colourists, mounters, and operatives engaged in the preparation of albumenised paper who are females. Of the hundreds of young ladies who are engaged in reception rooms we say nothing, as they scarcely come within the scope of the plan laid down by the promoters of the exhibition.

Nature tells us how the illuminated fountains at the Health Exhibition are made; arc lamps being used to project a cone of rays into the central portion of each stream of water as it issues from the jet; but the nature of the arrangement presents no features likely to be novel to attentive readers of the *Photographic News*.

The drawback of photographic albums is, that give what price you like for them, they *will* fall to pieces. We learn from the *Paper and Printing Trades' Journal* that some one has invented a flexible metal back, making what has hitherto been the weakest part of the book to become the strongest. The back is expanding, and the leaves can be added as required. Soiled leaves can also be replaced. If the album does all that is said of it, it will be a boon indeed.

Patent Intelligence.

Patent Sealed.

10,950. Alexander Henry Reed, 90, Cannon Street, London, Engineer, for "Certain improvements in photographic cameras."—A communication to him from abroad by Calvin Rae Smith, New York, United States, Artist.—Dated 5th August, 1884.

Specification Published during the Week.

4906. Arthur Fullerton Howman, George Street, Oxford, in the County of Oxford, Photographer, for "Dark slide for photographic cameras."—Dated 30th September, 1884.

A single dark slide in which the shutter is entirely withdrawn, the slot closing by a spring arrangement somewhat resembling that ordinarily used in America.

Reviews.

DE L'EFFECT ARTISTIQUE EN PHOTOGRAPHIE.

Par H. P. Robinson. (*Paris: Gauthier-Villars*).

Here we have a translation into French of Mr. Robinson's last book, the editing of the French edition having been excellently done by M. Hector Colard, of Brussels. To merely translate a book like that of Mr. Robinson is an impossibility, as he who endeavours to express such an author's meaning in another language must strive rather to write a new book embodying the sentiments of the original, than to translate. We congratulate M. Colard on his success in carrying out a difficult undertaking.

COMPETITION OF PROCESSES FOR LANTERN SLIDES

BY GEORGE SMITH.

An editorial article bearing this title which appeared in a recent number of the Photographic News (p. 674) seems to me to call for some remarks. Owing, doubtless, to some misapprehension, the negatives in question were handed to me for the purpose of reproduction by the Woodbury process, before I was made acquainted with the origin and object of the competitive trial. I was, unfortunately, not present at the meeting of the London and Provincial Association when the project was discussed, and had only heard accidentally that they were going the rounds. What I said at the recent meeting when the subject was again discussed has evidently been misunderstood. I went there for the express purpose of learning what was really wanted. First, how the slides were to be judged, and secondly, on what points. Neither appeared to have been considered. I could only gather that they would be examined, and the one which rendered the nearest the half-tones of the negative would be the one preferred. I still fail most completely to see in what way the proposed trial can possibly help the point in view. Who can doubt that from two admittedly good negatives, results that can leave nothing to be desired could be done by any process? Surely the necessary transparence of the shadows and clearness of the high lights can be guaranteed by an expert in any of the recognised photographic processes. The proposed test would therefore necessarily run the various photographic processes very close together, and become one of very nice discrimination to detect any difference whatever, except possibly in some. When, however, the highest skill of the various photographic processes becomes, as in this case, pitted against the mechanical process which I employ—and the test will evidently be strained to its utmost to distinguish between them—I thought it necessary to point out that it might very well happen that if it came to be a question of microscopic criticism, the inevitable, though slight, loss inherent in the conversion of a photographic picture into a printing mould would inevitably tell against the mechanical process.

The simple fact is, that the proposed trial cannot possibly lead, at any rate directly, to any decision whatever except that from picked negatives exceptionally good slides from a photographer's point of view, may be produced by any process, whereas, if judged by a general vote of the meeting simply from its appearance on the screen, it would, at the test, only indicate that—either by design or accident—the author of that particular slide had best *interpreted* the negative.

The reply to my question as to what would be considered the best slide, "the one which most faithfully rendered the negative," convinced me at once that the point to be considered in producing a transparency for the lantern had totally escaped the notice of the proposers of the trial.

Nothing is more certain than that a good negative always has a greater range of tones than can be printed by any process. I mean, of course, that unless some of the details are sacrificed, the general result is poor and flat in the extreme. In all ordinary silver prints, not only are the lighter half-tones lightened in the fixing, but the deeper shadows bronzed in the printing, thus giving a more brilliant pictorial effect at the expense of truth of gradation and of light and shade. This is far more the case with the modest gelatine negative than with wet collodion, the range of tones in the better plates being simply enormous, and far beyond printing capacity. It becomes, therefore, very necessary to dodge the printing, not with the view of greatest possible

amount of detail out of the negative—any one by any process can do that—but to get a brilliant picture from a flat negative. Now this is precisely the quality of these negatives, in my opinion. Technically they are excellent, but printed right out by any process, the pictures they will give must be flat and poor.

I foresee, then, that as the first idea is to see which process will give the greatest amount of detail of tone—while every artist would endeavour rather to get the best pictorial effect—the decision will be two-fold, and neither satisfactory. The technical party will squabble about detail, while the practical party will be guided only by general effect upon the screen, and neither will have the slightest chance of learning which is the best process.

Long experience has taught me that it is utterly impossible—or, I should rather say, perfectly useless—to attempt to get all that there is in a good negative. It can of course be done, but the pictorial effect is dull and heavy. This, at any rate, is not the defect in the Woodbury process, for I consider that there is no process which will so faithfully render every gradation of half-tones as this or its analogue, the carbon process.

It is only when the question of sharpness is likely to arise that I have the slightest doubt about the Woodbury process in my hands being treated upon any print. If this extreme sharpness is desirable—as, for instance, in the slides of shells and corals which I showed at the Photographic Society's lantern meeting Oct. 20th—it can easily be obtained.

It is precisely because the greater part of my photographic experience is in connection with the Woodbury and carbon processes that I always insist on the importance of a bit of clear glass in a negative. Nine negatives out of ten—I might say ninety-nine out of a hundred—are over-exposed. What is the use of getting detail which cannot possibly be printed? It may be an advantage on albumenized paper, as otherwise the printing might go too fast, and too many prints be lost from over-printing; but it is a positive curse to all mechanical printing processes, and has given rise to no little vexatious trouble in attempting to render the detail. I repeat, once more, that over-exposure is the glaring defect of the average gelatine negative, and abuse of the splendid power which the introduction of the gelatino-bromide process has given the photographer. I should explain that by over-exposure I mean practically imperfect development, for I am quite aware that it is possible to over-expose and restrain the development. I do not, therefore, advocate an under-exposed negative, but one which is fully exposed, but restrained, so that the deepest shadows shall remain practically clear glass. This will always allow of development being prolonged until proper printing density is obtained. Such a negative is fit for any printing process; but the poor, washed-out ghosts, with enormous amount of detail yet with no contrast, although they may pass muster from their purity and clearness as excellent negatives, are, to my mind, but a very sorry result compared with what judicious treatment would have produced from the same plate.

The standard of excellence in photographic prints is very well understood, and is a high one; but the standard of negatives has a much higher importance, and is very much neglected; while the standard of excellence in a lantern transparency would appear to be very imperfectly understood.

THE PHOTOGRAPHIC SOCIETY'S EXHIBITION.

[From *The Artist.*]

THE rooms of the old Water Colour Society have again been given up this year to a show of work in black and white, which is of considerable importance and unusual excellence. It is not our desire to enter into the chemical side of the art, and we will therefore content ourselves with the record of one fact—the absence, except in one case, of work in collodion. Everything now is gelatine, for everything must be, if not instantaneous, at least rapid. A careful inspection of the 600 odd subjects impresses us with some idea of the very rapid strides that photography has continued to make since the comparatively recent time of Daguerre in his scientific relations; but it also convinces us that though there is an evident endeavour to secure "pictures," there is not a corresponding knowledge of the various rules on which the success of a picture depends. In truth, very little purely "portrait-studio" work is exhibited here, and, with the exception of animal subjects, which, it must be acknowledged, are very difficult to secure, pictorial photography seems to receive by far the greater amount of attention. Amongst this, some of the earliest plates to attract attention are J. P. Gibson's very satisfactory set of subjects taken on the Tyne and on the Allen. Vittorio Stella, too, deserves commendation for the "Views in Switzerland," which have deservedly secured a medal. Not so far from this is a platinotype of Lady Brooke, by H. S. Mendelssohn, which, being hard and slatey, does not do credit to this process. The "Instantaneous Sea Studies," by W. P. Marsh, which have obtained a medal, are very fine; but here, also, the autotype enlargement of one of them, hanging on the other side of the room, is not a success. Four figure subjects, by H. P. Robinson (medallist), hard by, are very excellent, being brilliant and clear, "The Mill Door" deserving especial notice. They are undoubtedly the best figure subjects in the collection. The reproduction of Burne Jones's "Six Days of Creation" is a dismal failure; the "Breaking Wave," by C. Grassin, close by is, however, a very fine study of wave motion. B. Wyle's "Cloudland" is a set of four grand subjects, the bottom one being especially fine. The "Portraits," by J. Lafayette, though occupying the place of honour here, do not strike us as being particularly happy, and cannot be compared with the portrait of Miss Mary Anderson, in the Woodbury process, which is a wonderful photograph of a superb model. The negative of this is by W. & D. Downey. Another set of "Cloudland," by Benjamin Wyles, is very nearly as good as could be desired, and in its unpretending excellence compares very favourably with such subjects as the "Church of the Knights of Malta," by A. G. Tagliaferro. In fact, it will be found that in almost every instance the architectural studies are by no means up to the standard of the other work, and it is refreshing to turn to such work as F. M. Sutcliffe's "River Bank," or H. J. Godbold's "Rescued," which latter is a perfect gem of colour. The studies of flowers by Henry Stevens, are not, we think, quite up to his very high standard, but it may be that he has spoilt us in the past by the very superb work which he has from time to time shown. The portrait of Miss Constable, in the series for which H. S. Mendelssohn has obtained a medal, is stiff and constrained in attitude; but beneath it is one of the most successful photographs, that of Mrs. James in the same series, we ever remember to have seen. There are some good gelatino-iodo-bromide plates, by Captain Abney, of views on the Cherwell, which should not escape notice, and a set of portraits by W. N. Malby, notably that of the Chinese gentleman, deserve attention. "Mother's Love," by J. Hubbard, is poor in tone and unhappy in choice of picture. It has been awarded a medal. The "Yachts racing in the Solent," by G. W. West & Son, are very good, and much elaborate care has evidently been bestowed on them. "North Wales," by Captain Abney, should not be overlooked, and the six "Prize Dogs," by T. J. Dixon, are good. The "River Scenery," by W. McLeish, would be very good were it not so broken up; and G. Hadley's "Small Studies" well merit their medal. In this set, look at the old lady reading in the centre. There is a good subject near this, hailing from the School of Military Engineering, called "Near the Waters-meet, Lyn Valley;" and Edward Dunmore's "Views of Hampstead" are clever. The first series of portraits by Lafayette, which are prominent in this part of the room, have received a medal. The pose is in nearly every instance remarkably well chosen, and is evidence of considerable artistic feeling on the part of the photographer—a quality which is far too often absent. The London Stereoscopic Company have some good work on exhibition; but why Mr. Kyrle Bellew should have been photographed in the bank-holiday attire we see him in, is past comprehension. It is very evident that photographers have much to put up with. "A View on the Hebden," by H. Forsyth, is a good subject, somewhat marred by the waterfall. Edwin Smithells has an eye for real humour, the "Unfamiliar Tune" being decidedly amusing. W. Byrne's portraits of children are too well known to need more than passing reference, and, if the attitudes are a trifle strange, the work is in every way excellent, On the screens Symonds & Co. exhibit some of their unequalled "Yachts," a very clever use of shadow in the first of their series being a good point. Two landscape subjects, by A. Stoll Bailey and F. W. Broadhead, respectively, should be good, but can hardly be seen; and Mrs. S. G. Payne secures a medal with "Knuckle Down Tight," an amusing subject of no great pretensions. J. E. Mayall exhibits a very characteristic portrait of Henry Irving, and the set of "Views" by B. Wyles completes a necessarily prescribed list of what deserves especial mention. One hardly expects to see much improvement over the very good collection of last year, but we feel that this year the average of that season is certainly maintained.

MR. MACBETH'S ADDRESS TO THE EDINBURGH PHOTOGRAPHIC SOCIETY.

We have now reached the twenty-third year of our Society, and have good reason to congratulate ourselves on the life it still manifests. It has attained not only a high position in point of numbers, but many of its members have distinguished themselves in the production of beautiful work, as these walls to-night testify, exhibiting general intelligence in every branch of the art.

I had the honour of being called upon by the Photographic Club of Edinburgh during its last session to make a design for the diploma of its members. I represented photography there, not merely as a handmaid to nature, science, and art, but I designated her as the daughter—filia naturæ scientiæ artisque—a much higher and more endearing relationship, ever ready, ever willing, and ever lovingly endeavouring to meet the wants and profoundly respect the claims of each.

Something more than mere service is necessary in promoting the interest of any of its departments. It is love and devotion to any worthy pursuit that is felt to be the mainspring of successful effort. Any society depending upon mere awards for stimulus, apart from disinterested exertion, soon ceases to have the most wholesome influence. Emulation is good when it can be carried out without giving offence, but in the case of many professional men competing, I find it is the opinion of several of our best members that adjudication and the giving of awards is fraught with considerable danger—apt to make shipwreck of the best of feeling—at least, introducing elements of unavoidable jealousy and dissatisfaction. However, there may be an exception. In the case of young beginners, in the study of any profession, some stimulus is not only necessary, but helpful, and a prize becomes an object.

A society like this has many attractions, and none greater than the opportunities which it presents for the cultivation of taste. We cannot enter upon the smallest detail of any department of its study without feeling the need of acquiring proper methods of procedure, and we always find that the photographer who succeeds most, is one who well directs his work, and spares no pains in cleanliness, and great carefulness of manipulation.

It hardly becomes me to say anything regarding the education essentially necessary to a photographer. Nothing seems to me, who am but a novice in chemistry and the mechanical arts, more important and desirable for anyone proposing to follow photography as a profession than by every means in his power to acquire a sufficient practical knowledge of chemistry and its nomenclature, so as to be able at once to read and work out formulæ as they come from our best authorities.

I think also he should be well read in, and familiar with, some of our best books containing workshop receipts, enabling him to make good use of these in mechanical appliances, such as photogravure work or blockmaking to accompany types—arts which are fast encroaching upon the hitherto laborious and very expensive efforts made in the interests and requirements both of science and art.

Most of our young men who are following photography as a profession find they are best educated in the manipulative part of their work when their services are engaged as general assistants. It is a long time before they are entrusted with the arrangement of the sitter, seldom indeed till they are their own masters. During this early period they should not only be watching how their employers treat their subjects, but they should have an intimate acquaintance with all artistic arrangements, as so well explained and inculcated by Mr. Robinson and others, but more especially exemplified in the works of some of our standard painters such as Velasquez, Rembrandt, and Vandyk.

Then I would have the beginner to discard all painted backgrounds with the ordinary photographic accessories upon them. As the work is derived directly from living subjects, so should the background and surroundings, if such be desired or needed, be composed from real objects, and these as much as possible conforming to the associations of general good society. Any subject is greatly lessened in interest when the same painted background crops up under every arrangement. Much ingenuity has yet to be exercised in directing the light and shade of a background, so as to give full effect to the head and figure. It is in the practice of this treatment that the photographer, apart from development, will manifest his artistic knowledge and judgment.

In making such remarks, I cannot express an honest opinion without fear of offending some one. But permit me to say that photographic portraits are never finer than when thrown out in simple relief from a plain background; it may be painted in certain forms of light and shade, and by turning it round to any position it may be easily adapted to any pose. Simple dark or light cotton fabrics make beautiful drapery. Tapestry and real oak panels made plain, without ornament, are very serviceable; there is nothing more convertible, nor more likely to produce variety, than these. When special objects, such as the old hackneyed pillar and balustrade present themselves, you feel that they are allied to a past age in art. I hope the day is not far distant when there will be a demand for photographic portraits taken in one's home, with the individual associations about them. This would be a great advantage over the painter, unless he too availed himself of such; it would be telling on the originality of portraits were this more recommended and acted upon.

As an artist, I have taken a deep interest in those efforts of photography which are now unquestionably making some worthy appearance in the way of artistic arrangement: I refer more particularly to the treatment of subjects of ordinary human life. Hitherto such attempts have been greatly prevented by many unavoidable obstacles, but I am now not without hope that through general intelligence in the requirements of the picturesque much will be apprehended, especially through instantaneous work, of many beautiful compositions as seen in the unconscious and charming incidents of everyday intercourse, which, without the highly sensitive plate, would never be secured. Success in the gathering of such subjects is only to be had by the concealment of the instrument. I am told that Mr. Edwards, of London, carries nothing with him but apparently a small travelling-bag, with only the front of the lens exposed; and the focus always being suitable, he secures some wonderfully picturesque subjects in every way worthy of being completely treated on canvas.

Knowledge is power. Permit me then to advise all young aspirants aiming at the cultivation of an acquaintance with the beautiful in nature and in art, to look at the works of men famous in design, such as Sir Frederick Leighton, Burne Jones, or one of the most recent, Walter Crane, whose wonderful fertility appears in that beautiful work entitled the "The First of May." Works of such men as I have just mentioned may not be considered at all applicable to photography, because it does not pretend to be creative; but then such works make the best examples of arrangement and composition. Familiarity with good designs becomes educational; at least, to admire such makes one very difficult to please, and puts one in the pursuit of higher attainment. No photographer is to be excused who does not very frequently look at such publications as *The Century*, *Harper*, or the very cheap and interesting work, *The Magazine of Art*. A close and careful acquaintance with these will go far to foster a taste for art, and enable one eventually in some measure to imitate them.

Correspondence.

SWIFT'S OXYHYDROGEN MICROSCOPE.

Sir,—An illustration and brief description of Swift's oxyhydrogen microscope appeared in last week's News, but I think no one will be able to learn much of the purpose and capabilities of this apparatus from the too-condensed description given by the maker, and published in the Journal of the Royal Microscopical Society.

Primarily, I believe, this gas microscope was intended for exhibiting on the screen objects mounted on microscopic slides. Many lanterns for this purpose have been brought before the public from time to time, but all have been more or less unsatisfactory to the microscopist. They all failed in that most important point, *definition*; and when the image was much enlarged, or when any but very low powers were used, the picture was out of focus at the margin. For all but purposes of amusement each lantern has been of small utility, and a good lantern, capable of exhibiting microscopic objects with sharpness of detail and brilliancy of illumination, has been long a desideratum.

With these uses of the lantern I have at present nothing to do, but wish merely to point out in what way it is, in

my opinion, of far higher value than an instrument, no matter how perfect, for merely showing objects on a screen, and how it appears to be, in addition, one of the most complete and valuable pieces of apparatus the photo-micrographer can possess.

Shortly after this lantern was exhibited at the Royal Microscopical Society, one of our most eminent photo-micrographers suggested to the makers that they should try to use it for taking photo-micrographs, which was accordingly done, and with great success. A photograph of a fly's tongue, taken with the lantern and a one-inch lens of 40°, is decidedly the sharpest and most brilliant photo-micrograph I have ever seen. It was taken on a quarter-plate, but later experiments have proved this apparatus to be capable of making photographs of almost unlimited size, without any perceptible loss of sharpness. The illumination was given by a microscope lamp of good construction, burning paraffine, simply to test the general applicability of the lantern for photo-micrographic work, for it is not always convenient to use oxyhydrogen gas, although, had it been used, the exposure would have been considerably shortened. Doubtless, for great amplification, or with high powers, it would be advisable, or even necessary, to use gas, to get sufficient light; the same may be said with reference to using the polariscope, which always cuts off a large amount of light.

The smaller photographs were taken with convergent light direct from the condensers; in fact, the lantern was precisely in the same condition as when projecting on the screen in the ordinary way. When large photographs, such as would be suitable for lecture diagrams, are required, an achromatic meniscus lens must be used to elongate the circumferential rays, and thus get a flat picture; but with small pictures this is not necessary, as all requisite flatness of field is obtained without it.

For such a picture as the first one taken, fly's tongue, an exposure of three minutes was found necessary, with paraffin lamp, using Wratten and Wainwright's plates. The fact that this object, which, as every microscopist knows, is a good test of the definition of the lower powers, came out with such brilliance and sharpness, proves that this lantern is eminently suited to the requirements of the photo-micrographer, and I am glad to be able to call the attention of my fellow-workers to such an acquisition.

As a rule, photo-micrography is very troublesome and fatiguing work, and none but those who have devoted much time to it can appreciate what a real blessing it will be to get rid of the camera and all the paraphernalia of lamps, condensers, focussing eye-pieces, rods and screens, &c., &c., and use only a convenient lantern, mounted on a tripod stand. Instead of tiring and trying one's eye-sight by staring down a brilliantly-lighted tube to focus some troublesome object, it will be only necessary to focus the object by means of a milled head on a white card, fastened in a suitable position on the wall, or on a convenient holder, just as if one were making an enlargement from a negative. Instead of stooping in an unhealthy and uncomfortable position over a microscope on a low table, to perform the operations of illuminating and focussing, the worker can stand upright, and by means of the tripod raise the lantern to any height desired. Even though it be only possible to use lenses varying from 5 inches to a ¼-inch focus, this instrument will be of the greatest service, and I look forward to working it with no small degress of pleasure.—I am, sir, yours faithfully I. H. Jennings.

EXHIBITION AWARDS: HOW THEY WERE MADE AND ARE MADE.

Sir,—The expression of discontent by the many at the awards made to the few continues. Some go so far even as to doubt the capacity of the judges, without taking into consideration the method of judging. This method is no secret, as it has been described by yourself in the Notes of October 17th. Each judge examines and gives a number of marks to every picture. There is no communication between the members of the jury. After going through the painful and weary process of looking at and estimating every picture, the marks are collated, and the pictures that get the highest number of marks are medalled. This plan is of recent introduction, and is objectionable in many ways. It looks fair on the face of it, but I believe the judges themselves were astonished that some of the honoured pictures got medalled. It is most wearying to those who have to look at every picture, and especially unfair to those who send the largest number. For instance, a judge may say to himself, "Jones has sent a splendid collection, he ought to have a medal; I think No. 1 is best, and will give him 10," which he does, but he is so convinced No. 1 is best that he gives lower figures to Jones' other exhibits. Another judge is delighted with Jones' contributions, but likes No. 2 best, and gives it 10 marks, and less to the others, and so on with the other judges, each preferring different pictures. When the marks are collected it is found that the votes are so divided over Jones' pictures that he does not get a medal, while another exhibitor sending only one or two pictures has obtained the honour for very inferior productions, because the notes were concentrated. By this method, moreover, it is difficult to award the medals in classes—that is, to divide them between portraits, landscapes, genre, &c., which all the discontented seem to think desirable.

The method has one use, and one use only, as far as I can see. It enables the President to proclaim, when he presents the medals, that every picture had the careful attention of every judge. But this does not compensate for the well-founded discontent that has arisen since the method was introduced. The old plan was infinitely preferable. The judges met to find out the best dozen or so of the pictures, and to award the medal to the best man. Each judge made a list of the pictures that in his opinion professed the greatest merit, and it was not easy for a good picture to escape six pair of practical eyes. They then met together and discussed the matter, and made the awards. It would be absurd to say no mistakes were ever made by this system, but they escaped the wholesale discontent we are now experiencing. An Old Judge.

[We have already remarked that complaints as to the awards appear to us to have been fewer than usual this year, and seem to be almost entirely confined to those who have been disappointed in gaining medals; while, on the other hand, expressions of satisfaction are very numerous, and this may be taken as an indication of the value and fairness of the present equitable method. Surely our correspondent exaggerates the case in writing of "expressions of discontent by the many," and "wholesale" discontent. —Ed. P. N.]

Proceedings of Societies.

Photographic Society of Great Britain.

The first ordinary monthly meeting of this Society for the present session was held on Tuesday, the 11th inst., at the Gallery, 5a, Pall Mall East, Mr. James Glaisher, F.R.S., President, in the chair.

The minutes of the previous meeting having been read and confirmed, the following gentlemen were elected members of the Society:—Messrs. W. M. Crouch, F. Machell Smith, E. Smithells, G. E. Thompson, T. Furnell, W. Brooks, Hy. Smith, W. P. Marsh, Ernest E. White, G. H. Martin Whish, T. J. Smith, Jn. Mason Harrison, Chas. Harrison, C. F. W. Sage, W. E. Halse, A. Spiller, J. Harrison Low, M.R.C.S., M. Loring, S. Stagall Higham, T. C. Turner, Junr., B. G. Wilkinson, Junr., T. Scanlan, F. Maude, T. E. Freshwater, J. G. Gibbs, H. G. Moberley, M. H. Clerk, Rev. J. S. Knight, R.N., H. S. Mendelssohn, T. Whitehead, A. Mackie, K. B. Murray, F.R.G.S., F.S.S., G. H. Hunt, D. Barnett, M. Anty, G. Hadley, W. W. Winter, J. Lafayette, S. D. McKellen, H. Bambridge Hilditch, Hon. Slingsby Bethell, B. Wyles, J. Stone, and J. Duncan Pierce.

In reply to the Chairman's enquiry respecting the Exhibition medals, the Hon. Treasurer (Mr. W. S. Bird) stated that

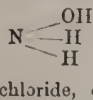
through some hitch the medals had not arrived in time for the meeting; he had a promise that they should be delivered by nine o'clock, and he hoped they would arrive before the meeting closed.

The Chairman said it would gratify the members to hear that the number of attendances at the exhibition was even better than last year. In 1883 the number of members was 718; this year it was 781, being 63 more than that of the previous year. In 1883 the number of tickets reached 4,046; this year the number was 3,732. In 1883 the number who paid was 4,057; this year there had been 4,477. The amount received at the doors last year was £227 9s.; this year they had taken £244 3s. As each year the attendance was larger than that of the previous year, and the money takings likewise increased, so he hoped it would continue; it was also satisfactory for the Society to know that their work was so much appreciated. Speaking of the jurors, he said their work was laborious; every picture was examined separately by each juror, who assigned a certain number to it; these figures were summed up, and from the totals obtained, the highest received the medals. The jurors had accomplished their difficult task in the most faithful manner, and he asked that the usual vote of thanks be accorded to them.

The vote being accorded,

The Chairman requested the members to accord a vote of thanks to the Hanging Committee, which was done. He then called upon Mr. Arnold Spiller to read a paper on "Hydroxylamine used as a Developing Agent."

Mr. A. Spiller, having traced the history of hydroxylamine, said he first brought it under notice about two months ago in an article published in the Photographic News; since then he had made further experiments, and now took the earliest opportunity of bringing it before this Society. Hydroxylamine, he said, was one of the numerous ammonia compounds, having the formula NH_3O. By replacing one atom of hydrogen with hydroxyl the compound is formed, and may be represented thus:



Hydroxylamine, hydrochloride, or hydrochlorate, could be easily produced in an aqueous solution, and it had the property of decomposing silver bromide, when in the presence of a caustic alkali, into metallic silver, bromide of soda, water, and laughing gas, as shown by the following equation:—

$$2NH_3O+4AgBr+4NaOH=Ag_4+5H_2O+4NaBr+N_2O.$$

This was illustrated by mixing the components in a beaker, when metallic silver was shown to be reduced. Mr. Spiller further stated that, unlike pyrogallol, this substance does not absorb oxygen from the atmosphere. Neither does it stain the film. It is now an expensive salt, but if in constant use there is no reason why it should not be cheap. The developer, suited to an ordinary good commercial plate, was given as follows:—

Hydroxylamine hydrochloride ...	2 grains
Caustic soda	5 ,,
Bromide of potassium	½ a grain
Water	1 ounce

The caustic soda takes the place of ammonia, and hydroxylamine supplants pyrogallol; it admits of a wide latitude of exposure, and, not being an oxygen absorbent, enables better colours to be obtained—especially so with gelatino-bromide paper. The only drawback is a reticulation of the film in those plates where soft gelatine has been employed. Examples of negatives and bromide paper so developed were passed round. By modifying the proportions, several colours could be obtained on gelatino-chloride plates, many of which were admirably suited for the lantern. In conclusion, he hoped photographers would give the new developer a trial, and make known their results.

Mr. W. E. Debenham remarked that Mr. Wellington had shown transparencies on bromide plates, developed with hydroxylamine; the colours were very beautiful, but they had a defect, viz., punctures somewhat like that of a needle point all over them. The plates were a slow batch, made expressly for transparencies.

Mr. J. Spiller remembered pyrogallol being sold at 16s. per ounce. There was not the least reason why hydroxylamine should not come down from its present high price, 10s. 6d. per ounce, like pyro has done.

Mr. Leon Warnerke enquired whether it was found to be a more powerful developer than pyro or ferrous oxalate?

Mr. A. Spiller, in reply, said the punctured marking referred to was a reticulation, caused by the use of a soft gelatine; it was due to an evolution of nitrous oxide in the film. It was not so powerful an agent as pyro or oxalate. By increasing the alkali there would be more detail obtained.

A hearty vote of thanks having been accorded to Mr. Spiller,

The Chairman said he was glad to find a new member making such a good beginning, and hoped to hear other papers from Mr. Spiller, and that other new members would follow his example.

Owing to the absence of Capt. Abney from London, his paper on "The Siemen's Unit Lamp applied to Photography," was read by the Hon. Secretary, W. F. Donkin, Esq., M.A., &c. Capt. Abney mentioned several forms of unit lamps hitherto recommended, but few worked as well as "Siemen's." The principal points in this lamp were the fixed diameter of wick, 3-16ths of an inch, and a guage fixed at a suitable distance, the top of which is 2·6 inches from the level of the wick-holder. Acetate of amyl, a substance very cheap in Germany, was found to be best suited to burn in this lamp, and in case of draught, Captain Abney suggested the addition of a glass chimney or cylinder; also an extinguishing screw-cap to prevent evaporation when out of use. He (Captain Abney) had tried it with a sensitometer eighteen inches off, and obtained the same illuminating power as the phosphorescent tablet, and the unit lamp is reliable. Any ordinary spirit lamp can be utilized if the burner is the same dimensions as that previously mentioned; and as acetate of amyl is easy to obtain, anyone can have a standard light much better than the ordinary standard candle.

Mr. J. Spiller remarked that there would be no difficulty in making perfectly pure acetate of amyl, should it be required for this purpose.

Mr. W. Bedford referred to difficulties he met with from reflections when testing standard lights, and said that as so much depended on the surroundings, an absorber was required as well as a reflector.

Mr. T. Sebastian Davis, having experienced similar difficulty, now took the precaution to place a reflector one meter behind the flame of his lamp.

Mr. Debenham suggested that Mr. Bedford should use the simple flame direct from the lamp, lining the lamp with black velvet, and making use of a velvet lined tube, thus cutting off all reflection.

A vote of thanks having been passed to Capt. Abney for his paper,

The Chairman congratulated the following, who were awarded medals by the Society:—Mrs. S. G. Payne, Messrs. Vittori Sella, W. P. Marsh, H. P. Robinson, The Autotype Company, Messrs. C. Grassin, G. Renwick, H. B. Berkeley, Sig. A. Tagliaferro, H. S. Mendelssohn, J. Werge (on behalf of the family of the late Mr. J. Hubbard*), G. West and Sons, Adam Diston, G. Hadley, J. Lafayette, T. and R. Annan, J. Atkinson, M. Auty. Extra medals:—J. Gale (transparencies), S. D. McKellen (improvements in cameras.) The medals not having arrived, the Chairman was unable to present them as usual.

The Chairman said there were many others who had sent pictures of great merit, and to whom he should liked to have presented medals, among whom were Miss Cotesworth, Messrs. Stevens, Dixon, Willis, Pointer, Gillard, Malcolm Clerk, Sutcliffe, Captain Abney, A. and G. Taylor, Seymour Conway, Wyles, School of Military Engineering, Robinson and Thompson, Wainwright, &c., &c., all of which were so good that he only wished medals had been awarded to them as well. Mr. Furnell's shutter was beautiful in its arrangements, and none the worse for the hard usage such things usually get. Mr. Cadett's new shutter was also good, and he could speak highly of all the apparatus shown. Their's was not a professional Society, yet professionals had a majority of the awards this year; hitherto, amateurs had taken the majority of medals. He must say that the amateurs were getting a little behind; he had noticed this elsewhere as well, and hoped that they would strive to keep up with, if not to surpass, their professional brethren.

Before closing the meeting, he wished to congratulate the Society on its large accession of new members; he hoped they would be all workers, and that the Society would do as good scientific work in the future as it has done in the past.

It was announced that the next technical meeting will take place on Tuesday, the 25th inst., and the next ordinary meeting on Tuesday, December the 9th.

Some of the medals having arrived after the meeting closed, the Chairman presented them to those medallists who were present.

* The sudden death of this gentleman was recorded in our issue of last week.

SOUTH LONDON PHOTOGRAPHIC ASSOCIATION.

THE ordinary meeting of this Society was held on Thursday, the 6th inst., at the House of the Society of Arts, John Street, Adelphi, W.C.; Mr. W. ACKLAND in the chair.

The minutes of the previous meeting having been read and confirmed, the Hon. Secretary and Treasurer read a letter from Mrs. Hughes expressing her thanks for the Society's vote of condolence, which was exceedingly gratifying to her, coming as it did from those whom her late husband liked to be amongst.

The CHAIRMAN remarked that as it had been decided to send circulars to the members ascertaining their views on the future of the Society, he would ask the Secretary to announce the result before calling upon Mr. J. Traill Taylor to deliver his lecture on Florida.

Mr. F. A. BRIDGE (Hon. Secretary and Treasurer) had only received twenty-six replies up to date; seven of these were in favour of winding up the Society, nine desired its continuance, and the others were doubtful; they thought the Society's composition must be changed if it were desired to continue. Mr. Bridge said it was in the hands of the members; any alterations of rules or other changes were subjected to notice which must then be given. If they decided to continue the Society he was quite prepared to keep it on. The meeting being favourable to its continuance, Mr. Bridge gave notice of certain modifications he should bring forward at the annual meeting, amongst them reducing the number of vice-presidents to three, and augmenting the committee to twelve. The nominations for office being completed, notice was given to alter the name to "The London Photographic Society," and to rescind that portion of Rule 13 which entitles country members to only subscribe 5s. annually.

In remarking upon the present crisis, Mr. Bridge inquired who started the cry of fire? He had yet to learn if there was any reason why the Society should be dissolved. The loss of their president was a great misfortune, but no valid reason why they should fall. The spreading the report that the Society would die had caused forty-five members to keep back the subscriptions which were due, so that it would be easy to settle the disposal of the funds. Added to this, a resolution had been passed by another society that they would admit the South London members without the usual entrance fee. He (Mr. Bridge) thought it was a pity they had not been allowed to die before receiving offers of burial.

The CHAIRMAN said he had pleasure in introducing a gentleman they all knew who had kindly promised to entertain them.

Mr. J. T. TAYLOR commenced by saying that his lecture would take the form of talk on "Florida," its orange groves and aspects, illustrated by photographic transparencies, thrown on the large screen by means of the lime light. Having traced the history of Florida and its position, the lecturer started from Glasgow, exhibiting many well-known scenes of that locality. Progressing down the Clyde, were shown some fine examples of shipping, moonlight effects, &c. After passing an iceberg New York was reached, several very interesting places being here shown, among them a portion of the great statue of Liberty, presented by France. After visiting Niagara, under severe frost, the lecturer proceeded to Florida; here he illustrated the method of clearing land of timber, and making ready for planting a grove of orange trees, following it up with scenes showing the various stages approaching maturity. Wild duck hunting, fishing, and shooting were illustrated, as also were the settlers' dwellings and tropical productions.

Mr. J. T. HOPGOOD passed round a large photograph of his own orange grove. Having just returned from Florida he would be happy to answer any questions respecting the place.

Mr. W. COBB said he was sure they were all greatly indebted to Mr. Taylor for providing such an interesting and instructive evening; he fully expressed the wishes of all present when he said, may Mr. Taylor be rewarded for his enterprise in the beautiful State of Florida.

The CHAIRMAN having thanked Mr. Taylor for his lucid lecture, moved a hearty vote of thanks, which was accorded.

Mr. TAYLOR, in reply, took the opportunity of bidding his old friends adieu.

The CHAIRMAN announced that the annual meeting would take place on Thursday, December 4th, and the annual dinner at the Holborn Restaurant, on Tuesday, December 16th.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

AT the usual weekly meeting on Thursday, the 6th inst., Mr. W. E. DEBENHAM occupied the chair.

Mr. T. WALTENBERG, having had occasion to use a fresh sample of ready-sensitized paper, had found toning very uneven with it. The prints took a very long time to tone, and were covered with markings and red spots. He asked if any of the members could explain the cause.

Mr. STARNES had experienced the same difficulty in toning with ready-sensitized paper, spots frequently appearing on the prints.

Mr. T. BARKER mentioned a like result from some paper he had recently used; he attributed it to the decomposition of the albumen. He afterwards tried some paper that had been in his possession for a considerable time; this toned easily, and with excellent results.

The CHAIRMAN said he believed the markings and spots were due to the condition of the toning bath caused by using ready-sensitized paper. He had given up using it on this account, and returned to his old plan of sensitizing the paper himself. He did not think it was due to the decomposition of the albumen—instancing the case of a paper giving off a most offensive odour, but toning excellently. The Chairman referred to a ready-sensitized paper that was in the market some years since, prepared with carbonate of silver. He asked if any of the members had seen any published formula of this preparation, as he considered it a far better ready-sensitized paper than that now sold.

Mr. HADDON remarked that he had failed to intensify some thin negatives with bichloride of mercury and sulphite of soda.

The CHAIRMAN said if negatives were washed after bleaching in the same vessel together with the plates from the fixing bath, the hyposulphite in the water would prevent subsequent intensification.

Mr. HADDON asked if there was any better way than the tentative method of finding the chemical focus of an object glass which had been corrected for visual rays only.

The CHAIRMAN suggested sloping the plate at a strong angle for obtaining the coarse adjustment—a gentle slope giving the fine adjustment.

The HON. SEC. read a letter of thanks from the members of the Edinburgh Photographic Club in reference to the recent prize competition of pictures.

Mr. J. M. McKellen, of Manchester, was elected a member of the Association.

EDINBURGH PHOTOGRAPHIC SOCIETY.

THE twenty-fifth annual meeting of the Society was held in 5, St. Andrew Square, on Wednesday, the 5th November, Mr. W. NEILSON in the chair.

The minutes of last annual general meeting and last ordinary meeting having been read and approved of, the ballot box was opened, and the following gentlemen declared duly elected:—Messrs F. W. Palmer, Edward Binning, Charles Waterson, and Alfred Tagliaferro.

The Council, in their annual report, congratulated the members on the continued prosperity of the Society; alluded in terms of regret to the death of Mr. John Lessels, who for seven years had been the esteemed President of the Society; and chronicled the fact that during the past session the Society had lost four members by death, and thirty-seven members by removal or resignation. Fifty-five new members had been elected, making an increase of fourteen; the total now on the roll being four hundred and six.

Then followed a list of the papers that had been read, of which our readers have from time to time been informed.

Among other matters of interest alluded to in the report were, the annual display of work at the December meeting; the presentation of photographs by the late Mr. Lessels; a portrait of the late Mr. John Lessels by Mr. Bashford; and a non-actinic lantern by Mr. Wardale; the distribution among members of packets of hydrokinone and samples of gloy; a ballot for photographs; the adoption of a revised edition of the laws of the Society; and a record of the three popular meetings held in Queen Street Hall.

The annual trip took place on the 10th July, when by the kindness of R. Dundas, Esq., a most enjoyable day was spent at Arniston.

The presentation print for 1882-3, entitled "Brambling," by Mr. Slingsby, of Lincoln, has been distributed, and that for the past session will be issued shortly.

The report was unanimously approved and adopted.

The Treasurer's report showed a balance in hand of £67 17s. 3d.

The Curator stated that he had prepared no written report

but that a sub-committee had been appointed during the past year, who had catalogued and examined all the property of the Society, and to their report he referred. The Society's property, as there specified, was in good condition.

The Society then proceeded to the election of office-bearers for the ensuing session, and on the recommendation of the Council, the following gentlemen were unanimously elected :—

President—Mr. Norman Macbeth, R.S.A.

Vice-Presidents—Mr. J. G. Tunny and Mr. Wm. Forgan.

Secretary—Mr. W. T. Bashford.

Treasurer—Mr. A. M. Forbes.

Curator—Mr. J. M. Turnbull.

In room of the four members of Council who retire by rotation, Messrs. W. Neilson, James Crighton, Wm. Crooke, and G. G. Mitchell were elected, and to fill the vacancy caused by the election of Mr. Forbes as Treasurer, Mr. Hugh Brebner was unanimously elected.

Mr. Macbeth then took the chair, and after a few preliminary remarks read a paper, of which an abstract is given on page 731.

Mr. NEILSON, in proposing a vote of thanks to Mr. Macbeth for his paper, remarked upon the great strides which photographers had made in the æsthetic department of their profession, and he asked the members to compare some of the pictures (?) which were still to be found in some of their old albums, where the fluted pillar and the vice-like head-rest predominated, with the artistically posed groups and other lovely specimens of the photographic art displayed on the walls. And not only that, but he observed a very marked improvement in the pictures from those of last year, both in artistic treatment and in manipulation. But there was still room for improvement, and he thought what was principally required was the artistic training of children.

Votes of thanks were then passed to the out-going and in-coming office-bearers, which were suitably acknowledged.

The President then called the attention of the meeting to the display of pictures on the walls, which, the curator explained, had been sent in by members for exhibition.

A discussion followed as to the continued publication or otherwise of the Transactions ; a first and imperfect proof of the presentation print for the past session was laid on the table ; members were reminded that subscriptions for the current year were due, and after a vote of thanks to the Chairman, the proceedings terminated.

DUNDEE AND EAST OF SCOTLAND PHOTOGRAPHIC ASSOCIATION.

THE second monthly meeting for the season was held in Lamb's Hotel, Dundee, Thursday, 6th inst. The President, Mr. J. C. COX, occupied the chair, and there was a good attendance. After the routine business had been disposed of, a discussion took place on the advisability of holding another Photographic Exhibition.

Owing to the great success of the previous one, the idea was warmly taken up, and it was agreed to hold an International Exhibition in the beginning of 1886. The committee will be elected at the next meeting.

Dr. TULLOCH then gave a lecturette on "Photographic Optics," illustrating his remarks by means of blackboard diagrams. The speaker was most attentively listened to, and at the close of his paper he indicated his willingness to answer any question relating to the subject. A number of inquiries were made and readily answered.

The Council have made arrangements for a Lantern Exhibition to be given in December, and the Chairman also intimated that a practical demonstration of the process of development would be given in the Society's dark room on Monday, 1st December. Members were invited to bring exposed plates with them, and an experienced member will be present to develop them.

COVENTRY AND MIDLAND PHOTOGRAPHIC SOCIETY.

THE monthly meeting was held on Thursday, November 6th, the President of the Society in the chair. After the nomination of officers for the ensuing year, &c.,

Mr. H. W. JONES, F.C.S., exhibited a very convenient method for using ordinary gas in his "Lancaster" ruby lantern, with an arrangement by which he could turn on the ruby light or white light at will.

Mr A. SEYMOUR also sent some negatives, which were thought to be very fine, not only for their artistic merit, but from the fact of their being developed by the soda developer.

The PRESIDENT then called upon Mr. T. Baynton for his paper on the "Making and Development of Gelatino-Chloride Plates" (see page 727)

The transpareneies passed round were very fine, and were much admired, especially when shown in the lantern by Mr. Ambrose.

After a hearty vote of thanks to Mr. Baynton, the meeting broke up at a late hour.

DERBY PHOTOGRAPHIC SOCIETY.

THE usual monthly meeting was held at the Loudon Restaurant, Irongate, Derby, on Wednesday evening, Nov. 5th ; Mr. Arthur J. Cox in the chair. The minutes of the previous meeting were read and confirmed.

Mr. J. W. PRICE then read a paper entitled "Reminiscences of the Old Collodion Days," during which he showed some excellent photographs of the "Roches."

Mr. J. MERRY proposed a vote of thanks to Mr. Price for his paper, Mr. Lovejoy seconded, and the vote was carried unanimously.

A vote of thanks to the Chairman brought the proceedings to a close.

The Annual General Meeting will be held on the 3rd inst., when a paper on "The Photographic Processes used in Copying Drawings," will be read by Mr. Thomas Scotton.

THE PHOTOGRAPHIC CLUB.

THE annual general meeting of this Club was held at Anderton's Hotel on the 5th of November last.

The report for the year was submitted by the officers to the meeting, showing a steady increase in the popularity of the Club by the numbers of attendances, which have been largely augmented during the past year, these amounting to 1,296 against 1,027 of the previous year, and 872 of the year before. A laboratory has also been built and fitted with the necessary appliances and chemicals, to which members have free access. The number of members is steadily increasing, and the financial condition of the Club is extremely satisfactory. During winter months the optical lantern has been a source of interest ; many new or valuable modifications of apparatus and processes of development have been shown or demonstrated. One very useful feature is, that if any new invention connected with photography, or new process, is laid before the Club, it has its *practical* value fairly and impartially ascertained. These considerations, together with the thoroughly pleasant and social manner in which the meetings are conducted, offer such special advantages to both amateur and professional photographers, as were quite unattainable previous to the establishment of this Club in 1879.

ST. HELEN'S ASSOCIATION OF SCIENCE, LITERATURE, AND ART.

Photographic Section.

AT a meeting held at the Association Rooms, Mr. HEATHER occupied the chair.

After the ordinary business,

The CHAIRMAN showed half-a-dozen views of the moon taken during the eclipse of the 4th ult. with his camera, the exposures varying from one to five seconds.

Mr. TAYLOR showed about twenty views of Dutch life and scenery.

Mr. SHERLOCK said, in regard to a difficulty some members appear to have in filtering emulsion, that he found it an excellent plan to use the vacuum pump, and suggested the use of asbestos or powdered glass for filtering through.

A few transparencies, made by members, were passed round for inspection.

Discussion then took place on the action by excess of HCl in emulsion, action by $AgNO_3$ in Fe_2Cl_6 toning bath, &c., and the meeting adjourned.

BRADFORD AMATEUR PHOTOGRAPHIC SOCIETY.

THE first meeting of this newly constituted Society was held in the Free Library on Thursday evening last, when there was a full attendance of members. The President, Mr. Duncan G. Law, delivered a short address touching on the rise and development of photography down to the present time. Afterwards Mr. Scorah, the Secretary, gave a Lantern Exhibition.

We understand that the Society commenced work with a full complement of members, and we congratulated the promoters on having made so successful a start.

Talk in the Studio.

SOCIETY OF ARTS.—Under the able and euergetic directorate of Mr. H. Trueman Wood, it is evident that the Society of Arts will thoroughly maintain its leading position; and we will now give a few particulars regarding the full and varied programme for the coming session. Captain Abney will give a short course (two) of Cantor Lectures on "Photography and the Spectroscope," the dates for these being fixed for April 20th and 27th. Another communication of especial interest to photographers will be one on "The Influence of Civilisatiou on Eyesight," by the eminent surgeon, Mr. R. Brudenell Carter, but the date for this is not yet fixed. Among others, the following papers may be mentioned:—George Buchanan, M.D., F.R.S., "The International Health Exhibition"; W. H. Preece, F.R.S., "Electric Lighting in America"; Ralph H. Tweddell, "The Employment of Hydraulic Machinery in Engineering Workshops"; George Clulow, "The History aud Manufacture of Playing Cards"; A. J. Ellis, "The Musical Scales of Various Nations"; B. W. Richardson, M.A., M.D., F.R.S., "The Painless Extinction of Life in the Lower Animals"; Professor E. Ray Lankester, M.A., F.R.S., "Marine Biological Laboratories: Their Organisatiou, Work, and National Importance"; Anton Jurgens, "The Preparation of Butterine"; Sir J. N. Douglass, "Recent Improvements in Coast Signals"; P. L. Simmonds, "Prospective Sources of the Timber Supplies of Great Britain"; Professor H. S. Hele Shaw, "The Evolution of Machines"; Frederick Siemens, "Tempered Glass." Besides Abney's Cantor Lectures on Photography, the following courses will be delivered:—"The Use of Coal Gas," by Harold B. Dixon, M.A.; "Climate, and its Relation to Health," by G. V. Poore, M.D.; "The Distribution of Electricity," by Professor George Forbes; "Artists' Colours," by J. M. Thomson, F.R.S.E., F.C.S., Lecturer on Chemistry at King's College, London; "Carving and Furniture," by J. Hungerford Pollen; and "The Manufacture of Toilet Soaps," by C. R. Alder Wright, D.Sc., F.R.S., F.C.S. A special course of Howard Lectures will be delivered on "The Conversion of Heat into Useful Work," by W. Anderson, M.Inst.C.E.

A PHOTOGRAPHER'S ART EXHIBITION.—The energy of Mr. Winter, of Derby, has been the means of gathering together a very extensive collection of objects of art, many being the work of amateurs in Derbyshire. Paintings on china formed a leading feature in Mr. Winter's exhibitiou, and there was also a good collection of oil and water paintings. Needlework paiutings upon silk, fretwork, inlaid work, and designs for Christmas cards, were also shown by the Derby amateurs. With a remarkably good taste, Mr. Winter did not give his own photographic work much prominence, and altogether he is to be congratulated on the success of his efforts.

THE ELECTRIC LIGHTS AT HELL GATE.—The installatiou of an Electric Lighting apparatus at this dangerous point is now complete, and the light was turned on for the first time on the 20th ult. There are nine arc lamps, each of 6,000 candle power, the lamps being arranged so as to form a circle. The tower consists of four iron columns, over a hundred feet high, and the *Scientific American* says that every outline on the shore can be distinctly seen, also that the fleet of vessels which come down the river each morning will now be able to pass without waiting for daylight as hithertofore. We should be glad if some of our New York friends would expose a few plates by the light of these exceptionally powerful electric lamps, and let us have prints from the negatives.

PHOTOGRAPHING A CYCLONE.—A photograph is said to have been taken of the cyclone which passed through Dakota on August 28th. The cyclone was discovered about four o'clock on a bright afternoon, when, with the exception of a few heavy banks of cloud, the sky was clear and the sun was shining pleasantly. Suddenly a monstrous funnel-shaped arm shot down from one of the clouds, aud a moment later the cyclone was formed and was moviug slowly across the prairie, carrying destruction to everything in its course. The cyclone remained in sight two hours.

PHOTOGRAPHING A PISTOL BALL AND SOUND WAVES.—In the current number of the *Photographische Correspondenz* is reproduced a series of diagrams of the apparatus employed by Professor Mach in his experiments on the production of instantaneous photographs of various physical phenomena. These experiments, which were described in the PHOTOGRAPHIC NEWS some four months ago, require little commeut now.

PHOTOGRAPHIC CLUB.—At the next meeting, the subject of "Collodion Emulsions" will be considered.

To Correspondents.

*** We cannot undertake to return rejected communications.

G. S. MACKIE.—If you make up the emulsion with less water, and dry your plates more rapidly, you will not be troubled any more with such markings.

PHILIP LERNAN.—The action is probably due to the reducing action of printing ink upon the salts of silver, and it is not likely that pressure has anything to do with the matter, except so far as it brings the sensitized paper in close contact with the printing ink.

C. F. BAILEY.—We do not think you will obtain them in England, but have no doubt that you can get them through any of the Paris dealers in photographic apparatus.

S. G.—It is very good of you to send it, and we will make use of it if possible; but we are not quite sure whether we can do so.

C. E. W.—Our publishers will get the photograph registered for you if you will forward them 1s. 6d. in stamps, and a copy of the picture.

J. HARRIS.—1. It is a very approximate estimate, and you must not attach too much importance to it. 2. It is not absolutely the best; it may be depended on as very good. To say any one form is absolutely the best would be misleading, as it depends on the general direction your work takes.

ED. SHARP.—Thank you: next week.

K. I.—The idea can only be protected by making a claim for building up the article in question out of photographs in the manner you describe, but we have some doubts as to whether the claim would be allowed by the examiners. Still there is no harm in trying, as you only lose a trifle over a pound, should the patent be refused. By registering each view separately, you can protect yourself absolutely as regards the pictures.

T. P.—A series of lessons will appear in the NEWS very shortly.

EXON.—It is due to the fact that on damping, the paper stretches more in the direction of the width of the sheet than the direction of the length. If you require the "long-faced" portraits, you must cut all the pieces of paper so that the length of the sheet is in the direction of the width of the sheet; but if, on the other hand, you require the face to be widened, you must cut the paper in the reverse direction. Generally speaking, the public prefer portraits in which the face is lengthened, to those in which it is made to appear broader than it should. An interesting communication on this subject—written by Mr. W. Coles—appeared on page 778 of our last volume.

JOHN MORGAN.—1. If the size is moderate (say, up to 12 by 10), you will probably find it convenient to make the enlarged negative on a gelatino-bromide plate. 2. The quality of the paper is not very material, but it must be sufficiently stout and tough to bear handling when wet. 3. It is very doubtful whether it will answer your purpose to go; and you would act very unwisely in doing so without making full enquiry.

SERIOUS.—We should certainly regard it as an infringement of the copyright, but you must not forget that there is no certainty when these matters are taken into a court.

C. M.—1. Send us details, and a photograph if possible. 2. As it dissolves in a little over its own weight of water, we cannot understand your difficulty. Possibly you may have had the "chlorate" given to you in mistake. 3. One part of white of egg and six of water.

W. M. BROWN.—You have not warmed the plate sufficiently.

LEARNER.—Your work does you much credit, and it is to be hoped that you will continue to devote time to photography. With respect to the portraits, we would suggest the use of a white reflector on the side opposite the light, so as to relieve the deep shades.

STUDIO.—If you have space you should make it four or five feet longer; the other dimensions will do very well.

L. L. M.—Certainly not. How would you like to be treated in the way you ask us to treat another?

WINDOW.—The ruby glass, of which you send a sample, is quite unsuited for the purpose; indeed, it is rather red brown than red.

MEDWAY.—The background is far too dark. As a rule, a light background should be used when vignetting is to be resorted to.

LUX.—Remove all traces of greasy matter by washing it several times in ether.

VOL. XXVIII. No. 1368.—*November* 21, 1884.

CONTENTS.

THE DUBLIN EXHIBITION.

THE Photographic Society of Ireland have good reason to congratulate themselves on the collection of pictures and apparatus that has been brought together by their endeavours within the walls of the Royal Hibernian Academy, and owe no little gratitude to the authorities of that Institution for their great kindness in lending their rooms for the purposes of a Photographic Exhibition.

The public portion of the building, which was erected by private munificence in 1830, was built especially for a picture gallery, and is exceptionally well lighted—at least, as far as the two principal rooms are concerned; the lighting of the third is much inferior to the others.

The collection numbers some seven hundred and thirty frames, together with several albums, a large stand of ceramic photographs, and a small table of cameras, lenses, shutters, &c. In point of quality we believe it will compare favourably with that recently on view in Pall Mall, many of the photographs exhibited there having been also sent to Dublin; while out of eighteen artists who obtained medals this year in London, no fewer than fifteen are represented. A very large number of the pictures have been already noticed in our columns in the notices of the Pall Mall Exhibitions of 1882, 1883, and 1884, so that we need not do more than mention a few of their names. Amongst these are Mr. Tagliaferro's interiors of St. John's Church at Malta (Nos. 163, 235, 308, 309, &c.) Mr. H. P. Robinson shows a large series—The Mill Door (No. 57), "He Never told his Love" (No. 43), "Come Across" (428), and many others.

Mr. W. P. Marsh shows his Sea Studies (No. 242), and Messrs. West a frame of yachts (No. 14), including that figured at page 643. Mr. Symond has two splendid frames of yacht studies (196, 212). M. Grassin's "Breaking Waves" (718) unfortunately came too late, and have been in consequence relegated to the third room, as have his "Folkestone Boat" (No. 720) and "Quai Gambetta" (719). Mr. Renwick shows a number of his inimitable frost studies, full of frosty fog, of which we like Nos. 152 and 445 the best; No. 218, an elaborate composition print of a skating scene, though very wonderful as a piece of manipulation, is not nearly so satisfactory. Mr. Berkeley shows some charming little platinotypes, "A Likely Place for a Trout" being perhaps the best. Messrs. Mendelssohn, Hubbard, Lafayette, Gibson, Koch, Clerk, Shadbolt, Anty, Godbold, Berry, Adams and Scanlan, Nesbitt, Brownrigg, Donkin, Whaley, and others are represented by one or more of their Pall Mall frames of this year, while the Autotype Company's enlargement of Mr. Mayland's great triumph "There's Sorrow on the Sea" (No. 210), and Mr. Robinson's "Nor' Easter," Professor Donkin's "Deut du Geant," both original (186), and enlargement (302). Mr. Pointer's "Brighton Cats" belong to 1883. From the 1882 Exhibition we notice Messrs. Chaffin's "Sisterly Intercession" (125), and "Cherry Ripe" (394); Mr. McLeish's beautiful "Misty Morning on the Wear" (69), as well as some of his more recent work. It would be obviously utterly impossible to notice in a single article, even by name, all the pictures deserving recognition, so we must ask those who are omitted to kindly take the will for the deed.

Before passing on to note a few of the especially Irish photographs, there are two we cannot pass by. One (No. 450), "Reading to Granny," by Mr. Gillard, a charming picture in platinotype, the attitudes of child and grandmother being most natural, and the lighting and general treatment all that could be desired. The other (355), "The Corn Doctor," by Mr. F. S. Seed, is also an admirable composition, the expression of both operator and patient being inimitable, while the technique is unexceptionable.

Taking a rapid survey of the rooms as the numbers go, and passing over those already mentioned and many others, in favour of native work, we may allude to a nice little frame of cloud studies, by Dr. Pearsall (24), and Mr. E. P. Johnson's capital picture of "The *Connaught* steaming out of Kingston Harbour" (59), and H.M.S. *Neptune* (53). Mr. George Mansfield shows a dozen charming studies in the Pyrennees and Spain, of which we fancy most those of "Sauveterre" (71 and 507), the former being unquestionably one of the very best landscapes in the room—no slight praise when McLeish, Renwick, England, Horsey, Brightman, and others are well represented. Messrs. Mavius and Vivash, of Belfast, show a fine frame of large portraits (No. 65), as do Messrs. Crawford, of Dublin, the latter on porcelain (No. 83). Mr. C. W. Watson shows three frames of nice little views (Nos. 79, 290, 529), which are, however, cold in colour, and their tone is further reduced and the effect marred by the folded maroon cashmere on which they are mounted. The last named, consisting of pictures of the Dublin Exhibition Palace, taken down a few years since, are deeply sunk in a frame of almost crimson plush. Mr. S. Baker has two large frames, each containing a large number of views (No. 121), chiefly in North Wales and (303) in various parts of Ireland, and illustrations of Druidical and other antiquities. They are all good and careful works, but in some cases betray the use of a lens of too short focus. At every corner we encounter Mr. J. L. Robinson, who is a most prolific exhibitor, and as he mounts in single frames, his exhibits occupy a large portion of the catalogue.

Mr. John Chancellor, a well-known Dublin portraitist, shows to great advantage; his pictures, though not so pretentious as those which gained a medal at Pall Mall for Mr. Lafayette (Nos. 200, 203, 209), are to our mind far more

refined in style and treatment. We would especially notice (94) "The Belle of the Evening," (116) "The Captain of the Team, (213) "Il Penseroso," and (403) a Portrait.

Mr. Greenwood Pim is represented by five frames; No. 173, Miscellaneous Studies in the neighbourhood of Dublin; of which, a scene in the College Botanic Gardens and a group of sheep are best. No. 211 contains views at Aix les Bains, Venice, and 314 studies of tree trunks in platinotype; 482, views in the English lake district, and 496, "Caught Napping," a gelatino-bromide enlargement from a carte negative of a young lady asleep in a sunny garden. The worthy Hon. Sec. of the Society (Mr. A. Conan) has several frames of Welsh and Irish scenery, snow scenes, &c. (215, 216, 241, 243). Besides Mr. E. P. Johnson, already noticed, instantaneous sea photography is represented (exclusive of Messrs. West and Symonds) by Mr. T. H. Smyth (208) and Mr. F. W. Monsell (175). They are of small size, and, though intrinsically good, are completely eclipsed by the larger pictures. Mr. Rigby sends several frames of pictures of Brazil, Buxton. Other Irish amateurs whose works we have not space to enter into in detail, are Messrs. Baston, Kellsall, Scott, Fleming, Roper, and Codd, whose snow scenes (50 and 51) are remarkably good; Mitchell, Walker, Whittaker, Yeates, &c.

In conclusion, we would draw especial attention to a magnificent series of views in Ceylon, contributed by Mr. W. L. H. Skeen; both originals and enlargements (Nos. 297, 312, and 333) being particularly noteworthy. Mr. H. N. White sends a large stand of ceramics. The chief exhibitors of apparatus are Messrs. Watson, Shew, Sands and Hunter, Mayne, and H. Robinson; the new patent camera of the latter being in especial favour in Ireland.

The medals will be awarded by the vote of the Society. We hope to publish the list next week, together with some further notes on pictures of necessity passed over in the present issue.

Our block print shows some of the pictures at the Dublin Exhibition with the tag labels attached; these labels being removed when all the pictures were hung. Commencing

THE DUBLIN EXHIBITION: MAKING THE CATALOGUE. Negative by Greenwood Pim; Phototype Block by the Meisenbach Co.

on the left hand, the frame standing by itself at the top contains a canvas enlargement by Messrs. Morgan and Kidd; immediately under this is Mr. Dixon's tiger; on each side of the tiger we have studies by Mr. G. Nesbitt. Mr. Mayland's "Sorrow on the sea" will be recognized as next in the same row, and immediately under Mayland's picture is a frame containing three portrait studies by Lafayette; while one remove to the right of this is to be found Mr. Simmonds' admirable collection of yacht pictures. Several other exhibits will be recognized by the reader. Our photograph is by Mr. Greenwood Pim, and he will himself be recognized as being shown seated in the lower right-hand corner. The gentleman seated at the desk is Mr. Mac Carthy, the curator of the Exhibition.

MR. W. COBB'S LONDON VIEWS.

THE photographer in London has much to contend with, and the atmosphere is seldom clear enough for long-distance work, unless very early in the morning; and more especially on a Monday morning, while the bustle and racket of street movement is by no means calculated to steady the photographer's nerves, and may lead to the overturning of the camera or other mishaps. Hence it is that, although one may now and again see a good view of street life in London, a series of such pictures is rare. Mr. Cobb has, however, acquired a reputation for this difficult class of work, and when he cannot use the tripod, he is content to fix his camera to the knife-board of an omnibus, or to the railings of a church, while some of his pictures have, we are told, been taken from the top of a pillar letter-box. On more than one occasion this indefatigable photographer has been mistaken for a dynamiter, and has had to explain his movements to the police; and in a paper communicated by him to the PHOTOGRAPHIC NEWS some twelve months ago, he relates how he was arrested—or perhaps, rather, detained—while photographing the Royal Exchange.

The picture which we present in the form of a supple-

ment this week is one of the best of Mr. Cobb's London views, the busy activity of the street being represented in a way rarely seen. The costermonger with his barrow, a boy wearing his empty basket helmet-fashion, and cab No. 2884, are caught while in quick motion in the immediate foreground. How advantageously such instantaneous views as that we now publish compare with the old style of London views taken with an exposure of some two or three minutes on a Sunday! In one case we have a live and active city represented; while in the other a mere skeleton from which the life and flesh have departed.

When, indeed, may we hope to practically realize the perfection of photographic representation—a series of instantaneous views combiued into active life by means of a zoetrope lantern? But hope and possibility may go even farther than this, for the moving representation may perhaps be made stereoscopic; but to reproduce the objects with all their natural colours appears to be much further removed from the possible.

THE COMPETITION OF LANTERN SLIDE PROCESSES.

On Thursday, the 13th November, the lantern slides which had been prepared by various members of the London and Provincial Photographic Society for the purpose of comparing different processes, were exhibited, and judgment was given on the merits of them.

There was a large meeting, and judgment was accorded by the voice of the whole of the members, the Chairman interpreting the general feeling of the meeting when there appeared to be any doubt. It was a notable feature of the proceedings that there was in almost every case the very nearest approach to unanimity of decision. First, a weeding-out process was gone through, those slides which were manifestly inferior being put on one side. The "accepted" slides were then again passed through the double lantern; in each case the one which had been adjudged best so far being kept in one of the lanterns, so that each slide as it came up might be compared with it, till one came which was adjudged *better*, after which this latter was kept on the standard with which others were to be compared.

"What was the general result of the trial?" will be the natural question. It was not very far different from what Mr. George Smith predicted in a recent number of the Photographic News that it would be. It was made evident that, in the hands of competent manipulators, excellent and almost equally good results could be got by any of several processes.

It should be explained that all slides were from the same negatives, of which there were two, both provided by Mr. W. Cobb. One was a very pretty picture of two children. The white pinafore of one of these, we may say, was a severe test of any process, the difficulty of getting detail in it, without over-exposing to destruction the rest of the picture, being very great. The other was an instantaneous view on the Thames.

By each process two slides of each subject were prepared. The slides from the last-mentioned subject were judged first, and at the end three of them were selected as being the best, and as being one as good as another. It will be understood that till the final judgment was given, no one knew by what processes the slides had been prepared, even the preparers themselves being in most cases unable to recognize their own productions.

When the names of the processes on the three slides adjudged best were read out, it was discovered that two were by the collodio-albumen process, one by the wet plate process. Here, certainly, it appeared that our old friend collodion triumphed; but the next judgment showed that other processes might at least equal it.

When the whole of the slides representing the two children had been gone through, one was adjudged to be pre-eminently good. Two others were considered to fall a little short of it, and to be one as good as the other.

It was announced that the slide declared to be the best of all was a Woodburytype, prepared by Mr. George Smith. The other two were—one a collodio-bromide, the other a platino-bromide plate, specially prepared by Mr. Wellington for transparencies. The beautiful colour of this latter slide was most notable. It was of the warmest possible red, almost approaching crimson. So much for platino-bromide, which most have believed was only capable of giving cold black tones.

The Woodburytype slide deserves somewhat more notice here than we have given it. It was chiefly characterized by the perfect rendering of the gradation of tone. There was not the smallest hardness, nor yet flatness; at the same time, there was no falling off of detail, either in the shadow or in the high lights. The slide was of a warm-brown colour. Mr. Smith created not a little surprise when he stated that the pigment used was pure carbon.

In reply to questions, Mr. Smith stated that he had for long been trying to get a lamp *black* which would be *brown!* the lamp blacks which were sold commercially being totally unfit for Woodburytype purposes. At length he had succeeded. He collected the soot deposited by the tip of the flame of a small benzoline lamp. A tedious process this, one would naturally suppose, and one giving but small returns; but it appears that the quantity of carbon thus obtained, necessary to make a suitable pigment, is infinitesimally small. Mr. Smith says he can make enough in a day to last him for months.

It is only fair to Mr. Smith to say that the slide which produced so much admiration was the only one that he prepared for the competition, otherwise Woodburytype might have come to the fore in the case of the instantaneous subject as well as in the portrait one.

One slide was exhibited which had been taken on a gelatino-bromide plate, and had been developed by the hydroxylamine developer, of which we have heard a good deal lately. It was, next to those adjudged to be the *very* best, considered amongst the best of those exhibited.

As was natural where the judges were all practical photographers, judgment was given more with reference to technical perfections than to general effect, correct rendering of gradations of tone being the thing most of all attended to. There is all probability that a jury of the non-photographic public would have given their decision in favour of the warmer coloured slides, such as those by the gelatino-chloride process. The colodion slides were of course black-and-white, or nearly so, and showed a tendency in the case of the instantaneous subject to give a moonlight rendering.

PHOTOGRAPHY AT THE NATIONAL GALLERY.

In reference to this matter, which we allude to elsewhere, the *Manchester Courier* says:—

"The pictures in the National Gallery are the property of the English nation, but the present Administration has refused permission to an English company, called 'The Fine Art Society,' to photograph certain pictures in the Gallery, and has, at the same time, freely accorded this permission to a German firm of the style or title of 'Braun and Co.' The 'Fine Art Society' did certainly receive permission to photograph pictures as they hung, but this was equivalent to a direct refusal; and although they offered the strongest guarantees for the safety of everything they handled, there was one insuperable objection to them—and one which they were unable to do away with—they were Englishmen. Messrs. Braun, on the other hand, had had full liberty to take down the pictures, take them from their frames, and beyond this, to erect an unsightly and disfiguring iron cabin outside the Gallery, in which to do with these pictures what seemed to them good. On the unfairness of this proceeding being put before the custodians of our great national repository, a reply

was received from the Director to the effect that these German people had been 'engaged for some time past in photographing pictures in the great public galleries on the Continent, where, also, owing to the high importance of the undertaking, unusual facilities had been afforded them.' How any man or body of men can thus proclaim his or their self-stultification passes our understanding. 'Messrs. Braun and Co.' says the Director, 'have received unusual facilities in their own country, and therefore you, as Englishmen, shall receive none in yours.' The 'high importance' of the affair seems to resolve itself into this, that if there be any profit, any praise, any encouragement of industry, to be derived from the reproduction of the artistic treasures of the country, they shall not, while the present people are in authority, be derived by the men of the country."

A block photograph of the galvanized iron building, which the writer of the *Manchester Courier* justly calls "an unsightly and disfiguring iron cabin," recently appeared in the PHOTOGRAPHIC NEWS (present volume, p. 562).

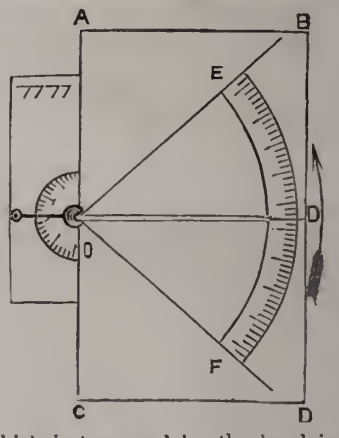
FRENCH CORRESPONDENCE.

PROGRESS IN PHOTO-TYPOGRAPHY—BOCA'S CHRONOMETRIC SHUTTER — PHOTOGRAPHS OF CHANTILLY — MAKING GELATINE FLOW ON GLASS—BALANCE WASHING TRAY.

Phototype Improvements.—Every day brings with it some new experiment to the perfection of photography as applied to the direct formation of typographic blocks. In Paris, M. Krakow, in the house of Lefman, has invented a process similar to that practised by Meisenbach, Angerer and Göscht, and others, and to him is entrusted the work of preparing the plates for the *Figaro Illustré* which has come out recently. I have seen a picture of Meissonnier's, one of Détaille's drawings, and other subjects reproduced in this way. The following is a brief description of the process. A copperplate of the required size, coated with a film of bichromated gelatine, is exposed behind a negative on which a thin pellicle covered with very fine lines is placed. After a sufficiently long exposure it is etched with perchloride of iron. When bitten deeply enough, the plate again receives a film of bichromated gelatine, and is exposed for a second time under the negative, care being taken that the lines coincide, and the pellicle, striped with lines, is placed in the reverse position, so that the effect of lines crossing in lozenge shape is produced. In the same way an engraved plate is obtained by the Talbot process, but that now described possesses the qualities necessary to the formation of a typographic block. The results shown by M. Krakow are very satisfactory. It is almost unnecessary to say that for coloured impressions the use of different negatives executed in this manner gives polychromatic prints having a charming effect. In Switzerland, the firm of Brunner and Kunkler have had the happy notion of making gelatine plates accompanied by a pellicle giving grained or finely striped surfaces, so that after developing, the negative presents the necessary character for being directly transformed into typographic blocks, only by M. Krakow's plan one can obtain successive impressions on the copper plate.

At Marseilles, in Cayer's printing office, another excellent idea is utilised, but in this case it is not photographic, but a method of transferring directly on to stone or zinc designs executed on a particular sort of paper, with a view to typography. It is as well to know something about all processes, because they hang closely together, and one may on some occasions find it easier to have recourse to one method, and at other times to a different one, whether photography be largely used, or only to obtain an accurate outline. Everyone knows that to execute a drawing to be reproduced in this way, the paper is required to have either a granular or striped surface. The drawing finished, recourse must be had to some photographic process to reproduce it on the stone. At M. Cayer's, a striped paper is manufactured similar to that of Angerer's, but with the improvement that the lines or stripes can themselves be transferred on to the stone. As soon as the designer has executed a drawing by scratching out the lights and putting in the shadows with either lithographic ink or chalk, it may, by simple pressure, be traced on the stone. I am assured that this prepared paper will preserve its properties for a considerable time. Photography may come in here for giving collotype images with both outline and modelling of light and shade on this typographic paper.

Boca's Chronometric Shutter.—Ever since the so-called instantaneous photography has been in vogue, amateurs, especially, have guessed their exposures, and no really simple method of measuring the time has been indicated. Several months ago I recommended the reproduction of the hand of a clock rotating on a dial, so as to make the complete circle in the space of one second. The motor was a person who, after a short practice, could effect the movement regularly in the required time; but still this mode of proceeding was more or less indecisive, and the demand for something chronometric resulted in my thinking of using M. Boca's chronometric shuttter. This instrument consists of a dial divided into three equal parts, and clock hand making complete rotation in three seconds. It is set in motion by a clock-work spring, and its speed regulated by a lever escapement. The diameter of this dial being too small for the gradations marked upon it to be legible, I have fixed in front of it a rectangular slide, ABCD, bearing an enlarged arc of a circle, EF, concentric



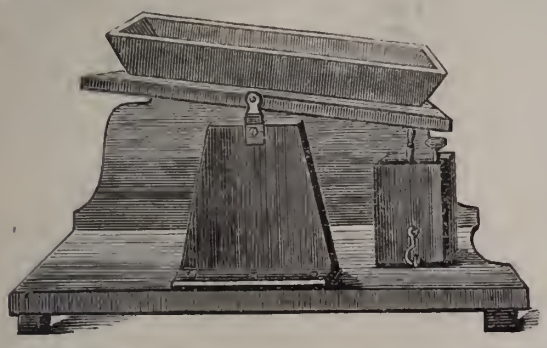
with that which is traversed by the hand in a second; this arc is divided into 200 equal parts, the hand is replaced by a longer one, OI (fifteen centimetres), so as to reach the gradations, and is painted white, while the surface of the slide is entirely black, with the exception of the gradations themselves, marked in white. To make a trial of it, let go the spring, the needle hand will move, and as soon as it has reached F, or shortly after, make the shutter act. On developing, the number of divisions traversed by the needle will be indicated by a blacker tracing on the negative than any of the surrrounding parts. If, for instance, the lighter part cover two or three divisions, it shows clearly that this length of exposure has been two or three two-hundredths, or else one-hundredth, or one-hundredth and a half of a second. A drop shutter having an aperture seventy-five centimetres long, the diameter of the lens being twenty-five centimetres, gave an exposure of nine two-hundredths. I have made two hundred divisions, because one two-hundredth of a second is sufficient for practical accuracy; but there is no reason why further sub-divisions should not be made if desired. Of course plates are required of such sensitiveness to be impressionable with these short exposures, and they do not yet exist; but should the day come, we still have a method of augmenting the speed of the needle as long as its action is regular.

Photographs of the Chateau of Chantilly.—The Due

D'Aumale, after having had the princely abode of the Condé's so intelligently restored, has entrusted nearly all the work of photographing it to M. Chalot. Very large gelatino-bromide plates were used with the greatest possible success.

Method of Making Gelatine Flow on Glass.—M. De Villechole, the maker of the plates used by M. Chalot, says that a cold infusion in water of the plant known as pellitory (filtered after soaking for from one to two hours) is very efficacious for brushing over plates before pouring on the gelatine emulsion, especially when they are large.

M. Leon Baluze's Balance Washing-Tray.—M. L. Baluze has invented a balance washing-tray, of which the diagram



shows the construction. It is set in motion by clock-work, and works from one to two hours. The rate may be increased or lessened at will. On the moving surface any dish up to 28 by 35 centimetres may be placed. I have seen the machine in action, and it does not work too violently to upset liquids, and makes no noise. It will be very useful in developing as well as in etching. LEON VIDAL.

IODO-CHLORIDE EMULSION.

BY V. SCHUMANN.

In some further remarks the writer describes the action of developers on iodo-chloride emulsion prepared according to formulæ given in a former communication (p. 715). Both Stolze's pyro-potash and Eder's oxalate were tried, but the latter gave better results, especially with the films poor in silver iodide.

Herr Schumann has only experimented with the spectrum on the plates, the latter producing, however, surprising results, quite different from the spectrum as represented on pure chloride or iodide films.

All these emulsions produce a higher colour sensitiveness; thus, films prepared by formula No. 1 were equally acted upon from the violet to the indigo, except in the lavender. Those films, which contained a comparatively low proportion of iodide, were extremely thin, and very liable to fog; the others gave a distinct spectrum of great intensity, and with care a negative free from fog.

The same films were also tested with Warnerke's sensitometric tablet, using for the standard light one inch of magnesium ribbon, burnt at a distance of thirty inches. Plate No. 2 showed 20 on the table, and plate No. 1 produced only 18 on the same scale. Thus, it is found, that through the addition of iodide, the general sensitiveness is reduced, although the sensitiveness for the rays of lower refrangibility is distinctly increased. A comparative trial by the sensitomer was also made with a film containing pure bromide prepared according to Eder's ammonia method, digested for three-quarters of an hour at 38° C. The sensitiveness appeared identical with the iodo-chloride film poor in iodide.

From the above results it will be seen that although films prepared according to *formula No.* 1 are hardly suitable for practical purposes, from their liability to fog, yet the plates from No. 2 yield negatives equal to those of gelatino-bromide. The writer has not yet obtained negatives in the camera on iodo-chloride films, but from his spectroscopic results one can easily draw fairly accurate conclusions. Thus, No. 2 formula would yield soft negatives with fine half-tones, while No. 3 should produce images of much brilliancy with very great contrast. Herr Schumann proposes to experiment with the action of ammonia, on the finished emulsion, for by treating an iodo-chloride film with dilute ammonia and drying by heat, it was found that the image fogged directly the developer was applied.

HINTS ON POSING AND THE MANAGEMENT OF THE SITTER.

BY H. P. ROBINSON.

CHAPTER VI.—GROUPS.

THE arrangement of a portrait group of figures is one of the most difficult things to succeed in accomplishing perfectly in photography; more difficult, certainly, than the composition of a picture that would take a much higher rank in art, but of which the materials were more under the command of the artist as regards selection and disposition. The portrait group is often nothing better than a pile of humanity fitted together like a dissected puzzle; a heterogeneous conglomeration of human atoms, and sometimes dogs, not one of which has any artistic relation to another; agreeing in nothing except that each individual of it shall keep rigid and stare at the lens. The painters also have felt the difficulty of making such an arrangement of a group that the result should be a picture without any sacrifice of the portraits. These things are managed better now than they were before the introduction of photography. Everyone is familiar with the ordinary family picture of orange-holding, or mythological women and children immortalized by Goldsmith; or as Byron describes a family group—

> "A lady with her daughters or her nieces,
> Shine like a guinea and seven-shilling pieces."

The photographer is nearly always heavily handicapped by having to give an equally good portrait of each individual in the group, while one of the great principles of art is that one component of a picture shall be more prominent and conspicuous than another. In a pictorial group a back is often useful as a contrast to the other figures; but this is not permissible in such groups as are usually demanded from the photographer. Every face must present a favourable portrait independent of the others; no figure must be sacrificed for the sake of pictorial effect, and therefore there can be little contrast or subordination, so necessary in artistic arrangement. This difficulty is felt by painters who can devote time and attention to each figure, and who also have the great advantage of being able to place their figures on different planes. This absolute necessity for placing all the figures in one plane, so that they may all be in focus, is not so stringent as it was before the introduction of gelatine plates. We can now employ lenses that cover a greater depth of focus than the old portrait lenses, and this enables us to get greater separation in the figures.

The group is the one thing that the photographer dreads especially if there is to be a baby or young child in it, for as the weakest link is the strength of the chain, so every thing depends upon the quietude of a part that can only be depended on to move. However well the photographer may have arranged the other figures, and however strong may have been his injunctions to them as to how they should stand, and in which direction they should turn their faces during the exposure, they have to be vigilantly looked after, and this is almost impossible while you have to devote

all your attention to keeping quiet a restless child. Moreover, the baby is always expected to be made a conspicuous point in the picture, and it is so comparatively small an object that it forms nothing more than a minute speck in the group. It is my experience that few people have any idea how small a baby is until they see it in the centre of a group of grown-up persons.

Groups are taken both in the studio and out of doors. We will begin with the former.

Rejlander used to say that it tasks the skill and attention of the photographer quite enough to see that the arrangement, lighting, and expression of one figure is perfect, and he never ventured upon more, if he could help it, except in combination pictures. But portrait photographers cannot always select their subjects, and must make the best of the material brought to them. Now the most frequent group upon which the photographer is called to operate is that which is composed of two persons, often children—I hope to give the latter a chapter to themselves—but oftener of grown-up people, and perhaps most frequently in holiday towns, young people on their honeymoon, who always seem to be animated with the very praiseworthy desire to have their portraits taken in their new relation. This is one of the easiest groups to take if managed well, but one of the most difficult if it is trifled with. As a rule, the best composition can be got if the lady is in a standing position, and the gentleman sitting. It need not be in a chair or in any very formal attitude, but on a table, or the end of a balustrade. This latter accessory, like all imitations, may be very good or very bad; it should not look clean-cut and new, and care should be taken not to make it prominent. If the picture under consideration is to be a three-quarter length—the most convenient form, perhaps—very little of the balustrade will show. Suppose, then, that the gentleman sitting, and the lady standing beside it, they need not be looking at each other; it is not often that a young couple can do this under the circumstances without laughing, but a common source of interest should be found or imagined. It is easy to suppose they were talking to a friend who does not appear in the picture, or that their attention is called to some interesting object. Resort should be had to device, to give the effect of life and movement to the group, and animation to the heads, and to take away that uneasy and penitential look of being sorry for it, so often seen in pictures of the kind. Here are a couple of sketches of variations on this theme, which may serve as hints for arrangement.

Where the balcony is used, or any other outdoor accessory, it is well to use also an outdoor background.

Very agreeable pictures may be made with two young ladies for the subject. In this case there are plenty of motives for the picture. The occupations of ladies seem to lend themselves to pictorial effect.

It is perhaps easier to make a well composed group of three figures than of two. With two it is sometimes difficult to get variety of line or a picturesque general form to the group, but with three figures the opportunities for variety, contrast, and a pyramidal form to the group, are much greater. So that the unity of the group is preserved, the greatest amount of variety of form should be sought for. Variety in position of the heads can easily be got. It is possible with almost any three figures to arrange the heads, so that they do not come exactly in a line with each other. For instance, it would be possible to arrange the heads formally, thus—

O
O O

but it is quite as easy and much more pleasant to break the uniformity, and arrange them thus—

O
O
O

The same principle is carried out in the group of three children—

If more than three figures are required in a group, it is better to turn the camera on its side, and make a horizontal picture of it. Indeed, in many cases when only three are included, the horizontal form is very useful, as in the following examples.

By placing three children at a table, the difficulties of feet and legs are got rid of, and the heads can be got larger without making the children look older than they are, the table and book suggesting scale. When the heads are all nearly of the same height, variety may be got by placing one of them at a distance from the other two.

In a group of adults, it is well to get some centre of interest, such as reading a letter, as in the last illustration

to this chapter; but care must always be taken not to sacrifice likeness to composition. One of the chief difficulties is to get the heads close together without appearing forced and unnatural.

EMULSIONS IN COLLODION.

BY J. NESBIT.*

The collodio-bromide emulsion process and its various modifications, for several years engaged the attention of experimentalists, but without arriving at the degree of rapidity attainable by its formidable rival gelatine. This has been pressed into every phase of photographic practice with a kind of feverish assiduity, whilst the good features of the older forms are almost ignored. There seems, however, to be some reaction setting in, as was evinced by your favourable reception of the albumen process given recently by Mr. Ackland. In re-introducing the process, for which we are indebted to the genius of one of the members of this Club, Mr. W. B. Bolton, I shall make no apology, and in no way as a competitor with any other system; let each stand on its own merits. I would willingly have ceded the position of exponent to other hands, so now I ask your indulgence whilst I prepare the emulsion in what may be termed its incipient form.

The formula stands thus—

	oz.	dr.	gr.
Plain Collodion.—			
Meth. alcohol	2	6	0
„ ether	2	2	0
Pyroxyline H. T.	0	0	60
Bromizing Solution—			
Meth. alcohol	1	0	0
Water, about			100 min.
Brom. ammon. (58 & 5 grs. exc.) ...			63 gr.
Sensitizing Solution—			
Nitrate of silver			100 gr.
Dist. water			60 min.

The mixture is made.

It will be observed that there is in the above a large proportion of water, but as our purpose is to obtain a finished and washed product, this is of no consequence. If it were to be used in its present form it would be quite necessary to use a bromide wholly soluble in alcohol, such as zinc or cadmium, as even the water imported into it with the silver has the effect of inducing reticulation in the film. Still, many good plates have been done by the simple emulsion process. They were coated with a mixture similar to this, washed singly, and flowed over with an organifier, such as tannin, &c. Now, that the washing of the whole bulk of emulsion, as afterwards proposed by the discoverer, was perfect in principle, is exemplified by the procedure with gelatine at the present day. As I cannot in the time at our disposal to-night go through the whole of the operations, I have brought examples of the different stages up to the final result. We have here our emulsion, which should be allowed to stand for a day, with an occasional shake. It should be then poured into a dish to set into the condition as found in this washing vessel. After soaking, the first water is tested, to find if the bromide be really in excess, and then the washing continued till all trace of soluble nitrate of ammonia and excess bromide has disappeared. The pellicle is now placed in a strong piece of calico, the water and remains of the solvents are squeezed out, and gathered up for drying. This may be done either in a water-bath or spontaneously. As it is now sensitive to light, care must be taken to let no white light reach it.

I show you a dried specimen, which is soluble in equal proportions of ether and alcohol—together about 8 ounces, which will keep good for several years.

This is a small quantity of filtered emulsion made by the above formula; the plates are prepared by simply pouring over in the usual way with collodion, and are ready for use without further treatment. I put in a plate to show the contrast between it and an ordinary gelatine film; also a negative and a transparency.

The reason I have given a formula divested of all the complications introduced subsequent to the first publication is, that I never found any appreciable advantages resulting from their adoption, whilst many difficulties arose, such as spots, fog, thinness of image, tenderness of film, &c. There are other salts capable of emulsification in collodion, chiefly iodide and chloride and their combinations. For the first no satisfactory developer has been discovered. I hope some day to find the iodide yielding up an image to appropriate treatment.

Mr. C. Ray Woods has kindly undertaken to deal with the chlorides.

A NEW DEVELOPER—FORMIC ACID IN THE DEVELOPER.

BY W. GOODWIN.*

There has lately been much correspondence in the photographic journals on the merits of various substances as preservatives of pyro: sodic sulphite has been well discussed, some swearing by it, others swearing at it. The truth seems to be that pure sulphite is a capital thing when you can get it, but difficult to procure, and to keep when you do procure it. For my own part, I prefer formic acid. Here is a red coloured concentrated solution of pyro and alcohol, with the addition of formic acid; it has been kept ten weeks, yet when diluted with water for use, gives a colourless solution. On the addition of ammonia and bromide, as for developing, you see it becomes very deep ruby colour, then in a few seconds clears to the colour of very pale sherry. It will remain like this for an hour; here is some mixed two hours and a-half ago, which is not yet dark enough to stain a plate.

In using this developer the image comes up with the same rapidity and vigour as with plain pyro. Formic acid is not in any sense a restrainer, but has itself been proposed as a developer; it however neutralizes a small part of the ammonia, so that rather more may be used than with plain pyro. The following is a convenient stock solution:—

Pyro	240 grains
Formic acid	1 drachm
Methylated alcohol	1½ ounces

Each drachm contains nearly 20 grains of pyro.

Dilute as required for the plates you use, but leave out of your formula any nitric or citric acid it may contain, as the formic acid replaces them.

* Read before the Glasgow and W. of Scotland Photographic Association.

Notes.

An artist who recently exhibited a "Study of a Cat" at Burlington House has had to acknowledge that the title was a misnomer. It was in reality a study of one of Mr Pointer's photographs, and very good indeed was the copy.

The exploring expedition cannot be considered to be well equipped now-a-days unless the camera is taken to put on record that which is visible to the eye, and the phonograph is taken to note down that which the ear perceives. When Herrn Tentgraff and Chavanne bring back with them a good supply of phonograph casts, and care is taken to reproduce these in a more durable material than tin-foil, we may have a combined photographic and phonographic display, in which the roar of the lion, the hiss of the

serpent, the chatter of the native, and the rush of the cataract, may accompany the exhibition of photographs on the screen. Still, some mechanical developments of Edison's talking machine must be made before all this is quite easy.

Mr. Anckorn's idea of showing three poses of the same individual on one carte, and forming what he calls a "triplet" photograph, was referred to a few weeks ago, and we now reproduce one of the triplets, as a Meisenbach block.

If we may judge by a circular, an attempt is to be made to hold an International Exhibition at the Alexandra Palace during the coming year; but it is regretted that the wording of the announcement is such as to lead many persons to confound the new venture with the International Inventions Exhibition of next year; and it is not quite easy to divest oneself of the notion that the promoters of the Alexandra Palace scheme do not very strongly object to this confusion as to the two exhibitions.

We had an opportunity the other day of taking a ramble through the exhibition buildings at Kensington, and a busy scene presented itself—the removal of some of the heavy exhibits involving the free use of pick and shovel to clear away the foundations or supports of masonry or brick.

Many exhibitors almost declined to remove their stalls, in the hope that they might be allowed to remain for the next exhibition; but the authorities have wisely determined to admit very few of such exhibits as have run through the Fisheries and the Healtheries, so the old exhibitors are now finding that their stalls will soon be removed for them.

Under these circumstances there was a great demand for photographers, but the exhibition authorities have ceded to one firm the exclusive "right" of photographing in the exhibition, so several arrangements made between exhibitors and photographers had to be cancelled.

Shall we confess? The companion who was with us carried a camera, the usual tell-tale stand being no tell-tale, as the legs folded in four. Our friend wished to secure a few photographs of the only quiet section of the buildings—a part fenced off by barriers marked "no admission," and placed under the charge of a representative of law and order.

An authoritative knocking at one of these barriers soon brought the helmeted guardian to us, and in reply to the question, "Which way in?" he indicated a small and previously-unnoticed door. Before long, however, a polite gentleman appeared on the scene, and mildly suggested that he represented the firm having the sole right to photograph in the building; but the worker at the camera boldly declared himself to have a proper authority—"indeed, would you like to see it?" he said, putting his hand into his pocket. "N-no, thank you," responded the polite gentleman, and went. As all the plates had now been exposed, the representative of law and order was saluted, and two persons might have been seen leaving the exhibition without staying very long to look around; but one remarked to the other: "I have never failed in a case like this; 'assume a *permit*, if you have it not.'"

The system of granting exclusive "rights" to photograph or otherwise reproduce educational collections made at the public expense is a very bad one, and, moreover, peculiarly English; as on the Continent of Europe it is usual to give great facilities to such persons as may desire to photograph or otherwise copy works of art in public collections, and special assistance is almost invariably rendered when the reproductions are intended for publication. There is nothing very surprising in this, as it may reasonably be considered that objects of art or exhibitions belonging to the public ought to be so used as to promote the culture of the people at large.

Our readers will recollect the great scandal which arose from the exclusive "right" formerly given to photograph at South Kensington Museum, and there seems likely to be a repetition of this scandal in connection with the National Gallery, those facilities to photograph the pictures, which were given to a German firm, being refused to an English art-publishing house (see page 739).

The Belgian Society has been invited to arrange an exhibit representing the actual condition of photography, at the Antwerp International Exhibition; and why should not the Photographic Society of Great Britain be asked to do something of the kind at our own Inventions Exhibition?

The *World* is much exercised in its mind concerning a photograph hanging in the Scarborough Station. The photograph is that of Lord Frederick Cavendish taken after death, and bears the announcement, "As done for Lady F. Cavendish and other members of the family." The *World* terms the photograph "an outrage upon good taste, if not common decency." As we have not seen the picture in question, we cannot say whether the remarks of our contemporary are justified.

The practical nature of the union between photography and bicycling will be shown at the next social meeting of the Temple Bicycle Club, when there will be a lantern exhibition, the slides for which will be confined to the work of the members.

The very animated discussion that followed the reading of Mr. Nesbitt's paper on "Collodion Emulsions" (see page 743) indicated the considerable value of the communication, and we are glad to find so much interest still taken in the subject. The present opportunity enables us to draw especial attention to the series of articles on "Lantern Slides," which was commenced in our last volume, and particularly to that article on page 818 of the last volume, and to articles which appear in the present volume (pages 401 and 721).

Mr. Francis Galton has not been slow to adopt our suggestion that he should give his opinion on the value of the "identiscope," a description of which we gave a few weeks ago. Mr. Galton, in a letter to the *Pall Mall Gazette* (which, however, only gives extracts from Mr. Galton's communication) doubts whether the fact of two genuine portraits blending harmoniously into a single resultant is "stringent evidence" that the portraits refer to the same person. He holds that the reason why photographic portraits blend so well together is that they contain no sharp lines, but only shades; that the photographic print of the iris of the eye does not afford a trustworthy unit of measurement; and that there would be no difficulty in selecting photographs of many different persons which should harmonise with the photograph of the claimant, a member of the Government ("Sir William Harcourt?" asks the *Pall Mall*), to wit.

To these objections the originator of the identiscope rejoins that the photographs are life sized, and when the combinations of the identiscope are projected upon a 24-feet screen, not a vestige of discrepancy appears in the admeasurement of the perpendicular. He also states that a complete section of one of the faces was removed, yet the parts were perfectly restored by the agency of the other portrait. The word "blend," says Mr. Matthews, is to "confuse"; the photographs in the identiscope perfectly "combine," but they are not "confused." As Mr. Galton presumably has neither seen the identiscope nor its results, it may be supposed that up to the present Mr. Matthews has the best of the argument.

If, in accordance with the recent decision at Nottingham (page 720), photographing a person against his will is to be regarded as assaulting him, curious complications of a similar character may arise, and whoever presents the camera in the direction of another person will run the risk of being roughly used, or having his apparatus smashed, so that photographing in the streets may some day become rather dangerous work; and as there may be little or nothing to show whether a camera is loaded with a plate or not, any one at whom the instrument may be levelled would certainly be justified in assuming it to be loaded.

To those who remember the old exhibitions of the Photographic Society, the change which has come over the relation between portraiture and landscape work is very remarkable. At one time portraiture absorbed at least three parts of the space, and landscapes occupied only a subordinate position. And the portraitists vied with each other as to who could produce the largest, and, it must be confessed, the ugliest pictures. Even a prize was on one occasion offered for the best large-sized head taken direct, and the result was certainly a collection of what would now be called monstrosities. Certainly size is not now regarded as a point of excellence, and so far we have progressed.

The International Congress for the protection of artistic and literary copyright has just held its seventh session at Brussels, and the Belgian Agricultural Minister has promised to introduce in the next session of the Belgian legislature a Bill to protect the rights of artists and authors. It will be interesting to see whether this Artistic Copyright Bill will have more success than the Bills for a similar purpose have had in England. Four Bills have been introduced within five years, and each has been dropped, and the question, more especially as regards photographs, is as far off as ever.

At the last meeting of the Royal Microscopical Society, a fitting tribute to the memory of Dr. Woodward, the eminent photo-microscopist whose death we alluded to some weeks ago, was paid by Mr. Beck. In the course of his remarks, Mr. Beck said that Dr. Woodward had the advantage of working under a Liberal Government, who provided him with apparatus suited to his requirements, and he thus possessed a magnificent collection of object-glasses, which he well knew how to use, as the beauty of his photographs abundantly testified. As it is so seldom an English Government is praised for its assistance toward scientific research, the circumstance is worth noting.

Plush for the borders of frames for photographs are, so a trade paper informs us, in greater favour than ever this season. It is satisfactory to know on the same authority

that vast improvements have been made in the manufacture of this material, both in its lasting and ornamental qualities. It is open to question, however, whether the photograph gains by these plush borders.

Patent Intelligence.

Applications for Letters Patent.

14,885. John Robert Sawyer, The Autotype Works, Ealing Dene, London, W., for "An improvement in photographic engraving."—Dated 12th November, 1884.

Specification Published during the Week.

114. Henry Vander Weyde, of Regent Street, in the County of Middlesex, Artist, Electrician and Photographer, for "Improvements in producing vignetted photographs." Dated 1st January, 1884.

My invention consists in the employment of a translucent or reflecting screen or screens interposed during exposure between the negative and the sitter or object being photographed, the shape of such screen being determined by the form of gradations desired.

In order to enable one skilled in the art to use my invention, I will now describe the operation. I place my sitter and proceed to take a head and bust portrait. Having posed, lighted, and focussed the sitter, I place the screen well out of focus, either outside the camera between the sitter and the lens, or inside the camera between the lens and the negative. If I use it inside, I construct the screen of a translucent material with an aperture in the centre. The material may be gauze or net or other open work fabric or tissue paper, or opal glass or other translucent material, the aperture being sufficiently large to allow the image of the head and the top of the shoulders to be transmitted uninterruptedly to the negative. The edges of the aperture may be graduated of different thicknesses or density, or the edges of the aperture may be jagged, the effect aimed at being to obtain a soft vignette into half tones extending to the very edges of the focussing glass. I then give the negative the ordinary exposure, and develop as usual. If the screen be placed outside the camera I may use either a translucent or opaque material; if translucent, I fashion it in the same manner as that just described, but on a much larger scale, as it is placed much nearer the sitter. Or I may use a reflecting instead of a translucent screen, of a white or light-coloured though opaque material, such as white cardboard, or white opal glass or metal. The reflecting side should face the lens, its surface being exposed to either direct illumination or to reflected light from a mirror or mirrors suitably arranged. In this case the edge of the mask nearest to the centre should be cut in the form of long V-shaped teeth.

1st. The herein described process of producing a vignetted photographic negative graduated off into a light or half tone, by the interposition, during exposure, between the lens and the sitter or object being photographed, of a translucent or reflecting screen or screens having an aperture of suitable shape and dimensions, substantially as herein specified.

2nd. The herein described process of producing a vignetted photographic negative graduated off into light or half tone, by the interposition during exposure between the lens and the sensitive surface of a translucent screen or screens, having an aperture of suitable shape and dimensions, substantially as herein described.

3rd. As a new article of manufacture, a vignetted photographic negative, graduated off into a light or half tone, substantially as herein described.

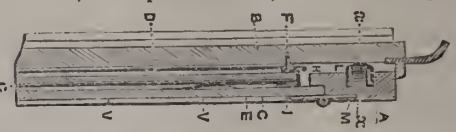
Patents Granted in America.

307,559. Hieronimus Mader, Isny, Wurtemberg, Germany, "Box for changing photographic plates." Filed June 13, 1883. (No model.) Patented in Germany Sept. 6, 1882, No. 22,569; in Belgium Jan. 16, 1883, No. 60,184; in France Feb. 14, 1883, No. 153,704, and in Austria-Hungary April 20, 1883, No. 5,045 and No. 16,709.

Claim.—1. The combination, with a shield and its slide, of a plate-holder fitting in the shield, and pins projecting from the outer surface of the slide of the plate-holder, the said pins being adapted to pass into apertures in the inner surface of the slide of the shield, substantially as herein shown and described, and for the purpose set forth.

2. The combination, with the shield and its slide, of a door in the back of the shield, and a plate-holder provided with a slide having devices for holding it to the slide of the shield, substantially as herein shown and described, and for the purpose set forth.

3. The combination, with the shield A, provided with the door U and its slide B, of the plate-holder C, and the slide D, provided



with pins F, entering sockets in the inner face of the slide B substantially as herein shown and described.

4. The combination, with the shield A, the slide B, and the plate-holder C, of the spring-pressed slide D, substantially as herein shown and described.

5. The combination, with the shield A and the slide B, of the plate-holder C, and the slide D, provided with the ledge H′ and the pins F, the slide L, and the spring M, substantially as herein shown and described.

6. The combination, with the plate-holder C, provided with the guide-grooves H, and the slide D, provided with the ledge H′, of the cap K and the springs S, substantially as herein shown and described.

COLLODIO-CITRO-CHLORIDE.

BY CAPTAIN ABNEY, R.E., F.R.S.

I have been asked several times lately how a collodio-citro-chloride emulsion is to be made when using citrate of ammonia instead of citric acid as the organic body necessary to combine with silver, which is to give vigour to the printed image. It is very easy to do, however, by a little artifice which I have thought might be worth describing. Citrate of ammonia is insoluble in alcohol, and therefore rather difficult to introduce into an emulsion in the ordinary manner; but it can readily be introduced into collodion by the following procedure. Take ten grains of pyroxyline and cover it with half an ounce of alcohol in which twenty grains of citric acid is dissolved, and then add one ounce of ether. This forms collodion containing citric acid. In order to get citrate of ammonia into the collodion in a very fine state of emulsion, ammonia (gas) dissolved in alcohol is added to the collodion. This is effected by inserting a bent tube in a cork in a test tube, which is a quarter filled with liquor ammonia. Placing this in warm water—in fact, nearly boiling water—the ammonia is given off rapidly, and can be made to pass through alcohol contained in another test tube. The alcohol absorbs the ammonia and takes up a large proportion of gas, as those who use sal-volatile may be aware.

This ammoniacal alcohol is next added to the collodion containing the citric acid, little by little, with shaking and stirring, and sufficient is added till reddened litmus paper shows a very slight trace of alkalinity. A very fine emulsion of citrate of ammonia is thus formed, the grain of which is indistinguishable by the naked eye, and, like other emulsions when first mixed, is orange-coloured when spread upon a glass plate. The emulsion is again rendered slightly acid by the addition of a few drops of a solution of citric acid in ammonia. If an emulsion of citrate of silver be required, there are two ways of effecting it—one by dissolving (say) ten grains of silver nitrate in the least possible quantity of water, to which is added one drachm of alcohol, and gradually dropping it into the collodion containing the citrate. It sometimes happens that this gives a granular emulsion. If, however, the silver nitrate be coarsely powdered and added to the emulsion, a very fine emulsion of citrate of silver is produced by shaking. This may be washed in the usual way, or may be precipitated by pouring in a fine stream into water. Another method of forming the citrate of silver is to pour out the

emulsion of citrate of ammonia into a flat dish, and when well set, to cover it with a solution of silver nitrate. It is then drained from the silver, washed, and dried as usual. When re-dissolved, the emulsified citrate of silver should be excessively fine.

To prepare a collodio-citro-chloride emulsion, two plans may be adopted: either to dissolve twenty grains of dry calcium chloride in a small amount of alcohol, and add it to the citrate of ammonia emulsion, and then to add 80 grains of silver nitrate to it in the usual way. What I prefer, however, is to make a collodio-chloride emulsion separately, and then to mix the citrate of silver emulsion with it, according to taste.

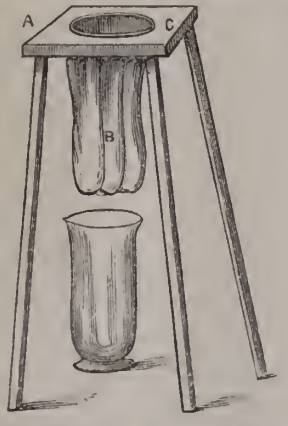
To make a pure collodio-chloride emulsion, I dissolve twenty grains of calcium chloride in half-ounce of alcohol; add to it five grains of pyroxyline, and then half-ounce of ether. To one ounce of plain collodion made similarly, I add sixty grains of silver nitrate dissolved in the smallest quantity of water, to which is added one drachm of warm alcohol. This produces an emulsion of silver nitrate in the collodion. To this the chlorized collodion is added drop by drop with stirring or with shaking in a bottle, and a perfect emulsion of silver chloride should result. This can be poured out to set in a dish as usual, and washed, dried, and re-dissolved; or can at once be poured out in a fine stream into a large bulk of water, squeezed, soaked in alcohol twice, wringing out in a cloth all excess of alcohol each time. It can then be re-dissolved in the one ounce of ether and one of alcohol, and should give a good emulsion. The two emulsions may then be mixed together as before stated. It is well to dissolve about five grains of silver nitrate in water and alcohol, and add to the emulsion in order to increase the rapidity of printing.

I propose to refer to the printing and toning of collodio-citro-chloride in a subsequent communication.

ON FILTERING GELATINOUS MIXTURES.

BY LIEUT.-COLONEL W. L. NOVERRE.

A SIMPLE and rapid method of filtering gelatinous mixtures will doubtless be acceptable to many photographers. The plans usually recommended are, the use of a funnel plugged with tow or cotton-wool, or a piece of cambric or other material spread over a jar, on which the solution is poured and allowed to percolate through. These plans are altogether unsuitable where large quantities of liquid have to be filtered, and even for small quantities the process is slow. The gelatine has to be kept warm till the operation is complete, and a rather open material must be employed, or the



solution will only fall through drop by drop. The plan here described will be found very expeditious, there is no waste, a filtering material of the closest texture may be used, and the warm mixture is filtered before it has time to thicken by cooling. It has been used successfully for filtering gelatino-bromide emulsions and the gelatinous mixtures employed in the preparation of carbon tissue. The arrangement referred to is shown in the annexed cut. A is a wooden stand 18 inches high, having a hole in the top four inches in diameter; C is a ring made of bent cane or whalebone, slightly larger than the hole in the stand. The filtering material, which must be of the closest texture, should be cut in a circular form about 22 inches in diameter; when secured to the ring with stout thread it forms a bag B, the ring C preventing it from falling through the opening in the stand.

To use the apparatus, the operator pours sufficient of the mixture into the bag to half fill it; he then seizes the bag, above the liquid, with his fingers, and presses the filtrate through into a receptacle placed below to receive it. Further portions of the mixture are poured in till the whole quantity has been filtered. With the measurements given above, quantities varying from 4 ounces to 40 ounces may be readily operated upon.

A WEEK IN SUFFOLK.

BY JOHN L. ROBINSON.*

THE ordinary Irish tourist in England generally confines his attentions to the large towns or fashionable watering places, and misses all that is most attractive to the lovers of art and nature. The quiet villages, the quaint cottages, the picturesque churches, cosy manor houses, and lordly mansions lie outside the ordinary routes of tourists. Visit an old cathedral town such as Worcester, or seat of an ancient monastery such as Shrewsbury or Bury St. Edmunds, and you will find that the towns themselves and the surrounding country will furnish a thousand subjects for the pencil for the artist or camera of the artistic photographer.

It has been my good fortune for the last five years to have had opportunities of exploring rural England. My first visit in 1880 was to Norfolk, the home of the wild duck and sportsman: where, like in Holland, the eye may wander for miles and see no other object than the meres and the towers of the many churches scattered so plentifully through that district. From one spot in Norfolk no less than thirty-six church towers may be counted, all built towards the latter end of the 15th century.

This year our party returned to East Anglia, and made Bury St. Edmund's our head-quarters. The 112 photographs which I exhibit to-night were, with the exception of the six Cambridge views, all taken by me during the week beginning the 11th, and ending the 16th of August.

This was the fifteenth excursion of the Architectural Association, a body comprizing 1,000 members. The excursion is limited to 38 or 40, and the details are previously arranged by a sub-committee. My thirty-seven companions sketch in pencil, water-colours, or ink, whilst I am the only photographer of the party; in several of the views my companions may be seen hard at work—in fact, taken in the act.

So much for the preliminaries. I was armed with one of Swan's 8½ by 6½ cameras with three double backs, and Hare's 5 by 4 camera with changing box for twenty-four plates. I was then enabled to take thirty views a day, as I also had a supply of four dozen whole plates, and a gross of 5 by 4. Each night, after dinner, by help of a ruby lantern, the day's plates were taken out of the slides, and changing-box filled with fresh ones for the next day; the former being packed in the latter's boxes, and sealed and labelled. I also notice in a book the number of plates taken at each place, which, together with pencil sketches made on the spot, enabled me to identify the views on development. I was very much troubled on my first excursion to notice the views, as all the churches got mixed up in my mind, and could only be identified by my sending prints to my sketching friends, who recognized the views.

On my way to Bury, on the previous Saturday, I visited Cambridge, and secured six views in and about Trinity College, for which I had to obtain permission. They are numbered 33 to 37. The old road shown in 33 and 34 is very beautiful, as may be seen from the photographs.

Sunday was devoted to devotion and strolling through the town; but two sets of enterprising individuals made carriage excursions to places not included in the coming week's work,

* Abstract of a paper read before the Photographic Society of Ireland,

with poor results, as the porch at Foston Church. (No. 38, taken at half-past seven in the evening) is all that I can show for my Sabbath breaking.

Our excursion proper commenced on Monday morning, and after breakfast, at eight o'clock, we left Bury at nine, arriving at Mildenhall (near Newmarket) at 10.50. The church here is illustrated in views 7, 8, 9, and 39 and 40, and is remarkable for the beautiful carved oak roofs on nave and aisles, which, I regret to say, seldom show distinctly in a photograph. The church is built of flints and stone, which are arranged to form tracery or chequer work in the walling. No. 41 is a view of the quaint market cross covered with lead. There is also a manor house of no great interest. After remaining two hours at Mildenhall, we left for Ichlingham, where we arrived at 1.30, devoting an hour to the interesting church, now disused; the nave and porch are covered with thatch, and are illustrated in Nos. 42, 43, and 44. After an hour's sketching, we left for the manor house of West Stow, with a very good entrance of brick and terra-cotta, beautifully mellowed by age, which I was unable to photograph, as the light was against me. The sailor and others may steer very close to the wind, but we photographers must keep the sun on our side or at our back if we do not want to have him peeping over the tiles and roofs, and looking into our cameras; I, however, secured a general view (45), and two interiors (46 and 47), the latter being a curious fresco on the wall of the room of the four (not seven) ages of man. The first is a youth, with a falcon on his wrist, and the legend, "This do I all the day." The second is a young man embracing a girl, and saying, "This do I while I may," and an old man further on, pointing at the last, exclaims: "This did I when I might"; and the last scene in this strange eventful history is a slippered pantaloon on crutches exclaiming, "Good Lord! will this world last ever?"

At 8.40 Morgan Hall, the seat of Lady Gaze, was reached, and two hours spent in sketching the details of this spacious Tudor mansion, which is illustrated in views 10, 11, and 12.

On Tuesday I secured views of Wetherden Church (50), a typical church of the district, built of flints, with a square tower at the west end. 51 illustrates the elaborately carved oak bench ends, with grotesque animals seated on the elbow rests of each; and 52 is the west door. Woolpit Church came next on our list; it has a stone spire (No. 53), and a very elaborate south porch (13 and 54). A view of the cosy rectory is given (No. 55), embowered in clematis, with sunflowers 8 ft. to 10 ft. high in the garden. Rattlesden Church has also a beautifully carved south porch (59), and font (58). The Church has a spire covered with oak shingles. Rushbrook Hall, standing in a beautiful demesne, and surrounded by a moat, is illustrated.

On Wednesday we visited another moated manor, Kentwell, of earlier date (20, 70, 71, 72, 73, 74), of which I have secured six views, and two of the finest Churches seen during the week.

Nos. 21, 22, and 82 illustrate Hawstead Church, visited on Thursday; and Stanninfield Church (83 and 84). Coldham Hall (23 and 24), a large red-brick mansion, is interesting on account of the secret rooms and means of escape contrived in the walls.

Plumpton Manor is to be seen as a background for our group (No. 25), graced with the presence of the ladies of the house. The house dwells in our memory far less for its architecture, than for the kindness and hospitality of its owner, Mrs. Bevan.

The church of Little Saxham, with a Norman round tower, was visited on our return to Bury, and also Jekworth, a stately mansion founded by a Bishop of Derby, now the seat of the Marquis of Bristol, who also entertained the visitors with noble hospitality; views of Jekworth are given (No 87 and 88).

On Friday, we visited the churches of Packenham and Inworth, the Manor House of Bardwell (29) and Church (30 and 31). Also Stowlangtoft Church and the very fine Church at Walsham Willows are fully illustrated.

When we awoke on Saturday morning with "Auld Lang Syne" ringing in our ears, our festivities did not reduce the number who mustered at the Abbey Gate, Bury at 9.30. They may be seen in No. 1, preparing to do Bury, which we did, inspecting the ruins of what was once the finest abbey in England. No traces of the Abbey remain, except the gateway and the Abbots Bridge, a structure illustrated in Nos. 2, 100, 104, and 105. There are also two very fine churches, St. Mary's and St. James's.

TELESCOPES FOR ASTRONOMICAL PHOTOGRAPHY.*

Before giving any suggestions as to the best kind of telescope to use, and the best methods to follow in the application of photography to astronomical observation and record, it may be more convenient to mention briefly what can be done in this way, particularly as the subject will be new to many who have not followed closely what has been recently done.

I wish to mention (1) That photography has now shown itself capable of giving us pictures of nebulæ that are superior to those made by eye and hand. (2) That anything that can be seen by the eye with a telescope of a certain size can be photographed, and, further than this, stars that are too faint to be seen in this telescope can yet be photographed by it with sufficient exposure. (3) That portions of the heavens of several degrees extent each way can be photographed, and stars therein of a magnitude smaller than that shown on the best existing charts or maps, pictured in their proper relative positions and magnitudes in a quicker, better, and more accurate manner than by the plan hitherto used. (4) That it is possible thus to make a complete series of such pictures embracing the whole heavens, that will be practically free from human error. (5) That each individual nebula, cluster, or group of stars, can also be taken on as large a scale as possible, and form a supplement to the picture-maps on the smaller scale. (6) That though such pictures may differ slightly from the eye observations, owing to the different colours of light not affecting the eye and the sensitive plate in the same manner, they would have the enormous advantage that they could be compared directly with other pictures, taken after the lapse of any number of years, under conditions that there would be no difficulty in making almost identical. (7) That there are other applications of this new power, as in direct enlargements of the surface of the moon piece by piece, of the planets, of double stars, and close clusters; and indirectly in the discovery of planets, either major or minor, by the simple process of direct comparison of star pictures taken at intervals, when the actual position of a planet will be recorded at each date. If there be a planet beyond Neptune, such a plan as this is, perhaps, the only way to detect it, especially if it is now near the Milky Way, where stars of its probable magnitude cluster so thickly that no process other than this could be used to chart the stars and detect movement. If these things can be done—and I most confidently say they can—then it must be admitted that nothing short of a revolution in observational astronomy must result, to the enormous gain of astronomy.

I speak relying entirely on my own work and experiments, which I shall refer to in detail further on, and I am strengthened in my opinions by what I hear has been done in a similar direction elsewhere, though I have not, except in one case, seen any of the actual work done.

The possibilities that are thus opened out really border on the marvellous. As has already been said by some one else, a library may now be made, not of books full of descriptions and figures, the accumulated work of many men working many years, each on his own system, but of pictures written on leaves of glass by the stars themselves.

Such a work will mark an epoch in astronomy, and its value increase as long as astronomers exist. No one can doubt for one moment the importance of such a work, nor the fact that, now it is possible, any delay in doing it will be a direct loss to astronomy. How it is to be done—whether by the slow process of letting it be done by the disjointed efforts of many amateurs of astronomy, or by being properly taken in hand and finished by united effort and proper means in the course of a few years—remains to be seen.

I propose to make some suggestions as to the practical part of this work in the selection of the best kind of telescope and mounting, the methods of working, the work to be done, and some other matters in connection. The most important matter is no doubt the selection of the best instrument to work with. Of the two kinds of telescopes now in use, the reflector seems to be the most suitable for this work, though a reservation may be made in favour of the refracting principle where large fields on a small scale are required. Both kinds of telescopes when of moderate dimensions—that is, not more than 18 inches aperture—are so nearly alike as optical instruments, that the chief distinction worth noting—neglecting for the present one or two points where they differ, and altogether such points as are rather matters of individual prejudice on the part of the

* *Nature*

observer, than qualities or defects in the instruments—is that of cost, the reflector being very much less expensive to make. It is true that the refractor has been hitherto generally considered the most satisfactory in use, and has been preferred when expense has not been a consideration of importance. I think this may be rather due to the greater care that is bestowed upon the more expensive instrument, both in the making of object-glass and the mounting, than to any real difference that there is between them. The first cost of the raw material alone differs immensely. For the reflector one disc of glass alone is required, and if it is only properly annealed it need not be optically pure. There is only one surface to work, though it is of importance that this should be properly figured; this is not a difficult matter, yet there is little doubt it has often been very imperfectly done in many so-called reflecting telescopes.

(*To be continued.*)

A METHOD OF TESTING FOR IODINE IN THE PRESENCE OF LARGE QUANTITIES OF BROMINE.

BY PHILIP S. BRITO, M.B.,

Late Demonstrator of Anatomy, Aberdeen University, and Science Student, University of Edinburgh.

When engaged in analytical work in the Chemical Laboratory of the University of Edinburgh I discovered the method of testing for traces of I. In the ordinary process of analysis, from a solution supposed to contain Br or I, we liberate the halogen by the aid of small quantities of chlorine, and carry it down with chloroform. The violet colour of I, or the dark sherry-brown of Br, picks out the element. But in a mixture containing both, the colour of the less abundant halogen is masked. When I preponderates it is got rid of by the addition of $CuSO_4$, and H_2SO_3. When, however, the Br is in very great quantity, I find that the addition of a crystal or two of $FeSO_4$ completely decolourises the brown colour, and renders visible the minutest traces of I dissolved by the chloroform. The value of this test may be gathered from the fact in the KBr supplied as a reagent in the laboratory, and which is supposed to be pure, the application of the $FeSO_4$ crystals demonstrates the existence of a trace of I as an impurity. Further, when the colour aloue is not decisive, and auy doubt exists, its application will settle the point. The behaviour of the Br is probably due to the oxidising power it possesses in common with its sister Cl. How far the decolourisation can be taken advantage of to determine volumetrically the amount of Br in a given exercise can be settled by actual experimentation. However, the ferrous sulphate method when used as a qualitative test works well, and my fellow-students and I have never found it to fail, so that although it transpires that the method is not new, yet if this contribution succeed iu directing attention to it I shall have done some slight service towards the furtherance of chemical knowledge.—*Chemical News.*

THE TROUBLES OF MR. MELANDER.

Anthony's Bulletin makes the following remarks iu reference to Mr. Melauder, who is the mouthpiece of some Western photographers in their complaiut against amateur photographers:—

"Amateurs in the true sense of the word take up the art from a pure love of it, and practise without a consideration of reward. But everyone understands, who knows anything of the universal rules governing the standing of amateurs in any branch of the arts, sciences, or of sports, that the moment one receives money for a performance, product, work of art, or it matters not what, he ceases to be an amateur, and becomes a professional.

"Surprising as it may seem, the number of these so-called amateurs among Mr. Melander's clients has become very large. Boys, with ten dollar outfits, are proposing to do portrait work, and, what is more to the point, actually take the orders and execute them at prices which pay little more than the cost of the plates and the ready sensitized paper on which they are printed, to say nothing of the cost of the mounts. Then, with a "cheek" that is phenomenal, they have in more than one instance asked Mr. Melander to burnish their work; sometimes assigning as a reason that the work is for one of his customers. Of course this class of work disgusts the customer, and he is likely to come and order another dozen or two from the gallery; but here is where the worst of the trouble begius to be felt. He says: 'I know what these things cost. You ask too much. Paper is worth so much, gold is so much, aud a graiu will tone a sheet; I caunot afford to pay you the old prices. I have a young friend in the business, and I know all about it.'

"Under such circumstances it is difficult to argue with a man; and, while it is sufficient to say that these are prices from which one cannot vary, the patrou is dissatisfied, and will probably take the first opportunity to go elsewhere for work. With such cases occurring from week to week, it is not difficult to see why, not only Mr. Melauder, but many other photographers in the West, have no love to lose for the renegade amateur who begins *business* as soon as he is able to make a development and print a picture."

Mr. F. C. Beach, the able President of the Amateur Association of New York, tells the story of a non-professional photographer after Mr. Melander's own heart.

"A gentleman spent his summer vacation uear a country village, in which was a resident photographer barely able to earn his support; while taking pictures, attracted by operating his instrumeut, many persons asked him to take their photographs, and what they cost. He always told them he would take a negative, and as it cost so little he would charge them nothing. He would make them a present of the negative, and if they wished auy prints they could deliver the plate to the village photographer, who would accommodate them. He had previously advised the protographer to charge a good price for the work. In a short time his orders became so plenty that he was soon placed in very comfortable circumstances. Thus it was shown that while there may appear to be an antagonism between the professional and amateur, he frequently renders to the former substantial benefit."

Correspondence.

EXHIBITION AWARDS.

Sir,—I have to call your attention to the extraordinary action of the Photographic Society of Great Britain in respect to the medal offered for lantern slides at the late Exhibition. The medal has been awarded to Mr. Gale. I have written to the Secretary to protest against it on the following grounds:—

1. That the slides exhibited by Mr. Gale were not qualified for competition.
2. That if they were, they were not worthy of the medal.
3. That they were uot submitted to the whole of the jurors.

The first of these objections is founded upon the conditions under which the medal was offered, that the slides for competition should be sent in by a certain date.

They do not appear in the original uncorrected catalogue, or in the second corrected edition. I am also in a position to show that they were not in the possession of the Society, at any rate, up to the 6th October, 1884, the day upon which the Exhibition was opened to the public. A series of slides by Mr. Gale was exhibited on the screen on that evening, I believe, but they were not the slides which were afterwards shown, and for which the medal was awarded.

The second objection applies, of course, still more forcibly to the first series of slides which were shown on the screen as Mr. Gale's, as they were in every respect far inferior to the final selection. I wish to give Mr. Gale every credit for the real artistic feeling which dictated these slides, but affirm that their technical defects were sufficieutly great to render them unworthy of the distinction of a medal.

As to the third objection, I am in a position to prove the facts. To this the Photographic Society may reply that the medals awarded to Mr. Gale and Mr. McKellen were extra medals. To this I should have uo objection whatever if *the* medal had been awarded for the slides actually sent in for competition. It is absolutely impossible for anyone knowing anything at all of the subject to deny that there were at least ten frames of slides, which were entered strictly in accordance with the regulations, worthy of a medal.

The fact is, that I (and I believe all the other exhibitors without exception) feel deeply aggrieved at the want of consideration or common courtesy allotted to us by the entire management of the lantern show both last year and this. Professional slide makers know that the optical lantern must become the great educational instrument of the future, and sent their slides in for exhibition on the faith of the Society's prospectus, fully expecting that their merits would be fairly judged, and that the public would thereby become acquainted with the progress made in so very important a branch of photography. Neither they nor the public wanted that ridiculous nightly apology for diverting the Society's lantern from its special purpose (of spectrum analysis in connection with photography!) to the comparatively base use of showing photographic transparencies.

The conditions laid down, that the negatives and transparencies should be the work of the same operator, were extremely ill-advised. The proof is that the exquisite slides by Mr. Brooks from Mr. Donkin's negatives would have been thereby shut out. The complete absence of all other conditions shows either consummate ignorance of, or utter indifference to, the great importance of the class. However, many excellent slides were sent in for competition, strictly in accordance with the Society's conditions, and the manner in which their claims have been ignored is an unpardonable insult to others besides

your obedient servant,
GEORGE SMITH.

26, *Colebrooke Row, N.*

SIR,—Considering that but few expressions of real discontent have appeared in the PHOTOGRAPHIC NEWS as to the distribution of medals at the late Photographic Exhibition, and that many have expressed their satisaction, it is almost needless for me to say anything on the subject. Still I must own that I agree entirely with the present excellent way of judging, and think that it is much to be preferred to the old way of the judges meeting together, choosing the dozen or so best pictures, and then awarding medals to several out of these. To say the least, the new method is very much fairer than the old.

While writing this, I can quite see that out of such a number of fine subjects it is extremely hard—nay, impossible—to please everybody; but I cannot help feeling that in this year's show there is far less ground for discontent than ordinarily.

A NON-EXHIBITOR.

[The London Exhibition being closed, the paper war between contented spectators and disappointed exhibitors had better stand over till next year. Possibly some novel point may then be raised.—ED. P. N.]

SPOTS ON PRINTS.

SIR,—Some proofs on albumenized paper that have been left some time without being mounted on cards get covered with little perfectly round white spots when they are damped for mounting. French photographers call this *petite verole*. Is the cause known? You would much oblige us by submitting this question to the numerous readers of your interesting journal.

Oporto, 11th November, 1884. A. A. P.

THE HYROXYLAMINE DEVELOPER.

DEAR SIR,—I should be obliged if you would permit me to explain more fully a rather important point raised by Mr. Warnerke in the discussion on my paper. The question was asked: Is hydroxylamine as powerful a developer as pyrogallic acid? In answer I stated that when using a solution containing the same proportion as alkali, pyro was certainly more powerful; but that in the formula given, a much larger quantity of alkali was present than suitable for pyro development. Thus, with my formula, the hydroxylamine developer was practically quite as powerful as that of pyrogallic acid. In proof of this assertion, it is distinctly stated in the editorial notice, page 691, that "in the case of the plate exposed under the sensitomer, the same figure was got as with the pyro-developer." I may also state, in confirmation of this result, that a plate exposed with a drop-shutter last month, on development with hydroxylamine, produced a negative full of detail, and exhibited not the slightest hardness or other effects which too often are met with in so-called instantaneous photographs.—I am, sir, &c.,

ARNOLD SPILLER.

ELECTRIC LIGHT FOR THE LANTERN: CLEARING SOLUTION.

DEAR SIR,—Has the electric light been tried for the magic lantern? I read that the electricity can be bottled up! If so, why should it not be used for lanterns? What is the best and safest light to use for lanterns at home?

I see in your paper of Friday last, page 727, a paper read by Mr. T. Baynton, in which he says: "Use for a clearing solution: alum, 1 oz.; sulphuric acid, 1 oz.; water, 20 oz. I think this must be a mistake, as I use 1 oz. sulphuric acid, 1 oz. to 40 of water, and find if plate is left in over 20", it will destroy the film. He must mean ½ oz. to 20 oz of water.—Yours truly,

A. R. DRESSER.

[Although the application of the electric light to the demonstrating lantern is almost as old as the first use of the arc, the electric light has not yet been used in a general sense as a lantern light: we shall be glad to record the experiences of our readers in this matter.—ED. P. N.]

Proceedings of Societies.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

A MEETING of this Society was held on Thursday, the 13th inst., Mr. A. HADDON in the chair.

The evening was occupied in discussing which process of making transparencies was the most suitable for ordinary work. The competing processes included collodio-albumen, wet collodion, carbon, Woodburytype, gelatino-bromide, gelatino-chloride, and gelatino citro-chloride. The same pair of negatives was used by each manipulator, in order to judge fairly the comparative results.

Messrs. C. and F. DARKER placed their oxyhydrogen lantern at the disposal of the Society, Mr. F. Darker personally superintending the arrangements.

Each transparency was shown upon the screen and its merits considered, the method of production being a secret; by this means a standard of excellence was arrived at which, in the end, resulted as follows:—River scenes—1, collodio albumen; 2, wet collodion. Figures—1, Woodburytype; 2, gelatino-chloride; 3, gelatine bromide (very slow emulsion).

An example of gelatino-bromide developed with hydroxylamine was shown by Mr. J. B. B. Wellington. The result, although good, was not considered quite up to the standard. The developer mentioned was hydroxylamine, 1 grain; caustic soda, 4 grains; ammonium bromide, 1 grain; water, 1 ounce. Twelve minutes were occupied in developing.

The CHAIRMAN considered it proved that good transparencies could be made by several processes.

Mr. COBB showed views on the screen of the Lord Mayor's procession; and

Mr. A. L. HENDERSON exhibited a picture showing the ceremony of laying the foundation stone of the Liberal Club, taken principally by electric light, with, he thought, the fastest plate ever made.

December 11th the subject will be:—"Avoiding Granularity in Copying," by Mr. W. E. Debenham.

CAMBRIDGE UNIVERSITY PHOTOGRAPHIC SOCIETY.

A MEETING was held on November 15th, Mr. SHAW, M.A., in the chair.

The minutes of the preceding meeting having been read and confirmed, the Chairman called on Mr. Elder to read a paper on the "Autotype Process."

Mr. Elder first gave a short historical sketch of the process, and then explained the different ways of working it. He also showed a great number of fine specimens which had been kindly lent by the Autotype Company.

A short discussion followed, and after a vote of thanks to Mr. Elder, and through him to the Autotype Company, the meeting adjourned.

Glasgow and West of Scotland Amateur Photographic Association.

The usual monthly meeting was held on Tuesday evening, 11th instant, Mr. High Reid (President) in the chair.

The following new members were admitted:—Messrs. J. R. Reid, David McSkimming, J. Bertram, James Lumsden, William Gray, John Conbrough, Archibold Auld, A. Brown, G. Logan, A. M. Donald, James Logan, and George Sheriff.

Mr. W. Goodwin then read a paper on "Isochromatic Plates," and passed round some very interesting results, which impressed the meeting very favourably. Mr. Goodwin also read a short paper on "A New Developer" (see page 743), and demonstrated the changes of colour before the meeting.

At the request of several of the newer members of the Association the President repeated his demonstration of the Platinotype Process, with great success. He gave all particulars regarding licence, paper, printing, &c., and developed a number of prints, which were distributed amongst the members present.

The nomination of office-bearers for 1885 was then proceeded with.

It was agreed that ladies be admitted members of the Association at a reduced rate, those joining in December to have the right of exhibiting at the forthcoming Exhibition in the middle of December.

Bolton Photographic Society.

The November meeting was held at the Baths, on the 6th instant, Mr. R. Harwood in the chair.

Messrs. J. Lomex, Junr., J. A. Walker, J. W. Walker, and R. Dickinson were elected members of the Society.

Dr. Johnson exhibited a number of prints from negatives taken during a recent visit to Norway.

It is intended to hold an "open" meeting on December 4th. Members were requested to bring as many good slides as possible.

Photographers' Benevolent Association.

On Thursday evening, 13th instant, the Exhibition of the Photographic Society of Great Britain was opened in aid of the Photographers' Benevolent Association, with a charge of sixpence admission; over 300 visitors passed the barrier. At 9 o'clock the Society's optical lantern was brought into use, and a series of most excellent transparencies were exhibited, Mr. Donkin, the Honorary Secretary of the Photographic Society, describing the different scenes. At the conclusion an admirable transparency of James Glaisher, Esq., president of the Society, taken by Mr. Mayall, was put upon the screen, and Mr. Thorne, in a short speech, informed the visitors that it was owing to the kindness of the President and Council of the Photographic Society that the Benevolent Association were receiving the benefit from the Exhibition and the use of the lantern, and asked them to join him in thanking those gentlemen, and also those who had very willingly lent the slides which they had seen that evening. The request was most cordially responded to.

Particulars regarding the constitution and objects of the Association may be obtained upon application to Mr. H. Harland, Secretary, 181, Aldersgate Street, E.C.

Leeds Photographic Society.

The ordinary meeting was held on Tuesday, November 11th, the alteration in the date of meeting being made so as to enable the members to spend the evening with Messrs. Bridge and Brooks, of the South London Society, who were in the town on that day.

The President (Professor Thorpe, F.R.S.) invited the members with Messrs. Bridge and Brooks to tea at the Yorkshire College. After an excellent tea, a vote of thanks to the President was proposed by Mr. J. W. Ramsden and supported by Mr. Teasdale and carried by acclamation. The members, under the guidance of Dr. Thorpe, then proceeded to view the various departments in the new College, and much admiration was expressed as to the completeness of its arrangements.

At 8 o'clock the ordinary business of the Society was commenced, Dr. Thorpe presiding.

Mr. J. W. Reffell (Treasurer) read the balance sheet of the Society, from which it appeared that £21 15s. had been received from subscriptions, and £11 19s.1d. expended in postage, printing, &c., leaving a balance in the hands of the Treasurer at the date the books were closed for audit of £9 15s. 11d.

Mr. Butterworth was elected a member.

The President then called upon Messrs. Bridge and Brooks to give their lantern demonstration.

The lantern, a triple oxy-hydrogen, was manipulated by Mr Brooks with his usual ability.

Mr. Bridge exhibited slides on gelatino-chloride plates, showing the different tones that can be obtained by this process.

Mr. Brooks—Slides prepared by his collodio-emulsion proces s

Mr. Pocklington exhibited some very peculiar effects obtained by toning gelatino-bromide plates with gold, nitrate of uranium, &c.

Mr. Ramsden—Transparencies on gelatino-bromide plates, own preparation.

Mr. J. W. Reffell—Transparencies on gelatino-bromide plates.

Photographic Society of Ireland.

The annual general meeting of this Society was held on Friday last, the 14th inst., in the Royal College of Science, Dublin, Mr. Herbert Bewley in the chair, when the report of the Council was presented, in which the Council announced a further increase of the Society, whose members now numbered 73, independent of those to be elected that evening.

A list of the papers of the session (which have appeared in these columns) was given; and allusion made to the varied collection of apparatus and photographic novelties that had been exhibited at the meetings, which, on the whole, had been fairly attended.

The annual lantern exhibition was held in March last, and was as usual a great success, all the pictures shown having been taken from negatives the work of members of the Society. It having been thought advisable to hold several short excursions on Saturday afternoons instead of the annual field day, arrangements were made, and Howth, Lucan, the Valley of the Liffey, and Glen Druid, were visited. The attendances at the last two of these meetings was not, however, sufficient to justify their continuance to the end of the season. The Council congratulated the members on having been the means of organizing the Photographic Exhibition now open, which, in the opinion of the Council, is one of the best collection of photographs which has ever been brought together; they feel confident that it cannot fail to elevate the standard of the art, and be of considerable service to photography in Ireland.

The report and statement of accounts showed a balance in hand of £50 8s. The report and statement of accounts were adopted. The President, Vice-President, Hon. Treasurer, Hon. Sec., and Hon. Assistant Sec., were re-elected for the coming year; as also the following retiring members of Council: Messrs. George Mansfield, Greenwood Pim, John L. Robinson, Thos. Mayne, Herbert Bewley, and E. P. Johnson.

Thanks were then passed to the Council of the Royal College of Science, for the use of their premises during the past year; and to the Council of the Royal Hibernian Academy of Arts, for having placed their premises at the disposal of the Society for the purpose of the Photographic Exhibition.

The following were elected members of the Society:—Messrs. S. Geoghegan, C.E., H. Magee, and Francis S. Hall.

Mr. John L. Robinson then read a paper entitled "A Week in Suffolk" (see page 747), being an account of the trip of the British Architectural Association for the present year.

Mr. Greenwood Pim (Hon. Sec. of the Exhibition Committee) announced the particulars as to the opening of the Exhibition on the 18th inst.

Sheffield Photographic Society.

The monthly meeting was held in the Masonic Hall on November 4th, Mr. W. B. Hatfield in the chair.

After the usual business of the Society, and previous to the special business,

The President made a few remarks on what he thought the best way of spreading useful and practical knowledge amongst the amateurs of the Society.

Mr. FOXEN then gave a lecture and demonstration on enlarging on argentic bromide paper. Two excellent enlargements were made from half-plate negatives, the light being an ordinary double-wick paraffin lamp and a tin condensor, a bellows camera and a whole plate Ross' symmetrical being used; the paper being pinned on an ordinary drawing-board.

The subject for the next meeting was announced to be "An Exhibition of Photographic Lantern Slides, and how to make them."

The meeting was one of the largest the Society has ever had.

Talk in the Studio.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The next monthly technical meeting of this Society will take place on Tuesday next, November 25th, at 8 p.m., at 5A, Pall Mall East.

THE NEW ORLEANS EXPOSITION.—Steps are being taken to make photography very thoroughly represented at the World's Exposition to be held in New Orleans next spring, the north gallery and east section of the main building having been set apart for photography. The following committees have been appointed for the various divisions of work in the photographic section:—On photographic apparatus and requisites, Col. V. M. Wilcox; on education, history, and literature, Prof. C. F. Hines; on amateur photographic societies, Mr. E. F. Beach; on practical photography, E. L. Wilson. The latter gentleman has also been appointed Superintendent of the Photographic Department.

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting, on Nov. 26, will be "Forgotten Processes."

To Correspondents.

*** We cannot undertake to return rejected communications.

THOS. E. LANSOM.—1. Although not sold here, they can be obtained at most of the dealers in photographic apparatus in Germany. 2. First rub powdered French chalk on the glass, and wipe off the excess with a piece of soft rag; next collodionize with ordinary plain collodion, and then coat with emulsion in the usual way. When the negative is finished and dried, collodionize it with a tough collodion containing about twelve grains of pyroxyline to the ounce. When this is dry, you can remove the film after having lifted the edges with the point of a penknife. If you send the collodiodized plate to a plate maker, he will, doubtless, coat them with emulsion for you.

CARBON.—1. We do not think that tissue containing an extra proportion of pigment is in the market. You will find full directions for making carbon tissue on page 453 of the present volume, and perhaps the following proportions (about three times the usual quantity of pigment) will suit you.

Nelson's transparent sheet gelatine ...	20 ounces
Loaf sugar	8 ,,
Water	50 ,,

Melt in a water bath, and stir in an ounce and a half of the moist and ground Paris black, sold in tubes for water-colour painting. 2. All the qualities of gelatine required for the purpose can be obtained from Messrs. Nelson Dale and Co., of Dowgate Hill, City.

J. H. R.—The course generally recommended is to try to work the poison out of the system by attention to the general health, and the use of Turkish baths.

MEADOW.—It will give us much pleasure to insert your letter if you will allow us to put your own name to it. Surely you cannot expect us to insert your long tirade against the picture. Do you think that your opinions will suffer by being printed over your name, or that your name will be injured by being associated with your criticisms? May we print the letter over your name?

ENQUIRER.—In such a case it is difficult to give exact quantities, as so much depends on the nature of the paper.

A. ELBERT.—Comprehensive articles on the subject appeared in our volume for 1881, p. 54, 511, and 595. See also our forthcoming YEAR-BOOK.

A. H. B.—The information is curious, and we shall make use of it.

W. E. G.—1. See the series of articles, of which one appeared last week. 2. Not so; it is obtained by writing with an opaque ink on the negative. 3. It is the best, and several manufacturers of plates use it. The "substratum" consists of an extremely slight deposit of silica, formed by the action of the atmosphere on the alkaline silicate.

JOHN GILPIN.—We imagine that you will have to make them yourself, or get them made to your own designs by one of the Birmingham houses.

H. HOWARD.—It seems to us that the mischief arises from the mount; but to test the matter conclusively, cut a print into two parts, mount one portion on the questionable mount, and the other on a mount such as you have previously used. If both are kept under similar conditions, you will probably obtain positive evidence.

B. BOOTHROYD.—Unfortunately, we do not know the address of the gentleman, but we will try to get it.

TONING BATH.—We should recommend you to make up a fresh bath, as the loss of time and uncertainty involved in trying experiments would more than balance any gain. The fact of such an accident not being likely to occur again is an additional reason for wasting no time with it.

ROBERT SIMPSON.—1. It can be done, but involves much work and care. Call on Mr. A. L. Henderson, of King William Street, London Bridge. Why do you enclose stamps? It puts us to the trouble of returning them, and, moreover, we fancy you give an insufficient address.

W. S. F.—It closed last week.

T. HANSON.—There is no book on the subject, but articles frequently appear in the PHOTOGRAPHIC NEWS. See page 628 of our present volume, also 2 of the last volume, 1883.

J. THOMPSON.—The book is not to be had, unless by chance from a second-hand bookseller. You will find that the "Silver Printing" of Robinson and Abney, and the "Instruction" of Abney; will give you later and more useful information than the work you mention.

VANDYKE.—It would not be kind of us to give you the addresses of photographers who use the electric light, as we know that much of their time is taken up by visitors who want to see everything. To set up a good lighting plant of dynamo and engine would certainly not cost less than three hundred pounds; and unless you yourself possess some engineering skill, you may reckon something considerable for current expenses. If, on the other hand, you prefer to have a battery arrangement, you cannot do better than use Mr. Jarman's arrangement of bichromate batteries described on page 500 of our volume for 1881. This will give a light equal to about a thousand candles, and lasting quite long enough to make a portrait, the cost of the apparatus being about the sum you name. Write to Mr. Jarman; his address is Macintosh Lane, Homerton, E.

B. C. J. SEYMOUR.—The original is a zinc plate, which is etched by the usual chemigraphic process, and that which you have seen is doubtless an electrotype reproduction.

'The Whittaker of the Photographer.'—*Chemical News*

OVER A QUARTER OF A CENTURY OF PUBLICATION.

ON DECEMBER 20TH, PRICE 1s., PER POST 1s. 4d.,
THE
Year-Book of Photography.

The simple fact that the YEAR-BOOK OF PHOTOGRAPHY has run out of print *during the past three years* within six months of its publication is proof sufficient of its popularity and wide circulation, and Messrs. PIPER & CARTER, in announcing its appearance for 1885, need put forward no better claim as to its value as an advertising medium.

Intending Advertisers in the YEAR-BOOK OF PHOTOGRAPHY AND PHOTOGRAPHIC NEWS ALMANAC should communicate with the Publishers at once at the Office, 5, Castle Street, Holborn, London, E.C.

The Photographic News.

STANDARD SIZES FOR PLATES.

THE Berlin Society of Makers and Dealers in Photographic Goods has (in a fashion which somewhat reminds one of the three celebrated tailors who, according to a well-known legend, resided very near the site of London Bridge Station) determined what are to be the future standards of size for photographic plates and carriers—at any rate in the German Empire—and the new standards seem in some hasty fashion to have obtained recognition by the Photographic Society of Berlin, as the standard sizes of the future.

The new arrangement—if, indeed, the hasty and haphazard selection of sizes by the apparatus makers of Berlin can be called an arrangement—appears to have been made entirely without reference to the dimensions of the photographs usually demanded, or to the original size of the paper used for making the prints, and ordains that the sizes of the future shall be as follows, the measurements being in centimetres:—9 by 12, 12 by 16, 13 by 18, 13 by 21, 18 by 24, 24 by 30, 30 by 40, 40 by 30, 50 by 60. Manufacturers and dealers are to try and influence their customers to select apparatus made to the new standard, and to consent to old ones being altered when repairs are made; but until the good time of absolute agreement comes, manufacturers of plates will be allowed to make the following sizes under protest—centimetres:—10 by 13, 16 by 21, 21 by 27, 26 by 31, 29 by 34, 34 by 39, 39 by 47.

The *Wochenblatt*, in its character as the official organ of the Berlin Photographic Society, gives publicity to the new arrangement; but Dr. Stolze is evidently in doubt whether the standard measurements refer to the carriers or to the plates, and to his article he appends a note saying that he assumes the dimensions to refer to the plates.

The new standards of size translate very badly into inches, and not one of them comes very near to any size commonly used in England. Indeed, it is difficult to see the practicability of establishing standard sizes which shall be at the same time equally convenient to those reckoning by centimetres and those who use inches; but considering that the greater number of civilised nations measure altogether according to the metrical system, while Germany herself is in a kind of halting position between inches and centimetres, it would have been much better for Berlin to have waited for the International Congress on Photographic Constants, which is to meet in Brussels next spring. On this occasion, not only the sizes of plates will have to be considered, but, what is also of much importance, the difference in size to be allowed between the carrier and the plate.

If the Brussels Conference succeeds in establishing universal sizes, the following circumstances will, among others, have to be brought into consideration; and to do this thoroughly will involve a good deal of enquiry and labour.

1. The sizes of finished pictures most in demand and more especially suited for given purposes.
2. The dimensions of the sheets of paper ordinarily used for photographic purposes.
3. The sizes in which glass is usually sent out from the works.
4. Plates and apparatus now commonly in use.

Having determined on convenient sizes—and, if practicable, sizes already in general use—the dimensions can be given according to any system which may be convenient for the manufacturer or the user.

The present variety of sizes is extremely inconvenient for those who are in a foreign country, and it is much to be hoped that the coming Congress will establish standard sizes which will be universally accepted.

CONFERENCES ON THE PICTURESQUE.

THE Edinburgh Photographic Society is fortunate in its new President. Ever since the formation of the first Photographic Society, of which Sir Charles Eastlake, President of the Royal Academy, was the original President, great artists — both painters and sculptors — have taken but a languid interest in the Art Science, abusing it sometimes, using it often; but Mr. Norman Macbeth, R.S.A., is distinguished as the one painter of eminence who has always believed in photography, and has done all in his power to make the followers of our art into artists. He has actually believed that it was possible to make pictures by aid of photography; he has known and taught that it is the man, and not the material, that makes the picture. For many years Mr. Macbeth has represented the pictorial side of photography in the Edinburgh Society, and whenever this genial gentleman discourses on art, his advice is direct and practical, while his hearers feel that they can go and apply it in practice in their every-day work.

In his admirable address, lately delivered to the Edinburgh Society, the President announced that every alternate monthly meeting would be set apart for a friendly conference on the works of those members disposed to submit them for that purpose. "But," continues the President, "as knowledge is what we aim at, I do not see that we should confine ourselves solely to our own productions. Anyone in possession of a photograph which he admires, should bring it to the meeting for inspection and consideration, if not for discussion; but in every case it should be distinctly labelled whether for discussion or not, always reserving the name of the author. We cannot look for examples for discussion from professional men unless they are pleased to be generous enough; but from amateurs, who have no object but the acquisition of knowledge and experience, I would fain hope there will be no lack."

The mechanical and chemical sides of the art have,

during the last half-dozen years, progressed with giant strides. Processes almost unhoped-for have become established facts, giving the operator opportunities for producing results of which he had not previously ever dreamt. One year we were boiling our developers in the almost forlorn hope of making a slightly shorter exposure sufficient with the wet process, and the next we were in possession of a method of working, of which it might almost be said that it leaves the photographer to think of nothing else but the art qualities of his work, and enables him to secure his results with the utmost rapidity and certainty. But has the photographer—the picture maker—taken all the advantage he should have done of his new opportunities? We think not. Art knowledge has, of course, spread among photographers, but has it been used in anything like proportion to the improvement in processes?

Pictures on the whole are probably better than they were in the days of collodion, but that is to a great extent owing to the shorter exposure necessary. It is disappointing, with all the facilities the photographer now enjoys, not to see some really great works in our exhibitions. Too many photographers try to run before they can walk, and neglect to study the few simple rules upon which all art is based; rules which have been observed from the time when representation emerged from the mere tracing of form and became art. These "Conferences on the Picturesque" ought—if they are conducted properly, as they no doubt will be under the presidency of Mr. Macbeth—to be of immense value in diffusing a knowledge of art among the members of the Edinburgh Society. There is just one thing against which those who send in pictures must guard themselves: they must not be afraid of a little friendly criticism, and must learn to listen to the most adverse opinions with equanimity. Given plenty of pictures to criticise and good temper in the criticised, and these conferences should be not only profitable, but delightful.

We hear that a number of contributions have been sent in, not only from amateurs, but from professional photographers, for the first conference which takes place next Wednesday.

We wish it every success, and recommend the idea to the consideration of other societies.

"THE OLD INN YARD" BY D. BARNETT.

AMONG those pictures which received no official recognition at the Pall Mall Exhibition, may be mentioned that which forms our supplement this week: No. 351, "The Old Inn Yard," by Mr. Barnett.

Poets and painters have long delighted to place upon record the charms of old country inns, where none of the pomps and vanities of the modern hotel are to be found, and where one feels, as it were, at home in a new home almost immediately on entering. Now and then one comes across a photograph of the old-fashioned and quaint hostelrie, but too often is all pictorial effect lost, either from the fact of the camera being set "square on" to the building, or by some prominent indication of progress of the last few years being made a prominent feature in the composition—let us suppose a tricycle or an iron milestone.

It is in the following words that the author of our picture laments the gradual disappearance of certain phases of the picturesque before modern civilisation, and tells us about the production of his "Old Inn Yard."

"It is a melancholy fact that as the knowledge and love of art is becoming more widely spread, so is the search for the picturesque becoming more and more a difficult task. To the painters, perhaps, the obstacles are not so great, but to the photographers they are often insuperable, and it is greatly to be deplored that some of the appliances of modern science cannot be made to assume less objectionable forms. What can be more out of place, amidst the wildest and most romantic scenery of Norway, than the ugly Telegraph post and wires which are constantly obtruding themselves, and which are of course always present when least wanted? Railway cuttings, mining operations, reservoirs, disfigure the most beautiful spots, and the dear old relics of past generations are fast disappearing.

"It was after a long day's tramp with my camera, in the neighbourhood of Stroud, that I came upon the 'Old Inn' at Nailsworth. It was rather an awkward spot for operations, being situated in the main thoroughfare; but the effect of shadow was so strikingly beautiful that I hastened to make the attempt. Of course the usual stuccoed atrocities were present in close proximity, but fortunately for me they were so situated that I was able to avoid them. So I exposed the plates, and right glad was I that I had lost no time, for the effect vanished almost as soon as I had finished."

THE SIEMENS STANDARD LIGHT.

AT the last ordinary meeting of the Photographic Society Captain Abney called attention to the Siemens or Hefner-Atteneck standard light, and the following details, received from a German correspondent, will be of interest. The light, as our readers know, is obtained by burning amyl acetate in an open burner, the diameter of thus being $\frac{5}{16}$ of an inch, and the height of the flame, after ten minutes' burning, 2·6 inches.

Experiments were made with various other substances in the same lamp, and the results obtained are given in the following table:—

	Light.	Seconds required to burn 1 gram.
Amyl valerate ...	1·03 ...	436
Amyl acetate (pure) ...	1·00 ...	388
Amyl acetate (com.) ...	1·00 ...	388
Amyl formiate ...	1·01 ...	372
Isobuttl acetate ...	·99 ...	373
Isobuttl formiate ...	·97 ...	355
Ethyl acetate ...	1·24 ...	212

It may be remarked that amyl acetate boils at 138·6, and is not explosive.

The employment of commercial instead of pure amyl acetate, the replacement of a hard spun wick by a soft one, and the mode of trimming the wick, do not appear to materially affect the luminosity of the flame. As the introduction of the new light should present no difficulty or uncertainty, it ought to prove useful for sensitometric work.

PRINTING BY DEVELOPMENT.

UP to the present, albumenized paper has tolerably well held its own as a material upon which to print photographs, and notwithstanding the fact that good development methods have been proposed and have been practised by a few, they have failed to come into general use for every-day work. Perhaps one reason for this is the circumstance that it has been difficult to imitate the style and get-up of an ordinary albumen print, and both photographer and customer are slow to adopt anything which differs in appearance from that to which they have been accustomed.

Quite recently, however, Messrs. Marion and Co. have introduced a printing paper which requires only an exposure of from two to four seconds on a dull winter day, and which yields prints having all the general qualities of those made on albumenized paper—with this exception, however, that the surface is a little better, if anything. The paper is obviously coated with a gelatine emulsion, and we fancy it also contains albumen, but of this we are not sure. As regards the sensitive silver compound, there is scarcely any doubt that it is a mixture of chloride and bromide, possibly with some additions.

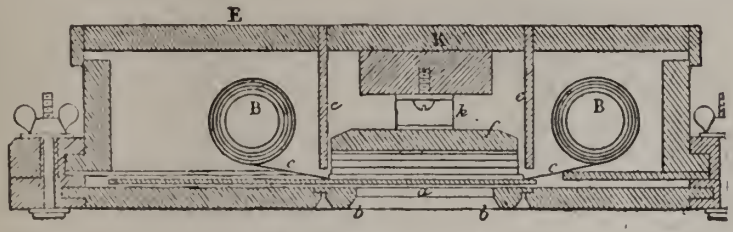
"THE OLD INN YARD."

PATENT OFFICE LIBRARY

The exposure can be made in an ordinary printing-frame, but, considering the shortness of the required exposure, those who have to make many copies will doubtless prefer to use a quick printing-frame of the Fontayne type, one of the simplest of these being that designed by Tromel, many of the complex adjustments of the original Fontayne frame being suppressed.



TROMEL'S PRINTING FRAME.

deseribe the mode of working with the new paper, especially as the "*Leading Journal*" has for a long time contented itself with dishing up the stalest and most unauthentie of photographic information to its readers, and it is only within the last twelve months or so that it has properly represented to its readers the current progress which has been made in photographic matters: and the artiele in which the process of printing by development is deseribed is so elearly written as to be intelligible to the general public, and so full and exaet as to be of value to the photographer. The *Times* in its issue of last Monday says:—

"The idea of coating paper with a gelatino-bromide of silver followed obviously enough on the suecessful employment of the same compound for the produetion of negatives, and many attempts have been made to produce in this mauner a paper which might give results equal to those of the process which is always known as silver printing, and at the same time be so sensitive to light as to allow the image to be impressed on it in a few seconds, instead of requiring an exposure often of hours; but the ehief objection to a gelatino-bromide paper is its cold gray, or even greenish, tone, and this appears the principal reason why pietures on it have not secured the favour of a publie edueated to a liking for the rich purple and ehocolate hues of ordinary photographs. The enlargements are generally a good deal worked up by hand, and when carefully finished form no bad imitation of a crayon drawing. The difficulty of proeuring warmth of tone and eonsequent brilliancy in the picture seems now to have been overeome in a new material which Messrs. Marion, the photographic dealers of Soho Square, have produced and are about to supply commercially. Messrs. Marion propose to work the process in sceret, believing that a safer method of proceeding than patenting it; and, consequently, the invention is of less interest to the scientific photographer than it would be if the manner of production as well as the results were revealed; but probably the effect on the photographic industry will be much the same. The paper is obviously coated with a gelatine emulsion of some sort, and in all probability rival experiments will before long find out its precise nature. As regards the results producible by its means, their value does not seem to admit of much doubt. No industrial process can properly be termed successful till it has stood the test of regular commercial work; but it is at all events safe to say that no improvement of such promise has been introduced into photography since the advent of gelatine plates. In Messrs. Marion's studio, on Saturday last, the writer saw produced three prints, which nobody could tell were not ordinary prints, produced with exposures of two, three, and four seconds, and he afterwards, at home, at 4 o'clock in the afternoon, with an exposure of fifteen seconds, produced on a first trial almost equally good results.

"The process of working the paper is quite simple. As may be supposed, the image has to be 'developed'—that is, no visible image is produced by the exposure to light. Consequently, the exposure has to be estimated, as it has in taking a portrait or a view. The development is effected in very much the same way as if an ordinary gelatine plate were under treatment, the developer being a weak solution of ferrous oxalate. After development the image is of a rich purple; but as this would change in the final, or 'fixing' bath, it is necessary to 'tone' the picture, as is done with an ordinary silver print, in a solution containing gold. After this the picture is 'fixed' in the usual manner. Considerable variety of tone can be produced, the tints ranging from a warm red brown to a purple, or even black.

"The objections to the process are that it requires rather more skill than the old system. It has to be carried out in greater darkness and with greater precaution. Nor are the results quite so bright and good as the best silver printing. It would, however, require an expert to tell the difference, and certainly no purchaser would be likely to complain if he were supplied with a batch of prints on the new paper. As regards permanence, only time can answer that question; but there seems no reason why it should be less permanent than the old, which, unfortunately, has in this particular not much to boast of. The new paper will, in all probability, come largely into use for winter work, and it ought to be used by all portrait photographers for sending out 'proofs' at once of their portraits."

The developer for Marion's paper is merely an ordinary oxalate developer, and the picture comes out quickly, and possesses a rich purple tone; but as this would more or less completely disappear in toning, it is necessary to use a gold bath, as in the case of ordinary albumenized prints. The fixing is effected in the usual hyposulphite bath.

It pleases us to note that the *Times* was the first to

Let us now quote from a leading article which appeared in the PHOTOGRAPHIC NEWS on January 5th, 1883:—

"We have frequently referred to the circumstance that gelatino-bromide or gelatino-chloride paper is likely to attain a position of some commercial importance, more especially when it may be necessary to produce a considerable number of prints in a short time; but very few photographers have yet learned to appreciate the power placed in their hands by the introduction of paper coated with gelatine emulsion.

"Some of our readers will remember that in 1860 (vol. iv. p. 270) we described a rapid photographic printing machine, which was invented by Mr. Chas. Fontayne, of Cincinatti. A strip of paper is drawn under the negative, pressed into close contact with it, and a measured exposure is given; solar light concentrated by a condenser being used. The series of operations is repeated, so that a number of impressions may be taken on the same strip of paper, it being merely necessary to turn a handle until the strip or roll of paper is exhausted. Although Fontayne used the most sensitive calotype paper obtainable when his machine was constructed, he did not find it possible to obtain more than 200 impressions per minute from one negative. This corresponds with a rate of 12,000 per hour, and by passing the exposed band directly into the developing, fixing, and washing troughs, the subsequent operations might be made to keep pace with the exposures.

"By reproducing the negative a sufficient number of times the turn-out of a machine constructed on the lines laid down by Fontayne might be increased indefinitely; and as a simple gas flame would serve in the case of bromide paper, we may before long hear of the steam photographic machines working all night, side by side with the steam typographic machines, for newspaper work.

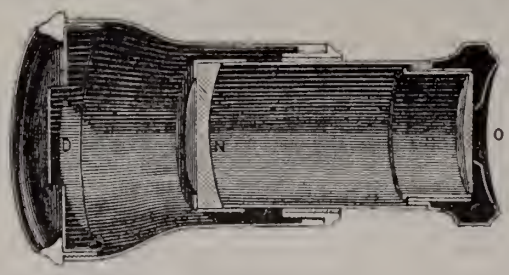
"Fontayne proposed to work his machine by steam, and the description given in the NEWS twenty-three years ago is so detailed and circumstantial that there seem to be very few novel points which the modern patent-hunter can add and lay claim to. We hope to hear of the actual use of Fontayne's machine during the present year.

"Ordinary photographic papers—such as Saxe or Rives—are, we believe, manufactured in widths of fifty-four inches, so that many negatives of ordinary dimensions might be printed from simultaneously."

ROSSIGNOLS' ICONOMETER, OR VIEW-METER.

AN apparatus likely to be of considerable use to workers in the field, is the iconometer of M. Rossignol, and we take the following description from a recent number of *La Nature*. In principle, as also in construction, the present form of Rossignols' iconometer does not differ very much from instruments which have been described in the PHOTOGRAPHIC NEWS; but notwithstanding this, the instrument now designed is so simple, convenient, and portable, as to well merit a detailed description at this time. Another point in its favour is the ease with which it may be constructed by any person having a moderate amount of skill in the use of tools. But we may assume that the amateur mechanician would often fail to give his apparatus the elegant form of the iconometer as represented below; unless, indeed, a discarded opera-glass be taken as the basis of its construction.

Rosignols' iconometer has the external form of a single opera-glass, but the arrangement of the lenses is reversed, O being a convex lens, and N a concave lens; this arrange-



ment serving to present a diminished image of the landscape to the eye of the observer.

In order that the landscape, as seen through the iconometer, may correspond to that included on the sensitive plate, a metal screen having a rectangular aperture of suitable proportions is fixed at the large end of the instrument, D; and by sliding the lens-carrying portion in or out, a position can be found corresponding to each lens carried. These positions must be determined and marked by the user on the tube of the instrument.

NOTES FROM NEW YORK.

INTERESTING MEETING OF THE AMATEUR SOCIETY—THE PLATINOTYPE PROCESS — AN IMPROVED DEVELOPING TRAY—A NEW DEVELOPER—PROPOSED EXCHANGE OF LANTERN SLIDES.

THE technical meeting of the Society of Amateur Photographers, held at their rooms, 1260, Broadway, on the 11th inst., was the most successful and entertaining of any held this fall.

Mr. Chas. A. Needham made a demonstration on the platinotype process, and explained very fully all the details necessary to properly work it. Several sheets were sensitized before the audience, special arrangements having been provided for that purpose; and before the close of the meeting, small samples were distributed among the members to take home for trial. Several prints previously made from some of Seavey's negatives were developed with a hot oxalate of potash solution, with such rapidity and perfectness as to excite the admiration of the audience, who greeted the success of the process with applause. Mr. Needham exhibited and described specimens of the latest boxes and apparatus required to preserve and work the paper.

Questions were asked concerning the permanency of the prints, one gentleman remarking that in some parts of Germany it was held that the prints turned yellow and faded.

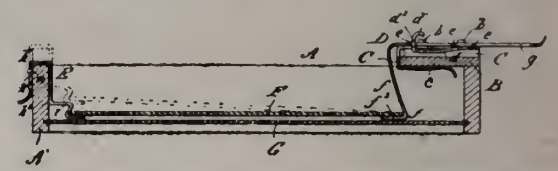
Mr. Needham, in reply, thought such effects must be due to some irregularity in preparing or working the paper, and believed if it was washed in the acid baths for the allotted time, as specified in the directions, the picture was as permanent as anything could be. With much artistic taste he had arranged a fine series of specimen prints, and enlargements upon one side of the room, most of which had been furnished by Mr. Willis and Mr. Wood, of Philadelphia, for the occasion. The exhibit included photographs on napkins and other linen articles, and also specimens of the new sepia tone, which were admired.

After passing a vote of thanks to Mr. Needham, a Hare camera and changing-box containing all the latest improvements were shown, one of its distinguishing points being the great length or draw of the bellows. Its fine finishing was much admired.

Mr. R. A. C. Smith, a member, and owner of the camera, explained its merits, and successfully operated the changing-box. I understand other members of the Society have sent abroad for duplicates, which would go to show that there is still a field in this market for English work.

Dr. John H. Janeway submitted a "Table of the Solubility of Chemicals in Water," which he had specially compiled for the amateur's use, and distributed printed copies among the members. A vote of thanks was passed to him for the work.*

Mr. Beach exhibited an improved developing tray, patented by Samuel B. Pratt, of Boston, Mass., October 17th, 1884, and sent by Mr. Chas. Parker, of Newark, N.J. It resembles in form the tray sold by Marion and Co., and is a wood frame provided with a glass bottom, having a pocket at one end, arranged to hold the developer when turned in a vertical position. Two adjustable brass spring feet press against the glass bottom inside, between which is held the sensitive plate. One foot is adjustable vertically, so that it may be raised up from the glass bottom half an inch. The other foot, which always lays against the glass, is adjustable horizontally, and permits different



sized plates to be held for development. A special spring-catch is provided in the sliding part of the foot, which holds it in any desired position. The model shown was adapted for three different sized plates. The advantages were, that the vertical adjustable foot enabled the operator to raise one end of the plate out of the solution, so that it might be removed without soiling the fingers.

A special method of packing the rubber joint between the glass bottom and wood frame had been adopted, which prevented leakage, a fault which trays of this class are said to possess.

Mr. C. W. Dean read an interesting paper on "The Relative Rapidity of Lenses and the Use of Stops." His labour was greatly appreciated, and the system of making stops which he advocated was voted to be adopted by all members of the Society. A special committee on lenses was appointed to experiment further on the subject.

Mr. Newton explained a new pyro developer, which he and a few of his friends had tried, and obtained results superior to the ordinary carbonate of soda developer. The strength advised for use in the development of a drop shutter-exposed plate was as follows:—

No. 1—Water	1 ounce
Carbonate of soda (granulated)	15 grains
Yellow prussiate potash ...	15 ,,
Sulphite soda...	5 ,,

* We shall publish this next week.

No. 2—Water	...	...	...	1 ounce
Chloride of ammonium			...	7 grains
Pyro (dry)	...	...	...	6 ,,

Nos. 1 and 2 are then mixed, and the whole flowed over the plate. The image appears rapidly, and the shadows remain clear, giving a negative, when fixed, of a steel-blue or black colour. Usually no bromide is required except for excessive over-exposure: in that case, half a grain of bromide of sodium to the ounce of developer is advised.

A new function of the bromide was discovered by Mr. Newton in connection with this developer which may prove of value. He stated that it was well known, when gelatine plates had been kept for any great length of time, the silver in the film became reduced where it was in contact with the cardboard separating frame, thereby injuring the plate to such an extent as to render the marking of the frame distinctly visible after development. By experiments which he had tried, he had ascertained that the addition of a small quantity of bromide of sodium to developer would prevent the showing of the separating mat marks and produce a clean clear negative. He therefore advised those who had plates which showed the reduction of silver at the edges, while using the ordinary developer, to use bromide of sodium with the improved developer.

The theory of the developer was that when Nos. 1 and 2 were mixed, free ammonia was liberated, which, in uniting with the yellow prussiate of potash, formed an extremely powerful developer; while the chlorine, uniting with the soda, formed chloride of sodium, which acted as a restrainer, and by its bleaching action tended to keep the shadows clear.

He showed several specimen negatives which illustrated the power of the developer in bringing out details on instantaneous exposures, where with the developer recommended by the manufacturer of the plate, only one-half to two-thirds of same details could be obtained.

Mr. W. E. Partridge had tried the same formula with much success, and showed two negatives.

Mr. Beach also showed two negatives which had had very short exposures, one of which was developed with dry pyro as recommended, the other with his sulphurous acid and sulphite solution of pyro added to No. 2 in place of the dry pyro. He found that the dry pyro developed plate was intense, and when fixed showed a greenish-yellow colour in the shadows.

Mr. Newton thought it was over-developed or exposed too long.

Mr. Beach stated that the developer mixed according to the formula was very clear, and had a light straw colour by daylight, which turned to a dark red after development. The development was rapid, clear, and vigorous; it seemed to him all that Mr. Newton claimed for it. The smell of liberated ammonia was very perceptible. The second plate, which had the same exposure, developed with the acid solution, bore a marked contrast to the first; the development was slower and more gradual, and when finished and fixed the negatives had a wet plate gray appearance, clear in the shadows, and less dense than No. 1. There appeared to be as much detail brought out as in No. 1, and the negative was perfectly free from the green yellow colour before noticed. Mr. Beach showed a sample of the developer after it had been kept for twelve hours; it was sherry red in colour, but quite clear. His opinion was that the sulphurous acid solution of pyro added to the developer improved it.

Mr. Newton stated that stock solutions of No. 1 and No. 2 could be made up to suit different tastes. Regarding the mode of procedure in the case of excessive under-exposure, he advised the mixing of equal quantities of No. 1 and 2 without the pyro, and the addition of a little at a time to the mixed developer, thereby forcing the development by degrees, until the details were brought out. He was also of the opinion that the pyro could be kept mixed in solution with No. 2, but intended to make further experiments in regard to it.

The subject of an exchange of lantern slides with other amateur societies was discussed, and a committee appointed to perfect details. Why could not an international annual exchange of slides be started? The expense would be light and the interest unending.

November 15th, 1884. THE NEW YORK AMATEUR.

HINTS ON POSING AND THE MANAGEMENT OF THE SITTER.

BY H. P. ROBINSON.

CHAPTER VII.—OUTDOOR GROUPS.

WHEN a group is to consist of more than three or four individuals, it is often convenient to take it out of doors. There are several advantages in getting out of the studio: you are not cramped for room, and need not pile your sitters together, as you are often compelled to do in the small space available in most studios. The exposure will be much quicker, taking not more than one or two seconds with a rapid rectilinear lens, and smaller diaphragm may be used than would be possible in the studio; the greater depth of focus thus gained allowing much wider freedom in the artistic arrangement of the group.

An outdoor group too often represents a mass of figures placed one over the other on a bank, with perhaps a brick wall for a background, without any attempt at artistic arrangement, like the sketch, which is copied from a photo-

graph, or a row of figures set up to be photographed, without any consideration as to their arrangement except to get them in focus. This latter disposition is sometimes caused by the impossibility of getting any help from the formation of the ground or place when the photograph has to be taken, for it nearly always happens that the large groups are taken "at home," and the photographer must do the best with the materials he can find. He should look out for and take advantage of any spot that would aid him in breaking up his group and giving variety to the general forms; if he should find a picturesque set of steps, he may consider himself fortunate; even one or two steps are better than nothing. In selecting his background he should endeavour to secure one with a broad expanse of light, such as a light wall, if not too blank. Much detail is objectionable, as it interferes with the figures. The worst background, but the one that is oftenest used for groups, consists of foliage, especially when laurel or any shrubs with large shining leaves have place. The white spots produced by the glittering foliage, especially when out of focus, is very disagreeable.

I give an illustration in which a flight of steps leading up to the door of an old Gothic house has greatly aided the photographer in arranging a portrait group.

When you have to arrange a group, you should begin by finding out the most important persons in the company, so that you may assign them conspicuous places. In a short time you will be able to discover "the funny man." There is always one in every group, who thinks it a rare joke to make some of the others laugh and spoil the negative. More groups are spoilt by this idiot than by any other cause. Everything must give way to his wit, and it takes a spacious magnanimity to endure his buffoonery. You must neutralise him, or you will do no good. If you have courage enough, go boldly up to him, and say something to this effect:—"So you are the funny man, are you? If I can get on with you, I can easily manage all the rest. If you will kindly suppress yourself for a few minutes, and let me have my turn, I shall be much obliged." He takes this usually in one of two ways—either he is a good fellow who sees a brother joker in you, and does all he can to help you; or he sulks. Either way will suit your purpose. In the illustration you will easily see the suppressed funny man in the one set against the wall, where he makes a capital balance to the principal group, and looks, in the original photograph, as if he had not quite made up his mind whether he ought to be ashamed of himself or not.

By this time you have got to some knowledge of the different members of the group, and have settled in your mind, apparently, how they are to be arranged. When you have quite made up your mind, and not till then, and when the camera is quite ready, place your figures. Don't make experiments or changes if you can help it; in other words, don't look like a muff, but let the members of the group see that you know what you are about, and mean to carry out the arrangement that you have mentally formed.

I have seen operators make an ostentatious display of the trouble they were taking, as if they were expected to earn their money by the sweat of their brow, making numerous changes until they wearied out their victims. People are quite up to this sort of display now, and laugh at it—until it becomes too serious.

In a well-designed group the principal rules of art will be observed, especially variety, balance, contrast, and breadth. Every line and form will be so arranged that a series of pyramids, intersecting and mingled with each other, are created. In the illustration, those to whom it was thought advisable to give most prominence are in the centre, and form a pyramidal group to themselves, but they become part of a series of pyramids, all blended into one, of which the top of the arch of the door is the apex. It may also be noticed of what extreme value a bit of pure black or white becomes when in the right place. In the photograph—it is not so easy to show it in the small cut—the white hat of the standing figure to the right absolutely redeems the group from failure. Imagine it away, and there is no artistic solidity in the group. This one small spot of white in the right place keeps everything together.

In the second group the place was different, and there

was not so good an opportunity of forming a fine group. The ground was flat, and there was no natural means of raising any of the figures above the others; the photographer had therefore to be content to break the line by seating some of his figures, and making others bend, as though talking to them. By this means he succeeded in forming a series of varied pyramidal forms, running into and connected with each other, so that the general effect should not be scattered. There should always be a "oneness" in a group; the string should run through all the beads, but should be more felt than seen.

There is another vast difference between the two groups: the first has for its surroundings a corner of a very fine Tudor Hall, partly overgrown with old English shrubs; the second is a sham Gothic battlemented verandah, protecting a large French window—an incongruous mixture—and the foreground consists of the geraniums, calceolarias, violas, and other kindred plants of an Italian garden.

There are some disadvantages about taking groups and portraits generally out of doors, the chief of which is the difficulty with the expressions from the excess of light. Some people are more affected by this than others; these should be carefully looked after, and so arranged that the light should be of the least annoyance to them. A por-

trait group should never be taken in sunlight if there is any possibility of avoiding it.

It sometimes happens that you have to get some other hand to expose. If you have to depend on a quite inexperienced person, it is as well to explain to him that the cap must be removed from *before* the lens as well as off it. I have sometimes seen the cap taken off and held in front of the lens. There is a certain butler who exposes a group in which the photographer annually appears, who talks learnedly of seconds and fractions of seconds, and firmly believes that he takes the photographs.

ISOCHROMATIC PLATES.

BY W. GOODWIN.*

You all know what a spectrum is, and have all seen it in the rainbow, or in a more homely form as thrown upon the wall by the prisms of a chandelier. When we examine such a spectrum, we find it to consist of a band of coloured light, graduating from red at one end, through orange, yellow, green, blue, and indigo, to violet at the other; these colours blended together, form the white light by which we take our photographs.

Now, if we expose a plate to this spectrum, and develop it, we find that only some of the colours have effected reduction of the sensitive salt.

It is evident that most of the work is done by the rays toward the violet end of the spectrum (a great deal is done by rays beyond that which are invisible to the eye), and that green has comparatively little effect. We can thus see why in landscape work we lose so much of the detail in shadows and foliage, the light which presents such detail to the eye being rich in green and red, but deficient in blue and violet. Could we obtain plates sensitive to green, we should get negatives giving a much more natural gradation.

Leaving out of the question the actual reproduction of colour, which is as yet a far-off possibility, let us see what can be done to secure in light and shade a better rendering of the value of colour. The meaning of this term value is, that light colours should give light tones, and dark colours deep tones. We know that if we photograph blue and red on an ordinary plate, they show in the print as white and black respectively, while yellow and green both appear dark; but if we can make plates sensitive to the so-called non-actinic colours, we will then obtain prints showing a more natural gradation.

The method used to obtain such plates is the addition of some substance to the film capable of absorbing and converting into chemical energy those rays which are inactive on an ordinary plate. These substances are dyes, mostly of the aniline series, and a few natural vegetable colouring matters. They are themselves sensitive to light, as manifested by a bleaching action under its influence. The rays which effect this bleaching are those towards the red end of the spectrum—that is, the very rays which we wish to capture and divert to our plate. The immediate cause of the bleaching is oxidation of the dye, but how this affects the silver salt is a matter of dispute.

Abney holds that the dye, in absorbing oxygen, acts as a developer, similarly to pyrogallic acid in the alkaline developer, this slight reduction serving as a nucleus for a further deposit of silver during development of the plate. This theory seems to be borne out by the fact that the dye is only a colour sensitizer in presence of a chemical sensitizer; that is, a body capable of absorbing the bromine, &c., set free during exposure. Gelatine is such a sensitizer; also silver nitrate in the case of collodion plates.

Vogel's theory is that the energy absorbed in bleaching the dye is transmitted to the silver haloid, upsetting its equilibrium, and rendering it capable of development. This theory seems to be proved by the fact that a dyed collodion film exposed to the spectrum will, if coated with collodio-bromide emulsion, and developed without further exposure, give an image of those parts of the spectrum to which the dye is sensitive. It is very evident, however, that the invisible photographic image is still in want of a satisfactory explanation.

A large number of dyes have been found more or less effective, and I might give you a long list bearing the delightfully simple and explicit names peculiar to the aniline and kindred series; but it will be sufficient to mention those which have been put to practical use. Amongst vegetable colouring matters chlorophyll extracted from green leaves, is a sensitizer for red, and turmeric extract for red, yellow, and green.

Most of the dyes which have been tried have slowed the plates, and have been most effectual on collodio-bromide; but Vogel has recently discovered a new substance which is most effective with gelatino-bromide, and which actually increases the sensitiveness of the plate. It is, however, such a recent discovery that I can learn little about it; he has named it azaline.

Next to azaline, eosine seems to be most useful, and plates prepared with it are now prepared commercially. Vogel has by means of eosine prepared collodion plates eight times as sensitive to yellow as to blue; but with gelatine his results have been less satisfactory, the plates being only twice as sensitive to yellow as to blue. This is a long way short of what is required, for in nature, yellow is about twenty times as luminous as blue to the eye, therefore in using these plates for copying oil-paintings it is found necessary to photograph them through yellow glass to restrain the excessive action of the more actinic colours. The above results are obtained on bromide plates, which are most affected by these colour-sensitizers; many substances which have a marked effect on bromide are inactive on chloride and iodide.

We are likely to hear a good deal about eosine, and it may interest you to know a little about what it is. Though commonly known as an alkaline dye, it is not really so, but is a potassium compound of fluorescin, which in its turn is derived from resorciu, a substance allied to pyrogallol, Pyrogallol, hydrokinone, and pyrocatechin, all yield bodies similar to fluorescin, and these produce dyes like eosine; therefore when we buy eosine it is rather doubtful what precise substance we get. This may explain why some experimenters have met with less success than others.

True eosine exists in two forms—iodeosine or blue shade, and bromeosine or yellow shade. It gives with silver nitrate a precipitate, soluble in ammonia, which is sensitive to light; a few drops of the ammonia solution added to an emulsion is found the most effective way of preparing the colour-sensitive plates. Ordinary plates, however, may be treated with a solution of three parts eosine in a hundred parts of water containiug ten per cent. of ammonia, and then dried. Here is such a plate, which you see is a faint rose-colour; here is a yellow plate stained with turmeric. I now pass round a colour-scale with negatives on two such plates, and on an ordinary plate. The latter shows the blue dense, and yellow almost clear glass; the turmeric plate shows the green denser, but on the eosine plate the difference is very striking; the yellow is nearly as dense as the blue, while both green and yellow show a notable gain in density.

It is not necessary to have a highly-coloured film—the merest trace is sufficient. Dr. Eder prepared a stained emulsion, from which he separated the bromide by means of Plener's centrifugal machine this he washed till the water came away colourless, and re-emulsified in fresh gelatine, and the resulting plates were as colour-sensitive as the original emulsion. The washed bromide was faiutly tinged, and Eder conjectures that an insoluble compound is formed between the bromide and the gelatine immediately surrounding the grains, which being stained is sufficient for the purpose in view.

* A communication to the Glasgow and West of England Photographic Association.

Notes.

It is probable that the time may come when a photographic studio will be considered an indispensable adjunct to every first-class picture gallery. What an opportunity was lost last January when the Sir Joshuas were gathered together in the Grosvenor Gallery! Next January an unprecedented collection of Gainsboroughs will be on view, but of course they will be allowed to depart un-photographed. A photographic studio will not always be an iron excrescence.

The photographic hat of Mr. Mendoza will suit those who may wish to take surreptitious photographs in a public building. A lens is fitted at the top of the hat, and may

be taken for a ventilator by the bystander. Inside the hat is the camera, with arrangements for focussing, changing the plate in exposing. With the apparatus Justice itself might be photographed on the Bench, unless the appearance of a person in a half-kneeling position, with his face buried in his hat, should excite the dynamite-hunting instincts of some of the guardians of the Court. To obtain clerical portraits with the hat-camera should certainly be very easy.

From America comes a suggestion to make bank notes on asbestos paper, and to use a vitrifiable ink for printing. Photographs upon asbestos paper have been made in this country, as we have already pointed out, but they generally have a coarse appearance.

The very un-English policy of the National Gallery authorities in granting facilities for the photographing of the master-pieces of their collection to a German firm, while they refuse to allow a London Fine Art Association to enjoy similar privleges, is to form the subject, it is said, of more questioning in Parliament, and surely with reason, for it seems to us that even on patriotic grounds English photographers had not been permitted to reproduce paintings in the great English Art Gallery, there should have been enough—well we will say, *camera-derie*, in the breasts of the Trafalgar Square officials to have induced them, if they granted favours at all, to make their own countrymen the recipients of them.

There exists—or, rather, is supposed to exist—a postal arrangement by which *bona-fide* trade samples can be sent at a low rate of postage from Great Britain to the various countries comprised in the postal union.

As far as transmission from Great Britain is concerned, the operation of the so-called pattern or sample post is so uncertain, and so liable are samples to be detained, that business people who have important samples to forward either prefer to pay letter postage for them, or to send them by private agencies.

We posted two small electrotypes of printing blocks, these electrotypes being properly prepaid, endorsed as samples, open for inspection, and quite valueless in themselves; they were, in fact, merely samples of a new process of photo-engraving. Instead of forwarding the samples, the postal authorities sent a letter to each of the addresses, asking for a remittance of three shillings and fourpence, on receipt of which they promised that the blocks should be forwarded as letters. If this were merely the result of a casual mistake, one would think but little of it; but it appears to be the outcome of a general order that all printing blocks are to be detained if posted as samples.

In reply to a letter of ours demanding that the blocks should be forwarded as addressed, they were returned to us with an unsigned and undated memorandum as follows:—"*These blocks are neither books nor samples.*"

A fresh demand on our part to have them forwarded was made, and they were forwarded; but a letter was sent to us requesting that before any more are posted, certain particulars should be sent to the postal authorities. In other words, before posting a sample package, you should advise the Post Office that it is coming, and give a full description; then it may, perhaps, be forwarded.

Now that photo-engraving methods are becoming of real commercial importance as substitutes for wood-engraving, many will desire to transmit block samples through the post, as to send a print is quite useless, the block or an electrotype reproduction being absolutely essential to enable a printer to estimate the real value of a process block.

According to the Postal Guide, two classes of articles are transmissible as patterns. First, "*Bona-fide trade patterns*," which we may suppose to include such articles as, a negative to show the quality of dry plates offered, any article to show the style in which an order can be executed, a stereotype or electrotype intended as a sample of work, or an example of a photo-engraving process. The second class comprises simply "*samples of merchandise*."

When the South London Society was established, it was intended that it should deal mainly with the art aspects of photography; but somehow or other this has not been the case, although one can hardly assert this without recalling to the reader the able discourse on art as applied to photography which Mr. Norman Macbeth delivered not long ago at a meeting of this Society. At the present moment, however, Edinburgh seems about to take the lead as the art society; indeed this is to be expected, for Mr. Macbeth is president. Our readers should turn to page 753, where they will find some remarks on the Art Conference which the Edinburgh Society will hold.

One of the lectures recently delivered by Sir W. Thompson at Philadelphia was on the wave theory of light. In this lecture billions are handled as though they were units. Sir William tells us that a wave of red light has 400 billion vibrations per second. When twice the speed is reached, violet light is perceptible; doubling this again, we get to the extreme end of the range of known light; while a fourth of the number of vibrations composing red light takes us at the opposite end of the scale to what is termed radiant heat. The longest wave yet found in the field of radiant heat was measured by Professor Langley, the number of vibrations being 30 billion per second. It is to be hoped that photographers will not get too much absorbed with these stupendous calculations, for although Sir William Thompson asserts that it is just as easy to conceive 400 billion as it is to conceive that twice two make four, everyone will not believe him. It would be very shocking if some rash photographer had his head turned in the effort of imagining what 800 billions of vibrations—violet light—are like!

A pretty little crop of troubles may be expected to

spring out of the forthcoming Beauty Show in Paris. Already fault has been found by the candidates with the judges, one gentleman in particular being objected to because it is rumoured he has a preference for pug noses. Then some of the ladies can't see why their photographs should be sold, and themselves get nothing out of the transaction, although it is obvious that without their assistance the photographs could neither exist nor be attractive. A third section are clamorously demanding that no advantage be given to wealthy competitors by appearing in silks and satins, and that, to make all equal, the costume shall be a white cotton dress, high up to the neck, with a holland pinafore. On the whole, it looks as if the promoters, before the Show is over, will wish they had never began it.

Of the many variations of photographic processes in use we are aware, but we have learned of the existence of yet another chemical method which certainly sounds simplicity itself. A friend of ours, inspecting some photographs of Royal personages which purported to be from original sittings, remarked, authoritatively, "Those photographs must be taken *cum grano salis!* they must indeed." He may be right, but the new method of making pictures with chloride of sodium sounds more suitable for marine news.

They receive all kinds of suggestions at Scotland Yard, and amongst those sent in there last week were two which have, at any rate, novelty to recommend them. One was that all policemen on night duty should wear over their ordinary blue tunic a coat (or great coat, as the case might be) of luminous paint, thus rendering a constable a bright and shining light, and a new terror to those who love darkness for reasons of a not altogether unfelonious nature.

But the second has novelty, but not so much. It proposes that all policemen going on duty should carry about them the means of obtaining the portrait of any suspicious character they chance to see on their beat: as it is, they often suspect where they cannot arrest, and the man suspected takes himself off. In future it is urged that the policeman should be in a position to take him on a prepared plate for purposes of subsequent identification, &c. A number of other suggestions as to the notion are given which we need not reproduce. The fact remains that it would be undoubtedly useful if our guardians could "take" a man without "running him in."

Regulations are pending, it is rumoured, which, if satisfactorily carried out, will result in all visitors to the Inventories, or Invenstrumentories, or Artificiers, or whatever the next exhibition is to be called, being provided with a "square meal," having their photograph and weight taken, their hair brushed, boots polished, and receiving a picture of "Old London," and all for the sum of one shilling!

A somewhat important communication was made at the last meeting of the Royal Astronomical Society by Professor Pritchard. Some time ago there existed a difference of opinion as to the relative light capacity of reflecting and refracting telescopes of the same aperture; comparisons were made, and the question was apparently settled to the advantage of neither system. But during the eclipse of the moon an occultation of four faint stars was observed, and of these only one was noticed with De la Rue's 13-in. reflector, while the other three were clearly perceived with the Grubb reflector of 12¼-in. aperture. Professor Pritchard was led to make experiments, and he has authoritatively fixed that the light transmitted by the Grubb refractor is to that received by the De la Rue reflector as 1·89 to 1. The importance of this fact to photographic observations was at once perceived by the meeting, and questions were asked by Lord Crawford and Mr. De la Rue on the subject. As Professor Pritchard remarked in his reply to Lord Crawford, "An investigation as to the relative photographic power would be interesting."

Mr. Zeitheim Focsani, the son of a photographer in the town of Roman, announces through the Berlin *Wochenblatt* his readiness to give his hand and heart to some young lady who is experienced in retouching. Applicants should not be over twenty-three years of age; ought to be of unblemished character, mild in disposition, and domesticated; but before all these qualifications comes good retouching as an essential. Parenthetically, Mr. Focsani adds that young widows without children, but with means and business experience, will not be altogether excluded from consideration. It is only reasonable that any fair reader who is disposed to compete for the double appointment should know that the advertiser describes himself as twenty-five years of age, *blond*, and not ugly. Letters should be addressed "Herrn Zeitheim Focsani, in Rumänien," and a photograph must be enclosed. But has the advertiser considered how woefully a skilful *retoucheuse* might deceive him with this latter?

Quite an old phase of the application of photography to matrimonial purposes has lately been revived in the suburbs of London.

A well-dressed gentleman seats himself in a railway carriage, and turns over the pages of a well-filled album; presently he hands it to his fellow-passenger with a few general remarks about photography. The well-dressed gentleman is a matrimonial agent, having offices in the Strand, and the portraits in the album are those of his clients.

Patent Intelligence.

Applications for Letters Patent.

15,202. William Griffith Honey, 3, High Street, Devizes, Wiltshire, for "A new or improved holder for manipulating a photographic plate."—(*Complete Specification.*)—Dated 19th November, 1884.

15,307. Hezekiah Nelson Heffner, 53, Chancery Lane, London, W.C., for "Apparatus for illuminating sitters and subjects to be photographed, and for other purposes."—Dated 20th November, 1884.

15,440. CHARLES GRAY and HENRY KEMP, 36, Southampton Buildings, London, W.C., for "Improvements in magic lanterns."—Dated 24th November, 1884.

Patent Sealed.

10,226. BENJAMIN JOSEPH EDWARDS, 5, The Grove, Hackney, Middlesex, Photographer, for "Improved apparatus for dissolving and changing pictures in the magic lantern."—Dated 16th July, 1884.

Specification Published during the Week.

8. FREDERICK WILLIAM HART, of 8 and 9, Kingsland Green, London, in the County of Middlesex, Manufacturer of Scientific Apparatus, for "Improvements in portable photographic camera." Dated 1st January, 1884.

I first construct the front framework of the camera in square or other rectangular form, such framework having a revolving flanged disc of the greatest diameter the framework will permit; such disc has an opening through it, half its width below the centre to near the circumference, the width being of such dimension as will permit the lens tube to be centrally placed and moved freely along the opening to near the circumference. On this revolving disc I place a slide diametrically over the opening, and of such length and width as will well cover the opening when the centre of the slide is brought over the opening near the circumference; on this slide the lens is to be mounted. I fix the disc and slide in any desired position by means of screws or cam clamps with my improved folding disc heads to such screws or cam clamps. The construction:—On the shank is a disc of metal, and across the diameter is hinged a half disc of like thickness which, when raised, enables the screws, cams, or racks and pinions to be actuated. When folded down, the whole does not project from the body of the camera more than one-eighth of an inch, thus permitting close packing, whereas the screw-heads at present in use project half to three quarters of an inch, thus preventing compact packing. The back framework and the flexible extending body is constructed as usual, with the exception that I employ my folding disc heads to all clamping screws and pinion heads. The advantage in using the said disc heads will now be seen in my main improvements to obtain extended range for lenses of long focus. I shut the body—as above described—up quite close, together with one or more dark slides, or a magazine plate-holder included, and form around them a casing, embracing the top, front, bottom, and back, three of these rectangles being hinged, and the fourth angle secured by lock, bolts, or hooks.—This, my improved baseboard, when unfolded, is made rigid by triangular bolts of metal—steel or bronze preferred—sliding in grooves in opposition to the hinges, means being provided by the enclosing plate for taking up wear so as to ensure continuance of the utmost rigidity. The camera body frame slides to and fro on this base board, being kept parallel by side guides in the ordinary manner. On the top face of the base board I employ two short lengths of rack—when weight is of moment—say one-sixth of the length of the base board, the solid base of which is V or half V, on the sides, with corresponding counterparts for them to slide in the base board. The end of each portion of rack has a spring detent pin in use at the time. Where weight is not an object, the metal rack may be fixed the entire length and cut at the joints for folding.

By these recited improvements I obtain greater range for focussing than hitherto; economy of space, rigidity, a square body throughout, thus making the camera available for lenses of short focus, including angle of 90 to 100° of subject on the plate, as well as narrow angle lenses of long focus for extreme distant objects.

As an illustration of improvements effected:—The latest tourist's cameras exhibited—say half-plate—have a range of focussing power of 12 to 16 inches, whereas, with my recited improvements as set forth in this specification, I obtain 24 to 26 inches focussing power, giving thereby greater facility for the production of artistic photographs from nature, also for copying.

934. WILLIAM HENRY DUNCAN, of Coalbrookdale, in the County of Shropshire, engineer, for "Improvements in apparatus for changing dissolving views." Dated 8th January, 1884.

This invention refers to changing slides and adjusting the dissolver by means of pedals, the claims being for:—

First. An apparatus for changing the picture slides of a dissolving view, or magic lantern, by pedals, moved by the feet or by levers, moved by the knees or hands of the operator.

Second. An apparatus for raising and lowering the light by pedals.

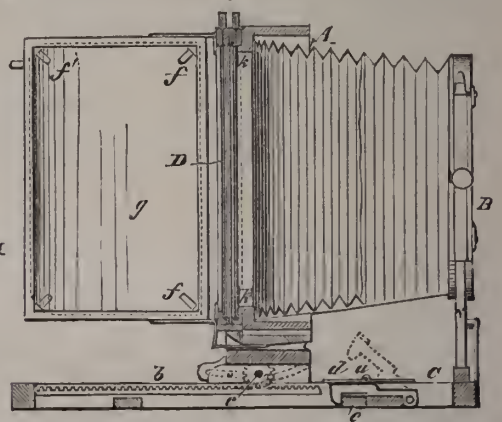
Third. The locking device for the pedals, substantially as described, and illustrated by my drawings and specification.

9026. HENRY GARDNER, of 166, Fleet Street, in the city of London, Patent Agent, for "Improvements in producing from photographic negatives, blocks or plates suitable for typographic printing."—Dated 16th of June, 1884.

The object of this invention is, attaching by any adhesive substance a film or sheet of any material which has been impressed with the form of an engraved surface, capable of printing in a typographic press a series of marks, producing the effect of an even tint or shade to a relief produced by photographic means; and the rubbing or pressing the surface thus produced with some straight or plane surface, with the effect of increasing the size of the marks on the raised portion of the relief, and consequently rendering them capable of printing a series of marks having the effect of a darker shade or tint than the rest, the surface produced being thus capable of printing in a typographic press a series of marks large in the darker portions of the picture which it is intended to reproduce, and smaller in the lighter portions.

Patents Granted in America.

307,965. WILLIAM H. LEWIS and ERASTUS B. BARKER, New York, N.Y., assignors to E. and H. T. Anthony and Co., same place. "Camera."—Filed May 2, 1884. (No model.)



Claim.—1. In a camera having a hinged or folding bed, the means, substantially as described, for holding the bed in position for use, consisting of hooks pivoted below the hinge, so as to bind the parts as specified.

2. In a camera, the combination of hooks, *d d*, with hinged bed-frame C, substantially in the manner and for the purpose specified.

3. In a camera, the corner-clamps *f*, formed with tongues *f'* combined with the object-glass and frame, substantially as and for the purpose specified.

4. In a camera, the combination, with the object-glass and frame, of spring holding-clamps, substantially as described.

5. The camera-box having a rib or flange, *k*, at the edges of the opening, combined with a plate-holder having an opening large enough to receive the rib, as specified.

6. A camera-box made with a rib or flange adapted to enter the opening of the plate-holder for retaining the holder in place, as specified.

FRENCH CORRESPONDENCE.

PHOTOGRAPHIC SOCIETY OF FRANCE—PHOTO-GRAVURES FROM DETAILLE'S DRAWINGS—ENGLISH SHUTTER—SUBSTITUTE FOR A CAMERA—ROTARY SWING MOTION FOR LENSES—NEW FIXING SOLUTION—DROP SHUTTER EXPOSURES—STANDARD SENSITOMETER—GELATINO-BROMIDE CARDBOARD PLATES.

Photographic Society of France.—This Society has recommenced its monthly meetings after two months' holiday; consequently, there were many communications brought forward, which I will review successively.

Photo-Engravings of Detaille's Drawings. — The old-established house of Goupil and Co. has changed hands, and the firm is now Boussod, Valadon, and Co. The first

result from the new house is an album of phototype reproductions of a splendid collection of drawings by Detaille, the battle painter. The process employed is no longer the granular method of which we have seen such fine specimens by Messrs. Goupil, but has a square network, like Manzi's process, by which the negatives are more easily printed in with the text.

English Shutter.—Among our amateurs, many use shutters of English make. They are generally excellent in construction, but rather heavy; that shown by M. Arwin is of that kind. It works with a central opening, giving different lengths of exposure.

Hat Used as a Camera.—One of our professional photographers, M. Marco Mendoza, has had the idea of utilizing a round felt hat as a camera. The lens is placed through a hole in the crown, and an oval framework to receive a ground-glass slide or dark-box is fitted accurately in the inside. A socket fixed to the brim enables it to fit on the top of a light metal tripod. The idea is not new, and it is far from perfect at present. If I mistake not, some similar experiments were made in England.

Rotary Swing Motion for Lenses.—M. De Thierry desired to replace the swing-backs of cameras by a rotary swing motion given to the lens, so that it may be brought round in any direction. The lens is fixed in a ball-and-socket joint. It is needless to mention that one cannot set the lens in a slightly oblique position without danger of distorting the object.

New Fixing Solutions for Prints.—Dr. Liesegang has been experimenting in search of another fixing substance for prints besides hyposulphite of soda. His efforts result in a mixture of common salt, chloride of ammonium, and ammonia. The action is much slower than hypo, but he is continuing his experiments so as to improve his formula.

Lengths of Exposure given by a Drop-Shutter.—In my last letter I spoke of the apparatus I used in connection with Boca's chronometric shutter for measuring the length of exposure given by instantaneous shutters. The following is a series of experiments made with a drop-shutter, with aperture from 5 millimetres to 9 centimetres, and lens 25 millimetres.

Aperture	5 millimetres,	length of exposure	$\frac{1}{100}$	of a second
,,	1 centimetre	,, ,,	$\frac{1{\cdot}5}{100}$	,,
,,	2 centimetres	,, ,,	$\frac{2}{100}$	,,
,,	25 millimetres	,, ,,	$\frac{2{\cdot}5}{100}$	,,
,,	3 centimetres	,, ,,	$\frac{3}{100}$	,,
,,	4 ,,	,, ,,	$\frac{3{\cdot}5}{100}$	,,
,,	5 ,,	,, ,,	$\frac{4{\cdot}5}{100}$	,,
,,	6 ,,	,, ,,	$\frac{5}{100}$	,,
,,	7 ,,	,, ,,	$\frac{5{\cdot}5}{100}$	,,
,,	75 millimetres	,, ,,	$\frac{6}{100}$	,,
,,	8 centimetres	,, ,,	$\frac{6{\cdot}5}{100}$	,,
,,	9 ,,	,, ,,	$\frac{7}{100}$	,,

It will be noticed that with apertures equal to the diameter of the lens, then two or three times greater the following relations will be seen $\frac{2{\cdot}5}{100}$, $\frac{4{\cdot}5}{100}$, $\frac{6}{100}$ of a second, only it is much more advantageous to use a large aperture and a spring to give greater impetus to the slide. Thus, an opening of 5 millimetres gives an exposure of only 1-100th of a second, but using a larger aperture and a spring reducing the exposure to the same as the first, and comparing the two results, the second will be found much more complete.

Standard Sensitometer.—One is still seeking after a perfect sensitometer, but for my part I hold to that of my sympathetic and clever colleague, Warnerke, until the day comes for absolute perfection, as it is very precise for practical purposes. I have an idea of adding to it a scale for various colours, of which I will write another time.

Gelatino-Bromide Cardboard Plates.—M. Thiebaut has invented a new system of gelatino-bromide plates by spreading the film on thin cardboard, so that one hundred do not weigh more than a dozen plates of the same size. The cards in question are as rigid as glass; they are developed, and the film stripped off when completely dry, which operation takes a somewhat long time on account of the quantity of liquid absorbed. I think the substance might easily be rendered impermeable. I am going to try some experiment with these plates, and then I shall not hesitate to give my opinion.

Leon Vidal.

THE DUBLIN EXHIBITION.

Second Notice.

The voting of the members for the prize medals concluded on Saturday evening, and the results are as follows:—

Landscape, 8½ by 6½.—A—T. A. Greene, "Grasmere and Rydal" (227)—silver. G. Mansfield, "Pas de Roland, Pyrennees" (76)—bronze.

Landscapes under 8½ by 6½.—B—W. F. Donkin, "Views in the High Alps" (186)—silver. H. B. Berkeley. "Noontide" (523)—bronze.

Instantaneous.—C—G. West and Sons, "Yacht Studies" (14)—silver. M. Auty, "Shields Harbour" (446)—bronze.

Interiors.—D—E. Brightman, "Mansion in the Olden Time" (494)—silver. A. G. Tagliaferro, "St. John, Malta" (541)—bronze.

Portraits, 8½ by 6½, and over.—E—J. Chancellor, "Il Penseroso" (213)—silver. J. Lafayette. "Portraits" (203)—bronze

Portraits under 8½ by 6½.—F—J. Lafayette, "Portraits, Boudoir" (239)—silver. J. Robinson and Son, "Portraits" (271)—bronze.

Opals.—G—J. Robinson and Son, "The Sisters" (454)—bronze.

Genre Pictures.—H—W. Gillard, "Reading to Granny" (450)—silver. C. Wyrall, "Peg in the Ring" (128)—bronze.

Enlargements.—I—Autotype Co., "Sorrow on the Sea" (210)—silver. J. Robinson and Son, "H.M.S. 'Cupid'" (82)—bronze. *J*—P. H. Fincham, "Lantern Slides" (715)—bronze. *K*—Rud. Schuster, "The Autodafe" (mechanical process, 7)—bronze. *L*—T. J. Dixon, "Animals" (108)—bronze. *M*—R. A. Hayes, "Micro. Photos." (731)—bronze. J. V. Robinson "Cameras"—bronze. *W*—G. Mansfield, "Sauveterre, Pyr. (71).

Special medals have been awarded to Messrs. Skeen (for his series of Ceylon views), Mendelssohn (for group No. 97, the class having been inadvertently omitted in voting list), and Renwick, for "Frost Study" (No. 152).

Continuing our remarks on the various exhibits, we notice that the School of Military Engineering, Chatham, sends several frames of charming scenes, chiefly in Devonshire and the Lake District (6, 263, 493). The last-named are platinotypes, "Stybarrow Crag, Ullswater," being surpassed by few landscapes in the room. Besides "Reading to Granny" (silver medal), Mr. Gillard shows "The Miser," from *Les Cloches de Corneville*, also a master-picee of pose and expression. Mr. T. G. Whaite has a large number of frames of little pictures of Breton life, bright and lively; but there are so many as to become slightly monotonous. Messrs. Marsh Brothers show their well-known views of Henley Regatta, and their studies of swans and pigeons, Medmenham Abbey, &c. Mr. Jackson, of Perth, sends, besides an album on the table, several frames of woodland studies; a weeping elm, Dunkeld, is among the best.

Professor Donkin's enlargements are always attractive; of these he forwards several—the Weisshorn, Matterhorn, &c. Mr. Wyrall's "Peg in the Ring" (128) has obtained a medal, and is an interesting group of boys at play. A. Diston has his well-known "Out of Sorts" (337), and "Gloamin'" (332). Mr. Suteliffe's frames of shore and boat studies are very attractive, and the plain oak mount sets them off admirably. Besides "There's Sorrow on the Sea" (silver medal), the Autotype Company have sent a most interesting series of their works, including reproductions of pictures, coins, fans, &c., as well as a frame illustrating the various stages of Collotype. The Woodbury

Company do likewise with Stannotype, and Mr. Schuster, of Berlin, sends a magnificent series of photo-etchings. These have deservedly taken the medal for mechanical printing. Portraiture is well represented, for in addition to Lafayette, and Chancellor, already noticed, Messrs. Robinson and Sons of Dublin, Debenham of Ryde, and Byrne of Richmond, are exhibitors; Mr. W. England contributes numerous scenes in Switzerland, chiefly on the St. Gothard route.

Mr. Brownrigg, of Guildford, is an exhibitor, and shows excellent studies of his native Surrey lanes, as well as of the Rialto, the Grand Canal, and other places in Venice. Some of these he tells us are instantaneous. Why he took them so is hard to see, as there do not appear to be many moving objects in the scenes depicted. Mr. H. Symonds, of Portsmouth, has two capital frames (196, 212) of yachting pictures, running Messrs. West very closely, and, like theirs, taken from a sailing boat. Three views in frame (196) are greatly spoiled by the vignetting; they would have looked far better with the natural border of sea and sky. In the other frame, several pictures show wonderful "go"; and one showing a topmast just gone by the board is most happy as a picture, though doubtless not so to the owner of the boat.

Mr. Godbold has some of his dashing sea studies, especially that of the "Rocket." Is the rope quite untouched? No. 425 is an interesting relic lent by Mr. H. Grubb, F.R.S. It is a group of the original Photographic Society of Ireland, which came to an end long ere the present one was started.

Mr. C. K. Dalton sends some nice landscape and cloud studies, chiefly from Lancashire. Messrs. Morgan and Kidd show examples of their enlargements on paper, canvas, and opals, and two instances of prints from negatives on their special negative paper. Messrs. York and Son, P. H. Fineham, Englard, and J. L. Robinson, show frames of lantern slides, for which Mr. Fincham fairly wins his medal.

In what may be termed "Miscellaneous" work, Mr. Woodworth has two good frames of micro-photographs of insects, diatoms, &c., but Dr. Haye's anatomical specimens, printed in colours by the Woodbury Company, are marvellous reproductions of minute structure. Mr. A. W. Wilson sends a huge frame (136), of peculiar design and most difficult to hang, containing "Studies of the Seven Ages of Man," photographed from life. Some of them are extremely good, but are of a decidedly brown tint.

The Platinotype Company, besides Mr. Berkeley's private exhibits, have a considerable series, illustrating both the ordinary and the sepia processes. The best are views of the Alhambra (316), and heads by Mr. Blanchard (363, 443, 457, &c.) Mr. J. B. B. Wellington shows several exceedingly pretty bits of country life and Thames scenery.

Spectroscopists will be interested in frames Nos. 704, 705, and 706, sent by Professor Hartley, F.R.S., and containing spectra of a large number of elements; the photographs have been enlarged from small negatives by the Autotype Company. Mr. H. Robinson, of Dublin, shows his patent camera—a form which has met with considerable appreciation in Dublin—and will no doubt, ere long, make its appearance on this side of the Channel; for lightness, compactness, and range of motion, it is remarkable. He also shows a new series of interiors and views in the Palm House, Glasnevin Botanic Gardens.

Mr. Dixon sends some wonderful pictures of Lions, Leopards, &c. The Tiger's Head, an untouched enlargement, life-sized, from a tiny negative, is a marvellous work. No. 108 takes a medal.

We regret we must leave many pictures and exhibitors unmentioned, even by name; this is unadvoidable when the number of exhibitors is 135 and the exhibits over 700. We trust the Photographic Society of Ireland will be encouraged by their success this year to try their fortune again, and would suggest that it might not be amiss to follow the lead of Bristol, and make the Dublin Exhibition an international and triunial reunion.

SOURCES OF FAILURE IN PRINTING ON ALBUMENIZED PAPER.

BY H. TRAUT.

In the current issue of the *Mittheilungen* M. Traut makes some interesting observations on the "pit-falls" which are often met with in silver printing. For some years past the double albumenized paper has come more and more into favour, from its power of producing a brilliant surface. Few, however, have any idea of the many disadvantages which are incidental to so liberal a use of albumen. Creasing and tearing of the film, and the discolouration of the latter in the space of two or three years, are of frequent occurrence. Moisture spoils the double albumenized paper very rapidly; and what is, perhaps, worse, the moist paper contracts very much on drying. Thus, during printing, if the paper is still moist, the print, when dry and finished, will present a distorted appearance. In sensitizing, through the expansion of the albumen film, the paper curls outwards, but on drying it contracts.

The contraction of the paper almost entirely takes place in one direction, namely, along the length of the paper as it issues forth from the machine. For this reason the distortion in portraits is less noticeable when the paper is so cut that the height of the picture corresponds to the length of the material. As an example of the enormous distortion which is sometimes met with in albumenized prints, the writer, on measuring the length of the head in a C.D.V. bust portrait, found it to be 22 m.m. in length, but on the negative the length of the head was only 20 m.m., thus the print showed an extension of 2 in 22, or nearly 10 per cent. Again, in a full figure print, the length of the model measured 154 m.m., while in the negative it was only 148; the width of the two were, however, identical. It is hardly necessary to remark that such a distortion cannot be without effect on the likeness. The writer has also experimented with the tinted albumenized paper. It is well known that manufacturers generally employ aniline dyes for the purpose, which, although very beautiful for a time, very soon fade; while madder, which is known to be permanent, is rarely used.

Various samples obtained from Dresden, Vienna, and Paris were "sunned" for four days; after which time, the beautiful rose and violet colours had in all cases given place to an unpleasant yellow. Is it surprising, asks the writer, that pictures produced on such paper lose their original freshness after one month's exhibition in a show-case? The writer concludes by advising photographers to take up the collodio-chloride process; for according to Herr Hoster's experience, the single objection to its use—namely, the tending to irregular toning—has now been removed by reducing the thickness of the paper support.

TELESCOPES FOR ASTRONOMICAL PHOTOGRAPHY.*

For the refractor two disks of glass are required; they must be optically pure, and their first cost alone is more than is often spent on the reflector, including the mounting. These disks must be wrought on four surfaces to proper curves, and time often spent afterwards in perfecting the object-glass; when this is done, the cost is found to be so great that it is felt to be worth a costly mounting. We cannot then be surprised that the better made and mounted telescope should be chosen, but that does not decide the question, Which is the best optical instrument? Nor can this question be decided definitively, because the images formed by each differ. If we look with a reflector at a bright star, the image is seen as an intensely bright point of light, dazzling to the eye if the telescope is large, and we see rays or coruscations round it of an irregular shape that are never steady. I think this effect is not due to the telescope, but is entirely subjective, and caused by this extremely small point of light exciting only a very small portion of the retina; for by proper precautions the light can be reduced, and these rays and the dazzling effect got rid of. With stars less bright it is not so pronounced, and on planets or objects of sensible magnitude it ceases entirely. The image of such a

* Continued from page 749.

bright star in the refractor is quite of another kind: it is seen as a small disk of light of sensible diameter surrounded by the well-known system of diffraction rings and outstanding colour. This disk of light, though small, has a different effect on the retina; it can be seen as a shape, pretty steady and free from too much dazzling glare. It is here that the refractor has such an advantage for micrometrical work, permitting bisections to be made with such precision.

The adjustments of the object-glass are considered more constant than those of the speculum, and though the troubles attending the reflector are much exaggerated, they have existed in the arrangements usually adopted. For certain instruments such as the transit-circle, where the connection between the optical axis and some part of the instrument has to be maintained, the object-glass is superior to the speculum; a tilt of the former that would not have an appreciable effect on the position of the image of a star would in the other displace this image twice the amount of tilt.

Both kinds have certain advantages, according to the use they are put to, and it is really not of much consequence which is the best instrument of this size. It is when we begin to consider the effect of increased size and all its attendant difficulties that the question of the suitability of either for the purpose of photography has to be answered.

With the reflector increase of size means proportionate increase in other qualities, in light-grasping power, in defining, and in separating power. With the refractor the greater absorption of light due to increased thickness reduces the light-grasping power, and definition becomes a matter depending not upon the optician, but upon the glass-maker; the correction for colour, which even in theory is approximate only, becomes more difficult, and the defects due to the necessarily imperfect correction become more apparent—and these two facts alone show that as the refracting telescope gains in size it becomes more and more unsuitable for photography.

Moreover, when the aperture of the two kinds of telescopes under consideration is the same, the focal length of one must be something like twice that of the other, and that means that the image is four times less bright, and there does not seem to be any indication that the focal length of refractors can be very much reduced. This is only one part of the question; the next and most important one is that of actual cost or difficulty of construction. In the case of the refractor the preliminary difficulty in getting the lumps of glass out of which the lenses have to be made is so great that the increase of the size beyond 30 inches seems at the present moment very doubtful—they may reach three feet or even four feet aperture, but it is most unlikely: the cost alone, good or bad, would be simply enormous, and such a size may be for the present left out of consideration. With the reflector the case is entirely different; from what has been said, it is easy to see that the gain by increase of size is proportionate here, and that only mechanical difficulties have to be met. Mirrors of glass covered or coated with silver for the reflecting surface are now in existence of three and four feet apertures; larger are in hand, and can be made at a cost absurdly below the cost of even a possible refractor; the only limit that I can see here is that of glass, and the limit in this case stops not at thirty inches, as with the refractor, but at something like seventy inches, and that and nothing else of a constructive character prevents the reflector being made much larger, and size is a great thing in photography. It is, in the case of eye-observation, a fact that you could positively have a telescope too big for the eye to use, but any increase that is at present possible in the reflector would only add to its photographic power.

The optical arrangements of the reflector are so varied that I propose to treat of them in detail for the purpose of indicating the most suitable.

Correspondence.

THE STRICTURES ON THE IDENTISCOPE.

Sir,—I have to thank you for the courtesy extended to me. Pray can you spare a corner for a brief summary of my rejoinder to the demurrer raised?

I have to reply to Mr. Galton as follows:—

1. The portraits are not "drawings," but high-class life-size photographs by Maull.

2. The combined photographs do not show any confused "blending." This is conclusively evidenced by the perfect restoration of the lines of admeasurement and the other details at that part of the visage where a defined and material section has been intentionally removed from one of the portraits.

3. Thrown upon a 24 feet surface by oxyhydrogen light, not a vestige of discrepancy results between the measured details.

4. A visit to the nearest photographer's will refute, on the instant, the allegation that the iris is not a trustworthy unit. Moreover, various eminent oculists, to whom the matter has been submitted, have conceded that the iris, unaffected by disease, affords a permanent and perfectly reliable unit of admeasurement.

"The iris, at its exterior circumference, is a permanent quantity in a given individual." The rim of the iris, in a well-executed enlarged photograph, is as reliable and as well-defined as the rim of the gilded porcelain from which the learned professor sips his afternoon beverage.

Bristol. William Matthews.

ART AND PHOTOGRAPHY.

Dear Sir,—You were good enough to make a selection of the largest portion of my address to the Edinburgh Photographic Society, to establish "Conferences on the Picturesque." To show how much the effort on our part is appreciated, I beg to enclose a kind note which I had from Mr. H. P. Robinson on the subject. He very kindly offers to send some photo. pictures for criticism at our first meeting. Such an example is very encouraging to others not to be afraid, but rather court opinion.

The two great objects of photography are *science* in its chemistry, and *art* in its arrangements. The former appears to me to be much ahead of the latter, and such a scheme as we intend prosecuting will, I trust, do not a little to promote sound views of proper treatment of the Picturesque.

Norman Macneth, R.S.A.

In the letter alluded to by our correspondent, Mr. H. P. Robinson says:—"In your capital address to the Edinburgh Society, you say 'we cannot look for examples for discussion from professional men unless they are pleased to be generous enough.' I take this as a hint. Would you like to have a selection of my pictures for the purpose? If so, when would you like to have them, and where shall they be addressed?

Allow me to take this occasion to express my appreciation of the sound advice in Art you give to photographers, and to thank you for the kindly notice you have taken of my endeavours in the same direction."

*** An article on this subject will be found on page 757.

LANTERN SLIDES.

Dear Sir,—In the interesting account of the lantern slide processes given in your last issue, it is stated that surprise was felt at the meeting that pure carbon should yield brown-coloured transparencies, lampblack being the form of carbon employed; it may therefore interest some of your readers to learn that a carbon print on paper from tissue made with this substance is brown, and not black, as might be expected. I believe the difference in colour of various forms of carbon arises only from the degree of fineness of the particles, and it is probable that lampblack obtained by collecting the soot from an oil lamp yields carbon of the finest kind possible.—Yours faithfully,

W. L. Noverre.

THE NORTHAMPTON EXHIBITION, 1884-5.

Dear Sir,—May I call the attention of those of your readers who intend exhibiting at our forthcoming exhibition, to the fact that the last day fixed for receiving exhibits is December 1st?

To prevent the possibility of any pictures being shut out, cases must be sent on at once.—I am, yours faithfully,

T. Manfield, Hon. Sec.

ELECTRIC LIGHT FOR THE LANTERN.

SIR,—I am glad to find that Mr. Dresser proposes to initiate a discussion upon this important subject, and if any convenient method of using the electric light is the result, I, for one, shall feel much gratified. Of course, at such a place as the Royal Institution, or the Society of Arts, where an engine and dynamo are available, there is no difficulty; and the result is all that one can wish for. Indeed, I have a lively recollection of the perfection and brilliancy with which Mr. Muybridge exhibited his "horse in motion" at the first-mentioned place.

What is wanted is some arrangement which involves less work than the charging of 50 or 60 cells of Grove's battery; a task equal to making preparations for three or four lime-light exhibitions. JOHN M. GORMAN.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

ON Tuesday last, the 25th instant, the mouthly technical meeting was held in the small room attached to the Gallery, 5A, Pall Mall East, Mr SEBASTIAN DAVIS occupying the chair.

Mr. FRANCIS COBB showed some gelatino-bromide plates in which the reduction of the silver was remarkably complete, the surface of the films being almost mirror-like, but very little or no trace of image was visible. These plates had beeu developed with a soda and pyrogallic developer, the development being much forced; but Mr. Cobb gave no particulars as to the preparation of the plates.

The CHAIRMAN, in connection with this subject, said that he never obtained such complete reduction of the silver, or such dense images with the soda developer, as when he supplemented the action of the soda with a dash of ammonia towards the end of development; but Mr. Cooking, on the other hand, had found that he could get all the required density with soda only.

Mr. WARNERKE pointed out a circumstance of which many appear to be ignorant—namely, that a given quantity of bromide of potassium restrains much more powerfully in a potash developer than in an ammonia developer. As far as Mr. Warnerke's experience goes, there is special advantage in using both potash and soda in the same developer; but potash is to be preferred to soda, as it gives negatives of a better colour. As a general rule, it may be taken that with the potash developer there is less tendency to frill than when ammonia is used, and plates which give green fog with ammonia will show no trace of this when potash is used. In addition to these advantages, less exposure is required with potash, two more numbers on the sensitometer beiug generally obtainable when potash is used. Mr. Warnerke compounds the developer as follows:—

No. 1.—Potassium carbouate	45	parts
Sodium sulphite	12	,,
Water	1000	,,
No. 2.—Pyrogallic acid	12	parts
Sodium sulphite	24	,,
Citric acid	2	,,
Water	1000	,,

For a normal development, equal proportions of No. 1 and No. 2 are used.

Mr. FRANCIS COBB, in replying to the Chairman, said that he had found potash to have some advantage over soda, as, when potash is used, the tint of the negative inclines more to a purplish-black, instead of the whitish-yellow tint obtained with the soda developer.

Mr. ASHMAN enquired whether any fresh experiments had been made with the hydroxylamine developer; but nothing transpired beyond what has already been published in the NEWS.

Mr. HOPKINS then exhibited his "simplex" dark slide, an apparatus which has already been explained to our readers.

Mr. GÖTZ then handed round some lenses constructed by Suter, of Basel; they are constructed on the well-known symmetrical or rectilinear type, and are fitted with flanges and diaphragms in accordance with the standards of the Photographic Society. The most rapid of these corresponds to a working aperture of $\frac{f}{6}$, making the instrument comparable to a portrait combination for speed.

Mr. DEBENHAM pointed out that it is of very doubtful advantage to construct lenses of the symmetrical type of such a degree of rapidity; the Petzval or portrait lens being preferable when an intensity of from $\frac{f}{4}$ to $\frac{f}{7}$ is required; and he further pointed out that his views were confirmed by the fact that opticians seldom construct "symmetricals" with an intensity so high as $\frac{f}{6}$

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

A MEETING of this Society was held on Thursday, the 20th inst., Mr. F. W. HART in the chair.

A discussion in reference to the lantern slides shown at the previous meeting was opened by Mr. HENDERSON, who doubted the utility of such comparisons. Owing to the protracted and desultory nature of the conversation which followed, the Chairman, at half-past nine, adjourned the meeting *sine die*.

Mr. A. HADDON was theu appointed chairmau.

Mr. J. H. TRINKS enquired why silvered paper kept between the leaves of a printed book, and excluded from light, received an impression of the letter press?

Mr. A. L. HENDERSON attributed the circumstance to the action of deleterious gases in the air.

The CHAIRMAN held a similar opinion, and considered the greasy ink protected the parts beneath it as a varnish would do.

Mr. A. MACKIE spoke of printed matter marking varnished negatives, and insensitive marks due to contact with printer's ink was alluded to.

The value of paraffin paper as a covering for plate boxes was brought forward, Messrs. Henderson, Cobb, and the Chairman relating their experieuces with it, which was favourable to its employment.

Mr. A. COWAN had not found any ill effects from the use of white pine boxes after two years' packing, although common deal was detrimental. It was thought the turpentine in common deal accounted for those boxes marking gelatine plates.

Mr. HENDERSON spoke of a peculiar mottle in certain plates, which he attributed to thymol; when the emulsion was filtered through wash-leather, the marks were absent. His impression was, that thymol and water formed a clotted emulsion, which in filtering became broken up.

This led to an enquiry as to the probability of an alcoholic solution of thymol producing clots in a gelatine emulsion; but it was thought that thymol would not act in this manner.

Mr. W. E. DEBENHAM said 50 per cent. of alcohol would not coagulate an emulsion, but mottled marks might be expected.

Mr. HENDERSON had used 80 per cent. of strong alcohol without getting these marks.

Mr. W. M. ASHMAN had coagulated a citro-chloride emulsion so that it was impossible to melt it; but he was uot certain whether it was by the addition of alcoholic thymol, or an excess of a citrate salt.

Mr. DEBENHAM said one of the greatest difficulties in working citro-chloride emulsions was due to the coagulation caused by certain citrates.

In lieu of thymol, oil of cinnamon, camphor, and bichloride of mercury were suggested. The latter, Mr. HART said, could be diluted to the extent of one part to one hundred thousand, and was the best antiseptic known, being more destructive to the lower organisms than any other poison.

Mr. TRINKS recommended pyroligneous spirit; he had preserved some microscopic specimens in this spirit for seven years.

Messrs. G. A Davenport and G. V. J. Perrin were elected members of the Association.

GLASGOW PHOTOGRAPHIC ASSOCIATION.

THE first general meeting of the session was held in the Religious Institution Rooms on Thursday, 13th November, the chair being occupied by Councillor ROBERTSON, who congratulated the meeting on having such a large attendance. The minutes of last meeting were read and approved of.

The next business on the list was to appoint a secretary in room of Mr. J. Craig Annan, when Mr. John Lennox was unanimously chosen.

Owing to Mr. J. Y. McLellan's departure to Russia, a vacancy was made in the Council, to fill which Mr. Patrick Falconer was appointed.

Mr. WM. LANG, jun., kindly offered to present members of the Association with a view of Cadzow Forrest, taken at last out-door meeting. The offer was accepted, and a cordial vote of thanks given to Mr. Lang.

Mr. Falconer proposed that there be a discussion at next meeting on "The Best Medium for the Dark Room," which was agreed to.

The Chairman then called on the Treasurer (Mr. Geo. Bell) to read his annual report, which showed a balance in his hands of £8 3s. 4½d.

A vote of thanks to the Chairman brought the meeting to a close.

Birkenhead Photographic Association.

The preliminary meeting was held on Thursday evening, 20th of November, at Berry's Grand Restaurant, Argyle Street, Birkenhead, Mr. John H. Day in the chair.

The undermentioned gentlemen were elected to conduct the business of the Association for the ensuing session :—

President—J. A. Forrest.

Vice-President—H. N. Atkins.

Treasurer—J. Maurice Jones.

Council—A. W. Beer, A. W. Cornish, R. W. Hill, T. Cragg, James E. Newall, and H. P. Phillips.

Hon. Secretary—John H. Day, 19, Milton Road, Birkenhead.

Thanks were given to Mr. Richard Hartley and Mr. C. Berry, the former of whom has placed his studio in Market Street, and the latter a room in his establishment in Argyle Street, at the disposal of the members for the purpose of holding their monthly meetings, &c.

The competitive element having proved a beneficial stimulus to the production of good work in kindred societies, periodical competitions were decided upon, the result of which it was proposed should be duly reported in the newspapers. It was also determined, should the funds of the Society permit, to present each subscriber annually with an enlargement, if possible, from some selected negative, the production of a member of the Association.

Arrangements are in progress for a miscellaneous concert, concluding with a lantern exhibition, to be held on Thursday evening, the 18th December, on which occasion a number of original and interesting photographic pictures, the work of amateurs and others, will be thrown upon the screen.

North Staffordshire Amateur Photographic Association.

The annual meeting was held at the Mechanics' Institute, Hanley, on Wednesday, the 19th instant, Mr. Charles Alfieri occupying the chair.

Captain West-Jones, Major Harrison, and Mr. T. G. Keeling, were elected members.

It was resolved to permanently lease a suitable laboratory in the Potteries for the Society's use.

As only photographs 8 by 6 had been sent in from two sources for selection as presentation priuts, the Secretary was instructed to endeavour to to procure some of a larger size for the same purpose.

It was also resolved that albums and note-books on the models of the Postal Photographic Society should be circulated among members of the Society, who, in many instances, live some miles apart.

The financial report of the Treasurer showed a very satisfactory balance of funds in hand. The annual report of the Council was read and unanimously adopted. It congratulated the members on having passed another year of the Society's existence—a year which, although not so productive of results in out-door work as might have been expected from the exceptionally fine summer, had still not been barren of results so far as photography is concerned. Pace was kept with the times, even veterans having for once and for all laid aside collodion with its baths and dippers. The artistic platinotype, and, to a large extent, the argentic-bromide paper process, had found favour, while carbon had still some votaries, the users of albumenized paper being in a minority. The monthly meetings had not, as a rule, been favoured by the attendance of so many of the members as could have been desired ; but as they lived farther apart than is the case with societies in less sub-divided districts, a large attendance could not be expected in unfavourable weather. Some of the meetings had been very well attended. A list of papers that had been read, and articles exhibited, was then given. Only two out-door meetings came off—one to Barlaston, the other into Derbyshire, and even these were poorly attended. The gentlemen, however, who went had the satisfaction of bringing home several gems of pictorial beauty.

The Association, as originally started, was composed of photographers, both amateur and professional. However, for various reasons it was, at the June meeting, after mature consideration, resolved that in the future only those gentlemen or ladies who practise photography as amateurs be admitted into membership. The subsequent election as members of many well-known gentlemen of county notoriety and local influence had given to the Society a good social status.

The meeting was then adjourned.

Newcastle-on-Tyne and Northern Counties' Photographic Association.

The ordinary meeting was held in the College of Physical Science, Newcastle, on the 18th instant., Mr. J. B. Payne in the chair. The minutes of the previous meeting having been confirmed,

The Chairman said he thought they might congratulate themselves on the result of the exhibition they had held during the past week. The number of exhibitors might have been larger, but the quality of the work he considered very good. He then presented the medal, given by Mr. Borrow for the best set of three pictures taken by a member at the outdoor meetings, to Mr. J. P. Gibson, of Hexham, and the prize (a very handsome album partially filled with views), given by Mr. J. P. Gibson for the best set of two pictures taken by a member who had not previously received a medal or diploma, to Mr. Edgar Goold.

Votes of thanks were duly passed to the judges and to the hanging committee.

The presentation picture for the year was announced by the scrutineers to be one by Mr. Edgar Goold, *Bywell*, this picture having received the largest number of votes.

Mr. Laws announced that Mr. Garland had promised a second medal for the transparency competition.

Mr. J. Pike read an extract from the *Photographic Times*, which he thought might be of use to some of the members, viz. :—"Negatives showing a turbidness on parts of the plates, after removal from the alum bath, may be cleared by treating them with sulphide (?) of soda solution or weak sulphurous acid The turbidness is caused by a separation of sulphur in the alum bath, the sulphur being retained in the film." He (Mr. Pike) said he had frequently been troubled with such a deposit on the negative, but it was always removable with a pledget of cotton wool.

The Chairman said that he had been informed recently that benzole, containing a small proportion of resin, had the effect of removing green fog.

Doubts were expressed as to the part played by the resin in this matter.

Mr. Pae remarked that he had found benzole by itself answer the purpose. He also suggested the use of benzole for reducing the density of negatives, locally or otherwise.

A question was found in the box :—"With some plates the leather (hinge) of the dark slide gives an *opaque* marking, and with others a *transparent* one ; how can this be accounted for ?"

Several members had experienced trouble with their dark slides, the plates of some makers being apparently more easily affected than others.

Mr. Dodds remarked that a trace of ammonia in the leather might account for the opaque marking.

The Chairman said that he had found common writing-ink painted over the leather a complete cure.

Mr. Pike had recently been working with argentic-bromide paper, and, as a consequence of manipulating large sizes of paper in a very small room, had been troubled with an occasional marking or stain of a very disagreeable colour, with metallic lustre. He had always discarded a print when marked in this way, but had found that the marking was removed by a solution of hydrochloric acid—one part of acid to twenty-five parts of water. He suggested the use of this acid in preference to sulphuric as a clearing solution.

Professor Herschel said that he had also found hydrochloric acid a much superior clearing agent to the acid recommended by the makers.

Mr. Joseph Gray showed some transparencies taken on chloride plates of his own make. They were developed with the ordinary pyro. and ammonia developer, and were of a very pleasing tone. He said that any of the various developers in use—sulphite of soda, washing soda, &c., &c.—were applicable, and gave a variety of tones. The transparencies shown were favourably criticised.

Mr. Pike called attention to the very fine character of the

image, and said that the emulsion had apparently been carefully filtered. Some commercial chloride plates looked as if this operation had been omitted.

A paper on and demonstration of the platinotype process was promised by Mr. H. G. Templeton, of Gateshead, for the December meeting.

Talk in the Studio.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—The annual meeting will be held at the House of the Society of Arts, on Thursday next, December 4th, at 8 o'clock. Several important matters in connection with the welfare of the Society will be discussed, and the election of officers for the ensuing year will take place. Intending competitors for the artistic competition are reminded that their pictures must be delivered between the 1st and 4th of December.

CITY AND GUILDS OF LONDON INSTITUTE.—On Thursday next, December 4th, the prizes and certificates won at the May Examination will be presented by the Right Hon. the Earl of Selborne, F.R.S., Lord Chancellor, at Fishmonger's Hall, London Bridge. The Lord Mayor is announced to take the chair at 7.30 p.m. A list of the candidates who were successful in photography will be found on page 497.

TESTING AND REPORTING ON COMMERCIAL PLATES.—Such dry-plate manufacturers as may desire to have their plates tested and reported on, can send samples to the Society of Amateur Photographers, 1262, Broadway, New York. In this country such a candid report as the Amateur Society of New York proposes to issue, would be almost certain to lead to actions for libel. In the United States, however, actions for libel are comparatively rare; the more practical process of administering a whipping to the offender being generally approved of. The Committee on Commercial Gelatine Plates consists of Mr. H. J. Newton, Dr. John H. Janeway, and Mr. Dexter H. Walker. We presume, however, that the President of the Society, Mr. F. C. Beach, takes an *ex officio* position on the committee.

REPRODUCING THE LINES OF MAGNETIC FORCE BY PHOTOGRAPHY.—The beautiful lines, produced with iron filings on a sheet of paper, under which is placed a magnet, have been successfully rendered permanent. Nickeles forms the lines on waxed paper, and then fixes them by placing a heated iron near enough to melt the wax. Meyer replaces the wax by shellac; but the result in both cases are not very permanent. Stevens has obtained excellent results by producing the figures on albumenized or other photographic paper, and exposing to light.

PHOTOGRAPHIC CLUB.—The subject for discussion on December 3rd will be on "Out-door Photography." There will also be an exhibition of photographs taken by the members during the past summer. Annual Dinner on Dec. 10th.

To Correspondents.

*** We cannot undertake to return rejected communications.

CARBON PRINTER.—Minute bubbles of air enclosed between the tissue and the collodion.

EDWIN MILES.—We remember the paragraph, but cannot tell you the date at which it appeared.

A. G. B.—1. The lenses appear to us to be of good quality, but not of the very highest attainable, and whether you have reason to be dissatisfied or not, must depend on the price you have paid. 2. As requested, we have attached your label, and forwarded the package.

T. R. YOUNG.—1. A few particles of fulminate, hardened by admixture with varnish, would certainly ensure its ignition; but you had better not try the experiment, as from your letter we can clearly see that you have not had sufficient experience to justify you in working with such dangerous materials. 2. We do not know: consult a lawyer, or enquire at a police court.

VERDANT GREEN.—Perhaps it is not what one might call a good shilling's-worth to one like yourself, but we have certainly seen worse.

J. WHITELAW.—1. It is not at all likely that you will obtain a set of working drawings of the best portable camera, especially as, in the first place, it is extremely difficult to determine which is the best; and the demand for the working drawings would not be sufficient to cover the considerable cost of their production. Any person of moderate mechanical skill can construct a good camera from such sketches as we have given. 2. Abney's "Instruction" is the best we know of.

G. F. WEBBER.—Our impression is that they are carrying on business, and we are surprised that no response has been sent to you.

PHOTO.—Cameras are occasionally made with an universal motion to the lens, but general experience is in favour of tilting the camera, and using the swing-back. We believe that Mr. W. E. Debenham has—in a somewhat lukewarm manner—advocated the former system. 2. The disadvantages are the great extent to which the front of the camera may require raising or shifting, and the mechanical difficulties in providing for this.

C. E. G.—Your suggestion is an excellent one, and shall be acted upon.

WILLIAM COLES.—We have not heard that a fresh edition is likely to be brought out soon, but a post card, addressed to the publisher, would doubtless settle the point at once.

M. C. H.—A hard, well-sized paper is coated with the following preparation:—

Water	300 parts
Gelatine	10 ,,
Perchloride of iron	20 ,,
Tartaric acid	10 ,,
Persulphate of iron	10 ,,

When dry, the paper is exposed under the tracing until the greenish-yellow tint of the paper has disappeared, except where covered by the opaque lines. Development is effected in a bath made by dissolving 20 parts of gallic acid in 200 parts of alcohol, and adding 1,000 of water. Fixation by simple soaking in water.

CLOUDLAND.—1. Not many persons besides Mr. Shadbolt have worked much in this direction, and of these very few have been successful; still, it is to be hoped that this important branch of photographic work will be developed in time. 2. As far as we know, the apparatus was never completed, but it is quite possible that the firm mentioned may possess the instrument in its unfinished condition. You had better write or call.

C. WILKINS.—Hydrofluoric acid is the only material available; it can be obtained in gutta-percha bottles from any dealer in chemicals.

MR. LAFAYETTE AND THE DUBLIN EXHIBITION.—Mr. Lafayette wishes our readers to know that he considers it a "glaring injustice" to publish such a criticism as ours before the award of the medals; and, moreover, he is highly indignant at what he calls the "provincialism," "petty localism," and "obvious unfairness" of our article. He also thinks that our article "must demonstrate, to any one giving the subject a moment's consideration, that the judgment was a foregone conclusion." It is by no means a novelty for the opinions of a critic to differ from those of an exhibitor; and if there were less pressure of important matter on our space, we would publish Mr. Lafayette's curious letter in full.

The Whittaker of the Photographer.'—*Chemical News*

OVER A QUARTER OF A CENTURY
OF PUBLICATION.

ON DECEMBER 20TH, PRICE 1s., PER POST 1s. 4d.,
THE
Year-Book of Photography.

The simple fact that the YEAR-BOOK OF PHOTOGRAPHY has run out of print *during the past three years* within six months of its publication is proof sufficient of its popularity and wide circulation, and Messrs. PIPER & CARTER, in announcing its appearance for 1885, need put forward no better claim as to its value as an advertising medium.

Intending Advertisers in the YEAR-BOOK OF PHOTOGRAPHY AND PHOTOGRAPHIC NEWS ALMANAC should communicate with the Publishers at once at the Office, 5, Castle Street, Holborn, London, E.C.

CLEAR GLASS IN THE SHADOWS OF GELATINE NEGATIVES.

MR. GEORGE SMITH, in a recent communication to the PHOTOGRAPHIC NEWS, touches upon a point which, although it may appear to be merely one of detail, is, in fact, one of the greatest importance.

Mr. Smith lays it down that, at any rate when the object is to produce a transparency, the negative ought to have perfectly clear shadows. He gives it as his reason, that if the detail in the deepest shadows is represented in the negative, it is all so much thrown away, because the whole range of detail, from the highest lights to the deepest shadows, cannot be reproduced in the transparency. Either the delicate detail of the high lights, or that of the shadows, must be sacrificed, and there is manifestly no good of getting in your negative what you cannot reproduce in your transparency. Moreover, by omitting the darkest detail of the shadows, we can get a better registering of detail in the high lights.

Now all this may apply, with more or less truth, to negatives for the production of transparencies—in fact, certainly does apply to those specially intended for the production of lantern slides; but in our opinion it does by no means apply to negatives from which ordinary prints are to be produced.

One of the things for which the photographer, and especially the amateur, is continually striving, is "clear glass in the shadows." We hold, that in making the attempt to get this he is mistaken: that with the dry plates of the present day a more truthful rendering of a subject will, as a rule, be got, unless the negative shows *no* perfectly clear glass but when there is a slight deposit even in the deepest shadows. If we are not very much mistaken, we remember Mr. Smith expressing the very same opinion some little time ago.

To explain one reason for considering that a negative which shows clear glass in the shadows does not give as good a rendering of the subject as one which has a little fog, we may take an illustration. The appearance of Warnerke's sensitometer tablets is now pretty well known to every photographer. It consists of twenty-five little squares, each presenting a slightly greater density than the one next to it. The difference of density between any two squares can be detected by the eye. It is evident that if a plate is exposed under this tablet, the portions which receive the least light—that is to say, which are behind the densest squares—represent in a manner the shadow portions of a plate exposed in the camera. Were the plate exposed under the sensitometer tablet, and afterwards developed, an exact counterpart of the tablet, or rather a correct inverse counterpart of it, the difference in density between each two squares of the developed plate should be the same as the difference of density between the corresponding two squares of the tablet.

Let us note, however, what will be the actual state of affairs. We expose for such a length of time that, when the plate is developed, the last one or two numbers of the tablet does not appear, but a certain portion of the plate remains as clear glass. We will now notice that the differences of density between the last figures which do not appear on the plate are very much less than the differences of density between the corresponding figures of the tablet. In fact, we shall probably find some three or four figures represented by a mere shadow of an image with scarcely any perceptible difference between the density of the first and the last. We have got anything but a true representation of the gradations of these squares of the tablet, and the same will hold good if, instead of so exposing a plate under a sensitometer tablet, that some clear glass is left, we had exposed a plate in the camera to a landscape, so some clear glass remained in the shadows. In the latter case the very blackest parts of the landscape have their true counterpart in the transparent portions of the negative, but the portions which are next in darkness to the very blackest do not have their true counterpart. They are represented by insufficient density. In fact, it is not the clear shadows themselves that are objectionable, it is the fact that with perfectly clear shadows there comes incorrect registration of the darker detail.

To return to our sensitometer tablet again, we shall suppose an exposure given which will cause an appreciable deposit on the last portion of the plate which has been under the last figure of the tablet. We shall find that in this case the difference between each two of the last figures is very nearly the same as that between the corresponding figures of the tablet.

So it will be with a plate exposed in the camera to a landscape. If the exposure is pushed so that there is a slight veil in the deepest shadows, the darkest visible detail will be far more correctly represented than it otherwise would be.

It is quite true that we cannot push the exposure as we have described, without losing something in the high lights. The detail of the very brightest parts must be somewhat sacrificed, but it would appear that of the two evils, loss of detail in high lights destroys pictorial effect less than loss of detail in the shadow does.

Of course there are exceptions to the rule which we have been, expounding as well as to every other. For example, in those subjects where the effect depends chiefly on the high lights, we may not only have a little clear glass in the negative, but in special cases a good deal. Amongst such subjects, perhaps the most notable are those in which the clouds form a prominent feature in the scene. For such subjects the golden rule may be reversed, and we may say,

"expose for the high lights, and let the shadows take care of themselves."

Another case is that in which there are one or two small spots considerably darker than any of the rest of the subjects. Here it would be inadvisable to expose until the parts of the negative representing these are veiled over.

Still another class of subjects may be noticed, in which it is not advisable to push the exposures till the deepest shadows are slightly veiled. These are portraits in an ordinary room. In all portraits the high lights—the face—are the parts to be chiefly attended to; but in the studio the lighting is so diffused that these will not suffer even when the shadows are very fully exposed. In an ordinary room it is different, however; the shadows here are so deep that if we expose till we get a slight veil in them, the lights are, as a rule, overdone.

GLASS.*

ELEVENTH ARTICLE.

Rolled Plate.—The methods of producing sheet-glass which have recently been described refer exclusively to the ordinary window-glass which is smooth on both its surfaces, and is that which is known as blown glass. The sheets are limited in their dimensions by the ability of the blower to wield the pipe with the weight of "metal" for the formation of a cylinder, and by the possibility of his hands and lungs combining to produce a cylinder of large area during such a period as the material itself will retain heat to remain plastic or workable. Sheets of window-glass, then, average 10, 12, or 14 feet each; extra large sheets will sometimes contain 20 feet, and are sometimes long and narrow, and at other times are almost as broad as they are long; extra sizes can only be produced by the most skilled blowers, are difficult to finish, and are, moreover, expensive.

It will have been seen that the process of making sheet-glass is a somewhat roundabout one; a cylinder has to be formed, then split open and flattened out into a sheet, and then annealed.

If we could just take, say, a ladleful of of glass and pour it out on a smooth surface one would think it should spread out and effect the same thing; but this is scarcely so as a matter of fact, for molten glass is not so fluid as molten lead, nor yet so dough-like that it can be manipulated just as we please. Nevertheless, it can be treated somewhat in this fashion.

Imagine a large furnace within the base of one of the brick-built "cones" familiar to the traveller who passes through Birmingham, St. Helens, or Sunderland; and whether that furnace contains six or eight huge pots, or is a tank furnace, is, for the moment, immaterial. In this furnace is melted the "metal," which, for the purpose of making rolled glass, does not require to be so "fine" as for sheet-glass. Around the furnace runs a narrow line of railway, and on the rails there rests an iron carriage supporting a slab of cast iron some three inches thick, about twelve feet long, and four feet wide. The upper surface of this iron slab has been planed by machinery, and there travels lengthways of this "table" a heavy roller of iron, running upon bearers on either edge; the roller being moved from end to end by means of wheels not unlike the steering wheel of a ship, fixed to its axis, and pulled round by the workmen; parallelism of the roller being maintained by rack-and-pinion, the pinions being on the axis of the roller, and the racks on the edges of the "table." The roller can be made to travel from end to end of the racks, leaving a definite space between the surface of the "table" and the periphery of the roller, which space determines the thickness of the glass.

All being ready for commencing operations, instead of gathering metal on the end of a pipe, there steps up to the furnace a powerful man clad in raiment of a heatproof character, wearing a pair of large leather mittens and armed with a Brobdignagian ladle. He is termed the "ladler," and he at once introduces his ladle into the metal in the pot, lifts the ladle brimfull of molten glass out, rests it an instant on the mouth of the furnace, and then strides towards the "table," and, with a dexterous twist of the ladle, he "plops" the molten glass down just in advance of the roller, which is drawn up at one end. Instantly the roller men seize the wheels and pull the roller the entire length of the table—the plastic "metal" is squeezed before it, being spread out into a sheet whose length and breadth and thickness is determined by the quantity ladled, the gauges to which the roller is set, and the approximate length and width which it has previously been desired to produce. When the roller reaches the farther end of the table the sheet of glass—now cooling to a deep red—is loosened from the table by sliding a thin blade between the sheet and the table, and the table is made to revolve horizontally, so that one end lodges upon a ledge opposite an horizontal slit in the side of the building. If we look into this slit we may see that it is the entrance into a kiln within which lambent flames are lazily circulating. When the sheet of glass has cooled to a very dull red, it is pushed or slid bodily off the table on which it has rolled through the horizontal slit into the kiln, where it reposes a few moments on a perfectly level surface to set; and if we pass through an adjacent door we shall find a couple of men at work with iron rods whose duty it is to slide the sheet along and dexterously raise it up on edge—to pile it—until the kiln is in this way filled with sheets of rolled glass. The process of ladling, rolling, and pushing into the kiln goes on very rapidly—a sheet can be ladled, rolled, and stacked in the kiln in from three to five minutes, and as each sheet contains from 15 to 20 feet, and is practically finished when it is safe in the kiln, there being no further operation necessary, it will thus be seen that the production is much more rapid than in the manufacture of blown glass. Where continuous-tank-furnaces are employed, there is really no necessity for any intermission in the process: as fast as one kiln is filled another is commenced, and so on, so that if the kilns were capacious enough and the tanks would hold together, the process might go on indefinitely; the difficulty is to provide kilns sufficient; hence where pot furnaces are employed, the kilns doing their work of annealing while the next "found" is going on in the pots, by the time the next "found" is ready for rolling the kilns, are ready to be drawn.

The manufacture of rolled plate is an outcome of the process of making cast plate from which polished plate glass is made, but the whole is a much less costly affair, in first cost of plant, &c., and in the manner of working. The entire credit of the invention is due to Mr. James Hartley, of Sunderland, who patented the process, and to this day, although the patent has long ago expired and the glass is made by several other manufacturers, it is known as "Hartley's Patent Rolled Plate." Rolled plate is generally seen of that kind with fine lines on one side; these lines are the impressions given to the molten glass by being rolled upon the "table," whose surface has the fine grooves left by the tool employed in the planing machine. Whatever the condition of the device upon the "table," such will be reproduced on the glass—for instance, tables are made quite smooth, in which case the glass also comes out very smooth, and there are tables planed or grooved with 12 grooves or flutes to the inch, the glass from which is known as "small fluted rolled"—and again there is a "table" grooved with 3½ flutes to the inch, and then the glass is termed "large fluted rolled." Tables are also made upon which glass known as Diamond rolled and Quarry rolled are made, but these latter descriptions have not much employment except for schools and churches.

Rolled glass can be made in substances of ⅛th, 3-16ths,

* Reference to previous articles, vol. xxvi., pages 675 and 737; vol. xxvii., pages 3, 98, 226, 419, and 757; vol. xxviii., pages 338 336, and 626.

¼, and ⅜ths of an inch, and in sheets averaging 20 feet each, which is larger than it is safe to employ in a single pane. The uses for rolled plate are so numerous that it is almost impossible to specify them; but it is per se *the* article for roofing, for side lights, for studios, greenhouses, workshops, and any position where it is desirable to exclude the vision, but not the light. Its remarkable strength, combined with its still more remarkable cheapness, have led to the use of this glass to an extent beyond conception—literally by the acre—for railway stations, markets, mills, &c.

A somewhat modern development of the manufacture of rolled glass has come about in the production of tinted glass called rolled cathedral. This is "metal" of any desired tint rolled upon a "table" whose surface is smooth, and it results, therefore, that both sides of the glass so produced will be tolerably smooth—quite smooth enough for the purpose for which it is employed, viz, in making up into the leaded windows now so much the fashion in houses as well as in churches, where transparency is not desired. The glass for this use is rolled thin, not over one-tenth or one-eighth of an inch, so as to get it easily into the grooved window lead. There is no end to the variety of tints that can be made in rolled cathedral. The so-called "cathedral green," which was some time ago advocated for use in dark-room windows, is simply rolled cathedral of the exact shade of green prescribed.

Excepting that the glass is tinted, and therefore somewhat more expensive to mix, the process is the same as in making rolled plate, and, as has already been stated, it is a much more simple method than that of blowing the same glass into cylinders; hence rolled glass is relatively much cheaper than sheet glass, over which, too, it has the advantage of extra size and substance, obtainable without any disproportionate increase in cost.

Some years ago it was the custom to glaze the roofs of studios with glass of a pale blue tint; that was in the collodion days, and the object sought was, doubtless, to obtain a more actinic light upon the sitter. The subject is not unworthy of re-consideration even in these days of rapid gelatine plates, seeing that we understand the theory of light and its action upon our sensitive surfaces much better than we did twelve years ago.

PHOTOGRAPH OF THE PALL MALL EXHIBITION BY A. L. HENDERSON.

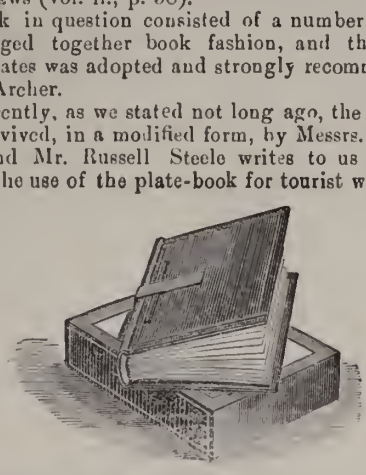
In the number of the Photographic News immediately following the opening of the Exhibition at Pall Mall, we reproduced a photograph of the Exhibition Gallery, taken by Mr. A. L. Henderson, and the photograph in question represented the room in such a state of disorder as one may expect to accompany the hanging of the pictures. When all was arranged and the hanging committee had finished their work, Mr. Henderson secured another negative; an impression from this forming our supplement of this week. Five members of the adjudicating committee, Messrs. Mayall, Mayland, England, Pringle, and Donkin, are shown; also Mr. Warnerke and Mr. Cocking; while many of the principal pictures are recognizable. Borderia's "Rheims Cathedral" is a prominent picture at the top, and a little to the left of Mr. Donkin; while immediately under this is Messrs. G. West and Son's frame of yacht studies. Immediately over the stove pipe, at the top, is Mr. W. P. Marsh's "Giant Breakers at Bognor," and one remove from this, towards the angle where Mr. Mayland is standing, will be seen Mr. Mayall's charming study "Marguerite," a three-quarter figure of a little girl. Almost over "Marguerite," but a little towards the angle already mentioned, will be seen Vanderweyde's portrait of Sir William Siemens, while at the end of the room one may easily recognize Mr. Tagliaferro's large picture of St. John's, Malta, which formed our supplement on Oct. 24th.

PLATE-BOX IN BOOK FORM.

The idea of making a plate-box in the form of a book is by no means a novelty, as an arrangement of this kind was described over a quarter of a century ago in the Photographic News (vol. ii., p. 58).

The book in question consisted of a number of carrier-frames, hinged together book fashion, and this plan of carrying plates was adopted and strongly recommended by Mr. Scott Archer.

Quite recently, as we stated not long ago, the plate-book has been revived, in a modified form, by Messrs. Sands and Hunter, and Mr. Russell Steele writes to us as follows regarding the use of the plate-book for tourist work.



"It is made to hold twelve dry plates, and when the book has been filled, a piece of stout broad elastic, which is attached to the covers of the book, fastens them in their places. The book is then inserted into an outer case, and this outer case into another case, which thoroughly protects the most sensitive films from dust and light.

"The covers of the book and two outer cases are made of stout millboard. Willesden paper, in my opinion, would be better.

"The wood-cut will explain the principle.

"During my summer holiday I made use of six of the books, and found them all that could be desired. The simplicity, ease with which the plates can be packed, and absence about the anxiety of light and dust gaining entrance, will, I feel sure, commend them to amateurs."

PHOTO-ASTRONOMY AT THE RIFFEL.

BY C. RAY WOODS.

No. IV.

In my last, I gave in detail some of the many difficulties I met with, and the attempts I had made to set at rest, one way or another, the objections that had been raised against the process for photographing the corona without an eclipse. I stated that, with reference to the backing, inequalities in the thickness of the asphaltum did produce false effects, but which effects could not for one moment be confounded with the corona-like appearances that Dr. Huggins had obtained in England, and which I have since obtained here. I also described the use of a disc to cut off the sun's image before it fell on the sensitive plate, and how its use removed several difficulties which I had already partially disposed of in other ways. With the introduction of the disc, indeed, most of my troubles may be said to have vanished; but had not a considerable number of experiments been first performed without it, the genuineness of Dr. Huggins' method might not have appeared so clearly as it, to my mind, has appeared. The disc was not tried till an almost complete elimination of error by other methods showed that when everything else had been taken into account, there still remained the great bulk of corona-like appearance round the sun which could not be accounted for by supposing that it could be due to instrumental errors. No alteration of any importance took place when the disc was applied. The form of the corona appeared the same. The only difference was, that my task was rendered so much easier, and I had only to go on

day after day, and get as good and complete a series as I could.

I said in my second article that my most promising results had been obtained on chloride plates. I can supplement this by saying that not only my best results have been obtained by the use of chloride of silver, but the greater portion of the corona photographs were obtained by its means. The plates I used were chiefly commercial ones, prepared for lantern transparencies, the chloride of silver being emulsified in gelatine. Some very good results were obtained on chloride of silver emulsified in collodion, but the difficulties in working them were greater. Each puff of wind raised a little dust about the Observatory, and some of this dust generally managed to settle on the plates before they were dry. Of course it would never have done to have used them whilst still wet, for the irradiation would then have obliterated the corona proper, or at least have confused it. I am not sure but that collodio-chloride is most suitable for the work, when it can be manipulated in a suitable and well situated dark-room; but for work in a temporary observatory, gelatine is best. The plates are already prepared, they only require a dusting-brush to be passed over them, will keep for some time, and are easily controlled in development. My collodio-chloride emulsion, however, was much quicker than the gelatino-chloride plates. I was somewhat surprised at this. It was prepared by the formula given in Captain Abney's book on "Emulsions," and not only contained excess of chloride as shown by the chromate of potash test, but had also been treated with chloride of copper to ensure freedom from fog. Collodio-chloride deserves more attention than it has hitherto received, and would have received, had it not been for the introduction of gelatine. In the days of collodio-bromide most amateurs made their own plates; how many do so now? The wet plate bath is no longer at hand, so that few amateurs use it, therefore, in preparing their lantern slides, and the number who use collodio-bromide is getting smaller and smaller. But since chloride for transparencies is coming into fashion, why not try it in collodion? There is nothing easier to make than a collodio-chloride emulsion, and it will stand the same developers as gelatino-chloride. It is not improbable, moreover, that a similar range of tone may be produced, and there is the additional advantage that it admits of silver intensification with a readiness equal to that of a wet plate.

To return from this little digression to the corona. I have succeeded in obtaining a record extending over two months—two solar revolutions; how far, however, the first month's observations are available remains to be seen. It is certain that the earlier photographs contain a great deal that is not genuine, but, on the other hand, a considerable number of photographs were taken on each day, and these can be made to correct one another. Altogether, about one hundred and fifty negatives have to be examined.

This season has been a very poor one for Switzerland. Something like three thousand visitors less than last year have been in Zermatt, and therefore I calculate I have escaped the stupid questions of one thousand inquisitive individuals. Better still, my own conscience has not been burdened with a corresponding number of untruths. You see, I like to let people have their own way, and if I have been asked whether my instrument was intended for photographing the mountains, I have said, "Yes!" When asked whether I was taking people on the Matterhorn, I said "Yes!" and so on. But when I told one individual that my instrument registered the number of persons, *including mules*, who went up the Gorner Grat, he walked away a little dissatisfied; although he had been trying to strike up a conversation for the past ten minutes, he did not, till then, notice that I was busy, and that he himself had an engagement elsewhere.

It was not till within a week or two before I left that I went up the Gorner Grat myself. To tell the truth, I had been rather frightened at the magnitude of the task when I saw strong, sturdy men being carried up on chairs by porters, or riding up on mules. When I heard, however, that there was no necessity for guides, ropes, and ice-axes, I ordered a carriage and pair, and resolved to do it, or perish in the attempt. The carriage never came, and I had to walk, putting my camera on the shoulders of a porter. The view from the top is magnificent, and my exposures were successful. The most important features in the landscape were the tourists sitting all around, and reading their guide-books for each other's edification; but I contented myself with photographing the minor features of the view, such as Monte Rosa and the Matterhorn. Somehow or other, though, two tourists and three guide-books managed to find their way in.

The badness of the season caused Mr. Seiler to close the hotel sooner than was expected. One morning in the middle of September we found nine inches of snow on the ground, and the feathery flakes were still descending. This was the last straw, and preparations for closing were made. On the 17th the Riffel House was shut, but by that time the weather had changed, and the snow had disappeared. I resolved, therefore, to keep my tent and instrument standing, and took up my quarters at the Riffelalp Hotel till the fine weather broke up. Clear skies lasted for a whole week, and each day I climbed up 1,100 feet to the Observatory. As soon as bad weather set in again, I telegraphed to Zermatt for men and mules, and ere long only a pile of spoiled plates and broken glass were left to mark the spot where my work had been done.

I cannot refrain, here, from raising a tribute of admiration to the business-like capacity of one of the muleteers. Four mules had arrived, and this man said that five were required. I told him to get another one, then. Instead of doing this, however, he put the things on the four mules, and took them to Zermatt, then calmly came and demanded the money for the other mule which I *ought* to have had. What is more, he said that though I paid M. Seiler for the four mules, I must pay *him* for the fifth one, which I had not seen. Unfortunately for him, I had a little business capacity also, and declined to encourage his endeavour to trade on no capital. To do the Swiss people justice, this was the only attempt at extortion I met with during the whole time I was there, and among so many honest fellows it would be strange indeed if one did not meet with one rogue.

Getting my things down was much easier than getting them up, but I had to stay a day or two in Zermatt before I could get everything ready and sent on to Visp. During that time I was able to obtain the services of the Junior Partner, and with his assistance took a few views in the neighbourhood, and packed the plates up for development at home.

I only took one photograph on the journey to Visp, and that was the interior of the church at St. Nicolas. Arrived at Visp, I entrusted my cases of apparatus to the tender mercies of the Railway Company, and took my ticket for Montreux, by the Lake of Geneva, where I had arranged to meet the German artist and two other friends. At Montreux I stayed two days; but must reserve my photographic doings by the Lake of Geneva for an article on "A Day with the Tricycle and Camera in Switzerland," which will conclude my Swiss series.

Twenty-six hours after leaving Montreux I was in London, and soon had the pleasure of developing some good negatives taken in Zermatt and the Rhone Valley.

FORGOTTEN PROCESSES.

BY F. H. CARTER.*

Photography comes to me only as a rare and valued amusement, in which I enter into the result of the labours of others,

* Abstract of a paper read before the Photographic Club.

without in any way contributing to them. It is open, however, to me to think over and to marvel at the progress that photography has made. Men are not now old—in the modern use of the word—who saw its birth as a science; but it had prior to this a long record of forgotten processes. It did not spring full-armed from the head of any inventor, like the block-making machinery at Portsmouth, which is probably unique, as no improvement in it has been found possible since it was first designed.

There were heroes before Agammenon, but they had, we are told, no Homer to record their deeds; so it is possible that others may have seen visions and dreamed dreams before Fabricius, in the early part of the 16th century, seeking the elixir we should all be so glad to find, to confer perpetual youth, threw some sea salt into a solution of nitrate of silver. He noted that the precipitated chloride of silver, which he found white as milk, became black by exposure to the sunlight. He recorded the fact in his "Book of Metals" published in 1536, but did no more. What bearing could such a thing have on the elixir of youth? Scheele, in 1777, re-discovered the fact; and in 1780, Professor Charles, the inventor of the hydrogen gas balloon, turned it to practical use by spreading a solution on paper. He then projected on it a strong beam of sunlight, with the head of one of his pupils interposed, and found that the part exposed became rapidly darkened, and following the outline of the head, the first silhouette was produced—the parent of those fearful and wonderful objects in black paper which are still occasionally to be met with, and were supposed to represent the grandfathers of the present generation.

It is a long leap from Prof. Charles to Isidore Niépce and Daguerre. The former, as an independent worker from 1817 to 1826, and afterwards in partnership with Daguerre, discovered that bitumen of Judea, if spread thin on metal plates, and exposed to sunlight under a print or similar object, became white in the exposed parts, and insoluble in essence of lavender. Subsequently, he etched the bare metal with acid, and named the process heliography. Meanwhile Daguerre had been working out his own idea, still with bitumen; but, by one of those happy accidents—which only genius appropriates—he chanced, it is said, to lay a silver spoon on a metal plate which had been treated with iodine; lifting it afterwards he discovered an image of the spoon on the metal. From that time bitumen was abandoned. Silver plates were exposed to iodine vapours and treated at first with petroleum and afterwards with mercury for a developer; and on the 10th August, 1839, Daguerre demonstrated his process before the Institute of France, and photography became a fact. Paul Delaroche, who was present, is said to have exclaimed, "Painting is dead from today;" but still it lives, and will never be killed by photography, for that deals only with the objective; the imagination in it has no place; it cannot "give to airy nothing a local habitation and a name;" and while poets dream and ideal beauty beckons, the painter will interpret them as best he may. It detracts nothing from the title of Daguerre to a place on the scroll of fame that the Daguerreotype must be classed with forgotten processes. So beautiful were its results, that they will always be regarded with interest, and it is possible that even now curiosity may here and there still cause it to find votaries; but from this begins the era of forgotten processes, for where now are the amphitype and autho-type of Herschel; the calotype of Talbot; the energyatype of Hunt; the coffee process, the tobacco process, the Beechy process, and hosts of others, dear to their discoverers, but to few besides? Where are last winter's snows?

But the world owes a large debt of gratitude to men like Robert Hunt, who gave time, and thought, and money, to the advance of this beautiful art. A few names stand out with especial prominence. Claudet, who in 1841 discovered the use of bromine as an accelerator for Daguerreotype plates, and made portraiture possible; Talbot, who invented the Calotype process; Herschel the astronomer, who discovered the use of hypo-sulphite of soda as a fixing agent; and, greatest of all in results, Scott Archer, who in 1851, with the generosity of a noble mind, gave to the world, free and unfettered, the collodion process; and although this, too, has been superseded by the gelatine process, the subjugation has not been complete: the two Richmonds remain in the field, and if the former is vanquished, it still retires with strife. And now what shall be said of the future? Has perfection been attained, or are there still worlds to conquer? If we look at the work of the masters of the art, some of whom are present, and whose blushes I will spare by not naming them, we might think the last page was written, and that nothing more remained to be done. But it is those whose work is the best who see room for improvement, and who still go on and strive for perfection yet unobtained. Still remains the dream of photographing in colours, more a wish than an expectation. But the constantly-advancing uses of photography are no dream. The Woodburytype process enables portraits to be multiplied to any extent without fear of fading. The photogravure of Goupil makes collectors of engravings despair; for the various "states" of a plate can be so exactly reproduced that no specimen can now be looked upon as unique if it has been in their possession. And its latest application, stellar photography, is perhaps to some the most interesting of all. The mind reels in contemplating the awful depths of space where worlds in myriads spangle the darkness like golden sands, or nebulæ in fantastic forms, the raw material of unformed systems, perplex the astronomer.

Photography is finding its way into book illustration, and it may be that, before many years are past, wood engraving may be driven from the field by its newest rival, which is ever seeking new worlds to conquer, and become a forgotten process. If, as it says in "Locksley Hall,"

> "Science moves but slowly, slowly,
> Creeping on from point to point,"

so far as photography is concerned, it makes good its advances, and these are due in no slight degree to the forgotten processes to which reference has been made.

HOW TO PHOTOGRAPH MICROSCOPIC OBJECTS.

BY I. H. JENNINGS.

Lesson IX.—Preparing Entomological Slides.

A glance at the catalogues of the professional preparers will show how popular are insect preparations. Nor is this surprising. The marvellous beauty of form, the gorgeous colours, the elaborate workmanship displayed in the construction of their various organs, together with the minute size of many of the insect tribe, all render them fit objects for microscopic study. Many of their beauties are apparent to the unaided eye, but under the microscope they are increased tenfold; while others alone reveal themselves to the scrutiny of the magic tube. But for it, the delicate mosaic of the butterfly's wing, the mysteries of the gem spangled elytra of the diamond beetle, the myriad-facetted eye common to the whole insect world, and all the wonders of their internal structure, would remain hidden to us.

As insects vary so much in size, colours, and texture, the modes of preparing them for photography must also vary to suit the subject under treatment.

1. *Opaque Mounting.*—This method is alone available in some cases, as the application of balsam or any medium would not only diminish the beauty of the specimen, but often prove destructive in effect. Such objects as scales, such as those of butterflies, the Podura and Lepisma, as well as some wings which are very transparent, as well as small insects like the Tingis and Thrips, which can be successfully photographed by reflected light, should be mounted dry. In the case of small flat objects, as scales, no cell will be required; all that is necessary is to place the scale in position on the slide, and cement a thin cover over it. Larger objects will require a cell, which, for photography, had better be of glass. Glass cells are sold at a cheap rate, look well, and have the advantage of allowing light to pass through their sides, which is often desirable. They can easily be manufactured at home by anyone who has a little skill, by cutting rings from glass tubing with a sharp flat file. Various cements may be used for attaching the cell to the glass slip; marine glue is the most trustworthy, but is somewhat difficult to manage, as it requires a strong heat to melt it. Gold-size, when good, is equally reliable, but the various cements which have been used of late years for mending broken china and glass, such as coaguline, appear to be quite satisfactory, and, being colourless, look best when used with glass cells.

2. *Mounting in Balsam.*—Whole insects are usually prepared and mounted in the following way:—Having

killed the insect, either by means of the cyanide bottle, or by immersion in spirits, it is set out carefully between two glass slides, which are tied together and put in a strong solution of potash—caustic potash one ounce, water twenty ounces. Here it must remain for some time, according to its colour and texture; but a frequent examination of the specimen is necessary, as some insects dissolve into a jelly if kept in potash too long. One or two days will suffice for most specimens, but others will take longer. When it becomes sufficiently soft, it is taken out of the potash, placed in a saucer of pure water, and gently pressed with a soft brush until the contents of the thorax and abdomen are expelled. It must then be washed with fresh water until quite clean, when it must again be set out on a slide in the position which it is finally to occupy, covered with a square of thin glass, and tied down with thread. Here the treatment may vary. The older method was to keep the slide in a warm place, under cover, until the preparation became quite dry, and then immerse it in turpentine.

The objection to this plan was that the insect became full of air, which it is almost impossible to expel, unless by the aid of an air-pump. The better method is, to drain all the water from the insect after washing, using blotting paper if necessary, and then immerse it in alcohol and water for about a day, and after that in pure methylated spirit to displace all the water. A second dose of pure spirit may be necessary in some cases. The whole of the water will thus be removed by the spirit, which will also render the preparation so firm that, on the application of the balsam, it will not alter from the position in which it was set. When quite free from moisture a few days' soaking in turpentine will give most specimens the necessary transparency. Some insects and parts of insects may, however, require to be left in turpentine for several weeks before they are fit to mount.

The tissues of some dark-coloured insects are best treated with some bleaching agent immediately after their removal from the potash solution; one of the best is as follows:—

Hydrochloric acid	10 or 12 drops
Chlorate of potash... ...	½ drachm
Water	1 ounce

This will remove the objectionable strong browns and yellows of the chitinous portions, which are so fatal to obtaining a good photograph. By examining the object occasionally, the right amount of transparency will be gained, but it is best not to let preparations remain too long in the bleaching solution, because if too transparent they will be as difficult to photograph as if too opaque. The writer recently photographed two splendid fly's tongues, or ligulæ, specially prepared by Topping. These were selected out of seventy-two similar preparations, but while both were perfection as microscopic objects, or for exhibition in the lantern microscope, only one was fit for photography. The other had been bleached too much, and was too thin to give a satisfactory photograph.

When the necessary transparency has been attained, and after the object has been successively treated with alcohol and turpentine, it is ready for mounting. A solution of balsam in benzol is better than pure balsam in many ways. The solution may be prepared by "baking" pure balsam in a slow oven until it becomes quite hard on cooling, and then dissolving in benzol, or may be purchased at the shop of any optician. The insect, or part of one, is removed from the turpentine and drained, placed in position on a slide, a cover-glass placed over it, and a small quantity of the balsam solution applied to the side, when it will be drawn under by capillary attraction. By a little care, air-bubbles may be entirely avoided. The slide is then put aside until the balsam has become quite hard, when it may be cleaned for the cabinet, and ornamented with rings of coloured varnish, as the mounter's taste may dictate.

Of late years many microscopists have objected to the "squashing" process usually employed in mounting insects, as, in many cases, it deforms and distorts the preparation almost beyond recognition; and now many amateur and professional preparers mount insects without pressure, first gaining the necessary transparency by prolonged immersion in turpentine, and finally mounting with balsam in a cell. Objects thus mounted are very beautiful, especially when illuminated with the paraboloid or spot-lens, but are somewhat difficult subjects for photography, unless a very low power, such as a five-inch, four-inch, or three-inch be employed, as great penetration is required.

It is best, when engaged in mounting insects specially for photography, not to mount indiscriminately any pretty object, but to set up a type-series, to illustrate the class *Insecta*, which, when photographed, would have a real scientific value. Something after the following style might be attempted:—

1. *Coleoptera.*—Many of the smaller species can be set up whole, after bleaching in the chlorate of potash mixture. A few feet may also be mounted; the paddle-foot of *Dytiscus*, the broad-padded foot of *Timarchus*, and the type-foot of *Carabus*. Some of the antennæ, as those of *Melolontha*, are also well worth mounting and photographing.

2. *Dermaptera* (the earwigs).—A specimen may be mounted whole for a five-inch objective: if possible, with the wings expanded. This subject will not require more than a few hours' treatment with potash.

3. *Orthoptera* (the cockroach).—*Blatta Orientalis* is a good type, although not a true English insect. Almost colourless specimens may be found in kitchens which these creatures haunt. These will require no preliminary bleaching.

4. *Thysanoptera.*—The diminutive insects so abundant and so troublesome in hot summers—insects which will persist in crawling over one's face, and into one's mouth and eyes, which swarm everywhere and on everything—constitute this order. One of the largest, *Phlæothrips coriacea*, measuring about $\frac{1}{4}$ of an inch in length, may be set up whole in balsam.

5. *Neuroptera.*—A portion of the large facetted eye of the dragon-fly may be mounted flat on a slide in balsam, and will form a very instructive photograph.

6. *Trichoptera.*—The larva of the caddis fly may easily be prepared. The internal parts must be removed, when, after washing and treatment with turpentine, it is ready for mounting. The mature caddis-fly may be set up whole.

7. *Hymenoptera* (bees and wasps).—The wings, showing attaching hooklets, may be mounted dry or in balsam. The feet will require to be bleached strongly, as most of the *Hymenoptera* are strongly coloured. The modified ovipositor, called a "sting," should be cut from the insect carefully, so as to have the poison-bag attached. The stings—for there are two—lie enveloped in a case of brown chitine, from which they may be dislodged with a fine needle. The poison-bag, owing to its extreme transparency, must be stained—not with *blue*, as in many professional preparations, but with brown. Bismarck brown is, perhaps, as good as any. Sufficient stain should be used to give this part as nearly as possible the same colour as the stings.

The saw-flies show another modification of—or, rather, addition to—the real ovipositor. This consists of a sawing apparatus, composed of four saws—two small and two large ones, the former fitting into the latter. This object is rather difficult to photograph when set up in balsam, as it becomes too transparent. A well-mounted *dry* specimen will give more satisfaction.

8. *Lepidoptera* (or butterflies) are interesting from their finely-marked scales, which form tests for low powers. They should be mounted dry.

9. *Homoptera* (frog-hoppers and *aphides*).—The former

possess saws, which may be prepared like those of the saw-flies.

10. *Heteroptera* (or bugs).—The "beak" of *Cimex lectularius* and the oar-foot of the water-boatman may be mounted in balsam.

11. *Aphaniptera* (or fleas).—The insects, to be successfully mounted, require a severe treatment with potash, and a long soaking in turpentine. Preliminary bleaching in the hydrochloric acid mixture is, perhaps, best to get rid of the yellow colour, which renders them difficult to photograph satisfactorily.

12. *Diptera* (or flies).—The feet of the dark-coloured species will require bleaching with chlorate of potash. The "tongues," or *ligulæ*, should also be bleached, but *not too much*. The proper way to mount a fly's tongue is to set it up in a shallow cell, *without pressure*. The specimens usually sold, being mounted flat, are distorted, and give an improper idea of the real shape of the organ.

For further information as to dissection, &c., the student is referred to "Practical Microscopy," by Mr. G. E. Davis.

DR. JANEWAY'S TABLE OF THE SOLUBILITY OF PHOTOGRAPHIC CHEMICALS.

Made for the Society of Amateur Photographers of New York.

Abbreviations.—s. soluble; ins. insoluble; sp. sparingly; m. moderately; v. very; alm. almost; dec. decomposed.

Reviews.

The Dynamo; How Made and How Used. By S. R. Bottone. (*London: Swan, Sonnenschein, and Co.*)

This is just one of those handy little works which not only the student, amateur electrician, or photographer, may read and study with advantage, but which the general public ought to know something about. It is perfectly astounding to find the great amount of ignorance which prevails among unscientific people upon matters electrical, and still more extraordinary is the positively erroneous notion, which perhaps nine people out of ten have, as to how electricity is produced by means of the dynamo machine. One has but to overhear the conversation in a railway carriage, or even at the table of an hotel, if perchance the subject turns upon electric lighting, and be compelled to listen to authoritative statements made with the utmost coolness, which are all wrong both in theory and practice, when one wishes the speakers could have read some such work as Mr. Bottone's. Mr. Bottone is not only an electrician, but is an authority on most photographic subjects, and what he writes can be depended upon as being sound. His book under review forms no exception to this. Within some seventy odd pages he has explained very clearly the principles upon which dynamo machines are constructed, and by the aid of drawings has shown how the amateur mechanic of ordinary ability may construct a hand machine capable of lighting four 5-candle power incandescent lamps, as well as performing many experiments which, if a battery had to be set up, would simply remain untried. Mr. Bottone says: "When the machine is doing its best work—that is to say, when the resistance of the interpolar is equal to the internal resistance of the machine—the current is equal to that of eight or ten Bunsen's cells against an equal resistance." That is a very good result.

For further information, we advise our readers to peruse the book.

Notes.

The bacterium, in his somewhat Proteus like aspects, is attracting much attention just now; and the more we can learn about him, or the more widely his portrait can be circulated, so much the better is it for the world in general. Just as sitters were photographed with whitened faces in the early days of the Daguerreotype, the bacterium must be stained before his portrait is taken. Apart from such difficulties as arise from the extreme transparency of minute organisms, it frequently happens that it is only by staining them that their structural details are brought out.

In a lecture given at King's College on Monday last, Mr. Thurston told his audience how to prepare and pose the bacterium, and he is good enough to furnish us with an article on the subject (page 779).

A correspondent writes:—"Would it be considered derogatory to the Photographic Society of Great Britain if an intimation were placed in the catalogue that copies of the pictures exhibited could be purchased by communicating with the artists? At exhibitions of paintings, from the Royal Academy downwards, the pictures are apparently shown for the purpose of being sold; but at photographic exhibitions all mention of buying and selling is carefully kept out of sight. I know several visitors who would have been very glad to have purchased copies of some of the pictures exhibited at the recent exhibition, but they did not know how to set about it. Perhaps it may be said that common sense would have suggested writing to the artist, whose address would be found in the catalogue; but everybody who has had anything to do with the public as a body, knows that it has not common sense, that it will not take any trouble, and that everything has to be made as plain to it as though it were a child. Is not this a matter worth considering by the Council?"

A lantern slide club! Mr. Henry Smith thinks that amateur lanternists should unite and form a club; a lending library of slides being the main feature of Mr. Smith's idea. His letter will be found on page 782, and we certainly hope the club will be formed. Why not as a branch of the Photographic Club?

It is curious, considering the thousand and one purposes to which photography has been turned, that no one has ever thought of adapting it as regards portraiture to Christmas cards. Photographs on Christmas cards are of course no novelties, but to send one's portrait surrounded by a tasteful border, and accompanied by an appropriate sentiment, has not yet been done. It no doubt requires somebody to set the fashion, and somebody else to design the cards and place them in the market. The sitting for one's portrait, especially when the head and shoulders alone are wanted, is, if people did but know it, a very small matter now-a-days.

On these latter points, by the way, the public need much enlightenment. Nine persons out of ten had the experience of fifteen years ago or so before their eyes, when photographers were not so skilful, artistic, or systematic as they are now. The head-rest was a source of tribulation, the slowness of the collodion plate and consequent risk of failure produced continual woe. The great majority of the public do not know that all this is changed. If everybody, men of business especially, were made aware that the loss of time once almost inseparable from a visit to a photographic studio is reduced now to a minimum, sitters would certainly increase in number.

A Mendoza camera hat was wanted at the magisterial examination of the man charged with committing the murder at Torquay. An artist detected sketching the prisoner was stopped by the magistrate, who, however, graciously gave him permission to take the portrait of anybody else he liked.

No doubt the artist got as much as he wanted before he was detected. Anyway, he was more fortunate than a friend of ours, who was sent to get the portraits of a miscreant whose wholesale murders at Uxbridge made a great sensation some twelve years ago. The artist who wanted the portrait for the current number of an illustrated paper could not wait for the examination, as it was with him a question of hours. His persuasive powers, however, were fruitless, for none of the officials of the prison, from the governor downwards, would let him have a sight of the prisoner. He was in despair, when meeting a friendly detective engaged in the case, the latter said, "Why, So-and-So," naming a small tradesman in the town, "is the very image of the prisoner." This was enough for the artist. Off they started for the shop, and while the detective engaged the proprietor in conversation, the artist got his features in his note-book. Two days after, the paper came out with a portrait of the murderer, "sketched from life"—a statement which, after all, was literally correct.

We have heard of two things lately which are hard to believe, but which may be true for all that. One is, that a Greenwich photographer possessed a large stock of plates which would frill in spite of every effort, until he adopted the simple method of heating his developer to a temperature of about 150° F. The other is a statement that a well-known photographer residing in Greenwich put up a prominent notice as follows:—"To-day being the anniversary of the decease of my mother-in-law, I will make all pictures at half rates." The two individuals referred to are not fellow-townsmen, as the first mentioned Greenwich is in Kent, and the second is in the United States.

That the pupils of eye expands to a definite extent under the influence of a constant light, is a principle which Mr. Gorham has satisfied himself to be true; and the outcome is the pupil-photometer, which was recently exhibited at a meeting of the Royal Society. Gorham's instrument is, in fact, a means of measuring the pupil. One merely looks in it, revolves the lid until the two images of the pupil presented to the eye just touch each other, and the diameter of the observer's pupil can be at once read off in hundredths of an inch.

We shall shortly give a fuller description of the instrument.

The wet plate tourist photographer has one advantage over the dry plate worker, as the former can make friends by taking and delivering pictures on the spot—ferrotypes, or positives on glass.

Dr. H. W. Vogel, in calling attention to this circumstance, suggests the desirability of making dry plates which

will serve for the production of direct positives. Ferrotype plates, or glass coated with a thin emulsion, should answer, but Dr. Vogel points out that a substratum would be required to enable them to stand rough and ready development under trying circumstances.

So decided has been the success of the Dublin Exhibition, that it will be kept open until Christmas. Over three thousand persons have already visited it.

Mr. Beach, of New York, suggests that metal frames or rims, for binding together the two glasses which constitute an ordinary lantern slide, should be introduced into commerce. They could be made of very thin sheet brass, something like the "binders" used for positives on glass.

The path of a comet can be better recorded by the camera than in any other way, according to Mr. A. Belopolski; but very good instruments are required, as long exposures are unavoidable.

Belopolski made a series of investigations in order to ascertain what lens would give him the best definition and the maximum of light, and of those he tried, the very best was a small portrait lens of English manufacture, this instrument proving first both as to speed and definition.

The lenses were tested by exposure on the Milky Way in Cygnus; the exposure being one hour, and the plates used showed a sensitiveness of 22 by Warnerke's sensitometer. Although the portrait lens was used without a diaphragm, it defined stars up to the ninth magnitude, and defined them so well that good measurements could be made on the plate; the actual diameter of the image of a ninth magnitude star being 0·036 of a millimetre, or considerably less than a six-hundredth of an inch.

French and German portrait lenses which were tried, did not compare well with that of English make, the star images being surrounded with a halo, and in one case with two concentric rings.

A correspondent of the New York *Photographic Times* says that he had some of Vogel's azaline plates sent to him to try, but they would fit none of the American plate-holders or "kits," so a new "kit" had to be made for them before they could be tested. Would it not have been simpler to cut down the plates, some of which were as large as 9½ by 7 inches, to the nearest smaller American size?

A correspondent who, evidently, forgets that the silly season has come to an end, writes to inform us that, encouraged by the success of Mr. Mendoza's hat-camera, he is now engaged in perfecting arrangements which, when complete, will, he hopes, enable him to present to the world yet another novelty in photographic apparatus in the shape of a pipe! The lens will be fitted into the side of a largest sized meerschaum bowl, so carved as to conceal its presence; whilst within this bowl (which will be rather large, he admits, for out-door use) will be a tiny camera. The arrangements for focussing, &c., are to be regulated by thin wires passing down the stem, and capable of being managed after practice by the teeth of the operator. All the possessor of one of these new pipe cameras will have to do will be to place the pipe between his lips, and of course point the lens at the object he wishes to take. "The rest," he adds, "will be simplicity itself." Quite so, including the credulous individuals who believe in this photographic fig, or rather little gooseberry.

Photographic business does not seem to be very brisk in the Russian capital just now, and rumour asserts that no less than eighteen photographers have permanently closed their establishments since the summer. One enterprising individual on the *Nevski* has issued a circular with the view of obtaining yearly subscribers, who pay down a sum of about £3, which entitles them to be photographed on six different occasions during the year, and to receive a dozen cabinets each time. As the subscriber may transfer his right to be photographed, the arrangement is much patronised by families; but when two sitters are to be taken on the same plate, there is an extra charge.

A correspondent who has lately returned from a sketching tour in the Highlands, says that he was gratified to see so many artists making use of the camera. He says: "I passed the last six weeks along with two R.A. associates, and we were often surprised to see the camera in the hands of well-known artists; indeed we found no less a person than Birket Foster's son using one; Birket was himself working not far from us on Loch Lomond side. But the curious thing was that we had not seen any but English artists with the camera; although, of course, we know that many Scottish artists of reputation appreciate its value."

The ferrotype studio which is under the shade of the Drachenfels has been wrecked by a falling fragment of rock. Fortunately, no one was injured.

Like our own Queen, the Sultan is a patron of the photographer; and he has recently given orders for the making of a monster album in which a portrait of every servant of the Court, from the highest to the lowest, is to be included. The Turks seem to have quite overcome those religious scruples which once made it difficult to persuade a follower of the true prophet to have his portrait taken.

Patent Intelligence.

Applications for Letters Patent.

15,542. Alfred Julius Boult, 323, High Holborn, Middlesex, for "Improvements in or relating to holders for photographic films."—Communicated by George Eastman and William Hall Walker, United States.—Dated 25th November, 1884.

15,757. Herbert John Haddon, 67, Strand, Westminster, for Improvement in heliographic copying apparatus."—Commu-

nicated by Hugo Sack, Plagwitz-Leipzig.—Dated 29th Nov., 1884.

Patent Sealed.

11,556. Eugen Himly, 28, Southampton Buildings, Chancery Lane, W.C., for "Improved method of, and apparatus for, taking photographs by artificial light."—Dated 22nd August, 1884.

Specification published during the week.

1380. R. Brown, R. W. Barnes, and J. Bell, "Preparation of pictures and photographs."

This embodies the additions and alterations referred to on p. 219 of our present volume.

1622. Alexander Crawford Lamb, of Reform Street, Dundee, in the County of Forfar, Hotel Proprietor, for "Improvements in Photographic Cameras." Dated 17th January, 1884.

The object of this invention is to enable photographic cameras to be carried conveniently in the pocket, while being readily opened up and adapted for use at any time.

The invention consists in connecting the front part of the camera, in which is fitted the lens, and the back part or frame which carries the dark slide, by means of springs or spring bars which admit of the front and back parts being brought close together to close the camera, or opened out and rigidly held when it is to be used.

According to one modification of the invention, the front and back frames of the camera are connected together by four jointed spring stays or bars similar to those used in collapsible opera hats, and fitted at each corner. Each spring stay is made in two lengths or bars and jointed in the middle, so that it can fold inwards to close the camera. Between the parts of the stay bar a bearing shoulder is formed, and the bars are held in their distended position by means of helical or other springs which are attached to hooks or catches formed on the bars. When fully distended, the two parts of each bar bear on each other at mid length, and form a rigid stay. The stays thus formed at each corner suffice to hold out the camera in its open position. The usual bellows or dark cloth is connected to the end pieces to form the box-like body of the camera.

HINTS ON POSING AND THE MANAGEMENT OF THE SITTER.

BY H. P. ROBINSON.

Chapter VIII.—Children.

There was a time when children were looked upon with dread by the photographer, and I knew two or three studios where they were absolutely refused. This was in the days when sitters were as plentiful as blackberries in autumn, and professional pleasure in overcoming difficulties was quite subsidiary to the number of guineas taken.

The true photographer will always take delight in a difficult sitter, just as a surgeon does in a beautiful case of compound fracture, or a physician in some obscure disease. To go on exposing a long succession of plates on easy subjects soon becomes monotonous; it is when a sitter calls for your reserve powers that he becomes interesting. There are certainly some bad sitters who are very depressing, with no redeeming points about them, such as those who begin by saying they hate being taken, following this pleasant observation up with the worn-out old joke about it being as bad as going to the dentist. It is a very curious thing how they all bring this ancient pleasantry out as if it was perfectly original, and a fine sample of wit. It is not very exciting amusement to work this sort of customer round into a happy frame of mind; but there is to me something almost fascinating about a fractious three-year-old who objects to have his portrait taken.

In a case of this kind it is your duty to so work upon that child that he shall not only willingly do all you require, but shall be so delighted with you that he shall howl when he is taken away after the operation, and will only be pacified by a promise that he shall come again.

"How is this to be done?" may well be asked. There are two things of primary importance. The child must not be forced, and mothers and nurses must be rigidly suppressed. When I have had a few minutes' interview with a child, I easily discover if it has been worried, and spoilt for my purpose, by some bungling photographer who has so frightened it that it dreads to enter a studio; or if it has been—shall I say tampered with?—by the mother or nurse. These latter will think they are doing the right thing when they solemnly impress upon the little sitters that they must be very good and keep quite still; but their well-intentioned warnings produce exactly the reverse effect to what is wanted. The child that insists upon being good is an unmitigated nuisance. He will do everything you ask him to do, and looks as wooden as an awkward lay figure.

With the great majority of children the battle is won or lost at the first introduction. The clever photographer will decide at a glance whether the child belongs to one of these classes—the fearless child who takes the sitting as part of the day's occupation and enjoys it; the nervous child who really would be good, but has a constitutional fear of any new experience; and, worst of all, the shy child. The first of these is easily managed; the chief thing to bear in mind is that the first of him will be the best, and that the sooner you take him the better. As he gets to know you better—familiarity breeds contempt—he will become less manageable. He will continue to smile and be very good and agreeable, but you will find that after a few exposures he will quietly slip off the chair, or run away from where you have placed him when you turn to go to the camera. He approves of you, and wants to have a lark with you. But when very young children begin to play practical jokes, I know no cure for the disease except sending them home to meditate on their sins, to come again another day if the exposures you have already made do not produce satisfactory pictures.

The nervous child wants very gentle management. It is no use attempting to proceed at once to serious business in a case of this kind. The subject must be led up to gradually. The photographer had better meet her—it is usually a girl—in the reception room, and quietly introduce himself. This leads to showing and getting interested in pictures, when the nervousness will probably begin to wear off. In my studio I have an intermediate room between the reception-room and the studio proper. The place is full of things interesting to children, and I find it very useful in gradually breaking the nervous little patient in, before my horrid purpose is fully divulged. If, after a few minutes' talk and looking at pictures, you should happen to have a squeaking toy or a musical box in your pocket, and you begin a gentle performance on it, you will have nearly got that child into a proper state of mind for a sitting, or, at all events, for going through the needful arrangements in the dressing-room. At first the child should not be allowed to see the toy; it should be an invisible performance, something for the mind of the patient to dwell on and wonder at during the dressing operation. By this time, if you have not mismanaged, you will have so "corralled the sympathies" of the child that she will have lost much of her fear of you; and if you will allow her nurse to keep close to her, she will allow you to jump her up on a table, and even, if you not bungle or hurry it, place the head-rest. When nervous children get over the first exposure and find it does not hurt them, they usually become very good sitters. But there are children whose nervousness it is almost impossible to get over. These have either suffered from a medical operation, or from the dentist, or, worst of all, they have had a bad quarter of an hour with a bungling or brutal photographer who had no patience or care for the management of children, and had to try to do by force what ought to have been done by guile. Photographers should recognise the fact that their principal weapon with children is 'wheedling," although there are, I admit, some cases in which a moderate degree of firmness is useful.

The shy child is extremely difficult to manage. She is not afraid of you, but simply shy, and endeavours to get behind her mother or nurse, and hide herself in her dress. In these cases it is often better not to try much persuasion, except perhaps a gentle attempt to make friends, but to proceed to the studio and go on with the sitting at once. A shy child will often take the sitting as a matter of course if it is done quickly, but would become troublesome if allowed time to think.

In all these classes there are, of course, all degrees and varieties, but I can only write generally on the treatment of the class; the photographer must modify his entertainment to suit individual cases; but if he is kind, quiet, patient, and judicious, he will not lose above one or two per cent. of the children brought to him for their portraits.

It is curious to observe the different idiosyncracies of children. The photographer will find it useful to classify them as I have done above; but there are many species in each genus. Notice the different ways they have of objecting to be photographed. Some object right out, and fight and scream against it. This is mere brute-force opposition, without any subtlety in it; but some children, you would almost think, had studied resistance as a fine art.

If a child fights, it is of no use to oppose force by force. Nurses will often attempt this, but you must stop them at once. The child must be a willing victim, or it must be sent away to come again another day. When a child will not sit, try to find out the cause. Analyse the subject as you would a problem in mathematics. Probably the mother is in the room; now mothers are a very useful institution, but they are terribly in the way when their children are to be photographed. Turn her out with all the civility you can command. You must then ask the nurse to do everything you direct intelligently and quickly, but on no account to help when not asked, as she may be doing something exactly opposite to what you required. The ground will now be cleared for dealing with your sitter; the time he has had to himself will have probably altered his convictions, and he will submit; if not, shake hands with him, and wish him good-bye, as you only want good children to play with. If this and other blandishments do not fetch him, let him go. The visit has done him no harm, and he will remember things that he would like to see again, and on a second visit will probably sit without any trouble.

It would be tedious to consider separately every variation in the characters of children, but if the photographer would succeed with these delightful little troubles, he must have great patience, a genuine delight in a difficult subject, and a strong determination to succeed with it. Above all, he must establish perfect confidence between himself and his sitter, to do which he must descend to the level of the child, and, remembering that little things please little minds, be able to enter into childish games, tell childish tales, and, above all, to play with toys!

Before concluding this subject, I must say a word or two on expression. The most beautiful thing about the most beautiful child is nearly always its expression. This can only be educed by stratagem, and should demand the greatest efforts of the photographer. A simple pose, such as sitting on a table (which, for a three-quarter vignette, is a very suitable position), will suit a child better than any elaborate arrangement, so that your attention shall not be unduly distracted from the bringing out of the best expression.

You will of course have a whole battery of toys ready when required to amuse your little sitters, for toys are the stock-in-trade of childhood, and he who understands their use and mystery best will soonest become at one with his subject. I should strongly recommend you to keep them strictly for your own use. If the child sees they belong to you, and can only be got through you, you will become a much more interesting person to him, and consequently have more power. If you allow the nurse to have the run of the collection, she will show them all at once, or quickly one after the other, and their power for use will be gone. Some toys are more adapted to keep children quiet, or awaken their expression, than others—those to which they have to listen, for instance. The ticking of a watch is the most familiar of these, but it must be a loud-ticking one, or the effort to hear will put too much strain into the expression. A musical box is good, but rather too elaborate; any toy that is new to the child is good, but those that have something comic about them, and make a noise, are best. I have found some of the india-rubber toys that squeak, when pressed, very effective.

There are some children who will sit as you place them without any trouble, but when you are thinking what an easy job you have got, and put your hand on the cap of the lens, you find them making faces. This generally takes the form of an awe-struck opening of the mouth. This is a case difficult to treat. You will not be so unwise as to tell it to close its lips, for to mention any feature to a child is to make it think of that feature, and proceed to contort it at once. Perhaps, if you have not warned her, the injudicious nurse tells it to shut its mouth, and the good, obedient little thing will at once close it so firmly that there is nothing more to be done until the child has forgotten it. I have found that the best way to deal with a case of this kind is simply to touch the child on the lower lip, and the mouth will assume its natural position.

I have made this chapter on posing children already too long without saying anything about posing them, making it something like Artemus Ward's lecture on Africa, in which the subject was not referred to except in the advertisements. The fact is, there can be very little posing of a young child: you must do, not what you would, but what the child will allow. There is one thing open to you—you may so arrange your furniture and accessories that the child shall ultimately take a good pose. I have already spoken of placing it on a table; this, with a rug and blocks of wood, will afford plenty of variety, and for older children a moveable platform may be provided, with perhaps a few rocks; for it does not do to look down too much on your subject—and working at a low camera is not conducive to comfort.

THE STAINING OF BACTERIA FOR MICRO-PHOTOGRAPHIC PURPOSES.

BY EDGAR THURSTON,

Curator of the Anatomical Museum, King's College, London.

By means of micro-photography, very faithful representations of the form and general grouping of bacteria can be reproduced, such as it is exceedingly difficult to delineate in a drawing, however artistically it may be executed. At the hands of only a few men has, however, the photographing of bacteria been really successful, and one too frequently sees the organisms represented as faint, indistinct bodies with ill-defined outline, and surrounded by a hazy zone, the first fault being due to unskilled execution of the staining processes, and the second to the employment of indifferent objectives and bad illumination of the object; on both which points special care must be bestowed, as nearly all bacteria require for their investigation high-power objectives.

Micro-photography, in its application to bacteria, must be dealt with under two headings: 1st, the preparation of the bacteria by suitable staining methods; 2nd, the process of photographing them; and I propose on the present occasion to deal with only the former.

It may be required to photograph bacteria under two distinct conditions, according as they are present—1, in the free state or in fluids; 2, in the organs and tissues of

the animal body; and for each of these conditions a special mode of preparation must be adopted.

As examples of bacteria occurring in a free state, or in fluids, I may take, from among many, the various coloured (chromalogenous) species of which colonies grow on the surface of eggs, meat, bread or potatoes; the putrefactive bacteria in decaying meat or vegetable infusions; the sputum (expectorated matter) from the lungs of a pneumonic or tuberculous person; or the blood of an animal suffering from splenic fever.

To stain such bacteria the following mode of procedure will be found the best:—Place a minute portion of the bacterial fluid, or of a bacterial colony, by means of a previously heated platinum needle, on the centre of two cover-glasses (·004-·005,) and, laying one cover glass over the other, squeeze them gently together between the fingers, so that the bacteria are diffused over their surfaces in a uniform layer. Then slip them apart and leave them to dry. After a few minutes, pass the cover-glasses rapidly through the flame of a spirit lamp, so as to fix the bacteria on the glass. Cover-glasses so charged may be kept for an indefinite time; and if an interesting growth of bacteria is met with, it is always well to reserve some specimens in this way for future reference.

For all practical purposes it may be said that bacteria of which micro-photographs are to be taken must be stained with a red or brown dye, and by far the best medium is a saturated watery solution of vesuvine or Bismarck brown, which should be filtered before use. For precise work, it is always best to use a freshly-made solution, inasmuch as bacteria, torulæ, and fungi, develop in it after it has been made some time, and their presence may give rise to an erroneous observation.

The cover-glass, with the bacterial surface downwards, should be floated on the top of the solution, and allowed to remain there for approximately an hour, though experience will show that the time required will vary according to the specimen of dye which is used. It is then removed from the solution, washed in water, and afterwards in a half or one per cent. solution of acetic acid, and allowed to dry—or, if time is an object, pressed between folds of blotting-paper—and its surface brushed with a camel-hair brush to free it from particles of dust, &c. It is then mounted in Canada balsam, and is ready for microscopical examination. The best form of balsam for mounting bacteria is that which is dissolved in xylol, which is very easy to work with, and does not abstract the dye from the bacteria. If the slide is to be examined with an oil immersion objective, the edge of the cover glass should be sealed, when the balsam is dry, with Hollis' glue. If the various stages of the staining process have been properly carried out, the bacteria should appear deeply stained and sharply defined.

Turning next to a consideration of bacteria as they occur in the organs and tissues of the body, I may cite, as examples, the various infective diseases of man and the lower animals. The organs must first be hardened by one of the numerous hardening processes, of which the one I generally adopt myself is to place the organ, or a selected portion of it, for forty-eight hours in dilute methylated spirit (1-2), and then transfer it to pure methylated spirit, in which it may be kept for an indefinite time. When it is sufficiently hardened, sections must be made by hand, or with one of the microtomes. For photographic purposes, the sections should be cut as thin as possible, for with thick sections a fogged picture will result. A perfect section, but one rarely met with, would be one which is of the thickness of a single cell throughout.

To stain the sections, they are placed in the saturated watery solution of vesuvine or Bismarck brown, and allowed to remain there about an hour, then washed with distilled water, and afterwards in a half to one per cent. solution of acetic acid, dehydrated in absolute alcohol, clarified in oil of cloves, and mounted, with Canada balsam, in xylol. The bacteria should appear as deeply stained bodies standing out in bold contrast with the diffusely and more lightly stained tissue elements. The specimen should be covered with an extra thin cover-glass (·004-·005), for, if a thicker cover-glass is employed, a high-power objective may not be capable of working through it. The thickness of the cover-glass can be easily guaged by Elliott's guaging machine.

The staining of bacteria, whether on the cover-glass or in sections, will be found, with a little care and practice, perfectly easy. The only difficulty is to hit off a mean between understaining and overstaining, so that the bacteria are neither too faintly nor too deeply stained; but this is easily overcome.

PHOTO-LITHOGRAPHY AND PHOTO-ZINCOGRAPHY.

BY MAJOR J. WATERHOUSE, B.S.C.,
Assistant Surveyor-General of India.

CHAPTER XVII.—MISCELLANEOUS PROCESSES—(*continued*)

2. *Oleate Processes.*—We have already referred, in Chap. XII., to the processes of Conduché, Cutting and Bradford, Morvan, and others, in which a negative chromocolloid image on the stone is washed over with a solution of soap, so as to form an insoluble soap with the lime of the stone. A few processes have also been proposed in which metallic soaps or oleates have been made use of to obtain an image directly on the stone.

Quaglio employed the oleate of silver, or so-called silver soap, prepared by precipitating a solution of Marseilles soap with a solution of nitrate of silver. The silver soap thus produced is a yellowish-white, soft, wax-like body. It is rapidly decomposed in sunlight, five to seven minutes' exposure blackening it completely. Rubbed on any suitable material, and exposed to light under a negative, it yields a proof with a fine glossy black colour, specially well fitted for working over in oil colours. The image is fixed with diluted hydrochloric acid, followed by hyposulphite of soda, or cyanide of potassium.

Quaglio first of all prepared the stone by treating it with a solution of nitrate of silver, followed by a solution of soap. This gave very good images, but the difficulty was to remove the unaltered parts without removing the image also. Cyanide of potassium was found to answer best.

M. Quaglio then took a sharp-grained stone, such as would be used for chalk drawing, and covered it first with a solution of gum-arabic; it was allowed to dry, and, after standing some hours, was washed over with water. The stone was then covered with the silver soap, applied with a small flannel pad, and rubbed on till the whole stone showed an even greasy lustre. It was then exposed under a negative for about half-an-hour in direct sunshine. The image produced was exceedingly sharp and beautiful. The stone was then washed with rectified naphtha, gummed, and then inked up, in the same way as weak transfers, with a sponge dipped simultaneously into gum-water, turpentine, and transfer ink, and rubbed gently over it, at the same time being rolled up several times with the roller.

A proof showed the picture with all shades of half-tone. After a few pulls the image may be etched with weak hydrochloric acid and gum. The gum is allowed to dry, and the stone left for some hours, and then rolled on and treated as an ordinary lithograph. Herr Liesegang found this process very successful for half-tone work.

Mr. Carey Lea has suggested the use of some other metallic oleate which will easily part with its oxygen, such as the per-oleate of iron, obtained by precipitating Castille or Marseilles soap with a neutral persalt of iron, or iron ammonia alum.

Mr. Isaac Rehn, of the United States Patent Office, has proposed a transfer process in which a soapy coating is given to the paper before exposure, and by its decomposi-

tion provides sufficient greasy matter to make the transfer without the transfer print requiring to be inked after exposure, as in the usual processes.

Paper is first coated evenly on one side by meaus of a soft sponge with a mixture of—

Gelatine or gum	4 parts
Sat. sol. bichromate of potash, ammonia, or chromic acid ...	8 ,,
Water	32 ,,

The paper may also be floated on or immersed in this solution, in which case the latter should be diluted one-third.

When the paper is dry it is exposed to light for ten minutes in order to thoroughly oxidize the coating, and can then be kept for use.

When required to be used, the sheets are coated a second time by floating on the warm gelatinous solution, and dried. They are next coated with a roller charged with a composition made by taking—

Yellow soap	1 ounce
Arrowroot, starch, or flour... ...	½ ,,
Water	1 quart
Colouring matter (blue by preference)	*quant. suff.*
Sat. sol. bichromate of ammonia ...	2 drachms

Dissolve the soap in a pint of water by heat, and the starch in the remaining pint, mix the two solutions, and evaporate to the thickness of lithographic ink. The colouring matter is added at any time before the mass is applied to the paper.

The bichromate is added at the time of using, and in a dark room. A stone is coated with the mass, just as with lithographic ink; the paper is laid face downwards upon it, passed through the press, and is thus coated with the sensitive compound.

The paper may also be sensitized by floating it on a warm solution of—

Gelatine	3 ounces
Dissolved in water	15 ,,
Soap	3 ounces
Dissolved in water	15 ,,

Mix, and add in the dark room—

Sat. sol. bichromate of ammonia...	12 ounces
Colouring matter...	*quant. suff.*

When dry, the paper is exposed as usual under a negative from five to fifteen minutes, and then is washed in tepid water, dried, and transferred.

The object of the oxidation of the first layer on the paper is to secure a smooth unmovable basis on which to make the impression, so that the lines may have a better and more clearly-defined edge.

The process is said to give very sharp results for line work, as there is no spreading or washing away of the lines.

LECTURE ON PHOTOGRAPHY.

BY PROFESSOR J. MILLAR THOMSON.

On Monday last, Mr. J. M. Thomson, F.R.S.E., F.C.S., delivered a lecture before the members of the Society of Chemical Industry, at Burlington House, entitled, "Photography for those engaged in industrial pursuits." The lecturer first explained the apparatus required, remarking that the cameras now in vogue are very much lighter than those employed some years ago. In speaking of the swing-back, he found the latter only of use in portraiture when it was necessary to reduce the size of part of the image—as, for instance, the feet of a person when in sitting posture. Diagrams of the various lenses were shown, the lecturer advising beginners to employ the single lens. Shew's camera adapter, and a shutter of the flap-and-drop principle, were next described. In speaking of dark-room illumination, it was stated that screens of "cherry fabric" were preferable to those of glass. The sensitive film was next discussed, the collodion process being first explained. Special attention was given to the collodio-emulsion method: the processes of emulsifying, washing, ripening, and pouring were all described in detail. Reference was then made to the gelatine process. A negative and positive were put in the lantern, and the applications of both explained.

In referring to exposure, the lecturer remarked that, so sensitive were the gelatine plates now in the market, that there was little fear of under-exposure even when a shutter was employed, error through over-exposure being more frequent. Formulæ, and details of working the various developers, were next given, also the theory and use of restrainers and accelerators. The effect of hypo in the oxalate developer was assigned to the conversion of ferrous bromide into ferrous hyposulphite.

$$FeBr_2+Na_2S_2O_3=FeS_2O_3+2NaBr$$

The process of enlarging on gelatino-bromide paper was demonstrated by exposing a portrait of the chairman in the lantern, and developing the film on the screen with a brush. Printing with the albumenized paper and the platinotype processes were referred to, a print of the latter being developed before the audience. In speaking of the applications of photography to scientific purposes, the lecturer regretted that the time at his disposal obliged him to touch only briefly on the subject. For photo-micrography it was stated that a small microscope and 5 × 4 camera answered most of the purposes of a more expensive apparatus. With large powers up to a quarter-inch, no difficulty would be met with, and the special correction of the lenses for the coincidence of the chemical and visual foci was hardly necessary. Koch's elaborate photo-microscopic apparatus for reproducing bacteria was shown; the focussing in his apparatus is performed by a cord attached to the fine adjustment, and wound on a wheel at the side of the focusing glass. Some beautiful photographs produced with the microscope were shown on the screen. Among the examples of special interest was that of starch granules produced with the aid of polarized light. In concluding the discourse, the lecturer remarked that he had attempted to describe the methods of photographing with the aid of simple apparatus, and if he had succeeded, his object of addressing the Society was attained.

Correspondence.

ELECTRIC LIGHT IN THE LANTERN.

Sir,—With reference to a question about the practicability of using the electric light in the lantern, by Mr. A. R. Dresser, in your esteemed paper of November 21st, I beg to give my mite of experience in this direction.

The arc light, of course, is expensive, and not steady enough, and is therefore seldom used. I tried the Swan incandescent light, worked with no less than nine good sized Bunsen cells, but soon abandoned its use, the trouble to put together the battery being too great. After that I tried a small one-candle power similar lamp, with an extra thick carbon thread; this, when worked with only three cells, gave a most brilliant white light, but after two hours' use it was burnt out. This light seems to me to be a very good light for the lantern, but the lamp wants improvement to stand the strong current.

Lastly, I tried the simple platinum wire made incandescent by galvanic energy, coiled up snake-like to produce an incandescent disc of about 1·5 cm. diameter. The wire is less than 1 m.m. thick. Working with three Bunsen cells, the light is all that can be desired for moderate intensity. It is cheap and safe; the cells are easily charged and kept in going order; the lamp is always ready for use, and on applying a simple current regulator the light is perfectly manageable. I never tried an accumulator, but think that it could be profitably used, the required current being comparatively weak.

Milan, Nov. 28. Frederico Widmer.

Dear Sir,—It is nearly twenty-five years since I began my first experiments with the electric light, when spectrum analysis, by means of the electric arc, was the grand climax of nearly all scientific lectures. Then, of course, we had to employ a lantern, and maintain the arc accurately in the focus of the objective, and we had no other source of electricity than that derivable from some 50 cells of Grove

or Bunsen, which it was not then thought such a stupendous effort to set up as to deter the attempt.

For a period of some ten or twelve week-day evenings I have set up 40 cells for the electric light, never having a failure; but, on the contrary, I could amalgamate my plates, mix my acids, charge the cells, connect up, and have the light at work giving a good arc a quarter of an inch long, and all this by the expenditure of about two hours' work. I have frequently set up 60 cells for the purpose.

The battery enables the exhibitor to give a demonstration which few would attempt if a dynamo and "power" had to be procured. A battery of 40 or 50 cells, acids, and all the requisites can be conveyed upon and within a four-wheeled cab; not so a dynamo, to say nothing of the engine. My 1200 candle Siemens' machine weighs over 3 cwt. Loudon cabs have been known to break down with the weight of the "fare" alone. A 1200 candle machine will consume 2-horse power, and need a 3-h.p. engine to give a steady light. Where power is obtainable and convenient I shall certainly run the machine, because the cost is much less when once the "installation" is set a-going.

It may not be out of place here to draw attention to the figures which have just been collated from the electrical installation at the Health Exhibition. It must be strongly borne in mind that the conditions were by no means favourable to show the best result attainable. There were 11 boilers and 6 engines, indicating a total of 1306 horse-power, and the coal consumption is stated to have been 3·2 lbs. per indicated horse-power per hour. No batteries yet constructed can compete with such figures as these, which, stated roughly in other terms, mean that about 600 candle-power could be maintained for one hour by a consumption of slightly over 3 lbs. of coal. Upon the authority of Mr. Preece—who for experiments employs a 2-h.p. *gas* engine, using street gas to drive a dynamo—he obtains about 50 per cent. more light than the same gas would yield if it were consumed in ordinary gas burners!

Gas-works are to be found in small towns now, and gas engines are very steady-going machines. What we want is a "portable" gas engine, 3-h.p., with dynamo all on one carriage. Attach a horse and trot it off to the place, connect the engine to the gas-pipe by a flexible hose, turn on the tap, strike a light, and, presto, there you are!

All the rest is mere detail. Should the subject from any point of view be considered worthy of exhaustive discussion, I should be glad to give your readers the benefit of my experience.—Yours truly,

George F. Williams.

A LANTERN SLIDE CLUB.

Sir,—In the present day there seems to be a mania for forming clubs: we have Photographic Clubs, Rifle Clubs, Tricycle Clubs, Athletic Clubs of all kinds, Gun Clubs, Chess Clubs, and, in short, clubs to meet every possible phase of sport or pastime, except only *Lantern Clubs;* and yet one would have thought the advantage of a number clubbing together so as to get the run of a large number of the somewhat costly slides would be so manifest as to induce someone to have started a Lantern Club long ere this.

The idea that suggests itself to me is a club to consist of (say) 20 or even more members, each member binding himself to purchase (say) 50 first-class slides, different to those to be purchased by any other member, and then proceed mutually to exchange upon the ever-circulating principle. By such an arrangement no doubt it would be possible to make advantageous terms with some good maker of slides, and thus each member in a club of 20 *would have the use in course of time of* 1,000 *slides at the cost of* 50. Or, the Club might be formed on a still different basis, under which each member paid an entrance fee and annual subscription, to be devoted to the purchase of slides, each member having the right to borrow a certain number at certain intervals.

Should there be any persons wishing to form such a Club, if they will address themselves to me, I will see how best to bring them together, so that a start in the direction I have indicated, or one of them, may be made before the present lantern season gets much further advanced.—Yours faithfully,

Henry Smith.

River Cottage, Hornsey, N.

EXTRA RAPID CEMENTED DOUBLETS.

Dear Sir,—Your report on the last technical meeting of the Photographic Society of Great Britain conveys the idea that there was an opinion prevalent at the meeting that there is no advantage in the extra rapid symmetrical doublet, that opinion being confirmed by the fact that opticians "*seldom construct symmetrical lenses*" with an intensity so high as $\frac{f}{6}$. Leaving aside the question whether that is a good reason against such a lens being turned to good account, the question arises which is the type of lens that is entitled to work with such an aperture. Mr. Dehenham gave it as his opinion that it was the Petzval portrait lens; but there is evidently a desire on the part of opticians to produce lenses besides the portrait form of greater rapidity than $\frac{f}{8}$, to wit, the "Steinheil Antiplanet." It seemed to me by no means clear that the meeting was of the opinion that a rapid doublet could not satisfactorily work with an aperture of $\frac{f}{6}$, and no reasons are given why it should be excluded from doing so.—I am, dear sir, yours respectfully,

J. R. Gotz.

EXHIBITION AWARDS.

Sir,—In the letter on the above subject, in your issue of November 21, signed George Smith, there are statements regarding matters of fact which are incorrect. Will you allow me to state that Mr. Gale personally handed to the Assistant-Secretary, at the Gallery, before 9 p.m., September 25th, a box of twenty lantern slides, made by himself from his own negatives, together with a letter of advice; that these were the only slides received from him, and that they are the same ones that were shown on the screen before the judges at the time of the competition for the medal. The paragraphs in the Society's circular, relating to lantern slides, read as follows:—"Slides (which must not exceed 3¼ inches in height) must be sent in either on or before Thursday, September 25th (to come with other exhibits before the Judges of Awards), and will only be eligible for award when both the negatives and slides are the work of the exhibitor." "The judges are instructed to reserve one medal for Lantern Transparencies (if they find them worthy of award)."

It will be seen, therefore, that the award to Mr. Gale was made strictly in accordance with the regulations.

I say nothing at present with regard to the other allegations in the letter referred to, which are either beside the point at issue (the legality of the award), or are matters of opinion only.—Yours faithfully,

W. F. Donkin,

Hon. Sec. Photographic Society of Great Britain.

Proceedings of Societies.

London and Provincial Photographic Association.

A meeting of this Society was held on Thursday, the 27th inst., Mr. W. Cobb in the chair.

In the course of a conversation on frilling, Mr. Ashman mentioned that where the usual remedies failed, heating the developer proved effective.

Mr. J. H. Trinks, when working in exceptionally high temperatures, prevented frilling by soaking his plates an hour in chrome alum solution, and surrounding them during development in a freezing mixture. He then showed a plate developed with mixed ferrous-oxalate and pyro, in which a black image was obtained. After treatment with hydrochloric acid 1-2, a clear and bright image remained. He wished to know why this occurred.

Mr. W. K. Burton said ferrous oxalate and pyro produced ink, and the acid dissolved it.

Mr. A. L. Henderson thought the ink must have prevented frilling. Emulsions, he said, precipitated with alcohol were less likely to frill than those containing meta-gelatine.

Mr. Hart's suggestion to introduce bichloride of mercury into emulsions was further considered, and certain experiments to prove its value were suggested.

Mr. Burton showed an application of the potassium chromate colour test for determining the duration of floating alb. paper on the sensitizing bath. This was demonstrated by brushing the solution over a portion of the back of the paper previous to floating. Soon after the paper was laid on the silver bath, a gradual deepening of colour occurred where the chromate salt had been applied. When the colour became deep orange, Mr. Burton considered the whole of the chloride was converted into AgCl, and the time occupied indicated the duration of floating necessary for that sample of paper.

The Chairman passed round sample prints, made by Marion's new method, on Alpha paper, and referred to a description of the paper published in the *Times* on the 17th ultimo (see page 755 of our last issue).

The prints—which were equal in vigour to good silver prints on albumen paper—were much admired, but it was considered that developed prints on gelatinized paper would not quickly supersede the older method of printing.

Mr. Trinks alluded to a plan which enabled him to make an ordinary platinum print appear as though it were a genuine copper-plate print. After washing, he passed the print through water (nearly boiling), which caused, if quickly dried, the surface to become uneven; it was afterwards put through the press.

A discussion then took place on developers, in which it was generally conceded that soda had the greatest power as regards the amount of detail obtainable, restrainers being unnecessary.

Mr. J. Henrick Trinks was elected a member of the Society.

Liverpool Amateur Photographic Association.

The annual meeting of this Association was held on Thursday, the 27th ult., Dr. Kenyon, President, in the chair.

The minutes of the October meeting were read and confirmed, and Messrs. Atkinson, Pooley, Pawson, Roose, Taylor, Webster, and Webb were elected members.

The appointment by the Council of officers for 1885 was as follows :—

President—Mr. J. H. Day.
Vice-Presidents—Mr. A. W. Beer and Mr. P. H. Phillips.
Treasurer—Mr. J. H. T. Ellerbeck.
Council—Messrs. W. Atkins, Rev. G. B. Banner, Rev. T. B. Banner, Messrs. R. Crowe, J. A. Forrest, Dr. Kenyon, Mr. W. H. Kirkby, Rev. J. H. Palmer, Mr. H. Rutter, Rev. A. J. Scott, Messrs. E. Twigge, and W. A. Watts.
Librarians—Messrs. R. Crowe and W. W. Hughes.
Auditor—Mr. W. H. Wharmby.
Hon. Secretary—Mr. W. N. Atkins.

The Hon. Secretary read the annual report, of which the following is an abstract :—

The accession to the numbers of names on the books has been the largest annual increase recorded in the archives of the Society. Thirty-seven new members have been elected. There have been seven resignations, and no losses during the year by death. The numbers of members on the books at the close of each of the last five years are as follows :—1880. 71 ; 1881, 78 ; 1882, 93 ; 1883, 115 ; 1884, 145. There has been no falling off either in the interest of the monthly meetings of the year, or of the numbers of members attending them. During the summer months numerous excursions have been made, which were productive not only of much enjoyment, but of profitable photographic experience and work. Donations to the Library have been received from Captain Abney, Rev. H. J. Palmer, Mr. Watts, Mr. Maurice Jones, and Mr. Scott ; and to the album from Messrs. H. N. Atkins, Watts, Williams, Hartley, Wharmby, and others. The beneficial effect of the annual competitions, as incentives to useful emulation, and as spurs to careful and artistic work, has shown no diminution in the past year, and the Council trust that the subjects selected for the competition of 1885 will be productive of a similar satisfactory result. These subjects are as follow :—"Instantaneous," "Farm Yard," "Rocky Shore," "Stereoscopic," "Cottage Door," "Animal Study," "Interior," and "Shipping or Marine." A presentation print will be selected by the Council before the close of the year for distribution among the members.

The report included a list of the papers contributed at the meetings, as also acknowledgment of thanks due for favours received from several quarters.

The report was passed.

The Treasurer's report showed a balance in hand of about £40.

The Rev. T. B. Banner and the Chairman spoke very warmly of the labours of the Hon. Secretary, now about to retire from his post.

The Rev. H. J. Palmer expressed his cordial thanks, not only to Rev. T. B. Banner and Dr. Kenyon for their kind words with regard to him, but also to every member of the Society, both present and absent, for their kindly feeling.

The following addition to the Rules was adopted :—"All members elected on and after the January meeting, 1885, shall pay an entrance fee to the Treasurer of 10s. 6d."

The Chairman reminded the members of the *soirée* in St. George's Hall, on December 10th, and gave notice that all exhibits for the Association's display should be sent to Mr. Ellerbeck's, 54, Bold Street, on or before December 9th, or on the 10th to the Committee in St. George's Hall.

In this year's competition the awards were announced as follows :—"The Brook," Mr. W. H. Kirkby ; "Cattle," Mr. J. H. T. Ellerbeck ; "Fruit," Mr. P. G. Hall ; "Architecture," Mr. W. H. Kirkby ; "Mountain Forms," Mr. P. G. Hall ; "Snow Scene," not awarded ; "Shipping," Mr. J. H. Day ; "Repose," Mr. P. G. Hall ; "Own Emulsion," Mr. W. H. Kirkby ; "Best set of Pictures," Mr. P. G. Hall ; "Best Picture of all," Mr. P. G. Hall.

Messrs. Thompson, Riley and Banks were re-elected, *nemine contradicente*, as honorary members.

The Chairman said that the Council would be glad to receive negatives suitable for enlargement for this year's presentation print, and requested that such negatives should be sent to Mr. Ellerbeck, 54, Bold Street, on or before Monday, December 15th.

A resolution was passed that the following bye-law, recommended by the Council, be adopted :—"That after due notice has been given by the Treasurer, that if arrears of subscriptions be not paid within three months, members in arrears shall cease to receive notice of meetings."

The members then adjourned to a lower room for the inspection of the competition pictures of the present year.

Hyde Amateur Photographic Society.

This Society, formed a fortnight ago, held a meeting on Wednesday evening in the Mechanic's Institute, when a collection of instruments, photographs, and etchings, were exhibited. Mr. W. Nuthall presided, and there was a very fair attendance of ladies and gentlemen. Round the room numerous photographic specimens and a few water colours were arranged, and the apparatus was displayed on a table. Amongst the instruments were various cameras by first class makers, lenses for the sciopticon camera, a neatly-constructed burnisher, various kinds of developing lamps and sciopticon lanterns, an oil lantern giving a beautiful ten-feet picture, consecutive delivery box (in the railway ticket style) for use in lantern exhibitions, and a biunal lantern, fitted with mixed jets, and capable of giving a picture up to twenty feet in diameter.

Mr. F. W. Cheetham (President of the Society) showed several water-colour drawings, and amongst a number of photographic specimens an excellent photo. of himself, executed by his own hand, which was accomplished in the following manner :—The table at which he sat was first focussed, and then the operator actuated the lens by means of cotton-thread.

Dr. Sidebotham (Vice-President of the Society) exhibited apparatus and a number of photographic specimens, as also did Mr. George Batty, one of the members. Cameras and lenses were also exhibited by Mr. John Crowther (Secretary), Mr. John Pennington (Treasurer), and Mr. McLean, (a member.)

Some time having been spent in examining the exhibits, Mr. F. W. Cheetham gave a magic lantern entertainment, throwing on the screen photographs of persons and places of interest taken by himself and Dr. Sidebotham. Remarks were made by the Rev. J. K. Smith, Councillor Cheetham, Dr. Sidebotham, Mr. H. Bardsley, Mr. F. W. Cheetham, and Mr. Crowther, and a very pleasant entertainment closed with thanks to the exhibitors and to Mr. Nuthall for presiding.

AMATEUR PHOTOGRAPHIC ASSOCIATION OF VICTORIA.

THE Association is progressing satisfactorily and doing good work. Practical demonstrations of the different photographic operations are given at nearly every meeting, with good results.

At the meeting held on 6th October, Sergeant FENTON read a paper on the "Preparation and Purification of Photographic Chemicals," and being an amateur chemist of known ability, a large number of members attended, and listened with great attention to his remarks, finishing by asking him innumerable questions, which were satisfactorily answered.

Talk in the Studio.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The next ordinary meeting of this Society will take place on Tuesday next, December 9th, at 8 p.m., in the Gallery of the Royal Society of Painters in Water-Colours (whose winter exhibition is now on view), 5A, Pall Mall East.

PORTRAIT OF MR. F. C. BEACH, OF NEW YORK.—Messrs. Morgan and Kidd have forwarded us an excellent gelatino-bromide enlargement upon opal from a cabinet portrait of Mr. Beach. Gelatino-bromide enlargements upon opal have certainly much to recommend them as superior to the old-fashioned collodion transfer, and it is remarkably easy to put artistic work upon gelatino-bromide pictures taken upon opal glass.

THE EFFECT OF MOISTURE ON THE REFRACTION OF POLARISED LIGHT, BY R. T. GLAZEBROOK.—The author has described some experiments he has been engaged on lately at the Cavendish Laboratory. Plane polarised light is made to fall on a plate or a wedge of glass at various angles, and the position of the plane of polarisation determined. It is found that this depends greatly on the hygrometric condition of the air in the neighbourhood of the glass. If moist air be blown on to perfectly clean glass, the plane of the polarisation of the emergent light is displaced from its normal position in one direction, while if dry air be blown it is displaced in the opposite direction. At an angle of incidence of 60° the difference between the two positions is from 6′ to 8′. If, however, the glass be not perfectly clean, the effect of moisture is at first the same as that of dry air, though on stopping the draught an opposite effect is observed. The author assigns as the cause of this the heating of the surface which, as Magnus discovered, is produced by a draught of moist air. He finds on repeating Maguus's experiment that the heating is not produced if the glass be clean, and he shows by an independent experiment that slight local heatiug does produce an effect on the plane of polarisation in the same direction as that due to the dry air.—*Chemical News.*

LECTURE ON PHOTOGRAPHY.—On Tuesday, the 2nd inst., Mr. T. C. Turner, jun., read a paper at the Finsbury Park Literary and Scientific Society, on "Photography and its Applications." The effect of light on certain substances was first explained, and as an example the blackening of chloride of silver by the actinic rays was shown. The process of development was successfully demonstrated before the audience by developing both a platinotype, and a gelatine plate. In speaking of instantaneous photography, the lecturer pointed out that by means of the new gelatine process, and a detective camera, it is possible to secure photographs without the knowledge of the persons photographed. After a brief description of the application of photography to the pigeon-post, the microscope, and astronomy, the lecture concluded with a lantern demonstration. Among the photographs shown on the screen were Mr. Cobb's celebrated London scenes, Mr. Jennings' photo-micrographs of the flea, Mr. Wellington's gelatino transparencies, and Mr. C. Ray Woods' astronomical slides.

PHOTOGRAPHIC CLUB.—The next meeting, December 10th, will be the Annual Dinner, at 7 p.m.

To Correspondents.

*** We cannot undertake to return rejected communications.

JOE.—1. Your nitrate of soda probably contained a large proportion of chloride, and the "mass like wet plaster of Paris" is the chloride of silver which was thrown down. Do not attempt to "tinker" the bath any more, but add enough common salt to throw down all the precious metal as chloride of silver, and either reduce this by fusion with carbonate of soda, or sell it to a refiner; then make up a fresh bath. 2. The best quantity to add to each ten ounces, is none.

TADRUNS HANNA.—1. The method of cleaning you speak of will answer very well; in fact, you cannot adopt a better method, although you may find one somewhat easier. 2. Isinglass is suitable, but before using it you should soak it in several changes of water to extract soluble matter. 3. There is no "best" developer, but that you mention is excellent for general use. 4. A deep ruby colour is generally preferred. 5. The gelatine solution never flows on glass so readily as collodion flows, but its flow can be facilitated by breathingon the glass. 6. There is no book that treats of emulsion making with special reference to the climate of Upper Egypt, and you can have nothing better than the book you mention.

CHEMICUS.—Carefully carry out the directions on page 619 of our present volume, and you will obtain a good result.

R. F. DIXON.—1. Yes, and in our opinion the enlargement will be much better than the original if the work is skilfully performed. 2. Undoubtedly it would be cheaper. 3. The lenses you refer to are excellent value for the money, but you must not expect them to approach in perfection the instruments of the best makers. Of those mentioned we should recommend the second; and certainly not the wide-angle lens for general work.

J. WHITELAW.—In last week's number there is an example of what we referred to (page 762). We have posted what you ask for.

CELT.—You cannot do better than to obtain a lens of a similar kind to that you already possess, but of about half the focal length.

G. F. WEBBER.—It will answer very well for the purpose you mention.

J. T. SMITH.—1. A series of articles on the ferrotype process appeared in our volume for 1881, and you can doubtless obtain the volume by advertising for it. 2. The so-called encaustic paste—white wax 1 ounce, and oil of turpentine 5 ounces.

T. D. P.—One of them, and that a very good one, is to be found in the very number containing the answer you refer to.

FRANK PIPER.—1. An article on the subject is to be found on page 613 of our volume for last year. 2. Under the circumstances it is extremely probable that the engraving is copyright, and if you make copies, you must not sell them.

R. W. G.—Parts by weight are intended—ounces, if you like—but if you only want a moderate quantity, you had better take it in drachms.

F. M. AND CO.—The address of the Meisenbach Company is 31, Farringdon Street, London, E.C.

S. S. F.—1. We cannot tell you of any one who will be sure to do what you require, but you might write to Messrs. Marion and Co., of Soho Square, London. 2. Thank you, we shall be pleased to have a copy.

R. V. H.—They were done in America, but you had better write to the Platinotypo Company.

ALEX. A. INGLIS.—Thank you for the photographs, which are excellent, and we hope to make use of some of them.

THIO.—We can hardly judge, but should suggest that your best way will be to write to Mr. Cowan. If you will send a letter to him under cover to us, we will forward it.

W. P. M.—We cannot tell you the exact dates, but as there is not much latitude possible, you can easily ascertain by inspecting the files at the offices of the journals in question.

C. R. BEAUMONT.—1. Mr. Carter's paper, which you will find on page 772, contains much that is interesting, and you will gather useful information from "Hunt's Photography," a copy of which can often be had second-hand. 2. We shall be very much pleased to have a description of your new camera.

C. N. AND CO.—With careful work, we think you ought to recover fully one half.

C. C.—If you colour with anilino dyes or with water colours (mixed with ox-gall) the varnish will not affect either colours or print. We assume you to refer to a print on albumenized paper, and as a varnish we recommend dammar dissolved in benzole, sixty grains of the gum to each ounce of fluid.

C. E. G.—We cannot tell you with certainty, but will post you the addresses of some Paris houses.

S. S.—If so, it shall be posted to you.

CONTENTS.

THE HYDROXYLAMINE DEVELOPER.

MANY persons are now experimenting with the hydroxylamine developer of Egli and Spiller, and among the most recent workers in this direction may be mentioned Herr Scolik, of Vienna, who read a communication on the subject at the last meeting of the Vienna Photographic Society.

In the first place, Scolik tried the original formula, and the image developed slowly, and was rather weak; Scolik also found, that to obtain the same vigour as with pyrogallic acid, a longer exposure is required. He, however, by leaving out both bromide of potassium and citric acid, obtained much better results, and the following is his formula:—

60 parts of water
3 ,, stock solution of hydroxylamine hydrochlorate (1 and 15 of water)
5 ,, stock solution of caustic soda (1 and 8 of water)

Under these circumstances the image appears more quickly than with pyrogallic developer, and well graduated vigorous negatives are obtained—in fact, results much resembling wet plate negatives.

If only three parts of the hydroxylamine are used, the developer is too weak for general use; but five parts of the solution may be used when a short exposure has been given.

Too much soda must, according to Scolik, be avoided, as it causes the films to frill or to blister; but these troubles may be generally avoided by adding alcohol towards the end of the development.

In commenting on the present high price of hydroxylamine salts, Scolik remarks that a reduction may be expected; and according to present prices he estimates the cost of the various developers as follows:—

Pyrogallic developer, with glycerine ...	1·2
Potash developer	1·4
Iron oxalate	1·5
Hydroxylamine developer	5 to 8

PORTRAITS OF PUSSY.

THERE is but one photographer who stands out prominently as a photographer of cats, and that photographer is Mr. Pointer, of Brighton. Puss—taking her in general—is by no means a good sitter, for who ever saw a cat absolutely still? Even when most intent on watching a mouse, or other head of choice game, there is invariably a swaying motion of the tail; and although a cat may be fast asleep, the motion resulting from respiration is always considerable.

It is not everyone who can become a successful photographer of cats, as there are many persons with whom puss will never be friendly: although we much doubt whether the cat's sentiment of dislike to a person is ever so intense as that of the Duke of Noailles towards the whole feline race; it being recorded of this gentleman that he was made uneasy even by the proximity of the picture of a cat, notwithstanding that the picture was unseen, and in an adjoining room.

Mr. Pointer presents us with his own portrait, as he once

appeared with three of his pets; and it seems to us that we have here the same trio of cats that are represented in our supplement; but one must not suppose that Mr. Pointer by any means confined himself to these in making the series of about two hundred cat pictures which he publishes. In the greater number of cases, he tells us, the cats were entire strangers to him; but he has seldom any difficulty, as Mr Pointer and a cat are always fast friends immediately after the first introduction.

On the next page we have "The Connoisseur," in which the white cat is looking at the portrait of—we will suppose, her master.

In "The Careful Nurse," and "The Attentive Pupil," we have two more of Mr. Pointer's best studies.

The photographer of cats has certainly one advantage

on his side, as it is by no means easy to make puss assume an ungainly or awkward position.

"THE CONNOISSEUR."

were reproduced as Meisenbach blocks, and accompanied by a suitable text; while others besides children would be pleased to possess such an album.

Method of Measuring Instantaneous Exposures.—M. de Labourne Puvinel recommends, as a means of measuring rapid exposures, the reproduction of a polished white

We cannot help thinking that Mr. Pointer's series of cat life would make an admirable child's book if the pictures

THE CAREFUL NURSE.

metal ball allowed to drop freely in front of a black curtain or screen, against which is placed a graduated scale. The shutter is set in action simultaneously with the fall of the ball, and on the negative a light line is visible, indicating, with the aid of the scale, the distance travelled by the ball during exposure. Of course several calculations, too complicated for practical photographers, have to be made to arrive at the exact duration; therefore M. de Labourne Puvinel has drawn up a table stating the exposures necessary for all the different lengths of the distances passed through from the top of the scale. It seems to me very intricate, and I much prefer the chronometric method described in my last letter. In this latter case, no such calculation is necessary, and it can be exactly determined by the angle subtended from the axis of the needle hand tracing two lines to limit it.

Standard Sensitometer.—The question of a standard sensitometer has again been discussed, with reference to a proposition made to the Photographic Society of France, that it should be entrusted to a special commission. I consider Warnerke's the best, only it seems desirable that a commission should be appointed for the thorough examination and comparison of all, so that the numbers given are absolutely identical. The thing does not present any difficulty so far, and I think a manufacturer might be easily found if Mr. Warnerke would consent to this proposal, leading to the first step in the establishment of a universal standard sensitometer. Other questions in this complex problem remain to be solved. A good standard of light must be determined upon. M. Warnerke's ingenious and convenient phosphorescent plate has several objections. Can all be gifted with an equal emissive power?—and is the duration of their luminosity warranted for a long time, and equal under all conditions? Replies have been made to these questions, but the doubt still remains. The lamp burning 42 grammes of oil in an hour is still used to verify the lighting power of gas, but this method is not easy to practise, and it is also liable to considerable variations—quality of the oil, state of the wick, &c. M. Bardy proposes Siemens' unit-lamp, as burning an invariable composition, the gauge regulating the height of the flame. The present price of the lamp here is forty francs, and that, with the illuminant costing fifteen francs the kilogramme, renders it too expensive to be generally used, and it seems doubtful

that the acetate of amyl is easily procurable. The use of a candle of a given size and make is liable to certain variations, but they may not be sufficient to interfere much with the practical value of the observations. It would be rash to comment upon a question of so much importance without experimenting; I therefore intend to make a thorough investigation, taking the Siemens' unit-lamp and comparing various candle flames with it. After a score or so of trials, I shall feel sufficiently up in the subject to pronounce upon my results. Similar experiments might be made with a petroleum lamp, trying various samples of petroleum, and noticing their differences. The necessity for determining upon a special developer has been objected to, but it may be rejoined that the film, showing the image least rapidly at first, by submitting to a prolonged development, comes out better than in those plates which give an image quickly.

M. Hutinet's Gelatino-Chloride Plates.—M. Hutinet, whose photographic mounting-board factory is so well known, is manufacturing wholesale both clear and opal plates covered with gelatino-chloride. They give very beautiful transparencies. The printing, toning, and fixing operations are carried on in the same way as albumenized paper prints. The exposure to light takes rather a long time, but the image may be watched as it appears on the transparent plates. For the opal plates, recourse must be had to photometric means, to ascertain when they have been sufficiently long exposed.

Photographic Accessories.—M. Stebbing has opened a depôt in Paris for photographic apparatus and accessories, particularly those of English make.

M. Chala's Acid-Proof Glaze.—M. Chala showed the Society a glazing substance having a carbon basis suitable for coating photographic dishes, cloth, paper, zinc, and other metals. The substance is called diamantine, and will bear a good rubbing without coming off.

Plates for Balagny's Pellicle Paper.—M. Balagny, with the view of having his pellicle papers used directly—that is to say, without having to put a glass in front of them, or expose between two glasses—proposes to deliver them provisionally attached to thin zinc plates, so that they may be detached during development. By this means the appearance of the image can be watched, and the reduction both in bulk and weight of plates is considerably reduced. To cause the pellicle to adhere, a solution of wax and a little resin in benzine is poured over the zinc plate. To apply the pellicle, paste them at the back, and press down on the waxed plate; they can be coated with gelatino-bromide in the usual way when dry. Pellicles already coated can be stuck down with an India-rubber preparation.

M. Alexeef's Typographic Process.—A Russian, M. Alexeef, has invented a typographic process, the results of which are similar to the "photo-ink" prints.

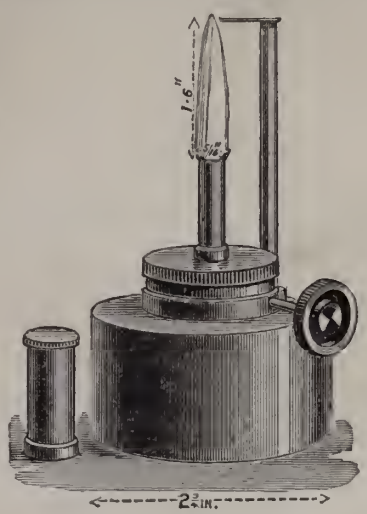
Reduction of the Bust of Daguerre.—A reduced copy of the bust of Daguerre, set up at Cormeilles-en-Parisis, has just been made. Anyone, therefore, desirous of possessing themselves of a bust of one of the fathers of photography, can procure one in Paris for the sum of eight francs.

LEON VIDAL.

THE SIEMENS UNIT LAMP FOR PHOTOGRAPHERS.

BY CAPT. W. DE W. ABNEY F.R.S.*

THERE are so many difficulties regarding a standard light that it has struck me that I might say a few words with advantage regarding the auxiliary standard which was proposed by Dr. Werner Siemens at the late Electrical Congress held in Paris in April last. Recently Dr. Siemens kindly presented me with one of them, and I have experimented with it both for photometric and photographic purposes. The lamp is illustrated in the figure. The two principal portions of it are a tube $\frac{5}{16}$ths of an inch in internal diameter, through which the wick passes, and a gauge to measure the height of the flame, which has to be 2·6 inches high. Whether the wick be a closely compressed one, or loose, does not seem to matter; cotton-wool will answer every purpose. The material burnt is acetate of amyl, which, though dear when obtained pure, is very cheap at all events in Germany, being sold at a few shillings a pound. It has a characteristic smell of pear drops, and is much used in confectionery. I am told, to give this particular flavour. The flame you see before you is a steady one when no draughts are about. In case of draught it may be enclosed in a glass tube with an air space beneath, but, as a rule, this is unnecessary.



The wick is trimmed even with the tube, and when out of use there is an extinguisher or cap which screws over it, making it air-tight, and thus precluding the evaporation of amyl acetate. After the lamp has been lighted a couple of minutes the flame assumes its normal height, and is regulated so that the point is just the height of the gauge. In this state it emits the light of a candle. It should be remarked that the acetate of amyl contains a large quantity of oxygen in proportion to the carbon, and hence requires but a small supply.

I have been trying this unit lamp for use with the sensitometer, and find that at a distance of 18½ inches from the plate, and with half a minute's exposure, it gives the same illumination as the phosphorescent tablet which is in my possession. I have repeatedly tried the same batch of plates at different times with the lamp, purposely disturbing the wick between times, and readjusting it to the height of the gauge. This gave always the same results on the plate exposed behind the sensitometer, showing that for this purpose it is a thoroughly reliable source of illumination. I cannot trace any effect of a difference in height of the barometer or thermometer. It is to be presumed that some slight variation must exist, but so far inappreciable, which is more than can be said when using the standard candle.

It may be asked, why substitute such a standard for the phosphorescent plate? The reason why I would do so is, that the light emitted by the phosphorescence is confined to one small portion of the spectrum, as a previous paper of mine has shown, and that as you mix iodide with bromide, the comparison of two plates, one iodo-bromide and the other bromide alone, when made by phosphorescence, is in favour of the latter, since the place of a maximum sensitiveness of the former is below the point in the spectrum at which the phosphorescent tables emits light. This being the case, I should like to see some such standard as this used, as it is handy, and only requires the application of a match to start it. It is also convenient for use in taking transparencies by contact. The exposure of a plate behind an ordinary dense negative, which registers 24 on the sensitometer at two feet distance, take one minute to give a good image. Such a lamp, too, is handy for travelling. It can be enclosed in a shade of orange paper, or by the cardboard lantern which I long ago recommended, and which is the simplest form of any lantern with which I am acquainted, and plates can be changed or developed by its light. Now as to the manufacture of such a lamp there is no difficulty; the form I have here is more expensive than is necessary. It will be seen that an ordinary spirit-lamp could be adapted to it, by replacing the tube usually supplied by a slightly longer one, and making the glass cover a little longer than is now done; even this is not necessary. The

* Read before the Photographic Society of Great Britain.

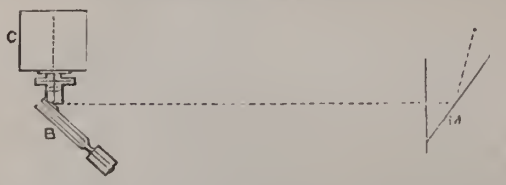
point to be attended to is to keep the heat at a fair distance from the spirit. I need scarcely enter into the subject of photometry with this lamp; suffice it to say that if the burner is of the dimensions I have given, and the flame kept to the standard height, every one has it in his power to reproduce the light of an unfluctuating standard candle. Here, then, is a point gained at once. Mr. Spurge brought forward the idea of using a gas flame of a certain height, and issuing from a hole of fixed diameter, to illuminate the screen he proposed to use with his sensitometer. As gas is not always available, it is probable that a modification, founded on the principles of the Siemens unit-lamp, might be utilised.

MEASUREMENT OF THE SPEED OF PHOTOGRAPHIC DROP-SHUTTERS.

BY W. H. PICKERING.

THE usual method adopted for this purpose depends on photographing a white clock-hand revolving rapidly in front of a black face. The chief difficulty in this case is to maintain a uniform rotation at high speed. To avoid this difficulty, and to determine the uniformity of exposure of any particular shutter under apparently like circumstances, the followiug method has been suggested. In carrying out the experiment in practice, I have had the assistance of Mr. J. O. Ellinger.

A tuning-fork, B, with a mirror attached to the side of one of the prongs, is placed in front of the camera-lens. This mirror is so arranged as to reflect into the camera C a horizontal beam of sunlight, which, before reaching the fork, has passed through a half-inch hole in a screen S, placed about ten feet distant. This produces on the ground-glass a minute brilliant point of



light. If the fork be set vibrating, the point will become a short, fine, horizontal line: if the fork be rotated about its longitudinal axis, the line will become a sinusoidal curve described on the circumference of a circle of long radius. A photographic plate is now inserted, and the drop-shutter attached. On releasing the latter, it will be found that a portion of the sinusoid has been photographed; and the precise exposure may be determined by counting the number of vibrations represented on the plate.

The mirror employed should be somewhat larger than the lens to be measured, so as to cover its edges during the whole exposure. The mirror may be glued directly to the prong of the fork with strong carpenter's glue, after first scraping off a little of the silvering at the edges of the glass. The rate of the fork is then determined, by comparison with a standard fork, by the method of beats.—*Science*.

COPYING MAPS AND PLANS.

BY THOMAS SCOTTON.*

THERE are various methods by which maps, plans, tracings, &c., may be copied. There is that of producing black lines on a white ground, but I shall now confine myself to two:—

First.—The ferro-prussiate process, by which copies may be produced with either white lines on a blue ground, or blue lines on a white ground.

Second.—The obtaining of copies with white lines on a blue ground.

The face of the drawing is placed against the glass of the printing-frame, and the prepared paper is then placed on the drawing (the prepared side on the back of the drawing). It is advisable that the paper should be somewhat larger than the drawing, so as to leave a margin exposed to show the action of the light upon it.

The exposure required in very bright sunshine varies from five to fifteen minutes, but in the very dull days of winter it may require two or three hours, or even a whole day. During the exposure to light, the paper assumes various tints, from a greenish blue to an olive tint. The print, when properly exposed, is taken from the printing-frame and immersed in clean water (which can be effected in any room) until the lines become purely white. The time required for washing occupies from five to ten minutes, but if warm water be used, the result is obtained much more quickly. Over-washing reduces the intensity of the blue ground. I find, from experience, the copies darken considerably whilst drying. If the prints are very large, say four or five feet in length, and three feet wide or more, great care is required in taking them out of the washing water to prevent them from tearing. To prevent this I generally get an assistant to hold a long wooden roller near, upon which the copy is placed.

If a line or figure has been left out by mistake on the original drawing before being copied, the same can be produced upon the printed copy by using a solution of soda and water.

To obtain blue lines on a white ground by this process, a negative must first be made, which is accomplished by placing in the printing-frame the drawing, with the back against the glass, then place over the drawing a piece of special ferro-prussiate paper (thin) prepared for the purpose, with the smooth surface against the face of the drawing, close the frame, and expose to the light. The progress of the negative print is rather difficult to verify and check; therefore, in this process the use of a second frame as a test frame will be found very useful. The negative print should be exposed at least three or four times as long as that by which white lines on blue ground are produced. The negative print, after proper exposure, should be washed in clean water, and dried as before mentioned. If this be properly done, the print when finished should show a clear dark blue on being held up to the light.

The negative print is then placed in the printing frame with the rough side against the glass, and thereon a piece of ferro-prussiate paper (the same as used for producing white lines on blue ground) with the prepared side against the negative. The exposure and operation to be the same as if producing white lines on blue ground. The copy thus treated will, when finished have blue lines on white ground.

I may also say the special negative paper can be used for producing white lines on blue ground by the following procedure as in the first instance.

Very pleasing pictures can be made by printing from negatives with this paper, which may be obtained ready prepared. If anyone choose to prepare his own paper he can do so by the use of the following formula:—

Ammonia citrate of iron	1 part
Water	5 parts
Ferricyanide of potassium	1 part
Water	4 parts

Mix together in equal quantities.

I now come to the process for producing dark blue lines on a white ground. The advantages of this process are many. It can be worked in all weathers, and requires no dark room. Copies can be coloured and varnished, altered and corrected, and last, but not least, they do not *fade*.

There are five distinct operations, viz.:—(1st) Exposure in the printing frame, (2nd) Developing of copy in yellow prussiate solution, (3rd) Washing in first water tray, (4th) Bleaching in acidulated bath, (5th) Brushing and flushing in second water tray, and finally drying.

The glass in the printing frame should be very clean and bright. Place the drawing to be copied in the printing frame, and upon it a sheet of the sensitized paper, put the felt over all, and smooth outwards from the centre with both hands, close the frame, and expose to the light. The time of exposure varies with the season of the year, state of the atmosphere, and quality and intensity of the light. In the sunlight in summer it only requires a few seconds, in the shade a few minutes, but in foggy and dull weather in winter, half to three-quarters of an hour. The exposure can only be determined by constant practice, and test slips. The test slips should be placed in the printing frame alongside the tracing being copied. These small test slips are inserted so as to be about two-thirds inside and one third outside the frame at the back. They can then be conveniently drawn out without opening or disturbing the print. The frame must be exposed to the direct action of the light, and no shadow allowed to fall on it. After a time, one of the test slips is drawn out, and dipped in the prussiate solution, and its chemical action watched for, from 40 to 50 seconds. Should the background remain perfectly yellow, and the lines come out blue, the exposure has been sufficient. During the testing the

* Abstract of a paper read before the Derby Photographic Society.

frame must be turned face downwards, or otherwise screened from the light.

It is not necessary to develop the copies immediately after exposure, therefore all the printing might be done while the light is strongest, leaving the development until the evening or the following day. After exposure, the copy should be placed face downwards on a board, and the edges turned up carefully, so as to form a sort of tray, three-quarter inch in depth. This renders the sheet more easy of manipulation, and leaves the back white when developed in the prussiate bath. The copy is now placed face downwards, and floated on the prussiate bath for about thirty seconds. The operator should see that uniform contact takes place everywhere while in this solution; raise the copy, inclining it to allow the solution to drip off one corner, then particularly notice how the lines seem to stand out. If they stand out, and the ground remains perfectly yellow, the development may be considered complete.

After development, the copy is floated or immersed in the first water bath, in order to check the further action of the prussiate, and then immersed face upwards in the acid bath, care being taken that the entire copy, both front and back, is saturated. In winter, the copies can be safely left immersed in the acid bath ten minutes or more; in hot weather three or four minutes may suffice. The surface of the copy should be worked all over carefully with a soft brush to start and loosen the blue mucilage.

The copy is next placed face upwards in the empty second water tray, and again well brushed to get rid of the superficial mucilage.

Finally it is flushed copiously with clean water, both front and back, so as to remove all traces of the previous chemical solution. For drying, lay the copies across semi-circular rollers about three inches in diameter.

Any blue stains on the copies may be removed, or alterations made by the use of the blue solving supplied with the paper; any blue stains on the hands may be quickly removed by a very weak dilution of caustic potash.

It is essential that the contents of the two chemical baths do not get mixed, or blue stains will appear. To prevent this, it is advisable to well rinse one's hands in clean water after each operation.

WITH THE BRITISH ASSOCIATION.

BY R. G. BROOK.*

THINKING that the members of this section would like to hear something of my photographic experiences during my recent journey to the Rocky Mountains, and amongst the marvels of that natural wonderland called "Yellow-Stone Park," I have jotted down the following notes. Before starting, I provided myself with one of Watson and Son's complete tourist's sets, including whole-plate camera with double swing-back, double action front, and three double dark slides; the whole fitted with a Ross rapid symmetrical lens, and packed in a solid leather case. I also took out nine dozen Fry's ordinary dry plates, three dozen special instantaneous, for drop-shutter exposures; a bottle of Fry's developer in order to bring out a plate or two by the way, to see how I was getting on; and two ebonite developing trays. Not a very bulky outfit, and I little thought, as the good ship *Parisian* steamed majestically out of the river Mersey, that the work I had before me would be so laborious, and the extra cost of travelling with a whole plate camera and twelve dozen dry plates as luggage, so formidable as subsequent events proved.

In the first place, I had only one ruby lamp, the glass of which got speedily smashed. Every one who takes a ruby lamp to sea should take also two or three extra glasses; but I would not take a lamp again, as I found that a couple of sheets of red paper (given to me by Mr. Watkins, the well-known photographer of San Francisco, whom I met with in Yellow Stone Park) put round a candle, answered perfectly, and carried me over the remainder of my tour.

In the next place, travelling photographers in a rough country should always take two or three extra squares of ground glass for focussing. I found it exceedingly awkward, when my camera was blown over and the focussing-glass shattered, to discover that the nearest glass shop was a thousand miles away.

I also found the want of a few small screws to fit the brass work of the camera; a want, the reality of which you will readily appreciate as I describe some incidents of my journey.

My ebonite trays were broken before I reached Montreal so I left my bottle of developer with Mr. Notman of that, city. I had exposed two plates on the voyage out, and the gentleman to whom I sent them to be developed spoiled one, but luckily sent for me before he tried the other. Here the Fry's developer came in, and the second plate came out all right. I left it to be washed and dried, but, on arriving home, I found that he had not half washed it, and had covered it with some rough composition intended for varnish; this covering turned a dead white, and was gradually destroying the film. I showed it to our chairman, Mr. Heather, who advised me to get another negative from it immediately, which I did, he also taking one. These negatives are better than the originals.

Besides these two plates, I tried several experiments during the passage across the Atlantic. I hoped and intended during the voyage to get a photo. of a rough sea, and on August 21st made my first attempt. It was blowing what I considered a gale, the waves being, if not exactly mountainous, at any rate considerably high; one man was holding on to each leg of the camera stand, another held me while I steadied the camera. I only wish some one had photographed the group—it would have formed a capital subject for a lantern transparency. But, notwithstanding all our efforts, the picture has not turned out very successful; indeed, I am sorry to say that most of my drop-shutter exposures have not turned out well, the shutter not being quick enough.

On sighting Belle Isle, we passed close to two fine icebergs. I expended a couple of plates on them, neither of which proved very satisfactory, partly because on this occasion I was prevented from getting a good shot at my object by the passengers crowding in front of the camera. I found, too, a difficulty in getting a dark-room on board ship in which to change the plates. The lamps are lighted all night in the passages, and the light comes over the top of the berths, so that I had to get a friend who occupied the berth above to hold his blanket over me while I changed the plates. However, through all the difficulties I succeeded in taking a group, including Lord Rayleigh, Lord Ross, Sir Frederick Bramwell, and thirty-six other members of the British Association, on the two plates already referred to as being developed at Montreal.

On arriving at Quebec, a party consisting of three friends and myself drove over to the Montmorenci Falls, where I exposed a plate from the wooden bridge across the river; my friends being stationed on the adjoining rocks. I then devoted two plates on the Falls themselves, and all three exposures have been successful. A little incident occurred here worth noting. While taking the Falls from the opposite bank on the edge of a precipice, the wind blew my instantaneous shutter off, and carried it a few yards down the side, which necessitated me scrambling after it, a somewhat dangerous operation, for had I slipped, the remains of R. G. Brook, supposing any to have been found, would have had to be returned in a box.

At Montreal we sojourned for a week, and here I found staying at the same hotel, Mr. Henderson, of London, and Mr. York, who came over in the *Parisian*. I got three views of Montreal from the mountain, two others from the top of one of the towers of the Cathedral of Notre Dame, from whence a splendid birdseye view of the city is to be obtained, and one from the window of the hotel. I also got views of Montreal Cemetery and of the Luchine Rapids. All my Montreal plates came out well except those of the Rapids, which I spoiled in developing by getting hold of the wrong bottle—one result of having too many bottles about one in a dark-room.

(*To be continued.*)

* A communication to the St. Helen's Association.

HOME PORTRAITURE: LIGHTING, POSING, AND RETOUCHING.

BY T. N. ARMSTRONG.*

IT is generally thought that, without the aid of a studio, with its special advantages for lighting, &c., the amateur can have no chance alongside a professional photographer who possesses this benefit. Now, I am not one of those who think thus; on the contrary, I maintain, and hope to be able to demonstrate that there is no reason why an amateur should not produce quite as good results in portraiture as the professional.

In the first place, allow me to say that one of the chief errors amateurs fall into lies in using too strong a light. If, for instance, you place a sitter (say) about five feet from any ordinary window having a good northerly or north-westerly exposure, and step back and carefully observe the effect of the lighting on the face, you will at once see that the contrast from light to shade is too great; the side next the window is too light, while the off side is too dark. This is the result of a want of diffused light.

Diffusion of light may be divided into two classes:—1. Natural diffusion; and 2, artificial diffusion. Natural diffusion may be described as follows:—The atmosphere everywhere, and at all times, is filled with floating particles of matter, and all of these are more or less opaque. Those which are opaque reflect a portion of light and absorb a portion. Those that are transparent refract a portion and absorb a portion; this constant changing of the course of the rays until they are thrown in every conceivable direction is known as "diffusion"—that is, natural diffusion. When any translucent screen is made to intercept the direct rays of light, and the atoms of which the screen is composed reflect or refract the rays, so that those which come through have lost their general direction—some passing one way and some another—they are said to be "diffused." This is artificial diffusion. Natural diffusion is beyond our control; not so artificial diffusion. With it we have all to do, and we bring it to our aid. By it we soften high lights, break up too strong shadows, and give proper modulation and solidity to our image.

Now, to obtain artificial diffusion. Procure a muslin screen, like this. I make it myself, and it cost me about threepence. lens, in such a manner that all the rays of light which fall on the face must pass through the gauze. Step back again and take another look, when you will at once see that a very material change has taken place. Not only has the high light on the face been softened down, so to speak, but the dark side of the face will appear to have been lighted up, thus reducing the violent contrast which had previously existed. Now procure an ordinary clothes-horse, commonly used for drying clothes on, throw over it a white sheet, and so fold the divisions of it into such positions that a reflected light (not too much of it, mind) just increases the light on the darkest part of the shaded side, and at the same time throws a little front light on the face, so as to soften or blend the high light into the shade, taking care to preserve some light and shade, which is the soul of portraiture, as well as other branches of our art. This done, your subject should be well lighted, which may be ascertained by seeing that the catch-lights are the same on both eyes.

If you examine the specimens I have brought with me to-night you will find at least four entirely different styles of lighting. No. 1 is an example of the Rembrandt style, and is a picture of my little girl. She was placed about four feet from the window with her side to it, so I moved my camera, as it were, into the middle of the room, and pointed against the light. No. 2 is an example of three-quarter lighting. The sitter was placed about five feet from the window and almost facing the glass, and then the head was just turned round until only a dash of light fell on the off cheek. In this case the camera was placed so that the lens pointed from the source of light on to the sitter—almost the reverse of the Rembrandt style. No. 3 is a style very popular with Americans. In this instance the sitter, as it were, turned the head away from the light, so that the light came from the direction of behind the ear, thus giving a full side view with the off cheek in shadow. Another pleasant way is to place the sitter so that the light falls on the cheek next the window, the off cheek being in shadow. A full face is obtained by this means.

You will thus see that the amateur is not tied down to any one style of lighting, but that he has quite a choice; so he may exercise his discretion in choosing this or that one as most suitable to the requirements of his various sitters. Can more than this be obtained in any studio? I think not.

Having said so much about lighting, I now come more particularly to the subjects we are specially to consider, in which later on I hope to give some practical demonstration, namely, retouching and enamelling. No matter how well and artistically you may light your subject (passing over the consideration of proper exposure, development, printing, toning, &c., with which, no doubt, you are all conversant, unless the amateur be able to retouch his negatives and then to finish his prints in a superior style, he will still be far behind the professional.

I have brought with me tonight some prints which I propose to enamel. They are here soaking in cold water. I have also beside me my glasses, upon which I shall place the prints later on. Now the first thing to do is to thoroughly clean and polish these glass plates. You will see me clean them with the ordinary plate-cleaning powder. Next you will see me rub the plates with this little bag of talc; then you well see me take a camel's-hair brush and dust them, and then you will see me take a small brush dipped in albumen (white of egg) and go round the edges of the glass plates, and when done they are set aside for the albumen to dry. When this has taken place, I take a bottle of collodion, coat each plate with the collodion, and again set aside to dry; while this is being done, I get ready my gelatine. I take two ounces of it and soak in clean cold water. The cold water is then drained off, and hot water applied to melt it; the quantity necessary for the two ounces of gelatine will be about eighteen ounces. When the gelatine is melted, I pass it through muslin into a flat dish. I have my gelatine ready so prepared, which I now place into a metal dish containing hot water to keep the gelatine warm.

When the plates are well set, I place my prints into the warm gelatine, and make sure they are thoroughly saturated. I then take them out one by one, rapidly place them on the collodionized plate, and lightly squeegee them on. The plates are then placed aside for a short time, and, finally, I give the prints a backing by placing on them cardboard, which is a very easy matter. I simply take the cardboard, soak it in water, and place between blotting-paper to absorb the spare moisture, and then, with a coating of gelatine, starch, glue, or paste, I press well into contact, and the thing is done. Now, the only difficult part of the operation is the collodionizing of the plate. Those of you who are familiar with the wet process will have no difficulty, while to those of you who have only worked dry plates, I say—do it coolly and deliberately, and with a little practice you will be able to coat a plate without spilling a drop. Let me, however, give you this word of caution:—Take care not to go too near a light with your collodion, or you will have a "jolly fine" blaze all round. The plates with the prints attached are then placed away to dry. I find a very good way is to dry them at a reasonable distance from an ordinary fire (not too near). They may then be left on the mantel-shelf all night, and in the morning they will be dry and ready to be removed from the glasses.

(To be continued.)

* Abstract of a paper communicated to the Glasgow and West of Scotland Amateur Photographic Association.

Patent Intelligence.

Applications for Letters Patent.

16,087. CHARLES SANDS and JOHN JAMES HUNTER, 53, Chancery Lane, London, W.C., for "Improvements in photographic cameras."—Dated 6th December, 1884.

15,887. WILLIAM MIDDLEMISS, Holmefield Mill, Thornton Road, Bradford, Yorkshire, for "Improvements in photographic cameras."—Dated 3rd December, 1884.

Specification published during the week.

1251. GEORGE RYDILL, of 52, Chancery Lane, in the County of Middlesex, for "Improvements of treating photographic transparencies or transfers so as to represent stained glass."—Dated 11th January, 1884.

The patentee appears to claim the process of cementing photographs on glass after the fashion of the so-called "crystoleum" process. The following is the definite or claiming clause of a long specification:—

The method of mounting photographic transparencies or transfers in connection with coloured transparent or translucent films and coloured glass, the whole being protected by sheets of glass, substantially as hereinbefore described.

Patents Granted in America.

308,468. Walter Clark, New York, N.Y., "Photographic Camera." Filed May 7, 1884.—(No model).

308,469. Walter Clark, New York, N.Y., "Photographic Camera." Filed Aug. 8, 1883. Renewed Aug. 14, 1884. (No model).

Particulars of both the above, with the illustrative drawings, will be given next week.

DEVELOPERS AND DEVELOPMENT.

BY ALFRED GUTHRIE.*

There are many developers and many modes of using the same developer. Some allow a rapid, and others a slow mode of working. Some like to use a rapid developer, and to get freedom from stain or fog (and with some plates this is necessary); others slow, so as to have more control over results. Each is good in its way, and excellent results may be got in either direction, but much depends upon the nature of the subject.

As to which is the best formula, or whether slow or rapid development is the correct thing, I am not able to say. There is no doubt but what a rapid-working developer is best or most suitable for portraiture in the professional photographer's hands, as it would be annoying and costly to have to keep customers waiting so long after each exposure till the operator could report upon the result and allow the sitter to depart. As far as the amateur is concerned, medium or slow development is, or I think should be, the most suitable, as it enables him to have more command over his plate. There are times, however, when rapid working would yield better results.

The professional photographer, working constantly with his apparatus and plates, can always estimate correctly, or, at least, within very narrow limits, what is the correct exposure to be given, and either rapid or slow development will give satisfactory results; but the amateur has necessarily a haphazard mode of guessing his exposure, and the result may be a very wide margin on either side of the correct one. In this case, slow development will give him more chance of correcting either over- or under-exposure. Again, there are some plates that will only yield fair results with very slow development, and if hurried in any way will only give ghosts of what they should be. Other plates will not give good results with slow development. Of course, if it were possible to get one good developer which would act equally well with all makes of plates, it would be a great step in advance, but I fear that cannot be.

During the last few years, there has been a constant stream of new developers, or modifications of old ones. The pyro, ammonia, and bromide have branched off into endless combinations—Edwards's, with glycerine and alcohol; Nelson's, with sugar; and Berkeley's, with sulphite of soda and citric acid. Then there is the soda developer, the potash, and the combination of both. We have the ferrous-oxalate, the hydrokinone, and now we are threatened with a new one with a regular jaw-breaker of a name which I am almost afraid to try and pronounce—hydroxylamine—hydrochlorate, and caustic soda. There is an endless variation in the proportions of the ingredients, and, of course, each one is best.

There is no use to lay down formal rules for development, for no hard-and-fast line can be drawn. Though formulæ are given, it is impossible to use them always in the proportions mentioned, even supposing the exposures to be correctly timed. There are so many cases in which a little more or a little less of any one or more of the ingredients is required to bring about the best result. You cannot take any formula as given by any plate-maker and adhere to it for all subjects—that is, if you want to make the most of the plates. We all know that pyro gives density; ammonia, soda, or potash (whichever is used), detail; while bromide restrains and keeps the shadows clear; but that is not all, for you must have a knowledge of how to proportion them so as to give the best results for each class of subject.

There are very few plates in the market but what will develop with any of the standard formulæ, if only they are watched and studied in the proportion of the ingredients; and there are very few photographers, professional or amateurs, who do not have a favourite formula—one which seems to give better results in their hands than any of the others. I have my favourite—1. Ferrous oxalate; and 2, the pyro and potash, though I very often use the sulphite of soda and ammonia developer. I think the best for amateurs is neutral oxalate of potash (saturated solution), protosulphate of iron (saturated solution), to which added one drop of sulphuric acid to each four ounces of solution, and used in the proportion of one to three. I find this developer gives good results with almost all makes of plates, and is very much under control. Any strength of negative can be made if the exposure be correct, the shadows clear and full of detail, and the high-lights perfectly dense. If the plates are over-exposed, a very small addition of bromide of potassium will give perfect command of the result, while, if the plate has been under-exposed and will not come up with sufficient density and detail, one or two drops of a one-per-cent. solution of hypo-sulphite of soda will do all that can be desired.

In all cases correct exposure will give the best results, but should there be, through any cause, much under or over-exposure, this developer will afford as good, if not better, results than any other that I have yet tried. Many plates can be developed in the same developer; and if it be returned to a stock bottle and exposed to sunlight for a short time it will recover its power to a great extent, and is preferred to newly-mixed developer for giving softness of detail. Another developer, for which I have a soft side, is the potash developer. It is an excellent developer for some plates which, with ordinary developer (pyro and ammonia), give red or grey fog. What I mean by grey fog is the negative having the appearance, when looked at by reflected light, of not being properly fixed—having a grey or yellow appearance all over it. When looked at by transmitted light it only seems slightly filled up in the shadows; but in most cases this developer will be found to give absolute clearness in the shadows.

There are some makes of plates, however, which do not work up in a satisfactory manner, the negative being weak in contrast. When this is the result (not from over-exposure) one or two drops of a weak solution of ammonia will usually give it all the energy needed. Another very handy developer, and one which I usually keep beside me, is the ordinary pyrosulphite of soda and ammonia. This I always use when copying anything, such as engravings from books. It is a very nice working developer, and though, in most cases, I prefer either of the developers I have named, yet this one is excellent. Either of these developers can be used over and over again till exhausted, and the results are equally good till the developer is exhausted—having no tendency to stain the film—and the colours of the resulting negatives are good for giving rich prints with plenty of contrast.

I have tried almost all the developers as they have appeared in the photographic journals from time to time (not that I was dissatisfied and intended to change, but just to see the effect), hydrokinone and hydroxylamine alone excepted.

(*To be continued.*)

* Abstract of a communication to the Dundee and East of Scotland Photographic Association.

Notes.

Under the Presidency of Mr. Ackland, the South London Photographic Society takes a new lease of life. At the meeting on Thursday last, not one hand was held up in support of the suggestion to dissolve the Society.

That Mr. Ackland should be President is most fitting, as he is actually the oldest member, and has been a steady supporter of the Association during the whole time of its existence.

The story of the origin of the South London Photographic Society has not yet been published, and here it is.

In April, 1859, Mr. A. H. Wall inserted an advertisment in the Photographic News, requesting such persons as were desirous of assisting in the formation of a new photographic society to meet him on a specified evening at the Walworth Literary Institution. Mr. W. Ackland was the only gentleman who responded; but, notwithstanding this,

the resolution to form the new society was formally proposed, seconded, and passed unanimously; as, when Mr. Wall found how things stood, he made a meeting by asking those gentlemen who were in the reading room to come and hold up their hands and express approval when the formation of a new photographic society was suggested.

In May, another meeting was held, and the Society was formally constituted in accordance with a resolution of Mr. G. Shadbolt; and a committee, consisting of Messrs. Ackland, Cotton, Harvie, Howard, Lake, and Wall was elected.

"Adventures in the Air," is the title of Mr. Cecil V. Shadbolt's new lantern lecture. It will be illustrated with some fifty slides, including Mr. Shadbolt's photographs taken in mid-air.

We learn that the Northampton Photographic Exhibition will be formally opened by a *soirée* on Wednesday, the 17th inst, and not on the 16th, as previously announced. The exhibition will remain open to the public until January 10th, 1885.

If gelatino-bromide plates are long in drying, fog results; and if dried too quickly, blistering results: at any-rate, this is what Captain Abney said on Tuesday last, at the meeting of the Photographic Society.

"What, then, is the proper time for drying?" has been asked. "Neither less than eight hours, nor more than twenty-four," was the reply of Captain Abney; so a considerable margin is allowable.

It is not long since that, *apropos* to the "striking" portrait which had been obtained of a flash of lightning, we intimated that the carte of a whirlwind, and a cabinet of a monsoon, would soon be forthcoming. Photographic enterprise has already fulfilled our prediction, and, as many of our readers will have noticed, a most satisfactory likeness of a tornado has been received from America. This development of the new and wide field for photographic energy cannot be but useful. Thus, as it is, information of most of our big storms is cabled across the Atlantic; and if it will now be possible to hurry over reliable cartes of our coming visitors, we shall of course be in a position to identify them as they arrive, and act accordingly.

The portraits of the tornado in question are quite plain, it appears; which shows they were taken from nature. Had they been photographed at second-hand from the Yankee reporters' accounts, they would have been "very highly coloured!"

Our suggestion of last week in reference to portraits of oneself, mounted Christmas-card fashion, has shown us how nearly the idea has been carried out, and we have received several examples.

The best design for general effect is from the well-known surgeon and microscopist, Mr. Charters White. We have here an artistically-arranged bordering of ferns and grasses, a portrait group of Mr. White, together with his family; also a Christmas greeting worded as coming from the whole of those represented. The whole appears to be printed from one combination negative. Mr. Moffat, of Edinburgh, sends us cabinet portraits with "A Merry Xmas and Happy New Year," printed on the sensitive paper, apparently from a second negative; while Messrs. Adam and Scanlan, of Southampton, send us something of the same kind, but with the greeting lithographed on the mount. Last of all, we mention the series of really elegantly designed mounts for Christmas, New Year, and Birthday cards, which Messrs. England Brothers forward to us; it being intended that amateurs or professionals should mount their own pictures on them.

After all the talk about the loveliness to be seen, and possibly conversed with, at the Paris Beauty Show next month, it turns out that the exhibition will be one of photographs only! The judges will be the public, and each visitor will have a vote, which he will place in an urn at the door.

The public will be graciously allowed to purchase Messrs. Braun's photographs of the National Gallery pictures at 12s. each. Messrs. Braun have photographed two hundred and forty of the pictures, and anyone who wishes to have a complete set can do so for the sum of £144, so that there is "no reduction" on taking a quantity. This price puts the photographs beyond the reach of the ordinary public, who will have to content themselves with looking at them in the shop windows, unless the National Gallery authorities discover that English photographers may be entrusted with valuable pictures, and allow a fresh series of negatives to be made. What virtue there is in a monopoly, or in what respect the art education of a nation benefits therefrom, is difficult to see.

The generosity of the authorities to Messrs. Braun is almost unexampled. When they granted permission, it seems not to have occurred to them to demand that a set of the photographs should be the property of the Gallery, and it was not until Messrs. Braun had entered upon their work that this arrangement was made.

The first "Conference on the Picturesque" took place recently at a meeting of the Edinburgh Society. The merits and demerits of a number of pictures were freely discussed, and a profitable evening was spent. The example of the Edinburgh Society is worthy of imitation.

A writer in the Christmas number of one of the monthlies has attempted to build a story out of instantaneous photography. From a photographic point of view, the effort is not a very successful one. An amateur photographs a tomb in the design of a cross in a country churchyard, and on developing, discovers the head of a beautiful girl looking over one of the arms of the cross. As he saw

no one by the tombstone, he imagines he has taken the portrait of a ghost, and engages in a little psychical research. The result of the enquiry is, that the portrait is identified with the face of the lady who lies in the tomb. Subsequently, the mystery is cleared up, and the portrait settled to be that of the lady's daughter, who, visiting her mother's grave, was roused by the movements of the photographer, "looked over the arm, saw my camera, and saw, too, that I was unaware of her presence, and, not wishing to be seen, bent down her head quickly." The whole business is supposed by the writer to be dependent upon the quickness of exposure, for, as he remarks, "the impression is taken literally *instantly*"—the italics are his. If so, we have to suppose the head is not only popped up at the exact instant of exposure, but popped up with the speed of a drop shutter! What was the photographer about that, at the time of exposure, he never looked at the object he was photographing? Surely he was a very careless operator!

In issuing a weekly illustrated journal of patented inventions, the English Patent Office has followed the lead of the United States Patent Department; but the English journal is, in every respect, far behind the American.

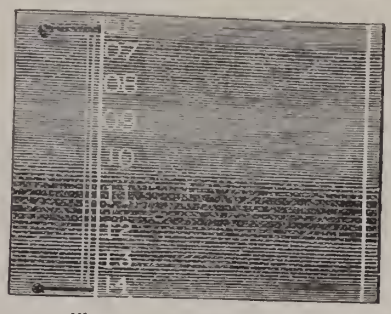
Some time ago we expressed regret that the negatives of the late Mr. O. G. Rejlander were not, after his death, purchased by some responsible person. As the pioneer of art photography, Mr. Rejlander deserved a better fate than having his studies exhibited side by side with portraits of half-dressed women, as bad from the point of art as from the point of decency. At the present time, in a shop-window not far from the Strand, may be seen a dozen or more of Rejlander's pictures, which were evidently trials, and never would have been shown by the artist himself. It is bad enough to have one's triumphs degraded by being associated with objectionable companions; but it is worse when one's failures are thus exhibited. No doubt there were circumstances which compelled the sale of Rejlander's negatives, but it is a thousand pities they could not have been weeded out before being sold.

A photographic artist lately wrote to one of the most popular occupants of the judicial bench, enclosing the recipes of three various preparations for coating paper with, and asking him to please select the best, adding that he sought his lordship's opinion with confidence, having always heard he was such an admirable "judge of a-'size.'" This libel on our profession appeared, need we add, in a so-called comic journal.

GORHAM'S PUPIL PHOTOMETER.

This beautiful and most ingenious instrument, to which attention was first called by Mr. Tindall, is as simple as it appears to be effective. It consists of a piece of bronzed tubing about 1·9 inches long, and 1·5 inches in diameter, with one end closed by a disc, in which are a series of pairs of minute holes pierced on radii of the circle, and drilled with absolute accuracy at distances varying from ·05 inches to ·28 inches apart. A cap with a radial slot in it so narrow as only to leave one of these pairs of holes visible at a time rotates over the brass disc; and round the cylinder just below the edge of the cap the linear distance of each pair of holes is engraved exactly opposite to it. Our first figure represents the cap as seen when looking down on

to it. The pair of holes ·10 inches apart are shown as visible through the slot. Fig. 2 exhibits the tube as seen sideways, to show how the figures are engraved upon it. The instrument seems to have been originally devised by Mr. Gorham for measuring the diameter of the pupil of the eye under the stimulus of light of varying intensities. It is used by looking through the open end of the tube (the bottom in fig. below), when two discs of



light will be seen, like a double-star. The cap is turned until a pair of these discs appear which are precisely tangent, or just touch one another at their edges. Then may the diameter of the pupil be read off on the scale by mere inspection to ·01 inches. But this is by no means the only—or, in fact, the chief—use of Mr. Gorham's instrument, inasmuch as the magnitudes of the pupil really furnish the measures of the intensities of the lights under whose influence its diameter varies. Hence it may be used as a photometer; and for this purpose we proceed as follows:—We set a Sugg's standard candle at a distance of 1 foot from the eye, with a white surface (such as a sheet of foolscap paper) behind it, in a room otherwise totally dark. We now take the diameter of the pupil in the way just indicated, and read it off from the scale. Leaving the photometer intact, we substitute for the candle the source of light whose intensity we wish to measure, placing a white background behind it, as in the previous case. Suppose that it is a duplex lamp which replaces our original candle. If we regard this from a distance of 1 foot, as before, we shall find our two discs of light, so far from touching, will be pretty widely separated, and we must slowly retire from the lamp until the circles have expanded sufficiently to become tangent again; when, of course, the pupil will have regained its original dimensions, from the light falling upon it being of identical intensity with that of the candle. It only remains to measure the distance of the lamp from the eye in feet and decimals of a foot to find its illuminating power, which obviously will vary as the square of the distance; *i.e.*, if we have to retire to a distance of 4 feet the lamp must give the light of sixteen candles, and so on. In a foot-note to Mr. Tindall's recent letter, a doubt was expressed as to the efficiency of Dr. Gorham's invention as a *quantitative* light-measurer. In connection with this we may mention that, as a preliminary to penning this article, we have been experimenting with a candle and a small reading-lamp, the relative intensities of whose lights we measured in succession by Rumford's method and by the instrument we are describing. By the former mode of measurement we found that the lamp gave 7·1113 times the light of the candle; by the new photometer it came out 7·111. It would perhaps be idle to contend that no element of "fluke" entered into this extraordinary coincidence; but it may serve

to show with what minute accuracy the relative intensities of various illuminating agents can be measured by this most simple apparatus. The incipient user of it will find it politic to keep his unused eye open; as, if it be closed, and then opened while the photometer is being employed, the stimulus of the light on the freshly-exposed pupil will cause the one viewing the hole itself to contract sympathetically, and so derange the measurement.

HYDROXYLAMINE USED AS A DEVELOPING AGENT.

BY ARNOLD SPILLER.*

Nearly two months have elapsed since Herr Carl Egli and myself published in the Photographic News the suggestion to use hydroxylamine as a developing agent, and I take this earliest opportunity to communicate to the Society the results of my further experiments. As hydroxylamine, prior to our publication, had not been introduced into the photographer's laboratory, perhaps it will not be out of place if I describe briefly the properties and preparation of the compound under consideration.

Hydroxylamine was discovered by Lossen, when investigating the intermediary products of the reduction of nitric acid to ammonia. This compound, which is represented chemically by the symbol NH_3O, is formed on the ammonia type, by the replacement of one of the atoms of hydrogen by the hydroxyl radical HO, as is seen in the following graphical representations:—

Ammonia.	Hydroxylamine.
$N\begin{cases}H\\H\\H\end{cases}$	$N\begin{cases}OH\\H\\H\end{cases}$

Like ammonia, it is a strong base, capable of forming several salts. It has not yet been obtained in the free state, but it can easily be produced in an aqueous solution. It possesses the somewhat remarkable property of behaving both as an oxidizing and as a reducing agent. Perhaps no better example of its reducing action can be taken than the decomposition of silver bromide in the presence of caustic alkali, whereby metallic silver, alkaline bromide, and nitrous oxide or laughing gas are produced.

The reaction is represented by the following formula:—

$$2NH_3O+4AgBr+4NaOH=Ag4+3H_2O+4NaBr+N2O.$$

Another important fact in considering the properties of hydroxylamine, is that it does not absorb oxygen, even in the presence of alkali; thus, during the process of development, there need be no fear of the developing solution becoming decomposed from contact with the atmosphere.

The preparation of this compound has not received much attention from chemists, and thus the process generally adopted is the same as that originally proposed by the discoverer, namely, the reduction of nitric ether by tin and hydrochloric acid. When this method is resorted to, a large proportion of the hydroxylamine is converted into ammonia, and thus the yield is comparatively small. Dr. Divers has recently published in the *Journal of the Chemical Society* a series of experiments on the formation of hydroxylamine from nitric acid. This investigator finds that a large yield of the desired compound is obtained by the direct action of tin and hydrochloric acid on nitric acid; in one experiment, 87 per cent. of the nitric acid was converted into the base. It may be of interest to know that the hydrochloride, or hydrochlorate, is already in the market, but as this compound has hitherto only been used for scientific investigations, the price is at present rather high, and would debar the professional photographer from adopting this method in his every-day practice; but there is very little doubt that, should a demand arise, the substance could be produced at a reasonable price.

With this, as with other developers, there is some difficulty in prescribing a definite formula, but the following, which is a modification of one recently described in an editorial article of the Photographic News, may be taken, I think, as a fair standard, and has given excellent results with certain brands of plates.

The following solutions are required:—

A.	Hydroxylamine hydrochloride ...	30 grains
	Alcohol	1 ounce
B.	Caustic potash	1 dram
	Water	1 ounce
C.	Potassium bromide	20 grains
	Water	1 ounce

The ingredients used are in principle similar to those employed with pyro. Caustic potash takes the place of ammonia, for the latter alkali is not sufficiently powerful to assist the reduction of silver bromide. The soluble bromide is used, as with pyro or oxalate, to restrain the action of the developer.

To develop a quarter plate with the above solutions take half a dram of A, 40 minims of B, and 10 minims of C, diluted to 1 ounce with water. The exposed film is plunged straight into the developer without previous moistening; the process proceeds rapidly, and is completed in about five minutes.

The advantages claimed for this developer are:—Wide latitude of exposure, non-deterioration of the solution from external sources, and absolute freedom from stain, a gain that cannot too strongly be accented, especially at this time of the year, when printing is so slow.

Against these important advantages I should state that there is a minor objection, and that is the liability to cause reticulation, with plates prepared with soft gelatine, from the softening of the film by the caustic alkali, and the evolution of the nitrous oxide gas from the decomposition of hydroxylamine.

This developer is particularly suitable for gelatino-bromide paper, for while the resulting tone is apparently identical with that obtained by ferrous oxalate, there is no after treatment with acid required to remove the brown stain which is so objectionable when the latter is employed.

Gelatino-chloride is very amenable to this developer, and by varying the alkali used, different tones are produced. Thus, potassium and sodium carbonates produce a sepia-brown tone; the same, but modified by the addition of a trace of ammonia, give a chocolate; and ammonia per se a brilliant purple.

A curious dichroic image is obtained with ammonia developer by reducing the alkali therein to one-fifth the normal amount, and exposing the plate about five-fold; the deposit, when moist, appears of a brilliant chestnut colour, which dries to a deep purple. This same purple image again appears as a brown in gas-light. My experience with gelatino-chloride is confined to only one make of plates, so that probably the tones would be somewhat modified when this developer is used with other brands; for Dr. Eder has already shown that films prepared according to various methods often yield different tones, even when the same developer is used.

For the development of gelatino-chloride films, the following solutions are required:—

D.—Hydroxylamine hydrochloride... ...	15 grains
Alcohol	1 ounce
E.—Potassium carbonate	6 drams
Water	1 ounce
F.—Ammonia ·880	1 dram
Water	1 ounce

A normal exposure for use with this developer is about ten minutes, one foot from a fish-tail burner. For a sepia-brown tone take half a dram of D, 40 minims of E, and 1 ounce of water. For chocolate tones the above mixture, to which has been added 1 minim of F. A purple image is obtained with half a dram of F and half a dram of D, diluted with 1 ounce of water. To obtain the dichroic tone, expose fivefold normal, and develop with half a dram of D, 6 minims of F to 1 ounce of water. The latter solution will probably prove useful for the development of gelatino-chloride prints, for I find that by backing a thin transparency of the dichroic kind with paper, a picture possessing a beautiful warm brown tone is obtained.

In advocating the hydroxylamine developer for gelatino-chloride, I claim freedom from stain, density of deposit, and variation of tone. It should be remarked that as the alkalies used are comparatively weak, no reticulation of the film is produced when the small proportion of alcohol included in the formula is used. In conclusion, I beg to express the hope that photographers will give hydroxylamine a fair trial, and communicate the results of their experience.

* Read before the Photographic Society of Great Britain.

Correspondence.

PROFESSOR THOMSON'S LECTURE ON PHOTOGRAPHY.

Dear Sir,—Will you kindly allow me to make a correction in your notice of my lecture on "Photography" to the Society of Chemical Industry, which I have just seen in the Photographic News of December 5th?

I am reported to have said that "the swing-back on cameras was in my opinion *only* of use in portraiture;" whereas I laid some considerable stress upon its great importance in architectural work. Again, in speaking of cherry fabric, I stated it to be preferable to glass only when travelling, on account of its greater portability.

Will you also allow me to point out that the word "large" in your report, with reference to microscope objectives, bears two interpretations. What I said was, that "with low powers up to a half-inch, the difference in chemical and visual focus is appreciable, but in powers higher than half-inch the difference is too small to be taken into account."—I remain, yours very truly,

JOHN M. THOMSON.

EXHIBITION AWARDS.

SIR,—Mr. Donkin's letter, replying to Mr. Smith on the recent lantern slide award, has *not* correctly stated the case. As Mr. Gale's slides were not on view anywhere in the Exhibition, as were the other slides, they could not come before the judges of awards with the other exhibits at the opening of the exhibition, as the prospectus implied they would. If they were received in time, why were they left out of the catalogue? Pictures at an exhibition are supposed to be on view the whole time it is open to the public, and to be catalogued. If Mr. West's and Mr. Robinson's pictures had been omitted in the same way, and had been kept shut up in boxes out of sight, as Mr. Gale's were, would they have been considered on view, and been awarded medals? In giving this award to one who was not in the competition, the judges have acted most dishonourably to the few who complied strictly with the regulations.—Yours truly,

P. H. FINCHAM.

Myton Road, West Dulwich.

[The tone of our correspondent's letter is to be regretted, as we are satisfied that the conditions of the prospectus were completely fulfilled in the case of Mr. Gale's slides. Mr. Fincham accuses Mr. Donkin of incorrectly stating the case, but mentions no instance of incorrectness. To accuse the Judges of acting dishonourably is ridiculous, and, moreover, inconsistent with another portion of Mr. Fincham's letter.—ED. P.N.]

LANTERN SLIDE CLUB.

DEAR SIR,—I read with interest the letter of Mr. Henry Smith in your last issue, on the above subject, and think it a capital idea. For some time past I have had a similar notion, that a society or club might be formed for the study of making lantern slides, and all matters connected with the lantern. The subject cannot be fully ventilated and discussed at the present existing societies, as there is no doubt that quite half, or perhaps more of the members, neither know nor care anything about either the lantern or lantern slides; and to such, the meetings on lantern matters would be very irksome. I therefore feel sure, with Mr. Smith, that a society of the kind is very much needed.

I should suggest that the society be open to all, and not confined to amateurs only; and, instead of buying the slides, let them be made by the members themselves. They could also contribute a certain number of slides annually, and there would be sure to spring up a mutual exchange of slides between the members. It is well known for a fact that there are thousands of negatives stowed away in plate boxes that have, perhaps, never been used, that would make exquisite lantern slides.

I have no doubt a meeting room could be found somewhere central, so as to be convenient. During the winter months fortnightly meetings could be held, but that is purely a matter of detail; but I should suggest that at least two first-class lantern exhibitions should be given—say one at the commencement of the season, and one at the end—on the best possible scale, making either a small charge for admission, or a subscription just sufficient to cover expenses and no more. I think the matter very simple, and that it could be established without much difficulty. I should be very pleased to assist in such an undertaking.—Yours truly,

WM. BROOKS.

Reigate.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

THE ordinary meeting of this Society was held on Tuesday, the 9th inst., at the Gallery, 5A, Pall Mall East, Mr. JAMES GLAISHER F.R.S., President, in the chair.

The minutes of the previous meeting having been read and confirmed, the following gentlemen were elected members of the Society:—Messrs. Hugh F. McConnell, C. A. Fernley, and Brougham Yonng.

Capt. ABNEY, R.E., then read a paper on "Testing Gelatine for Emulsions." He commenced by saying that his remarks might be considered as notes rather than a paper. Most gelatine plate makers, he said, are aware of the variable amount of water absorbed by different samples of commercial gelatine, and which have an influence on the character of the film after it becomes set on the plate. All gelatines dried on glass expand more or less, and to test the difference of expansion he coated a series of plates with various gelatines in the market. When dry, these films were stripped off, and the areas measured accurately. The series embraced hard and soft gelatines soaked with water alone, also with ammonia, potassium, and sodium salts added. Soft gelatines showed the greater degree of expansion, although it occurred more or less with the hard samples. The potash mono-carbonate showed less expansion than the sodium. A table of percentages was then given, which will shortly appear. Deviating from the title of his paper, he said that someone had recently mentioned that a substratum of one of the silicates caused emulsion to flow over the plates as easily as collodion, and it had been recommended to wash the plates after flowing over this substratum, or difficulties would arise. He had experienced a little difficulty in using the silicate of potash, and tried washing; but now he found he could use it without, by applying a very thin coating, and wiping it off with swandown calico.

The CHAIRMAN having invited a discussion on Capt. Abney's paper,

Mr. W. BEDFORD enquired whether soft gelatines treated with chrome alum would be likely to expand.

Mr. LEON WARNERKE, after referring to the penetrating power of his new developer, said if he desired to stop frilling he should use alum; he did not use it quite in the same manner as usually recommended, but preferred adding a small quantity to the first water in which the emulsion is put to wash. This plan is very convenient in the summer, when the temperature is high, as it makes the gelatine crisp; it also prevents the gelatine absorbing as much water as under ordinary circumstances, and still retain its permeability. The addition of alum he found to diminish the time required for development.

Mr. W. K. BURTON asked the previous speaker what proportion of alum he used in washing.

Mr. WARNERKE: Not more than five per cent..

Mr. T. SEBASTIAN DAVIS thought expansion depended a good deal on the length of time occupied in drying the films. In his own experiments he found that when bromide of potassium remains in the film, decomposition takes place, and frilling results Mr. Davis then described certain experiments he was engaged on, wherein he found a soft gelatine occupied four or five days in drying, and a hard sample dried under similar conditions in less than forty-eight hours; evidence of blisters being discernible in the soft samples after twenty-four hours in the drying cupboard; patches were also visible.

Colonel STUART WORTLEY supposed Mr. Davis alluded to plates for experimental purposes, as surely ordinary plates would dry quicker than that. He (Col. Wortley) would not be satisfied with plates that took over twelve hours to dry.

Mr. WARNERKE remarked on the difference in the results obtained by various experimenters. When he dried plates in two or three hours, they would blister; but not so if ten or twelve hours were occupied.

Colonel STUART WORTLEY considered a plate should become quite surface-dry in twelve hours, when it could be thoroughly desiccated by heat.

Mr. W. ENGLAND said if a plate required over twelve hours to dry, then it would be more sensitive in the middle than the sides; he had often observed that.

Mr. J. SPILLER believed Mr. Warnerke had touched on an important subject in his remarks concerning alum. Ordinary glue, he said, is rendered hard in manufacture either with alum, or one of the metallic sulphates, such as zinc; it might well form a fitting subject for experimenters. They might get some of the metallic salts to harden gelatine enough to obtain a suitable quality without loss of sensitiveness.

Mr. W. E. DEBENHAM enquired of Mr. Spiller what amount an emulsion was likely to bear without injury?

Mr. SPILLER merely suggested the idea. The amount of zinc sulphate used was very small. Manufacturers employed it to prevent the destructive change which occurs in extremes of temperature, as in very cold or hot weather.

Colonel WORTLEY mentioned half per cent. as the quantity of zinc sulphate employed.

Captain ABNEY, in replying, said that when soft gelatine was artificially hardened, its expansive properties would be lessened materially. He should expect to get fog as well as frilling if he prolonged drying to the extent mentioned by Mr. Davis; a substratum would prevent the marks spoken of. Drying should not occupy less than eight hours, or more than twenty-four. Plates dried by means of alcohol will frill, and the reason is not difficult to find, seeing that the top stratum is unequally strained from the lower. Slow drying in the centre, spoken of by Mr. England as productive of greater sensitiveness, would appear to be favourable to slow drying. Zinc nitrate has a remarkable tanning action on gelatine, but with a proper sample of zinc bromide, a quicker emulsion may be made than with the potassium salt. An uncertainty exists in dealing with the zinc salts. Referring to Mr. Warnerke's remarks, he (Captain Abney) said that by using the ammonia process, the film became more permeable to the developer, and did not alter by expansion, so far as his experiments had gone.

The CHAIRMAN called for a vote of thanks to Capt. Abney, which was accorded.

Mr. J. GORDON (Dundee) showed an apparatus for washing prints. It is a tank, fitted with a series of trays, about twenty in number, covered with wire or net, having receptacles for the prints to lie in during washing, so that no two prints could possibly touch each other. By means of an automatic syphon arrangement known as "J. Sturrock's Patent" the tank could be filled and emptied as often as desired, ranging from one to twenty times per hour.

Mr. DEBENHAM had seen one of these washers in use at a friend's house, and he was very pleased with its performance. After the water was syphoned off, the trays were left thirty seconds to drain before the next supply reached them.

Col. STUART WORTLEY observed that wood frames absorbed hypo. pretty freely, and wire frames were likely to mark silver prints.

Capt. ABNEY said he had tried wire, and found markings in consequence.

Several other members having expressed their opinions on this subject,

The CHAIRMAN thanked Mr. Gordon for bringing the washing trough before the meeting, and asked the members to pass a vote of thanks to Mr. Gordon, which was accordingly done. He (the Chairman) made the usual announcement regarding the election of officers in February next, and the meeting was adjourned.

The next ordinary meeting takes place on Tuesday, Jan. 9th, 1885.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE annual general meeting of this Society was held on Thursday, the 4th inst., at the House of the Society of Arts, John Street, Adelphi, W.C., Mr. E. W. FOXLEE in the chair. The minutes of the previous meeting having been read and confirmed,

The CHAIRMAN pointed out that owing to causes beyond their control, the list of officers nominated at the November meeting was not sufficiently full for them to elect a full committee, and, at his suggestion, the meeting was now voted special as well as general, to receive further nominations, which were then handed in.

The report was then read by the Hon. Secretary (Mr. F. A. Bridge). It alluded to the great loss the Society had sustained during the year by the decease of the President, the Rev. F. F. Statham, Mr. Jabez Hughes, and Mr. H. Baden Pritchard, all of whom were staunch supporters of the Society. When the President's death was announced, it was thought by some that the Society should cease to exist; over seventy circulars were issued with a view of ascertaining the feeling of the members on this subject, and the Committee regret that the responses showed so little interest displayed by the members in the Society's welfare. In reference to the work of the Society, the January meeting was the usual lantern evening; Willesden paper formed the subject at the February meeting. In April the lantern polariscope was practically illustrated by Messrs. C. and F. Darker, and the other meetings were occupied with papers from Messrs. W. Aekland, E. Dunmore, Norman Macbeth, F.S.A., and an illustrated lecture on Florida, by Mr. J. Trail Taylor. The report was adopted.

The voting in respect of the pictures sent in for competition was deferred, owing to the number of notices of motion to be dealt with; ultimately it was decided to deal with it at a future meeting.

Mr. BRIDGE presented his report as Treasurer, which was adopted. The subscriptions amounted to £25 13s.—this sum, with £10 17s. 3d. balance from last year, brought the total to £36 10s. 3d. After paying the usual disbursements, the sum of £4 6s. 1d. remained to provide for the presentation prints.

Mr. BRIDGE said, in reference to continuing the Society, "Will it pay?" Out of seventy-six members who paid last year, about thirty-six have become scared. If they continued, they must have members to pay their way; and could they get them?

The CHAIRMAN considered that in addition to Mr. Bridge's requirements, they needed men who were willing to work for the Society.

Mr. E. DUNMORE: Do we understand that the future of the Society resolves itself on the question of finance.

Mr. BRIDGE said that was practically what it amounted to.

Mr. C. POIRSON advocated a continuance if enough members could be ensured to pay the expenses of the year.

Mr. A. COWAN thought the scarcity of meetings had brought the Society to this pass—a view he held long ago. Experimentalists who had anything of interest could not be expected to keep it back from the weekly meetings because they were members of this Society as well. If the Society became modernized, there was room for it.

Several letters and a telegram were read from members in favour of the Society's continuance, when the Chairman requested Mr. Cowan to move that "The South London Society do cease to exist."

Mr. H. TRUEMAN WOOD thought it better that a motion should be taken, and he would second it. His opinion was not favourable to the object of the motion, as there was plenty of room and work for the Society to do in a technical and higher scientific condition, brought about by the advance photography is making.

The CHAIRMAN having remarked on his long connection with the Society, and his unwillingness to preside on this occasion, formally put the motion, which was unsupported.

The next motion, proposed by Mr. W. K. Burton, and seconded by Mr. H. Trueman Wood, "That the name be changed to that of the "London Photographic Society," was also lost.

The motion to increase the number of the committee to twelve, and reduce the number of vice-presidents to three, was carried unanimously.

The following gentlemen were elected:—

President—Mr. W. Aekland.

Vice-Presidents—Messrs. T. Bolas, H. Trueman Wood, and F. York.

Committee—Messrs. T. M. Ayers, W. M. Ashman, W. K. Burton, W. Cobb, T. J. Collings, E. Dunmore, G. A. Garrett, J. A. Harrison, C. Hussey, Jun., C. Poirson, W. H. Prestwich, H. Wilmer.

Hon. Secretary and Treasurer—F. A. Bridge.

Upon motion, a hearty vote of thanks was given to the Society of Arts, coupled with the name of Mr. H. Trueman Wood.

After the usual vote of thanks to outgoing officers, it was announced that the lantern meeting will take place on Jan. 1st, 1885, and the annual dinner at the Holborn Restaurant, on Tuesday, the 16th inst.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATON.

AT the usual weekly meeting held on Thursday last, Mr. A. L. HENDERSON occupied the chair.

Mr. W. E. DEBENHAM, agreeably with a promise made at a

previous meeting, exhibited some vignetting frames of the kind he has used for many years. On the front of the printing frame were fastened two thicknesses of millboard from which the centres had been removed. A card with the required size of opening inserted between the millboards could be shifted at will very easily, and was adjusted to the negative, but was held quite firmly enough to prevent any displacement accidentally. The different sizes of openings used were cut out on a separate sheet of cardboard and numbered, for convenience in registering the negative in case of future orders. The method adopted for greater softness was by distance, the front of the camera in this case being built up, and the distance increased towards the top of the print. For double printing Mr. Debenham used two sheets of glass, one masked with paper except the vignette opening, the other with the opening masked; the print was registered against the inner frame. Mr. Debenham said he could speak from a long experience of these frames.

The Chairman used two sheets of glass attached to the front of the printing frame, having a piece of opaque linen between, adjustable with the required vignette opening.

Mr. Trinks suggested a ready and simple way of ensuring parallel rays continuously falling on the plate during printing: a length of cardboard bent in the centre to an angle 45°, one side being fixed to the printing frame—the frame being so placed that the shadow of the other or vertical side of the angle reached the end of its base; the shadows being kept stationary by moving the frame as required.

Mr. Prestwich had recently seen published a patent for taking vignetted portraits direct in the camera. He showed two vignetted photographs taken by him direct upwards of twenty years since.

The Chairman spoke in favour of wire gauze being placed between the sitter and the lens; this gave a peculiar softness to the picture which he thought was not obtainable by any other method.

Mr. Trinks remarked that in his experience of societies of this kind he had found it much better to act than make suggestions; he wished to give force to his remarks by offering a prize of five pounds to be competed for by members of the Association. He did not wish to indicate in what form or direction the competition was to take; this he left entirely to the members.

It was ultimately proposed by Mr. F. W. Hart, and seconded by Mr. J. J. Briginshaw, that the mattee should stand over until the 18th inst., when details of the competion could be discussed and arranged. Members not able to be present on that evening were invited to send their suggestions to the Secretary with regard to object of the competition on or before that date.

Mr. J. B. Wellington, with regard to the discussion of the previous week on "Bichloride of Mercury as an Antiseptic," had tried it on an emulsion, using half-a-grain to ten ounces of emulsion, and found the speed of the plate materially affected, showing only 9 on the sensitometer—the same emulsion with the bichloride of mercury usually reaching 18. The plates developed very clear, and with plenty of density.

In reply to a question from the Chairman,

Mr. Wellington said he developed the plates with pyro.

Mr. Trinks said the subject of decomposition of gelatine brought to his mind a fluid that some time since caused a great amount of interest in medical and microscopical circles; it was called Wickersheimer's fluid. Any skeleton or animal substance dipped in this fluid retained all its original softness and pliability. The fluid, he believed, among other things, contained arsenic—the preservation of the object, in his opinion, being mainly due to the action of this chemical. He (Mr. Trinks) had still in his possession some microscopical specimens preserved with this fluid.

Edinburgh Photographic Society.

The second meeting for the current session was held at the Society's rooms on Wednesday, 3rd December, Norman Macbeth, Esq., President, in the chair.

The minutes of the last meeting having been read and approved of, the following gentlemen were declared duly elected:—Messrs. W. A. Bryson, G. Napier, Chas. Murray, Aitken, W. Skinner, J. W. Miller, Henry Cowe, Herbert W. Bibbs, Robert Lindsay, Donald Mackenzie, and Alexander Thompson.

The report of the Council on the study of the picturesque was then submitted.

The Chairman, in submitting this report, stated that of course this was a mere experiment, and it was impossible to say yet how it would succeed. It was thought by some that it would be well to hang the pictures for criticism on the walls, but after consideration it had been decided that it would be better to hand the pictures round for examination individually, and after all had been examined, then to give the members an opportunity of being heard on their merits and defects.

A large number of pictures were then laid on the table and handed round for inspection, after which, when they were all returned, the Chairman called the attention of the members to a portrait of a lady. He said that, in the meantime, the names of the artists were to be withheld, so that members might freely express their opinions; afterwards he would, so far as he knew, inform the members of the names of the parties submitting the work.

The comprehension of the comments made upon the photographs would be so dependent upon the illustration afforded by the exhibition of the pictures themselves, that we omit them.

Mr. J. B. Readman then read "A Plea for a Workroom for the Use of Members,' for which a hearty vote of thanks was passed.

Mr. Bashford then exhibited to the meeting a shutter analogous to that of Reynolds and Bransom, of Leeds, by Mr. A. A. Pearson. After explaining its working, he handed it round for inspection by the members.

The Chairman called the attention of the members to the annual dinner of the Society, which had been fixed to take place on Friday, the 12th inst., at half-past six.

A vote of thanks to the Chairman closed the proceedings.

Derby Photographic Society.

The first annual meeting was held at the London Restaurant, Iron-gate, on Wednesday evening, Mr. Richard Keene occupying the chair. The minutes of the last monthly meeting having been read and confirmed, the following officers were re-elected for the year 1885:—

President—Captain W. de W. Abney, R.E., F.R.S.

Vice-Presidents—Messrs. C. E. Abney, B.A., H. A. Bemrose, M.A., R. Keene.

Committee—Messrs. J. Cox, James E. Kaye, Thomas Scotton.

Hon. Sec. and Treasurer—Mr. Fred. W. Simpson, Mill Hill.

The Hon. Secretary then read the annual report, which was unanimously adopted. The Committee, in presenting their first annual report, congratulated the Society on the successful start which it has made. Although the Society had only been in existence six months, the members on the books numbered twenty-eight. The indoor meetings had been very fairly attended, and papers had been read. The Committee regretted that the out-door meetings had not been so well attended, and trusted that they might be more successful during the coming season. Excursions had been made to Duffield and Matlock during the past season. The thanks of the Society were due to Captain Abney as President, and to the retiring office-bearers; to Mr. A. J. Cox, for his kindness in providing a room for committee meetings; and to the proprietors of the photographic journals for copies of their papers. The balance-sheet showed the financial position to be satisfactory.

A vote of thanks was passed to the Hon. Secretary (Mr. F. W. Simpson) for his services during the past year.

Mr. Thomas Scotton then read a paper on "The Photographic Processes used in Copying Drawings" (see page 788), which he illustrated by some exceedingly fine specimens of the various processes, those by Pellet's process certainly carrying off the palm.

Votes of thanks were passed to the Chairman and Mr. Scotton, and the meeting was brought to a close.

Dundee and East of Scotland Photographic Association.

The third monthly meeting for the winter session was held on Thursday, the 4th instant, in Lamb's Hotel, Dundee, when there were about fifty members present. Mr. J. C. Cox presided.

An exhibition committee was elected, and Mr. D. Ireland, jun., was chosen as honorary secretary to the Exhibition, the joint treasurers being Mr. John Robertson and Mr. V. C. Baird.

Mr. Alfred Guthrie then read a paper on "Developers and Development" (see page 791), detailing his experiences with the different formulæ.

A very hearty vote of thanks was awarded to Mr. Guthrie for his instructive communication.

The Society's lime-light lanterns were then put in operation,

and a large number of slides were shown, the exhibitors being Messrs. Valentine, Mathewson, Ireland, Lawdon, and Jones. With the exception of Messrs. Valentine and Lawdon's slides, most of the others were on gelatino-chloride plates, which are now being extensively used for this purpose. Mr. John W. Lawdon, assisted by the Hon. Secretery, presided at the lauterns, and a vote of thanks was passed to these gentlemen for their services.

The Treasurer (Mr. Robertson) showed some large transparencies on gelatino-chloride plates of his own preparation, and another member kindly sent two frames of West's instantaneous photographs for exhibition.

The meeting was then adjourned.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

A SPECIAL Board Meeting was held of the above Association on November 21, to consider an applicatiou for assistance, which was granted.

On December 3rd, at the usual Board Meeting at 181, Aldersgate Street, the minutes of the previous meeting having been read and confirmed, another application for assistance was brought forward, and after the consideration of the facts connected with the case, a grant was made.

Mr. W. T. Smith and Mr. J. G. Gibson were elected as members of the Association.

The Board considered the advisability of appointing local secretaries in large towns, and would be glad to hear from any person willing to act in that capacity.

After disposing of other business, the meeting adjourned until Jan. 7th, 1885.

HALIFAX PHOTOGRAPHIC SOCIETY.

THE usual monthly meetiug was held on Tuesday evening, Dec. 2nd, REV. W. E. HANCOCK, M.A., in the chair. The minutes of the last meetiug were confirmed, after which the following new members were elected :—Colonel Chas. Grove Edwards, Rev. J. W. Hall, Messrs. L. Hanson, Rowley, W. Simpson, T. Helliwell, and Jas Thos. Smithson.

Mr. F. MYATT, who was to have given a practical demonstration of emulsion making, having beeu called away unexpectedly, the President exhibited his new four-wick lantern, together with a number of slides made from his own negatives. The great brilliancy of the light was a matter of much surprise to all the members. For pictures up to six feet in diameter it seemed to compare favourably with the lime light. The slides were produced by the wet collodion process, and were of high-class quality.

It was decided to postpone the next meeting to Tuesday, January 14th, when the usual annual lime-light exhibition will be given, the Rev. W. E. Hancock operating with his bi-unial lantern, and all the slides used on the occasion to be the work of the members.

Mr. E. A. CAW suggested that there was a considerable number of amateurs who would like to join the Society, but were prevented from doing so from possibly a feeling of diffidence, or an exaggerated idea of their own shortcomings iu the art; and he thought the Society, to give encouragement to such, ought to have evenings set apart for the special edification of those just enteriug up in the study of the art.

Mr. THOS. ILLINGWORTH quite concurred, and thought it was a very hard struggle for an amateur to attain technical excellence in matters photographic unaided; he was prepared to lead the way by giving an elementary demonstratiou of developing.

Mr. W. CLEMENT WILLIAMS, without meaning any slight to the professional element, considered that there were very few, even of them, who could lay claim to any mentionable knowledge of photographic chemistry. He thought, therefore, it would prove to the benefit of all members if certain half-hours of these meetings were devoted to the study of this branch of chemistry.

Mr. Councillor SMITH always liked to know the why and wherefore of everything; he infinitely preferred dabbling and experimenting among his chemicals, even if at times it ended in failure, than to be content with simply purchasing his plates and developing by a rule-of-thumb formula. He would be glad to do all in his power to assist in carrying out the proposals of Mr. Williams.

The PRESIDENT was prepared to do all in his power to further such praiseworthy objects.

Mr. JOSEPH WHITELEY promised to give lessons in making paper negatives.

Mr. EDWARD GLEDHILL would give a demonstration of micro-photography.

Mr. W. CLEMENT WILLIAMS would contribute papers on the artistic printing of negatives, and composition and light and shade in landscape photography.

Messrs. Birtwhistle, Hancock, Smith, Bingley, and Jones were also willing to contribute papers, the subjects of which to be left for future settlement.

It was stated Mr. Middlemiss would attend at the next meeting to introduce his new patent camera, the President reporting very favourably of its merits.

A vote of thanks to the President for his lantern exhibition terminated the meeting.

ST. HELEN'S ASSOCIATION OF SCIENCE, LITERATURE, AND ART.

Photographic Section.

A MEETING of this Section was held on November 19th, at the Association Rooms, 4, Salisbury Street, Mr. HEATHER in the chair.

Mr. BROOK showed a large number of full-plate negatives of American scenery; and Mr. HEATHER a series of lantern slides made from these.

Mr. BROOK read a paper on "Experiences with the Camera with the British Association" (see page 789), illustrated by transparencies projected on the screen.

A hearty vote of thanks to Mr. Brook brought the meeting to a close.

BRADFORD AMATEUR PHOTOGRAPHIC SOCIETY.

THE monthly meeting was held on the 4th inst., in the Law Institute, the President, Mr. DUNCAN G. LAW, in the chair.

The minutes of the November meeting were read and confirmed.

Several 15 by 12 photographs of Yorkshire scenery were exhibited by Mr. Forsyth, including some shown in the Pall Mall Exhibition.

A new French head-rest was also brought forward by the Secretary; being of metal nickel plated it is very strong but light, and fixes to the back of an ordinary chair; it is very suitable, therefore, for taking portraits in ordinary rooms.

A new patent camera was shown by Mr. Middlemiss, this having double swing front and back, and many novel points in its construction, besides being portable.

LEEDS PHOTOGRAPHIC SOCIETY.

THE annual meeting was held on Thursday, December 4th, Dr. THORPE in the chair. After the confirmation of the minutes, and the adoption of the report, the meeting proceeded to the election of the Committee, as follows :—Messrs. Branson, Denham, Marshall, Ramsden, Reffitt, Rodwell, Teasdale, Thornton, Thorpe, and Warburton.

The meeting then proceeded to the consideration of the following exhibits:—Mr. J. W. Reffit—Enlarging apparatus; Mr. Branson—Photo-micrograph apparatus fitted with electric lamp, instantaneous shutters; Mr. Teasdale—Photo-micrograph apparatus, micro-photograph apparatus, shutters, sensitometer, view-meter, and photometer; Mr. Warburton—Bellows camera; Mr. Foster—12 by 10 McKellen's new treble patent camera; Mr. Pearson—A new and very portable camera, the 12 by 10 size folding to 2½-inch thickness; Mr. Thornton—Bladey's pocket slide, Emerson's head-rest, &c.

GLASGOW AND WEST OF SCOTLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE usual monthly meeting was held in their Rooms on 2nd of December, Mr. HUGH REID, President, in the chair.

After approval of minutes, the following new members were admitted:—Misses M. H. Thomson, A. L. Robertson, Rev. Thos. Sommerville, Messrs. C. W. Laing, W. F. Finlayson, W. H. Gowans, James Fleming, John Dore, W. H. Turner, James Watt, and Robert Dalglish.

The election of office-bearers was then proceeded with, the result being that Mr. W. Snell Henderson was elected Treasurer, and the following six gentlemen members of Council for 1885 :—Messrs. James Elder, C.E., William Goodwin, R. Cutting, A. B. Ovenstone, T. N. Armstrong, and Charles Coulson.

Mr. T. N. ARMSTRONG then read a paper on "Home Por-

traiture" (see page 790), showing how variety of posing and lighting could be obtained in an ordinary sitting room. He then gave a demonstration of enamelling and retouching, and turned out a number of very fine prints.

Dr. Parker moved a vote of thanks to Mr. Armstrong, and after some conversation about the exhibition, which opens in the Fine Art Galleries on the 17th inst., the meeting closed.

North Staffordshire Amateur Photographic Society.

The usual monthly meeting was held on Wednesday, Dec. 3rd, at the Mechanics' Institute, M. C. Alfieri, president, occupying the chair.

A number of photographs from various sources having been exhibited, for the purpose of selecting a presentation print for the year 1884, upon taking the vote of the members, it was found that a 12 by 10 photograph by Valentin, entitled "After the Storm," had secured the greatest number of votes; the requisite number of copies was therefore ordered to be obtained.

After general conversation upon various topics of photographic interest, the meeting terminated.

Bury Photographic and Arts Club Exhibition.

The second annual Exhibition and Conversazione of the above Club was closed on Saturday last, after having been open five days; it was highly successful, and met with the approval of the public. There were no less than 270 photographs, 20 paintings in oil, and 16 water colours, in addition to paintings on plaques, and crystoleum paintings, the works of the members, which were placed round the room. The majority of the photographs were highly creditable, showing great taste in the selection of the views..

Mr. F. Cooper, one of the vice-presidents of the Society, sent 20 views, which were excellent in every respect. They included views of the interior of Walmersley Church, some pretty scenes in the Lake and North Wales districts, an exceedingly effective bit of Simpson Clough, &c. Next in order of position were 16 photos., principally cabinet size, by Mr. C. H. Openshaw, one of the younger members. These were excellent, and included views of Prestwich Clough and other scenery in the immediate locality. Mr. F. W. Livsey contributed a very large collection (no less than 85) to the photographic portion of the exhibition. There were among this large collection 15 views of Loch Riden and the Kyles of Bute, 12 views taken in Niddesdale. Miss Rosa Scott sent seven capital photographs of local views. Mr. T. J. Hutchinson contributed an equal number, and Mr. T. Entwistle four of views near Whitfield. The photographs exhibited by Mr. J. Nelson were very good; he, like Mr. Livsey, had gone somewhat wide afield with his camera, although in the opposite direction. Mr. Livsey's favourite haunts appear to have been in North Britain, while Mr. Nelson had gone to the south to spots sacred to Shakespere and Amy Robsart. Mr. H. M. Dearden contributed 60 views of Welsh scenery, Prestwich Clough, and other objects of interest in the neighbourhood. Of the 30 pictures shown by Mr. Robert Grundy, jun., of Parkhills, many dealt with Welsh scenery, and were beautiful in their effects. Mr. Grundy appears to have travelled over a considerable district in that part with his camera.

On Tuesday evening a conversazione took place, when an excellent string band, under the leadership of Mr. H. Sedgwick, played a selection of music. An exhibition of some of the works of the members projected on to a large screen by the oxy-hydrogen lantern was presented by Mr. E. W. Mellor, and Mr. F. W. Livsey gave the descriptive explanations.

Mr. E. W. Mellor exhibited Beard's patent self-centreing slide carrier, which had been kindly lent by Messrs. Stewart, of London, and which met with the general approval of the members.

Talk in the Studio.

Gossip from the Journal of the Photographic Society.—With respect to the nomenclature of scientific apparatus, it would appear that the wave of knowledge becomes very slow as its circle progresses towards the outside public; therefore it will not create surprise, when at one of the Lantern nights at the Exhibition a question was asked as to whether the Optical Lantern was a new method of electric lighting.—Is it an instinct, or what is it, that animates large bodies of visitors to judge so rapidly of the merits of pictorial photography? Whatever it is, there is something startling in watching the actual recognition of gems; at once, and as it were without hesitation, the voice of the many proclaims the judgment of the right thing. This was curiously evident every evening during the Lantern exhibition, when, after silence, a rush of applause immediately followed the appearance on the screen of some well chosen view, or choice bit of artistic effect.—One curious phase of the Exhibition was the intense interest taken in the apparatus by those who knew something about the use of the various articles on the table. Everything new or novel was scrutinised and examined with an eagerness which evinced a determination upon the part of the explorers to avail themselves of such exceedingly valuable methods, or ways, for enabling them to produce pictures, possibly in advance of what they had hitherto done, with also a pleasing idea of something new to be attempted.

The Prize for Improvements in Practical Photography.—Those reading a recent note may have supposed that it was Mr. H. T. Anthony, whose death we had to record not long ago, who offered the prize of 500 dollars. This, however, was not the case, as the prize was offered by Mr. E. Anthony, who is, we are glad to state, alive and in good health.

Paper Gummed on Both Sides.—Paper in sheets, half of which are gummed on both sides, and the other half on one side, and divided into strips and squares of different sizes by perforations, like sheets of postage-stamps, are very convenient in many ways—the doubly-gummed answering for fixing drawings in books, labels on glass, &c.—*The Chicago Lithographer*.

Death of Mr. H. Nathaniel White.—We regret to hear that this gentleman expired on Sunday last, at his residence in Sydenham. He has long been known as an enthusiastic amateur, and he received several medals for his enamel pictures.

International Inventions Exhibition.—The applications for space have now all been examined by sub-committees of the Council, and a selection has been made of the most promising. The number of applications has been so great that it has been decided to limit very strictly the admissions in those classes which may be considered to have been fully represented in the Exhibitions of the present and of the past year. The Council will, therefore, be obliged to refuse many valuable exhibits in such classes as those relating to Food, Clothing, and Building Construction. It will even be a difficult matter to accommodate those which have been selected, and it is feared that the list will have to be still further reduced. As soon as possible, information will be sent to those who have applied for space; but the enormous number of applications, far in excess of what was expected, have made it impossible to do this up to the present. The Guarantee Fund now amounts to £48,280, a sum considerably in excess of that subscribed for the Health Exhibition, or for the Fisheries, the amount for the former being £26,518, and that for the latter £26,656.—*Journal of the Society of Arts*.

Annual Dinner of the Photographic Club.—On Wednesday last, the annual festival of the Club took place at Andertou's Hotel, Fleet Street, Mr. W. Ackland in the chair, and something like sixty gentlemen sat down. The usual festive toasts were duly honoured; but the event of the evening was the presentation of a silver ink-stand and gold pen to the Honorary Secretary, Mr. E. Dunmore, as a mark of recognition for his services ever since the Club was founded in 1870.

Gas Explosion in Cheapside.—An explosion of gas took place last week at the establishment of Mr. E. Wood, Optician and Photographer, of 74, Cheapside, and two assistants were seriously injured.

Gelatino-Brom-Chloride Paper for Small Pictures.—Messrs. Morgan and Kidd inform us that as long as ten months ago they manufactured an emulsion paper containing chloride with a little bromide, and found that when this is developed with a weak oxalate developer, prints with warm brown tones result; also that by using a gold bath, any tone ranging from brown to a decided purple can be obtained. In order to obtain a smooth surface the finished prints are squeegeed face downwards on glass, and stripped when dry; but if mounted in the usual way the lustre is lost, as in the case of ordinary Lambertype prints. As the result of practical experience, Messrs Morgan and Kidd recommend the following method of mounting. When the prints have been squeegeed on the glass plates, the back of the paper is starched or slightly gummed, the prints being stripped when dry, as in the previously mentioned case. They are now trimmed and

made to adhere to the mounts by slightly moistening the latter with a sponge, and passing print and mount through a rolling press. Under the circumstances a pleasing half-gloss is the result.

CHEMICAL ACTION OF LIGHT.—According to D. Amato, many reactions which are said to take place through the direct action of light are not due entirely to that cause, but light appears to act only under certain determinate conditions of temperature; consequently, there are limits of temperature within which light does not act chemically. A mixture of chlorine and hydrogen, cooled to —12° C., can be exposed to the direct rays of the sun for hours without combination taking place. Care, however, should be taken that the chlorine is not exposed to the sun's rays even for an instant before cooling, as insolation renders chlorine capable of combining with hydrogen even in the dark. Silver chloride, if cooled to —12° C., is not decomposed by the direct solar rays; but if allowed to get warm, decomposition sets in immediately. Paterno has already observed that chlorine and olifiant gas do not combine in diffused light if the temperature is low.

A WATERPROOF VARNISH FOR PAPER.—One part Damar resin, and 6 parts acetone are digested in a closed flask for two weeks, and the clear solution poured off. To this 4 parts of collodion are added, and the whole is allowed to clear by standing.

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting, December 17th, will be "Microscopic Photography." Demonstration by Mr. T. C. White.

To Correspondents.

*** We cannot undertake to return rejected communications.

PRIORY.—1. Very full directions for preparing and working with gelatino-chloride plates will be found on page 168 of our YEAR-BOOK for 1882; and if you wish to obtain rich brown tones, the ferrous-citrate developer should be used. Dissolve 600 parts of citric acid in 2,000 parts of water, and add enough ammonia to make the liquid very slightly alkaline; but if excess of ammonia should be added by mistake, it can be got rid of by evaporating the solution until the excess is driven off. Next dissolve 400 parts of citric acid in the solution, and add enough water to make the volume of the liquid equal to double the water first used. Make up the developer by mixing 90 vols. of the above ammonium citrate solution, 30 vols. of a solution made by dissolving one part of ferrous sulphate in three of water, and six vols. of a solution of one part of sodium chloride in thirty of water. 2. We know of nothing which is better in this particular case.

JOHN H. WILSON.—The method described on page 90 of Eder's "Modern Dry Plates" is all that you require, if care be taken to properly follow the instructions.

ANXIOUS.—1. The coating on the paper is gelatine, but we cannot tell you whether it was originally a bromide or a chloride paper. 2. Those you mention are excellent, and we know of none that surpass them. 3. Yes, see page vii. of the advertisement sheet of last week's NEWS.

R. D. B.—1. A metal guide or templet must be used, and it is our impression that these can be obtained from most dealers in photographic materials. 2. They are ordinarily stamped or punched. 3. Judean asphaltum 4 ounces, benzole 10 ounces, masticated rubber 30 grains; dissolve the rubber first.

SUBALTERN.—The pictures are fair average work; but, perhaps, not quite up to the style of pictures issued from the best London studios. We can neither mention one as being exceptionally good, nor find one which altogether merits the term of reproach to which you refer. 2. Such language is too strong. 3. Unless the hundred sitters have proved exceptionally good ones, we should regard the enterprise as more akin to failure than to a success. 4. Without knowing all the circumstances, it is impossible to judge.

H. MILES.—1. You will probably find one of 5 inches focus (No. 3) the most useful. An adapter could be made. 2. It is only better when an extremely wide angle is required. 3. Such a proceeding would be of no service; the objectionable material must be removed. 4. Not for some weeks.

W. GOONE.—When parts are prescribed, everything must be taken by weight; but you may take your quantities in any term you like.

THOS. W. COOKE.—We should not hesitate a moment in deciding for the instrument which you mention first.

NOVICE.—Cyanide carefully used is the best thing: but even the best thing seldom removes the stain without ruining the negatives. Be more careful in the future.

A POOR PHOTOGRAPHER.—It is much slower, but there is no other disadvantage.

A. H.—A solution of "chloride of lime," soured by the addition of a little acetic acid, will remove the stains. The remaining part of your letter concerns the publisher, and has been handed to him.

C. D.—If there is any amount of silver worth saving in it, you must resort to the process of cupellation; but it is not probable that there is enough to make it pay.

H. D.—The plano or concave side should be turned towards the object, but the disadvantage of using it reversed is not very extreme. We imagine, however, that your lens is so mounted that you can turn it either way.

F. N. BRIDGEWATER.—The work is very carelessly done, and we think you should ask for the value of the mounts which have been spoiled. Of course a firm is very much at the mercy of the servants in a case like this, but better supervision ought to be exercised. We return the specimens.

CRYSOS.—1. If the manufacturers will not tell you, you cannot expect us to; but our impression is that the peculiarity rests with the colouring matters used. 2. Yes, a weak alkaline solution will carry the action further; try one part of washing soda in fifty or sixty parts of water. Of course this must be used warm. 3. It seems as if the tissue had been allowed to dry too slowly.

LIME-LIGHT.—Such processes as you refer to are modifications of the original calotype method, and very fine results may be obtained. The best account of them is contained in Abney's "Instruction" (page 167 of the last edition).

J. WHITELAW.—We posted them in an envelope, but with no other address than the name of your town. Enquire at the Post Office.

A. F.—1. You can only reach them by advertising. 2. They are not articles of commerce, so you you must get them made to order, or manufacture them yourself.

H. LAMBERT.—Thanks; next week.

S. DOBSON.—1. Unless the paper is coated with a layer of partially insoluble gelatine, it will not answer your purpose, and you had better proceed as follows: Dissolve one part of a tolerably hard gelatine in ten parts of water, and stir in one-twentieth of a part of bichromate of potassium. Float thickish paper on this solution, and hang up in a light place to dry. 2. There appears to us no reason why you should not use it as ordinarily sold, for a trace of moisture is of no importance.

RETOUCHER.—It would be unwise to use it, as the action would continue after you had finished; indeed, the only satisfactory method is to actually scrape away a portion of the film.

CONTENTS.

FLOATING ALBUMENIZED PAPER.

THE nitrate of silver which is taken up from the sensitizing bath when albumenized paper is sensitized, serves three distinct purposes. In the first place, double decomposition takes place between it and the soluble chloride in the albumen, so as to form silver chloride in the film of albumen, and a soluble nitrate, which remains in the solution. The silver chloride is, as all know, the principal sensitive substance in the paper. There is, besides this, another, however, an organic compound formed by the decomposition of the albumen itself by nitrate of silver. The formation of this second compound is a second function of the nitrate of silver. The third is that of acting as a "sensitizer." The silver chloride darkens only slowly if there be no silver nitrate present, nor any other substance which will take the place of the silver nitrate to absorb the chlorine given off when the chloride of silver is reduced by light.

To estimate the quantity of nitrate of silver necessary to convert the soluble chloride in the albumen into silver chloride is easy enough, if one knows how the albumen was salted, and how much each sheet takes up.

According to a formula given in Hardwich's, each sheet of paper of the usual size, 17 inches by 22 inches, takes up with the albumen about 7 grains of ammonium chloride. To convert 7 grains of ammonium chloride into silver chloride requires, as nearly as possible, 22¼ grains of silver nitrate.

We know of no reliable data for the amount of silver nitrate used to produce the organic compound referred to, but from experiments we have made with albumenized paper, estimating the amount of silver nitrate necessary to convert the soluble chloride, noticing the quantity of silver nitrate taken from the bath, and the quantity afterwards recovered by thoroughly washing the paper—without exposing it to light—we conclude that the quantity is very small, probably not more than two or three grains to the sheet.

The quantity of free silver nitrate remaining in the paper after sensitizing may very easily be ascertained. It is only necessary, after sensitizing a sheet, to wash the free silver nitrate out of it with distilled water, and to estimate the quantity of it in the usual volumetric manner. From estimations made by ourselves on the lines indicated, we may say that the amount of silver nitrate remaining in the paper in excess after sensitizing, is fairly represented by the actual diminution in bulk of the printing bath. We mean that, for example, if three sheets of paper take up one ounce of a sixty-grain bath, there will remain in each sheet of paper twenty grains of free silver nitrate, the further nitrate required to produce the chloride of silver and organic compound serving only to weaken the remaining solution.

Taking Hardwich once more as an authority, we find that an average quantity of bath to be used up by a quire of paper is eight ounces; that is to say each sheet of paper removes one third of an ounce of fluid from the bath.

Our own experience would incline us to put this figure a little higher in ordinary circumstances; the quantity absorbed varies greatly with the paper. Thick paper naturally absorbs much more of the bath than thin paper does. Making an average, we should say that a quire of paper reduces the bath by about nine or ten ounces. Taking this quantity as correct, and supposing the bath to be a sixty-grain one, we find that almost precisely the same quantity of silver nitrate is taken up merely to form a chlorine absorber, as is used to form the important sensitive salt. This appears to be somewhat extravagant, and has been felt to be so for a long time. More than twenty years have elapsed since it was pointed out that the silver bath might be greatly reduced in strength if part of the silver nitrate were replaced by sodium nitrate, which would serve as well as the silver nitrate to coagulate the albumen of the film. Doubtless economy resulted; but somehow, so far as we know, the method was never very popular.

There are other methods of economizing, however, which ought to be taken notice of. It is well known to practical printers that it is a great advantage to have the albumenized paper damp before it is floated. The edges do not curl away from the bath in the aggravating manner that they do when the paper is dry, and air-bubbles are less likely to be formed. These advantages are fairly well known, but we do not think that it is known how great an absolute economy there is in using the paper as damp as is practical, this economy arising from the mere fact that much less of the nitrate of silver bath is absorbed by paper when it is damp than when it is dry. We were astonished to find how great an economy really results from the use of damp paper.

Some time ago we were working with a very highly albumenized and very thick paper which reduced the bulk of the bath very greatly. We noticed that the amount of bath absorbed varied with the dampness of the paper, and determined to find out the extent of the variation.

We first used the paper very dry—as dry as it was practicable to handle it. We discovered that each sheet reduced the bath by more than half a fluid ounce.

We next made the paper as damp as was possible without danger of softening the albumen. We now found that each sheet absorbed barely one-third of an ounce of bath. The prints given by the paper sensitized when damp were of quite as good quality as those got on that sensitized dry. The bath which we were using was a sixty-grain one, and we found the damping of the paper to result in the saving of quite 12 grains of silver nitrate per sheet, or not far short of 380 grains per quire.

Concerning the manner of damping the paper, a few words may be said.

It is a common plan to keep albumenized paper in a damp cellar. In fact, this course is often recommended by dealers in albumenized paper. Many have not a cellar damp enough at their command. Moreover, it is objectionable to store albumenized paper in a damp place. It should merely be placed in such, if such be available, a few days before it is to be used, which often involves some trouble.

Abney recommends that the steam from a boiling kettle be allowed to play on the paper a moment or two before it is sensitized.

The following is the plan we have ourselves adopted:—On the shelf of a cupboard which has but one, the albumenized paper is laid flat, the albumen sides of the sheets upwards. Half an hour before commencing to sensitize, a vessel of boiling water is placed on the bottom of the cupboard. There is room for the steam to pass up between the front edge of the shelf and the door of the cupboard. The water is replenished from time to time during working. The paper is thus kept very damp, and apart from the saving in silver effected, the comfort in working is greatly increased.

AT THE WHEEL: BY G. HADLEY.

Mr. Hadley, at any rate, shows that it is quite possible, by the aid of photography, to make an effective picture out of an every-day subject, and the little study which forms our supplement this week was much admired by the visitors to the Pall Mall Exhibition. As regards the making of the picture, Mr. Hadley says:—

"It is one of a series of pictures taken during a short visit to Whitby during August last, and the weather being too dull for distant views, I went down to the quay with my apparatus, when I was attracted first by a group of two women selling fish at a rude stall, and, thinking this a fit subject, I lost no time in securing it. A little further on I noticed a group of fishermen lounging on their smack. After exposing a plate on this second group, I went further up the quay and saw a coasting-lighter, which had just put in with a cargo of coals. This, I thought, would make a capital picture, but as the man who was actually at the wheel had not, to say the least, a very picturesque figure, I went back to group two, and asked one of the men to stand at the wheel of the lighter. This he at once consented to do, and having obtained permission to go on board, in a few moments I had my picture. The man evidently knew his work, and I had therefore no trouble in posing him, beyond telling him to advance his left foot and grasp the wheel firmly with his right hand in order to bring out the muscles of hand and forearm. Perhaps it is not necessary to say that he was already provided with a short pipe when I engaged him.

"Before closing this short notice, I should like to point out to my brother photographers the absolute necessity for cultivating *the faculty of observation*, without which success need not be looked for. Effective 'subjects' are by no means so rare as many seem to think, though perhaps the faculty of seeing them may be dormant; for instance, while exposing my plates on these 'Whitby subjects,' two photographers were looking on, and could not see anything worth taking.

"With regard to the development of the picture, I may say that it was developed with 'hydrokinone,' as indeed were all my other exhibits. In fact, I have used no other developer for negatives for nearly three years."

NORTHAMPTON PHOTOGRAPHIC EXHIBITION.

The committee intrusted with the organization of this Exhibition have reason to be satisfied with the result of their labours, for in response to their invitation a very large number of photographers throughout the Kingdom have contributed, and consequently the present Exhibition may be regarded as a thoroughly representative one. The spacious and well-lit gallery, forming part of the Guildhall buildings, has been lent for the purposes of the Exhibition, and is most admirably suited for the display of pictures; the general effect on entering the room being most satisfactory. The walls are well covered, and in addition several large screens are completely filled; moreover, a well-lit corridor is devoted to Platinotype pictures and examples of photo-mechanical printing. There are 630 numbers in the catalogue; and the average excellence of the work is unusually high, the proportion of really bad pictures being very small indeed. We shall not give a detailed account this week, and for the present we will merely mention the awards of the judges, which are as follows:—

Large Landscapes—Silver medal (315), T. M. Brownrigg; bronze (433), T. A. Green.

Small Landscapes—Silver medal (567), W. B. Berkeley; bronze (319), T. P. Gibson.

Large Portraits—Silver medal (136), R. Faulkner; bronze (138 and series), H. E. Mendelssohn; extra bronze (317), J. Lafayette.

Small Portraits—Bronze medal (537), W. Gillard; bronze (13 and 16), F. Greene.

Instantaneous Marine Views—Silver medal (328), West and Son; bronze (389), W. P. Marsh.

Instantaneous Views—Silver medal (439), W. Cobb; Bronze medal (425 and series), T. G. Whaite.

Interiors—Silver medal (449), E. Dunmore; Bronze medal (295), T. Fall.

Genre—Silver medal (103), A. Diston; Bronze medal (458), G. Hadley.

Enlargement—Silver medal (190 and series), H. Dixon.

Transparencies—Bronze medal (514), P. H. Fincham.

Local views—Bronze medal (203), C. Law.

Extra silver medal for Landscapes with figures (121 and series), H. P. Robinson.

Extra bronze for Marine Studies (358), Abel Lewis; (284), F. M. Sutcliffe.

Extra bronze for Still Life (65), Mrs. Glen Payne.

Extra bronze for Photo-Mechanical Prints (603 and series), R. Schuster.

Silver medal (339), H. A. H. Daniel.

The opening ceremony, presided over by Sir Henry Dryden, took place in the presence of a large number of persons.

GLASGOW AND WEST OF SCOTLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

The second Annual Exhibition opened in the Fine Art Galleries on Wednesday, the 17th. Marked improvement, both in quality and in the number of exhibits, was noticeable. The prizes were awarded, as before, by the votes of the members.

First-Class.—"Scenes on Loch Lomond," S. Murray; "Old Church, Roseneath," and other pictures, W. Goodwin; "Toll House" and other pictures, W. Goodwin; "Afternoon Milk," J. L. Coulson; "The Artists," Miss Thompson; "Swans," J. L. Coulson; "Washerwomen," Chas. C. Coulson; portraits, T. N. Armstrong; portrait, T. N. Armstrong; groups, A. J. W. Reid; groups, W. A. L. Peock; "Three Horses," A. J. W. Reid; "Animal Studies," R. T. Cochrane; "Reflection on the Cart," W. C. Hume; "Thermac of Caracalla," Wilfrid Smith.

Second-Class.—Alex. McDonald, A. B. Ovenstone, T. N. Armstrong, R. T. Cochrane, D. Pratt, J. C. Oliver, H. G. Gillespie, W. Lang, jun., Chas. C. Coulson, W. S. Anderson.

Amongst the non-competitive pictures the best were Mr. Parker's, Mr. Finlayson's, Mr. Prate's, Mr. Napier's, Mr. McDonald's, and some lovely specimens of large heads by Mr. Stewart.

HINTS ON POSING AND THE MANAGEMENT OF THE SITTER.

BY H. P. ROBINSON.

Chapter IX.—Expression in Portraiture.

"Every man is as God made him, and oftentimes a great deal worse," said Sancho Panza; and, if we may judge by the productions of the majority of photographers, his opinion is singularly true. Let us not blind ourselves to the fact that ordinary photographs are very ordinary indeed. The dead level of good work has spread like a disease, and he is a very poor photographer who cannot take a passably good portrait—one that, seen by itself, would pass muster as real gold with the average unobservant person, but which would turn out mere tinsel when placed side by side with the work of a master. It would be difficult to at once tell what was the difference. An old friend of mine used to say that it was "That!" accompanying the word with a snap of the fingers, by which he meant to express that last touch by which genius carries its work just beyond the goal reached by mere talent—a mystery which it is impossible to explain, but which is felt in all art. In photographic portraiture it will be found to depend almost entirely on the expression of the face, aided by the attitude of the figure, which should be in keeping with the expression, and be easy and characteristic. To obtain the best expression, the photographer should be not only an art student, but a student of human nature. He should not only be able to pose his model in a graceful or appropriate position, to place him in an effective light, and to get a good technical negative of him, but, if he is to be the ideal photographer,

"That perfect monster which the world ne'er saw,"

he must be able to sum up his sitter at a first introduction, and determine at once, amongst other things, the expression which would best suit that face, and to work up to that expression during the usually brief interval that elapses between introduction and exposure.

Have you ever noticed, when you are about to take a portrait, and are endeavouring to call up an animated expression on the countenance of your sitter, what a dogged determination he sometimes has not to be beguiled out of the moody expression he has assumed? At last, when you have tried all the subtleties you know, you ask him, in desperation, if he has not got such a trifle as a smile with him. He immediately answers with a charming expression you long to secure, "Oh, no! when I smile in a photograph, I always grin." Here is another sample of a good model gone wrong through the stupidity of photographers. Many operators think that if they make their sitters smile—they don't care about the quality of the smile—they have done their duty in their own particular state of life, forgetting that many people look idiotic when their simpers and smiles are perpetuated. Others seem to think that all expression consists of gush, and wake up the features to an unnatural degree of intensity. The photographer should endeavour to represent his sitters as moderately calm ladies and gentleman; or, if they are not entitled to the courtesy title, then as decent men and women.

Some faces are beautiful in repose, hideous in movement. A broad laugh is often beautiful in nature, because of its evanescence; but it becomes intolerable when it is fixed on paper. But there is a look of animation, far short of a smile, which suits nearly all faces, and which is so permanently beautiful that it deserves to be printed in carbon or enamel.

John Gibson, the famous sculptor, considered a smile frivolous; but what would be undignified in sculpture may be proper to less severe modes of artistic expression. He says, in a letter to a friend:—"The fault of the portraits of the present age is, that every man is expected to look pleasant in his pictures. The old masters represent men thinking, and women tranquil; the Greeks the same. Therefore, the past race of portraits in paint and in marbl look more like a superior class of beings. How often have I heard the remark, "Oh! he looks too serious." But the expression that is meant to be permanent should be serious and calm."

This is true enough of the expressions of men, but I cannot help thinking that the cheerful expressions of ladies and children are their best, especially when they are educed with such art as to appear perfectly natural; indeed, some of the most delightful portraits of children represent them in a very happy frame of mind.

The quality necessary in a man to enable him to draw out the best expression is "a gift." It may be improved by education and practice, but it is not to be attained by those who have it not in their natures. The latter may do high-class work, but never that which electrifies. A fine work should always give that feeling of pleased surprise which sends a glow of pleasure through the frame. This is never obtained through the intervention of that photographer who has not the proper "music in his soul."

When a man goes to have his portrait taken, his mind will, consciously or unconsciously, dwell upon the ordeal he is to go through; he will think of how his coat fits, how he feels, and how he will look; it should be the business of the photographer to make him forget all this—and himself. The man's appearance is positively deteriorated by constant reference to self, and the consideration of how he looks when sitting for a portrait. Now what that phase conveys is exactly that which should be avoided. It is needless to tell photographers that one half their sitters think they know how to sit, and it is equally unnecessary to add that this knowing moiety are his worst sitters.

The kind of conversational treatment that would best suit every sitter must be left for each photographer to decide for himself.

Everything so much depends on such small things, that it would be difficult to say much about them without opening a wider subject than is here intended; but the photographer would find it would simplify his labour, and be a kind of aid to thought, if he made a rough classification of his sitters, such as those who are best let alone. These are those who are ordered to have their portraits taken by their friends, and do not care how it is done; they usually obey the photographer's directions without question, and their portraits are always natural. The nervous, who require very delicate treatment; those whom a bluff treatment would suit and those who claim the greatest show of respect; and, above all, those who "hate being photographed." These last-mentioned are the sort I like if I have time to deal with them properly. It makes one feel a professional pride to so work these difficult sitters that they shall feel that although they came to you with reluctance, they leave with regret. This, I find, is often the case with children. They will sometimes scream at being brought, and scream at being taken away. Then there is that much respected person who thinks he can teach you your business—the best way is to let him; it pleases him and doesn't hurt you.

A great deal of expression, and that of the most agreeable kind, may be produced by the action of the figure, as well as by the features. Appropriate action may give life and animation to a subject not otherwise attainable. A man would not look very happy if he held down his head, and tucked in his chin, smiled he never so pleasantly; while a very little animation in the features will have an agreeable effect if it is properly backed up and assisted by an animated turn of the head; but, at the same time, straining after expression must be avoided; the happy mean is what the judicious photographer should strive for and get.

Some photographers seem to do all they know to awe their sitters into their worst expressions. A lady who was recently sitting to me told me her experiences in getting her portrait taken in a well-known studio in London. An appointment was made beforehand. The door was opened by a man-servant in a gaudy livery. The lady was ushered up

stairs, and kept waiting for half an hour, with nothing to amuse her but the solemn grandeur of the place. In the studio there were three photographers to attend to her; one to work the camera, another to move furniture and place the head-rest, and a third in white kid gloves to take command of the posing. The two latter talked over the personal appearance of the sitter as if she was an unintelligent lay figure, which she says she felt she had become before the exposure commenced, and she looks like it in the print.

I cannot understand how it is possible to make a sitter feel at his ease if the operator has a lot of assistants to help him. Sitting for a portrait should be a matter for friendly intimacy between sitter and photographer, not a solemn ceremony.

Those who still look at photography with withering contempt—and some exist to the present day—just as it is thought that rare individuals of the plesiosaurus are yet to be found in the deep seas—complain that photography has no power to idealise; but if they had any knowledge of our mysteries they would know that it is no longer the truthful art it was when it was famous for having no mercy.

These critics take it as a foregone conclusion that a portrait should be idealised. The notion that the artist should invest his sitters with a grace not their own, seems never to have been doubted. Dr. Johnson said that it was one of the highest proofs of the genius of Reynolds that he contrived to give nobleness to the head of Goldsmith in his portrait, whose genial soul and fine intellect were not habited in a very dignified or handsome body. If Reynolds gave to Goldsmith a nobility of countenance which nature had denied, but which the painter conceived was more characteristic of the inner man than the actual presentment, then we have in the portrait Reynolds' conception of what Goldsmith ought to have looked like, and not the actual portrait of the man. If he merely depicted him at his best, happily catching the expression which lit up the face when it was aglow with some happy thought, then he did not give Goldsmith the noble look, but, with the true painter's skill, readily detected the noblest effect, and gave permanent form to a transient expression; he did what every photographer should try to do, and when he succeeds he may expect to hear the sitter's friends exclaim—

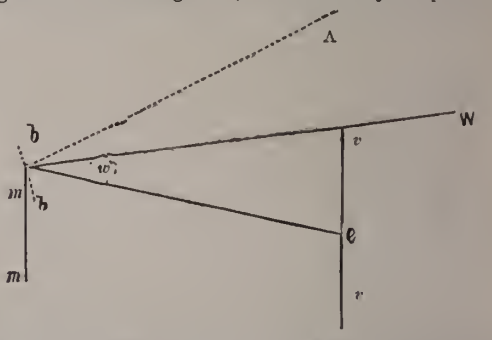
"Masterly done:
The very life seems warm upon the lips;
The fixture of the eye has motion in it,
And we are mocked by art."

AVOIDING REFLECTIONS AND GRANULARITY IN COPYING.

BY W. E. DEBENHAM.

In copying photographs and other pictures by the camera, the two chief difficulties that occur to those otherwise skilled in photographic manipulations, are the fogging or weakening of the shadows in parts, caused by reflections from the surface of the picture to be copied; and the granular appearance caused by photographing not only the picture itself, but the grain or irregularities of surface of the paper or other material upon which the picture has been produced. I have known a skilful operator—perhaps the most capable all-round portrait photographer as poser and manipulator combined that I ever knew—copy a photograph from which an enlargement had to be made, in such a light, that the irregularities of the paper of the original came out with so much strength and distinctness, as to require at least an extra day's time of artist's work in finishing the enlargement. Even then probably the resemblance to the original would not be so good as might have been the case, if the picture to be copied had been placed in favourable conditions of lighting. In this particular instance the original print was upon paper, the albumen surface of which had cracked all over, as was not unfrequently the case a few years ago, when very highly glazed surfaces were sought for.

In order to get at the principles which govern the occurrence or avoidance of interfering reflections when copying, let us take a case of a typical kind, and suppose that a mirror has to be so photographed, that the glass shall be represented by blackness, and the frame and any tracery, drawn (say) with French chalk here and there upon the glass, shall be represented in their proper form and gradations in the copy. This supposition is not a fanciful one, but actually represents very closely the copying of a Daguerreotype, and may be shown, though somewhat less obviously, to represent the copying of any picture where there are reflections to be avoided. It is assumed that the mirror is vertical to the direction of the camera. Well, an eye placed in the position of the lens will see itself reflected in the centre, and in the various other portions of the mirror will see those objects reflected whose images fall upon the mirror at the same angle as, but in the contrary direction to, lines drawn from the eye to each portion of the mirror. This fact is expressed in the well-known law of optics, that the angle of reflection is equal to the angle of incidence. Perhaps a diagram may help to make matters more clear. Let *m m* be a mirror, and *e* the eye of the observer, then if a window exists in the direction W, the eye will see itself in the centre of the mirror, about the centre of the face of the observer and at *w* an image of the window, together with the various other objects which fill up the intermediate space. All this in place of the blackness which the conditions assume as desirable and even necessary for the object required. The portion of the mirror where the image of the window is seen will appear so bright, that the chalk marks on the mirror, which were to represent light on a black background, will be dark by comparison.



Now let *v v* be a black velvet curtain, with a hole at *e* for the eye to look through; the pattern traced upon the mirror will show clearly against the black background of the velvet curtain. In order that this blackness may be more perfect, and not interfered with by reflections of the pile or folds of the velvet, or by the reflection of the eye looking through the hole, let there be no source of light in front of the curtain—that is, between the planes *m m* and, *v v* if both of them were extended infinitely—but let the light come from behind the plane of the curtain over its top and round its sides.

It will be noticed that the curtain *v*, *v*, must be of such dimensions that lines drawn from the eye to the extremities of the mirror, and returned at equal and opposite angles, shall fall within the surface of the curtain, therefore if the curtain be upon the same plane as the eye, it must be of at least double the dimensions of the mirror. In practice, the dark surface must be larger than this, and for the following reasons. The mirror is assumed, and may be considered to have a perfectly plane surface. The surfaces with which we have to deal are not perfectly plane; and although the deviations from flatness may be very small, they will be sufficient to require a certain allowance. These deviations are of two kinds—first, such as may be most strikingly illustrated in a Daguerreotype, the plate of which is bent, if ever so slightly. Suppose the Daguerreotype to be so much bent that that part of it which is at *w*, lies in the direction of the dotted line *b*, *b*, the angle of incidence would be in the direction of the dotted line *w*, A; and in order to prevent reflections from any light object being seen in the plate, and appearing as false light in what should be the shadows, the screen would have to be extended until it cut that dotted line. A picture to be copied is not likely to be as much out of truth of level as is shown in this diagram, but it is difficult to make slight variations from flatness evident in a sketch. Nevertheless, these variations occur, and must be provided for by a certain extension of the non-reflecting surface.

The second kind of irregularity of surface which requires the extension of the non-reflecting screen, is that which arises from the nature of the surface of the picture to be copied; that is, in the

* Read before the London and Provincial Photographic Association.

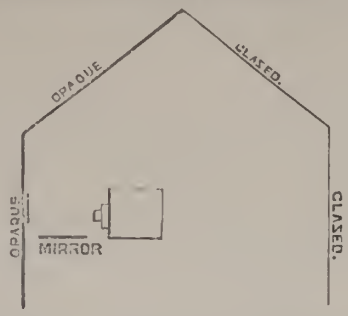
case of paper pictures, each elevation caused by the grain of the paper will have a surface on one side inclined towards, and on the other side away from, the source of light. This inclination is very small, but unless it is taken into account, and if the non-reflecting screen be not large enough to include lines drawn from the lens to each part of such inclined surface and carried back at a similar angle, there will be reflections from one side of each elevation or prominence. This will produce an effect which I dare say many will remember to have seen on the top of a copy of a paper photograph, the effect of a blanketn sort of texture.

The blankety texture just referred to is not to be confounded with what is known as granularity, although both proceed from the roughness or grain of the original. The former is confined to the side or top of the picture on that edge which is nearest the source of light, whereas the latter effect is visible all over. The former effect, moreover, may be got rid of by employing light falling at an angle nearly parallel to the plane of the picture; that is what is called strong side light, whereas the general texture or grain which proceeds from the irregularities or texture of the picture copied being lighted up more on one side than the other, is aggravated by this side light (whichever side, top or edge it comes from), and is ameliorated by the light being made to come as much from the front as possible. If a sheet of rough drawing paper be held so that the light falls upon it nearly sidewise, the grain will be strongly visible; but if the light fall on its surface almost perpendicularly—say over the shoulder of the observer who holds the paper square in front of him—the grain becomes almost invisible. If the paper be held so that two equal lights fall upon it from opposite directions the sides of the prominences that receive the least illumination from one source of light will receive the most from the other, and the surface will be greatly equalised. If, however, these lights be of the nature of what has been referred to as strongly side lights, there will be pits and prominences which receive more or less light, and some grain will still be apparent.

The question now arises, how is it best to carry out in practice the principles that have been discussed. First, the light must not come so much from the front as to cause reflection; second, the light must come as much from the front as possible, consistently with the first requirement, in order not to bring into strong relief the grain of the paper; third, there should be at least two sources of light proceeding from opposite directions. If a ring or circle of light could be secured coming from a direction behind and around the observer (or the lens), and at just such an angular distance as to avoid being reflected from any shining or polished part of the surface of the picture to be copied, the most favourable results should be obtained. This is very nearly the plan which was adopted and recommended long since, of laying the picture upon the ground, and suspending the camera vertically over it. Of course there must, in order to avoid reflections, be a screen on or below the camera, or else a canopy above, of the dimensions indicated by the requirements shown in the diagram.

The method of copying on the ground, however, is inconvenient, and other plans have been devised. One such plan consists in a prolongation of the camera by four rods at the corners, as far as the plane of the picture. This prolongation is surrounded by tissue paper; the sides which are nearest to the light diffuse it, and those farthest from the light reflect back a considerable amount, so that the grain is lit more or less from all sides, and is very little visible. The lens, however, receives as much light upon it or its mounting as the picture does; this light is just where it will cause the most reflection, so that the brass mounting should be provided with a tube or hood covered with black velvet. Another plan, and one that I have known adopted with success, is to cover a sheet of millboard with velvet, and fit it on to the hood of the lens. With this arrangement, however, the camera should be pointed so that the light from the window or sky does not fall upon the lens, as it would, for instance, if the whole arrangement were worked parallel with and close to the window. In such a case I have seen the brass rim of the lens reflected in a Daguerreotype which had been set up to be copied. Moreover, unless a lens of long focus be employed, the screen, if large enough to be effective with all sizes of picture that may have to be copied, will, especially when the lens is brought near the original in order to make an enlarged copy, be apt to cut off the front light too much.

The plan which I adopt is to fix the picture upon the middle of the wall of the shady side of the studio. The studio is of the ordinary central ridge kind, and the south side of both ridge and upright wall is kept opaque. The light from the whole of the opposite ridge and glazed side fall upon the picture, but reflections are in the ordinary way avoided by using a large camera, the front being more than twice as long as the picture to be copied, with a



lens of long focus, of course. If the picture is so large, or the surface so irregular, that the surface of the camera is not large enough to make sure against reflections, a background screen may be placed behind it. This, if so far removed from the picture as to receive light from the top or ridge light of the studio, should be tilted forward sufficiently to prevent that; or a simple plan may be adopted—that of placing something upon the camera just high enough to cut off reflection.

The light as arranged falls very much from the front, and from a considerable surface—twenty-four feet in length, twelve on each side of the camera—so that the grain of the paper is not very evident. In order, however, to make it still less so, a mirror is placed horizontaliy below the picture between it and the camera. A sheet of white card may be substituted as more convenient than the mirror, but is not quite so good.

What has been said has reference principally to copying photographs upon paper, and for other subjects some modifications may be necessary or desirable. Oil paintings and artistic designs generally are produced with the light coming over the artist's left shoulder, and the painting may show less grain when lit up from the same direction as that in which it has been painted than when equally lighted from all directions. In this case, while what has been said as to the avoidance of reflections will still apply, the direction of the light may be altered to what is required, by blinding one-half (the right) of the studio, or by copying in the length of the studio instead of its breadth. With Daguerreotypes, again, it will generally be desirable to place them upon their side, as the polishing of the plate (except those of the stereoscopic form) was in the direction of lines across the picture. If anyone hold a Daguerreotype under a vertical light and change its position as indicated, he will observe a great difference of brightness.

Various plans for avoiding granularity in copying have been suggested, which are not based upon the considerations that have been referred to. One such plan is to copy with a lens somewhat out of focus. Another is to move the lens during exposure. It is obvious, however, that with such methods the loss of sharpness of texture of the grain, must be accompanied by loss of sharpness of the details of the photograph, at all events of such details as are defined in lines not broader than the grain which has to be got rid of. Of course cases may arise in which it is desirable to lose the sharpness of the original picture, but not when an exact reproduction of it is required. I once had occasion to make an enlargement from a pen-and-ink sketch portrait of a gentleman; the enlargement was to match and form a pair with one of a lady which had been made from a photograph in the usual way. I therefore copied the drawing with a lens possessing no sharp focus—the back of a portrait combination—and the softened edges thus given to the ink lines, enabled the artist to paint the enlargement with a sufficient satisfactory resemblance to a photograph from life.

Naturally the less grain there is upon the surface of paper photographs, the less there will be to be copied; and an obvious preparation for copying is to roll the print well if the surface requires it. I have known burnishing successfully adopted for the same purpose.

DEVELOPERS AND DEVELOPMENT.

BY ALFRED GITHRIE.*

I shall now go over in a very short way some of the developers at present in use, and, as far as I can, the mode in which those developers should be employed. I have already alluded suffi-

Continued from page 91

ciently to the ferrous oxalate, and will take the pyro and potash developer. The formula is as follows :—

No. 1.—Pyro. Solution.

Warm water	2 ounces
Sulphite of soda	2 ,,

When cold add—

Sulphurous acid	2 ounces
Pyrogallic acid	½ ounce

In all cases these weights are calculated at 437 grains to the ounce.

No. 2.—Potash Solution.

A.

Water	4 ounces
Carbonate of potash	3 ,,

B.

Water	3 ounces
Sulphite of soda	2 ,,

When dissolved, mix A and B. These two stock solutions will keep a very long time. I have some made up last spring as good as when first mixed. In this developer purity of the ingredients is a *sine qua non*. For instantaneous exposures take three ounces of water, and add three drachms of No. 1 and 2 drachms of No. 2. This, being a very strong solution, will usually bring out the image rapidly and with full density; but if more strength be necessary, add No. 2. For ordinary exposures and very rapid plates (not drop shutter) less than half this strength of developer will be found ample; in fact, one drachm of No. 1 and half-a-drachm of No. 2 to three ounces of water will be found to give excellent results, with the shadows clear, and at the same time, having all detail. Should the plate, however, not give sufficient density, one or two drops of a solution of ammonia—one to ten of water—will be found to act very rapidly, and give density to the image. Though I have given these proportions they are, of course, subject to considerable variation with the nature of subject and amount of exposure given. If over-exposed, less of No. 2 and weaker development; if under-exposed, more of No. 2 and stronger developer—more of No. 1 for vigour, and more of No. 2 for detail. This developer does not stain or cause fog, though it is said by some to cause frilling. This, however, is not my experience.

Next, the washing soda developer :—Stock Solution No. 1—Add clear crystals of soda till no more will dissolve.

No. 2.

Water	40 ounces
Oxalic acid	96 grains
Bromide of potassium	40 ,,

For use : to one ounce of water add a-quarter of an ounce of No. 1 and pour over the plate. Then take one ounce of No. 2, add one grain of dry pyro, pour the soda solution off the plate into this, mix, then pour on the plate, and you will get any amount of density and detail if you have exposed properly. Another formula gives :—

No. 1.

Sulphite of soda	4 ounces
Hot water	10 ,,

Add four ounces of sulphurous acid, and pour into one ounce of pyrogallic acid.

No. 2.

Washing soda	3½ ounces
Sulphite of soda	¾ ounce
Water	64 ounces

For use; take one drachm of No. 1 to each ounce of No. 2. This formula will also give plenty of density and detail where correct exposure has been given. If plates are over-exposed, twice the quantity of water must be used. The washing-soda developer seems to have very little power to force up an under-exposed plate, and an alum bath must always be used to remove the yellow colour given to the negative. Of the two formulæ above, the one mentioned first gave me the most satisfaction.

Sulphite of Soda.

There are several formulæ given in the photographic journals, but the one I like best is—

Sulphite of soda	4 ounces
Hot water	56 ,,

Neutralise with citric acid, and then add one ounce of pyrogallic acid.

No. 1.

Ammonia	1 ounce
Bromide	180 grains
Water	40 ounces

With equal parts of Nos. 1 and 2 for correct exposure. This is an excellent developer, and I prefer it in every case when copying. For under-exposure more of No. 2, and for over-exposure less. With this formula you can have thorough command over your plate, though there are some plates which give green fog and metallic stains when any attempt is made to force them with this developer; but the rule is a brilliant, bright negative. The ferrous-oxalate, the potash, the washing-soda, and the sulphite-of-soda developers can be used over and over again till exhausted.

For a rapid developer the one I like best is Swan's :—

No. 1.

Pyrogallic acid	30 grains
Water	10 ounces

No. 2.

Ammonia	1 drachm
Bromide of ammonium	1 ,,
Water	10 ounces

With equal parts for correct exposure. This developer acts very rapidly, and, therefore, requires to be watched closely. For under-exposure more of No. 2, and for over-exposure less. The best way when using this developer is to add No. 2 a little at at a time till sufficient strength is obtained. New developer must be mixed for each plate.

THE PLATINOTYPE PROCESS.

BY H. G. TEMPLETON.*

Although this process has not yet become so popular as it ought to be, yet I think if its merits were better known it would be more appreciated by the public than it now is. Allow me, then, briefly to point out what I would claim as the peculiar merits of the platinotype process.

First, I would claim for it the permanency of its prints—a point on which so much discussion has arisen of late with regard to silver prints, which have been a source of anxiety and vexation to photographers so far, and I am afraid will continue to be until we have more light thrown on what is the precise nature of a silver print. In the platinotype print, as its title denotes, the image is formed by the deposition of metallic platinum, so, if the cause of fading in silver prints is due to complex silver salts, this difficulty is entirely removed. Again : no sulphur compounds are employed in the development and fixing, and if hypo. be the scapegoat in silver prints, we have nothing to fear from that source.

Next, I would claim for it the greater rapidity in printing, namely, from one-half to one-third the time required to print from the same negative on silver paper, especially in dull weather, when the platino paper has the decided advantage. This has been accounted for by supposing the blue rays of the spectrum are equally as active on the platino paper as the violet, whereas the violet rays are necessary to impress the image on silver paper.

In the next place, I would claim the artistic softness and delicacy of the prints, which, when properly printed from a suitable negative, more resemble a fine engraving or well-executed pencil drawing.

And last, but not least, I must not omit to mention the simplicity of the process, which renders it so admirably adapted to the requirements of amateurs who have not the time or convenience for the more troublesome washing processes necessary in silver printing, as the prints by this process can easily be finished off in half-an-hour, and when done they offer an excellent medium for the artist to colour upon without any fear of defects showing themselves afterwards. One of the chief objections raised against platinotypes is the coldness of the tone, but this has to a great extent been overcome by the introduction of specially-prepared paper and toning solutions, which give a sepia tint.

Another field has recently been opened for the platinotype process, namely, enlargements for the artist which can be readily executed by means of the solar camera or electric light, and form an excellent basis to receive the colours. Neither is this process

* A communication to the Newcastle-on-Tyne and Northern Counties' Photographic Association.

confined to paper, as equally good results can be obtained on linen or silk fabrics, and even on wood.

Having now put forth the merits of the process, allow me to explain the *modus operandi*. The paper is coated with a solution of ferric oxalate and potassic-chloro-platinite, and if I expose it to the action of light the ferric oxalate will become converted into ferrous oxalate, and if exposed behind a negative will give a faint brown image. All that now remains to be done is to cause this image to throw down the metallic platinum it contains, and this is readily done by floating it on a hot solution of neutral oxalate of potash, 130 grains to the ounce, and which I have raised to a temperature of 170° Fahr. in an enamelled iron dish, when the iron salts are dissolved out, and the metallic platinum thrown down *in situ*, forming a black image; or, if I use the special paper and add some of the toning solution to the bath, it will give a sepia-tinted picture. It only remains now to dissolve out any traces of iron salts which may remain in the paper by passing it through a two-per-cent. solution of hydrochloric acid, changing the solution when any trace of redness appears in it, and then washing them in frequent changes of fresh water for about thirty minutes, when they may be hung up across a string to dry.

Simple as the process may appear, there are, nevertheless, some precautions which must be observed:—First, the paper must be kept absolutely dry by being placed in a canister with calcium chloride, seeing that the printing-frames and pads are dry, and, especially in damp weather like the present, placing a piece of rubber cloth or oiled silk behind the paper in the printing-frame. By taking these precautions, there is little fear of the paper keeping; indeed, some I am using to-night I have had in my possession nearly two years. Second, not to continue the printing longer than is necessary to have a faint but distinct image on the paper. Third, to regulate the temperature of the bath to the amount of exposure the prints have received, under-printed ones requiring a higher temperature, and over-printed ones a lower temperature, always bearing in mind that the prints will appear darker when they are dry. Fourth, to see that the last acid bath is not in the least discoloured if you want to have pure whites. And, lastly, to obtain a licence from the Platinotype Company to work this process, which is a patent one, but which is not a serious obstacle, as for the payment of five shillings you can obtain a licence for the rest of your natural life on condition that you buy all your materials from them, which they supply at market prices.

HOME PORTRAITURE: LIGHTING, POSING, AND RETOUCHING.

BY T. N. ARMSTRONG.*

I now come to the other subject which we have to consider—retouching. It is to my mind the most delightful occupation an amateur can give himself up to. It is cleanly, and can be done even in the most elegant drawing-room. I should have preferred, had circumstances enabled me, to show you by daylight what little I know of this delightful branch of our art. Still I must do the best I can with the aid of artificial light. I wish it to be distinctly understood, however, that I strongly recommend all those who are desirous of practising retouching to do so by daylight.

It is now nearly fourteen years since retouching was first introduced, and for a long time there was a great outcry against it; but, like every other good thing, it has steadily advanced until it has now become a necessary branch of our art, and no gallery is complete without its staff of retouchers.

When I first made up my mind to practise portraiture I soon found out that retouching was a most necessary step to the success of my endeavours; and I set myself to study it. I read all the books and articles I could find. I was told it was very difficult, and that I had better give my negatives to a retoucher to have them properly done, as I would be sure to spoil any negative if I tried my "prentice" hand upon. But I said to myself, "I don't see if others can do it so easily, what is to prevent me;" so I decided to take a few lessons from a competent teacher. I was given to understand from what I had read that quite a dreadful list of articles were necessary, such as powdered cuttle-fish, ground resin, powdered black-lead, Indian ink, black-lead pencils, stumps, sable brushes, &c.; but I soon found out that in this, like other matters, the best thing was ocular demonstration. So I went to Mr. Horatio Paterson, who soon put me on the right road without the aid of anything but this little tool here, which is only a hard lead pencil—it is a 6 H Faber. At first I had not a retouching desk, but I made a very good substitute for one by simply using a printing-frame. Try it, and you will be surprised how well you can get on with one. If you can obtain a proper desk, however, by all means get one. It is no doubt a much more complete and comfortable way to work with its aid.

To assist those of you who desire to learn retouching, I propose to place on my desk two negatives. One of them will be a finished negative, so that I will be enabled to point out to you the difference between a re-touched negative and one that has not been so treated. By this means you will more readily be able to see the inequalities. The first thing to learn is to find out the bad places in a negative. This you will soon come to understand. It is just like knowing the disease is half the cure, and the rest follows. In the first place, examine the high-lights and see if there be any patches less opaque than their surroundings. If so, they must be made of the same opacity. See if there be any little specks, such as freckles would make. If so, they must be filled up, then blend the high-lights into the shaded parts, soften down the shadows, and, having done this, you will have accomplished a deal.

I find a very prevalent notion among amateurs is, that a negative requires some preparation before it is ready for retouching, such as the application of some retouching medium to cause the pencil to "bite," as the saying goes. Now it is only very seldom such is needed. If your negative has been varnished with the ordinary spirit negative varnish, it will need no medium. The varnish, when thoroughly hardened, will take the pencil well enough, and this just brings me to another point that amateurs make an error in. They think that unless they can see the marks the pencil makes with each touch they give, that the lead pencil is not doing its work, and that they must have recourse to some medium to enable them to see the work they are doing. This is just the very thing they must avoid doing.

I will just here tell you that I feel the mistakes most common to beginners are, that they do not use hard enough pencils, and they do not keep them sharp enough, nor do they touch lightly enough. The negative being varnished and perfectly hardened, it is then set on the desk, and the work begins, as you will see me operate presently. Let me say this before commencing: touch as lightly as you can. Only let the lead just touch the varnish, and do not press it on. Most retouchers acquire a special touch of their own, just like learning a special style of writing. You will with practice acquire the best way of touching. Although you do not see the marks the pencil makes, you will find the flaws you are touching gradually disappear, and this is just what you require to do. Do not go too near the negative, but so far away that you can only see the patches the flaws make, and which have to be filled up.

Some of you may think it would be best to take a magnifying glass, and with its aid touch out all the imperfections. No more fatal mistake can be made; for, where you to do so after all your exertion when you come to examine the negative, and are prepared to look with pride upon your persevering efforts, you would be surprised and disappointed to find it showing nearly the same appearance as at the commencement. Yet this should not be astonishing, for it is an artistically acknowledged fact that detail and effect are simultaneously unattainable, and this experience of retouching is further proof to the establishment of this fact. Do not use a magnifying glass. Never attempt to fill up a spot with one touch. The point of your pencil should be as sharp as a darning needle. This is obtained by rubbing it on a piece of fine sand paper. So soon as you sharpen your pencil, just touch a piece of paper with it to take off the scratchy point, but do not blunt it.

At first I recommend you to practise on small heads; you will find large ones more difficult. I will show you a negative I first retouched and a print from the same. What I have done, all of you are quite as well able to accomplish. Practice and patience are all that is needed. It sometimes happens that in lighting a sitter the catch-lights are not the same on both eyes. I will show you how to take out a false light, and so save many a negative that would otherwise be almost worthless.

Do not be frightened to touch your negative. You will thus soon be quite at home at the work, and after a little practice you will find retouching a valuable aid to development, printing, &c. I know of nothing better that enables one to judge of proper density than the examination of a negative for retouching; it will assist you to say at once. This plate is too thin, or this

* Continued from page 790.

too dense, or this under-exposed or over-exposed, or over- or under-developed. You will find it a most valuable aid to the other branches of our art, and he who is an adept at it must be a long way ahead of his brother who is not. I strongly recommend you all to practise it.

I hope I have not detained you too long. I will now proceed to work, which will doubtless interest you more than listening to my paper.

Notes.

To-morrow the YEAR-BOOK OF PHOTOGRAPHY for 1885 will be published, and those who wish to have it before Christmas should order it at once. Indeed, none who practise photography, either as professionals or amateurs, can afford to be without this Annual.

Chinese ink—so often called Indian ink—forms one of the best pigments for carbon tissue, especially when the tissue is required for making transparencies intended to be used in making enlarged negatives; but up to the present but little has been known concerning the manufacture of Chinese ink, excepting the mere fact that its essential constituent is carbon in a wonderfully fine state of division.

Mr. Chen-Ki-Souen, in his recent memoir on the subject, points out that soot obtained by carefully burning pine wood is generally used; but other varieties of lamp-black are occasionally employed. The binding material is gelatine, obtained by boiling the horns of the rhinoceros or the deer, but common glue is used for the cheaper inks. The grinding of the pigment between stones is a most laborious operation, and it appears that in this matter. European machinery will not successfully compete with hand labour in China.

Anthony's Photographic Bulletin is to be edited by Professor C. F. Chandler, of Columbia College, New York, and in his hands it will doubtless maintain the leading position which it has so long occupied in the United States.

The photographer of Aldershot who found some kind of an explosive cartridge and ignited it at a gas flame has fallen a victim to his rashness; but if the police can successfully "investigate the nature of the explosive" now, they possess far more ability than is usually displayed, even by the high-salaried functionaries who deliberate upon damage done by such dynamite explosions as give the Londoners subject matter for talk.

The damage done to London Bridge has been photographed, and the photographs are to be submitted to "microscopical examination."

But the most difficult part of the task has been to find the damaged portion of the bridge; and it required the united energies of Captain Cundill, R.E., Colonel Majendie, C.B., Her Majesty's Inspector of Explosives, and Dr. Dupre, F.C.S., &c., to find—after one day of fruitless search—"a 'long' irregular crack which can be *distinctly traced for several inches*, and is *nearly wide enough for the insertion of the finger nail!*" The work of the photographer was now easy, and if he takes his negative of the same size as the original, his photograph will very nearly resemble Mr. Auty's picture of lightning, which we reproduced on page 676. Still further examination has revealed the presence of a few more cracks, besides the "long" one.

If Her Majesty's Inspector of Explosives will take a walk across Waterloo Bridge, he will find several minute fissures very nearly resembling that discovered in the stone-work of London Bridge.

One of the "specials" of the *Pall Mall Gazette* has been investigating dry plate photography, which he terms "a winter amusement." In a number of the paper this week, he describes a visit to an establishment where there is a notice in the window to the effect that lessons in photography are given free to all purchasers of cameras. It may be interesting to our readers to know that the manager undertook to turn out the "special" a complete photographer after four lessons; that, as a rule, ladies are the quickest and most adroit of the pupils; and that although the winter is usually a slack time of the year, the firm can hardly execute their orders, they are so very busy with this now fashionable amusement.

The Stock Exchange, the Corn Exchange, and the great trading centres of Mincing Lane, have been sorely fluttered during the last fortnight. It appears that for a twelve month or more, a chiel has been among them taking notes of the features of the more prominent men. Unobserved, an industrious Italian artist has haunted these busy scenes of City life, and secured in his sketch-book some 200 or more portraits. These he has elaborated and coloured after the style of the *Vanity Fair* cartoons, and, when quite ready, burst upon the unsuspecting civic notabilities with a full-fledged collection, which he exhibited in a room in Mark Lane taken for the purpose. The charge for admission during the first two days was half-a-crown, and so thronged was the gallery with the subjects of the portraits, their friends and their enemies, that the enterprising promoter cleared, so it is said, over £40 before he reduced the admission to a shilling. The pictures are said to be exceedingly clear, the artist having caught the peculiarities of attitude or gait in each case with almost photographic literalness. Many of the unconscious sitters are not at all pleased at seeing themselves as others see them, and there has been a good deal of talk about actions for libel. If the portraits are not offensive, but only truthful, it is, however, difficult to see where the libel comes in.

The infant Duke of Albany is being brought up in the way he should go—photographing. Last week he sat for his portrait with and without the Duchess. The happy photographer was Mr. Byrne, of Richmond.

A photograph of lightning in which very many tree-like flashes are shown, has been taken by M. Desquesnes, of Billancourt, and in general appearance this photograph is very similar to that of Herr Haensel (page 2 of present volume).

It has sometimes been held as a reproach to photographers that they paid famous actresses, and equally famous professional beauties, to sit to them. Those who have been so blamed may take consolation in the fact that a well-known painter paid an equally well-known lady the large sum of £400 to be allowed to take her portrait, which was afterwards exhibited in the Royal Academy.

Someone at the French Embassy knows English well enough to attempt a *calembour* in it. "The copy of the Franco-Chinese Treaty (about which there has been such a hot controversy) turns out not to have been done by photography," says the waggish *attaché*. "It was prepared, forged alterations and all, by a process of photo-*lie*-thography."

Two dollars a dozen appears to be the price of cabinets in some of the studios at Philadelphia, and, what is more, the pictures are good ones.

The mania for collecting things is always acute. It is only the objects of the collector's industry which change. The fashion of collecting photographs of the hands of one's friend, first introduced some years ago for practical purposes by an artist, is now becoming quite widely spread, and albums specially designed—handsome ones, of course—may be seen on many a table. The offer of a photograph of a bachelor's hand to a lady is, however, a little dangerous, we should think. "Hand and carte" is rather too much like "hand and heart," for the present to be quite safe. As a matter of fact, the rage for hand cartes—dog cartes are now gone out to a great extent—is due in great measure to the revived taste for palmistry or chiromancy, a study which a recently-published work, containing reproductions of the hands of most of the celebrities of Europe, did much to encourage.

It is interesting to note how they make large representations of the structural characters of rocks in the National Museum at Cambridge, Mass. Photo-micrographic negatives of between two and three inches in diameter are first made from the rock-sections, and from these enlarged positives of about twelve inches in diameter are taken; but care is taken not to make these prints too dense. The colours and any features not brought out by the camera are then filled in by hand. In this way the greatest accuracy of detail is ensured, while the colouring materially assists the students.

A friend of ours, who is just back from the Highlands, has brought back a number of cartes, in which he appears in the most Gaelic chieftain-like garb, including sporran, phillibeg, claymore, and all the rest of it. As he had only visited the "land of rough moor and shaggy wood" for a fortnight, we wondered that he had so thoroughly identified himself with Caledonian notions in so short a time, and learned in reply that he owed his Gaelic "get-up" to the enterprise of the Fort-Williams photographer who took him. He had, in fact, been provided with the Highland dress at the studio free of charge, and from what he was told, it seems that a large number of tourists are annually induced to change the breeks for the kilt *pro tem* in a similar way. We should think, though, that though there is no announced charge for the dress, it is in some way included in the price of the cartes. It surely cannot be that these pseudo Highlanders are allowed to get off "Scot-free?"

It is not in Scotland only, however, that this kind of thing is done. If we are correctly informed, there are several cheap photographic galleries in London where a customer has the right, on payment of an extra threepence, to be "taken" in the military uniform (generally a guardsman's, with the bearskin hat well *en evidence*). So too, in studios specially patronised by domestic servants, the loan of items of massive spurious jewellery for the personal adornment of the sitters, is not uncommon; there is one enterprising artist, in fact, who not only loads his patronesses temporarily with aluminium ornaments, but for a small additional sum will take any servant girl on a specially prepared card, there being a corporal in full regimentals introduced in the background.

That a few energetic Radicals are determined, if possible, to bring in a Hindoo for some English or Irish constituency at the next general election is certain; and it is also a fact that an active correspondence is going on with leaders of the educated "Baboo" party in India, with a view to the selection of a suitable native candidate. Rumour has it, too, that at the last meeting of the English M.P.'s and others most concerned, the cartes of several Bengalee reformers were submitted with a view to the selection of this said candidate. But we can hardly believe that the choice will be made in this way. If it is indeed intended to choose an embryo statesman, it would surely be well to insist on seeing how he had come out in a "cabinet" rather than in a carte.

The taste just now seems to point in the direction of portraits suitable for framing rather than for placing in our albums. As there is nothing the public likes better than being saved trouble, photographers will do well to cater for this particular taste, not only by adapting their work, but by exhibiting it in a complete state—that is to say, in frames suitable for standing on tables, whatnots, mantel-pieces, and so forth. Attention to such little matters as this is one of the secrets of commercial success.

It would appear that photogravure is but slightly used in America. The plates have to be prepared in Paris, and as every one is printed by hand, the expense is very great, and, what is equally an obstacle in the estimation of the go-a-head American publishers, the time absorbed is very long. Apparently American book-buyers do not yet appreciate the qualities of *editions de luxe*.

Patent Intelligence.

Applications for Letters Patent.

16,334. SAMUEL DUNSEITH MCKELLEN, 18, Brown Street, Manchester, for "Improvements in photographic cameras."—Dated 12th December, 1884.

Specification published during the week.

13,774. JOHN MITCHELL DOWLING WORSNOP, of 154, Leeds Road, Bradford, in the county of York, Photographic Artist, for "An improved method of transferring the film of photographs, or a film of colour painted upon photographs to canvas or other surfaces." Dated 17th October, 1884.

I take the photograph upon glass or paper or any other suitable surface, which has been previously prepared by coating it with a thin layer of wax or other substance to which the film of the photograph will lightly adhere, but which will afterward allow such film to be easily peeled off. To transfer or remove the film of the photograph, the canvas or other suitable surface on to which it is to be permanently transferred is covered with dissolved gelatine or strong waterproof cement, and then pressed against the film and held there until the cement becomes firmly fixed to the film, when, by separating the canvas from the glass or paper, the film will be detached from such glass or paper and securely cemented upon the surface of the canvas where it is intended to remain permanently.

To transfer or remove a coloured photograph, or a film of colour which has been painted upon the surface of a photograph, the film is painted in the required colours before being transferred, and is then transferred temporarily to a surface prepared with wax as hereinbefore mentioned, the film is then finally transferred to the surface upon which it is intended to remain permanently fixed, and to which it is securely fixed by dissolved gelatine or strong waterproof cement, in the manner hereinbefore described.

Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is :—

Taking photographs or painting such photographs or pictures upon a surface covered with a slightly adhesive material which will admit of the film of the photograph or the film of colour painted upon such photograph or picture being peeled off and attached permanently to a canvas or other durable material in the manner hereinbefore described.

Patents Granted in America.

308,468. WALTER CLARK, New York, N.Y., "Photographic Camera." Filed May 7, 1884.—(No model).

Claim.—1. A photographic camera box having a partition forming a separate focussing-chamber with an object glass in one side thereof, and a movable lens constructed to coincide with either of said apertures, substantially as shown and described.

2. The combination in a camera-box having separate apertures *c d*, of partition *e*, mirror *f*, object-glass *g*, and movable lens-holder C, substantially as shown and described.

3. The combination with a camera-box having a separate focussing-chamber, of a lens fitted for movement into position at either the focussing or exposure apertures, substantially as described.

4. The combination with a camera having a separate focussing-chamber, of the pivoted lens holder C, and a catch for retaining the holder in a raised position, substantially as described.

5. The combination with a camera having a separate focussing-chamber, of the movable lens holder C, lens-tube *p*, provided with a rack, and a shaft and pinion, *q*, substantially as described.

6. The combination, with a camera having a separate focussing chamber, a pinion for adjusting the lens, and a movable lens having a rack that engages the pinion in one position of the lens substantially as described.

7. The combination, with a camera having a separate focussing-chamber, of swinging lens-holder, C, arm *n*, catch *s*, substantially as described.

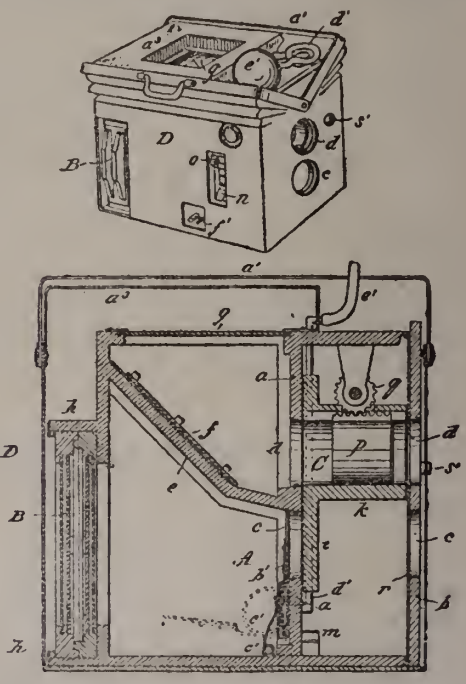
8. In a camera having a swinging lens-holder, the combination therewith of a buffer-spriug, substantially as described.

9. In a camera, the diaphragm or hood a^3, combined with a case having a folding top, substantially as described.

10. The combination, with a camera having a swinging lens-holder and separate focussing-chamber, of a movable shutter covering the exposure-aperture, and a trip for releasing the shutter substantially as described.

11. The combination, with a camera having a swinging lens-holder, and a separate focussing-chamber, of a pivoted shutter covering the exposure-aperture, and fitted to rotate for exposure of the plate, substantially as described.

12. The combination, with a camera having a swinging lens-holder and a separate focussing-chamber, of the pivoted shutter *r*,



spring *v*, and catch *s*, substantially as described, for operation as specified.

13. In a camera having a separate focussing-chamber and a movable lens, a moving shutter for instantaneous work, arranged to be automatically released by the lens-holder when moved, substantially as described.

14. The case D, having a hinged frame, *a'*, combined with a camera, substantially as and for the purpose specified.

308,469. WALTER CLARK, New York, N.Y., "Photographic Camera." Filed Aug. 8, 1883. Renewed Aug. 14, 1884. (No model).

Claim.—1. In photographic cameras in which the following elements are combined—namely, an adjustable lens, a device for holding and exposing the sensitive plate at the back of the lens, a focussing-glass in the top or side of the camera-box, and a reflector for throwing the image upon the focussing-glass—a photographic camera-box, provided with two compartments, the one of which carrying the reflector is constructed with an open side next the lens, and made capable of adjustment in or out of connection with the lens, while the other compartment serves for exposure of the sensitive plate, substantially as specified.

2. In a photographic camera having an interior inclined mirror and upper glass focussing compartment capable of adjustment into and out of connection with the lens or lens-case of the instrument, the combination, with said compartment, of a movable diaphragm arranged to move between the lens and the mirror, essentially as and for the purposes herein described.

3. In a photographic camera, the combination, with the lens, of the bellows E, mirror-case F, reflector G, and diaphagm L, essentially as herein set forth.

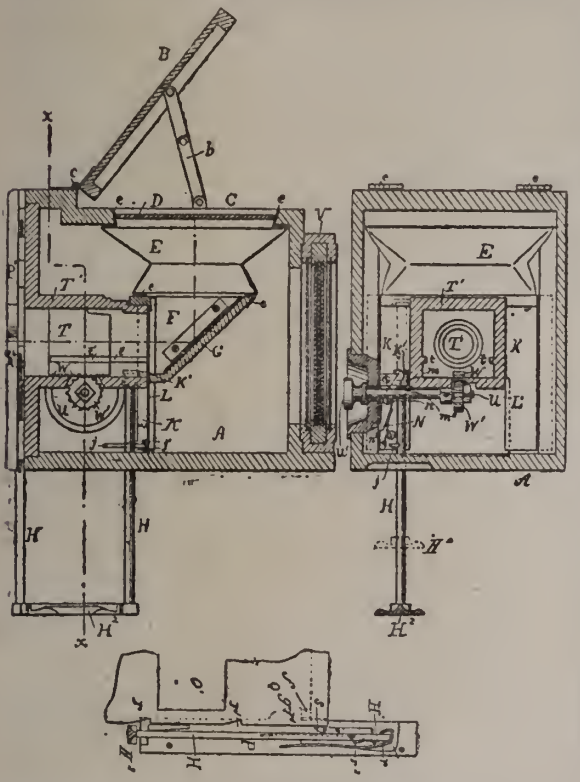
4. The combination of the sliding-rod H with its pin or projection *j*, the mirror-case F, and the spring-catch N, substantially as specified.

5. The combination of the sliding-rod H' with its attached spring r^2, the stationary spring r^3, and the drop Q, essentially as and for the purposes herein set forth.

6. The combination, with the camera-box A, bellows E, and mirror-case F, of the bent lapping strips *e e'*, for attachment of

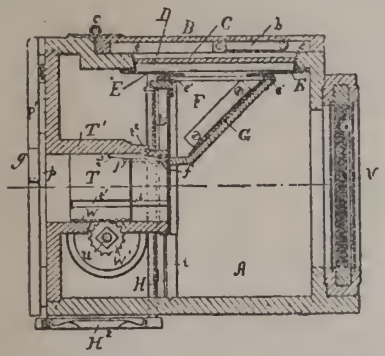
the bellows to the said box and case, substantially as herein shown and described.

7. In a photographic camera-box, the combination of the connected sliding rods H H′ with the focussing mirror-case F, its independently moving diaphragm L, the drop Q, and catches or



attachments connected with said rods for operating the mirror-case, its diaphragm, and the drop in relation with each other essentially as described.

8. The combination of the springs r^2 r^3 with the releasing



guide *s*, the rod H′, and the drop Q, substantially as and for the purpose specified.

9. In a photographic camera-box, the combination, with an interior focussing or mirror case, of the adjustable lens or lens-case T and frame T′, substantially as herin shown and described.

10. A photographic camera in which the following elements are combined : a camera-box fitted with an adjustable lens, and composed of an outer compartment for exposure of the sensitive plate, and an inner compartment or mirror-case adjustable into and out of line with the lens and inclosed on top by a fixed focussing-glass, and an independent moving diaphragm in front of said mirror-case, all arranged for operation in relation with each other other substantially as specified.

HOW TO PHOTOGRAPH MICROSCOPIC OBJECTS.

BY I. H. JENNINGS.

Lesson X.—Preparing Vegetable Tissues for Photography.

Dry-mounted vegetable preparations are not of much use to the photo-micrographer, except it be certain scales, such as those of the *Deutzia*, which can be successfully photographed with a low power by reflected light. In most cases the use of a bleaching liquid is necessary to get rid of the colouring matter, which must be removed before the tissues can be set up as transparent objects. The following bleaching liquids may be used :—1, Nitric acid ; 2, methylated alcohol ; 3, chlorinated soda.

1. Nitric acid must generally be used in a very dilute form, as many vegetable tissues, even those strongly impregnated with silica, are destroyed by it when pure. The stems of grasses, horsetails, and even leaves, as those of the *Deutzia*, may be bleached by gently heating in very dilute nitric acid. When the object appears sufficiently transparent, it must be well washed in distilled water to remove all trace of the acid, floated on a slide, and dried under cover. If the acid be used too strong, the object is decomposed, while if the washing be imperfect, crystals will form in its substance and render it useless.

2. Soaking in alcohol does very well for many objects, such as cuticles, and thin, semi-transparent leaves. They should be left in alcohol for some hours ; and when they have lost most of their chlorophyl the alcohol must be poured off, and some fresh added, until the objects become white. They may now be transferred to benzol or turpentine for some hours, when they are ready for mounting. Boiling in alcohol is hardly advisable, for although it considerably hastens the bleaching, it tends to make all plant-tissues too brittle for mounting.

3. The best mode of bleaching vegetable tissues is by means of chlorinated soda. The solution is prepared as follows :—Three or four ounces of good chloride of lime are taken, and put in about a quart of water. Stir the mixture a few times, and allow the sediment to settle ; after this the liquid had better be filtered through coarse filter-paper ; this is better than pouring the clear liquid off. Next, pour a strong solution of carbonate of soda into the chloride of lime solution, so long as a precipitate takes place, and allow the precipitate to subside. When clear, the solution should be tested with a few more drops of carbonate of soda, to ascertain if all the lime have been precipitated ; if not, more should be added, until no lime be left in the solution. Most of the solution, when clear, can be poured off, and must once more be filtered ; after which it should be stored in black or dark-coloured bottles, and well-corked, since both air and light speedily bring about decomposition.

A series of small glass pots should be provided to bleach the specimens. Shallow pomade pots are very suitable. Before leaves are immersed in the fluid, it is best to wash them in clean water with a soft brush, since all leaves are more or less covered with fine dust, which will sink into their substance if not removed when they are fresh. When they are quite clean, they may either be put in the bleaching liquid at once, or put between clean blotting-paper to dry. Dried leaves, as a rule, bleach more rapidly than green ones.

When a leaf happens to be more deeply coloured than usual, it is a good plan to immerse it in alcohol until most of the colour has been removed. This much facilitates the bleaching process. The time which tissues require to be soaked varies considerably. Some become translucent in a few hours, while others take many days ; others will show green patches which obstinately refuse to be bleached. In this case, remove the leaf, wash it well, and place it in alcohol for some hours. In this way all the chlorophyl will be dissolved out, when the soda solution will complete the processes. Care must be taken not to put too many

leaves at a time into one vessel; three or four is the average number.

When properly translucent, the leaves or tissues must be removed from the soda solution, and washed in distilled water, changing the water every few hours. If the tissues do not contain Raphides, the addition of a little hydrochloric or nitric acid to the second or third washing will increase their transparency. *Sulphuric* acid must not be used, or crystals of sulphate of lime, which is only slightly soluble in water and acids, may be formed in the tissues, and cannot be removed.

About twenty-four hours is necessary to properly wash the leaves; less time is not sufficient, and a longer immersion tends to disintegrate delicate tissues. The washing completed, they should be placed in alcohol, in which they must remain for some hours, and afterwards be transferred to turpentine until required for mounting.

The above bleaching process must be applied to sections of wood which are too strongly coloured for photography. It is hardly necessary to observe that all sections which are to be photographed should be of extreme thinness. Many which answer very well for examination under the microscope are far too thick for the photo-micrographer. Light-coloured sections, such as those of white pine, require merely saturation with benzol before mounting in the balsam solution. A section of deal, to show the characteristic "discs," should be mounted dry.

Spiral vessels, scalariform tissue, &c., will require but little treatment; the former, after drying and washing in alcohol and benzol, may at once be set up in balsam.

Cuticles may be prepared in the same way. In the case of very transparent tissues, staining will be of great use. Judson's dyes answer very well for this purpose, but all blue stains should be avoided in objects intended for photo-micrography.

Plant-crystals, or raphides, may be prepared either *in situ*, or separately. When mounted *in situ*, bleaching with alcohol is alone admissible. Raphides may be obtained from most plants by laying a leaf or stem on a slide, with the cut end about the middle; a gentle rolling pressure with a pencil will squeeze the juice and raphides out on the glass. Wash with alcohol, pour over a little turpentine, and mount in the usual way.

The following furnish good examples of raphides. Duck-weed, the onion, the willow-herb, the galium, or goose-grass. The large prismatic crystals of the onion or garlic polarise splendidly, and show better in a photograph when polarised light is used. In fact, many objects that are far too transparent to make good photographs can be easily managed by putting on the polariscope. When this is of no use, a piece of fine ground glass, or oiled paper, immediately below the slide will be of great service in softening the light. This will prolong the exposure, but give results that could not otherwise be attained.

For instruction as to staining vegetable tissues, the student is referred to a very valuable and practical paper by Dr. George D. Beatty, which appeared in "Science Gossip" for May, 1876; also to "Practical Microscopy," Chapter 12.

PHOTO-LITHOGRAPHY AND PHOTO-ZINCOGRAPHY.

BY MAJOR J. WATERHOUSE, B.S.C.,
Assistant Surveyor-General of India.

CHAPTER XVII.—MISCELLANEOUS PROCESSES—(*continued*).

3. *Dusting Processes.*—Several photo-lithographic processes have been proposed, founded on what is known as the dusting process—*i. e.*, the stone, zinc plate, or tranafer paper is prepared with some composition, which, either being hygroscopic and capable of attracting moisture from the atmosphere, loses this property by exposure to light, or the reverse, and the image is developed by dusting on a resinous powder capable of attracting printing ink.

So far as the writer knows, none of these processes have come into very practical use.

Mr. Hanniford coats paper with a mixture of bichromate of potash, ammonio-citrate of iron, albumen, honey, and water, and exposes when dry under a transparent positive. The parts acted on by light become hard and insoluble. The image is brought out with a resinous gum. The paper bearing the image is laid face downwards on a clean-grained lithographic stone. A warm iron is passed over the back, causing the resin to adhere to the stone.

Removing the paper, a solution of gum and nitric acid is allowed to remain on the stone for a time, and the ink roller being applied, the ink takes only on the resin.

Mr. Lallemand coats paper with a solution of perchloride of iron and tartaric acid to which some dextrine is added. When dry, the paper is exposed behind a negative, and then brushed over with a resinous powder composed of—

Lime soap, from tallow	1 part
Resinate of lime, from resin... ...	1 ,,
Lampblack	*quant. suff.*

These materials are mixed together and dissolved in benzole, and when the latter has evaporated the compound is reduced to powder; the exposed portions of the print absorb moisture and retain the powder. The developed design may be transferred to stone in the ordinary way.

The following process was patented by Mr. Window in 1870:—

Paper is prepared with a mixture of—

Honey	2 parts
Glucose	4 ,,
Albumen	3 ,,
Dextrine	1½ ,,
Sat. sol. bichromate of ammonia ...	7 ,,

The paper is exposed under a positive, and the image is developed in the usual way by brushing over with a resinous powder consisting of asphalt with one-fourth its weight of paraffin, or stearic acid or lampblack with one-fourth its weight of stearic acid.

The developed print is laid on the stone and heated sufficiently to melt the matter, and then passed through the press. On damping the back of the print the fatty powder is left in contact with the stone, and adheres thereto if the heating has been properly managed; while the moistened sensitive compound likewise adheres to the stone, and forms a protective coating against the fatty matters where the stone is rolled up in the usual way.

Herr Obernetter recommends the following process as peculiarly well adapted for the reproduction of line-drawings.

A copper, zinc, or glass plate is coated with a syrupy solution made of—

Gelatine	10 parts
Glycerine	2 ,,
Bichromate of ammonia	4 ,,
Water	50 ,,

This is dried upon the metal, and the plate is then exposed under a reversed negative. After exposure the film is dusted with very finely-powdered zinc, and if the picture is desired quite flat the operation is stopped as soon as the picture appears a positive by reflected light. If a deeper image be desired the plate is breathed upon, and the zinc powder is applied so as to penetrate deeply the unexposed portions of the plate. When the plate is sufficiently powdered, it is washed with water to get rid of part of the chromium salt. The remainder of the chromium salt suffices to render the whole of the gelatine surface insoluble on exposure to light, or by heating it to 15° C. When the film is insoluble it is etched with dilute muriatic acid, which, dissolving the zinc, liberates hydrogen, which renders the gelatine soluble again. By moistening with water the image may be printed from in the same way as a lithographic stone.

Herr Obernetter says the results are sharper than can be obtained by any other known process.

4. *Other Processes.*—In addition to these special processes, there are other modifications of the ordinary methods which may be mentioned.

Mr. A. Wood inks his transfers, after exposure, by laying the print face upwards on cold water, and allowing it to remain till the gelatine can be traced on the surface. It is removed and laid face downwards on a sheet of plate glass which has previously received a thin coating of greasy ink, and gently rubbed over the back so as to bring the drawing into close contact with the ink. On removal, it will be found that the ink has attached itself to those parts only which have been acted on by light, the ground remaining perfectly pure and clean. If the quantity of ink is found not sufficient, the process can be repeated till it is so. The coating of gelatine should be strong, and the paper which gives the best results is albumenised, the surface of which has been rendered insoluble by steaming.

In the Year-Book for 1871, Mr. Swan published a method of photo-lithography dependent on the fact that caoutchouc is so altered by the action of light that, whereas in its natural state it does not communicate to a clean lithographic stone an ink-imbibing quality, by being strongly pressed into contact with it, it will, after being exposed to a few hours' sunshine, set off by strong pressure, and give to a lithographic stone a strong affinity for greasy ink. Paper is coated with a solution of india-rubber in benzole, and after the thorough evaporation of the solvent, is exposed to sunshine under a negative, and can then be transferred to stone.

As might be expected, several operators have tried to utilise the ordinary pigment tissue in photo-lithography, both in line and half-tone. A process of the kind seems to have been tried at Woolwich Arsenal, but was abandoned as giving no advantage over the ordinary process.

There are two ways of working. First, by transferring a positive carbon print on to the stone; and second, by transferring a negative print; and it is in this latter direction that the method seems likely to be most useful.

The fullest description of the process is given in the News, vol. xv., p. 387, as described by a writer in the *Photographic Archiv* (believed to be Dr. Schnauss).

The tissue is floated for two minutes on a five per cent. solution of pure bichromate of potash, and dried in an air-tight box with chloride of calcium.

The negative should be such as is used in ordinary photo-lithography—opaque in the ground, and quite clear in the lines. The border of the negative is protected by masking. After exposure to light, the tissue is squeegeed down in the usual way on to a smooth stone. After resting for a few minutes, the stone is placed in a sloping position in a trough, and warm water is poured over it till the supporting paper is loosened. The soluble gelatine is gradually washed away by pouring on gently a stream of warm water from the edge of the stone, and not upon the image itself, for fear of loosening the lines. When the image is clear and strong, the stone is immersed in cold water until it has become cool. It is then allowed to dry. When dry, it is covered with a solution of gum, as in the case of an ordinary lithographic drawing. This is allowed to dry, again moistened, and the lithographic ink applied repeatedly with a roller. The stone can then be printed in the usual way.

Mr. J. R. Sawyer, in addition to a process similar to the above, describes a method patented by him in which the tissue is coated with india-rubber solution, then attached face downwards to a piece of paper also coated with india-rubber as in the original Swan's process. After development, the image is transferred to stone or a piece of plate-glass previously coated with a mixture of gelatine, albumen, and bichromate of potash. The adhering paper is removed by moistening with benzole, and the image can then be gummed, and inked as in the last process.

The second method was patented by Mr. F. W. Window in 1871. He prints a negative image on gelatine or other analogous colloid from the subject itself, or from a positive obtained from a negative of the subject. After printing, he lays down the exposed proof upon a stone or zinc plate, and develops it with warm water in the usual way. The stone supporting the image so obtained is washed with alum and allowed to dry. It is then inked-up in the usual way; the negative gelatine image is removed with a sponge and water, and the fatty image remaining is treated in the usual way for lithographic printing.

Dr. J. Schnauss has also fully described this method in his "Lichtdruck und Photo-lithographie." The positive *cliche* must be masked all round with black paper, and the pigment tissue should not extend beyond the mask. A very short exposure is given. The tissue is transferred to the stone with cold water, and allowed to remain for at least half-an-hour or an hour under pressure. The stone is then washed with warm water to develop the image.

This should appear as a very weak negative with very clear lights. The stone is allowed to dry, and is then rolled in with thin litho-chalk ink, which produces a black surface all over. The stone is allowed to remain for some hours, so that the fatty ink may be absorbed by the stone, and the surface is then rubbed with a flannel pad dipped in gum-water. By this means the negative pigment print is removed, while the fatty image remains, and shows a regular positive image which can be treated and rolled up for printing in the usual way.

In the next chapter we propose to treat on the subject of photo-lithographs in half-tone, and this will complete the series.

(*To be continued*).

Correspondence.

VIGNETTING IN THE CAMERA.

Dear Sir,—I notice in Photographic News of the 21st, that Mr. Van der Weyde has taken out a patent for vignetting in the camera, and also from outside, by means of a translucent medium between the sitter and lens, or between the lens and plate. In justice to myself and the profession I must state the following:—At the time M. Lambert was at Greenwich, Mr. J. Hughes and myself took out licenses to work the chromotype process, but on my return to Bath I found it very difficult to make vignettes by that process; so I set to work to make my vignettes on the negatives in the camera, and constructed a similar arrangement, which answered my purpose so well that I sent a print to Mr. Hughes to see, with which he was much pleased. Why I did not adopt it then, I found it difficult in getting, by the wet process, the even tint required; but by the dry plate that difficulty is removed. I have this summer made some improvement, and so made it easier to work, and shall now adopt it generally. You will see by the enclosed print and negative, that the style of hair is of the date of M. Lambert's introducing chromotype.—Yours truly,

Henry Lambert.

LANTERN SLIDE CLUB.

Sir,—I have received several replies from gentlemen desirous of joining the Club, and should like to have a few more, especially from those living in London.

Mr. Brooks, in his letter last week, opens out a pretentious line to that I have in view. I do not propose any educational, or social, or discussional club, but simply and only the utilitarian idea of co-operation, whereby each member of a small and select body may be able, at the cost of fifty good slides, to have the loan of (say) one thousand, and still remain the possessor of his own fifty. Of course, it is open to any one to get up a club on any wider basis,

but it seems to me that the lantern is such a merely mechanical affair, and the making of slides is so simple a matter, that a society formed for the study of making lantern slides, and all matters connected with the lantern, would be of a dubious advantage. There is nothing very abstruse in lantern matters, and the making of slides is carried on as a business, while the making of slides from one's ones own negatives is simplicity itself, as far as the actual work of making the slides themselves is concerned.

At the same time, there would be a very tangible basis for a lantern club with periodical meetings to show the efforts of the members on the screen, and the other objects indicated; but I personally, though I should like to belong to it, would not be prepared to give the time needful for the successful working.

My idea is merely a co-operative arrangement for the exchange of slides for use at members' own homes, or for a joint stock of slides, and for this a few more members are wanted.

Proposed Constitution of Lantern Slide Exchange.

The object of the Club to be co-operation by a limited number of members to procure first-class slides at a reduced rate.

Each member on joining to pay an entrance fee of £2, to be devoted to the purchase of slides in sets of fifty, and also suitable boxes for their safe dispatch by Parcels Post.

Any member leaving the Club to withdraw the slides purchased with his entrance fee, and his place to be taken by an additional new member.

There shall be an annual subscription of 10s. to pay the ordinary working expenses of the Club, and to purchase extra slides should there be any surplus.

Each member be entitled to the loan of fifty slides every week, but no member be allowed to have a succeeding set until the set last borrowed is returned to the Hon. Secretary.

The Hon. Sec. to keep a record of the slides standing to the credit of each member, and also a book recording the dates of loan and return of the slides.

Each member at the outset to pay the carriage to and fro of the slides he borrows; but this may possibly be modified later on.

Although, *prima facie*, one particular set of slides would be regarded as the property of each individual member, should that member detain any other set, his claim to the set standing against his name would lapse; the latter set being, in that case, placed to the credit of the member whose slides had been wrongfully detained, and the defaulting member would be severed from the membership.

Any member leaving the Club to lose all claim to the accumulated slides, save only the single set representing his original entrance fee.

Members to make good any fractures while slides are in their possession.

This is the rough idea I have in view in the first instance, and it can readily be seen that an immediate start can be made. Possibly later on additional features can be added, but at present I do not see my way to do more. It is a purely utilitarian idea by which we may have the run of a number of slides at the cost of a few; and the Association will be so constituted that any member can leave when he likes by keeping the set of slides represented by his own entrance fee.

I should of course give the members sufficient assurance of my stability and position to satisfy them that I should not "clear off" with the slides; and I should, so long as I managed the affair, take care that no member secured more than the allotted number of slides at one time. I could not undertake to conduct a Club numbering more than, at most, twenty-five members at present; but, of course, it is quite open to any one else to start a similar club if he feels so disposed.—Yours faithfully,

River Cottage, Hornsey, N. HENRY SMITH.

Proceedings of Societies.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

A MEETING of this Society was held on Thursday, the 11th inst., Mr. J. HEINRICH TRINKS in the chair.

Mr. J. GORDON exhibited and explained the action of a print-washing machine designed by Mr. Sturrock, of Dundee. The characteristic features are—isolation of prints during soaking by means of a series of trays, fixed period for draining between emptying and refilling, and syphoning at any desired interval from one to twenty times per hour.

Mr. W. E. DEBENHAM spoke favourably of the apparatus, and said that less water was required—an important consideration in many studios.

The CHAIRMAN, having thanked Mr. Gordon, passed to the principal business of the evening, Mr. Debenham's lecturette (see page 804), which Mr. Debenham read, fully illustrating his contentions by diagrams on the black-board.

In the discussion which followed, Mr. F. W. HART said some years ago he constructed a polygonal frame four feet in diameter, fitted with sixteen mirrors, for copying Daguerreotypes and glass positives; he obtained an enormous illumination, which resulted in a bright picture without reflection.

Mr. DEBENHAM said such an arrangement came very near to what was desired.

Mr. A. L. HENDERSON thought the screen mentioned by the Lecturer would intercept too much light when it became necessary to enlarge considerably with the lens near the object; in other cases there would be reflection at the edges. He then spoke of the probable advantages to be gained by using a sort of vista-scope, also Mr. Hughes's muslin screen for avoiding granularity, and concluded by describing his own method for centering the picture, which consisted in fixing a scale of numbers on the camera-stand, and another on the studio wall, the indexes being made parallel.

Mr. W. K. BURTON enquired if the Lecturer had any special reason for selecting the back combination of a portrait lens in the special case he had spoken of, as some held that there was a difference, although he could not see why they should.

Mr. J. BARKER made better copies of paper prints when glass intervened, and the closer to the picture the better the copy.

Mr. A. HADDON advocated soaking in water, and mounting in optical contact.

Mr. S. C. SALMON enquired if Mr. Debenham had any objections to putting the picture to be copied at the bottom of a box, and copying in that manner.

Mr. J. J. BRIGINSHAW preferred copying in open air.

Mr. DEBENHAM, replying, said Mr. Henderson would find it more convenient to mark the wall only, having a series of numbers running above and below the centre. Mr. Hughes's muslin screen was referred to in the lecture as tissue paper. If the screen were placed as shown in the diagram, the angle included the rays which caused reflection at the edges. His object in using the combination spoken of, was to get a blurred effect. Copying through glass keeps the print flat, and there is less chance of dust. For optical contact, wetting the print is necessary, and he observed chalkiness or want of tone in the lights to be the result. Copying at the bottom of the box had objections out-weighing the benefits; unless the box be twice the size of the picture, the angle of light reaching the picture would be such as he had shown caused reflection.

Mr. A. COWAN could not agree that the dark side of the studio was always the best for copying, and sketched on the black-board the arrangement employed by him, and which enabled him to move anywhere about the room.

Mr. W. H. PRESTWICH said granularity depended much on the positon of a print during copying; the texture would be seen to run in a certain direction, much after the fashion of buff lines in a Daguerreotype plate.

The avoidance of vibration in copying then became the subject of conversation, the CHAIRMAN warmly advocating the German system of swinging platforms which had been so efficiently illustrated by the late Mr. H. Baden Pritchard in his "Studios of Europe."

A hearty vote of thanks was then passed to Mr. Debenham for his interesting paper.

The CHAIRMAN then introduced Mr. E. Sollas, who gave an interesting account of photographic work in Yellowstone Park, U.S.A., and showed some very good results. He said the difficulties were great, and the camps being fifty miles apart would not

allow very long for choosing subjects. As an artist he thought photographs were usually made too sharp; the softer prints, which were often thrown aside, he much preferred for their artistic qualities.

Mr. W. Wright was elected a member.

The next lecturette, on Jan. 8th, will be "Experiences in Taking Instantaneous Views of London," by Mr. W. Cobb.

PHOTOGRAPHIC SOCIETY OF IRELAND.

THE usual monthly meeting of this Society was held in the Royal College of Science, Stephen's Green, E., on Friday, the 12th inst., Mr. Thomas A. BEWLEY in the chair. The minutes of the previous meeting having been read and confirmed, Mr. Frederick H. Campbell was elected a member. The Chairman then called on

Mr. GEORGE MANSFIELD for his communication "On Paper Negatives." In the course of his paper Mr. Mansfield drew attention to the old method of producing negatives on paper, and then waxing the material to render them translucid; and then gave a most interesting account of his recent experiments with various gelatino-bromide papers, both on what is known as "negative" as well as "positive" papers—those produced on the "positive" paper yielding in his hands the best results, while the "negative" paper gave the most trouble in rendering it translucid, on account of its extra thickness. He also handed round several excellent negatives and prints off 10 by 12 and whole plate size, the difference between the prints and those off ordinary plates being hardly distinguishable.

In the debate which followed, Mr. J. V. ROBINSON ventured to predict that the future basis on which all negative films would be held would be the material now brought under the notice of the meeting, the great advantage to be gained being the lessening of the weight to be carried by doing away with the glasses which at the present stage of photography are indispensable. Mr. Robinson also exhibited a most interesting collection of old waxed negatives, which for brilliancy and delicacy of detail were hardly to be beaten even by gelatino-bromide plates, or the still older collodion films.

Dr. SCOTT, who has also been experimenting in the same direction as Mr. Mansfield, detailed the results he had obtained, and passed round several negatives and prints, as also an instantaneous view of Kingstown Harbour, which was highly creditable as instancing the results this paper is capable of yielding.

Mr. WOODWORTH also exhibited a collection of paper negatives enlarged from quarter-plate transparencies, and some platinum prints from same.

The next meeting is intended to be held Jan. 9th, 1885.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES' PHOTOGRAPHIC ASSOCIATION.

THE ordinary meeting of the above Association was held on Tuesday, the 9th inst., in the College of Physical Science, Newcastle, at half-past seven o'clock p.m., Mr. P. M. LAWS in the chair.

The minutes were read and passed.

The CHAIRMAN announced that the Council had decided to join with the Tyneside Students' Association and three or four other societies in a *conversazione* to be held on the 8th January, and asked members to contribute pictures.

Mr. H. G. TEMPLETON, of Gateshead, read a paper on "The Platinotype Process" (see page 806), and gave a very successful practical demonstration.

Mr. PROCTOR gave some interesting details of the method he had adopted in taking his view without a lens, shown at the Society's recent Exhibition. The pictures taken late in October had fifteen minutes' exposure, the distance between the plate and aperture being about twelve inches.

A vote of thanks to the Chairman concluded the meeting.

CHELTENHAM PHOTOGRAPHIC SOCIETY.

A MEETING of this Society (till recently known as the Cheltenham Amateur Photographic Society) was held on Thursday, Dec. 11, the President, COL. DAWSON, C.B., in the chair.

The following gentlemen were elected members of the Society:—Messrs. White, R. Dighton, W. L. Ferguson, and Joyner.

Mr. BAYNHAM JONES exhibited one of Mr. Kellen's new patent cameras, half-plate size, square, with reversing frame.

Colonel DAWSON then read a short account of a potash and soda developer used by himself for some time with great success; his formula being:—

Carbonate of potash (London Pharm.)...	240 grains
Washing soda	240 „
Potassium bromide	20 „
Dissolved in water to make	20 ounces

This solution contains 3 grains of each article in every drachm. In each ounce of developer one drachm of the above is used with 2 grains of pyro.

Prints were exhibited by several members; those of Mr. Beetham, from negatives taken in the neighbourhood of Torquay, being very much admired.

Some transparencies were also shown.

MANCHESTER PHOTOGRAPHIC SOCIETY.

THE usual monthly meeting of this Society was held at the Manchester Technical Schools, on Thursday, Dec. 11th, the President, Mr. JOHN S. POLLITT, in the chair. The minutes of the previous meeting were read and confirmed.

The following gentlemen were elected members of the Society—viz., Messrs. B. Ellstor, F. Barker, C. Estcourt, F.C.S.

Mr. J. W. LEIGH read a short paper, and gave practical illustrations of several methods of effecting the printing of skies in landscape pictures. Mr. Leigh explained that where, as was often the case, the sky portion of a landscape negatives was defective, the first thing to be done is to screen the sky portion during printing, so as to get a print with a white sky. This he effects by taking a sheet of cardboard and tearing this so as to follow roughly the sky line; this is then attached to the printing-frame by pins, and the whole exposed to diffused light; the sky mask being given a slight curl upwards, does away with any mark or line at the junction. The print is then taken out of the frame and laid on a large sheet of glass, and the cloud negative laid upon it, the right position being easily determined by looking through the negative and print together. To mask the landscape portion of the film, Mr. Leigh places over it one or more pieces of cloth—*e.g.*, the pads from the frame—and rolls these back at the sky line in order to soften the edges, and again exposes to diffused light till the clouds are sufficiently printed. Mr. Leigh also showed a simple plan he made use of when any part of a negative was much thinner than the rest, and would necessarily give an uneven print. He commences the print in the usual way, and as soon as the thin part is done enough, he masks that portion by attaching a tuft of cotton-wool by means of gum to the back of the negative, and pulls out the edges to get the necessary softness. At the conclusion of his paper, Mr. Leigh referred to a question in the question-box at the last meeting, as to the quantity of hypo necessary for a given number of prints; and, quoting from Captain Abney's book, called attention to the necessity of using the hypo solution strong, to ensure perfect fixation, and the complete removal of the hypo during the final washing.

Mr. RISHTON agreed with Mr. Leigh on the hypo question, and remarked that it was desirable to have the fixing bath in an alkaline condition, and he was in the habit of adding ammonia for this purpose.

Mr. ATHERTON said common washing soda answered the purpose equally well, and suggested three ounces of hypo to the pint of water as about the correct amount for fixing one sheet of paper.

The PRESIDENT said he had found the use of tepid water in the final washing a great advantage. Referring to Mr. Leigh's plan of masking with cotton-wool, he had for some years made use of Prussian blue painted on the back of the negative, and softened by dabbing in the usual way. In the printing-frame he had also found it desirable to lay a sheet of thin cardboard next to the sensitive paper, and he found that by this method he obtained complete immunity from cockling of the print in damp weather.

Mr. CHILTON asked the President if warm water for washing prints affected the surface and brilliancy of the print?

The PRESIDENT replied that if the water were used tepid he had never found any ill effects, but if the water were used hot, the prints would certainly suffer.

Mr. GREATOREX asked for information as to the best method of masking a sky in which there was a church steeple, tower, &c.

Mr. LEIGH said he should block the sky out with black varnish.

Mr. MCKELLEN recommended making a print, and cutting out the image of the steeple, &c., and laying the mask so formed on the negative with the smallest quantity of paste.

Mr. ALAN GARNETT showed two very charming prints on Alpha paper, which were much admired. He also exhibited an ingenious

contrivance for the gas jet in an amateur's dark-room by which the gas could be turned apparently out, and on turning the tap up again, the flame at the burner was re-kindled, the small spark kept in being concealed by a metal cap round the jet.

The HON. SECRETARY (Mr. W. J. Chadwick) exhibited a simple contrivance which he made use of when mounting prints on plain boards, remarking that he had frequently seen amateurs fail in getting the print in the centre of the mount or square with it. His plan consisted in using a guide or mask made from one of the mounts in use, in the centre of which an opening is cut $\frac{1}{8}$th of an inch each way larger than the print to be mounted. This mask is laid on the mounting board and attached thereto by a pair of American clips. The print, coated with the mounting medium, is now placed in the opening of the mask, which latter being removed, the print may be rubbed down on its board, and its central position settled upon.

The meeting was then adjourned to the 8th Jan., 1885.

Talk in the Studio.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The next monthly technical meeting of this Society will take place on Tuesday next, December 23rd, at 8 p.m., at 5A, Pall Mall East.

THE ANNUAL DINNER OF THE SOUTH LONDON PHOTOGRAPHIC SOCIETY.—On Tuesday evening last this event took place at the Holborn Restaurant, Mr. W. Ackland, President, occupying the chair. There seemed to be a feeling that the Society is about to enter into a period of increased usefulness and activity, the Secretary stating that he had received many promises of interesting papers for the future meetings. Several gentlemen entertained the company with songs and recitations, and it was late when the assembly broke up.

PURIFICATION OF ALBUMEN, AND AN IMPROVED SUBSTRATUM FOR DRY PLATES.—A reader who uses an albumen and water-glass substratum for gelatino-bromide plates, tells us that he finds Dr. Reichart's method of purifying albumen with carbonic acid gas to be excellent; as when the stream of gas is passed through the diluted albumen, the membranous and other impurities settle down rapidly, and the liquid may then be filtered. In order to avoid the trouble of preparing the gas, ordinary "soda water" may be used to dilute the albumen; there being quite enough carbonic acid gas present for the purpose. Here is the formula for a substratum made with the soda water:—

White of two eggs
Soda water ... ... 1 bottle

Beat well and add—

Soda water ... ... 1 bottle

Carefully filter, and—

Make up to 30 ounces with distilled water

Then add—

Soluble silicate of soda ... ... 1 ounce

To use this, flow it over the cleaned plates, and allow the excess to drain off at one corner.

A DROPPING-BOTTLE FOR THE DRY-PLATE DEVELOPER AND A BYE-PASS STOPCOCK FOR THE DARK-ROOM LAMP.—From Messrs. G. Houghton and Son we receive two useful appliances. In the first place, a dropping-bottle of the kind described on page 104 of our present volume, and mentioned by us as coming to hand from Germany; and in the second place, a stopcock, with a bye-pass arrangement by which a small jet of gas is left burning when the principal flame is turned out. This stopcock is furnished with the usual $\frac{3}{8}$ thread (brass), and can be screwed on the ordinary fittings. It may be mentioned that the reserve jet which is fed by the bye-pass is screened by a shield, so that no light can be seen.

OPENING OF THE NEW ORLEANS EXHIBITION.—At the opening ceremony on Tuesday last, the Exhibition buildings, which cover more than sixty acres, were crowded in every part. President Arthur declared it open, and started the machinery by telegraph, direct communication being established between the White House and the Exhibition, and when the great engines commenced to move, the whole became active and animated. The Exhibition is, however, far from complete, as many of the exhibits are not yet unpacked. There are many exhibits of photographic interest, especially the north gallery and east section. Mr. E. L. Wilson is superintendent of the photographic department.

DEATH OF PROFESSOR KOLBE.—This distinguished chemist expired on the 25th of last month, and his contributions to scientific chemistry will long be remembered; indeed, modern chemical theories of organic chemistry, as based on the supposed self-saturating properties of the carbon atom, may be regarded as mainly the outcome of Kolbe's investigations and writings.

MR. GORHAM'S PUPIL PHOTOMETER.—It should have been stated that the article on p. 793 is reprinted from *Knowledge*.

To Correspondents.

*** We cannot undertake to return rejected communications.

*** NOTICE TO ADVERTISERS.—Advertisements intended for insertion in the issue of the PHOTOGRAPHIC NEWS of December 26th, should reach the Publishers not later than noon on Tuesday, December 23rd.

A. J. H.—1. About forty cells of the Bunsen battery. 2. The cost of the former would be at least double.

K. A. B.—The address of the Company is 31, Farringdon Street.

A. G. BROPHY.—1. It will keep for a few weeks, but not so long as the best samples of ready-sensitized paper. 2. No, the result will be an emulsion of less sensitiveness. 3. It is equally efficient, but hardly so convenient.

THOS. E. SANSOM.—1. By the selection of a suitable kind of gelatine, and by avoiding air-currents during the period of drying. The addition of plaster of Paris is not advisable, but you may add a little of the finely-ground sulpqate of baryta, which is sold as "mountain snow" or "permanent white." The thinner the film, the less the relief. 2. You can strip the gelatine negatives by the method of Mr. Plener, (see page 465 of the present volume.) 3. We do not know of any good method. 4. No, it is useless, you should obtain a clear and hard gelatine.

H. SPINKS.—It simply means this: that 98 parts of bromide of ammonium will decompose the same amount of nitrate of silver as 119 parts of bromide of potassium, but we do not see that this will help you much in compounding what you require. 2. It seems to us that it is rather in using it and adapting it to the exposure of each plate, than in originally compounding it, that the difficulty steps in. 3. We shall be very glad to see it, and will take an early opportunity of doing so.

GEORGE SMITH.—Unless under very exceptional circumstances, we should not think of publishing letters addressed to other persons; consequently, we are obliged to omit those you send.

PACO.—1. Probably that of Rossignol, described on page 756. No doubt you can obtain it through Messrs. Marion and Co. 2. Not when the views are taken from the street, or from private premises; but there are, in many cases, regulations against photographing in parks and public gardens without permission. The gate-keepers or persons in charge will always give information as to whom to apply to, and there is seldom any difficulty in obtaining permission. 3. This depends on special circumstances; but we may mention that a permit to photograph in Kew Gardens is often available for twelve months, but only during the time when the Gardens are closed to the general public. We are always very pleased to give our correspondents any information in our power, or to endeavour to obtain information for them.

F. STANLEY.—The best method is to burn a weighed portion of the cuttings, and to fuse the ash with twice its weight of dry carbonate of soda. A white heat is required, but in the case of a small quantity, it is sufficient to keep the mass in a state of fusion for ten minutes.

W. A. O.—You can copy it on a reduced scale, but the camera will not expand to a sufficient length to enable you to make a reproduction of the same size as the original. You can, however, fit a conical extension-piece to the front of the camera. Thank you for the paper, of which we shall make use.

A. L. T. H. HAAKMAN.—We will endeavour to obtain the best information on the subject, and will write to you.

BOX.—A few words on the subject in this column would be of no use to you, but we will treat of it in a special article before long.

POLISH.—The best is the so-called encaustic paste—

Best white wax ... ... 1 ounce
Turpentine ... ... 5 ounces

Melt together with a gentle heat.

QUANDARY.—From the appearance of your samples, we think it likely that the mischief arises from the presence of some deleterious material in the mounts. Cut some prints in two pieces, and mount one set of halves on the mounts now in use, and the other set on mounts such as you have used before. Now keep all the samples under similar conditions, and if those on the fresh mounts should fade, make a claim for damages against the firm supplying the cards.

GEO. N. FELL.—Make a solution containing sixty grains to the ounce, and add two drops or more of this to each ounce of the solution, according to the extent of the over-exposure.

WOLL.—Add one drop of sulphuric acid to each three or four ounces of the iron solution, and use it while fresh. Thank you for the cards; we shall make use of them, and of your letter.

THE PHOTOGRAPHIC NEWS.

VOL. XXVIII. No. 1373.—*December 26, 1884.*

CONTENTS.

SENDING OUT PROOFS.

THERE are many photographers who think that anything will do for a proof, and photographers adopt various methods of sending samples of their work to their customers. Some there are who send out proof prints as they come from the printing frame; the negatives untouched, the prints untoned and not fixed, with but a few minutes' life if shown to the light. Everything is done to convince the sitter that the operator has a thorough contempt for his own work, and is scarcely in a position to appreciate the characteristic expression and the graceful pose, if these desirable qualities exist. How are the friends of the sitter to judge of a print which is—

"Like the snow-fall on the river,
A moment white, then gone for ever?"

How can any reasonable photographer expect to get orders for copies under these circumstances? Others tone, fix, and trim their proofs, but send them unmounted, and from untouched negatives, accompanied by a printed label stating that if any of the proofs are considered satisfactory, the negatives will be retouched. This, we believe, is the practice of a large number of photographers; but the curled-up, unmounted prints do not give the sitter a fair chance of judging them; consequently, those who take a pride in their work go further than this, and send out their proofs, or the best of them, completely finished; and they are indeed wise in going to the extra trouble and expense, for the finest sample must *always* bring in the largest order.

We have inquired regarding the sending out of proofs of many photographers, and give the method of two of them whose studios are well-known in the profession as model establishments. The one is in London, the other in the country.

The London photographer sends two or three proofs, one of them completely retouched, the other partly so; accompanying them is the following circular:—

"Mr. A—— begs to enclose proofs of Miss —— photographs.

"It is particularly requested *that all* the copies may be returned, and the numbers required from each selected position stated on the reverse sides of the chosen proofs."

There is also sent another printed slip as follows:—

"*Re-Sittings.*

"Should a re-sitting be desired because of an unsatisfactory expression, unsuitable dress, or in consequence of any defect for which Mr. A—— cannot be held responsible, half the fee will be charged for the second sitting; for which sum, however, half the number of copies will be sent in addition to the original order."

"*Sale of Photographs.*

"As it is Mr. A——'s strict rule never to publish portraits of private individuals, copies of these photographs will on no account be sold to anyone applying for the same without the direct written authority of the sitter."

There is no price mentioned, an omission which is not made by our next example. We fear, also, that the paragraph touching re-sittings is a direct invitation to his sitter to—shall we say?—sympathise with Ananias, or at all events to try to prove that the necessity for a re-sitting was not caused by any fault of his own.

Mr. B——, we believe, grants re-sittings without making any inquiry as to whose fault it was that made one necessary. He only desires to know what is objected to, and asks for any suggestions for alterations. These questions, he informs us, in connection with the paragraph on his envelope printed below, which is intended to frustrate the wicked designs of those who scheme to obtain a quantity of proofs to select from, often saves re-sittings, which he finds he gives to the extent of four per cent. of the number of persons who sit to him—not a very extravagant quantity.

Mr. B—— sends several proofs, all mounted on plain mounts. One only of the negatives is retouched, and the following label is affixed to the print from it:—

"Mr. B—— has retouched the enclosed Portrait much more highly than the rest. If any of the others should be preferred in expression or general effect, the order can be given from them, and they can, if required, be finished in the same manner."

The whole of the proofs are sent in an envelope on which is printed something to the following effect, the prices, of course, varying according to the size and style of the portraits.

Cabinet Portraits.

"The portraits in this envelope are eight for £1 1s., one dozen for £1 8s. 6d., two dozen for £2 10s., fifty for £4 10s.

"The whole number required may be ordered from one, or made up from several of the enclosed proofs.

"Proofs not approved may be returned or counted in the number required."

☞ If a re-sitting is desired, the proofs now submitted must be returned and destroyed before the second sitting is given.

This method of sending proofs is very plain and straightforward. The list of prices not only prevents disagreeable mistakes, but the "reduction on taking a quantity" often induces a larger order than would otherwise have been given.

DEATH OF MR. HENRY GREENWOOD.

WE are pained to have to record the death of Mr. Greenwood, of Liverpool, a gentleman well known in photographic circles as the founder, printer, and proprietor of the *British Journal of Photography*. He also established the *Liverpool Journal of Commerce*. Mr. Greenwood, whose age at the time of his decease was 64, had been ailing during the last few months, but the end came very suddenly

at an early hour on Tuesday morning, the 16th inst.; he having transacted business up to a late hour on Monday night.

NORTHAMPTON PHOTOGRAPHIC EXHIBITION.

Second Notice.

On looking round the walls of the well-lit Gallery, formerly the home of the Northampton Museum, one cannot help being struck by the number of old favourites that meet the eye at every turn; but, of course, this of necessity must happen where there is no restriction as to prior exhibition, and would apply to all the country photographic exhibitions which have of late become so popular. Several of the pictures lately on the walls at Pall Mall have gained immensely by the capital light in which they are seen, notably "The Cuckoo" (112), by H. P. Robinson. This very beautiful composition was skied in Pall Mall; but here it is well hung, and in consequence all its merits are offered to the eye without difficulty: the result is an old friend with quite a new face.

We will now proceed to make a tour of the Gallery, and in our review of the pictures will follow the order of the catalogue. A striking frame of Boudoir portraits (4), by J. Lafayette, arrests the attention. They are very uniform in quality, and technically good.

Near them is a frame of portraits (10), by T. Galloway. The portraits do not call for special mention, but in the frame are two or three studies of a more ambitious character. They are broad in treatment and Rembrandt in effect, and one of them, an old toper, jug in hand, is excellent, and has borrowed its inspiration from the old Dutch masters. "A Cock-and-Bull Story" (12), by Malcolm H. Clark, is an ambitious attempt, and tells its tale fairly well. A bronze medal has been given to "Both Faces," a series of cabinet portraits (13) by F. Greene. The show of small portraits is extremely moderate, and this frame does not call for any particular mention. "Too Late," by Chaffin and Sons, is a capital picture, but has been already described in reviews of former exhibitions. "Under a Shady Tree" (22), by G. Mald, is a group of gipsies, and they are very shady indeed. "The Village Corn Doctor" (25), by F. J. Seed, is a study of peasant life. The expression on the faces is good.

The Rev. B. Holland sends several frames; the best in our estimation being "Paddlers" (29), a group of boys bathing in a shallow winding stream. As a photograph it is a little hard, but is a pleasing picture notwithstanding. "Spanish Imperial Eagle," an enlargement in carbon, by T. J. Dixon (36), is an old friend, but shows extremely well in this gallery.

"Just Let Loose from School" (62), by E. Smithells, is a good photograph, but the grouping is a little formal. "A Study of French and English Partridges" (63), and "A Study of Fish and Moor-hens" (65) may be regarded as a friendly competition between Mr. and Mrs. Payne. They are perfect examples of still life, and both in grouping as well as technical excellence leave nothing to be desired. To the latter, by Mrs. Glen Payne, an extra bronze medal has been awarded.

In frame 66 are a series of views in Derbyshire and Wales, by C. E. Abney. They are small in size, but large in quality, and, taken as examples of artistic selection and manipulative skill, will hold their own against the more pretentious efforts in the Exhibition. J. H. Mendelssohn, in the portrait of Master Newman (68), has scored a great success. It is so gracefully unconscious in pose as only children can be. "Meditation" (169), by T. Whaley, is a very good picture; it is low in tone, but very harmonious. A graceful girl is before a fireplace, in deep thought; the background is well carried out, and in perfect keeping. No. 76, by W. Telf, is a yacht race, and is one of the many capital marine pictures in this Exhibition. A group of three ladies (79) is a capital example of unconventional portraiture by Rupell and Sons. Mrs. W. E. Gladstone and daughter (88) is an extremely good portrait study by T. Fall. "Darby and Joan, Cochin China Prize Birds" (89), by J. Negham, is a very fine carbon enlargement. "Homeward" (90) is a most charming rustic study. It is a three-quarter length figure of a little village maiden, jug in hand. The pose is perfect and the drapery free, and yet well showing the graceful lines of the figure. The background, however, is too prominent, and, being nearly of the same colour as the figure, tends very much to spoil an otherwise very fine picture.

Some large portraits, printed in carbon (9), by Mavius and Vivash, are worthy of notice. They are large heads, and are very forcible, and yet not wanting in delicacy, and though hung far above the line, are very striking, and command attention.

There is an unusually fine collection of Adam Diston's beautiful pictures, all of which are old favourites; but never have they been seen to better advantage. A silver medal has been given to 103, "Out of Sorts; but "Industry," "The Poor of the Village," "Gloaming," and "The Smithy," are all so equally good that the award was practically for the series.

"Bad News" (111), by Malcolm H. Clark, is an ambitious attempt in a worthy direction, and in spite of some shortcomings there is great promise. The scene is well chosen, and great pains have been taken with the costumes of the models; but great knowledge is wanted, as well as special fitness on the part of the photographer, to give the proper animation and expression to the actors of the scene. Practice will do much, and we advise Mr. Clark to go on and prosper.

THE ASSOCIATION OF PHOTOGRAPHIC ASSISTANTS IN VIENNA.

A pamphlet of over fifty pages tells us of the organisation formed in Vienna by the rank-and-file of the photographic workers; and if we may judge by what the Society has done during the past two years, a useful future is before it.

Not only does the Association take means to provide situations for those members requiring them, and afford monetary help to those who have been victims to illness or other misfortune, but it holds monthly meetings, at which photographic topics are discussed, and papers read. Just to give an idea of the activity of the Association in this direction, we may enumerate the subject matters brought forward, or papers read, at three successive meetings—March, April, and May, in this year.

March Meeting.—"Yellow fog on gelatine plates," by L. Grillich; "Exhibition subjects," by Ch. Scolik; "Lighting of the sitter in the studio," by F. Leyde; "Tourist apparatus of ebonite," by J. Czerny; "Digestion apparatus, emulsion filter, electric lighting apparatus for the dark-room, instantaneous shutter, and a collection of views," by Lieut. L. David; "Illustration of Eder's reducing method," by R. Hamsa; "Collection of supplements issued with photographic publications," by the Committee.

April Meeting.—"Report on Kopecky's reduction method," by the Committee; "Hints on work away from home," by A. Schild; "Retouching," by F. Hejda; "Photographic decoration," by H. Möser; "Lighting studies," by A. Schild; "A collection of photographs from Singapore," by F. Skalnik.

May Meeting.—"Demonstration of Henderson's emulsion process," by Gelpke and Scolik; "A quick shutter," by R. Scalla; "A collection of photographic colour-prints," by F. Leyde; "Photo-engravings," by C. Scolik; "A pocket dark room lamp," by J. F. Schaschek; "Instantaneous pictures," by K. Schierer.

Another good feature is the lending-library, which now contains the most important standard works on photo-

graphic subjects, together with the principal photographic publications.

As regards money matters, the Vienna Association appears to be, not only in a thoroughly solvent condition, but to have funds to spare: as apart from the regular contributions of over two hundred members, it receives liberal yearly contributions from nearly all the large photographic firms in Vienna.

The Photographers' Benevolent Association of London would require many modifications and changes to make it as useful and efficient as the Vienna Society; but it is worth while for the Committee to consider how far it may be possible to endeavour to make the Society a closer bond of union among assistants, by providing them with the means of culture and improvement as regards the technical or artistic aspects of their occupation. It is by no means improbable that if the Benevolent Association were to extend its operations to the limits embraced by the Vienna Society, it would meet with increased support.

In speaking of the *brochure* referred to at the beginning of the article, we omitted to mention the excellent collotypic print which accompanies it. The collotype is from the establishment of Herr Eduard Türk, of Vienna, and consists of a grouping of the portraits of the Committee; that of Herr Hans Lenhard, the President, occupying the central position.

AN ARTIST ADVERTISING FOR PRETTY BABIES.

The *New York Tribune* says:—

"Hegger, the artist, advertised for some pretty babies the other day, and at the appointed hour a dozen or more nurses appeared at his studio, each leading or carrying a child. To a casual observer they were a pretty lot, the babies, and one could not but wonder why they all were children of wealthy parents, for their dress plainly indicated that they were. Mr. Hegger came in, and, in his brisk business-like manner, began a survey of the little group, gently removing or pushing back the bonnets, caps, and hoods, so that he might fairly see the faces. He completed the inspection in ten minutes, said none of the children would do, and sent them away, many of the nurses evidently disappointed at his poor taste.

"'What were you looking for in those babies?' a friend asked of the artist.

"'I was hoping to find a pair of eyes large and wide apart, a short upper lip, regular nose and ears, and an oval chin. I was disappointed. Will have to try again.'

"There were some pretty children among the number, but not one that would make a good picture. No one but an expert can imagine how difficult it is to find a baby that will answer the purposes of the photographer. They are compelled to take the countenance in detail, and there is a certain combination of features that makes a handsomer picture than all others. It is not always the prettiest face that makes the prettiest picture. Oftentimes the unattractive baby in rags is the ideal that all artists are searching for, and only an artist would ever discover its beauty."

ISOCHROMATIC PLATES.

With reference to the making of isochromatic plates with chlorophyl, Mr. Ives writes as follows:—

"Having just tested some of the blue-myrtle chlorophyl solution which was made up six weeks ago, and left in the bottle with leaves and some zinc powder, I find it works exactly as good as when fresh. I have often used a two-months old solution, which was kept without the zinc powder, but it always required two or three times more exposure, and showed relatively less colour sensitiveness, necessitating the use of a deeper coloured yellow screen. I find the solution made up with fresh leaves, and the addition of zinc powder, not only keeps good, but gives the best effects with a much lighter yellow screen than I formerly used.

You may remember I expressed a belief that the colour sensitiveness of isochromatic plates was due to a chemical change, and not to the mere colouration of the silver bromide. One proof of this is the fact discovered by me six years ago, that a collodio-bromide plate treated with an infusion of black tea, when exposed through the yellow screen, shows the same colour-sensitiveness as with eosine, giving even better (clearer) negatives, but requiring longer exposure. The tea organifier, after standing on the plate about a minute, must be washed out as thoroughly as possible (like eosine) to give the greatest sensitiveness, and it does not colour the silver bromide at all. The experiment has no value, except to show that the colour-sensitiveness depends upon a chemical change, because chlorophyl gives so much greater sensitiveness to colour that no one who knows its value will use either tea or eosine.

"I have only recently learned that the evergreen plant here known as 'blue myrtle,' is in some localities called 'periwinkle.' I find it described under that name in Chamber's *Encyclopedia*, which gives the botanical name *Vinca Minor*."

Details of Mr. Ives' process of isochromatic photography with plates stained by the chlorophyl of the blue myrtle, will be found on page 566 of the present volume; also in the Year-Book, where a striking example-print is given. The print consists of two reproductions of a chromo-lithograph, one on an ordinary plate, and the other on a chlorophyl plate.

CHAPTERS IN PHOTOGRAPHIC HISTORY.

BY FRANK BISHOP.

A representative of the *Pall Mall Gazette* has interviewed Mr. Bishop, and thus reports what this gentleman says:—

"So you want me to begin at the beginning, do you?" "Well, it is a long story, and I won't go into details about who did or who did not discover the art. That is ancient history, but I will begin with the introduction of the carte-de-visite, which was undoubtedly the great popularizer of photography. About twenty-five years ago, a Parisian photographer conceived the idea of printing the portrait of a person upon a visiting card instead of the mere name, and when he carried his idea into execution it was adopted by all the *élite* of Paris. Instead of the ordinary visiting card, a small portrait of the visitor was handed in, and hence the name carte-de-visite, which, as you know, is still used to describe the smaller kind of portraits. Very soon it became fashionable to make collections of these cards, and as people became more and more curious to see pictures of great men and handsome women, they were exposed for sale in the publishers' windows, and birth was given to a trade which has now developed to such an enormous extent, that it is impossible to estimate it. We ourselves were the publishers who introduced the carte-de-visite in England; but as the demand increased—and it did increase to such an extent that it was quite impossible to meet it—other publishers took up the trade, and the sale went on merrily. Portraits of people whom the purchasers knew nothing whatever about were eagerly bought up. It was the proper thing then to have a collection of these particular pictures, and it mattered little who the originals were." "How did the portraits come to be public property?" "Well, in this way. If a photographer was known to have taken the portrait of any member of the Royal family, or of any notable person, and he could succeed in getting permission to publish that portrait, our policy was to make arrangements with the photographer at once, and secure the monopoly of the sale. In this way we purchased £27,000 worth of portraits from one London firm alone during the first three or four years.

"When any great event happened, then was the time for the photographers. On the death of the Prince Consort, the rush for photographs was something enormous; and again, when the Prince of Wales brought his Royal bride to England, there was a perfect *furore*; it was impossible to print their portraits fast enough. And here I should like to say how much the latter-day photographers are indebted to the Prince of Wales. I know of many cases where he has put himself out of the way to give them

a good sitting, and expressed a hope that the picture would be a successful one from the photographer's own particular point of view. This is no foolish vanity of his: nothing more than a kindly desire to oblige. Some people, when photographs were first published, were always 'sitting,' and took a delight in it. Others were very difficult to get. Lord Brougham, for instance, was continually sitting for his portrait, and if he passed a shop window in which his photograph was exhibited, he would go inside and ask how they were selling. Mr. Disraeli, on the other hand, was very coy. He had a decided objection to being photographed. His wife over and over again urged him to have it taken, and the carriage was many times brought to the door, but he would at the last moment make some excuse about want of time, and then there would be another disappointment. At last the importunity of his wife prevailed, and Mr. Disraeli was driven off to Miall's, and successfully photographed, though sorely against his will.

"About ten years after the introduction of the carte-de-visite, the cabinet size portrait came into use, and that is now the popular size, although the recently-introduced panel-shape and promenade kinds are in great favour among the wealthy folks. The little carte portrait to-day receives its chief support from the poorer classes, and large numbers are still distributed by what is called the club system. Only a few days ago we supplied one well-known photographic firm in London with 2,000,000 cards to mount their 'club' carte-de-visite portraits 'upon.' Photographic views, when originally introduced, were generally large and very expensive. When the carte-de-visite mania, however, was at its height, large numbers of smaller views were sold, while in the shape of stereoscopic slides they were produced by the million. Now we absolutely cannot sell this kind of photograph. They were crushed out of the market by the productions of unscrupulous men who flooded the trade with vulgar, brutal subjects. Latterly, as in the case of portraits, larger views are in demand, and the excellence and beauty to which photography has been brought was, as you say, very clearly shown at the Photographic Exhibition in Pall Mall. English photographers always stood pre-eminent for the excellence of their landscapes, and foreigners could in no way approach them; but in portraiture the reverse held good. Paris led the way for excellence and artistic production; then Vienna came to the front; and at last Sarony, of New York, stood first. But within the last few years the English photographers have forced themselves into the front place in portraiture, as they have always done, and still do, in landscape work.

"You ask me about photography among amateurs. I could say a good deal upon that subject, for the recent improvements in the art have rendered the study of photography one of the easiest, as certainly it is one of the pleasantest, studies it is possible to find. Amateur work may be said to owe its existence to the introduction of dry plates, and especially to the Britannia plates, because they are easy to work and develop so readily. Apart from the vast number of persons who use photography merely for an amusement, there is scarcely any set of professional men that does not include amateur photographers, who find a pursuit of the study something more than a pleasure. It is taught to the soldier and the naval man in our military and naval colleges; the painter makes use of it, though he does not always let it be known; the architect and the engineer find it invaluable; by its means the medical man records typical cases as they come under his notice; and outside the professions ladies, as well as gentlemen, can pursue the study with success at the very outset of their experiments. For an expenditure of 45s., one can buy everything that is necessary for a young beginner to take portraits and landscapes with little or no tuition, and to those who can afford to spend more money, there are all kinds of useful and convenient appliances. The pedestrian may go off in search of the beautiful with a little 'Academy' camera in his pocket, the miniature plates, all ready for exposure, being conveniently carried in the camera itself; the tricyclist may take a more elaborate set, and since the plates have only to be exposed and then replaced in the dark box to be developed at some future time—six months hence, if needs be—photography may now be said to be within the reach of all. Lessons are given free to purchasers, although very little tuition is needed. Look at this scrap-book and you will be convinced. There are some very good landscape views which were taken by Sir Henry Bessemer's grandson with a cheap set of materials, and his first dozen plates. So you see what was once a very impracticable study for any but professional men, is now an eminently practical one, and within the reach of everybody—ladies as well as gentlemen, and young people too. Depend upon it, the next two or three years will see a wonderful development of photography among amateurs."

HINTS ON POSING AND THE MANAGEMENT OF THE SITTER.

BY H. P. ROBINSON.

Chapter X.—Suggestion and Interference in Posing.

The photographer is often annoyed by the ridiculous suggestions made by the friends of the sitter, and sometimes by the sitter himself, although the latter oftener takes the character of a hopeless victim.

It is a question how far such interference is to be tolerated, and how it is to be met?

Many photographers object to their sitters being accompanied by a friend, and prefer to have them to themselves. I do not agree with this exclusion, and always welcome the presence of one or two of the sitter's friends, if they are not fussy people, and gladly accept their hints and suggestions if they are made at the proper time—that is, before I begin to pose the model; any interference after I have begun is sure to do mischief. Everything depends upon the temperament of the sitter. She—it is the ladies usually who object to come alone—may like to have a friend with her to give her confidence, but prefers not to be looked at as the exposure is going on. It is always easy to manage in a case of this sort. The friend may turn away her head, or sit behind a curtain; in my own place I have a sort of ante-room to the studio, made attractive and comfortable, into which I send the friends when I find they are doing mischief by remaining in the studio. This is sufficiently near to satisfy the most nervous sitter, and they do not interfere with the operation. It is the practice of some photographers not to permit any one to be present, but it is not wise to draw a hard-and-fast line. It should be absolutely at the sitter's choice whether friends should be present or not; it is surely better to humour the sitter and get a good portrait, than to have your own way entirely and an inferior production. But when the friends have left the studio they should remain away until the exposure has taken place. Nothing is more disturbing than people going in and out. Above all, never allow peeping. Friends will sometimes go away, and then creep quietly back and peep through the door or through a curtain. Nothing could be more calculated to make the sitter nervous than this sort of thing, and it quite prevents all endeavours to try what might be called experimental expression. Sitters are often inclined to think they lose dignity if they do not look dignified. It is often possible to talk them into a genial state, or get them to act the part—"assume a virtue if they have it not"—but this is quite out of the question if you or the sitter feels all the time that there is some one taking a surreptitious peep, and listening to all that is said.

Having made it clear that I do not object to two or three of the friends of the sitter being present, let us see how far these visitors are to be allowed to interfere.

Information is always valuable, and any information a photographer can get he should be thankful for, and use at his discretion. Of course, the size and style of the picture required has been settled in the reception room; but it is often of great advantage to get some further knowledge than can be obtained at first sight of your subject. It is well to know if former photographers have failed, and why. Was it expression, pose, dress, bad photography, or what? Useful hints of what to avoid can be easily gathered, and you may learn what is best to be done by judicious conversation; you should also find out the sort of thing that would be likely to please, such as any characteristic attitude or expression. All this will aid you in getting a picture that the friends will declare is "*so* like." I need not say that you should find out whether a sitting or standing pose would be preferred. It often happens that after the operator has taken the number of

negatives he thinks necessary or desirable to use in the particular case, and the job is, in fact, finished, some kind friend will suggest that she should so like to have "one in a hat." This you would have been very glad to do if you had known in time, but it is difficult to refuse, and you expose another plate. This might have been avoided if proper enquiries had been made at the outset.

Then there are those who want to see the pose, and will promise to go away when you are ready. These people are not easy to deal with. It is difficult to explain to them before the sitter that you may possibly want to surprise her into a characteristic attitude or expression; that would be to expose your carefully masked plot, and moreover, if you do let them stay, they will, perhaps, not go at the last minute, and the sitter will feel constrained, and tire while you are getting them out. My rule is, in *or* out, just as the sitter pleases, but not in *and* out on any pretext.

There are some people who are quite irrepressible. They promise not to interfere, and mean to keep their promise, but for all that jump up just as the cap is about to be removed from the lens, to alter a bit of drapery or set a lock of hair straight, or to make a brilliant suggestion, such as that the pose of the hands might be improved—when you are taking the head only! They knew very well that the hands would not be in the picture, but such people cannot restrain themselves, and should be got rid of if possible. When these vexing little incidents occur it is better to break off, make the sitter walk round the room, and begin again.

Some sitters will bring a friend to pose them. "It is such an an advantage, you know, to have the assistance of an artist," they will perhaps insult you by saying, on the strength of their friend having passed the second grade examination in free-hand, or copied some smudgy flowers on terra-cotta, but who, nevertheless, has never heard of composition. Of all the irritating assistance the photographer has offered to him, that of the amateur artist is the most difficult to accept smiling—or, perhaps, I should say, *without* smiling. The highly-trained artist is bad enough, as I shall presently show, but the combined ignorance and assurance of the amateur is quite fatal.

Then there are those who kindly endeavour to teach you your business—who explain that hands come large if placed too forward; that blue photographs badly, that yellow does not "take," and that photographs taken abroad are better than those done in this country because the light is clearer; and, finally, those who prefer to give you their instructions in learned words suited to the occasion, just as they would talk to a foreigner in his own tongue—and puzzle him. These wise ones want their portrait to be "a small focus," or "a large focus," and are surprised if you tell them that there are no different sizes of focus, and that focus has no other dimension than length.

How much help you are to admit in dealing with young folks, I have alluded to incidentally in the chapter on photographing children. It is quite impossible to get on if children are accompanied by a troop of friends, especially lively grandfathers and grandmothers. A father may sometimes be admitted if he be of an exceptional sort, but even in his case it is better to keep him in reserve for use if the usual means fail. Nine out of ten mothers are useful, but the tenth should be kept out of the studio. A nurse who knows her business is the best help you can have. Even she will sometimes want a standing portrait of a ten-month old baby, but it is easier to tell the nurse she is an idiot, than the mother.

It might be thought that artists, and those who have been trained to art, would be able to give very efficient advice in the studio; but I have found it quite to the contrary, and this invariably. Even experienced portrait painters are very much at a loss how to pose a sitter for the photographer, although they may require the photograph for their own use, and may have had time to consider the matter. The fact is, that painters are in the habit of going about their work in a more leisurely manner than photographers, and cannot pose quickly. They find it to their advantage to go quietly to work, as they can call up expression when they want it, or leave it to a future sitting; while the photographer knows that if he harrasses his sitter too much, he knocks the life out of him. Yet there are some photographers who gladly accept the aid of a brother artist if he can prove that he really is skilful in his business.

There is a story, that once upon a time, when an illustrious prince and his noble entertainer returned from deer stalking, they sent for a photographer to make a pictorial record of their successful day's sport. When the stags were being arranged, Sir Edwin Landseer, who was present, made some suggestions for the improvement of the composition of the group. The photographer resented this interference, declaring that he could not get on if those who knew nothing about art altered his arrangements. "But I am Sir Edwin Landseer," said the great artist; "surely you know my pictures." "Oh! if you are in the trade it is all right," replied the photographer, and gladly accepted Sir Edwin's assistance.

To conclude. Be strong, but hide your strength; be gentle in manner, but vigorous in the deed; make up your mind what you mean to do, and do it. If your sitter or her friends think all the credit is due to themselves, let them think so. It pleases them and does not hurt you; in fact, it is in your favour, for they will like the picture all the better if they fancy its merits are due to their own valuable suggestions.

MORE ABOUT THE SODA DEVELOPER.

BY W. M. ASHMAN.

The necessity of being always prepared to develop a gelatine plate with absolute certainty, and at the same time obtain the most perfect results, is apparent to everybody, and to say that anyone could not do this would be to assume grave responsibilities. In case there is an individual so incompetent, my further remarks may be considered to be addressed to him.

Alkaline development is more popular in England than ferrous oxalate, so alkaline pyro development shall alone be treated. The selection of a suitable alkali is somewhat limited, since, for practical purposes, only the carbonates and hydrates of ammonia, soda and potash, have been found valuable. There appears to be an intense struggle going on among experimenters in both hemispheres to establish in some way a sort of claim to the discovery of one or other of these methods. The duty of assigning each claimant his due will come with better grace from the perpetrators of history than from my pen, so for the nonce it will be sufficient to assume that pyrogallol was known to be affected by certain alkalies before gelatine bromide plates were discovered.

Now it is known that with certain precautions, exactly similar effects—both as regards colour and density—may be produced with either of the accelerators just mentioned; therefore, in choosing a stock developer, the main consideration is to find out which alkali offers the least number of disadvantages in proportion to the advantages.

Probably ammonia hydrate gives the highest percentage of trouble, for among its attributes we find complaints regarding uniformity of strength, liability to occasion red or green fog, and in susceptible constitutions a predisposition to produce colds, catarrh, &c. The prejudicial effects complained of have induced many to abolish ammonia from the developing formulæ altogether, and instal the less harmful soda or potash, the value of which is at least equivalent.

It has frequently been stated that soda is capable of producing density even more readily than ammonia; also

that the colour of the negatives so obtained are invariably yellow; but with neither of these statements can the writer agree, as any reasonable degree of opacity may be obtained with ammonia if the necessary precautions are observed, whilst the colour of a soda developed negative need not of necessity be yellow; in fact, yellowness is always absent when a liberal proportion of pyro is employed in conjunction with sodic sulphite and sulphurous acid as originally recommended by Monroe. Some writers having expressed a doubt regarding the value of sulphurous acid in the soda developer, it might be worth while recording an opinion favourable to its use founded on the practical evidence afforded by its continued employment for some months. The negatives so obtained leave nothing to be desired—a fact fully admitted at a meeting of the London and Provincial Association, before whom several examples were shown. Why others fail to get like results I do not know; it may be attributable to the sample of soda used, or the particular sample of sulphurous acid employed.

Solution of sulphurous acid gas made by an amateur chemist is not a product to be relied on. Should any doubt exist on this point, a very simple experiment is capable of verifying the assertion. Acidum sulphurosum B. P., if tested volumetrically, will be found to require three volumes of a one per cent. solution of ammonia (reckoning strong liquid ammonia to contain 30 per cent. of ammonia) to each volume of the commercial article, and I doubt if any home-made solution of the gas obtained by displacement will give a reading higher than volume for volume. Again, cold water dissolves thirty volumes of the gas under ordinary atmospheric pressure; but it dissolves considerably more under greater pressure and at low temperatures, therefore it will be found less troublesome to use the preparation made according to the pharmacopiæ, and obtainable at any of the wholesale chemists.

It does not seem at all necessary to use a very pure sample of soda, since common washing soda (mono-carbonate) fulfils all the necessary conditions.

To obtain the most uniform results, it is better to crush the crystals up rather small, and expose them on sheets of paper in a dry atmosphere for some time until efflorescence takes place. When the salt has considerably whitened, it is in a fit condition for use, and nine ounces may be dissolved in each gallon of water used in making up the stock solution, the strength of which will be about 24 grains per fluid ounce—half this strength being sufficient for most ordinary purposes—in conjunction with four grains of pyrogallol preserved in solution by means of sodium sulphite acidified with sulphurous acid. A developer of this kind causes neither frilling or fog (provided the plates are fairly good) and may be safely relied on for equality; moreover, the dark grey colour of the film enables printing to be carried on with the same rapidity we formerly experienced when dealing with good collodion negatives. Although a soda developer such as this can be used for several plates in succession, it is not advisable to go beyond three or four plates, neither is it wise to dilute it beyond the strength named, as the prolonged development necessitated by the weakened solutions do not yield such perfect negatives.

Reviews.

DEUTSCHER PHOTOGRAPHEN-KALENDER, TASCHENBUCH UND ALMANACH FUR 1885. Von K. Schwier: *Weimar. Preis M* 1·50.

WE have here an excellent and useful little companion for the German-speaking photographer. It is, in fact, a photographers' diary, with a clear space of about one inch by three, for each day in the year. Besides containing the usual matter of an almanack, it includes an excellent summary of photographic progress during the year, formulæ, lists of members of the principal photographic associations of Germany or Austria, and much general information of value to the photographer. The book is not too large to be carried conveniently in the pocket. It is bound in cloth, and provided with a socket for the pencil.

WASHING TROUGHS FOR GELATINE NEGATIVES.

BY W. COLES.

WITHOUT going into the question as to whether hypo-sulphite of soda, or sodium thiosulphate, left in the film, is injurious or not, it may be taken for granted that all photographers make some attempt at washing it out. In the good old collodion days there was not much apparatus required. Plenty of water in the cistern, free from dirt, and a tap to let it flow out, were generally considered sufficient.

When gelatine plates first came into use it was attempted to wash them in the same way, and some do so up to the present time. It was soon found, however, that this did not well carry out the end in view, and with large plates especially the space necessary to wash in this manner was more than could be spared.

Flat dishes being already in use about the operating room, were brought into requisition, the negative being laid face upwards and covered with water, which was changed sometimes, but as often forgotten. Of all the ways of trying to wash gelatine plates this is undoubtedly one of the worst. We have in a plate, just removed from the fixing-bath, a solution of hypo, which will tend to diffuse itself into water rapidly enough, if on a level with it, but which, being heavier than plain water, has little tendency to mix with water above it, unless shaken up. If, however, the plate can be propped up in the dish with the film downwards, the hypo-solution very quickly mixes with the rest of the water; but as this is not very convenient to arrange, vertical troughs holding several plates have come into use. The grooves should, however, be set on a slant (not upright as is ordinarily the case) so that as the water next the plate becomes charged with hypo, it can sink down and be replaced by fresh. The inflow should be at the top, and the outlet at bottom. The exit is generally by a tap or syphon; if the former, there is always a difficulty in adjusting the in-and-out flow so that they balance each other; either the trough is half-empty, or water is running over. If there is a separate tap to supply the trough, the water can be kept running, provided the supply is plentiful; but where only the tap over the developing sink is available, it is often necessary to fill the trough, and stand it on one side for a time.

With syphons as usually arranged, the bend of the tube is just on a level with the top of the plates. It should be at least an inch higher. If the water is not turned off the moment the level of the top of the syphon is reached, or if in moving the trough it is tilted at all, the syphon commences to act, and continues till the vessel is empty.

The little improvement I have to suggest, which I have found to be a convenience myself, is to make a small hole on the upper side of the bend of the syphon, so that water does not run out unless the trough is full, and only continues to do so while water is running in. The advantage of this is, that whether the inflow is much or little, the trough is always full, and the water running out just as fast as it enters. I frequently at night leave the trough under the tap, and the water trickling in, with the certainty of finding it full in the morning, whether the cistern happens to run dry or not. One of the best troughs I have seen is that of Mr. Edwards, in which a perforated tube carried round the edge inside allows water to be thrown as a fine spray between the plates. If the syphon

of this had a hole at top, as I suggest, it would, I think, be an improvement. It must be borne in mind that to get the washing over quickly, it is desirable now and again to empty the vessel completely. If a strip of metal is made to slide in grooves so as to close the hole when required, like the ventilators in a railway carriage, the ordinary action of the syphon can be obtained, and the water drained off. Large troughs should on this account be fitted with a tap having a good-sized bore, as well as a syphon. In practice it will be found better to have two or three small troughs for different sized plates, than one large one holding several sizes. The water in the smaller ones being renewed more frequently, the washing is better done.

THE ACTION OF LIGHT ON SILVER COMPOUNDS.

BY P. C. DUCHOCHOIS.

In the communication of a theory of the action of light on silver salts I made in June, I certainly made no pretence of having solved a problem which has always embarrassed photographers since the early days of the discovery of Niepce and Daguerre.

I know that the development of the latent image by reaction would not be accepted without comment, and would, perhaps, revive a discussion always interesting to those who have studied the changes light effects on certain compounds. I did not, however, expect to find among the opponent photographers who sustained —and not without good arguments—the physical theory to explain the formation of the image by a deposit of the silver reduced by an acid developer, for the dynamic theory, if it can be so called, explains in a similar manner the alkaline development. If the molecular change—or motion—imparts to the silver salt the property of attracting particles of metal, it may also cause the reduction of the insolated salt by reagents possessing a great affinity for the haloid which tends to separate from its combination with silver, as shown by the behaviour of an iodide of silver film which can be developed by an acid or alkaline developer, the image acquiring, however, in the latter case, little or no intensity.

It has been objected that in the impossibility of drawing a limit where the reduction becomes visible, it can be assumed that the invisible image is identical with the visible one. But the atomic motion necessarily preceding the chemical change, which is only a consequence, one may as rightly say that the action of reagent is altogether independent of any reduction, and results from the separation of the elements forming the bi-atomic molecules which become momentarily mono-atomic, and therefore in a state favourable to form new combinations; moreover, that impressions can be obtained without the direct intervention of light in circumstances which hardly admit that a reduction could be effected. I allude to the images of Moser and to the experiments of Hunt, Draper, and Niepce de St. Victor. Among the experiments of Moser I will cite the following, which is certainly very interesting:—A silver plate was iodized after the manner of Daguerre, and, at night, a medal cut in agate, an engraved silver plate, a horn ring, and several other objects were placed upon it. The plate was afterwards exposed to the vapours of mercury, and the image of each of these objects was perfectly reproduced. But the most extraordinary result obtained by Moser to show that this phenomenon was not due to an action of contact is, that these images were also produced in the most complete obscurity by bodies placed at a small distance from the iodized plate. From his researches Moser concluded that "all bodies radiate light in in the dark," and that "there is latent light as well as latent heat." R. Hunt was led to attribute this phenomenon to a different cause. His hypothesis, which he sustained by many ingenious experiments, was that they were due to an exchange of heat between the bodies placed in presence. At the time the experiments of Moser and Hunt were made (1841-1842), the correlation of the forces was not scientifically established; hence, probably, the divergent theories. To-day they could easily be concilliated, since heat and light are the same mode of motion.

It is hardly possible to imagine that in these experiments the latent image is formed by a chemical change, and if a deduction based on analogy has any value, one can admit that there is no reduction also when the light acts on the silver salts for the fraction of a second; moreover, that no means can detect any trace of elimination of the haloid, although the ten-millionth of one grain of bromine to the square inch eliminated from a 40 by 36 inch plate exposed under a thin layer of water would suffice to form a precipitate. The fact that an exposed plate can receive another impression when kept in darkness for a certain period, tends also to prove that no reduction has been effected, for, as the haloid has been evolved, how could this remarkable phenomenon be explained? Let us, however, suppose *a priori* that the silver salt is reduced either to a sub-salt or to metal. If the latent image be formed of metallic silver the development (alkaline) is inexplicable otherwise then by the theory now under discussion. This needs no comment; the silver being already reduced, the reaction can only be that of a substitution of base. As to the reduction in a sub-salt, it has been shown in the former paper that the insolated silver chloride was a mixture of silver and of unaltered salt. The arguments and the deductions from the analyses were objected to because—first: The sub-salt does not directly result from the dissociation of the haloid, but from the combination of the metallic silver in a nascent state of reduction with the silver chloride not acted on by light (?); second: The insolated substance is insoluble in nitric acid, and can even be formed under that acid; third: The isolated substance is a compound of a sub-silver salt first formed, of metallic silver resulting from the reduction of the sub-salt, and lastly of unaltered chloride.

The insolubility of the reduced salt—or a part of it—in nitric acid, is certainly a very remarkable fact, but not conclusive. The anomaly may arise from an allotropic modification or from a peculiar arrangement of the metallic particles with the unaltered silver salt. There are even some cases of isomerism which are more curious; such is that of the ferric hydrate, which becomes insoluble in acids when kept under water for some time.

The last objection has a certain value, and deserves to be taken into consideration, as the previous analysis may leave a doubt on the real composition of the insolated substance. A series of experiments were accordingly made, and, instead of investigating whether the haloid disengaged during the insolation was an equivalent of that necessary to combine with the precipitated silver. The solvents were also tested for chlorine or bromine, for, if one of the components of the insolated salt be a sub-salt, the liquid ammonia employed to dissolve the unaltered salt and precipitate the silver from the sub-salt must contain the haloid:—

$$3(AgCl, +Ag_3Cl) + 4NH_3 = 3AgCl + 3Ag_2 + 3NH_3, HCl + N,$$

or,

$$3(AgBr, +Ag_3Br) + 4NH_3 = 3AgBr + 3Ag_2 + 3NH_3, HCl + N.$$

The analysis showed no trace of either chlorine or bromine in the solvents after the unaltered salt had been precipitated by neutralizing the ammonia with nitric acid. Two grains of silver nitrate were used in each experiment, and after the addition of half a grain of sodium chloride or bromide at once formed a precipite with the silver nitrate added. In acid the silver bromide after one hundred hours' insolation, was hardly discoloured, only 0·55 grains of bromine having been eliminated, while under water the elimination was 2·17 grains. The silver chloride in the same circumstances gave 2·65 grains chlorine in acid, and 3·96 grains in water. In these experiments 68 grains of silver nitrate were precipitated by a slight excess of sodium chloride or bromide, and the silver salts washed by decantation before being insolated. The compounds insolated in water were partly insoluble in nitric acid, and the amount of silver found in the solutions, together with that precipitated by ammonia, was as near an equivalent of the haloid eliminated by the luminous action as can be expected in such analysis. The results were as follows:—

1. *From the silver bromide insolated in nitric acid.*

Silver bromide from the haloid in the acid	1·29	grains
Silver bromide from the silver precipitated by ammonia	1·45	,,

2. *From the silver bromide insolated in water.*

Silver bromide from the haloid in the water ...	5·10	,,
Silver bromide from the silver dissolved by nitric acid	1·20	,,
Silver bromide from the silver precipitated by ammonia	4·625	,,

3. *From the silver chloride insolated in nitric acid.*

Silver chloride from the haloid in the acid ...	10·70	,,
Silver chloride from the silver precipitated by ammonia	11·30	,,

4. *From the silver chloride insolated in water.*

Silver chloride from the haloid in the water ...	16·00	,,
Silver chloride from the silver dissolved by nitric acid	2·05	,,
Silver chloride from the silver precipitated by ammonia	15·10	,,

It is manifest, therefore, that the theory based on the formation of a sub-silver salt cannot stand the test of experiment, which proves without contest that the reduction is entire; that consequently the visible image is formed of metallic silver before fixing, and that although it may be supposed, as the contrary cannot be demonstrated scientifically, that the invisible image consists of particles of reduced silver, the alkaline development is nevertheless independent of that reduction, and results, as before explained, from an atomic motion which, in attenuating the affinity of the haloid for the silver, causes the former to combine with the reagents, and thus to deposit the metal which ultimately forms the photographic image.—*Anthony's Bulletin.*

Notes.

As one who has made a special study of out-door photography in winter time, Mr. Renwick stands pre-eminent, and his view taken across the Trent, with Stapenhill Church just visible through the haze, almost chills one when looked at. Those who propose to take out the camera during the next few months would do well to read Mr. Renwick's article on page 826.

Frost studies would make excellent Christmas cards, suggests Mr. Renwick in his paper: and he follows up his words by sending us half-a-dozen cabinet pictures, mounted on cards with suitable inscriptions. A little effect is realized by sprinkling the surface with the thin blown glass or "glitter," so much used for decorative purposes.

More Christmas Cards come to hand, those sent by Mr. Duncan, of York, being especially worthy of mention; a view of the Cathedral, the city arms, and a suitable inscription being tastefully combined.

The Sultan is, as we previously hinted, about to set an example which might well be followed over here by the masters of large households. The Commander of the Faithful having, it would seem, some difficulty in knowing who does and who does not belong to his domestic establishment, has issued an order for everyone to have his or her photograph taken. The list is to commence with the ladies of the harem, some of whom, so rumour has it, are personally unknown to his majesty; then follow the household employés of a superior order; then the servants and workmen; while at the bottom of the list figure the chief ministers of state and their clerks. All these photographs, the number of which the imagination dares not picture, are to be contained in one gigantic album which is now in course of preparation. A volume of the *Times* will be nothing to it.

The micro-photograph, as mounted on one end of a kind of Stanhope lens, is a familiar object to our readers; and the cheapness with which these can be produced commercially is surprising, as photograph, lens, and the fancy article which serves for a mount are often sold retail in the bazaars of Paris for half-a-franc—something less than fivepence.

In our "Patent Intelligence" will be noticed a curious suggestion, Mr. Galland-Mason proposing to mount a series of minute lenses and photographs on the top of one's spectacles or eye-glasses. Under these circumstances one might have at hand a series of maps of a district while travelling; a lawyer might carry a reduced copy of the more important notes of his case; or the detective might carry a whole album of portraits, and, while looking out for a suspected character, he could be studying his photograph.

We have already pointed out that micro-photographs might be applied to some of the above-mentioned purposes, and we cannot help thinking that for general purposes it would be better to group the lenses in separate mounts, somewhat after the fashion of the chambers the in breach of a revolver, than to mount them on the rim of one's spectacles, as now suggested.

The American photographer who tried the experiment of telling his sitters to look at the notice "Positively no Credit," while the exposures were made, has secured a fine series of pictures illustrative of the sentiment of discontent.

Among filtering materials, few substances have so many good qualities as are possessed by asbestos. It is not acted upon by water, wine, beer, vinegar, or petroleum; and but few of the solutions used in the photographic laboratory attack it. Dr. Weichselbaum says that if packed closely, it is, perhaps, the very best medium for freeing drinking water from spores and germs. Mere heating to redness serves to restore the asbestos, however loaded with organic matter it may have become.

During the past eight or ten years the trade in asbestos has become one of great importance, large quantities of the material having been found in the mountainous districts of North Italy.

According to Mr. P. L. Simmonds, who contributes a comprehensive article on "The Timber Supplies of Great Britain" to the *Journal of the Society of Arts*, box wood is getting extremely scarce, and the wood engraver will shortly have to find a substitute. Photography, however, comes to the rescue with the various chemigraphic processes as substitutes for wood engraving. At the present time one may estimate fully one-half of the block work done for illustrated periodicals to be "process."

The Austria-Hungarian Bank has adopted the Waterhouse process of photo-engraving for the production of bank-note plates.

A carbon print is developed upon a silvered coppered plate, and upon this as a mould, copper is deposited by the electrotype method until a plate about one-eighth of an inch thick is produced. These plates, when coated with steel by the method of Joubert, are said to yield 50,000 impressions; the printing being done on a machine.

WINTER.

PATENT OFFICE LIBRARY

picture behind. The distance is so short that, coming from the busy High Street, one cannot suppress an exclamation of surprise at the scene that bursts on the view. Here, from various points, I have taken some of my prettiest pictures, both in summer's heat and winter's frost; and though I have seen much of the vaunted scenery afar, that tourists delight to honour, yet for simple beauty I have found none to excel this favourite spot at home. I have spoken of winter's frost, for, thanks to the introduction of the dry plate, the photographer can now wrest his picture even from the cold grip of the frost king, and the beautiful effects of the hoar-frost can be seized by the camera and made into a picture, upon which one may gaze with delight in all seasons of the year. Many a photographer, before the invention of the dry-plate, has longed to catch the hoar-frost before the envious sun had melted its beauty, or the bustling wind had blown it away. It must be caught in a motionless air and while still freezing; and under such circumstances many a disappointed operator has found that, before his purpose could be effected, his old-fashioned wet plate had become a plate of ice.

I took some of my prettiest hoar-frost views on one of the coldest November mornings I can remember. A heavy fog hung over the town, such as we occasionally do get down the valley of the Trent, when, perhaps, in more elevated places, little of it is seen. The cold was severe, and the hoar-frost everywhere, no single straw in the street having escaped. The light was very feeble, in consequence of the fog; but I thought it an opportunity not to be lightly neglected, so I looked out my cameras and determined to do my best. I took three cameras, sizes 12 by 10, 10 by 8, and a half-plate. I took a dozen plates. The lenses I used were a 12 by 10 Dallmeyer's rapid rectilinear and an 8½ by 6½, same make, using this latter for the 10 by 8 as well as the half-plate cameras. My man looked blue as he assisted me to pack up; and presently he asked if I intended to try the "wet process?" I replied, "Certainly not"; but discovering a merry twinkle in his eye, I could not forbear laughing. I put him through the "wet process" by means of a bottle of Bass's best, warmed up my own system in like manner, and we started for the artistic realms of "Jack Frost." I nearly ran against my medical adviser in the fog. He noted the cameras, and said, derisively, "You can't do anything in photography on a day like this; the light you want will be *mist*." I smiled at his *hazy* pun, and told him that what *could* be seen could be photographed.

My experiment succeeded well; for, of the dozen plates I took with me, I made as many successful pictures. That presented herewith was one of that dozen. The fog had lifted a little, and I was just enabled to distinguish the village church of Stapenhill at no great distance. I wanted that, if it were possible, so I selected for the foreground a single-plank bridge, over a narrow section of the Trent, overhung by two old willow trees, glorious in their garb of hoar-frost. The bridge is used chiefly by anglers and bathers in the summer time, commodious dressing-rooms being provided for the latter, and both angling and bathing are free. Ugh! it made one shiver to think of those pleasant recreations just then. The parted palings show the cattle ford to and from Alligator Island, on which stands the solitary tree in the picture. A little to the right, but, unfortunately, just out of reach of the lens, is situated the antiquated halfpenny ferry, the boat being plied all day long between the Burton and Stapenhill banks of the Trent—a nuisance to the hurried man of business, but to the artist or antiquarian a scene of primitive beauty, and a relic of the good old times.

It was too cold on the day of which I speak to waste any more sentiment than was needed in the pictures, so having exposed my stock of plates I hurried homewards, intent on dealing with plates of a more substantial character, and of rather a warmer kind. I must not omit to say that I used for my pictures the prepared plates I obtained from Messrs. Fry and Co., and the exposure I allowed was thirty seconds, using smallest stop. I did not develop the pictures on the same day, as the light was not favourable. An over-wecning anxiety to see the results I had obtained would have been fatal to the whole. When they were developed I felt well repaid for the cold exposure both they and I had undergone.

Since these pictures have come within our reach I do not find they have been used for a purpose to which I think they are admirably adapted—viz., Christmas and New Year Cards. If printed in platinotype, they would make a valuable acquisition to that pleasant custom, and would be rendered permanent pictures. No colour would be needed, for an obvious reason. Unlike many of those now in vogue, they would be *bona fide* representations of one of winter's most beautiful phases, and faithful exponents of the Psalmist's exclamation, "He scattereth the hoar-frost like ashes. He casteth forth his ice like morsels: who can stand before his cold?"

FILM NEGATIVES FOR TOURISTS.

BY ARNOLD SPILLER.

Of the whole kit included in the photographic tourist's knapsack, nothing is so weighty or fragile as the packet of sensitive plates. In fact, it is the plates that debar the pedestrian tourist from carrying a larger apparatus than the so-called pocket camera. Whilst touring in Switzerland last summer, I used a 7½ by 5 apparatus, but then part of my route lay along the St. Gothard Railway, and thus I was able to send on a supply of plates by rail. Notwithstanding this help, I found that the couple of dozen or so sensitive films which I was, of course, obliged to take with me, added very considerably to my burden, and made the latter almost unbearable. It generally happens that the finest scenery is met with where the iron horse has not yet put in its appearance, and thus one is not able to avail oneself of its aid. Then, again, think of the predicament one is put to if, on enquiring at the luggage office, it is found that the baggage has not arrived.

It is thus evident that any practical substitute for glass to support the sensitive film, corresponding to the calotypic or collodio-bromide tissue processes should be hailed with joy, and add, to no small extent, to the capabilities of touring photographers. I do not propose to enter now into a historical account of the various methods designed for carrying out the desired end; suffice it to say that from my experience with the "negative-paper" prepared on the lines indicated by Mr. Warnerke some three years ago, and recently introduced into the market, I believe the application of photography to the requirements of the photographic tourist has entered upon a new era.

The "negative paper" is apparently prepared by coating paper, which has first received a substratum of hard gelatine, with gelatino-bromide emulsion. The material can be obtained either in single sheets or in bands. In the latter form it is used with the well-known roller-slide, the numerous advantages of which over the ordinary double back can hardly be too highly estimated. In the first place, the apparatus and sensitive tissue sufficient for fifty exposures are only slightly heavier and more bulky than a couple of dark slides; then again, one's daily exposures are only limited by the number of unexposed films that are on the roller, whilst with carrying three double dark slides, the number of exposures cannot exceed six, unless the somewhat inconvenient changing bag be used.

Another important advantage of using the roller slide is pointed out in the late Mr. Baden Pritchard's delightful paper entitled, "Photography from a Holiday-Maker's Point of View*." He said, "There is no changing of plates when you get home, and of all the tedious and distressing labours that a fagged-out pedestrian can be called upon to

* Photographic News, March, 1877.

perform, while his comrades are in bed and asleep, that of unpacking and re-packing dry plates, dusting and labelling them, and putting them in or taking them out of the slides, is about the worst. It is often, too, difficult to secure a suitable place for the purpose. In Norway, I remember, I was very much put out on this account. I meant to change my plates, as usual, at night-time, but found I had reckoned without mine host; to my dismay, it was as light at midnight as it is in England on a summer's afternoon. With the roller dark slide such difficulties as these fall away altogether."

Although I consider the roller-slide very valuable, at present my experience with the "negative paper" is confined to the use of separate films exposed in the ordinary dark slide. If the latter opens in the centre, and the plates rest on the rabbets, then a sheet of the sensitive material, cut to the exact size, is placed on the rabbets, and a solid support, such as a plate of glass or ebonite, is inserted behind. When the slides are of the solid form, and plates rest on the four corners only, it is necessary to use carriers made specially for the purpose.

The negative paper is made in two grades of sensitiveness; the *ordinary* ranges from 10 to 19 on the sensitometer, the *extra-sensitive*, from 20 to 25.

Before describing in detail the after treatment of the exposed film, it will be as well to remind the reader of the principle of the process. The film is first developed with alkaline pyro, whereby not only is the sensitive salt reduced, but also the gelatine in the immediate neighbourhood of the deposit is tanned by the product of oxydation of the pyro, and this becomes insoluble in warm water. The developed film is placed, face downwards, on a glass plate, and pressed tightly in contact with it. The plate, to which is attached the film, is immersed in warm water, the paper soon peels off, and the gelatine, containing the unacted-upon silver salt, dissolves away, leaving the developed image bare, and thus not requiring the usual fixing with hypo.

So far for the principle of the process. Here follow the details. The manufacturers advise for development the pyro-potash solution, as given on page 766; but I find that this solution is hardly sufficiently restrained, so I prefer to use the ordinary pyro and ammonia developer. Of course, as with gelatine plates, it is impossible to prescribe a universal formula, but the following may be taken as a fair standard for rapid films:—

A—Pyrogallic acid	...	...	...	8 grains
Citric acid	...	...	...	2 „
Water	...	...	...	1 ounce
B—Ammonia (·880)	...	...	...	4 drams
Potassium bromide		...	...	40 grains
Water	...	...	...	10 ounces

For a quarter-plate use 1 dram each of A and B diluted to 1 ounce with water.

The film is placed in the dish, and the mixed developer is poured on direct, without previous moistening. The process goes on just as with a plate, the image being sufficiently dense after some five minutes' treatment. After slightly washing in water, it is ready for transferring to the glass support, which process can be done in yellow light, or even gaslight.

In order that no time should be lost between the processes of development and transfer, before developing a glass plate of best polished crown or patent plate, measuring at least a quarter of an inch each way larger than the film, should be covered by means of a camel's hair brush with powdered French chalk, cleansed, and finally polished with a washleather pad. The plate is then covered with plain collodion and placed in a dish of water, so that by the time the development is finished, the greasiness on the collodion film will have disappeared. The developed negative is placed face downwards on the collodionized plate, and both are removed together from the dish, taking care that there are no air-bubbles between the two surfaces. Two sheets of blotting-paper and one of brown paper—or better still, india-rubber cloth—are placed on the back of the paper negative, and then thoroughly rubbed with a squeegee in order to press out as much water as possible between the gelatine and collodion films. It will be now found that on taking away the blotter, the negative paper will stick firmly to the glass, so that after allowing it to stand for ten minutes or so, it is ready for the warm water bath.

The plate is next put in a good deep dish containing plenty of water, which should be warmed to a temperature of about 100° F. After about a minute's soaking, the paper support can be peeled off; the gelatine and sensitive salt, unacted upon by the developer, is then removed from the image by gently brushing with a tuft of cotton-wool or a "Buckle's brush," while the film is still immersed in the bath. As a trace of the silver-salt generally clings to the surface of the film, it will often be found necessary to soak the plate in hypo, which will immediately clear the deposit. As there is such a comparatively small proportion of gelatine in the deposit, only a very slight washing is required to move the fixing salt. If the image is not dense enough, it can be intensified by the pyro and silver solution, or any of the methods used for carbon prints; but in my experience nothing is so simple as the treatment with mercury, and then with silver and potassium cyanide. It should be remarked that if the films be under-exposed, and the process of forcing by adding more ammonia be resorted to, the whole film will become more or less insoluble, and the plate will especially require fixing with hypo. On the other hand, if it is necessary to develop with a solution containing less than the normal proportion of ammonia, as with over-exposure, very slight insolubility of the image will take place, so that after the paper has been peeled off the plate, the latter should be placed directly in the hypo bath, without risking the treatment with the Buckle's brush.

To return to the negative: while it is attached to the plate, it is reversed, so that unless it is required for the "single-transfer," or kindred processes, the film must be stripped from its support.

A sheet of gelatine—such as is used for tracing engravings, and to be obtained from Messrs. Corneleisen, of Great Queen Street—is soaked in water until pliable, and then squeegeed to the film on the plate. After drying, the film may be easily separated from the glass by a little help with the penknife. In conclusion, it should be remarked that such film negatives can be printed from either side, a fact of considerable importance.

WITH THE BRITISH ASSOCIATION.

BY R. G. BROOK.*

WHEN the meetings of the British Association were over we dispersed in different directions. I decided to go to Ottawa on my way to Toronto, as I wished to call at Sharbot Lake, both to take views and get a day or two's fishing, and on this trip my first experience with the "baggage smashers" occurred. This is a very appropriate name for the porters on the American railways, and my first transaction with them convinced me of its accuracy, for on handing a parcel of eight dozen plates over the counter at Montreal, a demon of a fellow pitched it head-over-heels down a wooden shoot into some region below; I expected to find most of them broken, but I had taken the precaution to have strong tin cases made to hold each two dozen, and these again wrapped up in strong paper secured with leather straps. When I next met with the parcel, I found one dozen plates broken, and afterwards never parted with it in spite of all the grumbling of the car conductors about having too much luggage in the car.

At Ottawa I got a view of the Houses of Parliament, one

* Continued from page 789.

"After trying many experiments in double mounting on muslin, I have adopted the following method. I prepare several yards of cloth at a time by sizing with starch, and always keep a roll of it on hand ready for use. While damp the cloth is stretched not too tightly on a frame, and sized pleutifully with warm starch paste made rather thin, and spread on evenly. Where large quantities of muslin are used, perhaps tenter bars might be employed to advantage for stretching. When dry cloth is cut to the size required before mounting, allowance being made for the expansion of the prints, if the starch for mounting be used while warm (which I think is preferable), it should be as stiff as can be conveniently spread on the print, for the reason that it will expand the cloth less and dry quicker From the moment the first print touches the cloth dispatch is important; therefore both prints are first pasted, one being laid aside ready to be picked up quickly. The first print is rubbed down with a hand roller, which can be done more expeditiously than with the hands. When the second print is properly laid on the side there is less occasion for haste, and rubbing down by hand is preferable; because, although the roller does the work perfectly on the first print mounted, it is liable to leave air-bubbles in rolling down the second one. To avoid bubbles in the hand rubbing, the strokes should be toward the middle of the print, and not in every direction from the centre. When the mounting is completed, the prints are placed between papers and covered immediately with several folds of cloth of sufficient weight to keep them in place. To facilitate drying they may be aired after an hour or two, and placed between dry papers and again covered with the cloth."—*Scientific American.*

Correspondence.

"THE QUALITY OF THE SMILE."

DEAR SIR,—The above expression in last week's NEWS prompts me to say that every one who has skipped in a studio, or roved with a camera, must feel that they owe a debt of gratitude to Mr. H. P. Robinson for his continuous efforts to ennoble the art of photography. No man has laboured so long and so assiduously to place the latest-born of the Arts in the first rank of æsthetic form. Over and over again have I seen and felt the artistic ring of his mind in both his graphic and literary work. Doubtless, innumerable photographers have done the same, although it must be confessed they have not all absorbed the fructifying essence in volume enough to enable them to throw over their productions the unnamable aroma of true art; not that all may not be trying their individual best, but to catch hold of the principles of vitalising form requires not only a searching eye and analytic mind, but a keen and rapid perception of things fitting and beautiful. Without these qualifications and attainments it will be hard to know "The Quality of the Smile," or any of the other qualities adorning enjoyable art.

Quality in art! It is as rare and partial as any good thing can well be. Look, for instance, at the works of the President of the Royal Academy, and you will feel that it is the quality of the form which engages you; but rob them of their sculpturesque grandeur, and see if the colour don't vex you now it is the other way. Glance at the early morning pictures of Corot, and the quality of the colour will entrance, while the form will perplex and tantalize; and so in modified detail the same sermon on quality may be preached all round.—Yours, &c., J. PATRICK.

Edinburgh.

Proceedings of Societies.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

A MEETING of this Society was held on Thursday, the 18th inst., Mr. W. H. PRESTWICH in the chair.

Mr. W. E. DEBENHAM announced, with feelings of the deepest regret, the death of an esteemed member, Mr. Henry Greenwood, which occurred on the 16th inst.

The CHAIRMAN expressed his sorrow in suitable terms, and said his own sentiments were in accord with those of all the members of the Society. A vote of condolence was then passed, and the Secretary was requested to forward a copy of the resolution to the relatives of the deceased gentleman.

Messrs. MARION and COMPANY then demonstrated the method of printing and toning their *Britannia Alpha Paper*, and exhibited several specimens illustrative of its capabilities.

Several exposures were made under negatives of fair density, for periods ranging from nine to forty seconds respectively, within a few inches of the source of illumination, which was a pair of albo-carbon gas jets, ranged parallel, and six inches apart; this form of light being said to possess three times the actinic power of the ordinary gas burners of similar size. Daylight exposure would have required three or four seconds. The prints were then developed with ferrous-oxalate, the formula being:—

No. 1 Solution.

Oxalate of potash	...	...	1 pound
Bromide of ammonium	...	...	320 grains
Warm water ...	...	...	64 ounces

Filter—

No. 2 Solution.

Sulphate of iron	...	4 ounces	250 grains
Water ...	...	80	,,

Equal portions of Nos. 1 and 2 were used, and development was complete within five minutes. The further treatment of the proofs consisted in passing them through several changes of water, then soaking fifteen minutes in a saturated alum solution, and after well washing the alum out, toning in the following bath, which took rather less time than ordinary albumenized paper does.

Toning solution:—

Water ...	...	...	...	1 pint
Acetate of soda	...	...	...	60 grains
Chloride of lime	...	...	...	4 ,,
Chloride of gold	...	...	...	2 ,,

Fixing in hypo and washing concluded the demonstration. In reply to queries, the demonstrator said his rule was to use a given quantity of developer for as many prints as he could pass through in fifteen minutes. One print would set up sufficient decomposing action to render the bath useless ten minutes afterwards, so that several should be developed at the same time. The length of exposure determined the final tone—too little gave blackness—too much, redness; over-exposure and under development favoured the purples, and under-exposure with over-development the greenish and grey colours. Regarding suggestions to add salt or bromide to check developing action in the first washing water, he said it might be found to answer.

Mr. A. CLARKE passed up a print for development made on alpha paper by aid of the lamps, while journeying in a railway carriage that evening; the negative, which was very dense, required four days to get a print off in the ordinary way. A good result was obtained.

Mr. W. K. BURTON had used the paper, and succeeded very well with it. He considered it would be the printing process of the future.

In answer to a query regarding spotting out, the CHAIRMAN observed that albumen was a satisfactory medium to mix the colour with; when dry, it would be coagulated with methylated alcohol.

Mr. COWAN and others supported this statement.

Mr. A. L. HENDERSON showed an opal; the colours not being satisfactory, he toned it with acid gold and alum. The edges had since become pink. Had hypo and gold been employed, he believed the change would not have taken place. Gold and gelatine had formed an unstable compound in this case, so he thought.

Mr. LEON WARNERKE said he found yellow-stained films required enormously greater exposures for papers similar to that just shown, than was requisite when the shadows were free from that colour.

A vote of thanks having been passed to Messrs. Marion and Co.,

Mr. T. HEINRICH TRINKS said he was sure the Society had gleaned much information. It occurred to him that a well-fitted dark-room was much needed by the Society for demonstrative purposes; he therefore proposed a fund should be started for that purpose, and headed it with £5 5s.

A prolonged discussion ensued, but no definite decision was arrived at.

The Society then went into Committee, when the following resolution was carried:—"That the prize of five pounds offered

by Mr. Trinks be given, not to a specific article, process, or such like, proposed as a matter for competition, but be given for whatever original article, improvement, matter, or proecss of any kind may be brought bcfore the Soeiety by a member, and which shall appear to be of the greatest benefit to photographers in general; a limit of time to be fixcd at six months, and the determination to bc by a ballot of the whole Society. A condition to be that all details eonnccted with the matter are to be open to the Soeiety.

Mr. E. Solles was elccted a membcr of the Society.

BOLTON PHOTOGRAPHIC SOCIETY.

THE December meeting was held on the 4th inst. at the Baths, Bridgman Street, Mr. ROBERT HANROOD in the chair.

Mr. J. N. Anstwiek was elected a member of the Society.

The Rev. J. W. CUNDRY gave a lantern exhibition, the slides including an iuteresting set of Switzerland from the Lanternist's own negatives.

Dr. JOHNSON exhibited a set illustrating a recent visit to Norway, many of which elicited applausc.

Slides were also shown by Messrs. Parkinson, Dulta, Knowles, and Leueh, those of Mr. Knowles being espeeially worthy of remark.

At the eonclusion, Mr. Robert Knott moved a vote of thanks to Mr. Cundry and the exhibitors, which was seconded by Mr. John A. Walker, and suitably acknowledged by Mr. Cundry.

Talk in the Studio.

A RAILWAY CAR STUDIO.—One of the most ambitious novelties we have yet had the pleasure of inviting attention to is the Railway Studio, as our old friend, Messrs. Reed and Wallaee, of Mobile, have advised us through the medium of a little leaflet called *The Photographer on Wheels*. It is built in the ordinary form of a railway carriage 47 feet in length, 10 feet high, and 10 feet 4 inches in width. From the front platform the reeeption and ladies' room are entered, which have all the usual requirements for comfort. The central portion is the skylight, 24 feet in length, fitted with many novel applianees. The roof has a combination sash, curtains and shades, so arranged as to be shifted from side to side as the hour and position of the car may render necessary. Both the dark room and the operating room are supplied with everything for first class work. The rear is devoted to eulinary and other purposes. Under the car is a locker for rails, cross-ties, and everything necessary to form a side track, and over the ear a large substantial awuing can be drawn to afford ventilation and shelter from the sun. We are not aware of the cost, but the expense can eertaiuly not be inconsiderable, and we trust the enterprisiug gentlemen will find their venture a pleasant and profitable one.—*Anthony's Bulletin.*

COLONEL DAWSON'S POTASH AND SODA DEVELOPER. — The account of the mode of preparing this developer, given on p. 815 of our last issue, is not sufficiently full, and we are indebted to the Colonel for the following details. To make the developer, take :—

Carbonate of potash (London Pharm.)...	1 ounce
Washing soda	1 ,,
Bromide of potassium	20 grains

Dissolve the whole in sufficient water to make up a total of 20 fluid ounees. This solution may be regarded as containing ten per cent. of the mixed salts; and in mixing the developer for use, although one drachm of the above solution may be used with two grains of pyro made up to a fluid ounce with water, it is generally advisable to add the alkaline solution by degrees, and sulphite may be used with advantage. In short, the 1 drachm must be regarded as a variable quantity. In the YEAR-BOOK for 1885 (page 68), Colonel Dawson gives full particulars as to the above developer; also many hints whieh are ealeulated to prove of great value.

To Correspondents.

*** We eannot undertake to return rejected communieations.

A. G. F.—1. The most suitable glass is the "stained red," which is recommended by Captain Abney; but the "stained red" is rather deep orange than ruby. 2. An ordinary carbon print; but if you wish to go to the extreme of permaneney, you will naturally prefer a picture vitrified on enamel, 3. Thank you for your remarks.

H. M.—1. It will answer very well as a single lens, and will correspond in focus to near about the extreme length of your camera; but any marginal lines in the subject will be slightly curved, this distortion being barrel-like if the stop is in front of the lens (that is to say, if you place tho lens in the rear end of tube), or pincushion-like if the stop is behind the lens. 2. It is a matter of opinion which is to be preferred. If the leather hinges were fitted by a professed camera-maker, send the slides back to him for alteration, as it is his business to select a quality of leather which will not injure dry plates. Parchment or vellum is, however, to be preferred to leather. If brass hinges are used, very careful work is required to make the joint perfectly light-tight. 3. The simple expedient you mention answers extremely well, if a little judgment is exercised in taking care that the light from the top does not shine directly against a ceiling or other white surfaee.

COMMONER.—It will be far better for you to purchase it ready-made in the first instance.

W. H. B.—There is but little inducement to prepare dry pyrogallic acid on a small scale, as when manufactured on a large scale it can be turned out at a much less cost than when made in an amateurish way. A good method is to mix gallic acid with twice its weight of coarsely-powdered pumice-stone, and to heat the retort on a sand bath, while a current of carbonic acid gas is allowed to flow through it. Under these circumstances, pyrogallic acid condenses in the receiver; and if the work is carefully done, the gallic acid yields one-third of its weight of the pure product.

G. HERBERT.—The powder contains silver, but apparently not very much; still you cannot expect us to make an assay for you. When you add hydrochloric acid to the hyposulphite, you throw down a large proportion of sulphur, hence sulphide of potassium should be used in this case. To protect yourself in the matter of residues, you should do one of three things: 1st, reduce them yourself by fusion with an equal weight of dry carbonate of soda; 2nd, assay a small portion (after thorough mixing) by the above process, and then send the bulk to a refiner; 3rd, divide the batch into several equal parts, and send them to different refiners.

SURPRISED.—You are altogether wrong in imagining that the white cuttings from the edges of fixed vignettes contain silver. Indeed, the amount of silver to be obtained by burning ordinary fixed prints is so small as to render it scarcely worth while to preserve the cuttings, but cuttings of unfixed prints are well worth preserving.

V. BRAMBURN.—1.—As the photographs you mention have been produced by Government officials for use by the police, it is extremely unlikely that you will be able to obtain copies. 2. Without seeing them we cannot form any opinion.

ARTIST.—It may be quite true, but you have no reason whatever to be surprised at your correspondent resenting the suggestion if accompanied by such remarks.

'The Whittaker of the Photographer.'—*Chemical News*

OVER A QUARTER OF A CENTURY
OF PUBLICATION.
NOW READY, PRICE 1s., PER POST 1s. 4d.,
THE
Year-Book of Photography.

The YEAR-BOOK is now regarded as an essential for every photographer, whether professional or amateur, as it is a complete guide to every day work in the studio or the field, and contains contributions by the most distinguished photographic workers.

It contains photographs from nature printed in the copper-plate press, and on the type press; also an example of orthochromatic photography.

PIPER & CARTER, 5, CASTLE STREET, HOLBORN, E.C.
