In cases where the telegraphic method cannot be employed, longitudes are determined by observations of the eclipses of the satellites of Jupiter, of solar eclipses, of moon culminations, of occultation of stars, and by transporting chronometers. The results obtained by these methods are of varying degrees of accuracy depending upon the inherent errors of the methods themselves.

Azimuth.—Astronomic observations of azimuth are made to ascertain the directions of the lines established by a survey relative to the true meridian. Azimuths differ in grade according to the purposes for which they are required. For exploration work and reconnaissance, or for magnetic observations, theodolites with 3 to 6 inch horizontal circles are used to observe on the sun or on Polaris. For tracing meridian lines, or for tertiary triangulations, theodolites with 6 to 10 inch horizontal circles are used to observe on circumpolar stars. For primary tri-

angulations, requiring the determination of high grade azimuths, only circumpolar stars are observed with theodolites having 12 to 16 inch horizontal circles reading to single seconds by micrometer microscopes. In this class of work accurate time is always provided for except when the observations are made at elongation. A terrestrial mark is always used in connection with all azimuth observations.

Terrestrial Magnetism.—The complete magnetic work embraces the determinations of the three magnetic elements: the "declination" or "variation" of the compass, the "dip" of the magnetic needle, and the "intensity" of the magnetic force.

As it is impossible to represent the earth's magnetic condition for more than a definite moment of time, it is of great importance to provide for a continuous record of the innumerable fluctuations of the magnetic needle. In the work of the Survey, this is accomplished by the establishment of certain base stations equipped with sensitive magnetic instruments which make a continuous record, day and night, of the variations of the magnetic forces. At the present time these stations are situated at Cheltenham, Maryland; Baldwin, Kansas; Sitka, Alaska; Vieques, Porto Rico; and near Honolulu, Hawaii. From their records the magnetic charts are brought up to date and surveyors and mariners are provided with the exact amount of variation or change at any point between any two given dates. In addition to this work, true meridian lines are being established near the various county seats throughout the country for the purpose of enabling the surveyors to test and verify their compasses.

Hydrography.—The various processes which comprise the hydrographic work, and by means of which the shape of the submerged portions of the earth's surface is determined and subsequently delineated on the maps in the form of channele banks, and shoals, may be summarized as follows: (1) by triangulation certain points are established on the land from which the positions of the soundings subsequently taken are determined; and (2) by a topographical survey the positions of the shore lines, wharf lines, rocks that show above water, and the limits of dry shoals and banks are obtained. The data thus obtained is plotted on a map based on a suitable projection, the scale of which depends upon the minuteness of detail with which the submerged features are to be delineated. A scale of $\frac{1}{10,000}$ is considered as well adapted for the survey of most harbors.

Such a map shows the geographic positions of the various points such as church spires, chimneys, peculiarly shaped rocks and trees, and signals built over triangulation stations, selected as suitable to observe upon in locating the positions of the surroundings.

When a sufficient number of such signals and objects is available, and the tide gauge or staff has been erected at some point in the vicinity of the work, the lines of soundings are run by a boat and the soundings taken with a leadline.

A sounding party usually consists of the officer in charge, two observers with sextants, a recorder with watch or clock and record book, the leadsman with his leadline, and four oarsmen.

The method of operation is as follows: Beginning at a point, the position of which relative

COAST AND GEODETIC SURVEY

to the shore is noted by the recorder, the observers measure the angles between three signal points on shore and read the angles measured; the leadsman gets a cast of the lead and calls out the number of feet or fathoms; and the recorder records all of these together with the time when the boat commenced to move along the line of soundings. Once started the boat continues without stopping to the end of the line. In the meantime other pairs of angles are taken by the observers at three or four minute intervals, or as often as necessary, each set of angles locating the position of the boat at the instant of observation. A final set of angles is taken at the end of the line, and the boat is then moved to position at the beginning of a new line of soundings. When the depths change rapidly the soundings are taken as frequently as possible, the time being noted to seconds; but, when the depths are nearly uniform, indicating a comparatively level bottom, the soundings are preferably taken at equal intervals of time. When practicable the lines of soundings are run on ranges, i. e., the boat being kept on the same line with two objects on shore. The correction for the difference of level due to the rise and fall of the tide during the sounding operations is obtained from the readings of the tide gauge, such readings usually being made at five or ten minute intervals by an observer specially detailed for that purpose, and all the soundings reduced to the common plane of mean low water, the plane of reference adopted by the Survey for its charts of the Atlantic and Gulf Coasts. In smooth, shoal water, it is required that the reduced soundings on lines crossing each other shall not differ more than $1\frac{1}{2}$ per cent. of the depth. In deep-sea work, offshore, the tidal correction is not applied to the soundings.

At the end of each day's work the results are graphically transferred to the map, every position of the boat corresponding to any pair of angles measured on any three points on shore being plotted by means of a three-armed protractor. The successive positions of the boat being thus located on the map, the various soundings are easily and accurately spaced between them from the number and time intervals shown in the record.

The methods described above are employed to develop the slopes of the bottom, but in regions like the coasts of Maine and Alaska, which are characterized by many isolated rocks and ledges on the bottom, or like the coasts of Florida, Porto Rico, and the Philippines, fringed with coral reefs and numerous coral heads, supplemental special examinations are made where soundings on the regular lines shoaler than the surrounding depths indicate the existence of yet shoaler water. Such examinations are greatly facilitated by the use of the "channel sweep." This device is attached under the vessel and gives it any desired draft of water up to 6 fathoms. By its use many rocks are discovered which the leadline fails to develop. It is also used to verify channels that have been marked out through reefs, or areas of broken ground.

In the work of deep-sea sounding, the leadsman is replaced by a sounding machine, the leadline by a fine steel piano wire, coiled on a drum, and the lead by a solid spherical shot weighing about 100 pounds. While sounding, the ship remains in sight of land, her position

being determined in a manner similar to that explained above in the case of the boat. The depth is obtained by recording the number of revolutions of the drum, the shot being automatically detached from the wire when it reaches the bottom.

Topography.—The principal method employed by the Survey in the execution of its topographic work is that which requires the use of the plane table and stadia. All the necessary operations for producing the topographic features of the map are executed by those instruments in the field with the country as a model. In special cases other instruments are employed as auxiliaries, but in general the plane table alone fulfills all the requirements. On account of the rapidity and comparative accuracy with which the results are obtained by the graphic solution of the three point problem by the plane table, thus enabling the topographer to ascertain his position at an unknown point, together with the effective use of the stadia, this method is peculiarly fitted for delineating coast topography, usually characterized by such features as outlying islands and ledges, inaccessible rocky bluffs, and large marshy areas intersected by numerous streams.

Tides and Tidal Currents.—The vertical motion of the water surface is called the "tide," and the horizontal motion of the water itself is called the "tidal current" or the "tidal stream." The latter is oftentimes of much greater importance to navigation than the former, and on account of the many difficulties which have to be surmounted in obtaining sufficient information to enable predictions relative to their direction and velocity at any particular time and place, they require very careful consideration. Tidal observations are made either upon a simple graduated staff, or else by means of a self-registering gauge. The latter is always employed in places where a long series of observations is desired. It consists of a simple but ingenious combination of a clock mechanism with a recording apparatus in which a pencil, controlled in a lateral position by the rise and fall of the water, traces an undulatory curve upon a long strip of paper which moves slowly at right angles to the motion of the pencil and is regulated in its progress by the clock which controls the apparatus.

Leveling.—The work of leveling is executed by two principal methods: (1) by the use of precise spirit levels; and (2) by vertical angulation.

The precise level used by the Survey differs from other instruments of this class in the following particulars: The telescope and level are irreversible; the Y's are absent; the level is rigidly fastened to the telescope, and is placed closer to its center line by being countersunk into the barrel of the latter; the use of an alloy of nickel and iron, having a small coefficient of expansion, in the construction of the telescope and the adjacent parts; the protection of the level vial and the middle of the telescope from sudden and unequal variations of temperature by incasing them in an outer tube, and the provision of an arrangement by the use of which the observer is enabled to see, without changing his position, the level bubble with his left eye at nearly the same instant the rod is read through the telescope with his right eye.

In the execution of the field work, a line of precise levels is always run twice, usually in

COAST AND GEODETIC SURVEY

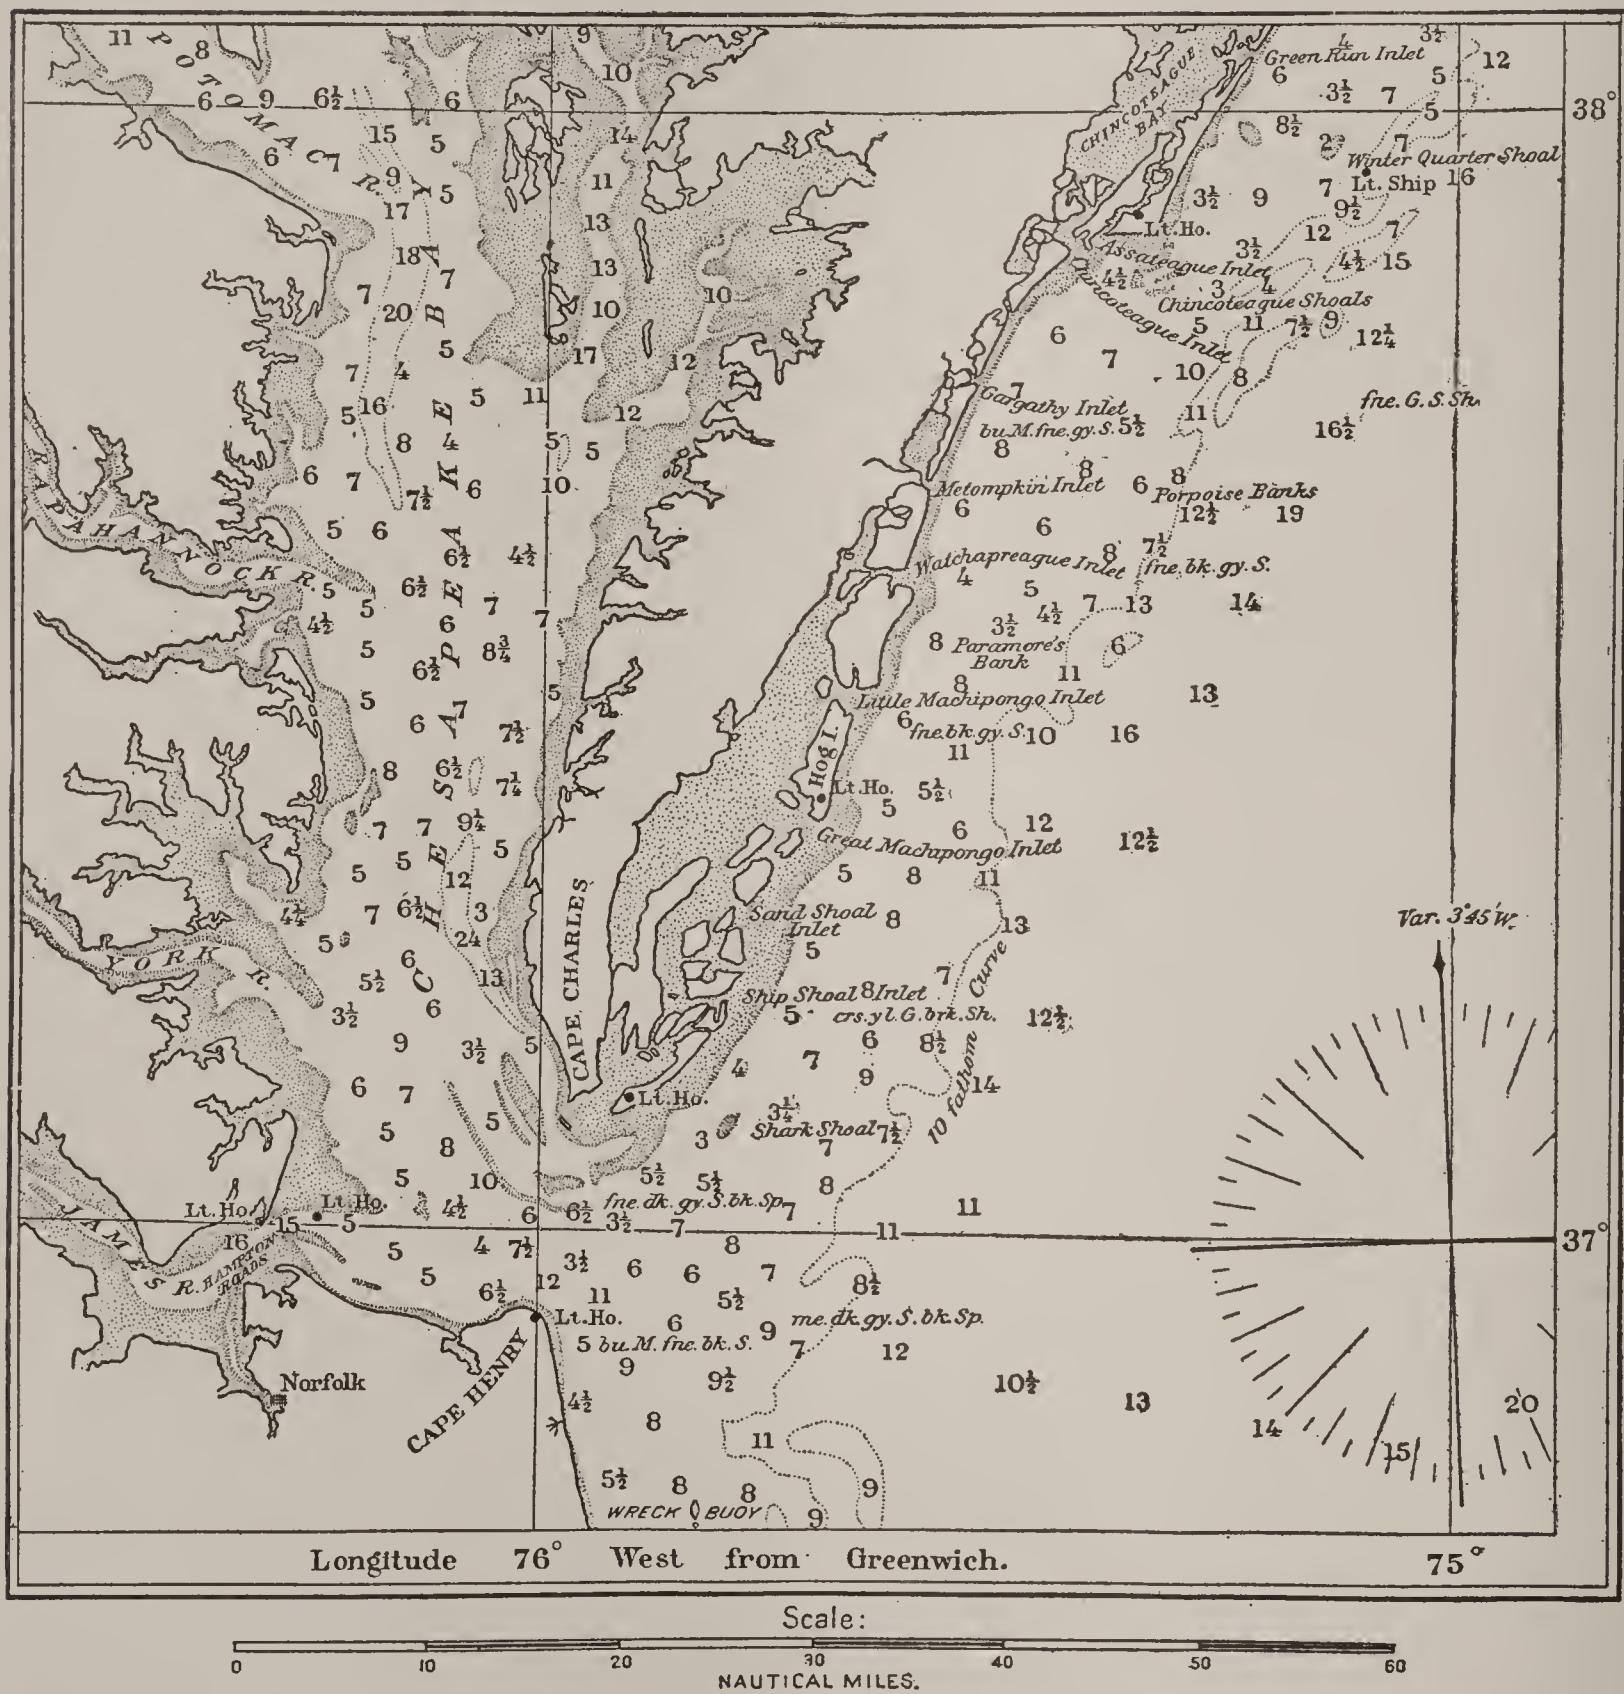

opposite directions, and if the results disagree beyond prescribed limits between adjacent bench marks, the leveling is repeated. The maximum discrepancy allowed between two measurements on a section 1.6 kilometers (1 mile) long is 5 millimeters or one-fifth of an inch. For sections of other lengths, the allowable discrepancy is made proportional to the square root of the length.

A much more severe test of accuracy is obtained from the closures of large circuits. In

now indicated by the circuit closures is 0.074 millimeters per kilometer, or about one two-hundredths of an inch per mile. This work is now executed at the average rate of 8.9 miles of single line per working day, at a cost ranging from 7 to 11 dollars per mile.

Leveling by vertical angulation consists of the determination of differences of elevation by the measurement of vertical angles. This work is carried on in connection with the work of triangulation, the angles of elevation or depres-

Portion of the United States Coast and Geodetic Survey "Sailing Chart"

the network of precise level lines which cover the eastern half of the United States at the present time, there are 50 large circuits, varying in circumference from 100 to 1,800 miles. The greatest error indicated in any line of the entire system of nearly 20,000 miles is 1.8 millimeters per kilometer, or about one-tenth of an inch per mile. The errors of closure have been still further reduced by the use of the new instrument already described, and the greatest error

of one or more distant stations being measured from any station. The sight varies in length according to the character of the region. In mountainous regions, under favorable meteorological conditions, they frequently exceed 100 miles. The distance to the station sighted being known, the difference of elevation between them is computed. The necessity of applying large corrections for refraction, a very variable factor, having different values diurnal and

COAST DEFENSE

seasonal, the laws of which are comparatively unknown, brings the accuracy of the results obtained by the method considerably below that of spirit leveling. Tests for accuracy in connection with precise leveling work indicate that vertical angulation gives results that are correct to within one inch to the mile.

Coast Pilots.—See COAST PILOTS.

Chart Publications.—See CHART.

The accompanying map is a portion of a "Sailing Chart" which as published embraces the Atlantic coast of the United States between Cape Cod and Cape Hatteras. It shows only the outline of the continent, the seacoast lights, and the special geographic information useful for the purposes for which the map is intended, namely, a guide to navigation in close proximity to the coastline.

Gravity.—The gravity work is now accomplished by the method and instruments suggested by Dr. T. C. Mendenhall, Superintendent of the Survey, in 1890, which permit of the accomplishment of the work with an ease and precision far superior to any of the methods previously used. See GRAVITY.

Geodesy.—See GEODESY; GEODETIC ARCS.

For the latest information on the different subjects consult the following publications of the Survey: Map Reductions, etc.: Appendix 20, Report for 1860; Magnetic Work, etc.: Appendices 8 of 1881, 1 of 1895, 5 and 6 of 1902, and 3 of 1904; Gravity: Appendices 12 of 1893 and 6 of 1897; 'Tides,' etc.: Appendices 7, 8, and 9 of 1897; Signals in Triangulation, etc.: Appendices 10 of 1882 and 4 of 1903; Triangulation: Appendix 9 of 1882; Plane Table Manual: Appendix 7 of 1905; Some Instruments: Appendix 8 of 1894; New Level: Appendix 6 of 1900; Astronomical Work: Appendices 7 of 1897-8, and 8 of 1904; Hydrography: Appendix 6 of 1905.

Coast Defense, systematic protection of a country against hostile attack along its coastlines. In providing such defense a nation will consider not only the safety of its territory, but also the security of its commercial interests. In any system of coast defense a good navy is the most important feature; and so essential is it considered, that all other means are regarded as adjuncts or auxiliaries of the navy. Along a well-defended coast, in suitable places, are stations or points of support where is stored the requisite material for building, equipping, repairing, and supplying naval vessels, and where provision is made for furnishing men when additional force is needed. Forts are built in places where the coast artillery may co-operate with the navy in obstructing the advance of an enemy intending to capture a city or to invade the country; where their guns may command the entrance to a harbor or other approach by water; wherever they may cripple the enemy's attack on the defensive fleet, leaving it free to attack the enemy in turn; where forts may assist each other, and co-operate in repelling an invasion or preventing a blockade or a bombardment; where minor channels of approach may be closed or guarded, thus enabling the navy to give entire attention to the main channel, etc. Torpedo-boats, harbor-mines, the searchlight, which illuminates the harbor and permits detection of the enemy's manœuvres, are all valuable aids for the forts. The unfortified coast, as well as the

land approaches to cities, must be defended in time of war by whatever means are at command.

The guns for coast defense change with the places and purposes for which they are to be used. To pierce the side armor of battleships, the flat trajectory, high-power guns are used; for projectiles intended to fall on the decks of an enemy's ships, the high-angle guns (mortars or howitzers) are employed. The number and size of guns vary with the estimated number and calibres of those which may be brought to bear by an enemy. From the depth and length of the channel may be determined how many and what classes of ships the enemy can operate in it, their armament, etc., and from these data the number and calibres of guns needed may be calculated.

The difficulty of obtaining naval supplies after war has been declared makes it necessary to store them during times of peace. Besides quantities of supplies at points of support for the navy, important harbors are generally equipped with torpedo storehouses, cable-tanks, mining casements, etc., for use in emergencies.

The tactics of coast defense have changed greatly since the beginning of the last decade of the 19th century. Besides defense against attack upon fortified places preparation is also necessary for resisting assaults upon unfortified coasts. The length of the United States coast-line makes its secure fortification a matter of great difficulty and expense.

Methods of reconnaissance are important for defense as well as for attack. The defense seeks to veil all batteries, and even in times of peace a journey along a fortified coast might not discover many forts or other means of defense. The enemy, in preparation for attack, or in action, seeks to discover the nature and strength of the defenses; and the defense in turn uses all possible methods of ascertaining the number and classes of the enemy's ships, the probable line of attack, and whatever else may be discoverable in regard to his strength and purposes. Pictures of every important warship in the world are studied by certain officers of every navy, and so close are some of these studies that a war vessel may be recognized by such an officer in any position in which he sees it. For the important work of reconnaissance observation stations are fully equipped for the coast artillery, photographs, drawings, descriptions of warships, telescopes, etc., for use in procuring information of the enemy, being fully provided.

In times of peace a country may, to its peril, neglect its coast defense, as was shown by the condition of the defenses of the United States at the beginning of the war with Spain. European nations have for years divided their tide-water regions into naval zones, and have assigned to each zone reserves, torpedo divisions, lighthouse establishments, coast-guard services, and signal stations.

In France the naval authority is made paramount, and all naval affairs are in charge of the minister of marine, assisted by a chief of staff. Not only the mobile defenses, but the coast fortresses, submarine mines, and the fort batteries are under control of the minister or his aid. In June, 1903, the general board of the United States navy made public the details of a plan for its reorganization with a general staff

COAST GUARD — COAST PILOTS

in several grand divisions, under a chief of staff, with the secretary of the navy, as now, at the head of the department.

In recent times the navies of all leading countries have been enlarged, forts multiplied and strengthened, and more attention given to training young men in the tactics and strategy of defense, involving immense increase of national expenditure. In this general advance of naval preparation our own country is now maintaining a steady and quickened pace, and questions of coast defense must here be solved with equal energy and intelligence. The work of providing a proper armament for the exposed harbors of the United States has been progressing as rapidly as the congressional appropriations would permit. Since the outbreak of the war with Spain, Congress has been more liberal with its provisions for pushing this work. According to the annual report of the United States board of ordnance and fortification for 1895, at the rate of progress then being made it would require 50 years of work to place the great stretch of seacoast in proper condition for defense. The board recommended an appropriation of \$2,000,000 for engineer work in the construction of implements, fortifications, etc., and one of \$5,000,000 for the construction of guns, mortars, gun-carriages, seacoast armament, and ammunition. Concerning future advancement, the board recommended that it be along the following lines: the development of smokeless powders; the development of a high explosive that can be safely discharged in a shell at a high velocity with certainty of detonation; the selection of armorplate for sea forts; the development of rapid-fire field and seacoast guns, and of an efficient system of fire control for harbor defenses. Recent reports show that satisfactory progress has been made in all these lines except that the use of armor-plates in forts has been abandoned for the more satisfactory earth and concrete emplacements. The bill making appropriations for the construction of fortifications and coast defenses in the year ending 30 June 1900, carried a total of \$4,744,798. The department submitted estimates for works to cost \$12,151,898. In the 11 years from 1889 to 1899 inclusive Congress appropriated for these purposes \$48,761,747. The bill for the year 1898-9 carried \$9,377,494, and the further sum of \$8,674,898 was provided in deficiency acts. In addition \$12,865,841 was allotted for the same object out of the \$50,000,000 appropriation for the national defense, making a total of \$30,988,233 made available for fortifications and the armament thereof at that critical period.

The total appropriations made for fortifications and other works of defense since 1888 amounted in 1900 to \$77,000,000. In April, 1900, the secretary of war issued a general order to the army announcing the names of 56 new batteries that had been recently constructed and the sites for works yet to be constructed along the seacoast.

The reorganization of the control of the coast defenses of the United States has embraced more thorough and systematic information regarding this branch of service. In one of its recent orders the navy department gives the following instructions: "As a part of the scheme of naval defense each district will provide means of obtaining and forwarding information to and from the coast, and of communicating with ves-

sels of our own navy, and this system, as a whole, shall be designated as the naval patrol."

The sea and lake coasts of the United States have been divided into 13 naval districts. Torpedo boats are to be part of the defense of each district, and torpedo-boat bases will be established in them. Each district is to be in charge of an officer known as commandant. The districts follow:

1. Eastport, Me., to include Chatham, Mass.; torpedo-boat base, Rockland; commandant of the Portsmouth navy yard in charge.

2. Chatham to include New London, Conn.; torpedo-boat base, Narragansett Bay; officer specially detailed from Narragansett Bay headquarters in charge.

3. New London to include Barnegat, N. J.; officer detailed from headquarters in New York in charge.

4. Barnegat to include Assateague, Va.; torpedo-boat base, Delaware River; commandant of League Island navy yard in charge.

5. Assateague to include New River Inlet, N. C.; torpedo-boat base, Norfolk; commandant of the Norfolk navy yard in charge.

6. New River Inlet to include Jupiter Inlet, Fla.; torpedo-boat base, Charleston; commandant of Charleston navy yard in charge.

7. Jupiter Inlet, to include Tampa, Fla.; torpedo-boat bases, Tampa and Pensacola; commandant of Key West naval station in charge.

8. Tampa, to include Rio Grande; torpedo-boat base, lower Mississippi and West Gulf coast; commandant of Pensacola navy yard in charge.

9. Lake Michigan. 10. Lakes Erie and Ontario. 11. Lakes Huron and Superior. All these in charge of the commandant of the Lake training station near Sheboygan, Wis.

12. Southern boundary of United States on Pacific coast to lat 42° N.; torpedo-boat base, Mare Island; commandant of Yerba Buena training station in charge.

13. Pacific coast from lat. 42° N. to northern boundary; torpedo-boat base, Puget Sound; commandant of Puget Sound navy yard in charge.

Information collected in these districts is to be sent to the office of naval intelligence. In time of peace the aide to the commandant, or some other line officer, is to be second in command in each district; in time of war lighthouse inspectors are to be second in command. See BLOCKADE; BOMBARDMENT; FORTIFICATION.

Coast Guard, a British force formerly under the customs department, and intended only to prevent smuggling, but now organized also for purposes of defense and governed by the admiralty. The men, who are generally old men-of-war's men of good character, have high pay and are furnished with free cottages. The force numbers, with officers and men, about 4,000.

Coast Pilots are compiled to assist mariners in the navigation of their vessels, and, when from any cause they are without charts, to enable them to safely carry their vessels from port to port along the coast. The governments of all large maritime nations publish works for these purposes.

As early as 1796 a volume known as 'The American Coast Pilot', by Capt. Lawrence Furlong, was published in Newburyport, Mass., by Edmund M. Blunt, and the first edition met

¹ A 12-Inch Mortar. ² Rear View of 8-Inch Gun Showing Compressed-Air Attachment and Dummy Shell.
³ Working Model of 8-Inch Gun.

SHELL PRACTICE WITH MODERN COAST-DEFENSE GUNS IN A CITY ARMORY

COASTAL PLAIN

with so ready a sale that a second edition of the same work was published in 1798. Since the latter date numerous compilers have published coast pilots of the coast of the United States and its harbors. These works were compiled from charts, from reports by shipmasters published in the newspapers, and from surveys and the personal knowledge of the compilers, some of whom were experienced shipmasters.

The vessels of the Coast and Geodetic Survey, while engaged in surveying the coast and harbors of the United States, collected much information of importance to mariners which could not be shown on the charts or completely given in 'Notices to Mariners.' 'Coast Pilots' are published and distributed by the Coast and Geodetic Survey at the cost of the printing and binding. Similar information can not be collected by private enterprise except at great cost and with imperfect means, and at the present time all the private publications containing such information relating to the coast of the United States are compilations from government publications and based generally on the work of the Coast and Geodetic Survey.

The compilation of the 'Coast Pilots' necessitates work in the office and in the field. The office work consists of the collection of the latest data from the reports and surveys of hydrographic and topographic parties, from the reports and surveys of the United States engineers engaged in the improvement of harbors and waterways, and from correspondence with local authorities and engineers. This information, in manuscript, is then put in the form of a volume which experience has shown to be convenient for the use of the mariner.

For the field work a vessel of the survey, with the compilers of the 'Coast Pilot' on board, visits every part of the coast which is treated in the volume; the information collected in the office is verified and, if necessary, corrected on the spot; the sailing lines and directions are tested by running over them; such artificial aids and natural landmarks as are of use to the mariner are noted, and hydrographic examinations of reported dangers and changes are made; pilots, shipmasters, and local authorities are interviewed and the latest information is incorporated, together with such notes as can only be obtained by observation and experience in the locality.

On returning to the office from the field work this manuscript, correct to date, is prepared for the printer, and when printed the volumes are issued with a supplement or insertion sheet containing the changes which have occurred since the date of the preparation of the volume and while the matter was going through the press.

The 'Coast Pilots' published by the coast and geodetic survey contain:

1. A tabular description of lighthouses, light vessels, and fog signals; lists of life-saving stations, storm-warning display stations, and sea-coast telegraph stations, and information regarding tides, tidal currents, variation of the compass, etc.

2. Nautical descriptions of the coast and harbors and general information concerning the several bodies of water and harbors, including notes relative to pilots, depth of water, draft of vessels entering the harbor, supplies; facilities for making repairs, usual or best anchorage,

and other matters of practical value. In each case the information of this nature precedes the sailing directions and is printed in smaller type.

3. Sailing directions, with subordinate paragraphs treating of prominent objects, dangers, aids to navigation, etc. The arrangement conforms to the order in which these matters would be considered in practice, and be available when wanted promptly. For this purpose, and to afford a ready means of reference from one part to another, the sailing directions, where long, are divided into numbered or lettered paragraphs, printed in large type, each followed by its own subordinate remarks in smaller type.

4. Appendices, containing rules of the road at sea and in inland waters; laws and regulations relative to pilotage, harbor control, national and local quarantine, and Marine Hospital service; and information regarding storm-warning displays.

5. Views of important points. These are only inserted in volumes which treat of localities which have not yet been surveyed or where the lighthouses and other aids to navigation are not sufficiently numerous to readily locate and navigate a vessel.

6. Sections of charts covering the coast treated in the volume to aid in finding the geographic positions of different localities. Index maps showing the limits of the charts covering the localities treated in the volume.

The 'Coast Pilot' publications of the United States Coast and Geodetic Survey include:

Seven volumes of the 'United States Coast Pilot, Atlantic Coast', in eight parts as follows:

Parts I-II. From St. Croix River to Cape Ann.

Part III. From Cape Ann to Point Judith.

Part IV. From Point Judith to New York.

Part V. From New York to Chesapeake Bay Entrance.

Part VI. Chesapeake Bay and Tributaries.

Part VII. From Chesapeake Bay Entrance to Key West.

Part VIII. Gulf of Mexico, from Key West to the Rio Grande.

One volume of the 'Pacific Coast Pilot'; California, Oregon, and Washington.

One volume of the 'Pacific Coast Pilot; Alaska, Part I, Dixon Entrance to Yakutat Bay, with Inland Passage from Strait of Fuca to Dixon Entrance'.

In addition to the above 'Coast Pilots', bulletins containing the latest information obtainable from all sources about the little known waters of northwest Alaska and Bering Sea are published for the use of mariners navigating those waters.

It is manifest that publications of this character must be subject to numerous corrections in the details after the lapse of a few years. To maintain the volume in a useful form corrections are issued in 'Notices to Mariners,' insertion sheets, and supplements; and each volume is revised and passed to a new edition when the corrections have assumed proportions that impair its usefulness, or more recent surveys show changes or furnish additions that render the old volume untrustworthy.

Coastal Plain. Where the foothills of a range of mountains descend to a lowland that slopes gently to the sea, this lowland is called

COAST RANGE

a coastal plain. It represents what was once the sea floor, being composed of material eroded from the mountains and deposited in the sea. With further elevation the original surface of the plain may be removed by streams cutting their valleys and by the weathering of the valley slopes. The coastal plain of the Atlantic Seaboard extends from New York to Georgia. In the Carolinas and Georgia it is divisible into belts parallel to the shore. The outer is a smooth plain, often swampy, perhaps 50 miles wide with a gently rolling surface. Further inland, where the streams have cut valleys, the surface is more hilly, and 100 miles inland is a belt of hilly country some 600 or 700 feet high covered with pine forests where the original surface of the plain has been nearly destroyed. Back of this come the higher hills, formerly mountains, of the old land, forming what is known as the Piedmont belt. Other instances of coastal plains are the east coast of Mexico, north and south of Vera Cruz, and the east coast of India, skirting the Bay of Bengal.

Coast Range. The Pacific shore of the United States rises abruptly from the ocean along nearly its whole length, with practically no coastal plain of any size from southern California to the Strait of San Juan de Fuca. The hills and low mountains which border the ocean are given the general name of the Coast Range. They do not form, however, a continuous ridge, but are rather parts of more or less disconnected uplifts, lower and possibly younger than the Sierra Nevada and Cascade ranges. North of the Strait of San Juan de Fuca the mountains of Vancouver Island and the Island range of British Columbia mark the continuation of these uplifts, although in British Columbia the name of Coast Range is given to the mountains which border the continental shore and are spurs of the Cascades.

In California the coast range comprises two parallel ridges, 400 miles long, 30 to 60 miles apart, and parallel to the coast from Point Concepcion in lat. 35° to Cape Mendocino, the ridge on the coast being the coast range proper, and the inner the Monte Diablo range, the two separate the Sacramento and San Joaquin valleys from the Pacific. In the south the coast ranges and the Sierra Nevada coalesce and the topography is complicated by east and west ranges; thus opposite the Santa Barbara channel is the Santa Inez range, having a height of about 4,000 feet, and farther south is another east-and-west range, the Santa Monica. Still further south the uplift is much broken and irregular without strongly marked ridges but with portions rising into central dominating points like the San Bernardino and San Jacinto mountains, about 11,000 feet high.

North of lat. 35° , toward San Francisco Bay, there are no very high peaks. The highest peaks near the bay are Monte Diablo, 3,856 feet, an isolated peak that is a conspicuous landmark for miles; Mount Helena, 4,343 feet; and Mount Hamilton, 4,400 feet, the latter famous as the site of the great Lick observatory. North of San Francisco Bay the heights of the summits gradually increase, and 150 miles north is Mount Bailey, 6,357 feet. Farther north the coast range becomes gradually a series of disconnected mountain groups, and near the Oregon line east-and-west ridges develop which unite

with the Cascades, the most important of these being the Calapooia Mountains in Oregon.

Along the Oregon coast the uplift is low, being generally less than 3,000 feet. In Washington also the uplift is not great except in the Olympic Mountains between Puget Sound and the Pacific Ocean, which culminate in the fine peak of Mount Olympus, 8,150 feet.

Extending along such a length of coast, the coast ranges have a wide variety of climate and differ much in vegetation and attractiveness. In California, north of lat. 38° to San Francisco Bay, much of the outer range is covered with brush and has some timber. South the mountains are covered with a thorny undergrowth known as chaparral. Near the coast, from Santa Barbara to San Francisco, there is a fair rainfall in the interior. The climate is very dry, and the mountains are generally bare. North of San Francisco Bay the rainfall increases, and the mountain valleys are fertile and picturesque. In Oregon the rainfall is heavy, and in Washington very heavy; the mountains being covered with thick forests of fir, pine, and spruce.

Geologically the mountains of the coast uplifts, besides being newer than the Sierra Nevada and Cascades, are also less broken through by granite than the Sierra Nevada, and less covered by lava than the Cascades. The upheaval began in late Tertiary time, and perhaps continued into the Quaternary, Pliocene rocks being upturned at a high angle near San Francisco Bay. South of San Francisco Bay the rocks are mostly of the Miocene series, though there are large areas of Cretaceous in the east side of the Monte Diablo belt. North of San Francisco Bay and in Oregon the proportion of Cretaceous increases, and the Tertiary is much less. On Vancouver Island an uplift took place in Jurassic time.

Generally speaking, the rocks of the coast range in California are much metamorphosed, and large masses of serpentine and similar rocks are not uncommon. In places these serpentines sometimes contain workable deposits of chrome iron ore, though, owing to the limited demand, the production is small. The chief mineral wealth of the coast range is in quicksilver and petroleum, though some gold has been washed from placers in southern California. The quicksilver occurs at a number of places in the range where the altered rocks are silicified, and the total production, though the ore is generally of low grade, has been large.

South of San Francisco Bay, in the Miocene, in places is a great thickness of bituminous shale, there being several thousand feet of it near Santa Barbara and Los Angeles. This shale has been used extensively as a material for paving streets. Within the past eight years a valuable oil-field has been developed near Los Angeles. But little coal has been found in the range in California, and that is of poor quality. In Oregon is the Coos Bay field.

In Oregon and Washington the coast range contains very few mineral deposits of importance. On Vancouver Island, however, promising copper deposits are being developed on the west coast, and on the east coast are large and important coal mines.

The coast range naturally has no river systems, nor, except in California, is it a barrier to rivers of the interior. It is crossed by the

COASTING TRADE — COBALT

Columbia, Coquille, Rogue, Klamath, and other rivers.

For mineral resources of the range see COAL; PETROLEUM. See also BRITISH COLUMBIA; CALIFORNIA; OREGON; WASHINGTON.

Coasting Trade, trade carried on by sea between the ports of the same country. In some countries the coasting trade is retained as a home monopoly, and this used to be the case in the United Kingdom, but by recent laws the coasting-trade of Great Britain has been opened to foreign vessels, subject to the same rules, dues, and regulations as British sailing ships and steamers; but power was given to impose by an order in council retaliatory prohibitions and restrictions on the ships of such countries as should impose restrictions and prohibitions on British ships. The dues and regulations to which vessels engaged in the coasting trade are subject are different from those which relate to vessels engaged in the oversea trade, and masters are required to keep books showing that their cargoes are strictly such as are allowable by the rules of the coasting trade. In the United States the coasting trade is restricted to vessels belonging to the country. The commerce of the Great Lakes is included in the coasting trade. The great length of the sea and lake coasts, the number of good harbors, and the fact that much of the coast region of the United States has been settled makes the coasting trade of this country the most extensive in the world. Many hundreds of sailing craft and steamers are used in this trade, carrying the products and people of one part of the country to other parts. This trade is increasing rapidly, the licensed tonnage of fisheries and trade in 1900 was 4,338,145 tons, an increase of nearly 1,250,000 tons in the preceding 50 years. The annual amount of tonnage passing through St. Mary's Falls Canal is much larger than that of the annual tonnage of the Suez Canal, and the amount passing through St. Clair River is about four times that recorded at St. Mary's Falls Canal.

Coat of Arms, heraldic insignia, originally embroidered on the tabard, a short coat worn by knights over the armor. They originated in the age of chivalry, when they were assumed as emblematic of the adventures, and hopes of the knight and were useful for distinguishing individuals whom it was difficult to recognize when in full armor. The favorite emblem of the knight later became the adopted badge of the family, the figures or characters employed in the coat of arms began to receive names, and so the language and science of heraldry came into existence. Modern nations have adopted coats of arms, in monarchical countries, sometimes an adaptation of the heraldic insignia of a dynasty. The coats of arms of the United States and of the individual States are arbitrarily adopted emblems without true heraldic significance. The emblem of a State sometimes represents its leading industry; some cities have also adopted similar coats of arms. See HERALDRY.

Coat of Mail, a piece of armor in the form of a shirt, consisting of a close net-work of iron or steel rings, or of a strong linen or leather jacket covered with small laminæ or plates, usually of tempered iron, overlapping each other like the scales of a fish. See ARMS AND ARMOR.

Coatbridge, kōt'brīj, Scotland, a municipal burgh in Lanarkshire, nine and a half miles east of Glasgow. It owes its rise to the working of the coal and iron-stone found in the surrounding district, and has grown rapidly from a village to a thriving town. The chief manufacturing interests are the numerous iron works in the town and neighborhood, about half of the blast-furnaces of Scotland being situated in this locality. There are also important engineering establishments and other industries. Pop. (1901) 36,981.

Coates, Florence Earle, American poet: b. Philadelphia, Pa., 1 July 1850. In 1879 she was married to Edward Hornor Coates. She has made many contributions to various magazines and published her collected 'Poems' in 1899.

Coates'ville, Pa., a borough of Chester County, situated on the Pennsylvania and the Wilmington & No. R.R.'s. It has a number of important industrial interests, including large boiler works, iron and steel works, foundries, and woolen and paper mills. Pop. (1900) 5,721.

Coati, an American animal somewhat related to the raccoons, of which two species are known, constituting the genus *Nasua*. One inhabits Mexico and roves as far north as southern Arizona; the other lives in Brazil. The Mexican coati, or "coati-mundi" (*N. nasica*) is about the size of a house-cat, has a long cartilaginous snout which may be reflexed or stiffened at will, according to its owner's needs. Its fur is long, thick, and a warm brown in color; and its tail is ringed like that of a raccoon. The Brazilian coati (*N. rufa*) is somewhat smaller than the Mexican, and its fur is not so fine. Both species feed on fruits, eggs, insects, and sometimes on small birds. They are readily tamed, and make as good pets as the domestic cat.

Coaticook, kō-āt'i-kuk, Canada, a town of Stanstead County, Quebec, situated on the Coaticook River, and the Grand Trunk R.R. It has a number of factories and is a manufacturing centre. Pop. 3,000.

Coatzacoalcos, kō-āt-sa-kō-āl'kōs, a river of the isthmus of Tehuantepec in Mexico, rises in the Sierre Madre, and empties into the Gulf of Mexico, 130 miles southeast of Vera Cruz. It is navigable for large vessels for 30 miles, and is interesting as part of a route which has been surveyed for an inter-oceanic canal, a city of the same name, with a population of about 3,000, is situated at the mouth of the river.

Cobalt, a metal which occurs combined with arsenic, nickel, and other metals; also as a sulphide and as an arsenate. After the ore has been calcined, oxide of cobalt remains, but impure from the presence of other metallic oxides. When this oxide has been purified and reduced to the metallic state the cobalt is obtained of a white color inclining to gray, and, if tarnished, to red, with a moderate lustre. Its fracture is compact; it is hard, brittle, and of a specific gravity of 8.5 to 8.9. Like nickel, it is strongly magnetic. It undergoes little change in the air, but absorbs oxygen when heated in open vessels. It is attacked, though slowly, by sulphuric or hydrochloric acid, and is readily oxidized by means of nitric acid. Two basic oxides of cobalt are known, and some inter-

COBALT-BLUE — COBB

mediate oxides. The protoxide is of an ash-gray color, and is the basis of the salts of cobalt, most of which are of a pink hue. When heated to redness in an open vessel it absorbs oxygen and is converted into a higher oxide. It may be prepared by decomposing the carbonate of cobalt by heat in a vessel from which atmospheric air is excluded. It is easily known by its giving a blue tint to borax when melted with it. It is employed in the arts, in the form of smalt, for communicating a similar color to glass, earthenware, and procelain. *Smalt*, or powder blue, is made by melting three parts of fine white sand, or of calcined flints, with two of purified pearl-ash and one of cobalt ore previously calcined, and ladling it out of the pots into a vessel of cold water; after which the dark-blue glass, or zaffer, is ground, washed, and distributed into different shades of color, which shades are occasioned by the different qualities of the ore and the coarser or finer grinding of the powder. Smalt, besides being used to stain glass and pottery, is often substituted, in painting, for ultramarine blue, and is likewise employed to give to paper and linen a bluish tinge. The chloride of cobalt is well known as a *sympathetic ink*. When diluted with water so as to form a pale pink solution, and then employed as ink, the letters, which are invisible in the cold, become blue if gently heated. It is prepared by dissolving precipitated oxide of cobalt in hydrochloric acid with the aid of heat, and diluting with water. The nitrate of cobalt is readily got by dissolving cobalt or its oxide in nitric acid and crystallizing the solution. It is a deliquescent red salt, which dissolves in water with a pink color. The peroxide of cobalt is black, and is formed by adding a solution of bleaching-powder to a cobaltous salt, or by passing a current of chlorine gas through water holding cobaltous hydrate in suspension. It does not unite with acids; and when digested in hydrochloric acid the cobaltous chloride is generated with the disengagement of chlorine. When heated it is converted into one of the intermediate oxides.

Ores of Cobalt.—“Bright white cobalt ore” is the popular name for the mineral cobaltite (q.v.), a sulph-arsenide of cobalt. “Gray cobalt ore,” also sometimes called “tin-white cobalt,” is the mineral smaltite (q.v.). It is the chief ore of cobalt and is essentially cobalt diarsenide, though it always contains nickel and iron. “Red cobalt,” also known as “cobalt-bloom,” is the mineral erythrite (q.v.), a hydrous cobalt arsenate. “Earthy cobalt,” or “black cobalt,” is the mineral asbolite, a variety of wad containing up to 32 per cent. oxide of cobalt. “Cobalt pyrites” is the mineral linnæite, a sulphide of cobalt, often containing much nickel. The principal supply of cobalt is derived from the smaltite of Germany and the cobaltite of Norway and Sweden.

Cobaltite, “bright-white cobalt,” an important ore of cobalt, is its sulph-arsenide, CoAsS , and contains 35.5 per cent. of cobalt. It occurs granular massive, but also in isometric-pyritohedral crystals. These usually have a brilliant metallic lustre and a white color slightly tinged with copper-red. Their hardness is 5.5 and specific gravity 6 to 6.3. The most important localities are in Norway and Sweden.

Cobalt'-blue, or **Thenard's Blue**, a compound of alumina and oxide of cobalt, forming a beautiful pigment often used in the arts. Some-

times it contains also the phosphate or arsenate of cobalt, according to the mode of manufacture employed. It is non-poisonous, and unacted on by acids and alkalies.

Coban, *kō-bän'*, or **Vera Paz**, Guatemala, a city 90 miles northeast of the city of Guatemala. It is the capital of the department of Vera Paz, on the left bank, and near the source of the Dulce or Dolce. It was formerly a mission station of the Dominicans, whose memory is still revered. The Dominican monastery is now deserted. The valley is exceedingly fertile, and covered with plantations of sugar-cane, bananas, and pimento trees, and various kinds of fruit-trees. Pop. about 30,000.

Cobb, Henry Ives, American architect: b. Brookline, Mass., 19 Aug. 1859. He studied at the Massachusetts Institute of Technology, and graduated at Harvard 1880. In 1881 he established himself in Chicago, and has built up a large and lucrative general practice in that city and other parts of the country. In 1893 he was one of the national board of architects of the World's Columbian Exposition, and at present is retained as a special architect for the United States government. Among the prominent public buildings erected from his designs are, the Newberry Library, Chicago, opera house, University of Chicago, and Church of the Atonement, in Chicago; the Pennsylvania State Capitol, American University at Washington, D. C., and government buildings at Chicago, League Island, Annapolis, etc.

Cobb, Howell, American statesman: b. Cherry Hill, Ga., 7 Sept. 1815; d. New York City, 9 Oct. 1868. He was graduated at Franklin College in 1834, became a lawyer in 1836, and in 1843 was elected to Congress as a Democrat. He served eight years and was speaker of the House one term. Elected governor of Georgia in 1851, he returned to Congress in 1855, and was made secretary of the treasury by President Buchanan in 1857, resigning in 1860 to urge secession. He held a Confederate military commission in the Civil War, but saw little service.

Cobb, Sylvanus, American novelist: b. Waterville, Maine, 1823; d. Hyde Park, Mass., 2 July 1887. He was editor and publisher of a periodical called the ‘Rechabite’, and besides contributing to other publications, was a most prolific story-writer. His most popular novels are: ‘The King's Talisman’ (1851); ‘The Patriot Cruiser’ (1859); and ‘Ben Hamed’ (1864); ‘The Gunmaker of Moscow’.

Cobb, Thomas Reed Root, American lawyer and soldier: b. Cherry Hill, Jefferson County, Georgia, 10 April 1823; d. Fredericksburg, Va., 13 Dec. 1862. He graduated at the head of his class at the University of Georgia, 1841, was admitted to the bar, and was reporter of the Georgia supreme court 1849-57. As a lawyer he enjoyed a wide reputation and large practice. In the Confederate Congress he was chairman of the Committee on Military Affairs, but later became a general in the army and was killed at the battle of Fredericksburg. He wrote: ‘Digest of the Statute Laws of Georgia’ (1851); ‘Inquiry Into the Law of Negro Slavery in the United States’ (1858); ‘Historical Sketch of Slavery from the Earliest Periods’ (1859).

Cob'ban, James Maclaren, Scottish novelist: b. Aberdeen, Scotland, 24 April 1849. He is the author of 'The Cure of Souls' (1879); 'Tinted Vapors' (1885); 'Master of His Fate' (1890); 'A Reverend Gentleman' (1891); 'Sir Ralph's Secret' reprinted in America as 'The Horned Cat' (1892); 'The Red Sultan' (1893); 'The Burden of Isabel' (1893); 'The White Kaid of the Atlas: a Boy's Story' (1895); 'The King of Andaman' (1895); 'Wilt Thou Have This Woman?' (1896); 'Her Royal Highness' Love Affair' (1897); 'The Angel of the Covenant' (1898); 'Pursued by the Law' (1899); 'An African Treasure' (1899); 'Cease Fire!' (1900); 'I'd Crowns Resign' (1900); 'The Golden Tooth' (1901); 'The Green Turbans' (1901); 'Life and Deeds of Earl Roberts' (1901); 'The Last Alive' (1902); 'Julius Courtney'; 'Royal Exchange'.

Cobbe, köb, Frances Power, Irish rationalistic writer: b. Dublin 4 Dec. 1822; d. London, Eng., 5 April 1904. She took a deep interest in the anti-vivisection crusade and for 18 years acted as honorary secretary of the Victoria Street Society for the Protection of Animals from Vivisection. Some of her works are descriptions of her travels in Italy, Greece, Egypt, and Palestine, the others treating mainly of theological, religious, and humanitarian questions. The most important are: 'Essay on Intuitive Morals' (1855); 'Religious Duty' (1857); 'Pursuits of Women' (1863); 'Broken Lights: an Inquiry into the Present Condition and Future Prospects of Religious Faith' (1864); 'Hours of Work and Play' (1867); 'Dawning Lights' (1868); 'Darwinism in Morals' (1872); 'The Hopes of the Human Race Hereafter and Here' (1874); 'Duties of Women' (1880); 'The Peak in Darien' (1882); 'The Scientific Spirit of the Age' (1888); and 'The Modern Rack' (1889). She also wrote an enormous number of pamphlets and edited an edition of the works of Theodore Parker.

Cobbett, köb'ët, William, English writer and politician; was the son of a farmer and publican: b. Farnham, Surrey, 9 March 1762; d. near Guildford 18 June 1835. In 1783 he set out to try his fortune in London, and arrived there with only a half a crown in his pocket. He succeeded in obtaining a situation as copying-clerk to an attorney of Gray's Inn, where he remained for nine months. Determined to find some other sphere of employment he quitted London for Chatham, enlisted in the 54th Regiment, and after continuing there for a year proceeded with it to New Brunswick. During his stay at Chatham he set himself assiduously to study and the improvement of his mind. He remained four years in America, during which time his regular habits and ability and attention in the discharge of his military duties effected his promotion to the rank of sergeant-major. In 1791 he returned to England with the regiment, and shortly after arriving there obtained his discharge. After a short stay in England, and a stay of six months in France in 1792, he embarked at Havre for America. He landed in New York in October, 1792, and continued in America for eight years, where he occupied himself with literary labors, chiefly of a political kind, commencing his career by an attack on Dr. Priestley, then recently landed in America, in

a pamphlet entitled 'Observations on the Emigration of a Martyr to the Cause of Liberty', and signed "Peter Porcupine". Under this famous *nom-de-plume* a succession of papers appeared, all of a strongly anti-Republican tendency, which were afterward republished in England. Before leaving America he published a life of 'Thomas Paine'. In June, 1800, he sailed for England, and on his arrival started the 'Porcupine', which zealously supported the measures of Pitt, but met with little success. In a subsequent paper, the 'Weekly Register', he was more fortunate; and it continued to appear regularly every week up to the period of his death. Not long after its commencement symptoms of a gradual change began to appear in Cobbett's political opinions, and from high conservative he passed over to extreme radical principles. In 1803 a prosecution for libel on the lord-lieutenant and other officers of state in Ireland was instituted against him, and resulted in his being sentenced the following year to a fine of \$2,500; while a second action, brought almost immediately afterward, subjected him to a second fine of the same amount. In 1810, owing to some remarks of his in the 'Register' of 10 July 1809, on the flogging of some militiamen, he was again prosecuted for libel, and sentenced to imprisonment for two years and a fine of \$5,000. This last was paid by a subscription among his friends. Nowise daunted, he continued his attacks on government as soon as he was liberated, and commenced his celebrated 'Twopenny Trash', which reached a sale of 100,000, and from its supposed influence on the working-classes brought about the passing of the noted Six Acts. Partly to escape their operation, he retreated to the United States, and remained here for two years, residing principally in Long Island. He returned to England in 1819, and in 1820 endeavored, unsuccessfully, to be returned member for the city of Coventry. About the same period he commenced in the 'Register' a series of papers entitled 'Rural Rides', afterward reprinted, which present most charming pictures of English country scenery, and are among the best of his productions. In 1824-27 he published a 'History of the Protestant Reformation in England and Ireland', in which he vilified Queen Elizabeth and the leading reformers, but added in no way to his literary reputation. The work was eagerly adopted by the Roman Catholics, who caused translations to be made of it into various European languages. In 1831 he was again prosecuted for libel, on the ground of an article in the 'Register' alleged to be published with the view of exciting the agricultural laborers to acts of violence. He conducted his own defense in a speech of six hours, and the jury not being able to come to a verdict the trial ended in their discharge. On the passing of the reform bill in 1832 Cobbett was returned member to Parliament for Oldham; but his success in this capacity was indifferent. Nevertheless, at the general election in December, 1834, he was again returned to Parliament for Oldham. In addition to the writings already referred to Cobbett is the author of an English and a French Grammar; 'Advice to Young Men and Women', containing many useful hints; 'Cottage Economy'; 'Village Sermons'; 'A Year's Residence in America'; and other works. Cobbett wrote in a pure and vigorous English style, and his

COBDEN — COBLENTZ

writings contain a great amount of information and sound practical advice. See E. Smith, 'Life of Cobbett' (1878).

Cob'den, Richard, English economist, the great "apostle of free trade": b. Dunford, Sussex, 3 June 1804; d. London 2 April 1865. After receiving a very meagre education at the grammar-school of Midhurst, he was taken as an apprentice into a Manchester warehouse in London belonging to his uncle, where he rapidly made up for the defects of his education by his own diligence, and soon acquired a thorough acquaintance with the business. In 1830, being left to his own resources, he obtained some advances of money, and, with some relatives, started a cotton manufactory in Manchester, which in a few years succeeded in producing fabrics equal in point of quality to the best manufactured in London. By several journeys that he now made to France, Belgium, Switzerland, and the United States, chiefly in the interest of the firm, he not only increased his business connections, but matured and enlarged his views. His first political writing was a pamphlet on England, Ireland, and America, which was followed by another on Russia. In both of these he gave clear utterance to the political views to which he continued through his life rigidly to adhere, rejecting the course of policy based upon the theory of the balance of power, advocating non-intervention in the disputes of other nations, and maintaining it to be the only proper object of the foreign policy of England to increase and strengthen her connections with foreign countries in the way of trade and peaceful intercourse. These views, although disregarded or considered as visionary in Parliament were warmly received in industrial and commercial circles, and secured Cobden a considerable number of followers, especially in Manchester. After returning from extensive travels in the East and in Germany, he entered actively on a course of agitation with the view of carrying into effect his political views. Soon after the Anti-Corn Law League was formed in 1838, it was joined by Cobden, who expended all his energies on behalf of the cause to support which the league had been founded; and it was chiefly the extraordinary activity and perseverance of Cobden, joined to the zeal of his supporter Bright, that brought about the final victory of free-trade principles. In 1841 Cobden was returned to Parliament by Stockport. In his very first speech in Parliament he took occasion to point out the unjust way in which the corn-laws operated, and, undeterred by the failure of his first attempts, returned again and again to this subject. After five years of unwearied contest he at last succeeded in convincing Sir Robert Peel himself, at that time prime minister, of the pernicious action of the corn-laws, and in inducing him to bring in a bill for their repeal. The bill passed both houses of Parliament before the end of June 1846, and Sir Robert Peel was the first to congratulate Cobden on his victory in a speech delivered in the House of Commons. During this long struggle Cobden had been obliged to neglect his business, which before agitation commenced had been a highly prosperous one. As a compensation for the loss he had thus sustained a national subscription was made, and a sum of about \$350,000 presented to him. After again visiting several countries on the Continent,

where he was generally received with enthusiasm, he returned to his parliamentary duties in 1847, having been returned without opposition as one of the members for the West Riding of Yorkshire. He now appeared chiefly as the advocate of parliamentary reform, economy, and retrenchment in the management of the finances of the country, and a policy of non-intervention; in all of which he found a firm and ready ally in Bright. His advocacy of a peace policy did not in every case add to his popularity. His opposition to the policy of Lord Aberdeen in 1853, which ultimately led to the Russian war, met with no success; and although in 1857 he carried a vote of censure on Lord Palmerston's Chinese policy, his action in this case was displeasing to the country generally. In 1860 he negotiated a treaty of commerce with France, and in reward for his services on this occasion was offered a baronetcy, a seat in the privy-council, and several other offices and dignities, all of which he persistently refused. A collection of his political writings appeared in 1867, and a collection of his speeches 'Speeches on Questions of Public Policy' (1870). Consult Garnier, 'R. Cobden, les Liguers et la Ligue' (1846); McGilchrist, 'Life of Richard Cobden' (1865); Morley, 'Life of Richard Cobden' (1881-3).

Cobden Club, The, an organization named after Richard Cobden, formed about a year after his death, through the influence of John Bright and others, for encouraging the diffusion of free trade and the other economical and political principles with which Cobden's name is associated. The Cobden Club has distributed a vast number of books and pamphlets.

Cobego, kō-bā'gō. See COLUGO.

Co'bern, Camden M., American Methodist clergyman: b. Uniontown, Pa., 19 April 1855. He was educated at Allegheny College, and the Theological School of Boston University and entered the ministry in 1876. He has published 'Ancient Egypt in the Light of Modern Discovery' (1892); 'Ezekiel and Daniel: a Critical Commentary' (1901).

Cob'ham, Lord. See OLDCASTLE, SIR JOHN.

Cobija, kō-bē'hā, or **Puerto La Mar**, Chile, a seaport in the territory of Antofagasta (formerly belonging to Bolivia), on the shore of the Pacific. It stands in a desert region, and is entirely dependent on the mines in the neighborhood. The roadstead is tolerably safe, but the landing-place is far from good. All the water used for drinking must be obtained by distillation, and the means of subsistence come from a considerable distance. The population is about 4,000, including those who are going to and from the mines.

Co'ble, or **Cobble**, a flat-floored boat with a square stern, furnished with a lug-sail and also propelled with oars. It has a sharp high bow, is admirably constructed for encountering a heavy swell, and is used in fishing, especially on the east coast of Great Britain. The rudder extends for some distance below the stern. There is also a small rowing-boat with the same name used by salmon-fishers and others.

Coblentz, kō'blēnts, Germany, a fortified city, anciently called *Confluentes*, from its situation at the confluence of the Rhine and Moselle. It is the capital of Rhenish Prussia, and is finely situated on the left bank of the Rhine,

COBOURG—COBURN

in the angle between that river and the Moselle, and connected by a pontoon bridge over the Rhine with Ehrenbreitstein. Pop. 46,000.

Cobourg, Kō'berg, Canada, town, port of entry and county-seat of Northumberland county, Ontario, on the Grand Trunk Railway, 69 miles northeast of Toronto and 92 miles west by south of Kingston. It has a safe and commodious harbor on Lake Ontario and enjoys a large export trade in provisions, lumber, flour, etc. It has regular steamboat connection with the important United States and other Canadian lake ports. The town is well built and has many fine residences. There are six churches, a large new collegiate institute, several schools, and a large public hall. It was formerly the seat of Victoria University now located at Toronto (q.v.). It has woolen mills, a car factory, carpet and matting factory, breweries, etc., banks and weekly newspapers, electric lights, gas and water works. Pop. (1901) 4,239.

Cobra di Capello, the Portuguese name of an East Indian serpent, the *Naja tripudians*, and sometimes applied to an African genus, the *Naja haje*, or asp, both reptiles of the most venomous nature. The former inhabits India and southeastern Asia, Java, etc. The species of the viper kind are all remarkable for the manner in which they spread out or distend the sides of the neck and head when disturbed or irritated. In the cobra di capello the conformation necessary to this action is found in the most perfect condition, as some of the ribs are loosely articulated and moved by appropriate muscles on the sides of the neck, which, when expanded, give the anterior part of the body the appearance of an overhanging arch or hood, on the middle of which, posterior to the eyes, is a greenish-yellow mark, resembling the rim of a pair of spectacles. From this mark we have the name "spectacled snake." When disturbed by the approach of an individual or otherwise, the cobra raises the anterior part of its body, so as to appear to stand erect, expands its hood, and is prepared to inflict a deadly wound. The poison fangs are attached to the anterior end of the maxillary bone, and are permanently erect, not movable, as in the rattlesnakes. So exceedingly poisonous is its bite that in numerous instances which are well authenticated death has followed within a few minutes; under ordinary circumstances a few hours is the longest term that intervenes from the infliction of the bite till the death of the sufferer, where prompt measures for his relief have not been resorted to. So numerous are these snakes in India, and so bold in frequenting human habitations, that the census returns attribute not less than 10,000 deaths annually to their bites.

To minister to the curiosity of the multitude, the jugglers of India select these venomous reptiles for their exhibitions, and having extracted their fangs keep them in cages or baskets to exhibit as dancing snakes. When the cage is opened, the juggler begins playing upon a pipe or other instrument; whereupon the cobra assumes the erect attitude, distends its hood, and remains balancing itself in this position until the music is suspended. It is most probable that this snake in common with lizards and other animals, is peculiarly affected by musical sounds. With the exception of the spectacle mark on the back of the neck and its distensible

hood, the cobra is not especially distinguished as regards coloration or form. Consult Gunther, 'Reptiles of British India'; Boulenger, 'Snakes of the British Museum'; Gadow, 'Amphibia and Reptiles.' See HAMADRYAD.

Coburg, kō'boorg, a noted family of Germany, dating from the 5th century, distinguished for intermarriages with royal houses, especially during the 19th century. A sister of Duke Ernest I. became Duchess of Kent and mother of Queen Victoria; the Duke's brother Leopold became king of the Belgians, and married in succession daughters of George IV. of England and of Louis Philippe; one of his nephews, Ferdinand, married the queen of Portugal, and was regent of that kingdom, 1853; another, August, married a daughter of Louis Philippe; one of his sons, Duke Ernest II., declined the crown of Greece, 1863, and another, Prince Albert, was the husband of his cousin, Queen Victoria of England.

Coburg, or **Koburg**, Germany, capital of the duchy of Saxe-Coburg-Gotha, situated on the left bank of the Itz, 106 miles east by north of Frankfort-on-the-Main. Among the principal buildings is the Ehrenburg Palace, one of the town residences of the Duke of Saxe-Coburg-Gotha, formerly a monastery of the Recollets, but converted into a ducal residence in 1549. It contains some interesting pictures, tapestry, etc. Some of the old doors exhibit beautiful specimens of marquetry or inlaid work. There are one or two other palaces, and various monuments, including a statue of Prince Albert, consort of Queen Victoria. The chief church is the Moritzkirche, a spacious building in the late Gothic style, with a tower 334 feet high. The government house is a handsome structure in the Italian style. The educational institutions comprise a gymnasium (founded in 1605), real school, normal school, etc. On an eminence overhanging the town is the ancient castle or fortress, now a museum, from which extensive views are obtained. In the museum are relics and writings of Luther, who resided here for three months in 1530, and here wrote some of his works. This castle was occupied by the Swedes in 1632, and was unsuccessfully besieged by Wallenstein during the Thirty Years' war. Coburg has manufactories of porcelain and ceramic wares, carriages, furniture, etc., and has also malt-works, breweries, and other establishments. Pop. (1900) 20,460.

Coburg, a thin fabric of worsted and cotton, or worsted and silk, twilled on one side, for ladies' dresses, intended as a substitute for merino.

Coburn, **Foster Dwight**, agricultural writer: b. Jefferson County, Wis., 7 May 1846. After serving in Wisconsin regiments during the Civil War he went to Kansas in 1867. He became secretary of the Kansas Board of Agriculture in 1894 and still holds that position. He is the author of 'Swine Husbandry'; and 'Alfalfa'; and also of the following books on agricultural topics prepared for and issued by the Kansas State Board of Agriculture: 'Feeding Wheat to Farm Animals'; 'Alfalfa-Growing'; 'Alfalfa, Irrigation, Well Water Supply and Subsoiling'; 'Corn and the Sorghums'; 'The Helpful Hen'; 'Cow-Culture'; 'The Beef Steer (and His Sister)'; 'The Plow, Cow and Steer'; 'Pork Production'; 'The Modern

COCA — COCAINE

Sheep'); 'The Horse Useful'; 'Forage and Fodders'; 'Dairying in Kansas'; 'Short-Horn Cattle'; 'Hereford Cattle'; 'Polled Cattle'; 'Kansas Wheat-Growing'; Railroads and Agriculture.'

Coca (*Erythroxylon coca*), a shrubby plant belonging to the natural order *Erythroxylaceae*, found wild in the mountainous regions of Peru and Bolivia, and cultivated in districts 2,000 to 5,000 feet above sea-level. The leaves are gathered and dried in the sun, and chewed with a little powdered chalk. When taken in some quantity they produce an intoxication like that of opium. As the indulgence is repeated the appetite for it increases, while that for wholesome nourishment diminishes; the miserable victim loses all power of resisting his craving, and becomes reduced to a condition of physical and mental prostration. When used in moderation coca lessens the appetite for food and enables those who have partaken of it to sustain greater fatigue than they otherwise could. It has been found the best preventive of asthmatic symptoms caused by the rapid ascent of lofty mountains. An infusion of the leaves is also used with the same effect.

Cocaine, kō'ka-ĭn, or -ĕn, a vegetable alkaloid, with the chemical formula $C_{17}H_{21}NO_4$, obtained from the leaves of the coca shrub (*Erythroxylon coca*) of South America. The leaves are digested with ether, and the solution is evaporated to dryness and extracted with boiling water. Magnesia is then added, and the solution again evaporated, after which the cocaine is removed by solution in amyl alcohol. Cocaine crystallizes in small, monoclinic prisms, which melt at 208° F., and are but slightly soluble in water, though they dissolve freely in hot alcohol and hot ether. Salts of cocaine are precipitated from solution by numerous reagents, among which are ammonia, caustic potash, sodium carbonate, picric acid, tannic acid, gold trichloride, and platinum tetrachloride. The substance popularly known as cocaine is the hydrochloride of the true alkaloid, this being the form in which the base is usually administered in medicine. Although an alkaloid first called erythroxyline, which subsequently received the name cocaine, was obtained from coca as long ago as 1855, the history of the agent in actual therapeutics does not begin until 1884 when Karl Koller demonstrated its practical utility. Since then its use has been developed to a very extensive degree, and many applications have been found for it both in medicine and surgery. Cocaine when taken internally is a cerebral stimulant, and moderate doses usually cause a pleasant sense of exhilaration and temporary increase in mental and physical power, though this is apt to be followed by a corresponding period of depression. The sense of hunger and fatigue is lessened so that privations may for the time being be better endured under the influence of the drug. Moderate doses powerfully stimulate respiration, and to a less degree, the heart and circulation. The body temperature is not affected by small amounts, but in overdose it may be elevated several degrees. The drug is to a large extent oxidised in the body though small amounts may be excreted by the kidneys. It is alleged that the quantity of nitrogenous material eliminated in the urine is decreased, indicating a reduction in tissue waste, but this has not yet been clearly

proven. In poisonous doses cocaine produces narcosis — sometimes with epileptiform convulsions — with depression, followed by paralysis, of the sensory nerves and to a less degree of the motor nerves. The symptoms of poisoning vary greatly in different individuals. Moderately toxic amounts may give rise to disagreeable mental excitement and unrest, nausea, faintness, pallor, cold perspiration and prostration, or to a sense of malaise and depression. Large doses cause rapid respiration, feeble and accelerated heart action, dilated pupils, headache, dryness of the throat, and muscular twitchings. General convulsions may supervene — or collapse occurs, the skin is cyanotic and cold, the blood pressure falls through great cardiac depression, respiration becomes slow and shallow and death occurs through failure of this function. The treatment of poisoning includes the evacuation of the stomach if the drug has been taken by mouth, and the use of stimulants such as ammonia, coffee, strychnine, ether, or alcohol. If convulsions are present these must be combated by the inhalation of small amounts of ether or chloroform and the cautious administration of sedatives. Morphine is said to be the best physiological antidote. Cocaine is used internally to some extent as a stimulant in certain febrile and mental conditions, as well as on account of its topical action in gastric disorders or in obstinate vomiting, but its most important field of utility is the production of local anesthesia in minor surgery. When applied externally in proper strength it produces a loss of sensation, particularly to pain and touch, through paralysis of the terminations of the sensory nerves. Applied to the eye it causes anesthesia, contraction of the blood vessels, reduction of intraocular tension and dilation of the pupil, but the reflex to light is not lost and there is little or no paralysis of accommodation. Brought into contact with the tongue it destroys the sense of taste for bitter substances, though salt may still be recognized and sweet and sour fluids do not entirely lose their flavor. The sense of smell may be entirely abolished by the application of cocaine to the mucous membrane of the nose, but it is not absorbed from the unbroken skin. When injected under the skin or applied to mucous membranes a feeling of numbness is produced and incisions or other painful manipulations may be practised on the part so treated without giving rise to discomfort. For this purpose solutions varying in strength from 2-10 per cent are usually employed.

The applicability of local anesthesia has been greatly extended by means of what is called nerve blocking. It has been found that on the injection of a small amount of a weak solution of cocaine into the trunk of the main nerve supplying a part sensation is cut off in that region and painless operating is possible. A plan which enables extensive areas to be anesthetized with but small amounts of the drug is called Schleich's infiltration method. For this purpose a very weak solution of cocaine, morphine, and sodium chloride is injected into the tissues until considerable local swelling or edema is caused. In this way the effect of pressure on the local nerve filaments and the local anemia combine to aid the action of the very small amounts of the alkaloids.

Owing to its more or less serious disadvantages, particularly its tendency to produce

COCCEIUS — COCCULUS INDICUS

grave poisoning in some persons even in small doses, and the difficulty of sterilizing solutions of it without impairing their virtue, numerous substitutes for cocaine have been produced by the synthetic chemists and it is not likely that a more satisfactory local anesthetic may yet be the result. Even as it is, the province of local anesthesia has been greatly extended and even laparotomies can in this way be performed without the use of a general anesthetic under conditions in which the administration of the latter would be unsafe. A very great advance was made when it was found that it was practicable to produce anesthesia embracing almost the entire body by injecting cocaine solutions into the spinal cord by means of a long hypodermic needle usually inserted between the fourth and fifth lumbar vertebræ. Anesthesia of the legs and trunk about as high as the breasts is produced within 15 minutes and lasts from two to five hours. For this purpose as for use in other ways small quantities of adrenalin are often added to the cocaine solution with the idea of neutralizing some of its undesirable qualities. Spinal anesthesia, however, is not altogether without dangers or drawbacks, and will probably never be used as a routine procedure. Cocaine is sometimes used in the treatment of the morphine habit, not infrequently with the result that the victim only exchanges one form of bondage for another no less pernicious. Many persons innocently acquire the cocaine addiction through the medium of various nostrums ostensibly intended for the cure of nasal catarrh, hay fever, etc. The temporary alleviation of his symptoms produced by the compound induces the sufferer to continue its use until he is fairly in the grip of a servitude leading to certain destruction unless its fetters are cast off by the exercise of almost superhuman fortitude. The cocaine habitué has to suffer from progressive loss of flesh and strength, digestive and circulatory disorders, trembling of the limbs, insomnia, headache, vertigo, etc. Hallucinations and even outbreaks of maniacal fury are not unusual and there is complete decadence of the mental and moral qualities. The cocaine fiend respects no convention or obligation, and will lie, steal, or use any other base means to gratify his passion for the drug, being lost to all considerations of duty or social position. In most large cities the number of these unfortunates is very great, but fortunately owing to a popular realization of the sources of danger legislative measures are being introduced into the various States which are intended to safeguard the unsuspecting from falling into the trap of the nostrum maker. According to the United States Pharmacopœia of 1900 the average dose of cocaine is said to be 30 milligrams, or one-half grain, but deaths have been recorded from amounts not much larger than this. On the other hand recovery has been observed in cases in which 20 grains and more of the drug had been taken by mouth.

Cocceius, Heinrich von, hīn rīh fōn kōk-tsā'yoos, German jurist: b. Bremen 1644; d. 1719. He studied at Leyden, and Oxford; was in 1672 professor of law at Heidelberg, and in 1688 at Utrecht; in 1690 regular professor of

laws at Frankfort-on-the-Oder. He went to The Hague in 1702, without giving up his office, on occasion of the disputes as to the hereditary succession of the house of Orange; and received for his services, in 1713, the rank of baron of the empire. As a lawyer he was the oracle of many courts, and his system of German public law ('Juris Publici Prudentia') was almost a universal academical text-book of this science.

Cocco, Cocoa-root, Eddoes, Taro, various plants of the genera *Caladium* and *Colocasia* of the natural order *Araceæ*. They are widely cultivated for food in the tropical and subtropical islands of the Pacific, the West Indies, and adjoining continental regions, and to a less extent in other warm countries. The edible part most desired is the starchy acrid tuber which is eaten like potatoes or made into *poi*, a substance obtained by roasting the tubers, pounding them with water to a paste and allowing the mass to ferment before being eaten either in that form or again prepared for the table. In this form the roots are a staple food of the Hawaiians. During the process of roasting or boiling the tubers lose their acidity, which quality is, in some varieties, almost wanting. The young leaves of some species are used as pot-herbs. The principal species is *Colocasia antiquorum* var. *esculentum*, a perennial herb with heart-shaped peltate green leaves often three feet long and nearly as wide; and an inconspicuous spadix. It is very popular as a bedding plant in the United States, since it gives a subtropical effect, especially when grouped with cannas and crotons. Popularly it is known as elephant's ear. It is easily grown, being started in the greenhouse, transplanted to the open ground after danger of frost, freely supplied with water, and at the approach of frost in the autumn, stored in a cool, dry cellar.

Coc'colith, the name given in 1858, by Huxley, to one of certain minute oval or globular calcareous bodies found in countless numbers in the ooze of the Atlantic, either detached or adherent to small pieces of protoplasm. They have since been dredged up from other places, and found in chalk, and, according to Guembel, in limestone of all ages. Carter thinks they belong to *Melobesia*, a genus of algæ.

Coccosteus, kōk-kōs'tē-ūs, a genus of fossil placogonoid fishes, pertaining chiefly to the Devonian and Old Red Sandstone systems, but met with also in Silurian strata. The head was protected by a great shield covered with tubercles. Besides this bony cuirass there was also a ventral shield, but the rest of the body was naked. The mouth was furnished with small teeth.

Coc'culus In'dicus, or fish-berry, as it is commonly known in the United States, is the seed of a herbaceous climbing vine (*Anamirta paniculata*), a species of *Menispermaceæ*. The dried berries are imported from the East Indies. The drupe resembles a round berry, the size of a pea or larger, wrinkled externally, and with a brittle husk. The kernel is intensely bitter. It contains about one fiftieth of its weight of a powerful bitter narcotic poison called picrotoxin, also bases called menispermene, a crystalline base, paramenispermene, and several organic acids. Picrotoxin is used as an adulterant in enriching

COCCUS

and imparting a bitter taste to malt beverages, and is thrown into rivers in which fish abound to stupefy them, so that they may be readily caught. It has been used in the form of an ointment in certain skin diseases, and in decoctions for killing vermin in the hair of children and animals, although death is sometimes caused through this latter use. The symptoms of poisoning are twitching and incoördination of the muscles, increased reflex excitability, convulsions, coma, and death from asphyxia.

Coccus, in zoology, a genus of insects of the order *Hemiptera*, family *Coccidæ*. Generic character: antennæ filiform, of 10 articulations in the male, nine in the female, shorter than the body; rostrum pectorale, conspicuous only in the females; males with two large incumbent wings; females apterous, subtomentose, fixed, and becoming gall-shaped or shield-shaped after impregnation. These little insects are remarkable for many peculiarities in their habits and conformation. The males are elongated in their form, have long, large wings, and are destitute of any obvious means of suction; the females, on the contrary, are of a rounded or oval form, have no wings, but possess a beak or sucker formed of the extremely modified appendages of the mouth, by which they fix themselves to the plants on which they live, and through which they draw their nourishment. At a certain period of their life the females attach themselves to the plant or tree which they inhabit, and remain thereon immovable during the rest of their existence. In this situation they are impregnated by the male; after which their body increases considerably, in many species losing its original form and assuming that of a gall (whence Réaumur's name, *Gallinsecta*, for the family), and, after depositing the eggs, drying up and forming a habitation for the young. This change of form is not, however, constant to all the species, which has given rise to a division of the genus into two sections: those which assume a gall shape, in which the rings of the abdomen are totally obliterated, are called "kermes" by some authors; and those which retain the distinct sections of the abdomen, notwithstanding the great enlargement of the body, are called "true cocci," or "cochineal" (q.v.). They are impregnated in the spring, after having passed the winter fixed to plants, particularly in the bifurcations and under the small branches. Toward the commencement of summer they have acquired their greatest size, and resemble a little convex mass without the least appearance of head, feet, or other organs. Many species are covered with a sort of cottony down. Each female produces thousands of eggs, which are expelled by a small aperture at the extremity of the body. As soon as they are produced they pass immediately under the parent insect, which becomes their covering and guard; by degrees her body dries up, and the two membranes flatten and form a sort of shell, under which the eggs, and subsequently the young ones, are found. Soon after the death of the mother the young insects leave their hiding-place and seek their nourishment on the leaves, the juices of which they suck through the inflected rostrum placed beneath their breast.

But it is with a view to their importance as an article of commerce, arising from their use

in the arts, that the insects of this genus are particularly interesting. When it is considered that the most brilliant dyes and the most beautiful pigments, as well as the basis of the most useful kinds of cement, are their product, it will be acknowledged that to none of the insect tribe, except, perhaps, to the bee and the gall-insect, are we more indebted than to these singular and apparently insignificant little beings. Kermes, the scarlet grain of Poland, cochineal, lac-lake, lac-dye, and all the modifications of gum-lac, are either the perfect insects dried, or the secretions which they form. The first-mentioned substance is the *Coccus ilicis*. It is found in great abundance upon a species of evergreen oak (*Quercus coccifera*), which grows in many parts of Europe, and has been the basis of a crimson dye from the earliest ages of the arts. It was known to the Phœnicians before the time of Moses; the Greeks used it under the name of *kokkos*, and the Arabians under that of *kermes*. From the Greek and Arabian terms, and from the Latin name *vermiculatum*, given to it when it was known to be the product of a worm, have been derived the Latin *coccineus*, the French *cramoisi* and *vermeil*, and the English "crimson" and "vermilion." The early Jews, the Greeks, the Romans, and until lately the tapestry-makers of Europe, have used it as the most brilliant red dye known. The scarlet grain of Poland (*Coccus polonicus*) is found on the roots of the *Scleranthus perennis*, which grows in large quantities in the northeast of Europe and in some parts of England. This, as well as several other species, which afford a similar red dye, have, however, fallen into disuse since the introduction of cochineal. The introduction of aniline dyes has greatly injured the cochineal industry.

Lac is a secretion from a species of *Coccus* inhabiting India, where it is found in astonishing abundance on the *Ficus religiosa*. In its native state, not yet separated from the twig on which it has been deposited, it is called "stick-lac"; when separated, powdered, and the coloring matter washed from it, it is denominated "seed-lac"; "lump-lac" when melted into cakes; and "shell-lac" when purified and formed into thin laminæ. Lac-lake is the coloring matter of stick-lac precipitated from an alkaline lixivium by means of alum.

Coccus is also the name of a family of bacteria characterized by their spherical form and consisting of a number of genera, all named for certain growth characters. Thus cocci that grow in chains are termed *Streptococci* in which group the virulent bacteria that cause blood-poisoning, septicæmia, and the organism of erysipelas are found; Cocci that grow in pairs are termed *diplococci*. The *diplococcus* of pneumonia, and the *diplococcus* of gonorrhœa are in this group. Others grow in bunches,—*Staphylococci*. The common organism of pus is *Staphylococcus pyogenes aureus*, by bacteriologists usually called *S.p.a.* Other spherical forms are known as *Micrococci*, one of which group, the *Micrococcus urea*, is found in the urine as causative agent in excessive urinary fermentation. Some forms of this family group grow in packets. These are termed *Sarcinæ*. They are very abundant in the air, and are frequently associated with chronic gastric fermentations. A large number of different forms of this family are known, the greater majority of which are

COCCYGODYNIA — COCHIN-CHINA

not pathogenic but very useful in agriculture and the arts, particularly in agricultural processes. As many as a hundred different species have been found in the air, and Chester has described 36 species of *Streptococcus*, 91 species of *Micrococcus* (*Staphylococcus* here included), 14 species of *Sarcinæ*, 3 species of *Planococci*, or movable cocci, and 3 species of *Planosarcinæ*. See BACTERIA.

Consult: Chester, 'Manual of Determinative Bacteriology.'

Coccygodynia, kŏk''sĭ-gŏ-dĭn'ĭ-a, a painful affection usually situated at the end of the spinal column, in and about the region of the coccyx. It is probably many affections rather than one, as neuralgias, arthralgias, and sympathetic pains may be felt in this region. It is an affection more common in women than in men, being more prevalent in those women who have had children. Pain is felt, usually of a decided sharp character, and definitely localized and in the region, on rising after sitting down, walking up and down stairs, and on defecation. The diagnosis may be extremely difficult and the treatment purely medical or surgical.

Coccygomorphæ, an order or suborder of birds, proposed by Huxley, and nearly equivalent to the *Cuculiformes* of some authors. All have the palate desmognathous or provided with a more or less well developed band of bone binding the two maxillary bones together across the palate; but, owing to the great diversity of characters exhibited by the families, a brief definition is impossible. The following families are included by Stejneger, and indicate the limits of the group: *Cuculidæ*, cuckoos (q.v.); *Coraaciidæ*, rollers, of Madagascar; *Alcedinidæ*, kingfishers (q.v.); *Upupidæ*, hoopoes (q.v.), of the Old World; *Musophagidæ*, plantain eaters (q.v.) of Africa; *Todidæ*, todies (q.v.), of Mexico and the West Indies; *Momotidæ*, sawbills (q.v.); *Bucerotidæ*, hornbills (q.v.), of the Old World; *Rhamphastidæ*, toucans (q.v.), of tropical and sub-tropical America; *Caprimulgidæ* (q.v.), goatsuckers, cosmopolitan; *Bucconidæ*, barbets and puffbirds (qq.v.); and *Indicatoridæ*, guide-birds (q.v.), of Africa.

Coccyx, kŏk'sĭks. See OSTEOLOGY.

Cochabamba, kŏ-chä-bäm'ba, Bolivia, a central department of the republic, bounded on the north by the department of Beni, on the east by Santa Cruz, on the south by Chuquisaca and Potosi, and on the west by Oruro and La Paz. Its area is about 22,000 square miles. The following list shows its provinces and the varieties of climate: Tarata, Mizque, Punata, and Ayopaya are tropical; Chaparé, Tapacari, Totorá, Arque, and Furacares are semi-tropical; the capital district is temperate. The gold-mines at Choquecamata in Ayopaya have been worked for a long time, and were famous during the period of Spanish supremacy. Silver and marble are found at Palca; gold and silver at Sayari; silver in Mizque, Colcha de Arque, and Quioma. Cochabamba has been called "the granary of Bolivia." It is the great wheat and maize growing section of the country, and is also noted for its fine horses bred from imported Peruvian and Chilean stock. All classes of agricultural products can be grown on the extensive and rich plains of Sacaba, province of Chaparé, where useful medicinal plants are also found, and alfalfa grows luxuriantly. In

the province of Ayopaya there are great tracts of pasture land, and wool, barley, etc., are produced. In Tapacari all the European fruits and cereals thrive, and herds of llamas, cattle, and horses abound. All cereals thrive in Mizque, a province which also contains extensive vineyards, and produces the excellent and nutritive Cochabamba corn. The agricultural products are manufactured on a limited scale. According to the census taken by the national committee and approved by President Pando, 5 Dec. 1902, the department has 328,163 inhabitants.

Cochabamba, Bolivia, the capital of the department of the same name. It is one of the principal centres of trade in the republic, and its elevation (8,400 feet above the level of the sea) gives it a cool and healthful climate. The city has manufactures of leather goods, woolen cloths, and other products. Pop. over 40,000.

Cochin, Charles Nicolas, French engraver: b. Paris 1688; d. 1754. He practised painting till his 23d year, and this was of considerable advantage to him in the art of engraving, to which he afterward devoted himself. In 1731 he became a member of the Academy of Painting.

Cochin, Charles Nicolas, French engraver: b. Paris 22 Feb. 1715; d. Versailles 29 April 1790. He was a son of the preceding, and his productions are superior to those of his father. The collection of his works contains more than 1,500 pieces, among which there are 112 likenesses, in the form of medals, of the most renowned French scholars and artists of his time, who were almost all his friends. Besides his essays in the memoirs of the Academy, he published 'Voyage d' Italie' (1758), and several other works. His frontispieces and vignettes are remarkable for neatness and taste. His views of 16 French seaports are of great value. His composition in general is rich, delicate, and pleasing. He was a member of the Academy, and occupied several places of importance.

Cochin, kŏ'chĭn, India, a seaport of Hindustan, in the Malabar district of the Madras presidency, situated on a small island. It is a picturesque place with many quaint old Dutch buildings. Its harbor, though sometimes inaccessible during the southwestern monsoon, is the best on this coast. Cochin was one of the first places in India visited by Europeans. In 1502 Vasco da Gama established a factory and soon after Albuquerque built a fort; he also died here in 1524. In 1663 the Dutch took the place, in 1795 the British. Pop. about 18,000.

Coch'in, a variety of the domestic fowl, imported from Cochin-China. It is a large, ungainly bird, valuable chiefly owing to its fecundity, eggs being laid even during the winter.

Cochin-China, a country forming part of the peninsula of southeastern Asia, and generally regarded as comprising the whole of Anam and Lower or French Cochin-China. Three of the six provinces into which the latter was divided were acquired at one period, and the remaining three at another period. A persecution of the French Roman Catholic missionaries in Anam furnished the French with an occasion of regaining a footing in the East. An expedition against Cochin-China was decided on in 1857, and Saïgon was occupied. The Austro-

COCHIN-CHINA — COCHINEAL

Italian war deferred further operations till 1861, when the conquest of Metho gave the French possession of the most fertile district of Lower Cochin-China. The war continued till 5 June 1862, when a peace was concluded at Saïgon with the king of Anam, which was ratified at Hué 15 April 1863. By this treaty the king agreed to cede to the French the three provinces of Bienhoa, Saïgon, and Metho, along with the island of Poulo Condore, to permit the Roman Catholic religion in his kingdom, to open three of the ports in Tonquin to French ships, and to pay an indemnity of 24,000,000 francs (about \$4,800,000). Although the inhabitants were found to be on the whole sufficiently tractable, yet a few revolts took place, whereupon Admiral De la Grandière, on the pretext that all these disturbances had their origin in the provinces of Lower Cochin-China which had remained to Anam, namely, Vinhlong, Chaudoc, and Hatien, took possession of these provinces, and declared them French territory, 25 June 1867. The territory thus acquired by France in this peninsula covers 21,710 square miles, and in 1894 had a population of 2,226,935. It is now organized in departments, prefectures, sub-prefectures, and cantons. In 1882-3 France asserted a claim to the protection of Tonquin, and indeed the entire Anam territory, and after some fighting this claim was conceded by the king. Tonquin was accordingly taken possession of by France in 1884, and is now under French administration, native resistance having now entirely ceased. Anam (q.v.) forms a protectorate.

The northern and eastern parts of French Cochin-China are hilly, but the rest of the territory consists almost entirely of well-watered low alluvial land. The lowlands, where the waters stagnate, are covered with a rank vegetation from three to ten feet high; contiguous to the flowing streams are extensive rice-grounds. Where the soil is somewhat raised above the water-level it is very fertile, and in some places ranges of low hills follow the line of the rivers. In the more elevated districts are grown tobacco, sugar-cane, maize, indigo, and betel. Among the other products are tea, gums, coconut oil, silk, spices, and various farinaceous and aromatic articles. The Anamites raise also great numbers of buffaloes, cattle, hogs, and birds; the first being employed in agriculture, and, as well as oxen, for draft purposes; but since the French conquest oxen are reserved more strictly for food. Industrial arts are as yet limited among the natives. They are skilful in all kinds of basket-work, in which they use the reeds and other similar materials which abound in the low lands; silk and cotton are also wrought. But they excel in the use of wood, of which their temples, pagodas, and tombs are built, and ornamented with elaborate carving. They live in villages—numbering nearly 1,000—adjacent to the rivers, which, in the unsuitableness of the country for land traffic, form almost the only means of communication. Their houses are either tiled or thatched with straw, the roofs being supported with wooden pillars; the better class are in two sections, the inner apartments and the outer veranda, which serves for use in the daytime; they are often well furnished, and not devoid of comfort. The only roads at present are those connecting Saïgon, the capital, with the principal towns. Telegraphic communication between many of the

principal places has been opened, and is being extended. The principal export is rice, of which there is annually exported about 7,000,000 hundredweight, mainly to China; cotton and silk are also exported.

Cochin-China, Upper, or Dong-trong, a narrow strip of land, consisting of four provinces, on the east coast of Anam, to which empire it belongs, extending from Tonquin on the north to Champa on the south. The most important river is that on which the chief town P'hu-thua-thien or Hué stands. In the most fruitful parts of this region aloes wood (of the *Aquilaria ovata*), corn, sugar-cane, and cinnamon flourish. From October to January the weather is often very stormy, and typhoons rage frequently. The climate is healthy and pleasant. Camphor is produced in the district in the utmost perfection.

Cochineal, an insect (*Coccus cacti*), used as a dye. It is a native of Mexico, but has been introduced into Europe and Algiers. Even the live insects were imported, and plantations of cactus were cultivated for their nourishment. The French and Spanish kermes, which at one time was in high repute, disappeared and was soon entirely forgotten. It is a small insect with the body wrinkled transversely; its abdomen of a deep mulberry color, and bristly in the posterior part; the legs are short and black, the antennæ subulate and about one third the length of the body. The male has two erect wings, the female none. The principal district in which they are reared is in the province of Oaxaca, those of the district of Mestique being considered the best insects. There are plantations of the nopal (*Opuntia coccinellifera*), upon which they feed, the insects being tended with care equal to that ordinarily bestowed upon silkworms. Before the rainy season sets in, branches of the nopal covered with insects are cut off and brought under shelter to protect them from the weather. At the close of the wet season, about the middle of October, the plantations are stocked from these supplies by suspending little nests made of some soft woody fibre, each containing 8 or 10 females, upon the spines of the nopal. The insects, warmed by the sun, soon emerge and lay their eggs, each female producing more than 1,000 young. These spread rapidly over the plants, and as the young females become impregnated they attach themselves to the leaves and swell to great size, presenting the appearance more of vegetable excrescences than of animated creatures. In this condition they are gathered for the cochineal. The males, which are few in number, not more than one to 100 or 200 females, are of no value for this purpose. The females are picked off with a blunt knife, the first crop about the middle of December, and subsequently several more of as many successive generations, the last being in May. A laborer can pick off only about enough to make two ounces of cochineal in a day. Those taken off full of young lose about two thirds of their weight in the process of drying, to which they are subjected as soon as they are killed, which is done either by dipping them in a basket into boiling water, or placing them in a hot oven, or on plates of hot iron. By the first method, usually considered the best, the insects turn to a brownish red color, losing a portion of the white powder with which they

COCHINEAL-FIG — COCK

were previously loaded between the wrinkles of the body. In the oven they retain this, and their color is then gray. Those killed on hot iron turn black. Such is the origin of the different varieties known in our market as "silver grains and black grains," and the "foxy" of the London market, the last being those killed by boiling water, though others ascribe it to the former being the female before laying her eggs, and the latter after she has parted from them. The quality of the cochineal is the same in both cases. When dried, the cochineal presents the form of grains, convex on one side and concave on the other, about one eighth of an inch in diameter, with the transverse wrinkles still visible. It is stated that it takes about 70,000 insects to weigh a pound.

Cochineal-fig, a name given to *Opuntia coccinellifera* and two other species of cacti, natives of Mexico and the West Indies, the plants on which the cochineal insect lives. See CACTUS; COCHINEAL.

Cochituate (kō-chīt'ū-āt) **Lake**, Mass., a narrow body of water, about four miles long, in Middlesex County, 17 miles west of Boston. From this lake for many years Boston has derived its principal water-supply.

Cochlea, kōk-lē'ā, an important part of the internal ear, so called from its shape, which resembles that of a snail-shell. See EAR.

Cochlearia, kōk-le-ā'rī-ā, a genus of annual maritime herbs of the mustard family (*Crucifera*). It numbers upward of 25 species, all natives of the colder parts of the north temperate zone, and not familiar generally. About four species are found on the Arctic and northern Pacific coasts of North America. Two very distinct species quite well known are the horse-radish (*C. armoracia*), escaped from cultivation, and now found wild in the moist ground along streams, and scurvy-grass (*C. officinalis*), considered of great value as an antiscorbutic. If eaten fresh, it is a stimulant and diuretic, but is feeble if allowed to dry before being taken.

Cochran, John, American soldier and lawyer: b. Palatine, Montgomery County, N. Y., 27 Aug. 1813; d. New York 7 Feb. 1898. He was graduated at Hamilton College 1831, practised law in Oswego from 1834 to 1845, when he removed to New York, where his talents as lawyer and orator at once brought him into prominence. He was surveyor of the port of New York 1853-7, and a Democratic member of Congress 1857-61, serving as chairman of the Committee on Commerce. During the Civil War he commanded the 1st United States Chasseurs in the Peninsula campaign; was commissioned a brigadier-general 17 July 1862, and commanded a brigade in Gen. Couch's division of the Army of the Potomac; was with the reserve at the battle of Antietam and took an active part in the pursuit of the enemy. He was attorney-general of New York State 1863-5. He was active in securing Greeley's nomination for President in 1872; was president of the New York Common Council 1872, and acting mayor when Mayor Hall retired during the Tweed ring disclosures; again a member of the council in 1883, and a police justice 1889.

Cochrane, Thomas, 10th Earl of Dundonald, British naval officer: b. Annsfield, Scotland,

14 Dec. 1775; d. Kensington, England, 31 Oct. 1860. He entered Parliament in 1806. In 1814 he was accused of conspiring to circulate a false report of Napoleon's death for speculative ends, and though he protested his innocence he was imprisoned for a year, fined, and was expelled from the navy and the House of Commons. In 1818 he accepted an invitation to organize the navy of Chile and performed many brave exploits during the contest with Spain. He left the service of the Chileans and was commander of the Brazilian navy from 1823 to 1825, when he resigned, because accused of insubordination. In 1827 and 1828 he commanded the Greek army. In 1832 he was cleared of the charges brought against him in 1814, and restored to the Order of the Bath and to the English navy. He was appointed vice-admiral in 1841; admiral in 1851, and rear-admiral of the United Kingdom in 1854.

Cock, the male of the domestic fowl. At what time this valuable species of pheasant was brought under the immediate control of man it is now impossible to determine; but, as the forests of many parts of India still abound with several varieties of the cock in the wild or natural condition, it is reasonable to conclude that the race was first domesticated in Eastern countries, and gradually extended thence to the rest of the world. It is stated that the cock was first introduced into Europe from Persia; and Aristophanes speaks of it as "the Persian bird." Nevertheless it has been so long established throughout western regions as to render it impossible to trace its progress from its native wilds.

The cock has his head surmounted by a notched, crimson, fleshy substance called "comb": two pendulous fleshy bodies of the same color, termed "wattles," hang under his throat. The hen has also a similar, but not so large nor so vividly colored excrescence on her head. The cock is provided with a sharp horn or spur on the outside of his tarsus, with which he inflicts severe wounds; the hen, instead of a spur, has a mere knot or tubercle. There is, in both sexes, below the ear, an oblong spot, the anterior edge of which is reddish, and the remainder white. The feathers arise in pairs from each sheath, touching by their points within the skin, but diverging in their course outward. On the neck they are long, narrow, and floating; on the rump they are of the same form, but drooping laterally over the extremity of the wings, which are quite short, and terminate at the origin of the tail, the plumes of which are vertical. In the centre of the cock's tail are two long feathers, which fall backward in a graceful arch and add great beauty to the whole aspect of the fowl. The plumage is infinitely varied in both colors and markings, being in some breeds of the greatest richness and elegance, and in others of the simplest and plainest hue. Except in the pure white breeds, the plumage of the cock is always more splendid than that of the hen. The cock, when in good health and full plumage is apparently conscious of his personal beauty and courage. The cock is strongly attached to what may be called his harem, and is often seen strutting at the head of 10 or 15 hens. His sexual powers are matured when he is about six months old, and his full vigor lasts for about three years, varying

COCK-FIGHTING — COCKBURN

in earliness of maturity and duration with his size and the climate. See also HEN.

Cock-fighting, an ancient sport of unknown origin, but practised among both the Greeks and the Romans. An annual cock-fight was instituted at Athens, and Æschines reproaches Timarchus, and Plato the Athenians in general, with their fondness for the cock-pit. The breeds of Rhodes and of Tanagra in Bœotia were in great esteem in Greece. The Romans seem to have used quails and partridges also for this purpose. This sport has long been a favorite with both Americans and English, although repeatedly denounced and prohibited by the laws. The size proper for game-cocks may be said to be not less than four pounds eight ounces, nor above four pounds ten ounces. The strain from which the cock is chosen ought to be distinguished for victory. For the combat they are armed with steel or silver spurs, or "gaffles." The place appropriated to fighting is called a "pit," and consists generally of a mound of earth covered with sod, and surrounded by seats in circular tiers. The battle is conducted by two "setters-to," who place the cocks beak to beak. When they are once "pitted" (this verb owes its origin to the sport of cock-fighting), neither of the setters-to can touch his cock so long as they continue to fight, unless their weapons get entangled. In the Philippine Islands cock-fighting is pushed almost to the verge of a craze. Nearly every village has its pit, and every peasant his cock. The peasant, too, is said to rescue his fighting-cock rather than his wife or child in the event of fire, and wherever he goes he takes it with him. The sport is there practised in a very cruel form, and many are ruined by excessive betting. Throughout all Spanish-America cock-fighting is more or less in favor. It was formerly a regular sport in the public schools of England, and schoolmasters received dues in connection with it. Cock-fighting is still prevalent in China, Persia, and Malacca.

Cock-Lane Ghost, a famous hoax by which many people of London were deceived in 1762, arising from certain knockings heard in the house of a Mr. Parsons, in Cock Lane. Dr. Johnson was among those who believed in the supernatural character of the manifestations; but it was found out that the knockings were produced by a girl employed by Parsons.

Cock of the Plains. See CAPERCAILZIE.

Cock of the Rock (*Rupicola crocea*), a South American bird of a rich orange color, with a beautiful crest, belonging to the family *Cotingidæ*. The name, or its French equivalent, is also applied to several related species.

Cock of the Woods. See CAPERCAILZIE.

Cockade (Fr. *cocarde*), a plume of cock's feathers, with which the Croats in the service of the French in the 17th century adorned their caps. A bow of colored ribbons was adopted for the cockade in France, which soon became a national emblem and party signal. During the French Revolution the tricolored cockade — red, white, and blue — became the national distinction. National cockades are now to be found over all Europe. In Germany cockades of black, red, and gold, after being forbidden in 1832, were again allowed in 1848, and even introduced into the army. Since 1850, however, they

have again ceased to be publicly worn. In Italy the former emblem of the party of progress, the green, red, and white cockade, was recognized by the government of Piedmont in 1848, and since the formation of the kingdom of Italy it has formed the national cockade.

Cockaigne, kōk-ān', **Land of**, an imaginary land of idleness and plenty, in which the houses were roofed with cake, the rivers ran wine, and roasted fowl offered themselves to be eaten. The term was applied in derision to both London and Paris. The corresponding term in English is "lubberland," and in German "*Schlauraffenland*." 'The Land of Cockaigne' was the title of a satirical poem written not later than 1300.

Cockatoo, an English rendering of a Malayan name for certain species of birds of the parrot family (*Psittacidæ*). They are comprised in *Cacatua*, and five other genera forming a sub-family, which, besides having some peculiarities of internal anatomy, is distinguished from true parrots by the greater height of the bill, and its being curved from the base, and by the lengthened, broad, and rounded tail. The head is also large, and in the true cockatoos is surmounted by a crest of long and pointed pink or yellow feathers, with their tips directed forward, which can be erected and expanded like a fan, or depressed, at the pleasure of the bird. The true cockatoos are also all of generally whitish plumage, but often finely tinged with red, orange, and other colors, or mixed with these colors in more brilliant displays. The cockatoos are confined to the Australian region and the neighboring Malayan islands, with the exception of a single Philippine species. The sulphur-crested cockatoos (*Cacatua sulphurea* and *galerita*) are well-known cage-birds which may be taught a few words, but their vocal efforts are chiefly limited to the harsh cry "cockatoo."

Cock'atrice, a fabulous serpent or serpent-like monster anciently believed to be hatched from a cock's-egg. It is often simply another name for the basilisk (q.v.).

Cockburn, kō'bērn, **SIR Alexander James Edmund**, English jurist: b. 24 Dec. 1802; d. 20 Nov. 1880. He studied at Cambridge; was called to the bar in 1829, and soon became distinguished as a pleader before parliamentary committees. In 1847 he became member of Parliament for Southampton in the Liberal interest; became solicitor-general and was knighted in 1850. He was made chief justice of the common pleas in 1856; and lord chief justice in 1859. Among the many famous trials over which he presided were the Wainwright case and Tichborne case. He represented Great Britain at the Geneva arbitration tribunal for the adjustment of the "Alabama Claims," 1871-2.

Cockburn, **Alicia** or **Alison Rutherford**, Scottish lyrist: b. Fairnilee, Selkirkshire, 8 Oct. 1713; d. Edinburgh 22 Nov. 1794. In 1731 she married Patrick Cockburn, advocate, and in 1753 was left a widow. She died having for 60 years and more been a queen of Edinburgh society. In person she was not unlike Queen Elizabeth. Of her lyrics the best known is the exquisite version of 'The Flowers of the Forest' ("I've seen the smiling of Fortune beguiling"), commemorating a wave of calamity that swept over Ettrick Forest, and first printed in 1765. Mrs.

COCKATOOS (Cacatuinæ).

1. The Slender-billed Cockatoo (*Licmetis nasicus*).

2. The Black or Crow Cockatoo (*Calyptorhynchus galeatus*).

COCKBURN—COCKLE

Cockburn in 1777 discerned in Walter Scott "the most extraordinary genius of a boy"; in 1786 she made Burns' acquaintance.

Cockburn, Sir George, English naval officer: b. London 22 April 1772; d. Leamington 19 Aug. 1853. He entered the navy in early youth, and about 1812 obtained the rank of rear-admiral. He took part in the capture of Washington City in 1814 and conveyed Napoleon to Saint Helena in 1815. He was a lord of the admiralty from 1818 to 1828, and sat in Parliament for many years.

Cockburn, George Ralph Richardson, Canadian educator: b. Edinburgh, Scotland, 15 Feb. 1834. He graduated at Edinburgh University, 1857, and studied in France and Germany. He went to Canada in 1858, became rector of the Upper Canada Grammar School; was commissioned to inspect the higher educational institutions of the province, and study the subject in all its phases. The investigation lasted two years, and he presented its results in two able reports. In 1861 he was made principal of Upper Canada College, and a member of Toronto University senate. Under his administration of 20 years the college attained a high reputation for the excellence of its teaching and discipline.

Cockburn, Henry Thomas, Lord, Scottish judge: b. Edinburgh, Scotland, 26 Oct. 1779; d. Bonaly, near Edinburgh, 26 April 1854. It was chiefly in connection with political cases that he rose to eminence in his profession, one leading transaction being his gratuitous defense of several persons tried for treason in the year 1818. He became solicitor-general for Scotland in 1830, and in 1834 one of the lords of session. 'Memorials of His Time' (1856) is an invaluable record of the social history of Scotland, narrated in the raciest and most genial manner. Not less interesting is his life of his friend Lord Jeffrey (1852).

Cockburn, Sir John Alexander, Australian statesman: b. Crosbie, near Duns, Scotland, 23 Aug. 1850. He was educated at Kings' College, London, and settled in South Australia in 1875, was mayor of Jamestown 1877-81; sat in the House of Assembly for Burra 1884-7, and for Mount Barker 1887-98. He was minister of education 1885-7; premier and chief secretary 1889-90; chief secretary 1892; minister of education and agriculture 1893-8; agent-general for South Australia 1898-1901. He represented South Australia at the International Commercial Congress in Philadelphia in 1899, and other important conferences. He was knighted in 1900.

Cockchafer. See CHAFER.

Cock'er, Edward, English engraver and teacher of writing and arithmetic: b. 1631; d. 1675. He is said to have published 23 books of exercises in penmanship, one of which is preserved in the British Museum. The great work with which his name is so intimately associated that the phrase, "according to Cocker," has become proverbial, was first published in 1678 under the title of 'Cocker's Arithmetic, Being a Plain and Familiar Method, Suitable to the Meanest Capacity, for the full Understanding of that Incomparable Art, as It is now Taught by the Ablest Schoolmasters in City and Country, Composed by Edward Cocker, late Practitioner in the Arts of Writing, Arithmetic,

and Engraving.' The book reached a 37th edition by 1720, and upon it most of the succeeding treatises on arithmetic were based. Two other works bear Cocker's name—a treatise on 'Decimal Arithmetic' and an 'English Dictionary,' but it has been surmised that they are not of his authorship, but of that of his publisher, Hawkins.

Cocker, a variety of spaniel (q.v.).

Cockerell, kök'ër ël, Charles Robert, English architect: b. London 28 April 1788; d. London 17 Sept. 1863. He wrote monographs on the mausoleum of Halicarnassus and other archæological subjects. Advancing to the front rank of his profession, he became an associate of the Royal Academy in 1829, a member in 1836, and professor of architecture in 1839, delivering lectures which were highly esteemed and largely attended. He was happier in following classic models than in the Gothic style. He built the Bank of England and many other public and private buildings. He wrote on the 'Iconography of Wells Cathedral'; 'Sculptures of Lincoln and Exeter Cathedrals'; 'Tribute to the Memory of Sir Christopher Wren'; etc.

Cock'ermouth, England, a town in the county of Cumberland. It is situated at the confluence of the Cocker with the Derwent, 24 miles southwest of Carlisle, and 260 miles northwest of London. The old castle, supposed to have been built soon after the Conquest, stands on a bold eminence. Mary Queen of Scots was imprisoned in it in 1568, and in 1648 it was dismantled by the parliamentary forces. Cocker-mouth is the birthplace of the poet Wordsworth, in memory of whom a fine stained-glass window has been inserted in the church of All Saints. Pop. (1901) 5,355.

Cockle (*Cardium*), a genus of bivalve shellfish forming the type of the family *Cardiidae*. The general characteristics are—shells nearly equilateral and equivalvular; hinge with two teeth, one on each side near the beak, and two larger remote lateral teeth, one on each side; prominent ribs running from the hinge to the edge of the valve. The animal has a powerful foot, with which it burrows in the sand. For this purpose it first distends it with water, to give firmness to it. This foot may also be used to enable the animal to move from place to place, for by first bending it and then suddenly straightening it the animal may project itself to a considerable distance. The common cockle (*Cardium edule*) is common all round the coasts of the British islands wherever it finds suitable sand-beds to live in, and is also found in the Baltic, and elsewhere. It is much used as an article of food. A prickly species, the *Cardium aculeatum*, found on the coast of Devon, is also eaten. Among American species, which, however, are not eaten, are *C. islandicum*, found to the north of Cape Cod, and *C. pinnulatum*, found about Long Island Sound. On the coast of Labrador *Serripes groenlandicus* reaches a large size, being nearly four inches long, and two inches thick. This genus is represented by fossils from the Devonian Period onward, but it attains its maximum in recent seas.

Cockle, kök'l. See CORN-COCKLE.

Cockle, Order of the, that of St. Michael, the knights of which wore the scallop as their badge. This order was instituted by Louis XI.

COCKLEBUR—COCKSCOMB

of France, who began to reign 1461 A.D. The dress is thus described from a MS. inventory of the robes at Windsor Castle in the reign of Henry VIII.: "A mantell of cloth of silver, lyned withe white satten, with scallope shelles. Item, a hoode of crymsin velvet, embraudeard with scallope shelles, lyned with crymsin satten."

Cock'lebur, a coarse annual plant, a species of *Xanthium*, belonging to the rag-weed family (*Ambrosiaceæ*). There are five or more species widely distributed throughout the temperate regions. Three of these species occur very commonly in waste grounds in nearly every part of the United States, excepting the interior region east of the Mississippi River, where the plant is rare. A distinct native of this country is the American cocklebur (*X. canadense*), while two other species (*X. strumarium* and *X. spinosum*), had their advent from Europe or Asia. Wool-growers are seriously troubled by the hook-spined burs of this plant, which catch in the sheep's wool, depreciating its value. In South Africa the injury to the wool industry is so great that strict laws are enforced to keep the plant from multiplying.

Cock'ney, a nickname for a native of London, especially for a person both born and bred there, the term being often used with a certain sense of disparagement, and as implying ignorance of other than city affairs, or as suggesting effeminacy. As to the origin of the word there has been much dispute, and many explanations, some of them sufficiently absurd, have been propounded. In the 14th and 15th centuries it was used to mean a petted or cockered child; and, according to the most recent etymology, its original meaning was "cock's egg," a small or misshapen egg.

Cockpit, in old-time men-of-war, a place situated under the lower gun-deck, where the ship's surgeons tended the wounded. The term is also applied to the open space in a yacht or canoe in which the crew or passengers sit.

Cockran, kōk'ran, **William Bourke**, American lawyer: b. County Sligo, Ireland, 28 Feb. 1854. He came to America in 1871, and taught school for several years, while studying privately for the bar. He soon attained prominence as a lawyer, and entered actively into New York politics, his eloquence causing him to be much in demand as a Democratic public speaker. He was a member of Congress 1891-5, made noteworthy speeches at the Democratic national conventions of 1884 and 1892, at the latter of which he opposed Cleveland's nomination; and in 1896 refused to follow his party on the silver question, campaigning for McKinley, and advocating the gold-standard in effective addresses.

Cock'rell, **Francis Marion**, American senator: b. Johnson County, Mo., 1 Oct. 1834. He graduated at Chapel Hill College, Mo., 1853, studied law, and practised that profession until his election to Congress. During the Civil War he was a brigadier-general in the Confederate army, was severely wounded during Hood's invasion of Tennessee, and commanded a division in the operations around Mobile, Ala. He was chosen United States senator to succeed Carl Schurz, took his seat 4 March 1875, and has been re-elected four times, his present term expiring 3 March 1905.

Cockroach, any of the species of *Blatta* or allied genera, belonging to the family *Blattidæ*, order *Orthoptera*. The body of the cockroach is much flattened, being adapted to life under the bark of trees, under stones, in cracks, etc. The four wings are much alike in size and net-veined; the antennæ are long and slender, and to the end of the body are appended many-jointed antenniform limbs which contain olfactory organs like those in the joints of the antennæ. Cockroaches are hatched in nearly the same form as the parent, differing mainly in not having wings. The eggs are deposited in a bean-like case (*oötheca*), which is divided into two compartments, each containing about 30 eggs; these egg-sacs are carried about for some time by the female, projecting from the end of her hind-body. One small native species (*Platymodes pennsylvanicus*) lives under stones, but the species so abounding in our homes have been introduced from the Old World. The peculiar odor given out by cockroaches is expelled from glands in the hind-body, and either present in both sexes, or only in the males. In the croton bug, or common small cockroach of our cities, these glands are very large, giving out a fœtid odor, and occur only in the males.

While nearly a thousand species of blattids are known to be now living and 200 fossil species are described, mostly from Palæozoic strata, chiefly the carboniferous states, several forms are household pests. They swarm in our kitchens, spreading through those parts of the house warmed by hot water or steam pipes, and are troublesome from eating clothing, cereals, devouring the paste in bindings of books; they also abound in ships, where they devour ship biscuit, etc., impregnating the pantry with their disagreeable odor. On the other hand, the cockroach is an enemy of the bed bug, doing great service in reducing their numbers. The development of the cockroach is slow and the number of eggs deposited not great. *Phyllodromia germanica*, the German roach or croton bug, reaches maturity in from four and a half to six months.

Of the many species known the most annoying is the German roach, whose native country is, however, not known, though supposed to have had an eastern origin. The Oriental cockroach (*Periplaneta orientalis*) is derived from tropical Asia, and is supposed to have been introduced into Europe two or three centuries since. The female is nearly wingless, it is a large dark brown species, living in colonies. The best remedies are insect powder, phosphorus paste, and a proprietary substance called German snowflake powder. Consult the text-books on entomology; also Howard and Marlatt, 'The Principal Household Insects of the United States.' (Bulletin No. 4 U. S. Department of Agriculture, Division of Entomology. Washington, 1896.)

Cock's-foot Grass. See GRASSES IN THE UNITED STATES.

Cocks'comb, a name sometimes given the genus *Celosia cristata* of the amaranth family *Amaranthaceæ*. It is an annual plant, native in the tropical regions of America, Asia, and the East Indies. The naturalized plant from tropical America is found during the months of August, September, and October as a weed or herb in waste places, also in cultivated ground, throughout the United States. The cultivated plant grows with an upright stem bearing a

brilliantly colored and wavy crest, formed by the minute flowers on the surface of the pointed bracts.

Cockswain, colloq. kōk's'n, the officer who manages and steers a boat, and has the command of the boat's crew.

Cock'ton, Henry, English humorous novelist: b. London 1807; d. 26 June 1853. His stories were very popular in their day, the most noted among them being 'Valentine Vox, the Ventriloquist' (1840).

Cocles, kō'klēz, **Horatius**. See HORATIUS COCLES.

Cocoa. See CACAO.

Cocoa Butter. See CACAO.

Cocoanut, or **Coconut**, a palm tree (*Cocos nucifera*) native of islands in the Indian Ocean, but widely distributed in warm countries throughout the world. Geology shows that it had a wider distribution than at present, since specimens have been discovered in Central and South America. The tree grows naturally upon sandy soil bordering the sea or not far inland except where planted by man. It is remarkable as one of the first tree species to gain a foothold upon newly formed tropical islands. Its stem, which often attains a height of 100 feet is crowned by a rosette of long pinnatisect leaves from 10 to 20 feet long, gracefully curving upward at their bases and downward at their tips. From among the bases of the leaf-stems appear large pointed spathes from which proceed yellow or white flowers followed by large hard-shelled nuts. Several of the spathes in various stages of development are usually found upon the trees, which often commence to bear when less than 10 years old and continue productive for more than half a century, yielding about 100 nuts as an annual crop.

Since the tree does not produce well when remote from the coast, it is planted along the shores upon sandy or shelly land where little else of value will grow. The seeds are the sole means of propagation. They are planted in rows in the nursery and when the seedlings are large enough they are transplanted about 20 feet apart, where they are to remain, given clean cultivation for three or four years, and then allowed to shift for themselves, occasional mulches of seaweed, etc., but no manure, being given. The only part of the United States in which the cocoanut palm bears fruit with reasonable certainty is the extreme south of Florida, but even there it has not become commercially important. It may be taken as an index of the dividing line between the tropical and sub-tropical regions, since it thrives best in regions where frost never comes.

This palm is one of the most important economic trees of the world. Its fruit is a staple food either ripe or unripe, raw, or prepared in various ways, in many tropical countries. It is also exported to temperate climates, where the nuts are used in confectionery and for cake and dessert-making. The oil, of which there is about 70 per cent in the nuts, from which it is obtained by expression or heating in water, is largely used for making soap and candles and for food. (See COCOANUT OIL.) The central part of the stems of young plants is used for food, as is also the terminal bud or "cabbage." A drink and a kind of

sugar are made from the sap of the young spathes. The dried leaves are used for thatching, baskets, mats, etc., and the petioles for oars. The wood in the lower portions of the trunks of old trees is commercially important under the name of "porcupine wood," which is used in cabinet-making, etc. The fibrous centres of old stems are used for cordage-making, as is also the fibrous husk of the nuts (see COIR). This latter is widely used for making cocoanut-matting, which is put down in corridors where there is a great deal of tramping. It is exceedingly durable. The cocoanut shell is used for drinking cups, bottles, etc., and for ornament when carved and polished. The fibre of the husks is used by florists as a moisture-retaining medium in which to plunge potted plants and in which to propagate various seedlings and cuttings.

Cocoanut Crab. See ROBBER PALM.

Cocoanut Oil, a solid vegetable fat, largely used in candle-making and in the manufacture of soaps and pomatum. This fat is expressed from the albumen of the cocoanut kernel, and is as white as lard, and somewhat firmer. From Manila and Ceylon large quantities of the oil are exported.

Cocoa-plum, the fruit of *Chrysobalanus icaco*, belonging to the family *Rosaceæ*, which is eaten in the West Indies. It is about the size of a plum, with a sweet and pleasant though somewhat austere pulp. The root, bark, and leaves of the plant are employed as remedies in diarrhœa and other troubles. It has simple, alternate leaves and cymose flowers.

Cocoa (kō'ko) **Root**. See COCCO.

Coco de Mer, or **Sea** or **Maldivé Double Cocoanut**, the fruit of the *Lodoicea seychellarum* palm. Its double kernel has long had an extraordinary value over a large area in the East. As a sovereign antidote to poison, and long known only from specimens thrown up on the Maldivé coasts, it was supposed to grow on a submarine tree, and had other fables attached to it. The tree on which it grows is peculiar to some of the Seychelles Islands, reaches a height of 100 feet, and has very large fernlike leaves.

Cocoon, kō-koon', the web or ball spun by caterpillars before passing into the chrysalis state. The valuable product thus obtained from the silk-worm is well known. Also the silken case spun by spiders for the reception of their eggs.

Cocos, a genus of palms. There are about 30 species, natives, with one exception (*C. nucifera*), of South America, but cultivated for their fruits or for ornament in many warm countries. They vary considerably in height, but are all characterized by absence of spines, ridged trunks, pinnatisect leaves in a terminal crown or rosette, spadices erect at first, but later drooping, spathes two, flowers white or yellow, fruit of various forms. Some species are cultivated under glass on account of their graceful foliage. The most important species of the genus is unquestionably *C. nucifera*, the coco palm or cocoanut tree (see COCOANUT). Of the other species the following are perhaps best known in the United States. *C. flexuosa*, a medium-sized Brazilian species often planted in southern Florida and southern California as a street tree and to some extent cultivated in northern greenhouses. *Ceriospatha*, a stouter, somewhat taller

COCOS-KEELING — COD

species from southern Brazil, by some considered the hardiest of the genus and often planted along avenues in the regions mentioned and in the West Indies. It is little cultivated under glass because of its rather coarse leaves. *C. datil*, an Argentine species, found to be hardy in southern California as a street tree. Its fruits which are edible, resembling those of the date palm. *C. plumosa* is the most generally cultivated street tree of the genus; it is of quick growth, soon reaching a height of 30 feet, and, with age, 50 feet. It is indigenous to central Brazil. *C. medalliana*, a dwarf species from central Brazil, is unquestionably the most popular greenhouse palm, not only of the genus, but of all genera. Its foliage is small, delicate, and graceful, and on this account it is frequently used as a table decoration. It is probably the most easily cultivated of the palms used in house decoration, and since it is of slow growth it retains its beauty for a considerable time, never becoming coarse or unattractive.

Cocos-keeling (kō'kōs-kē'ling) **Islands**, British India, a group in the Straits Archipelago, being a little horseshoe-shaped cluster of isles lying south of Java at about the distance of a three days' sail by steamer. The group is little known, but is said to be among the most picturesque in the British empire. The inhabitants, numbering about 600, are divided between the Cocos natives and coolie laborers from Java. The islands have a romantic history. A Scotch sailor named Ross landed here in 1825 and established himself as ruler; in 1851 he hoisted the British flag; but in 1857 the islands were formally annexed to Great Britain; and authority over them still remains in the hands of the Scotch sailor's descendants. An enlightened civil government is maintained; schools have been established; and industries connected with cocoanut and other products are carried on.

Co'cum-butter, or **Cocum-oil**, a pale, greenish-yellow solid oil obtained from the weeds of *Garcinia purpurea*, a tree of the same genus with mangosteen, used in India to adulterate ghee or fluid butter.

Cocy'tus (from Gr. *kōkuein*, to lament), a river of ancient Epirus which falls into the Acheron. Also, among the ancient Greeks, one of the rivers of the lower world. Pausanias advances the following conjecture respecting this river: "At Cichyrus is Lake Acheron, with the rivers Acheron and Cocytus, whose waters are very ungrateful to the taste. Homer, I imagine, had seen these rivers, and in his bold description of hell gave to the streams in it the names of those in Thesprotia."

Cod, the typical representative (*Gadus calarias* or *Gadus morrhua*) of a family (*Gadidae*, q.v.) of marine fishes of pre-eminent economic importance. Although most widely and generally known as the codfish, or simply cod, perhaps not less than 50 other names are applied to it more or less colloquially, many of them derived from the same root as cod. The cod is moderately elongated, heavy in front, with a large head, and tapering gradually into a slender tail terminated by a slightly notched fin. There are three dorsal fins, none of which is elevated, and two anals, and the ventral fins are normal in structure and placed far forward on the throat. The mouth and eyes are large, and the chin bears a long barbel. Very small scales

cover the entire body and most of the head. Although varying much in shade, the color is usually reddish-brown with small rounded spots of darker brown and a conspicuous pale lateral line. Unlike the haddock, all of the bones of the shoulder girdle are thin and lamellar; much variation in size has been observed, certain localities and schools always yielding large fish, others small or mixed ones. An average length is from three to four feet; and the weight from 7 to 40 pounds, but very much larger ones, several exceeding 100 pounds, and one of 160 pounds, have been recorded.

The cod is a fish of cold waters, apparently preferring a temperature of from 35° to 45°. Whether there is more than a single species is doubtful, though it is well known to fishermen and ichthyologists that the Alaskan cod have much larger swimming-bladders than those of the Atlantic. Waiving this question, the cod may be said to have a circumpolar distribution, ranging south in the Atlantic as far as the Bay of Biscay on the European side, and to Cape Hatteras on the American shore. In the Pacific it is abundant in the waters of Alaska and Bering Sea, and occurs on banks off the mouth of the Columbia River, though there are no cod fisheries at the latter point. Northward they are found to at least 80°, and probably beyond. Sometimes it will even enter fresh water, ascending rivers, as was formerly frequently recorded in the Delaware, perhaps in pursuit of food. That any north-and-south migration takes place is doubtful, but seasonal migrations between deep and shallow waters, and irregular ones in search of food, are well known both on our coasts and on those of Europe. Thus Prof. Sars has described the so-called "mountains of fish" which annually approach the coast of Norway. North of Cape Cod the fish approach the shores during the summer and retire, upon the approach of cold weather, to the deeper waters of the off-shore banks, where they are followed by the Gloucester fishermen. On the shores of New Jersey and Virginia no cod are found except during the winter, the shallow waters becoming so warmed in summer that they are driven seaward to the cold Labrador current. Rocky and stony banks, where a rich fauna has congregated at moderate depths to about 120 fathoms, are the favorite resorts of the cod, but considerable numbers are taken down to 250 fathoms on the edges of the outer banks, and the trawl has brought up cod from a depth of 300 fathoms.

Little need be said concerning the food of the cod. It devours everything of an animal nature that it comes across, and a mere list of the species which have been taken from its stomach would fill a volume and be little short of a catalogue of marine animals. Great clams are swallowed in their shells, and, after being digested, the hard parts are regurgitated in such numbers that the bottom over large areas is said to be paved with them. Spawning takes place at moderate depths, but the buoyant eggs rise to the surface, where they float until hatched. On the European coasts the spawning season is in March and April, but with us during the winter. The fecundity of the codfish is truly astounding, not less than 9,100,000 eggs having been estimated to be produced in a single year by a 75-pound fish, while 2,000,000 to 4,000,000 is the average yield of those of ordi-

COD

nary size. The eggs are small, about one seventeenth of an inch in diameter, and, although buoyant, have no oil globule, as do many other pelagic eggs. They hatch in from 12 days to 3 weeks, and the young fry, which feed on small crustaceans, grow rapidly, becoming about two inches long in four months and about one foot at the end of a year, though the variation in size is very great. That there has been a great decrease in the numbers of cod frequenting the inshore banks is well known, and many suggestions have been made to account therefor. The late Prof. Baird connected it with the decrease in the number and size of the schools of herrings, a favorite food of the cod, itself due to the building of dams and other obstructions which have prevented their entrance into the rivers for spawning purposes. In an attempt to overcome this condition the United States Fish Commission has been engaged for several years in collecting and hatching enormous numbers of cod eggs at its Gloucester and Woods Hole stations, with every promise of a considerable degree of ultimate success. During the winter of 1901-2, the last season for which statistics are available, no less than 338,000,000 cod eggs were thus handled.

Next to the herring, the cod is the world's most important economic fish, and in the United States the most important. During 1901 the aggregate value of the fresh and salt cod landed at Gloucester and Boston, the two largest shipping points, was nearly \$3,000,000, and the total annual value of the cod-fisheries of both sides of the North Atlantic cannot be less than \$25,000,000.

Some idea of the magnitude of the cod-fishing industry may be gathered from the fact that out of a total population in Newfoundland of 220,000, more than half that number gains its livelihood from it. The Newfoundland cod fisheries are the oldest in America, and a description of the methods pursued there may well represent those of other and younger stations.

The island was discovered, or, granting an earlier discovery by the Northmen, rediscovered, by John Cabot, 24 June 1497. Soon after this event Portuguese, French, Basque, and Spanish fishermen established fisheries on its shores. When, in 1583, Sir Humphrey Gilbert took possession of the island in the name of Queen Elizabeth, small English colonies were established along the east coast, and several French ones on the southern shore. In 1713 the Treaty of Utrecht declared Newfoundland and its dependencies to belong wholly to Great Britain, but reserved to the French a right to fish and cure on parts of the coast, now known as the "French shore," extending from Cape St. John on the east to Cape Ray on the southwest. This reserved right has given rise to many complications, but more with respect to the lobster fishery than the cod industry. Of such prominence is the cod in the social economy of the island that the local courts have determined that the word "fish," if unqualified, must be deemed to mean codfish, which, in the northern and southern coast settlements, is so often used as an equivalent of money as to be called "Newfoundland currency." It is measured by the quintal of 112 pounds, and in this form pays for food, clothing, and medicines, as well as fees for physician, the clergyman, and the lawyer. The fish "flakes" (see below) are so

numerous in all the towns, that it would be impossible to guard their contents; so stringent laws have been passed to prevent theft, and the convicted thief is frequently sentenced to several years' imprisonment, though he may take but a single fish.

While Newfoundland craft are to be seen in numbers upon the Grand Banks, during the last few years the crews have confined their operations largely to the waters in the vicinity of the island. Although the cod are somewhat smaller, they are fully as numerous and of excellent quality, while, in a good season fish weighing 10 or 12 pounds are frequently caught. The vessels range in size from the schooner, 125 feet long and over 100 tons burden, to the sailboat manned by two men, who cast their lines or set their nets under the lee of the rocky shores perhaps not more than 500 feet from land, for schools of fish are to be found in proximity to the coast as well as 100 miles away from it, depending largely upon the course of the Labrador current, which furnishes their principal food supply. The larger vessels are schooner-rigged, and usually carry two jibs, a mainsail, foresail, and main topsail, with sometimes a small jigger extending over the stern, and staysail rigged between the two masts. In addition, they carry a triangular riding-sail to assist in steadying them when at anchor. The larger ones are manned by from 15 to 30 men, provided with lines for deck-fishing as well as with set-lines and trap-nets. Each carries its complement of boats, and, on arriving at a fishing-ground, a part of the crew throw their lines over from the deck, while others bait and put out the set-lines and the trap-nets from the smaller boats, visiting them at regular intervals to gather in the fish, which are taken to the schooner to be hastily cleaned, salted, and packed in the hold until the "fare" is completed. The captain usually keeps his boat anchored as long as the school which has been "struck" remains. The fish may stay on one feeding-ground four or five days, or perhaps disappear in four or five hours after the vessel has cast anchor. Then the set lines and nets are taken up, the vessel weighs anchor, and search for another school begins.

In offshore fishing the trap-net is also used in addition to set-lines, and the larger boats occasionally use hand-lines as well, if the fish bite freely. A very large catch is made, however, with the set-lines and nets, and the boatmen go out every morning to take out the fish and bait the hooks, perhaps paying another visit in the evening. Upon the return of the men to the home settlement with their boatload of fish, the women and children join them in cleaning the fare, salting it, and spreading it on "flakes" to dry. At times the fishing is so good that the men make three and four trips daily to the nets and lines, carrying home a good load on each trip. Then the women and children prepare the fish in order to save time.

The time required to cure the codfish varies from 4 to 10 days according to the weather. With a succession of sunny days, the fare will be thoroughly cured in less than a week, but the fish must be protected against rainy weather, in spite of the salt with which they are rubbed after being cleaned.

The "flakes" are composed of platforms of boughs, elevated from 6 to 10 feet above the ground upon scaffolding; and the fish are laid

COD-LIVER OIL — CODAZZI

upon the boughs so closely together, that at a distance the "flakes" look as if they were covered with pieces of white canvas. Each fish is turned over at least once every 24 hours, in order to cure both sides thoroughly; and when the process is completed the fish is as stiff as a piece of board. No other ingredient except salt is required for the ordinary curing, although some of the cod prepared at the larger settlements are ground into fine particles after being dried, and mixed with a jam made of small berries. This is placed in jars and sold as a preventive of scurvy. The fares secured by the larger vessels remain in their holds until the cargo is completed. On arrival at St. Johns, or the home port, the cargoes are sold, in a partly cured condition, to the merchants, who finish the preserving process. In buying the fish from the large vessels, as well as from the fishermen in the settlements about the coast, the cod are valued according to their weight, and generally sorted in three different sizes, the largest bringing a proportionately greater price. The merchant, as he is known in Newfoundland, is the large dealer who exports the fish to the tropics and Europe. He buys from both the fishermen and the "planters." The latter are a sort of middlemen, and usually have "stations" located at different points along the coast. These stations include general stores containing everything required by the fishermen. The people in the vicinity can go to the station and exchange their harvest for what they need at home and the outfit required for fishing, and, if anything is left to their credit, can obtain its equivalent in money. Many of them, however, are usually in debt to the planter, and, in a good year, the surplus remaining after obtaining their necessities goes in payment of the debt of a previous season. The planters also buy schooner loads, and many of them own steamers and sailing vessels which make regular trips around the island, carrying the fish purchased by the planter to the general market at St. Johns or one of the other large towns.

While the number of cod caught varies considerably according to the season, the average catch is from 1,250,000 to 1,500,000 quintals, the value, of course, depending on the price. Within the last two or three years the revenue from this source has aggregated about \$5,000,000, not counting \$300,000 for codfish oil, and a small sum for the oil derived from the livers of the codfish for use in medicine. The number of crews engaged in codfishing can only be estimated, owing to the variety of craft and the wide field of their operations. Authorities on the subject, however, estimate that fully 60,000 men are engaged in the fishery each year, and that a fleet of fully 1,000 two-masted vessels, hailing from the island alone, ply upon the nearby waters and on the Banks. Practically all of these vessels are home-made, the wood for both hulls and spars being secured from forests in the interior, while the sails and rigging are imported chiefly from England. For a full account of the natural history of the codfish, consult Goode, 'American Fishes'; and for statistics of the fisheries and other information, the 'Annual Reports' of the U. S. Commissioner of Fish and Fisheries.

Cod-liver Oil, an oil extracted from the livers of different kinds of cod—the *Gadus*

morrhua being specified in the pharmacopœia — and allied species. It has a fishy taste and odor, is insoluble in water, but dissolves in ether, and is colorless or pale yellow. The tint, however, depends on the mode of preparation, some kinds being pale brown, and others dark brown. The finest and palest oil is produced from fresh and carefully cleaned liver, the oil being extracted either in the cold or by a gentle heat. The darker kinds are obtained at a higher temperature, and often from the livers in a putrefying state. Only the pale oils are used in medicine, the dark oils are too rank and acrid, and they are only used in dressing leather. The oil is prepared in Great Britain, in Newfoundland, and in Norway, and it has also been prepared in Iceland.

Cod-liver oil has a specific gravity of 0.93. It is a somewhat complex substance, but the main ingredients appear to be olein and margarin. Acetic, butyric, and other acids are also present, and to these the oil may owe some of its odor. It contains, besides biliary matters, a peculiar body called gaduin, and inorganic substances, including minute quantities of iodine, bromine, sulphur, and phosphorus. It is questioned, however, whether iodine and bromine are constant constituents.

In medicine cod-liver oil is very highly prized, because it is a readily assimilable fat, splitting readily in the intestines and easily digested. Perhaps next to milk fat or egg fat it is one of the most easily taken up of the fatty bodies. It is therefore particularly valuable in the treatment of the chronic wasting diseases, proving especially serviceable in consumption. It is also of service in weak, puny children, and can be taken to advantage by adults with chronic nervous disorders. In fact cod-liver oil is very valuable in most affections of the nervous system. As it is the fat in cod-liver oil that is valuable the various forms of proprietary preparations on the market that claim to contain the active principles without the oil should be looked upon with suspicion. The oil is usually very unpalatable; hence the many emulsions that are put up. These, if they contain the pure oil in reasonable quantities, are excellent. There are many commercial cheats in cod-liver oil, and reliable preparations only should be used.

Codazzi, Agostino, ä-gōs-tē'no kō-dät'sē, Italian engineer: b. near Ferrara 1792; d. Colombia June 1859. He made several campaigns under Napoleon, and afterward distinguished himself as an engineer in South America. He entered the Colombian service with the rank of lieutenant-colonel of artillery, and was employed in making charts and in preparing plans of defense. In 1831 he was appointed by Paez to prepare partial charts of the new republic of Venezuela. This work occupied nearly nine years, and was twice interrupted by military defensive expeditions, in which Codazzi took part. He was rewarded with the rank of colonel. He devoted the years 1838-9 to exploring the wilderness of Guiana, and penetrated nearly to the sources of the Orinoco. The important additions to geography which were obtained from this expedition induced the congress of Venezuela to furnish him means to make public the result of his labors. For this purpose he went to Paris, where his work appeared in 1841, entitled 'Resumen de la Geografia de Venezuela,' accompanied by an

CODDINGTON — CODE

extensive chart of Venezuela. Codazzi afterward established a German colony in Venezuela. In 1848 he was employed by the government of Colombia in a topographical survey of that country.

Cod'dington, William, New England colonist: b. Boston, Lincolnshire, England; d. Rhode Island 1 Nov. 1678. He was one of the founders of the colony of Rhode Island. He arrived in Massachusetts in 1630, remained in Boston for several years, but not being able to agree with the authorities of the colony, he removed in 1638 to Aquidneck, or Rhode Island, where he founded a colony to be governed "by the laws of the Lord Jesus Christ." It was soon found necessary to abandon this vague scheme, and in 1640 he himself was chosen governor, and in 1647 aided in the formation of a regular body of laws. He was unable to secure the reception of Rhode Island into the colonial confederacy. In 1674 and 1675 he was again elected governor.

Code, a term now generally confined to jurisprudence, and used to designate a systematic compilation of law authorized by governmental authority to take the place of prior existing law. It is in this sense applied to the codes of Theodosius, Justinian, and Napoleon. The word is used more generally in the United States as applied to a concise, comprehensive, systematic formation and re-enactment of the law, deducted from both its principal sources, the pre-existing statutes, and the adjudications of courts as distinguished from compilation of statute law only. Codes such as here described have been adopted and are in use in many of the States. They are, in the most part, modeled upon the Code of Civil Procedure of New York. The purpose of a code is to simplify methods of legal procedure and to model and bring together in a codified form the confused mass of laws, contradictions, repetitions, and disorder which have grown up during a long period of time. Such a codification of law has always been deemed a most difficult task, and though many times agitated in England, it has never been earnestly undertaken, and is not likely to be for some time. The same causes which made such a codification necessary in the time of the Emperor Justinian exist to-day in many countries and in most of the States of the United States. While the *Corpus Juris Civilis*, or body of civil laws, drawn up by Justinian's commission of 10 learned civilians, was the most important and complete of ancient codes up to that time, there had been other compilations under the empire. These compilations had been made by private lawyers, and formed the basis of the *Codex Gregorianus et Hermogenianus*, which in turn were the models for the imperial codes of Theodosius and Justinian.

The *Codex Theodosianus* was the work of a commission of 16, to whom, in 435 A.D., the Emperor Theodosius entrusted the task of collecting the edicts and constitutions. It was published in 438 A.D., was a work of great importance, and formed the masterpiece on which every later code was based. It was the initiative of a digest of the whole Roman law. In 528 the Emperor Justinian ordered a new collection to be made, and for this purpose appointed 10 commissioners with full power to make such changes as they might deem neces-

sary in the language of the constitution. They were authorized in their compilation to use the codes, Gregorian, Hermogenian, and Theodosian, and the constitutions, with the understanding that the new code was to supersede the sources from which it had been compiled. The Code Justinian was completed within 14 months, and was subsequently revised to take in new decisions and constitutions of the emperor. The original code was lost. The revised one, which has been preserved, was published in 534, and is divided into 12 books and each book into titles.

Code Napoléon.—The civil code of France in force at the present day takes its name from the great Napoleon. It was undertaken under the consulship of Napoleon by the most eminent jurists of France, and was published in 1804. It is the most celebrated of modern codes. The *Code Napoléon* (under which name four other codes of commercial law, criminal law, penal law, and the law of procedure, drawn up at the same time, are often included) was a code in the fullest and strictest meaning of the word, in that it was not merely a collection of the law, but was a complete and thorough statement of the law. The need of a codification of the laws of France had been urged by eminent jurists and statesmen for some time before Napoleon took the matter up and carried it through. Previous to the adoption of the *Code Napoléon* there had been some partial codes in France; such as the *Code Henri*, made by Brisson in the reign of Henry III.; the *Code Murvillac* or *Michau* under Louis XIII. (1629), relating to judicial procedure, and the *Code Louis XV.*, by Chaussepierre, containing the ordinances from 1722 to 1740. There were several of these ordinances enacted in the reign of Louis XVI. No decided move was made to bring about a codification of the confused condition of the laws of France for the purpose of shaping them into a homogeneous jurisprudence until the Revolution had cleared the way. By the consular decree, 12 Aug. 1800, a commission was constituted to compare the order which had been followed in the preparation of the projects for a civil code "hitherto published, to determine the plan which the commissioners should think best to adopt, and to discuss the chief principles of civil legislation."

Napoleon, on becoming consul, appointed a commission headed by M. Tronchet, and including Portalis, Bigot de Préameneu, and Maleville, to review all previous efforts at codification and to suggest a new plan. In 1801 the commissioners reported a draft for a civil code, which was submitted to the court of cassation and other courts of appeal, and with the reports of the judges, was finally brought before the council of state, in which Napoleon (then first consul) presided in person and took part in the discussion as to the terms and scope of the code. The whole revision after much debate was finally adopted under the title of *Les Cinq Codes*, consisting of the civil code, distinguished by the name *Code Napoléon*, the code of criminal procedure, penal code, the code of civil procedure, and the code of commerce. The entire work was first published under the title *Code civil des Français*, but Napoleon subsequently had it published as the *Code Napoléon*, as he considered the code one of the crowning glories of his reign. The *Code*:

CODE OF KHAMMARUBI—CODE NAPOLEON

Napoléon consists of 2,281 articles. It has been said of this code that it is the product of Roman and customary law, together with the ordinances of the kings and the laws of the Revolution. Although political upheavals have caused some changes and modifications, the code remains virtually the same as when it left the hands of its framers. The extent of its influence upon the laws of other countries has been very great, as it formed the basis of the codes of the two Sicilies (1819), the Netherlands in 1837, the Swiss cantons from 1819 to 1855, Bolivia in 1843, and the civil code of the State of Louisiana.

Code Frederic.—This is a revision of the Prussian laws, published by Frederick the Great 1749–51, and revised after 1780, but not in force until 1794, was intended, according to its preface, to obviate the difficulties of the Roman codes, the disputes of the commentators, and the contradictions between Roman and German law. It has been subjected to many changes.

Codes in the United States.—The first important experiment with a code in the United States was made in Louisiana, which State, originally a French colony, afterward ceded to Spain, again returned to France, and subsequently acquired by the United States from France, has had many changes of law. After the United States acquired Louisiana there arose a strong demand for a code, owing to the great confusion of laws. In 1806–8 a code was adopted, but only to supersede the ancient laws when they conflicted with it. A complete civil code was adopted for the State in 1824, which had for its basis the *Code Napoléon*, although some provisions of the common law were injected into it.

The most important code ever undertaken in the United States is the one which was prepared for the State of New York many years ago under the guidance and supervision of David Dudley Field. This code, although published, and having formed the foundation for many of the codes adopted by the various States, was never accepted by the legislature of New York. As early as 1839 David Dudley Field advocated and urged the adoption of a code by that State. The revised constitution of New York (1846) ordered the appointment of two commissions: one to reduce into a system the whole law of the State, the other to revise and simplify the rules of pleading. Both commissions were appointed by the legislature in 1847. The commissioners to revise and simplify pleadings and practice made a report on 27 Feb. 1848, which contained an incomplete code of civil procedure and practice in the courts of record. This report was immediately adopted by the legislature, but the complete codes of civil and criminal procedure were never adopted. On 6 April 1857, the legislature created a new commission to prepare codes. The commissioners named were David Dudley Field, William Curtis Noyes, and Alexander W. Bradford. After some eight years they reported a code—or rather three codes—which was never adopted, although reported favorably by the committees of several legislatures.

The code of civil procedure of the David Dudley Field commission formed the foundation, and was largely adopted in the codes of Ohio, Indiana, Missouri, Wisconsin, Iowa,

Minnesota, Kansas, Nebraska, Nevada, California, Oregon, North Carolina, South Carolina, Washington, Montana, Alabama, the Dakotas, Wyoming, Utah, and Arizona, and it is the basis of the present codes of civil and criminal procedure in the State of New York, which are codes of practice and pleading, as distinguished from a code of substantive law. The principal feature of the code of civil procedure as adopted by these States was the fusion of law and equity and the simplifying of the written pleadings.

LEWIS P. CLOVER.

Code of Khammurabi. See HAMMURABI.

Code Napoléon, a code of laws in France, framed by a committee appointed by Napoleon Bonaparte when first consul. This committee, consisting of Portalis, Bigot-Préameneu, Malleville, Tronchet, and the minister of justice, was directed by a decree dated 24th Thermidor, VIII. (13 July 1800),—

—to compare the order which had been followed in the preparation of the projects for a civil code hitherto published, to determine the plan which the committee shall think best to adopt, and to discuss the chief principles of civil legislation.

In the following year, 1801, these commissioners reported a draft of a civil code, which was in the first instance submitted to the court of cassation (q.v.) and the various courts of appeal. With the reports of the judges of these courts the draft was submitted to the council of state, over which the first consul presided, and in which every part was thoroughly discussed. In the work entitled 'Conférence du Code Civil, avec la Discussion Particulière du Conseil d'État et du Tribunat, etc.' (8 vols. Paris 1805), a detailed and very carefully prepared report of these discussions is contained. Each article, after having been discussed in this body, was presented to the tribunate, where it underwent another discussion, and was returned to the council of state as adopted, rejected, or amended.

Of the five codes prepared in this way, namely, the 'Code Civil,' published in 1804; the 'Code de Procédure Civile,' published in 1806; the 'Code de Commerce,' published in 1807; the 'Code d'Instruction Criminelle,' published in 1808; and the 'Code Pénal,' published in 1810; the first was called by way of eminence, by a law of 3 Sept. 1807, 'Code Napoléon.' At the restoration its name was changed back to 'Code Civil,' and during the time of the second empire it was again called 'Code Napoléon.' It is divided into 2,281 paragraphs, which are numbered, and consist of a few lines each. The work is divided into three books (livres); each book into a certain number of titles; each title is comprised in one or more chapters. A preliminary title, 'On the Publication, Effects, and Application of the Law in General,' precedes the whole. The first book is entitled 'Of Persons,' and in 11 titles treats, (1) of the enjoyment and privation of civil rights; (2) of civil acts, such as the registry of births, marriages, and deaths; (3) of domicile; (4) of absentees; (5) of marriages; (6) of divorce; (7) of the relations of father and son; (8) of adoption and official guardianship; (9) of the paternal power; (10) of minority, guardianship, and emancipation; (11) of majority, of guardian-

CODEINE — CODEX ARGENTEUS

ship of persons of age (interdiction), and judicial counsel. The second book is entitled 'Of Property and the Different Modifications of Ownership,' and in four titles treats, (1) of the distinction of property into real and personal (*immeubles et meubles*); (2) of ownership; (3) of usufruct, of use and habitation; (4) of servitudes (easements, *des servitudes ou services fonciers*). The third book is entitled 'Of the Different Modes of Acquiring Property,' and in 20 titles treats, (1) of successions; (2) of donations *inter vivos* and testaments; (3) of contracts, or conventional obligations in general; (4) of engagements formed without a convention; (5) of the contract of marriage, and the rights of the parties respectively; (6) of sale; (7) of exchange; (8) of the contract of letting to hire; (9) of partnership; (10) of loan; (11) of deposit and sequestration; (12) of contracts connected with chance (*aléatoires*, such as wagers and life-rents); (13) of powers of attorney; (14) of becoming security; (15) of transactions; (16) of bodily duress in civil cases; (17) of furnishing security; (18) of mortgages; (19) of taking and setting off by execution; (20) of prescriptions.

The work already quoted, 'Conférence du Code Civil,' is indispensable to a complete understanding of the code, because it gives the history of each law. It first presents each article in the code as finally adopted. Next follow the different forms and drafts of each article discussed in the council of state, with the report of the discussions. To this succeed the observations made in the section of legislation of the tribunate. We learn from this work how active a part Napoleon took in the formation of the code, as his remarks are given as well as those of the others, and he was present during almost the whole of the debates. Under the first empire the adoption of the 'Code Napoléon' was made obligatory on all the countries subject to the French. After the battle of Leipsic, in 1813, which freed Germany from the power of France, it ceased to be obligatory in the German states, but it continued to influence considerably their legislation. At present this code is recognized in the kingdom of Belgium (with some modifications), in the grand-duchy of Baden, in the kingdom of Italy, and elsewhere in Europe. In the United States it was a model for the code of Louisiana.

Code'ine, Codein, Codeina, or Codeia (Gr. κώδεια, "poppy-head"), a vegetable alkaloid closely allied to morphine and constituting about 0.5 per cent of the weight of opium. Codeine has the formula $C_{17}H_{18}(CH_3)NO_3 + H_2O$, and is known to the chemist as methylmorphine, since it is derived from morphine by substituting methyl (CH_3) for one atom of the hydrogen that morphine contains. Codeine may be prepared by adding calcium chloride to an aqueous extract of opium and evaporating to the point of crystallization. The hydrochlorides of morphine and codeine which are obtained in this manner are dissolved in water, and the morphine is precipitated by the addition of ammonia. Codeine hydrochloride remains in solution, and may be obtained by evaporation and crystallization, and further purified by recrystallization from ether. Codeine acts as a strong base, and its solution reddens litmus paper, neutralizes acids, and precipitates solutions of lead, iron, and copper.

From aqueous solution it is deposited in the form of trimetric crystals, as indicated by the formula given above. Crystals free from water may be obtained by deposition from a solution in carbon disulphide. When treated with strong sulphuric acid and a small quantity of ferric chloride ($FeCl_3$), codeine compounds give an intense blue color. This reaction is of great value in testing for the presence of the alkaloid. Codeine is used in medicine as a narcotic and hypnotic. Its properties are very similar to those of morphine, but by reason of the methyl groups introduced it has more action on the spinal cord than morphine has. It thus does not cause sleep or relieve pain as readily as morphine, and causes more reflex excitability. It may even cause convulsions in children. It is valuable where a milder sedative than morphine is desired, as there is less euphoria produced and less likelihood of forming a habit. Its use is not free from danger, however, and very small doses have been known to prove fatal.

Codemo, Luigia, loo-e'jē-ä kō dā mō, Italian novelist: b. Treviso 5 Sept. 1828. In 1851 she became the wife of the Chevalier Karl von Gerstenbrand. Her first work, 'Memoirs of a Peasant' (1856), evinced a true insight into lowly life; and in the numerous sketches and tales that followed it, she showed a profound sympathy with the common people. Her writings have passed through several editions. Among her works are: 'Miseries and Splendors of the Poor'; 'The New Rich'; 'A Lady of Heart.'

Co'dex, with the ancients, the trunk of a tree stripped of the bark. Before the invention of paper, wooden tablets covered with wax, which were written on with the style, and put together in the shape of a book, were called codex. The word was afterward retained, in times when paper was used for writing, to denote a large book. Thus important works, particularly old manuscripts of poets, historians, etc., which had been preserved, were called *codices manuscripti*. In like manner a collection of laws was called codex, with the addition of the name of the sovereign under whom, or of the person by whom it had been compiled, as *Codex Gregorianus*, *Codex Theodosianus*, *Codex Carolinus*.

Codex rescriptus (Latin, a re-written codex) is the name given to ancient manuscripts, which, in the Middle Ages, were used, after the original writing had been in a great measure effaced, for the copying of other works, generally ecclesiastical treatises. Thus the Institutions of Gaius, discovered by Niebuhr at Verona in 1816, and published by Göschen in 1821, is a *codex rescriptus*. Some skill is required to read the ancient letters under the others. The Greek name for *codex rescriptus* is *palimpsest*, now more frequently used. The biblical writings themselves have been sometimes effaced to make way for homilies and legends. One of the oldest manuscripts of the New Testament, designated by the letter C, is a *codex rescriptus*, on which the works of Ephraem Syrus have been written. See PALIMPEST.

Codex Argenteus, a translation of parts of the Bible in the Gothic language, attributed to Ulfilas, bishop of the Dacian Goths in the 4th century. It is written on vellum, the leaves of which are stained with a violet color; and on

CODEX SINAITICUS — CODRUS

this ground, the letters, all uncials or capitals, are painted in silver, except the initials, which are gold. The book, however, gets its name from its elaborately wrought silver cover, and not from its lettering. It throws much light on the kindred languages of Germany. The 'Codex' contains only fragments of the gospels and of the epistles of Paul, some psalms, and several passages from Esdras and Nehemiah. It was discovered by some Swedish soldiers in the monastery of Werden in Westphalia, in 1648; then deposited in Prague; afterward presented to Queen Christina, who placed it in the library of Upsala; next carried off by Vossius; and finally restored to the University of Upsala, which regards it as its most precious possession.

Codex Sinaiticus, sī-nā-īt'ī-kūs, a very ancient and valuable manuscript of the Greek Septuagint version of the Old Testament (including the Apocrypha), the whole of the New Testament, the Epistle of Barnabas, and a part of the Shepherd of Hermas, discovered in the monastery of St. Catherine, on Mount Sinai, by the German scholar Tischendorf, 4 Feb. 1859, while traveling in the East by the desire of the Czar Alexander II. When the discovery was made Tischendorf endeavored to persuade the monks to make a present of the manuscript to the czar, and although he was not immediately successful, he was allowed to take it to St. Petersburg on loan. Ultimately, in 1869, the manuscript was formally presented to the czar as Tischendorf had desired. In 1860 an account of the manuscript was published by the discoverer at Leipsic. It is written on parchment in four columns, in early uncial characters, and bears every mark of possessing great antiquity, perhaps being even older than the Vatican MS., which, before the discovery of the Sinaitic MS., was recognized as the oldest known manuscript of the Old and New Testaments. It is assigned by Tischendorf himself to the 4th century. The Old Testament in this manuscript is defective, but the New Testament is complete, not a word being wanting, which is the more remarkable, inasmuch as it is the only manuscript of the New Testament which is complete. From this circumstance, as well as from its great age, it acquires a value in relation to the text of the New Testament, which can scarcely be overestimated. Two gaps in the Old Testament part of the manuscript are curiously supplied by another manuscript which Tischendorf had discovered in the same monastery in 1844, and which he had brought to Germany and named *Codex Friderico-Augustanus*, in honor of the king of Saxony. From this coincidence, as well as the general resemblance of the two manuscripts, it is inferred that the last-named manuscript is really a part of the Codex Sinaiticus, which is generally believed to be the case. A splendid fac-simile of the manuscript was published by Tischendorf under the auspices of the czar at St. Petersburg, in 4 volumes folio, toward the end of 1862. This was followed in 1863-4 by two smaller editions of the New Testament part of it.

Codex Vatica'nus, an ancient Greek MS. of the Old and New Testaments, so called from being contained in the Vatican library at Rome, where it was placed early in the 16th century. It is written on thin vellum, in small uncial characters. In the greater part of the manuscript

there are three columns to a page, and this fact is regarded as one among other indications that it is later than the Sinaitic manuscript, which has four columns to a page. The manuscript is assigned to the 4th century, and until the discovery of the Sinaitic it was regarded as the best manuscript of the Old and New Testaments. The greater part of Genesis in the Old Testament, and the whole of the pastoral epistles and the Revelation in the New Testament are wanting. The first collation of this MS. was by Bartolucci, in 1669. An edition of it by Cardinal Mai was published in 1857, after having been 19 years in print without being published; but it did not satisfy the expectations of scholars. A fac-simile of it was published in 1868.

Cod'icil, an addition to, qualification of, or change in a will. It must be in the same form as a will, and be executed with the same formalities. All the laws applying to wills are the same for a codicil. A codicil properly executed is a republication of the will, and makes the will speak from the date of the codicil. The will and codicil are read together as one instrument. There may be more than one codicil to a will; and where there are several, if the last one is properly executed, referring to a former paper in such a manner as to identify it, that paper, although not properly executed, may be read into the will. See WILL.

Codification. See CODE.

Codil'la, the coarsest part of hemp, which is sorted out by itself. This term is also applied to the coarsest part of flax.

Codlaeum. See CROTON.

Codlin-moth, a moth the caterpillar of which attacks the fruit of the apple (q.v.).

Cod'man, John, American sea-captain and miscellaneous writer: b. Dorchester, Mass., 1814; d. Boston, 6 April 1900. He was the author of: 'Sailors' Life and Sailors' Yarns' (1847); 'The Mormon Country' (1876); 'Round Trip by Way of Panama, etc.' (1879); 'Winter Sketches from the Saddle' (1888); etc., besides many newspaper and magazine articles on current topics.

Codogno, kō-dōn'yō, Italy, a town in a fertile district between the Po and Adda, 17 miles southeast of Lodi. It has a large trade in Parmesan cheese and wheat, and carries on a number of manufactures. The French defeated the Austrians here in 1796. Pop. 10,000.

Cod'rington, Sir Edward, English admiral: b. 27 April 1770; d. London 28 April 1851. He entered the navy as midshipman in 1783, became lieutenant in 1793, and the following year received the appointment of captain. He obtained a gold medal for his services at the battle of Trafalgar, took part in the Walcheren expedition, and was afterward actively employed both in the Peninsular and second American wars. In 1821 he became vice-admiral. His name is principally famous in connection with the battle of Navarino, where he commanded the united squadrons that overthrew the Turkish fleet in 1827. In 1837 he became full admiral.

Co'drus, the 17th and last king of Athens. Tradition tells that during his reign Attica was attacked by the Dorians, or, according to some, by the inhabitants of the Peloponnesus, or the

CODY — CÆCILIAN

Thracians The assailants, inquiring of an oracle what would be the result of their incursion, received for answer that they would be successful if they avoided killing the Athenian king. Codrus, becoming acquainted with this answer, resolved to sacrifice himself for his country. He disguised himself in a peasant's dress, entered the enemy's camp, provoked a quarrel with the soldiers, and was slain. The Athenians, upon hearing of this, sent a herald to demand the body of their king. The courage of the assailants was so damped that they retired without striking a blow. In honor of their patriotic monarch the Athenians abolished the royal dignity, substituting that of a responsible archon, esteeming no one worthy to be the successor of Codrus. They also used his name as a common term to express a man of distinguished excellence.

Co'dy, William Frederick, American scout, hunter, and showman, best known as "BUFFALO BILL": b. Scott County, Iowa, 26 Feb. 1846. His parents moved to the country about Fort Leavenworth, Kansas, where the father was killed in the "Border War" with the Indians when the boy was but an infant. When still very young he was employed by the express companies as a rider to carry packages and valuables on horseback across the country, a most dangerous occupation. Soon he became known as a fearless and perfect rider, a keen scout, a reliable plainsman and hunter. When but little over 21 he attracted the notice of United States army officers, who were constantly in need of the services of expert scouts who could be depended upon and who knew the habits and languages of the red man. In 1868-9 he was made chief of scouts by Gen. Sheridan, then campaigning against the hostiles. Colonel John Schuyler Crosby, then adjutant under Sheridan, says of Cody: "He carried despatches 100 miles for Gen. Sheridan through terrific fire of hostile bands of Indians and returned with replies safely." This and his many personal encounters with the Indians, in some of which he saved the day for the troops, made him a noted man. He is the last of the six great scouts of America — Boone, Crockett, Carson, Bridger, "Wild Bill," "Buffalo Bill." He gained this name from his dexterity as a hunter, his record being 4,862 buffalo in one season — 69 in one day. He continued actively engaged in frontier work for many years, killing the Cheyenne chief, "Yellow Hand" in a celebrated personal encounter during the Sioux war of 1876. Early in the eighties he began the carrying out of a cherished idea — to gather about him some of the remaining elements which went to make up a frontier life and exhibit this unique existence in the eastern States and in Europe. He presently accomplished this end, forming the exhibition called the "Wild West," now known the world over. In this he has gathered scores of Indians, some of whom were once his mortal foes; hundreds of "cow-boys"; the old "Deadwood coach," used so many years to carry mail and passengers, and much other really valuable material. With this gigantic show he has toured America and Europe for nearly 20 years, amassing a fortune which he has invested in lands in Nebraska and Wyoming. In the latter State is a town named after him, on his land. In 1901 he became president of "The Cody Military College and Inter-

national Academy of Rough Riders," a school to be established on his property in Wyoming where young men may learn to ride and become masters of themselves and their horses—a post-graduate school in manhood, as he terms it. In 1872 he was elected to the Nebraska legislature, later became judge-advocate general of the Wyoming National Guard, and, with others, has written: 'The Great Salt Lake Trail.'

Coe, Edward Benton, American clergyman: b. Milford, Conn., 11 June 1842. He was graduated at Yale 1862, studied at Union Theological Seminary 1862-3, and in France and Germany 1864-7. From 1864 to 1879 he was Street professor of modern languages at Yale, and on 2 Oct. 1879 was ordained by the Classis of New York as one of the ministers of the Collegiate Reformed Dutch Church. He was pastor of the Fifth Avenue and West 48th Street Church till January 1899, since when he has been senior minister without charge of a specific congregation. He has published a number of sermons, and a volume entitled 'Life Indeed' (1899).

Coe, George Albert, American educator: b. Monroe County, N. Y., 26 March 1862. He graduated at the University of Rochester 1884, and in theology at Boston University 1887 obtaining the traveling fellowship of the latter college and studying at the University of Berlin 1890-1. He was acting professor of philosophy in Northwestern University 1891-3, when he was elected to the John Evans chair of philosophy there. Besides articles in philosophical and theological journals, he has written 'The Spiritual Life: Studies in the Science of Religion' (1900).

Coe College, an educational institution for both sexes, located at Cedar Rapids, Iowa. It was organized in 1881, under the auspices of the Presbyterian Church, and reported at the end of 1902 that it had 25 professors and instructors, 305 students, and 3,500 volumes in the library.

Cæcilian, or **Cæcilian**, sē-sīl'yān, limbless amphibians, constituting a family, *Cæciliidæ* or *Cæciliidæ*, and an order *Apoda* or *Gymnophiona*. They are remarkable for the entire absence of limbs, even the internal limb girdles having disappeared, and the bony roof to the temporal region of the skull. In the latter feature they simulate the extinct *Stegocephali*, to which some zoologists believe them to be rather closely related, though the temporal roof is formed by different bones. The form is worm-like, and, notwithstanding that the number of vertebræ may exceed 200, the tail is very short. A series of annular scales, somewhat embedded in the skin, protect the body externally, and as a further adaptation to their burrowing habits the eyes are rendered nearly or quite useless by being buried beneath the skin, the deficiency in sight being compensated by the presence of a pair of nearly unique retractile sensory tentacles.

Some species are viviparous, others oviparous. In the case of the latter the female coils about the eggs and protects them until hatched. The young of many are noteworthy in the possession of external gills, while the respiration of the adults is pulmonary. Their food consists principally of earthworms and subterranean insect larvæ.

COEDUCATION

Dr. Boulenger recognizes 17 genera and 40 species, but probably many remain undiscovered. None have been found except in a zone encircling the earth, chiefly within the limits of the tropics; South and Central American species are numerous; but none are certainly known from North America. Consult: Boulenger, 'Proceedings of the Zoological Society of London' (1895); Sarasin, 'Forschungen auf Ceylon' (Vol. II.).

Co'educa'tion, a term meaning joint education, has come to be specifically applied to the education of both sexes in the same class or institution. In the western States and Territories of the United States it is almost the only system of education, and it is rapidly becoming the prevailing system in the South, where the influence of the State universities is predominant. On the other hand, in the New England and middle States the great majority of the youth of both sexes are still receiving a separate college education. Coeducation was introduced into colleges in the West as a logical consequence of the so-called American system of free elementary and secondary schools. During the great school revival of 1830-45 and the ensuing years until the outbreak of the Civil War in 1861, free elementary and secondary schools were established throughout New England and the middle States and such western States as existed in those days. It was a fortunate circumstance for girls that the country was at that time sparsely settled; in most neighborhoods it was so difficult to establish and secure pupils for even one grammar school and one high school that girls were admitted from the first to both. In the reorganization of lower and higher education that took place between 1865 and 1870 this same system, bringing with it the complete coeducation of the sexes, was introduced throughout the South both for whites and negroes, and was extended to every part of the West. In no part of the country, except in a few large eastern cities, was any distinction made in elementary or secondary education between boys and girls. The second fortunate and in like manner almost accidental factor in the education of American women was the occurrence of the Civil War at the formative period of the public schools, with the result of placing the elementary and secondary education of both boys and girls overwhelmingly in the hands of women teachers. This result proved not to be temporary, but permanent, and from 1865 until the present time, elementary and secondary education of both boys and girls has been increasingly in the hands of women. When most of the State universities of the West were founded they were in reality scarcely more than secondary schools supplemented, in most cases, by large preparatory departments. Girls were already being educated with boys in all the high schools of the West, and not to admit them to the State universities would have been to break with tradition. Women were also firmly established as teachers in the secondary schools, and it was patent to all thoughtful men that they must be given opportunities for higher education, if only for the sake of the secondary education of the boys of the country. The development of women's education in the East has followed a different course because there were in the East no State universities, and the private colleges for men

had been founded before women were suffered to become either pupils or teachers in schools. The admission of women to the existing eastern colleges was, therefore, as much an innovation, as it would have been in Europe. The coeducation of men and women in colleges, and at the same time the college education of women, began in Ohio, the earliest settled of the western States. In 1833 Oberlin Collegiate Institute (not chartered as a college until 1850) was opened, admitting from the first both men and women. It was the first institution for collegiate instruction in the United States where large numbers of men and women were educated together, and the uniformly favorable testimony of its faculty had great influence on the side of coeducation. In 1853 Antioch College, also in Ohio, was opened, and admitted from the beginning men and women on equal terms. From this time on it became a custom, as State universities were opened in the far West, to admit women. Utah, opened in 1850; Iowa, opened in 1856; Washington, opened in 1862; Kansas, opened in 1866; Minnesota, opened in 1868; and Nebraska, opened in 1871, were coeducational from the outset. Indiana, opened as early as 1820, admitted women in 1868. The University of Michigan was, at this time, the most important western university, and the only western university well known in the East before the War. When, in 1870, it opened its doors to women, they were for the first time in America admitted to instruction of true college grade. The step was taken in response to public sentiment, as shown by two requests of the State legislature, against the will of the faculty as a whole. The example of the University of Michigan was quickly followed by all the other State universities of the West. In the same year women were allowed to enter the State universities of Illinois and California; in 1873 the only remaining State university closed to women, that of Ohio, admitted them. Wisconsin which, since 1860, had given some instruction to women, became in 1874 unreservedly coeducational. All the State universities of the West, organized since 1871, have admitted women from the first. In the 20 States which, for convenience, are classified as western, there are now 20 State universities open to women, and, in four Territories—Arizona, Oklahoma, Indian, and New Mexico—the one university of each Territory is open to women. Of the 11 State universities of the southern States the two most western admitted women first, as was to be expected. Missouri became coeducational as early as 1870, and the University of Texas was opened in 1883 as a coeducational institution. Mississippi admitted women in 1882; Kentucky in 1889; Alabama in 1893; South Carolina in 1894; North Carolina in 1897, but only to women prepared to enter the junior and senior years; West Virginia in 1897. The State universities of Virginia, Georgia, and Louisiana are still closed to women. The one State university existing outside the West and South, that of Maine, admitted women in 1872.

The greater part of the college education of the United States, however, is carried on in private, not in State universities. In 1897 over 70 per cent of all the college students in the United States were studying in private colleges, so that for women's higher education their admission to private colleges is really a matter of much

COEDUCATION

greater importance. The part taken by Cornell University in New York State in opening private colleges to women was as significant as the part taken by Michigan in opening State universities. Cornell is in a restricted sense a State university, inasmuch as part of its endowment, like that of the State universities, is derived from State and national funds. Nevertheless, there is little reason to suppose that Cornell would have admitted women had it not been for the generosity of Henry W. Sage, who offered to build and endow a large hall of residence for women at Cornell University. After carefully investigating coeducation in all the institutions where it then existed, and especially in Michigan, the trustees of the university admitted women in 1872. The example set by Cornell was followed very slowly by the other private colleges of the New England and Middle States. In Massachusetts Boston University opened its department of arts in 1873, and admitted women to it from the first; but no college for men followed the example of Boston until 1883, when the Massachusetts Institute of Technology admitted women. This school, like Cornell, is supported in part from State and national funds. In 1892 Tufts College was opened to women. In the West and South the case is different, and the list of private colleges that one after another have become coeducational is too long to be inserted here. Among new coeducational foundations the most important are, on the Pacific coast, the Leland Stanford Junior University, opened in 1891; and in the middle West, Chicago University, opened in 1892. (For Chicago's recent attitude, see UNIVERSITY OF CHICAGO.)

Of the 480 colleges for men enumerated by the commissioner of education, 336, or 70 per cent (or, excluding Catholic colleges, 80 per cent) admit women. In the western States there are, excluding Roman Catholic colleges and seminaries, out of 195 colleges 182 coeducational, and only 13 colleges for men alone. In the southern States and southern middle States, excluding Roman Catholic colleges and seminaries, out of 161, there are 125 coeducational and but 36 colleges for men only. Among these 36, however, are some of the most important educational institutions in that section—Johns Hopkins University, the University of Georgia, the Louisiana State University, Tulane University, and the University of Virginia. In New England and the northern middle States, out of 64 colleges, excluding Roman Catholic colleges and seminaries, only 29, or less than half, are coeducational. The colleges for men only include (with the exception of Cornell) all the largest undergraduate colleges in this section—Harvard, Yale, Columbia, Princeton, Pennsylvania.

Five important universities, closed to women in their undergraduate departments, have each affiliated to them a women's college through which women obtain some share in the undergraduate instruction given, the most important being Harvard, Columbia, and Western Reserve University. Of these five, four (all but Harvard) admit women without restriction to their graduate instruction, and in addition Yale, the University of Pennsylvania, and New York University make no distinction between men and women in graduate instruction. The Johns Hopkins University maintains a coeducational medical school. Princeton is the only one of the large university foundations that excludes

women from any share whatsoever in its advantages.

All the arguments against the coeducation of the sexes in colleges have been met and answered by experience. It was feared at first that coeducation would lower the standard of scholarship on account of the supposed inferior quality of women's minds. The unanimous experience in coeducational colleges goes to show that the average standing of women is slightly higher than the average standing of men. Many reasons for the greater success of women are given, but the fact, however it be explained, remains and is as gratifying as astonishing to those interested in women's education. The question of health has also been finally disposed of; thousands of women have been working side by side with men in coeducational institutions for the past 25 years and undergoing exactly the same tests without a larger percentage of withdrawals on account of illness than men. The question of conduct has also been disposed of. None of the difficulties have arisen that were feared from the association of men and women of marriageable age. Looking at coeducation as a whole, it is most surprising that it has worked so well. Not only is the number of coeducational colleges increasing, but the number of women relatively to the number of men is increasing also. Between 1890 and 1898 men in coeducational colleges increased 70.0 per cent, but women in coeducational colleges increased 105.4 per cent. There is every reason to suppose that this increase of women will continue. Already girls form 56.5 per cent of the pupils in all secondary schools; and 13 per cent of the girls enrolled and only 10 per cent of the boys enrolled graduate from the public high schools. It is sometimes said that men students, as a rule, dislike the presence of women, but statistics show that the number of men increases more rapidly in coeducational colleges than in colleges for men only. It is women who have shown a preference for separate education; women have increased more rapidly in separate colleges for women than in coeducational colleges. It will be observed, however, that the separate colleges for women, like the separate colleges for men, are in the East; it is in the East only that any preference for separate education is shown by either sex. This preference is natural, since college life as it is organized in a woman's college seems to conservative parents less exposed, more in accordance with inherited traditions; and girls, who in their own homes lead guarded lives, are to be found in women's colleges rather than in coeducational colleges. Then, too, for the present, much of the culture and many of the priceless associations of college life are to be obtained, whether for men or women, only by residence in college halls, and no coeducational, or even affiliated, colleges have as yet organized for their students such a complete college life as the independent woman's college. In professional schools, including the graduate school of the faculty of philosophy, coeducation is even at present almost the only method. There are in the United States only four graduate schools for men closed to women, and only one independent graduate school maintained for women offering three years' consecutive work leading to the degree of Ph.D.

M. CAREY THOMAS,
President of Bryn Mawr College.

Coehorn, koo'hörn, **Menno**, BARON VAN, Dutch engineer: b. near Leeuwarden, Friesland, 1641; d. The Hague 17 March 1704. In his 16th year he entered the service as captain, and soon rose to the rank of a colonel. During the siege of Graves he made use for the first time of the small mortars, called in honor of their inventor *coehorns*, used for throwing grenades. In the war of 1689, against France, he again distinguished himself. His defense of Fort William, in 1692, which he himself had planned, against the attacks of Vauban, attracted much attention. Both commanders displayed all their talents. In 1702 he published at Leeuwarden his new theory of fortification. In 1703 he directed several sieges. He fortified almost all the strong places in Holland. Bergen-op-Zoom he considered his masterwork. His system, and that of Vauban, are entirely different. Vauban operated by manœuvres, and by the skilful direction of his ordnance and his men saved both, and wearied and divided the forces of the enemy; Coehorn crushed by an overpowering mass of artillery and men, and sacrificed both for a rapid and powerful effect.

Cœle-Syria, sē'lē-sīr'ī-ā ("Hollow Syria"), the ancient name of the large valley lying between the Lebanon and Anti-Lebanon mountain ranges in Syria. The valley is about 100 miles in length. Near its centre are the ruins of Baalbek, or Heliopolis, and near the ruins rise the rivers Orontes and Litany, which water and fertilize the plain. The name also at one time included all the country (except Judea and Phœnicia) extending from Seleucis to the confines of Egypt and Arabia.

Cœlebs (sē'lēbz) in **Search of a Wife**, a moral tale by Hannah More, published 1808. This is the best-known work of fiction by that prolific moralist. It was written after she had passed her 60th year, and was intended as an antidote to what she considered the deleterious influence of the romantic tales of that day. In 'Cœlebs' she sought to convey precepts of religion, morals, and manners, in the form of a novel. The book had an instant and great popularity. The first edition was sold in a fortnight, and 11 within a year. Its republication in the United States was also highly successful.

Cœlenterata, sē-lēn-tē-rā'ta. The zoophytes or radiate animals of older writers included, among others, the *Actinia* or sea-anemone, the coral, the fresh-water *Hydra*, the sea-firs (*Sertularia*), and the *Medusidæ* or jelly-fishes. These forms were united under the common designation *Cœlenterata* by Frey and Leuckart, and recent observations tend to include the sponges likewise in the same class. Omitting the sponges, however, as their relations are still uncertain, the *Cœlenterata* may be defined as animals whose body wall, consisting of two layers, ectoderm and endoderm, encloses a cavity which has only one external aperture, and which discharges the function at once of digestive and circulatory organ. The outer sur-

face may secrete a horny sheath, as in the sea-firs, or may develop in its substance the hard calcareous skeleton of the corals. The *Hydra*, if divided transversely at any point, shows only a single circular boundary; but the *Actinia*, if similarly treated, is seen to consist of an external and an internal circle, between which radial partitions pass. This is due to the fact that the oral margins are prolonged inward for a short distance as a funnel, which terminates by a truncated open end: the matters received into the funnel and then digested circulate in the compartments outside the funnel, while the effete portions are rejected by the mouth. The *Hydra* and *Actinia*, which are the simplest representatives of the two principal divisions of the class, are at first sight alike in their perfect radial arrangement; but in the *Actinia* bilateral symmetry may be recognized, in so far as the presence of a tubercle within the tentacular circle indicates the point through which a section would divide equally the cylindrical animal. The structure of the coral will be given under that heading. The Venus' girdle (*Cestum veneris*), the spherical *Cydippe*, and the *Beroë*, are the commonest members of the *Ctenophora*, whose locomotive organs consist of cilia arranged on definite bands which divide the surface. The *Hydrozoa* comprise a very varied assemblage of fixed or free-swimming forms, of single animals or clusters aggregated into a compound mass by a process of gemmation, the various members of the group giving off buds which remain in organic connection with the parent mass. This, the simplest mode of multiplication, is obviously asexual, and the development of ova may take place at some part of the compound mass. But the most interesting phenomena are presented by those forms which illustrate what is known as alternate generations, when from the egg is produced an organism which is unlike that which gave it birth, but whose progeny exactly repeats the form whence the egg was derived. Thus from the egg may be produced a fixed compound structure like the sea-fir, from which a free-swimming zoöid is given off; and in this an egg is produced whence the fixed form is again developed. These free-swimming zoöids are the familiar umbrella-like disks of our jelly-fishes, and these are either gymnophthalmous, or naked-eyed, the eye-spots on the margin of the disk being exposed; or else these spots are covered by a fold of the body-wall, as in the covered-eyed or steganophthalmous *Medusæ*. These free-swimming forms move by the contraction of their umbrella; but the airsacs developed in the Portuguese man-of-war and the like assist or supersede the muscular action of the disks. The majority of these *Medusæ* are known to be merely the sexual phases in the alternate generations, and the difficulty of their determination may be guessed from the fact, that the one "generation" may consist of zoöids seven feet in circumference, while that from which they proceeded is only half an inch in height. The researches of Allman have shown a beautiful series of gradations connecting the apparently quite dissimilar members of the group. Thus the umbrella-like zoöids may remain in connection with the parent mass of which they are buds, and the free-swimming zoöids are shown to be merely detached reproductive organs.

CÆLIAC ARTERY — COFFEE

Cœliac Artery, an artery issuing from the aorta just below the diaphragm. It is called also the cœliac axis.

Cœlost, sē'lō-stāt, an astronomical instrument in which an image of the sky is shown reflected in a plane mirror. Such an instrument was completed in 1903 for the Smithsonian Institution at Washington. It will be used primarily for the study of solar phenomena.

Cœnogenesis. See RECAPITULATION.

Cœphori. See ÆSCHYLUS.

Coercion Acts. See IRELAND.

Coethen, kē'tĕn, Germany, a town in the duchy of Anhalt, in a fertile and attractive district on the Ziethe, about 80 miles southwest of Berlin. It was, till 1853, the capital of the former duchy of Anhalt-Cœthen. It consists of the old and the new town and several suburbs; has a fine Protestant cathedral church in the Gothic style, with old glass-paintings and a fine organ; the former ducal residence with library, picture-gallery and museum; a gymnasium, normal and several other schools. There are manufactures of machinery and metal goods, and various other industries. Beet-sugar is a staple article of commerce. The town dates back to the 10th century. Pop. 23,000.

Cœur, Jacques, zhāk kēr, French merchant and royal treasurer: b. Bourges toward the end of the 14th century; d. Chios, in the island of Scio, 25 Nov. 1456. His vast commercial enterprise attracted the attention of Charles VII., who in 1435 appointed him master of the French mint, and afterward treasurer. His excellent management of affairs caused the king to ennoble him, and to intrust him with high functions in the French provinces, and diplomatic missions in Italy. Cœur contributed 200,000 crowns to help the king in rescuing Normandy from the English. After the successful end of the war, his influence became so great as to give offense to envious persons, who after the death of the king's mistress, Agnes Sorel, charged him with having poisoned her, and caused him to be arrested (1451), and his vast property to be confiscated. Although the charge was proved to be groundless, he was detained in prison until 1455, when he effected his escape. Repairing to Rome, he was kindly received by Pope Nicholas V., and was enabled to gather the broken remains of his fortune. He had vainly claimed the clemency of Charles VII. in favor of his family, and it was under Louis XI. only that his memory was exculpated from all charges, while a part of his property was afterward restored to his descendants.

Cœur d'Alêne, kēr dā-lān (Fr. "awl-heart"). 1. A name given by the French *voyageurs*, traditionally from the stinginess of a chief, to a tribe of Indians of the Salishan stock, though with a dialect widely different from the other members. Their own name is Skitswish, which Lewis and Clarke rendered Skitzoomish. When found by Lewis and Clarke they occupied a considerable tract in northern Idaho and Washington, near the lake named after them. There were perhaps 2,000 of them, rather squalid and unadventurous, though cruel; they lived on roots, fish, and small game, and did not visit the buffalo grounds. Father de Smet visited them in 1841, and the next year a Catholic mission was established among them,

and they became Christians. They had regular dwellings and a mill; but they were hostile to the encroaching whites, and in 1858 their chief, Vincent, with a band of his warriors, joined in a war on them, which was only put down by Gen. Wright after two sharp battles, at Four Lakes and Spokane Plains. In 1867 part of them were placed on a reservation in Idaho, and in 1872 the rest were removed to the Colville Reservation, between the Okanogan and Columbia rivers.

2. A lake in northern Idaho, situated among mountains of the same name. The rivers Cœur d'Alêne and St. Joseph flow into the lake at its southern end, and the Spokane River is its outlet at the north. The region is a mining district, and has been the scene of serious labor troubles, especially in 1892 and 1899.

Cœur d'Alêne, a novel by Mary Hallock Foote, published 1894. It is a story of the Colorado mining camps, full of realistic details. Its situations turn upon the labor strife between union and non-union miners in 1892, which forms the sombre background of a bright lovers' comedy.

Cœur de Lion, kēr dē lē-ôn, a title given to several historical personages, as Richard I. of England; so called from the prodigies of personal valor performed by him in the Holy Land; Louis VIII. of France, frequently called *Le Lion*; and Bolaslus I. of Poland, also called "The Intrepid."

Coffee, the seed of an evergreen shrub, which is cultivated in tropical countries, supposed to be native to Abyssinia, although it was early found in Arabia. The plant belongs to the genus *Coffea*, order *Rubiaceæ*. In the wild state it grows to a height of from 6 to 30 feet, but in cultivation it is pruned and kept between 6 and 10 feet. The leaves are green, glossy on the upper side, and somewhat resemble those of the laurel, but less dry and thick. The flowers are white, fragrant, and grow in clusters from the axils of the branches. The fruit, often called berries, grows in clusters of from 3 to 12, each with a short stem or sessile. The fruit when ripe resembles in appearance a dark-red cherry, or a medium-sized cranberry. Each berry contains two seeds embedded in a yellowish, sweetish pulp which, when ripe, is delicious.

The trees are raised from seed grown in nurseries, and when of a size to endure variations of temperature, usually in about six months' time, they are transplanted to the coffee orchard. They begin to bear when three years old, and yield fruit for about 20 years. Considerable space is left between the trees, and corn, bananas, and plantain are grown among them, especially when young. The first year's crop is small, but when in full bearing a tree will yield from one to five pounds, according to location and variety. The regions best adapted to the growth of coffee are between the parallels of 15° north and 15° south latitude, and from 1,000 to 4,000 feet above sea-level. It is cultivated from lat. 25° N. to 30° S., in places where the temperature does not fall below 55° F. Moist and somewhat shady slopes are found most desirable. Little streams of water are conducted to the roots of the trees, which are kept very wet until the fruit is nearly ripe, then the water is turned off to keep the fruit from becoming too succulent. The fruit varies in size and color

COFFEE

according to the altitude in which it grows; that from highlands is small and green; that grown on lowland and near the coast is larger and of a yellowish tinge. The wild trees of Liberia, which grow in the lowlands, produce the largest fruit known, but it is of inferior quality. The coffee from the Far East can be distinguished by its large bean of a yellow color, while that of Central and South America is smaller and of greenish color. The fruit is harvested with great care, cloths being placed under the trees before shaking them. The fruit is then exposed to the sun to dry, after which it is pulped, washed, dried again, hulled, cleaned, and sorted before it is ready for the market. In some places, especially Brazil, the bean is pulped by machinery as soon as it is taken from the tree, and thus the time necessary to get the coffee ready for market is shortened.

Some of the coffee-producing countries of the world to-day are: Brazil, the Philippines, Hawaii, Cuba, Porto Rico, Jamaica, Central America, and parts of Africa, Arabia, Java, and Ceylon. Brazil has a larger coffee-bearing area than any other country; it produces more than two thirds of all the coffee consumed in the world. One year, when the crop was unusually good, Brazil produced 660,000 tons, and that same year the world's consumption was 600,000 tons. Coffee planting in Brazil has been the most successful farming in the world. Sao Paulo, a city of 250,000, owes its existence to the trade in the coffee raised in the great orchards in the vicinity. In some of the orchards there are about 5,000,000 trees. Large quantities of the Brazilian coffee are shipped annually to Aden (Arabia) and reshipped to other parts of the world as mocha. The producing of coffee in Yemen, or Wady Negram, or anywhere near Mocha is a thing of the past; but one kind of coffee-berry raised in Brazil and in some other countries much resembles in form and flavor the old market mocha. Coffee planting is no longer pursued to any extent in Ceylon. The red lands in the province of Sao Paulo, in Brazil, seem to be particularly favorable to the growth of the tree, and this section seems immune to the leaf disease which has destroyed the industry in Ceylon and in some parts of the West Indies. Giving the soil a rest or changing crops may result in again placing Ceylon among the places producing an excellent quality of coffee. The names given to coffee are usually those of the cities from which shipments are made.

The difference in taste of coffee as found in our markets is principally due to two causes: (1) the roasting to either a reddish-brown or a dark brown; (2) the picking of coffee when some berries are green, others red, and still others a dark purple, the last being the ripe fruit. Thus we have three grades from each tree; add the difference in roasting, as mentioned, and we have six grades; then take the perfect berry, which is flattened on one side, and the spherical berry, the so-called mocha, and that gives 12 grades of coffee.

In Porto Rico and Cuba coffee of a good quality is raised, but as yet in small quantities. In the Hawaiian Islands coffee of excellent quality is produced, and the orchards are increasing in size and number. Hawaiian coffee brings the highest price of any on the Pacific coast. In the Philippines there are splendid orchards, espe-

cially in the southern islands of the archipelago, known as the Sulu or Jolo group. On the island of Jolo are fine coffee-trees that bear much earlier after planting than those of Brazil. There are large tracts of land in the Philippines which are as favorable for coffee growing as any in Brazil, but the area that may be devoted to coffee farming is not so great.

The United States leads the world in the consumption of coffee. The yearly consumption in Great Britain declined steadily during the last half of the 19th century. This is attributed to the adulterations which at one time were extensively practised. Probably few articles of food are subjected to so much adulteration as coffee. Substances of an entirely foreign nature are often palmed off as genuine coffee, or are offered as substitutes. Dandelion, parsnip, carrot, and beet roots, beans, lupins, rice, and various cereals, roasted and ground, have all been employed, and within recent years the manufacture of artificial coffee has been undertaken on a considerable scale, the material being mixed to a stiff paste and run through a machine for which patents have been granted, and from which it emerges in the shape of "coffee-beans," which, after drying and roasting, are well calculated to deceive the eye, though not the nostrils or palate. These adulterations can be readily detected, for genuine roasted coffee may be soaked in cold water indefinitely without the bean losing its smooth surface or hard, tough consistency, nor will it impart its color to the water; whereas chicory and other imitations become soft and spongy and render the water muddy. As far back as the eighties it was estimated that something like 18,000,000 pounds of various vegetable substances were annually sold as coffee.

In Medicine.—Many of the leading medical men of the day hold that the action of coffee on the body is due to two or three factors. If coffee is mixed with milk or cream, it gives a certain amount of nutritive matter; but its action is usually that due to the volatile oils, and to the caffeine contained. The volatile oil, like others in this class, stimulates peristalsis, and assists to overcome constipation—in this respect coffee and tea being quite opposites—and it also aids in the expelling of flatus; but taken too often and in too large quantities the oil contributes to the causation of a certain amount of gastric indigestion. The more delicate the aroma of coffee the less the oil, and the better from this standpoint. The action of caffeine is much more complex.

So far as coffee-drinking is concerned, the action of caffeine is that of a cardiac stimulant, a nerve-muscle excitant, a diuretic, and a cerebral excitant. Thus it may cause a sense of undue fullness in the blood vessels. It almost invariably causes a slight muscular tremor, which is not noted in those who do not use their hands for fine work, as artists, for example. It causes an increased flow of urine, and tends to prevent sleep. Time, custom, usage, dose, and the individual's reaction all modify these general laws; but these reactions occur, although none of them may be of sufficient grade to make the observer cognizant of the action. Thus many people are not kept awake by coffee. They have probably habituated themselves and require larger doses.

Hot coffee is one of the best heart tonics known, and it is sometimes used in large quan-

COFFEE-BUG — COFFIN

tities by rectum in cases of shock, opium poisoning, pneumonia, etc. Coffee is also valuable in many types of headache and in many cases of nausea. Its excessive use leads to great muscular irritability, gastritis, restlessness, and sleeplessness. It is held by many medical men that the effects of coffee as a beverage are wholly bad. They say that the caffeine in the coffee, or in other vegetable substances—tea, coffee, kola, guarana, and maté, or Paraguay tea—is a stimulant to the brain, nerves, heart, and kidneys. In small doses it helps to resist fatigue, increases mental power and promotes excretion of urine. Large doses or continued use, however, tend to make a person nervous, to induce irritability of the heart with considerable depression, and to upset the stomach. The mildest results of an overdose are a tendency to wakefulness, but there are recorded a number of deaths from heart-failure due to its employment in large doses. It is used largely as a heart-stimulant and diuretic, but its action is characterized by great variability. Individual susceptibility to it varies so greatly that what would be a poisonous dose for one person would scarcely affect another. The usual dose is half a grain to three grains.

History.—The early history of coffee is obscure; as an article of diet, its introduction is recent; to the Greeks and Romans it was wholly unknown. It was first introduced into Persia from Abyssinia, and next in the 15th century by a Mohammedan priest at Aden. From Aden it was carried to Mecca, where first the pilgrims or Hadjis, and then the rest of the people, began to use it. From Arabia it was taken to Cairo, Egypt, where in 1511 it was prohibited because it was believed to be an intoxicant and came within the class of things forbidden as food by the Koran. The Sultan Causon removed the prohibition, and coffee passed along the coast by way of Syria and around to Constantinople. Again it was opposed as one of the articles not to be used as food according to the Koran. Thus its use was permitted and allowed for many years. The Turks are now immoderate coffee-drinkers.

Prior to the 18th century all the coffee used in Europe was brought from Arabia Felix via the Levant. In 1652 Edward, a merchant, in trade with Turkey, introduced coffee into England; in 1697 Van Horn introduced it into Batavia, and from there it was taken to France and the West India Islands. In 1754 Father Villaso, a Franciscan monk, took a plant to Rio Janeiro and cultivated it in the garden of the monastery of St. Anthony. This one plant was the means of introducing coffee into Brazil.

Bibliography.—Cook, 'Shade in Coffee Culture' (United States Botany Division, Bulletin 25); Hangwitz, 'The World's Coffee Trade in 1898' (United States Consular Reports, Vol. LX. 258); Hewitt, 'Coffee, Its History, Cultivation, and Uses'; Lock, 'Coffee, Its Culture and Commerce in all Countries'; Caswell, 'Coffee Culture in Our New Islands,' in the 'Overland Monthly,' new series Vol. XXXII. 459; and United States Bureau of American Republics, 'Special Report on Coffee Culture in Central and South America.'

Coffee-bug, an insect (*Lecanium coffeæ*), of the *Coccus* family (*Coccidæ*), very destructive in coffee plantations.

Coffee House, a house of entertainment where persons are supplied with coffee and other refreshments. Such houses were formerly the chief resorts of every class for purposes of conversation and information, and the meeting-places of politicians, literary men, etc. Constantinople is believed to have been the first European capital in which coffee-houses were instituted, the year of their establishment there being 1554 A.D. In 1650 the first one in England was opened in Oxford. They were suppressed by Charles II. in 1675, but were soon allowed to be reopened.

Coffee-nut: Coffee-tree. See Kentucky Coffee-tree.

Coffer-dam, a water-tight enclosure round a space where it is intended to found the pier of a bridge, quay, etc., so constructed that the water may be pumped out of it and the masonry executed "in the dry." It is formed of one or more rows of piles (usually two), between which clay is rammed. The piles, generally driven close together, are sometimes grooved and tongued; but if the water be not very deep the piles are placed some distance apart, and boards let into the grooves. Of course great care must be taken that no water can enter at the joints or at the junction with the natural soil, and that the structure is sufficiently strong to resist the great pressure of water from without. If the bottom is of rock, and piles cannot be driven, coffer-dams may be formed of two parallel stone walls, the intervening space filled up with clay. Iron caissons are also used instead.

Coffer Fish, or **Trunk Fish**, a peculiar genus (*Ostracion*) of bony fishes in the small order *Plectognathi*, and in the suborder *Sclerodermi*, which also includes the file-fishes. The body is enclosed in a firm box formed of hexagonal bony scales fitted into one another like a mosaic. The snout, the bases of the fins, and the end of the tail are the only soft-skinned parts. Over a score of species are known from tropical and sub-tropical seas. The best-known form is *O. quadricornis* from the tropical Atlantic.

Cof'feyville, Kan., a city of Montgomery County, situated on the Verdigris River, and on the Missouri P., Atchison, T. & S. F., and other railroads. There are gas wells in the vicinity, and the city has a large trade with Indian Territory, and a number of manufacturing interests. Pop. (1900) 4,953.

Coffin, Charles Carleton, American novelist and lecturer: b. Boscawen, N. H., 26 July 1823; d. Brookline 2 March 1896. He began life as a civil engineer, and afterward gave his attention to telegraphy. In 1851 he began to write for the Boston papers; and during the Civil War and the Austro-Prussian war of 1866 was war correspondent for the *Boston Journal*, writing over the signature of "CARLETON." His books include: 'Days and Nights on the Battlefield' (1864); 'Four Years of Fighting' (1866); 'Our New Way Round the World' (1869); 'Story of Liberty' (1878); 'Boys of '76' (1879); 'Old Times in the Colonies' (1880); 'Life of Garfield' (1883); 'The Drum-Beat of the Nation' (1887); 'Marching to Victory' (1888); 'Freedom Triumphant' (1891).

Coffin, Sir Isaac, English admiral: b. Boston, Mass., 16 May 1759; d. England 23 July 1839. He entered the English navy as midshipman in 1773, served on various ships on the

COFFIN

American station, in 1778 was appointed lieutenant, and in 1781 commander. On 16 March 1781 he acted as signal-lieutenant to Admiral Arbuthnot in the action off Cape Henry, and in 1782 was present as a volunteer under Admiral Hood in the engagement between Rodney and De Grasse. In 1798, when Minorca fell into the hands of the English, he was appointed superintendent of the arsenal at Port Mahon. In 1804 he was advanced to the rank of rear admiral of the blue; next year was made a baronet; in 1808 vice-admiral, and in 1814 admiral. In 1826 he founded a school in Nantucket, Mass., still called by his name.

Coffin, James Henry, American scientist: b. Williamsburg, Mass., 6 Sept. 1806; d. Easton, Pa., 6 Feb. 1873. He was graduated at Amherst, 1828. He taught at Greenfield, Mass., Ogdensburg, N. Y., 1829-40; at Williams College 1840-3; Norwalk (Conn.) Academy 1843-6, when he was elected professor of mathematics and astronomy in Lafayette College, Easton, Pa., where he remained till his death. His reputation is due to his achievements in meteorology, a subject he began to investigate as early as 1838. In 1853 he published his theory of atmospheric circulation, including the principle quoted in Europe since 1860 as 'Buys-Ballot's Law.' He wrote: 'Solar and Lunar Eclipses' (1845); 'Winds of the Northern Hemisphere' (1853); 'Psychrometrical Tables' (1856); 'The Orbit and Phenomena of a Meteoric Fire-Ball, 20 July 1860' (1869); 'Elements of Conic Sections' (1874); 'The Winds of the Globe; or, the Laws of Atmospheric Circulation over the Surface of the Earth' (1875), completed by his son, S. J. Coffin. See Clyde, 'Life of J. H. Coffin' (1882).

Coffin, John Huntington Crane, American mathematician: b. Wiscasset, Maine, 14 Sept. 1815; d. Washington, D. C., 8 Jan. 1890. He was graduated at Bowdoin 1834, and in January 1836 entered the United States navy as professor of mathematics, serving in the West India squadron, and at the Norfolk navy yard. He had charge of the mural circle in the Naval Observatory at Washington from 1843 to 1853, when he was transferred to the Annapolis Naval Academy, taking charge of the department of mathematics, and later astronomy and navigation. From 1865 to 1877 he had charge of the 'American Ephemeris and Nautical Almanac.' In 1877 he was placed on the retired list. Bowdoin conferred the degree of LL.D. upon him in 1884, and in 1863 he became one of the corporate members of the National Academy of Sciences, named by Act of Congress. He published 'Observations with the Mural Circle, with Formulas, Tables, and Discussions, 1845-9', published in the observatory volumes for those years; 'The Compass' (1863); 'Navigation and Nautical Astronomy' (1868); 'Observations of the Total Eclipse of the Sun, August 1869' (1884).

Coffin, Joshua, American antiquary: b. Newbury, Mass., 12 Oct. 1792; d. there 24 June 1864. He was graduated at Dartmouth College in 1817, and was a teacher for many years. Whittier was one of his pupils, and addressed to him the poem 'To My Old School-Master.' Coffin was an ardent abolitionist, being a founder and first recording secretary of the New England Anti-Slavery Society 1832. He compiled:

'Sketch of the History of Newbury, Newburyport, and West Newbury, 1635-1845' (1845); 'List of Some of the Descendants of Mr. E. Woodman (of) Newbury, Mass., 1635' (1855); 'The Toppans of Toppan's Lane: Their Descendants and Relations' (1862).

Coffin, Levi, American philanthropist: b. near New Garden, N. C., 28 Oct. 1798; d. Avondale, Ohio, 16 Sept. 1877. He was a farmer's son, and early evinced interest in the negro's welfare. Proving successful in business, he actively aided slaves to gain freedom, largely through the "underground railroad." Thousands of escaping slaves were aided on their way to Canada by him. He helped found the Freedman's Bureau in 1863, and after the Civil War was active in schemes to advance the welfare of the colored people. He was known popularly as "President of the Underground Railroad."

Coffin, Robert Barry, American journalist and miscellaneous writer: b. Hudson, N. Y., 21 July 1826; d. Fordham, N. Y., 10 June 1886. He was on the staff of the 'Home Journal' of New York (1858), and was also art critic of the *Evening Post*. His humorous sketches, which appeared in many periodicals over the pen-name "BARRY GRAY," have been extensively read. Among his publications are: 'My Married Life at Hillside' (1865); 'Cakes and Ale at Woodbine' (1868); and 'The Home of Cooper' (1872).

Coffin, Robert Stevenson, American printer and poet: b. Brunswick, Maine, 1797; d. Rowley, Mass., 7 May 1827. He served his apprenticeship as a printer in Newburyport; was a sailor during the War of 1812, and at one time a prisoner on board a British frigate, and subsequently worked on newspapers in Boston, New York, and Philadelphia, publishing occasional verses in the poet's corner. He came to be known, perhaps from his own pretentiousness, as "The Boston Bard," and his poems were collected in a volume entitled the 'Oriental Harp, Poems of the Boston Bard.'

Coffin, William Anderson, American painter: b. Allegheny, Pa., 31 Jan. 1855. He was graduated at Yale 1874, studied art in the United States 1874-7, and then in Paris under Leon Bonnat 1877-82. He opened a studio in New York 1882, and has become well known as a painter of landscapes and figure pieces. In 1886 he won the Hallgarten prize of \$200; was awarded a medal at the Paris Exposition 1889; received the Webb prize of the Society of American Artists 1891; and was gold medallist of the Philadelphia Art Club 1898. He was art critic of the New York *Evening Post* 1886-91, and of the New York *Sun* 1896-1900. In 1901 he was director of fine arts at the Pan-American Exposition in Buffalo, N. Y. Among his best-known pictures are: 'The Rain,' in the Metropolitan Museum; 'Une académie de peinture moderne'; 'An Examination' (time of Louis XIII.); 'The Close of Day' (1881); 'The Hayfield' (1886).

Cof'fin, a box or case designed to hold a corpse for interment or cremation. Coffins were used by the ancients mostly to receive the bodies of persons of some distinction. Among the Romans it was latterly the almost universal custom to consume the bodies with fire, and deposit the ashes in urns. Even at the present time coffins are not used in the East, either by

Mohammedans or Christians. In Egypt coffins seem to have been used in ancient times universally. They were of stone, earthenware, glass, wood, or a kind of pasteboard made by gluing cloth together. (See SARCOPHAGUS.) Coffins among Christians were probably introduced with the custom of burying. (See BURYING-PLACES.) It has been often proposed that they should be made with a hole opposite the place of the mouth of the body, so as to allow breathing in case of revival. Of course it would be necessary, at the same time, to let the coffin stand for some days in a convenient place, as is the custom in some parts of Germany. It has recently been proposed to employ coffins of wicker-work, while some strenuously advocate the burning of all dead bodies. See CREMATION.

Cofre de Perote, kō'frā dā pā-rō'tā, Mexico, a mountain about one mile from the town of Perote, and 70 miles northwest of Vera Cruz. It is 13,414 feet high. The English name is the Four Parts, or the Square Mountain. It is formed of basaltic porphyry.

Cog-wheel, a wheel with cogs or teeth. The pitch of such a wheel is the distance, measured along the pitch-line (explained below), between the centres of two successive teeth. The pitch-surface is an imaginary smooth surface between the tops and bottoms of the teeth, which is such that the velocity-ratio which would be produced by rolling contact with the pitch-surface of another toothed wheel would be the same as that actually produced by the action of the cogs. The pitch-circle (or pitch-line) of circular wheels is a section of the pitch-surface made by a plane perpendicular to the surface and to the axis of the wheel. The distance from the centre of the wheel to the pitch-line is the primitive radius, that from the centre to the crest of the cog being the true radius. The face of a cog is its outer surface, and the space between two adjacent teeth is the interdental space. Various kinds of toothed wheels are in use, such as the spur-wheel, the crown-wheel, and the bevel-wheel.

Coggeshall, England, a town in the county of Essex, 42 miles northeast of London, on the left bank of the Blackwater. The place was once famous for the manufacture of a kind of baize, celebrated under the name of "Coggeshall whites." The hamlet of Little Coggeshall is on the opposite side of the Blackwater, which is crossed here by an ancient bridge of three arches, said to have been built by King Stephen, who founded here also an abbey for Cistercians.

Coghetti, Francesco, frän-chës'kō kō-gët'tē, Italian painter: b. Bergamo 4 Oct. 1804; d. Rome 21 April 1875. He was a profound student of Raphael and is best known by his masterly frescoes in the basilican church at Savona. He adorned several Roman palaces with frescoes, and was knighted for his 'Condemnation of Saint Stephen.'

Coghlan, kög'lan, Charles Francis, American actor: b. Paris, France, 1841; d. Galveston, Texas, 27 Nov. 1899. He was educated for the bar in London, but went on the stage, making his American début in 1880 as Captain Absolute in 'The Rivals.' He took leading parts for many years, being a refined and capable impersonator of old school gentlemen. He wrote: 'Jocelyn'; 'Lady Barter'; and other plays.

Coghlan, Joseph Bullock, American naval officer: b. Frankfort, Ky., 8 Dec. 1844. Graduated in 1863 from the United States Military Academy, he at once saw service as ensign in the Civil War, in 1868 rose to be lieutenant-commander, and later served successively on board the Richmond, Saugus, Monongahela, and Indiana. In 1882 he was promoted commander, and in 1896 captain. As commander of the Raleigh of the Asiatic station from 1897, he took part in the battle of Manila Bay, 1 May 1898. On 2-3 May he commanded expeditions for the reduction of all Spanish batteries at the mouth of the bay, and on 7 July an expedition for the capture of Isla Grande, Subig Bay, Luzon. He was commissioned rear-admiral in 1902 and appointed to command the Caribbean squadron of the North Atlantic fleet.

Coghlan, Rose, American actress: b. Peterborough, Eng., 1853. She rose from humble roles in England to be leading lady, making her American début in 1872. From 1880 to 1889 she was Wallack's leading lady and since 1893 has "starred" in various American and English companies.

Cognac, kōn-yäk, France, in the department of Charente, on the Charente River, 22 miles west of Angoulême. It is situated on a hill crowned by an old castle. It is famous for the brandy which bears its name and which is exported to all parts of the world, chiefly to England, the north of Europe, and America. Some English houses, established here in 1780, began the manufacture of this brandy and developed its enormous trade.

Cogniet, Leon, lā-ôn kōn-yä, French historical and portrait painter: b. Paris 29 Aug. 1894; d. there 20 Nov. 1880. He studied under Guerin, obtained the Grand Prix de Rome in 1817, and became a member of the Institute in 1849. Many famous artists of a later day were pupils in his studio. The Church of the Madeleine in Paris contains a 'Magdalen' by Cogniet.

Cogno'vit, in law, a written confession given by the defendant that the action of the plaintiff is just, or that he has no available defense.

Cogs'well, Joseph Green, American librarian and bibliographer: b. Ipswich, Mass., 27 Sept. 1786; d. Cambridge, Mass., 26 Nov. 1871. He graduated at Harvard in 1806, and practised law for a few years in Belfast, Maine. He was a tutor at Harvard 1813-15, and after four years of study in Europe he was made professor of geology and mineralogy, and librarian at Harvard. In 1823, in connection with George Bancroft, he founded the famous Round Hill school at Northampton, Mass., the plan and methods of instruction being based on an examination of the best English and German systems of education. The school was discontinued in 1836. After a period of editorship of the New York 'Review,' Cogswell, with John Jacob Astor, Fitz-Greene Halleck, and Washington Irving, formulated the plan of the Astor Library. Cogswell was appointed its chief (1848), a place for which his remarkable attainments as a bibliographer eminently qualified him,—he went abroad to purchase books, and laid the foundation of the present collection with rare discrimination and economy. He presented to it his own fine collection of bibliographical works, and prepared a catalogue of its contents. Advancing years

COGSWELL — COHERER

caused his retirement in 1861. He was a frequent contributor to the leading reviews, such as the 'North American Review,' 'Blackwoods,' and the 'Monthly Anthology.'

Cogswell, Mason Fitch, American physician: b. Canterbury, Conn., 28 Sept. 1761; d. Hartford, Conn., 10 Dec. 1830. He was adopted by Samuel Huntington, president of the Continental Congress and governor of Connecticut, and graduated valedictorian at Yale 1780. He studied medicine with his brother James, at the soldiers' hospital in New York during the Revolution, and eventually became one of the best-known surgeons in the country. He was the first in the United States to remove a cataract from the eye, and to tie the carotid artery (1803). Mainly through his influence the first asylum for deaf-mutes was founded in this country at Hartford, and his daughter Alice was its first pupil. He was also a founder of the Retreat for the Insane in the same city.

Cohen, Alfred J. See DALE, ALLEN.

Co'hen, Jacob da Silva Solis, American physician: b. New York 28 Feb. 1838. He graduated M.D. at the University of Pennsylvania 1860, and in 1861 became assistant surgeon of the 26th Pennsylvania regiment, serving with the expedition to Port Royal and with the South Atlantic blockading squadron till January 1864. In 1866 he settled in practice in Philadelphia, and has made a specialty of diseases of the throat and chest. He has written many important articles and books on these topics, chief of which are: 'Diseases of the Throat and Nasal Passages' (2d ed. 1879); 'The Throat and the Voice' (1880); 'Treatise on Inhalation'; 'Croup in its Relations to Tracheotomy,' and since 1880, 30 other special studies, which have been published in the New York 'Medical Journal,' Philadelphia 'Medical News,' etc.

Cohen, Katherine M., American artist: b. Philadelphia 18 March 1859. Receiving her early training at private schools and Ogontz, Pa., she displayed a taste for art which was developed by study at School of Design, Pennsylvania Academy of Fine Arts, Students' Art League under Saint Gaudens, and six years in Paris schools. She has been engaged in sculpture since 1880 and her chief works have been portraits and bas-reliefs, decorative works and paintings of figure and landscape. Among her principal successes have been: Portrait of Gen. Beaver for Smith Memorial, Fairmount Park; 'The Israelite'; 'Priscilla'; 'Rabbi-ben-Ezra'; 'Romola'; 'Lorna Doone.'

Cohen, Mendes, American civil engineer: b. Baltimore 4 May 1831. Educated in private schools he soon displayed a bent toward engineering, and engaged in practical study at the locomotive works of Ross Winans, Baltimore, 1847-51. His active service became continuous, first at the engineer corps of the B. & O. R.R. 1851-5; then as assistant superintendent Hudson R.R. 1855-61; and, 1861-3, as president and superintendent O. & Miss R.R. (of Illinois). For some years he was engaged in the special service of Phila. & Reading, and became controller and assistant to the president of the Lehigh Coal and Navigation Company. In 1894 he was appointed by President Cleveland as member of the board to examine and report a route

for the Chesapeake & Delaware Ship Canal. In Baltimore he has long been honored with important civic trusts.

Cohen, Solomon, American lawyer: b. Georgetown, S. C., 15 Aug. 1802; d. Savannah, Ga., 14 Aug. 1875. At an early age he became a lawyer and he soon was classed with leading lawyers of his day and State, who directed the political thought and education of the people. In 1838 he settled in Savannah, where he maintained a leading position at the bar, attaining so deserved a popularity that he was sent to the Legislature, and assumed a prominent part in municipal affairs. He was one of the founders of the system of public education in the State. He was appointed postmaster of Savannah by President Pierce, and was continued by President Buchanan, holding the same position under the Confederate government. In 1866 he was elected member of Congress from the first district of Georgia, but was not allowed to serve.

Cohen, Solomon Solis, American physician: b. Philadelphia, 1 Sept. 1857. After a course of study at the Central High School in his native city, he graduated from Jefferson Medical College in 1883. From 1888-1902 he was lecturer in, and since 1902 has been professor of clinical medicine at Jefferson Medical College, and from 1889-1902 professor of clinical medicine and therapeutics at Philadelphia Polyclinic and College of Graduates in Medicine. He was elected president of the Philadelphia County Medical Society, 1898-9. His published writings include: 'Therapeutics of Tuberculosis'; 'Essentials of Diagnosis,' and he has edited 'System of Physiologic Therapeutics.'

Coherer, an electrical instrument, part of the receiver in Marconi's system of wireless telegraphy, consisting of a small glass tube about one and a half inches long, into which two silver plugs are tightly fitted. A small gap separates these plugs, and in this gap a mixture of nickel and silver filings is placed. Under ordinary conditions the resistance of this gap is too high to allow of any current passing from the local cell or battery; but under the influence of electric waves these filings instantly cohere, and the tube becomes a comparatively good conductor. Connected with this tube is a cell and a relay. By the cohesion of the filings the current from the cell is allowed to pass through the tube and actuate the relay. When once this is achieved, it becomes a very simple matter to make a bell ring or work a Morse siphon.

The filings, however, having cohered under the influence of an electric wave, remain in this condition unless shaken up. An automatic tapper, or discoherer, somewhat similar to an electric-bell tapper, minus the bell, is so adjusted as to tap the tube and shake the filings up, thus decohering them and bringing them to their normal condition, when they are again in a state to receive another impulse.

The oscillations set up by the transmitter at a distant station act on the vertical conductor or resonator which is connected with the sensitive tube at the receiving station, cohere the filings in the tube, and allow the local cell to actuate the relay. This, in its turn, causes the larger battery to pass a current through the tapper, or interrupter, and also

COHESION — COHOES

through the electro-magnets of the recording instrument. See WIRELESS TELEGRAPHY.

Cohesion, the force by which the various particles of the same material are kept in contact, forming one continuous mass. Its action is seen in a solid mass of matter, the parts of which cohere with a certain force which resists any mechanical action that would tend to separate them. In different bodies it is exerted with different degrees of strength, and it is measured by the force necessary to pull them asunder. According to Sikingen, the relative cohesive strengths of the metals are as follows:

Gold	150,955
Silver	190,771
Platinum	262,361
Copper	304,696
Soft iron.....	362,927
Hard iron.....	559,880

Cohesion in liquids is very much weaker, the parts being disjoined with much more facility; and in substances existing in the gaseous form it is entirely overcome, the particles repelling instead of attracting each other.

Cohesion in bodies is weakened or overcome by two general causes — by the repulsion communicated by heat, or by the attraction which may be exerted by the particles of one body on those of another.

Heat communicated to a solid body always diminishes the force with which the attraction of aggregation or cohesion is exerted; if the heat be increased to a sufficient extent the cohesion is so far weakened that the body passes into the liquid form; and if carried still farther, the attractive force is entirely overcome, repulsion is established between the particles, and the body passes into the gaseous state.

The same effects are produced by the exertion of that attraction which unites the particles of one body with those of another. If a liquid be poured on a solid, it often happens that their mutual attraction is sufficiently powerful to overcome the cohesion of the solid; its particles are consequently disunited, to combine with those of the liquid, and it entirely disappears. This forms the chemical process of solution (q.v.). A similar effect is sometimes produced by the chemical action of a gaseous body.

When these powers, whether of heat or of chemical attraction, are withdrawn, cohesion resumes its force, but with results which are different, according to the circumstances under which this happens. When the attraction of aggregation is suddenly and forcibly exerted, the particles are united, in general, indiscriminately, and according to no regular law. If a body which has been melted is suddenly cooled to a sufficient extent, it becomes solid, and forms a mass of no regular structure or figure; or if its cohesion has been suspended by the chemical attraction exerted by another body toward it, and if this attraction suddenly ceases to operate, the force of cohesion is resumed, and the solid substance appears in the form of a powder. This latter case forms the chemical operation denominated precipitation (q.v.). But if the force of cohesion is exerted more slowly the particles are united, not indiscriminately, but usually with regularity, so as to form masses of regular structure and figure, bounded by plane surfaces and determinate angles. This forms the operation of crys-

tallization; and such masses are denominated crystals (q.v.).

Cohesion Figures. When small drops of various liquids lighter than water, and slightly soluble in it, are allowed to fall on the surface of perfectly pure water, the drops form curious figures on account of the differences between the capillary tensions of the air surfaces of the liquids. (See CAPILLARITY.) These are called cohesion figures. They were investigated by the late Mr. Tomlinson, the results of whose researches are published in various papers in the 'Philosophical Magazine' since October 1861. Creosote, for example, forms a disk which sails about on the surface with a rapidly quivering motion. Ether, again, forms a circular figure composed of a central boss, surrounded first by a flat depressed ring, and then by a raised ring, the edge of which is waved. Mr. Tomlinson has observed many other liquids. The figures last for a short time, gradually disappearing as the drop becomes dissolved in the water. The slightest impurity in either liquid changes the figure by altering the superficial capillary tension of the liquid. Hence Mr. Tomlinson proposed to observe the figure as a test of the purity of certain essential oils. In applying the test it is necessary to have the water perfectly pure and clean, and Mr. Tomlinson has given special methods of cleansing the glass vessel into which distilled water is put. Mr. Tomlinson has also examined cohesion figures of fluids dropped on other liquids besides water, as coconut oil, castor oil, melted paraffin, etc.

Cohn, kōn, Adolphe, American educator: b. Paris, France, 29 May 1851. He was graduated from the University of Paris in 1868 and served as a volunteer in the French army during the Franco-German war from July 1870 to February 1871. In 1875 he came to New York and taught languages for some years, when his ability secured him a tutorship in French at Columbia University in 1882, in which he served as instructor for two years. He was instructor at Harvard 1884-5, and assistant professor in French 1885-91. In 1891 he became professor of Romance languages and literature at Columbia, which position he still holds. He is a singularly successful teacher, and many of his pupils hold posts of prominence. In addition to numerous contributions to literary periodicals, he has published: 'Voltaire's Prose' (with Woodward) (1897); 'Le Sage's Gil Blas' (with Sanderson) (1899).

Cohobation, an operation in which a fluid is converted into vapor by heat, and is then condensed, but instead of being collected in a separate receiver, as in distillation, it is made to flow back into the heated vessel. It is employed to produce a change in the fluid by continued heating, but more frequently to subject some substance to the action of a fluid without either loss of the latter or the necessity of adding fresh quantities of it.

Cohoes, kō-hōz', N. Y., city of Albany County, at the confluence of the Mohawk and Hudson rivers, and near the junction of the Erie and the Champlain canals, and on the New York Central and the Delaware & Hudson R.R.'s, nine miles north of Albany. The Mohawk River has a fall of over 70 feet at this point, and supplies great power, making Cohoes a very important manufacturing community.

COHORT — COIN

The Mohawk River is crossed by a dam above the falls, and the water is supplied to the mills and factories by means of canals. There were in 1900, 316 manufacturing establishments, capitalized at \$11,316,482, and producing goods to the value of \$11,636,130. The principal manufactures are hosiery and knit goods, foundry and machine shop products, paper boxes, lumber and planing mill products, patent medicines, saddlery and harness, printing and publishing, etc. The city is connected with Albany, Troy, and other neighboring cities by electric street railways. Cohoes was first settled by the Dutch, and for some time a portion of the city was included in the Rensselaer Manor. It was chartered as a city in 1870. Pop. (1900) 23,910.

Co'hort, a division of the Roman army, the tenth part of a legion, containing three maniples or six centuries. The number of men varied with that of the legion, the 10 cohorts always containing an equal number. When the legion numbered 4,000 men, the cohort consisted of 60 triarii, 120 principes, 120 hastati, and 100 velites, in all 400 men. The centurion of the first century of the first maniple of the first cohort was the guardian of the eagle or colors of the legion, and hence the first cohort was always regarded as superior in dignity to the others.

Cohosh, *kō-hōsh'* (*Cimicifuga racemosa*), also called black snakeroot, is a plant belonging to the crowfoot family (*Ranunculaceæ*). Besides this species there are about four others also called cohosh, herb-christopher, and rattlesnake herb, which are widely distributed from Nova Scotia and Anticosta, south to Georgia, westward to Missouri, and northward to British Columbia. It is an erect perennial herb growing in woods. The plant has powerful medicinal properties and is a valued remedy in rheumatism, epilepsy, etc. The blue cohosh (*Caulophyllum thalictroides*) is a powerful antispasmodic and emmenagogue. It is also a diaphoretic and diuretic, and has been used successfully in this country as an anthelmintic.

Coif (French, *coiffe*), the badge of serjeants-at-law, who are called serjeants of the coif, from the lawn coif which they wore under their caps when created serjeants. The cap worn by women of religious orders, usually white, and worn under the veil. The name is sometimes given to the small cap worn by monks who have the tonsure.

Coimbatore, *kō-īm-bā-tōr'*, or **Coimbetoor**, British India, a district in Madras presidency, with an area of 7,842 square miles. The country has on the west the range of lofty mountains called the Western Ghats; a continuation of which also bounds it on the north. On the east it is bounded by Salem and Trichinopoly, and south by Madura and Travancore, west by Malabar and Cochin. It is fertile, producing sugar, cotton, rice, and tobacco; and well watered by several rivers. The climate is very malarious in some parts. The principal towns are Coimbatore, Errood, and Carroor. In 1799, on the death of Tipu, and the division of his territories, Coimbatore was ceded to the East India Company.

Coimbatore, British India, city and capital of the district of Coimbatore, situated at the foot of the Western Ghats, on the river Noyel,

90 miles south of Seringapatam, 252 southwest of Madras. It has wide streets, is well built and well drained, has an agreeable climate, and is more suitable for the residence of Europeans than most Indian towns. It suffered much in the wars between the British and Mysore sovereigns. Pop. (1901) 52,968.

Coimbra, *kō-ēm'brā*, Portugal, capital of the province of Beira, on a hill above the Mondego River, here crossed by a stone bridge, 135 miles northeast of Lisbon. Its streets are steep and narrow, its manufactures confined chiefly to earthenware and combs, and its interest consists mainly in its historical associations. The place derives its name from the Roman Conimbria, traces of which lie to the south; it was held by the Goths, and from them passed to the Moors, from whom it was finally conquered in 1064, by Fernando the Great, aided by the gallant Cid. Coimbra was the capital of Portugal for about two centuries and a half from its erection into a kingdom in 1139, and many of the early kings are buried in and around the old town. Of the public buildings, the most noteworthy are the older of the two cathedrals, the Church of San Salvador, and the ruined Convent of Santa Clara; across the river is the Quinta das Lagrimas, "House of Tears," where Inez de Castro was murdered. The University of Coimbra, the only one in Portugal, was originally established at Lisbon in 1288, but was transferred here permanently in 1537. It has five faculties and some 900 students; attached to it are a museum, an observatory, a botanical garden, and a library of over 80,000 volumes.

Coin, Spain, city in the province of Malaga, 21 miles north of the city of Malaga. It consists of well-built houses, spacious and clean streets, three squares,—in the centre of the largest square is a handsome fountain. The chief manufactures are linen and woolen fabrics, esparto mats, soap, paper, hempen shoes, wine and oil. The exports are cattle, grain, and fruits. In the neighboring hills are marble quarries, and jasper of all colors. Pop. 10,000.

Coin. The coin of a nation is said to be the life-blood of its trade. The "Mint" is the place of its origin. Coinage is therefore a monopoly, possessed and exercised by all firmly established governments. The mint of the United States was authorized by Act of Congress 1792, and its general operations began in 1793. At that time the appliances of coinage were few and crude, the striking of coin being by the old screw hand press, and the annual output confined to narrow limits. It was not until 1836, when the mint was removed from Seventh Street, Philadelphia, to more commodious quarters at Chestnut and Juniper streets, that improved appliances were introduced. At that time the steam operated coining-press invented by M. Thonnelier, a Frenchman, was introduced, and greatly facilitated the process of minting. Twenty years later this press was remodeled and much improved, continuing in use for 14 years, when it was superseded by the perfected machines now in use. The introduction of the steam coining-press inaugurated the improvements which have made the mint of the United States one of the finest equipped mints in the world. From 1836 to the present time the progress of the mint has been largely experimental. New and improved machinery

COIN

has been added from time to time and improved scientific processes have been adopted. The humid assay process for determining the fineness of gold and silver was introduced in the year 1836. The platinum apparatus for the assay of gold was introduced in 1867. This was an English invention, and a great improvement upon the method formerly in use. Automatic machines for the separation of coin blanks into "standard," "heavy," "light," and condemned "light" pieces were introduced in 1877. Improved rolls for converting ingots into coin strips, as well as gas annealing furnaces, may be said to have completed the equipment of the mint.

The organization of the mint, under the original and subsequent Acts of Congress, and until 1873, provided for a director, located at the parent mint at Philadelphia, an assayer, melter and refiner, coiner, and engraver of dies, with a necessary subordinate clerical force, the assayer, melter and refiner, coiner, and engraver, being designated as "operative officers." The director was subject to the orders of the Secretary of the Treasury. After the creation of branch mints and assay offices the heads of such institutions reported to the director at Philadelphia. By the Act of 1873 the mint was reorganized, with a bureau at Washington, where the director was located. The resident chief officer at the mint was by that Act designated as superintendent, ranking with the chief officers of the mints at San Francisco and at New Orleans, and the chief of the assay office at New York. The chief officers of the branch mints and minor assay offices were designated as "assayers-in-charge," reporting to the director at Washington. The mint service is now under this reorganized form. The superintendents and the operative officers are appointed by the President and hold their official positions at his pleasure.

The processes of the mint can best be considered under the head of routine. The mint purchases at its counter all gold presented in value not less than \$100, providing the deposit is not too base for economical conversion into coin or fine bars. All deposits are made with the weigh clerk at the weigh room, who carefully weighs the same on the delicate balances, which are adjusted to show variations of one hundredth of a troy ounce. The weight is carefully recorded in the books of the weigh clerk and registrar of deposits, together with the description of the bullion and the name of the depositor, both officers being present and carefully noting the same. The deposit is then locked in a copper box and sent to the deposit melting room, where it is melted and cast in the form of a bar. From this bar the assayer cuts clips, weighing from 18 to 20 one hundredths of an ounce, two clips being taken, one from the upper side at one end, the other from the under side at the other end. These clips are assayed separately to determine the homogeneity of the metal. This assay determines the proportions of fine metal in the bar, and upon this assay the money value is determined and the depositor is paid. The loss of weight by melting is carefully noted and recorded. A slight allowance is made after melting to the melter and refiner and the weight so established becomes the true weight. As soon as the fineness of a day's deposits is reported by the

assayer, they are delivered to the melter and refiner, and by that officer sent to the refinery, where the silver is separated from the gold and the base metals eliminated wholly, only the precious metals being accounted for.

The next step in the conversion of bullion into coin is the assembling of the refined metal into "melts" of about 3,000 ounces to which sufficient copper is added to render the melted mass 900 parts fine, which is the standard fineness of United States gold and silver coin. When melted the metal is cast into ingots of the size proper for the production of the coin required. This alloy is rigidly tested by assay, and if found standard within the legal tolerance it is so declared, and the ingots are delivered to the coiner for conversion into coin. They are first taken to the rolls, "broken down," annealed, and delivered at the finishing rolls, where they are converted into coin strips of the requisite thickness for coin blanks. The strips are then taken to the cutting machines, where they are converted into coin blanks which go to the selecting tables for the elimination of imperfect pieces and fragments. The accepted blanks are then sent to the adjusting room, where, if gold, each piece is weighed, the heavy pieces being reduced by filing and brought within the limit of legal tolerance. If the blanks be silver they are passed through automatic selecting machines which separates them into standards, heavies, lights, within tolerance, and condemned lights. The blanks are next passed into a machine and "upset," or "milled," which process so raises the edge of the piece as to protect the work on the stamped coin from abrasion. The blanks are then annealed, treated to a dilute sulphuric acid bath, and cleansed and brightened, and when thoroughly dried are ready for the coining presses. These presses work automatically, the only hand action being to fill the feeding tubes. The pieces are automatically seized by conveyers and centered between the obverse and reverse dies within a collar a little exceeding the piece in diameter. The impact of the dies, brought together by the operation of a toggle joint, forces the metal to flow to the full diameter of the collar, which is grooved inside, and puts a fine reeding upon the edge of the coin. The finished coin is then automatically passed on, and is followed by others, the delivery for large coins being at the rate of 80 or 90 per minute. Dimes are struck at the rate of 100 and 120 per minute.

The standard, heavy, and light coins are then separately counted by gauge, and made into drafts of \$5,000 each, if gold, and drafts of \$1,000 each, if silver. As the standard weight of gold drafts of \$5,000 is 268.75 troy ounces, the standard, heavy, and light coins are mingled in due proportion to make that standard weight, no greater variation than 1/100 of an ounce being allowed. The standard weight of \$1,000 in silver dollars is 859.375 ounces, and of subsidiary silver 803.75 ounces, with a tolerance of 2/100 of an ounce. The perfected drafts are then weighed in the presence of the superintendent, enclosed in canvas bags, and delivered to that officer. The mint balances are adjusted to the troy pound (5,760 grains) which is the mint unit of weight. This weight is a duplicate of the troy pound established by a royal commission in England in 1758, reaffirmed in 1838. It is kept in a special safe at the Phila-

COINAGE

delphia mint. In order to secure an exact conformity in weight and fineness of United States coin, a fixed number of coins is taken from every delivery, sealed in the presence of the superintendent and the assayer, and deposited in a receptacle called "the pyx," each of those officers having a key, both keys being required to open the pyx. These reserved pieces await the assembling of the Assay Commission, annually appointed by the President to meet on the second Wednesday in February, when the pyx is opened and exhaustive tests of the weight and fineness of the contents are made.

Location and Equipment.—The mint of the United States is located on Spring Garden Street between Sixteenth and Seventeenth streets, Philadelphia. The construction is of light granite and of the Roman Ionic order. It has an interior ground floor space of 58,000 square feet. Its equipment consists of eight boilers of 1,200 horse power capacity, for heating, ventilating, and electric lighting. To avoid the transfer of power by shafting the machinery is chiefly operated by independent motors. The building is lighted by 4,000 incandescent and 16 arc lights. There are 51 telephones connecting the departments and various offices. A gas plant capable of delivering upward of 20,000 cubic feet per hour furnishes fuel for the melting, annealing, and assaying furnaces. The ventilating is by fans operated by attached motors. The spacious melting department is equipped with 13 gas and 3 coal heated furnaces, with power topping machines. The coining department has 23 coining-presses with an average capacity of 110 pieces of finished coin, each, per minute; 10 milling, or upsetting machines, each capable of an out-turn of an average of 500 milled blanks per minute; a full equipment of trains of break-down and finishing rolls; 8 strip annealing gas furnaces, and 1 furnace for annealing blanks; 8 automatic presses for cutting blanks from coin strips; 6 automatic weighing machines for the separation of blanks into standard, heavy, light, and condemned pieces, together with appliances for cleaning, whitening, and drying blanks after annealing. The assaying department is equipped with every known appliance for determining the fineness of gold and silver, both by the platinum and the humid processes. The refinery operates largely the acid process of separating, but it has a plant for refining by electrolysis, and the process has proved a success, considerably increasing the capacity of the refinery.

The engraving department provides all of the coin dies used in the mints of the United States. It has every facility for die-sinking, hubbing, and annealing the steel from which dies are produced, as well as a geometric lathe for transferring designs. The department for the manufacture of medals of a national character is in charge of the engraver, who provides the dies. The medal department is equipped with three hydraulic presses of the respective capacity for exerting a pressure of 1,100, 400, and 300 tons. These powerful presses are operated by electric motors. The machine shop has every appliance for the construction, or the assembling and finishing, of all machinery used in the mint. There are 20 steel-lined vaults for the storage of coin and bullion and for the use of the operative officers. One of these vaults has a floor-space of 5,200

square feet, with a storage capacity of 112,000,000 silver dollars. Another has a floor-space of 4,160 square feet. Six others have each a floor-space of 2,562 square feet. The basement vaults are built wholly independent of the enclosing walls, with a free passageway around them. The doors are massive, and provided with the finest locks procurable, to which time-locks are attached. More than 3,250,000 pounds of steel enter into the construction of these vaults. The vestibule is highly ornate, the corridor extending through the cross section from east to west is finished in richly variegated marble, and the main staircase is of white marble. The floors are of messanine, the symbolic panels in the vestibule of glass mosaic. The ceilings are finished in white and gold.

The cabinet, or museum, is in a spacious room at the head of the main staircase in the rotunda. It contains a fine collection of the coins of all nations, ancient and modern, a full line of medals of a national character, and many rare medals of foreign countries. There is also a fine collection of curios, many of them collected in distant lands. The working capacity of the mint considerably exceeds the national demand for its product. Congress has therefore authorized coinage for other nations at a fair remuneration. Pursuant to this authorization the mint has coined much gold and silver, as well as copper and nickel coin, for several of the South American and most of the Central American states. Prior to the annexation, the mint at San Francisco coined money for the Sandwich Islands. Admission to the mint is free to the public on every working day between the hours of 9 A.M. and 2 P.M. The building is patrolled day and night by an armed guard.

JOHN H. LANDIS,
Supt. United States Mint, Philadelphia.

Coinage, the process of converting an authorized alloy of the money metals into the circulable coin of the country. The metal is alloyed and cast into ingots of sizes suitable to the production of the denomination of the coins required. Thus, for the double eagles, our largest gold coin, the ingot is cast $12\frac{5}{8}$ inches in length, $1\frac{1}{2}$ inches in width, and half an inch in thickness. Such an ingot weighs about 80 ounces troy, of the approximate value of \$1,488. The ingots for the eagles are cast 11 15-16 inches in length, 1 2-16 inches in width and half an inch in thickness. The weight of such an ingot is about 62 ounces troy. The half eagle requires an ingot 12 inches in length, $\frac{7}{8}$ inch in width and 7-16 inch in thickness. The ingots are taken to the break-down rolls in drafts of about 50 ingots, where they are passed through the rolls several times, according as they prove more or less malleable. If passed through the rolls six times the dimensions of a double eagle ingot will be increased to $26\frac{1}{4}$ inches in length, 1 9-16 inches in width, and 7-32 inch in thickness. The broken-down ingots are then sent to the annealing furnace, heated by gas fuel to about 1,500 degrees F. and being laid singly upon a carrier traveling the whole length of the furnace, remain until the strips become a uniform cherry-red. They are then removed and plunged into a bath of cold water to remain until cool enough to handle. The strips are then wiped dry and passed on to the finishing rolls.

THE MANUFACTURE OF COINS AS CARRIED ON AT THE UNITED STATES MINT, PHILA., PA.

COINAGE

The next step will depend upon the condition of the metal. Should it retain indications of the hardness and springiness resulting to the breakdown process, it is subjected to a second breakdown by being passed three or four times through the rolls. The malleability of the metal being sufficient, the strips are taken to the finishing rolls or "rolls of precision." After being passed through these rolls four times the strips develop the required thickness and uniformity for the production of blanks. At this stage the double eagle strip attains a length of $47\frac{3}{8}$ inches, a width of $15\frac{5}{8}$ inches and is reduced to a thickness of 7-64 of an inch. For ease in handling the strips are now cut in half by multiple shears and delivered at the cutting presses, where test planchets are cut from several strips and weighed, to determine if the strip, when converted into planchets (coin blanks), approximates to standard weight. The cutting presses are automatic. The strip is seized by a grip and drawn under a steel punch working in a matrix cutting the planchets at the rate of 80 each minute. The planchets are next cleansed and sent to the selecting table where the imperfect pieces are separated from the perfect and the latter are sent to the adjusting room. The adjusting consists in the careful weighing of each blank separately to ascertain if it corresponds to the standard weight and legal tolerance, the latter being for double eagles and eagles $\frac{1}{2}$ grain per piece, and $\frac{1}{4}$ grain each for half eagles and quarter eagles. Pieces found in excess of legal weight and tolerance are reduced by filing the edges until they conform to the limit. Such pieces are placed by themselves and marked "heavies." Pieces a little less than the standard weight, but within the limit of legal tolerance, are placed in another receptacle and marked "lights." Those found of exact legal weight are placed in another receptacle and marked "standard."

The planchets so adjusted are then taken to the milling machines by the operation of which a protecting edge is raised on each piece. This edge is to preserve the face of the coin from abrasion. When milled the planchets are conveyed to the cleaning room where they are annealed until of a cherry-red and then treated to a bath of dilute sulphuric acid, by which process they are thoroughly cleansed and brightened. The annealing of the planchets after the milling process having prepared them for the stamping, when cleansed and brightened they are washed in boiling water, dried by riddling in sawdust, when they are ready for the coining press. It will be understood that the three descriptions of blanks, namely: "Heavies," "lights," and "standards"—have been kept separate throughout the processes, and are never mingled until the coiner makes up the drafts of finished coin for bagging. The planchets therefore go to the presses by those divisions.

The coining press used in all first-class mints is a wonderful exhibition of mechanical skill. Its frame is of cast-iron of several tons weight, with a central arch in which are placed the working parts. The frame combines stability and rigidity. The mechanism of the working parts is automatic. The setting of the dies is a work of precision and can be properly done only by a person, who, being a skilled mechanic, has reinforced his native ability by long experience. In order to set his dies properly he must

take into account the condition of the metal to be stamped, whether it be soft and ductile or hard and brittle. Upon these qualities of the metal depends the distance apart of the dies at the moment of their impact upon the planchets. The blanks are fed into a vertical tube of equal diameter, and when the press is in motion automatic fingers seize the bottom planchet by its periphery and carry it forward to a collar, a little larger than the piece to be stamped. The piece drops into the collar, and a toggle joint causes the dies to approach each other and exert a pressure of about 160 tons upon the soft planchet. The planchet, being ductile, is by this pressure made to fill the entire space within the collar, which is grooved, and imparts the reeding to the edge of the coin. The finished coin is automatically released and falls into a pan below, to be followed by other coins at the rate of 90 or 120 per minute. The first number relates to large gold coins and silver dollars, the latter to small gold and small silver coins. It should perhaps be stated here that while the essential processes in coining are the same in all modern mints the routine is not uniform. In the mint of the United States the coin after stamping is returned to the adjusting room and each piece weighed separately. The necessity for this arises out of the possibly defective rolling of the strip from which the blank is derived. The density of the metal varies somewhat, and there may be also defective sonority developed in the process of stamping. In order to secure sonorous coin it is sometimes the practice to ring every piece (this relates to gold coin and silver dollars), and if any fail to give the proper tone they are rejected and sent to the melting pot. The pieces which stand the test are then returned to the coiner for conversion into uniform drafts for delivery to the superintendent, or other officer authorized to receive and hold coined money of the government.

As a matter of law and regulation the coiner is required to make up gold coin into drafts of \$5,000 of the uniform weight of 268.75 troy ounces. As the weight of the pieces separately weighed are not uniform, though all within the limit of legal tolerance, the coin is separated by the adjusters into "heavies," "lights," and "standard." Gold coins may vary from $\frac{1}{4}$ of a grain in the half and quarter eagles to $\frac{1}{2}$ a grain in double eagles and eagles. The coiner takes "heavies," "lights," and "standards" in such proportions as will make drafts of 268.75 ounces and mingles them in the delivery pans. The drafts are then weighed, after counting the pieces in detail, and being found of the required weight, are set aside for final delivery. The drafts must not vary to exceed 1-100th of an ounce above or below the standard weight of \$5,000, stated in the foregoing. Before delivery to the superintendent the latter takes a good number of pieces at random from the proposed delivery and carefully weighs them. If found within the legal limit of tolerance the delivery is accepted; but if the weight of any piece proves it outside that limit the delivery is rejected, to be weighed, readjusted, and recounted. It is proper to say that such a necessity seldom arises.

The practice now is to adjust all silver coins, excepting dimes. Dollars are made in drafts of \$1,000 of the weight of 859.375 ounces. These

COINAGE

drafts are constituted of "heavies," "lights," and "standard," and the only variation from that standard weight is 2-100 of an ounce. Subsidiary silver coin is delivered in drafts of \$1,000, of a weight of 803.75 ounces, with an allowance of 2-100 of an ounce for half and quarter dollars, which are adjusted, and 1-100 of an ounce for dimes, which are not adjusted. It will be seen that all of the processes involved in coining money are works of precision, from the breaking down of the ingot to the issue of the perfect coin. All must be rigidly calculated, nothing can be left to chance. The presence of any of the base metals, as well as of the rare and valuable ones, may destroy the ingot for coinage. Arsenic lead and antimony cause most of the unworkability of the money metals, but this disability is lessening through the processes of advanced science.

Great advances have been made in the processes involved in coining as conducted in modern times. The substitution of the coining press operated by power for the hand screw press of olden times practically revolutionized the business. The introduction of automatic weighing machines for separating the blanks into "heavies," "lights," "standard," and "condemned," has simplified the process of adjusting. In fact the silver coins, with the exception of dimes, are now separated by the automatic weighing machines. The very great improvement in rolls for producing the coin strips from the ingot has made this new and rapid mode of selection possible. The draw-bench, made necessary to cure the defects of the rolls, has practically disappeared. Constant trying has produced rolls of such precision that the thickness of a coin strip can be regulated to the thousandths if required.

The automatic selecting machine in use at the mint of the United States at Philadelphia was invented and constructed by Seyesse, an Austrian, at Vienna. The blanks are fed into the machine through a vertical tube the size of the diameter of the blank. The feed is automatic and the pieces are conveyed into minute balances finely adjusted to grains, and by a complex and ingenious arrangement of parts are, according to weight, whether light, heavy, standard, or condemned lights; shunted into the conduits strictly according to their varying weights, and through these conduits, or ways, are delivered, each to its proper receptacle at the discharge end of the machine. The standard and the accepted light pieces are then ready for milling. The heavy pieces are adjusted by weighing on a delicate balance, and if found to exceed the legal tolerance are reduced by filing the edge of the piece. By this method the necessity for hand adjusting is minimized, and the rapid production of coin greatly facilitated. Other automatic selecting machines are employed in the mints of foreign countries, but have not been found so satisfactory as the Austrian machine, in this country.

One of the most difficult of the processes of coining has been the annealing process, because it is vital to the successful reduction of the ingot to the coin strip. Formerly the process was conducted in a furnace heated by wood fires. Much depended upon the fuel. Perfectly seasoned hard wood, preferably oak, was required for good work. In annealing gold strips in a

wood furnace the strips were enclosed in copper canisters, sealed to air tightness, and remained in the furnace about three fourths of an hour. Silver strips were sometimes subjected to the heat for an hour or more. In all annealing of strips in the wood-fire furnaces the strips were superposed unavoidably, and it was not always easy to determine when the draft reached a uniform cherry-redness. Delays, and refractory metal, were common with the old method of annealing. Besides, the method was the reverse of economical, owing to oxidation of the metal.

In substituting the gas annealing furnace for the wood-fire furnace the work of rolling the metal soon became a work of precision. A considerable saving of time was also effected. The gas annealing furnace for strips has a heating chamber 10 feet in length, 17½ inches in width, and 10 inches in depth. A score of hollow rolls, named "conveyers," mounted on hollow shafts of cast-iron, are so ribbed as to divide the face into several parts conformed to the width of the strips. These ribs separate the strips and prevent superposition. The gas burners enter the heating chamber at the bottom and are in sections, in order to secure independent control. Through these burners a mixture of gas and air is injected along the whole length of the chamber. The strips to be annealed are placed on the rolls at the entrance of the furnace, the rolls are rotated by worm wheels, and pass entirely through the chamber, to enter a hood at the discharge end of the furnace. In this hood the strips, now of a cherry-red, are met by a flame surcharged with gas to prevent oxidation. A spray of water is applied to the strips outside the hood to cool them before they reach the air. This prevents the oxidation of the copper with which the metal is alloyed. The process thus described occupies about six minutes, instead of the hour, or even more, by the wood-fire furnaces. The time required in annealing silver is about 20 or 25 minutes as to the larger denominations. Dimes, however, not being adjusted, and the coin strip being produced from the dollar ingot, require a more prolonged annealing. The improvement in annealing has made it possible to produce from the ingot strips as high as 83 to 96 per cent of standard blanks, and blanks within the limit of tolerance, suitable for coining. This high percentage of good blanks is undoubtedly due to improved annealing and rolling. It is a higher percentage than has ever been secured when the defects in annealing and rolling were in part remedied by the draw-bench. As that machine is still employed in mints not strictly up to date, it may not be amiss to say, that in principle the draw-bench is a wire-drawing machine. As under the old mode of developing the ingot into the coin strip the ductility of the strip was not uniform, some parts being more refractory than others, and hence not reduced to a uniform thickness by the rolls. It was found necessary to pass the strips through a rigid die. The strips were then pointed so as to be firmly gripped by the nippers of the draw-bench which, retreating, drew the strip through the rigid die and gave it a uniform thickness, now imparted by rolls of precision without wasteful annealing. This improvement not only works a reduction of waste, but saves a delay between the finishing rolls and the cutting presses.

COIR — COKE

The preparation of the strips, the cutting of the blanks and the striking of medals is, at the mint of the United States, part of the coiner's duty. Medals may be of gold, silver, copper, or alloys of copper. The strips are rolled to the required thickness, which is usually with reference to the diameter of the proposed medal. The strips are then conveyed to the cutting press of great power and converted into blanks, which are annealed and placed between the dies of a hydraulic press capable of delivering a blow of from 300 to 1,100 tons. Nearly all medals of a national character require from three to six blows, owing to the high relief of the design and the sluggish flow of a large quantity of metal. Medals three inches in diameter require a press of higher power, and must be annealed after each blow until the finishing blow is delivered. The process of medal striking is therefore necessarily slow. Small medals of low relief may be struck by an ordinary coining press. Gold and silver medals of a national character are, respectively, of metal practically fine.

The processes of coining are of such precision that seldom a single piece in a million pieces will be found beyond the legal tolerance of $1\frac{1}{2}$ grains for silver and from $\frac{1}{4}$ to $\frac{1}{2}$ grain for gold.

JOHN H. LANDIS,

Supt. United States Mint, Philadelphia.

Coir, kīr, the outer coating of the coconut, often weighing from one to two pounds; when stripped off longitudinally it furnishes fibres from which are manufactured matting, bagging, sails, ropes, and cables. The general preparation is simple; after being soaked for some months in water the fibrous coats become soft; they are then beaten to remove the other substances with which they are mixed, which fall away like sawdust. The fibres thus cleaned are ready for being spun into long yarns, woven into sailcloth, or twisted into cables. Cordage made of this material rots in fresh water and snaps in frost, but from the fact of its being strengthened by salt water, and its extreme buoyancy as compared with hemp cables, floating as it does in water, and also its great strength and elasticity, it is preferable in many respects to ropes of hemp. It has been proposed to employ it in the construction of deep-sea telegraphs, as being much cheaper and lighter than gutta-percha.

Coire, kwär, or **Chur**, Switzerland, capital of the canton of the Grisons, on the rivers Plessur and Rhine. It is irregularly built, and possesses many houses in the ancient style of architecture. The most remarkable buildings are the old Romanesque cathedral, partly dating from the 8th century, and the old Episcopal palace. Adjoining this is a lofty tower believed to be of Roman origin. Among modern buildings are a Protestant church, government buildings, and a hospital. Not far from Coire the Rhine begins to be navigable for small vessels. Until 1498 Coire was a free imperial city, but at that time came under the government of the bishop, who was under the Archbishop of Mentz. After having been repeatedly in the hands of the Austrians, French, and Swiss, in 1802 it was definitely united to the Swiss republic. Pop. 9,500.

Coit, James Milnor, American educator: b. Harrisburg, Pa., 31 Jan. 1845. He graduated

at Hobart College 1865, and was manager of the Cleveland Tube Works 1873-5. In 1876 he became master in natural sciences at St. Paul's School, Concord, N. H., and is now (1903) acting head master there. He is a member of the leading scientific societies of the country, and has published: 'Manual of Chemical Arithmetic' (1886); 'Treatise on the X-Rays and Their Relation to the Medical and Surgical Sciences' (1897); 'Liquid Air' (1899).

Coit, Stanton, American lecturer on ethics: b. Columbus, Ohio, 11 Aug. 1857. He was educated at Amherst and Columbia colleges, and Berlin University, and has for many years lived and lectured in London, England, where he is chairman of the West London Ethical Society. He has published in German and Dutch, 'The Ethical Movement in Religion'; in English, German, and Dutch, 'Neighborhood Guilds.'

Cojutepeque, Central America, a town in the republic of Salvador, and on the direct route between the town of San Salvador and San Vincente. There is a lake of same name at some miles distance, the fish of which are often cast ashore dead in considerable quantities. Pop. 5,000.

Coke, kōk, **SIR EDWARD**, English jurist: b. Mileham, Norfolk, 1 Feb. 1552; d. Stoke Pogis 3 Sept. 1634. He was educated at Trinity College, Cambridge. From the university he went to London, and entered the Inner Temple. He pleaded his first cause in 1578, and was appointed reader of Lyon's Inn, where his lectures were much frequented. His reputation and practice rapidly increased, and he was placed in a situation of great respectability and affluence by a marriage with a co-heiress of the Paston family. He was chosen recorder of the cities of Norwich and of Coventry; was engaged in all the great causes at Westminster Hall, and in the 35th year of Elizabeth chosen knight of the shire for his county, and speaker of the House of Commons. In 1592 he became solicitor-general, and soon after was appointed attorney-general. He acted the usual part of a crown lawyer in all state prosecutions; and one of the most important that fell under his management, as attorney-general, was that of Essex, which he conducted with great asperity. Soon after the accession of James I. he was knighted. The celebrated trial of Sir Walter Raleigh followed, in which Coke displayed a degree of arrogance to the court, and of rancor and insult toward the prisoner, which was universally condemned at the time, and has been deemed by all posterity one of the greatest stains upon his character. On the discovery of the gunpowder plot he obtained great credit by the clearness and sagacity with which he stated the evidence; and in 1613 he succeeded to the important office of chief justice of the Court of King's Bench, but was in much less favor with James than his rival Lord Bacon. He was, in fact, too wary and staunch a lawyer to commit himself on the subject of prerogative; and as his temper was rough, and his attachment to law truly professional, he could scarcely forbear involving himself with a court so notorious for arbitrary principles as was the English during the reign of James. The honorable zeal which he displayed in the execrable affair of Sir Thomas Overbury, and in the prosecution of

COKE

the king's wretched minions, Somerset and his countess, for that atrocious murder, made him enemies; and advantage was taken of a dispute, in which he erroneously engaged with the Court of Chancery, to remove him, in 1616, both from the council and his post of chief justice. His real offense, however, was a refusal to favor the new favorite Villiers in some pecuniary matter. Coke was reinstated in the council in 1617, and actively engaged in prosecutions for corruption in office, and other crimes of a nature to recruit an exhausted treasury by the infliction of exorbitant fines. On the accession of Charles I. he was nominated sheriff of Buckinghamshire, in order to prevent his being chosen member for the county, which, however, he represented in the Parliament which met in 1628. The remainder of his career was highly popular; he greatly distinguished himself by his speeches for redress of grievances; vindicated the right of the Commons to proceed against any individual, however exalted; openly named Buckingham as the cause of the misfortunes of the kingdom; and, finally, sealed his services to the popular part of the constitution, by proposing and framing the famous "Petition of Rights," the most explicit declaration of English liberty which had as yet appeared. This was the last of his public acts. His principal works are: 'Reports,' from 1600 to 1615; 'A Book of Entries' (1614); 'Institutes of the Laws of England,' in four parts; the first of which contains the commentary on Littleton's 'Tenures'; the second, a commentary on Magna Charta and other statutes; the third, the criminal laws or pleas of the crown; the fourth, an account of the jurisdiction of all the courts in the kingdom; 'A Treatise of Bail and Mainprise' (1636); 'Reading on the Statute of Fines, 27 Edward I.' (4to); 'Complete Copyholder' (1640).

Coke, Thomas, first bishop of the Methodist Episcopal Church in the United States: b. Brecon, South Wales, 9 Sept. 1747; d. at sea 2 May 1814. He was educated at Oxford, and entering the ministry of the Established Church, obtained a curacy at South Petherton. Sympathizing strongly with the Methodists, he sought an interview with Wesley, which resulted in his joining that society, and being appointed to London. He rendered valuable assistance to Wesley in procuring what was called the deed of declaration, which provided for the settlement of the Methodist chapels in the connection, and restricted the conference to 100 of the preachers and their successors forever. He was appointed president of the Irish conference in 1782. Wesley set apart Coke by ordination as bishop of the Methodist Church in America, and gave him authority to ordain Francis Asbury to the same office as joint superintendent. In 1784 he arrived in New York, and proceeded on the 27th to ordain Asbury a bishop, and as such they were duly accredited as the joint superintendents of the Church in America. In company with Asbury he traveled, visiting the different conferences, until June 1785, when he returned to England, and visited Wales, Scotland, and Ireland. Subsequently he returned to America. The first mission which he established was in the West Indies, in 1786, whence, after visiting the several islands, he went to South Carolina

and engaged again in the regular work of the episcopacy. After traveling through the States, he embarked from Philadelphia for England in 1787. He revisited the West Indian and other American missions again and again, crossing the Atlantic 18 times in all. He was a prolific author and published: 'Commentary on the Holy Scriptures' (1803-7); 'Life of Wesley' (1792); 'History of the West Indies' (1808); etc.

Coke.—*Introduction.*—One of the most important fuels of to-day is coke. It has influenced to a greater extent than any other one fuel the immense advances made in the iron and steel industry of the present time. The immense production of pig iron is due in a great measure to its peculiar adaptability to the special requirements of the blast furnace. Its manufacture has influenced many millions of dollars invested in the development of its by-products, and from these by-products have been developed, especially in Continental Europe, many important industries. Tar is the raw material in the aniline dye and briquette industry, as well as others of great importance; from the gas, light, fuel and oils are obtained, and from the ammonia, sulphate, the anhydrous and aqua ammonia utilized to such a large extent in refrigerator plants. The present is an "era of coke," as well as of iron, steel, and electricity, for without this wonderful fuel the others would hardly have been possible.

Definition.—Coke is the product remaining from the dry distillation of bituminous coal.

(a) Analysis of sample as received.

Discovery and History.—The exact date of the discovery, of the beginning of coke manufacture is not clear. Coke is reported to have been an article of commerce in the Chinese province of Hunan some 2,000 years ago. As far as is known, the coking or "charking" of coal in Europe was an offshoot of the charcoal industry that flourished extensively in the middle ages. Coke was made in Germany in 1584, at the Hohenbuechen mines in the Harz, by Duke Julius von Braunschweig-Lüneberg, and at about the same time the master of the Anhalt mint, Daniel Stumpfelt, made a similar discovery. It appears that in both in-

COKE

2. By-product Coke Ovens. Semet Solvay System.
3. Bee Hive Coke Oven.

COKE

stances the coke was desired for use as a smokeless fuel, rather than for iron smelting, a use that developed later on. In England a patent for the "de-sulphurizing" of bituminous coal was granted to the Dean of York in 1590, and in 1619 Dud Dudley, an ironmaster of Worcestershire, was successful in making coke.¹ Up to this time the coke appears to have been made in the same way as charcoal, namely by burning in a mound or "meiler," the coal lumps being so piled as to leave draught openings and the whole covered with coal dust or earth. This primitive method gave place to a pit dug in the ground, or to a walled enclosure, into which the coal was piled, and later into a covered structure known as the "bee-hive oven," so-called from its shape. Such an oven was patented by Sir William St. John and others in England in the year 1620, particular mention being made of the use of the coke so made in manufacturing iron or steel. The bee-hive oven did not come into extended use in England until about 1735, when Abraham Darby operated a blast furnace at Colebrookdale, Shropshire, with coke, an example soon followed by others. This innovation was hastened by the increasing scarcity of wood for charcoal, which was the fuel first used for iron smelting. In France, Gabriel Jars, who had visited the English iron-works, is reported to have introduced the use of coke at the iron works in Sainbel. In Germany, Prince Wilhelm Heinrich made coke in closed muffle-ovens of peculiar design, at Sulzbach near Saarbruecken, in 1767, and with it made, it is stated, the first coke-smelted iron on the Continent, at the Fischbacher furnace, near Sulzbach.*

Bee-hive ovens of the English type were built in rows or batteries, both for convenience in operation and to save the heat radiated from one to another, instead of to the atmosphere. Later, modifications were made in the design of the oven, to improve its thermal efficiency and to cheapen the operation. These gave rise to the elongated shape instead of the round or square section, and the retort type of oven was thus gradually developed. The Belgian oven is typical of this form. In it the coking chamber was from 20 to 30 feet or more in length, 5 or 6 feet high, and 18 to 30 inches wide, closed by movable doors at either end, and the coke was removed by a pushing ram which forced out the coked mass as in the present form of by-product oven. This oven was heated by the gas from the coal, which burned in vertical or horizontal flues built into the walls separating adjacent ovens, air being supplied by ducts from the top, and draught from a stack located at one end of a battery of such ovens, connected with them all by an underground flue. Ovens of this general type were constructed by Rexroth, Coppée and Smet about 1857-60. In 1856, however, Knab was experimenting with a closed retort oven, externally heated, from which he obtained both coke, and by-products, at Comentry, France. A modification of this oven was built by Carvès, and later, by Huessener, who built a plant at Gelsenkirchen, Westphalia, in 1881. At the same time, an experimental

plant of ten ovens was built at Wattenscheid, Germany, by Otto, the two last mentioned being of the true by-product type. Thus, while the origin of the by-product oven may be conceded to the French experiments of Knab, the development was due to Germany. The Wattenscheid experiments gave rise to the type of oven known as the Otto-Hoffmann, since widely extended, particularly in Germany. The modification of the Knab-Carvès oven by Simon, known as the Simon-Carvès oven was of the by-product type, and was further developed by Semet, a Belgian, who in 1881 took out a patent for the oven known as the Semet-Solvay.*

In the United States the beginning of the development of the coke industry dates about 1810-1813. For the same reason that England was forced into its manufacture so was America. The Pennsylvania Society for the Promotion of Internal Improvements about this time sent an expert to England to study developments in the Mother Country in the person of W. Strickland. This occurred about 1825.

Mixtures of charcoal and coke were tried, and in 1835 in Pennsylvania a premium of a gold medal was offered to the person who would manufacture in the United States the greatest quantity of iron from the ore during the year, using no other fuel than bituminous coal or coke, the quantity to be not less than 20 tons. Results were not satisfactory, probably due to the poor quality of the coke, possibly through selecting a poor coking coal, or in the method of blast furnace practice.

Not until 1856 was its use augmented to any great extent, but at this time there were established in Pennsylvania alone 21 furnaces in blast on coke. A gradual increase in its successful use was made during the period from the use of Connellsville coke up to the year 1880. At this point the growth was extremely rapid, and its effect of increasing the iron output of the world most vital.

Methods of Manufacture.—Coal was first coked in heaps or mounds in the open air, this being a copy of the charcoal burners, and although resulting in a first class quality of coke was an extremely wasteful method of production. It consisted in arranging rectangular heaps or mounds with longitudinal, transverse and vertical flues to obtain a draft, sufficient wood having been distributed in the mass to produce ignition. The mound was ignited and the fire allowed to spread to the whole mass. After the gaseous matters had been expelled, which was determined by experience and controlled by the flame, the mound was partially smothered by fine coal dust, the final operation consisting of the application of a small quantity of water, which permeated the whole mass. The application of the water tended to develop a coke with few cells, and under proper management a low moisture. The yield of coke was in the neighborhood of 55 to 60 per cent, the loss being 40 to 45 per cent of the coal.

The second advance in manufacture was that of inclosing the mound in a furnace, thus utilizing to some extent the heat passing off from the coal. This form of manufacture was termed the "Bee Hive Oven," and finally resulted in having a series of ovens, utilizing the

¹ "Gluckauf," 1905, p. 876.

Durre, 'Den Neuren Koksofen,' p. 54.

COKE

heat on three sides of the oven and the heat of the escaping gases, to assist in coking. There was also a development in this form of oven which endeavored to throw down the solid constituents of the escaping gas in the form of tar, but the methods were, comparatively speaking, very crude, and resulted in saving but little of the 40 per cent unaccounted for.

About 1881-1882 two forms of ovens appeared, which, since that date, have been developed to such an extent that but 10 to 15 per cent of the calorific efficiency of the coal is lost. In America to-day there are two standard types of ovens, the bee hive and the by-product, both of which will be explained more in detail a little later.

Chemical and Physical Qualities.—These two qualities of the coke do not seem to hold much of any relation to each other—that is, the coke may have a fairly good analysis, and yet, if its physical qualities were below the standard, it would be useless for the metallurgist.

As to the theoretical reason for the coking of the coal, there are several theories, and that held by M. Lemoine is presented but the question is still very much undecided. Lemoine comes to the conclusion that there is a substance which he calls "Carbene," which determines the coking quality of coals. This substance he claims resembles a "fat coal." It is black, solid, friable, with a tendency towards crystallization, and is of the formula $C_{22}H_{14}O_5$.

Carbene, he says, has the property of adhering to solid bodies and spreading itself over their surface to an extent which is unknown in any other body. When a large amount of coal is subjected to distillation, as in a coke oven, the carbene may be driven from one part of the heated coal to settle itself upon the cooler portion of the mass, and thus to increase the agglutination of this part. This process may continue throughout the entire thickness of the mass until the coke is formed.

M. Lemoine claims that laboratory experiments have shown the possibility of transforming a non-coking coal into a good coking coal by means of the addition of 2 per cent of carbene. In one coal tested, which had 10 per cent volatile, the yield was 93 per cent. In conclusion, he claims we may therefore hope to produce good coke from coals which have hitherto been considered non-coking coals, and further experiments in this direction are being carried on.

The physical characteristics of a coke are of far greater importance than its chemical characteristics. Hardness is exceedingly important, and porosity is of the greatest importance. Certain coals in the coking operation, in giving off their volatile ingredients, produce in the viscous mass a greater amount of cellular structure than others. According to Fulton, good coke has a hardness of body of two to three. Condensed coke does not mean great hardness, but, on the other hand, means softness.

An important point which goes to prove the extreme adaptability of coke in blast furnace and lime kiln practice is the fact that, due to its cellular condition or porosity, the heat can be more readily prepared for combustion, and con-

sequently after it has in its descent reached the zone of combustion it is in the most perfect state possible for such action, and yet, due to its hardness, it has held its form and sustained the immense mass above it without being crushed, thereby allowing the highest per cent efficiency for blast.

Another consideration is that in equal quantities of anthracite coal and coke from the calorific point of view, the mass or volume of space occupied by coke is much greater than that of coal; hence, it can distribute its heat to a greater mass of burden than the coal and avoid that concentration of an excessive heat applied at one point when using anthracite coal in order to obtain the heat necessary for the action throughout the mass.

Economical and Commercial Consideration of Coke Manufacture.—These features of the consideration should not be considered independently. As stated previously, the waste product from the bee-hive method of producing coke to-day is enormous; not alone is part of the coal utilized in the coking operation, but all the gases and volatile matters passing out of the furnace contain material of immense value.

The construction of the by-product oven of to-day requires in its management a large amount of chemical and metallurgical skill. The problem of marketing the by-products is an important one and requires great familiarity with the arts of manufactures into which the by-product enters, since it is only by the preservation of these markets and the maintenance of fair prices for the products that the continued growth of the by-product oven is possible. A most conservative policy is essential to the industry. This is especially the case on account of the peculiar conditions surrounding the tar market, for from one ton of coal 60 to 100 pounds of tar is produced. There are great fluctuations in the supply of and demand for tar, and in case of an over supply there is no resource but to burn it as fuel. Moreover, there are relatively few industries in which tar can be disposed of in large quantities, especially in the United States, at the present time.

Among the industries for its utilization are the following: The saturation of paper or felt with tar for roofing purposes is an industry of considerable importance. As a fuel in combustion engines, by-product tar may be used as successfully as petroleum oil. Upon the products of the distillation of tar various industries are dependent. The utilization of pitch in the manufacture of briquettes is comparatively new in this country, but is destined to become of great importance, particularly in working up into valuable form the anthracite culm piles of Pennsylvania and the breeze of coke plants.

Plants have recently been installed in Scranton, Detroit and Montreal for the manufacture of briquettes. Tar macadam roads, made with regular foundation and an upper layer of three inches of a mixture of fine spawls and a certain grade of pitch, make a pavement perfectly impervious to moisture.

The distillate from tar has many uses, the most common being the well-known one of creosoting railroad ties. Railroad men are convinced, from long continued experience, that

COKE

no other method of treating ties to preserve them is as satisfactory as creosoting with coal tar distillate which must have a high content of naphthalene. Large quantities are used for making lampblack. As the consumption of pitch for briquetting purposes increases, which requires the distillation at a high temperature, anthracene will be produced in large quantities and will be shipped to Europe for alizarine manufacture.

Another branch of the by-product industry is the recovery of aromatic oils from the gases. Of the 10,000 cubic feet of gas produced from a ton of coal, 6,500 cubic feet are required in the coking process. This gas contains on an average 0.75 per cent of benzene and its homologues. The heat value of this gas is affected only slightly by the removal of the benzene. By washing gas with petroleum or coal tar oil, a benzolized oil containing 2 to 3 per cent of benzene is produced, and by distillation of crude benzene, light oil is obtained.

Only slight quantities of impurities, carbon disulphide, hydrogen sulphide, thiophene and naphthalene are found to be present, and purification and redistillation furnish a benzene 100 per cent pure, and suitable for nitrifying and converting aniline.

From the oil which is with the pitch (the result of the distillation of crude coal tar) is obtained anthracene. From creosote oil are obtained naphthalene, carbolic acid, and other homologues. Carbolic acid is the base of picric acid, which is the main ingredient of the latest high explosives, as English Lyddite, French Malenite, the Japanese Shimose powder, and our own Maximite. Carbolic acid, as is well known, is used very largely as a disinfectant. Yet all these uses thus far developed in this country will not consume any important part of the country's production of tar, or offer any material relief to the responsibility of those interested in the uses of tar products. So America must continue to look across the water for the supply of most of these articles until there have been many failures and much time and money expended in experimenting.

The by-product ovens are the leading producers of ammonia in the country, and this crude product forms the raw material for refined ammonia products, and also furnishes a supply for the manufacture of soda by the ammonia process. Ammonia is also being used for the manufacture of explosives, and for the production of the refined aqua ammonia which is largely consumed in refrigerator machines, either as aqua ammonia or anhydrous ammonia. Sulphate of ammonia, which forms the main ammonia product of the German coke oven, is still being imported into this country, although the production of sulphate from the by-products of coke ovens here is rapidly increasing. This form of ammonia is, of course, mainly consumed in the manufacture of fertilizer. The consumption of fertilizer is growing in this country, especially in the South, and it has been demonstrated many times in Continental Europe, where the subject has been studied, that sulphate of ammonia is the most valuable form of nitrogen or plant food that is on the market. Commercially speaking, therefore, the by-product oven cannot have a healthier growth

than is justified by the industries that consume its by-products.

The Bee-Hive Oven.—The type of this oven is as shown in the sketch. It is 12 to 13 feet in diameter, with a 7 to 8 feet height of dome above floor level, lined with silicious brick backed with concrete or masonry. The charging hole is on top, and the oven door slightly higher than the level of the charge, in order to avoid waste.

Various systems have been established to utilize the waste gases and heat of the coking operation, either by surrounding the furnace with ducts, or utilizing the heat in an adjoining plant. All these steps in the progress of development tend toward the by-product oven, but more particularly is it true when it is the aim to save the by-products.

At the close of 1905, practically 89 per cent of the coke in the United States was manufactured in Bee-Hive ovens, due to the non-available market for the by-products, and the lack of supply of good coking coals. The cost of erecting a Bee-Hive oven is very small in comparison with that of a by-product oven, hence the commercial policy of replacing the Bee-Hive oven with a by-product oven as fast as the market conditions demand the by-products.

The By-product Coke Oven.—A plant of one hundred ovens has been taken for explanation as applying the principles underlying by-product oven practice to-day in the United States.

The ovens are arranged in two groups or batteries of 50 ovens each. Each oven is an air tight retort, consisting of a rectangular chamber 43 feet 6 inches long, 17 inches wide, and 6 feet 6 inches high. The ovens are placed side by side, and are supported on a steel structure, consisting of light I-beams, running the length of the battery, which rest on cross girders supported by steel columns. The construction allows the brick work to be inspected at all points. The primary object, however, is the uniform distribution of fuel gas to the combustion chambers for heating the oven retorts. The retorts are separated by hollow walls, which are divided into 10 compartments, each compartment containing 4, preferably vertical, flues. Alongside this chamber, and directly under the vertical flues above referred to, are 10 combustion chambers. The gas supply to each of the chambers is controlled independently, and a uniform heat is maintained throughout the entire length of the oven. The air for combustion is admitted through an opening in the wall between the air and combustion chambers. The air is heated to 1,800 degrees F. by a pair of regenerators, placed together under the centre of the battery and running its entire length. A vertical flue conducts the air from the regenerator to the air-chamber under the oven.

The well known Siemens principle is used in operating the air regenerators, with reversals every 30 minutes. The fuel gas is reversed at the same time as the air by means of a suitable valve; but the gas is not regenerated. The gas unites with the hot air in five combustion chambers, ascends through the vertical flues to a horizontal flue above, through which it passes and descends through the five chambers in the

COKE

other end of the oven, hence through the air chamber and vertical flue connection to the regenerator, and through the reversing valves to the stack. The regenerators are built entirely independent of the oven structure, so that their expansion does not affect the oven brickwork.

Coal Handling.—A steel coal storage bin of a capacity equivalent to about two days coal consumption is placed between the batteries. The coal is elevated to the bin from a hopper placed under the coal receiving track, by a belt or other type of conveyor. A coal larry of 8 tons capacity runs on a track on the top of the batteries and under the coal bin. The larry consists of a long narrow bin with 8 spouts in the bottom, through which the coal is run into the oven retort through holes in the top of it, and is leveled by means of a bar worked through a small opening in the doors at the ends of the oven. The larry is operated by an electric motor and receives its load of coal from the storage bin, under which it passes. A very dense metallurgical coke can be produced, and the output of an oven largely increased by compressing the coal into a mold slightly smaller than the retort and charging the mass through the oven door.

Coke Handling.—Upon the completion of the coking process, the oven doors are raised, and the mass of 6 tons of coke is pushed upon a movable platform by means of a ram. The pushing ram, as well as the machine on which it is mounted, are operated by electric motors. The coke after being pushed upon the platform, is quenched and allowed to cool. The platform is then tilted by an electric motor, and the coke slides off into cars, which run on a track at the back of the machine.

Gas Mains.—The gas distilled from the coal during the coking process is conducted to the condensing house by two independent systems of mains. These mains run on top of the battery the entire length—one on each side. Each oven is connected to each main by a vertical pipe and valve. During the first part of the process, the rich gas is taken off through the rich gas main. The valve to this main is then closed and the balance of the gas is taken off through the poor gas main. When the coking is completed, the valve to the poor gas main is closed, disconnecting the oven from both mains.

Condensing Plant.—The gas leaving the coke ovens is divided into two fractions, viz., the first fraction of "rich" gas, which is sent out as illuminating gas, and the second fraction or "poor" gas, which is used for heating the ovens. The cooling of the gas and the removal of the tar and ammonia are done in the usual apparatus, hence it is not necessary to discuss it here in detail. Both the rich and poor gases are treated in the same manner.

The rich gas when freed of tar and ammonia leaves the condensing plant and passes into the purifying plant, and from there into a large gas holder for illuminating gas, from which it goes into the city. The poor gas, after being treated in the same manner as the rich gas, leaves the ammonia washers and passes through two benzol scrubbers. Here it is mixed with producer gas, when necessary, and carried to the ovens for heating. The benzol extracted from the poor gas is then transferred to the rich gas, so as to increase its candle power.

The tar oil by which the gas is washed, runs first from a tank through the second benzol scrubber into another tank. From here it is supplied by a pump into the first benzol scrubber. The tar-oil enters the tank with about 5 per cent of benzol, and finally leaves the washer with about 15 per cent of benzol. It is collected in another tank. From here it is fed by a pump into a still, in which the benzol is reduced again to about 5 per cent. The exhausted oil collects in another tank. From here it is taken by a pump through the oil cooler in order to be again supplied to a tank for a new absorption.

A small additional plant is needed, by which a small percentage of the oil is revived, in order to keep it active for benzol absorption. This consists of a simple tar still and condenser, in which the tar-oil is freed from most of the naphthalene and other hydrocarbons incidentally absorbed. The presence of an excessive percentage of them in the tar-oil would interfere with a complete benzol absorption.

The benzol vapors which are driven off in the still are carried into the rich gas system by means of a gas current coming from the pressure side of the rich gas condensing plant. This greatly facilitates the distillation of tar-oil passing through the still. The mixture of the gas and benzol vapors then passes through a pipe, preferably to the inlet of the exhausters of the rich gas condensing plant. In this manner, the vapors do not come in contact with a large body of tar, which would be liable to absorb a part of the benzol. It is unnecessary to describe here the details of the benzol distilling plant. A great number of these are in operation in connection with German by-product plants.

Coke Oven Brick.—Under construction the principal feature of an oven is in the brick used. What is termed silica brick is now being used, and probably will be the standard coke oven brick of the future. It has been determined that the fusing point of a silica-alumina brick reaches the lowest temperature at 60 per cent silica and 40 per cent alumina, but if the silica is increased up to say 90 per cent., an infusible brick of the highest quality is the result.

For all classes of work, a good high grade plastic No. 2 fire clay, with possibly a small amount of flint clay, should be used. This will make a creamy, sticky slip, which will make an excellent joint. The joints are always weak spots, and are therefore a necessary evil. The brick should always be dipped into the mortar, which should be of the consistency of cream, and rubbed on each other to make a good tight contact.

Coking Coals.—There are three principal coal area sections in the United States supplying good coking coal. The Connellsville section in Pennsylvania was the first developed, and it is reported that this supply is fast disappearing. The second section is that of the Pocahontas Field in West Virginia, and the third is in Colorado. As the good coking coal fields disappear, so will the by-product ovens come into use, for it is possible to coke a coal in a by-product oven that it is practically impossible to coke in the Bee-hive type.

Exportation of Coke.—The value of coke

COLA-NUT—COLBERT

exported from the United States in 1905 amounted to \$20,000,000, while that of coal was about \$11,000,000. A large part of this went to British North America. The output of coke in 1904 was 23,661,106 short tons. The value of this coke was \$46,144,941, or an average price of \$1.95. The output of coke for 1905 was 32,231,129 tons, the value being \$72,476,196, the average price being \$2. The increase in number of coking plants during the year 1905 was twelve, numbering 3,968 ovens. Of these, 64 per cent were in Pennsylvania, 10 per cent in West Virginia, and 8 per cent in Alabama.

The writer wishes to express his appreciation of the writings of Dr. F. Schneiwind, Mr. J. D. Pennock, Mr. John Fulton, Mr. W. H. Blauvelt, and Mr. C. G. Atwater, from whom he has quoted direct parts of the preceding paper.

ABRAM T. BALDWIN,
Assistant Manager Soda Ash Department, The Solvay Process Company, Syracuse, N. Y.

Co'la-nut, the seed of a tree (*Cola acuminata*) from 20 to 30 feet in height, belonging to the natural order (*Sterculiaceæ*), whose habitat is a region of west Africa stretching 500 miles from the coast into the interior, between Sierra Leone and Lower Guinea. The tree has become naturalized in the West Indies and Brazil. It bears a profusion of purplish flowers. The flower yields a large brownish-yellow fruit, which enfolds in the same follicle the red and white seeds called cola-nuts. In its tenth year the tree reaches its greatest fecundity, and then yields 120 pounds of seeds. They are gathered in October and November from a June flowering, and again in May and June from a December flowering. In the tropics the natives use the cola-nut as a stimulant and for medicinal purposes, and only recently has the nut passed from the narrow use of the aborigines into an extensive service of civilized man. An analysis of it shows that it contains nearly all the constituents of coffee, tea, and cocoa, and other constituents not possessed by them.

Colberg, or **Kolberg**, Prussia, seaport and watering-place in the province of Pomerania, on the Persante, near its mouth, 170 miles north-northeast of Berlin. It stands on a hill, surrounded with three suburbs. The principal

church dates from 1316. In 1102 Duke Boleslaus of Poland vainly besieged Colberg, which endured long sieges in the Thirty Years' war, in the Seven Years' war, and again in 1807, when it was most gallantly defended against the French. Colberg has manufactures of woolens, agricultural machines, and spirits; and salmon and lamprey fisheries. Pop. 18,622.

Colbert, Jean Baptiste, zhõñ bāp-tēst kōl'-bār, French statesman and financier; b. Rheims, 29 Aug. 1619; d. Paris 6 Sept. 1683. He entered in 1648 the service of Cardinal Mazarin, who availed himself of his assistance in the financial administration of the kingdom. Mazarin rewarded him in 1654 with the office of secretary to the queen, and recommended him to the king at his death in 1660. Louis XIV. made Colbert intendant of the finances. His task was to remedy the evils which the feeble and stormy reign of Louis XIII., the splendid but arbitrary measures of Richelieu, the troubles of the Fronde, and the confused state of the finances under Mazarin, had occasioned. He found fraud, disorder, and corruption prevailing everywhere. The domains were alienated. Burdens, privileges, and exemptions were multiplied without measure; the state was the prey of the farmers-general, and at the same time maintained only by their aid. The revenues were anticipated for two years, and the treasury empty. He began with establishing a council of finances and a chamber of justice. For the purpose of alleviating the public burdens he endeavored to lower the interest of the public debt; and in order to mitigate the odium of this measure consented to a considerable diminution of the taxes, and the remission of all arrears up to 1656. He abolished many useless offices, retracted burdensome privileges, diminished salaries, and by a better distribution and collection of the taxes was able to reduce them almost one half. Notwithstanding the expenses of nearly 10 years' war, and the prodigality of a luxurious king, Colbert succeeded in 22 years in adding to the revenues more than 28,000,000 livres, and making an equal diminution in the public burdens; and at his death in 1683 the revenue actually received amounted to 116,000,000. To his talents, activity, and enlarged views the development and rapid progress of industry and commerce in France were largely due. He constructed the Canal of Languedoc; formed the plan of that of Burgundy; granted premiums on goods exported and imported; regulated tolls; established insurance offices; made uniform laws for the regulation of commerce. Naval schools were established, and order was introduced into all branches of the marine. By the advice of Colbert Louis XIV. caused the civil and criminal legislation to be improved, and the arts and sciences encouraged. Under the protection and in the house of the minister (1663) the Academy of Inscriptions was founded. Three years afterward he founded the Academy of Sciences, and in 1671 the Academy of Architecture. The Academy of Painting received a new organization. He enlarged the Royal Library and the Garden of Plants, and built an observatory in which he employed Huyghens and Cassini. He began the measurements of the meridian in France, and sent men of science to Cayenne.

COLBURN — COLCHICUM

After having conferred the greatest benefits on his country he died, out of favor with the king, and dreading the exhaustion of the treasury by the new war Louis was resolved upon making against Holland. See Gourdautt, 'Colbert, Ministre de Louis XIV.'

Colburn, kōl'bĕrn, Warren, American mathematician: b. Dedham, Mass., 1 March 1793; d. Lowell, Mass., 13 Sept. 1833. He at first worked at a machinist's trade, but developed a taste for mathematics, and graduated at Harvard 1820. He devised important improvements in machinery, and for many years was a popular lecturer on the sciences. He is best known for his 'First Lessons in Intellectual Arithmetic' (Bost. 1821) which he had planned while a student at Harvard. He also published a 'Sequel' to the arithmetic (rev. ed. 1833), and an 'Algebra' (1827).

Colburn, Zerah, American mathematician: b. Cabot, Vt., 1 Sept. 1804; d. Norwich, Vt., 2 March 1840. Before his sixth year he began to manifest wonderful powers of arithmetical computation. In 1812 he was taken to London, and after traveling over England, Scotland, and Ireland, went to Paris. Returning to London in 1816, he was placed by the Earl of Bristol in Westminster School, where he studied for three years. He lost his father in 1824, and returned to America, where he was employed again in teaching. In 1825 he became connected with the Methodist Church, and after nine years' service as an itinerant preacher settled in Norwich, Vt. He was professor of languages in the university of that town till his death.

Colburn, Zerah, American engineer: b. Saratoga, N. Y., 1832; d. Massachusetts 4 May 1870. After working on a farm in New Hampshire, he went to Boston and worked in the Lowell machine-shop, and on the Concord Railroad. He became superintendent of some locomotive works in Boston, and later occupied a similar position in Paterson, N. J. In 1854, he started an engineering journal in New York, known as the 'Railroad Advocate,' and for this journal wrote a series of papers on machine and locomotive works in France and England, the result of his investigations while on a trip abroad. He again visited Europe in 1857, and in 1858 began writing for the London 'Engineer,' of which he shortly became editor. At one time he returned to the United States for a few months, and started the Philadelphia 'Engineer,' but gave up that enterprise, and resumed the editorship of the London journal till 1866. He then began the publication of 'Engineering' in London, but in 1870, when he became partially insane, he returned to the United States, where he finally committed suicide. He wrote 'The Locomotive Engine' (1851), and a number of valuable technical papers.

Colby, Frank Moore, American writer: b. Washington, D. C., 10 Feb. 1865. He graduated at Columbia University 1888, and took graduate studies in political science there. He taught history at Amherst College 1890-1; was lecturer in history at Columbia 1891-5; professor of economics in New York University 1895-1900, when he became an editorial writer on the *Commercial Advertiser*. He has done a large amount of editorial work on Johnson's 'Cyclopædia'; the 'International Cyclopædia,' and 'International Year Book,' editing the latter since its founda-

tion in 1898, and was the managing editor of the 'New International Cyclopædia' (1902-3).

Colby College, a coeducational institution in Waterville, Me.; founded in 1818, under the auspices of the Baptist Church. After the first year's work, the courses are nearly all elective. The average number of students, each year, is 200. In the library are 37,900 bound volumes and about 21,000 pamphlets. The college is endowed about \$500,000, and the property is valued at \$254,000.

Colchester, kōl'chĕs-tĕr, England, a borough and river port of Essex, on the Colne, 50 miles northeast of London. It is partially encircled by a wall built during the Roman period, and among relics of the past it contains a castle whose enormously thick walls date from the time of William Rufus, a picturesque, ivy-grown ruin of Saint Botolph's priory, while in the Church of the Holy Trinity is a Saxon doorway. The most important modern structure is the spacious and handsome Town Hall, completed in 1902. Colchester was known to the early Britons and the Romans as Camulodunum, and to the Saxons as Colneceaster. It has a large oyster-fishing trade, and exports of corn and malt. In 1648 Colchester stood a memorable siege of 11 weeks against the Parliamentary forces, who eventually starved out the royalist garrison and hung the leaders. See Cutts, 'Colchester' in 'Historic Town Series' (1889).

Col'chicine, a vegetable alkaloid obtained from plants of the genus *Colchicum* (principally from the roots and seeds) by successive extraction with hot alcohol, water, and chloroform, and subsequent repeated crystallization from all three of these solvents. It is a yellowish-white powder, with the probable formula $C_{22}H_{23}NO_6$. It acts as a weak base, but most of its compounds are decomposed by water. Preparations of colchicine are used in medicine for the treatment of gout. It is very actively poisonous, half a grain having proved fatal.

Colchicum, kōl'chĭ-kŭm, a genus of herbs of the natural order *Liliaceæ*. About 30 species, natives of the Mediterranean region, have been described. They are nearly all autumn-blooming perennial plants which produce their leaves in spring from corms. The perianth, which resembles but is much larger than that of the crocus, is long and tubular, and varies in color from white to purple (in one species yellow). The leaves, which are broad and long in proportion to the size of the plants, die in early summer, and the flowers appear when nature is preparing for the winter. For this reason the autumn-blooming species are very popular in gardens. They are of easiest culture, the bulbs being planted in late summer and protected in severe climates with a winter mulch of litter or straw, which is removed in the spring. Beds once planted will need no further attention for several years, when they should be dug up, the corms divided and set in fresh soil in a sunny situation. The plants of some species are very acrid and are reputed poisonous, and when cattle have access to them are said to produce injuries of various kinds. Ordinary clean cultivation will soon rid any land of the plants. The corms and the seeds have been used in medicine for gout and rheumatism. *C. autumnale*, the best-known species, is popularly known as mea-

now saffron and autumn crocus, names also given to other species.

In medicine the corm and seeds of *Colchicum autumnale* are used, in which the active principle is found in from .3 to .5 per cent. *Colchicum* has in medicine but one use; that is, in attacks of acute gout. These it cuts short, relieving the pain and shortening the attack better than any other drug. The reasons why are at present unknown, and the remedy is one of the few now remaining in modern medicine that are still used on empirical grounds only. Poisoning by this drug is not uncommon. The symptoms are those of an acrid gastro-enteric poison, with great pain, nausea, vomiting, and diarrhoea. There is marked depression of the pulse and of the respiration, and death is due to shock and collapse. Washing of the stomach is the first indication for treatment, notwithstanding the self-conservative vomiting. Castor oil, heat, alcohol, and mucilaginous drinks are indicated.

Colchis, kōl'kīs, or **Colchos**, the ancient name of a region at the eastern extremity of the Black Sea, resting on the Caucasus, and corresponding partly to Mingrelia. It is famous in Greek mythology as being the destination of the Argonauts. The people were celebrated for frugality and industry, and from their dark complexion, crispy hair, language, and customs, Herodotus is of opinion that they were of Egyptian origin. The country abounded, according to Strabo, in all kinds of fruits and material for ship-building. Linen was an important branch of manufacture, and wool of fine quality and in great quantity was produced. It was fruitful in poisonous herbs. In the 15th century it was subdivided into several principalities, and is now comprised in the Russian government of Trans-Caucasus.

Col'cothar, red oxide of iron, ferric oxide, Fe_2O_3 . The reddish-brown powder that remains in the retorts when ferrous sulphate is distilled in the manufacture of Nordhausen sulphuric acid. It is used for polishing glass, and also as a pigment, under the name of "Indian red." When in the finest state of subdivision it is known as "rouge," and is much used for fine polishing by jewelers and others. Colcothar was the *caput mortuum vitrioli* of the alchemists.

Cold. 1. In physics and physiology, a relative want of heat. Since there are no determinate boundaries between cold and heat, it is a mere arbitrary distinction to call the degrees of the thermometer below the freezing-point degrees of cold. When the atmosphere, or any substance which comes in contact with the body, is at a lower temperature than the skin, it absorbs heat from the body, and is called cold. The physiological action of cold on the animal organism requires a brief notice. All animals (the warm-blooded animals to the greatest extent) have a certain power of maintaining the heat of the body in defiance of external cold. This power is mainly due to a process analogous to combustion, in which carbon and hydrogen taken into the system in food are made to unite with oxygen derived from the air by respiration. If the combustible materials are not duly furnished, or if the supply of oxygen be deficient (as in various diseased conditions), there must be a depression of temperature. Now, if the temperature of a bird or mammal (except in the case of hibernating animals) be lowered

about 30° below its normal standard (which in birds ranges from 100 to 112° , and in mammals from 96° to 102°), the death of the animal is the result. The symptoms indicating that an animal or a man is suffering from a depression of the temperature of the body are: (1) retardation of the circulation of the blood, causing lividity of the skin, which is followed by pallor, in consequence of the blood being almost entirely driven from the surface through the contracting of the vessels; (2) a peculiar torpor of the muscular and nervous systems at the same time, manifesting itself in an indisposition to make any effort or exertion, and in intense sleepiness. The respiratory movements become slower and the loss of heat goes on, therefore, with increasing rapidity, till the fatal limit is reached and death supervenes. In hibernating animals (the marmot, dormouse, bat, etc.) the power of generating heat within their own bodies is very slight, their temperature following that of the external air, so that it may be brought down nearly to the freezing-point. Great or prolonged atmospheric cold is a most powerful depressing agent, and is a fruitful cause of disease and even of death. Whenever the temperature of the atmosphere is suddenly reduced, and particularly when it is reduced below the freezing-point, a considerable addition takes place to the mortality of the region. The effects of cold are, in ordinary circumstances, most apparent among the aged and the very young, and among those suffering from chronic disease.

2. In medicine, cold, as well as heat, is frequently employed for its therapeutic value. Cold is one of the most valuable means of obtaining lowered temperature. Cold sponging, ice-packs, alcohol evaporation, are useful in most fevers, are indispensable in sunstroke, and very refreshing in minor indispositions. Cold applied to an inflamed area diminishes the blood-tension by contracting the blood-vessels, and thus tends to limit inflammation. Cold applied to the skin, as by a wet pack, or as a shower, is a tonic, increasing metabolism, augmenting the appetite and giving mental and physical vigor. Cold applied as iced drinks, or cracked ice itself, is one of the best agents in nausea and gastric distress. Cold by means of ether or ethyl chloride spray is an excellent local anæsthetic for the treatment of local boils, felons, ulcers, etc., and is also used frequently in the extraction of teeth.

Catching cold is a term of wide popular use, and signifies an affection which is little treated of in medical literature, although an affection widespread and unpleasant. Catching cold is a process of disturbed equilibrium of the blood vessels. It is usually due to excessive evaporation from the skin caused by drafts of air, to which is added contraction of the blood vessels of the periphery of the body, with consequent engorgement and congestion in some internal organ. Keeping quiet, taking hot foot-baths, or hot drinks, sweating, etc., are measures that tend to bring the blood to the contracted areas, and away from the congested areas, with consequent good results. If, however, the disturbance becomes marked, if the exposure has been excessive, the congestion in an area becomes so serious that its local functions are diminished or aborted, and the congested blood vessels may be over-distended and paralysis result. Then an inflammatory reaction may ensue; the reduced

COLD CREAM — COLD HARBOR

vitality of the part encourages the multiplication of ever-ready bacteria, and an acute diseased process may result. It may be a simple acute inflammation of the kidney; or if the pneumococcus is present in the lung, a pneumonia; or it may be a bronchitis. Taking cold is therefore a distinct process that predisposes to more severe affections. In most cases the secondary reaction of taking cold manifests itself in the mucous membranes of the air-passages, and running from the nose, some degree of cough, general malaise, languor, and muscular and joint pains are the results. Secondary infection, frequently through the superimposed influenza bacillus (if the condition be not primarily induced by that organism), results in the "grippe," following which bronchitis and pneumonia are very frequent.

No cold in the head, no general cold, should be neglected. Rest in bed, cathartics, hot drinks, and medical advice are desirable.

Cold Cream, a cooling ointment made by melting four ounces of white wax in one pound of almond oil by means of a gentle heat. Then mix gradually with a pint of rose-water in a warm mortar. Another recipe is: Take two parts of spermaceti, two parts of white wax, and three parts of almond oil; melt together, and then add rose-water as before. This ointment cools the skin, rendering it soft and pliable, and is successfully applied for the cure of chapped hands.

Cold Harbor, Battle of. By a series of bloody assaults and flank movements, beginning at the Wilderness 5 May 1864, Gen. Grant had, at the end of the month, forced Gen. Lee back to within a few miles of Richmond, and confronted him on the line of the Totopotomoy. On 31 May his army was along the road from near Hanover Court-House to Cold Harbor; the Sixth corps about six miles southeast of the court-house; to its left, in the order named, the Second, Ninth, and Fifth corps, these near Bethesda Church. The Eighteenth corps was at White House, on the Pamunkey, where it had just arrived from the Army of the James. Gen. J. H. Wilson's cavalry division was on the right of Grant's line, and Sheridan, with the two cavalry divisions of Torbert and Gregg, on the left. On the 31st Sheridan, after a severe fight, occupied Cold Harbor, but was so hard pressed by the Confederate cavalry division of Fitzhugh Lee and Clingman's brigade of infantry, and his position so exposed, that he fell back at night; but receiving an order from Gen. Meade that the place must be held at all hazards, he returned, and during the night entrenched. Lee's position was so strongly entrenched and so difficult of access that Grant determined again to extend by his left on Lee's right, and in view of this extension Cold Harbor was an important point, as there the roads concentrated from Bethesda Church, Old Church, White House, New Bridge, and all the bridges across the Chickahominy above and below New Bridge. Grant extended in that direction by transferring from his right. At 11.45 on the night of 31 May, Gen. H. G. Wright's Sixth corps was ordered from its position on the right to march along the rear of the army to Cold Harbor, 15 miles distant, and to be there by daylight on 1 June to support Sheridan, who, it was believed, would be heavily attacked at daybreak; but it

was nine o'clock before he arrived, and Sheridan meanwhile had repulsed two determined attacks of Kershaw's division. At 3 P.M. 31 May the Eighteenth corps, Gen. W. F. Smith, was ordered by Gen. Grant to march from White House and form on the right of the Sixth. By a mistake in the order given it, it was late in the afternoon of 1 June when it reached its position. Opposing the two corps were the Confederate divisions of Gens. Hoke, Kershaw, Pickett, and Field, their main entrenched line about 1,400 yards distant; the interval between mostly open ground. About 300 to 400 yards in advance of the main line was a line of rifle-pits. It was necessary to take this position before Gen. Lee could concentrate on that flank and thus cover this road to Richmond. Between 5 and 6 P.M. Wright and Smith assaulted, and under heavy artillery and musketry fire Smith carried the advanced Confederate works and held them, taking many prisoners. Wright carried the advanced line and, breaking the left of Hoke and right of Kershaw, took parts of the main line, some of which he held, the Confederates falling back to a new line. The loss in the two assaulting corps was about 2,200. On the night of the 1st Sheridan had been ordered to attack on Wright's left, but received the order too late to execute it. On the morning of the 2d he advanced Gregg's division to Sumner's Bridge, on the Chickahominy, attacked a force of infantry, cavalry, and artillery, posted near the bridge, carried their advanced position, and held it until Hancock's corps arrived. Hancock's Second corps moved after dark of the 1st from the extreme right, under Meade's order to march with all speed, join Wright by daybreak of the 2d, and take position on his left, extending the line if possible to the Chickahominy. By an error of Hancock's engineer a wrong road was taken, and it was after seven o'clock when his head of column arrived; then under heavy skirmishing he formed line across the road from Cold Harbor to Dispatch Station. It had been the intention to attack the Confederate line early in the morning. Smith declared that the idea "was simply preposterous." Hancock's men were in an exhausted condition, and the attack was suspended until 5 P.M., and then deferred until 4:30 A.M. 3 June. At this time Grant's line was held on the right by Gen. J. H. Wilson's cavalry from the Pamunkey to Bethesda Church; Warren's Fifth corps, which had not moved, stretched from Bethesda Church about three miles to Beulah Church. Burnside's Ninth corps had been ordered to withdraw from the extreme right and form in Warren's rear to support his right. The Eighteenth corps was on the left of the Fifth, a wide interval between them; the Sixth and Second corps were on the left of the Eighteenth. Lee had observed that Grant was transferring the right of his army, by successive movements, to the left, and not proposing that Grant should take the initiative in attack, took it himself. On the morning of 2 June he ordered Early with three divisions to attack Grant's right flank and drive it down in front of the Confederate line. Early found Burnside in the act of withdrawing from near Sydnor's Mill, to take position in Warren's rear, attacked and captured the skirmish line, which had been left in the works, and fell upon his rear division, by which, with the assistance of the other divisions, Early was checked, but not before he had got in the

COLD SPRING HARBOR — COLD STORAGE

rear of a part of Warren's skirmish line, from which he took many prisoners. Warren repulsed Rode's division, which had attacked his front, and at night both sides entrenched. The Union losses 1 and 2 June were over 5,000 killed and wounded. Meanwhile Lee closed in to the right and formed his lines in front of Grant's left, his right on the Chickahominy, near Alexander's Bridge, his left extending a little west of north in the direction of the Totopotomoy. A. P. Hill's corps was on the right; Longstreet's, commanded by R. H. Anderson, in the centre; and Early's on the left, cavalry covering both flanks of the infantry. The line included the ground on which was fought the battle of Gaines' Mill, June 1862, and covered all the main roads to Richmond, being about six miles from the main exterior fortifications of the city and but half that distance from its most advanced works. Grant's whole line, except the cavalry on the left, was ordered to assault Lee's lines at 4.30 A.M. 3 June. Wilson, re-enforced by 2,000 cavalry and 3,000 infantry, was ordered from Hanover Court-House to Hawes' Shop to attack Early's left and rear. The main work was to be done by the Second, Sixth, and Eighteenth corps, supported by the Fifth and Ninth. No reconnaissance had been made in front, where the Confederate works were so constructed as to give a cross-fire upon assaulting columns. At the signal the assault was made at 4.30 A.M. On the left Barlow's and Gibbons' divisions of the Second corps leaped their works and, under a severe fire of artillery and musketry, drove in the enemy's advanced line and in many places gained the main line, but the latter was soon retaken and in 20 minutes from the time the signal was given the Second corps was repulsed with a loss of 3,000 men, including many of its most promising officers, who were killed on the works. The men did not retreat far, but lay down within a few yards of the Confederate works, and with bayonets, tin cups, and plates, began to entrench, skirmishing all the while. It fared no better with the Sixth corps. Its three divisions went forward, carried some advanced rifle-pits, assaulted the main line, and were met by a severe musketry fire and an enfilading artillery fire. They were repulsed with a loss of 800 killed and wounded, but gained positions at some points only 30 or 40 yards from the enemy's works, and held and entrenched them. On the right of the Sixth corps, the Eighteenth was obliged to form one division to the right to protect its flank, Martindale's and Brooks' divisions assaulted and were quickly driven back by a cross-fire of artillery and musketry, and it desisted from further effort after a loss of about 1,000 men. In less than an hour the three corps had lost nearly 5,000 in killed and wounded. Warren, on the right, reported that he could not advance unless the troops on his left advanced at the same time. Wright said that if he advanced without a corresponding advance of Smith on his right he would be taken in flank and reverse, and he was waiting for Smith and Hancock to move; and Smith said he could not move unless Wright covered his left flank. Gen. Meade ordered another assault, each corps to go forward without regard to those on the right or left, but it was not made, Hancock would not take the responsibility. Smith had all he could do in holding his own; Wright, also Hancock, merely transmitted the order to brigade and regi-

mental commanders without enforcing it; and the men opened fire from their sheltered positions, without an effort to advance. Meade gave a third order for an advance of the entire line. Smith positively refused to obey, as it meant but a wanton waste of life to attempt it. Wright and Hancock merely transmitted the order, and again the men complied with it only by renewing fire from their positions. Grant got the opinion of his corps commanders that further assault was inadvisable, and at 1.30 P.M. orders were given to entrench "with a view to moving against the enemy's works by regular approaches." Farther to the right Burnside with the Ninth corps and Warren with the Fifth, who were to support the main assault, attacked Early in the morning, occupied some of the positions taken from them on the 2d, entrenched close up to Early's main line, and were about to assault, when they received orders to suspend attack. They had fought sharply during the morning, the Fifth corps losing about 500 killed and wounded, the Ninth corps about 800. Wilson's cavalry had a sharp engagement at Hawes' Shop, driving the enemy with some loss, and attacking the left and rear of Heth's division; but failing to connect with Burnside, they withdrew to Hawes' Shop. The loss of the Army of the Potomac for the entire day of 3 June was about 7,000 killed and wounded. All night of the 3d both armies were entrenching; no pickets could be thrown out, so close were the lines, between which lay many wounded. Some of the wounded were brought in, but it was not until the 7th that a truce was agreed upon, by which all could be removed, when exposure and starvation had transferred the greater part of them to the death-roll. Regular approaches were made by the Union lines, accompanied by constant and heavy skirmishing; an assault gave no promise of success; and on the night of the 12th Grant withdrew to cross James River. Grant had 103,000 "present for duty" at Cold Harbor. His loss (1-12 June) was 1,845 killed; 9,077 wounded; 1,816 missing; an aggregate of 12,738. Lee had not to exceed 65,000 men. His loss cannot be accurately given, but probably did not exceed 2,600 killed and wounded. Gen. Grant, in his 'Personal Memoirs,' says: "I have always regretted that the last assault on Cold Harbor was ever made. No advantage whatever was gained to compensate for the heavy loss we sustained." Consult: 'Official Records,' Vol. XXXVI.; U. S. Grant, 'Personal Memoirs,' Vol. II.; F. A. Walker, 'History of the Second Army Corps'; A. A. Humphreys, 'The Virginia Campaign of 1864-5'; I. R. Pennypacker, 'Life of General Meade'; The Century Company's 'Battles and Leaders of the Civil War.'

E. A. CARMAN.

Cold Spring Harbor, N. Y., a village of Suffolk County, on Cold Spring Harbor, and on the Long Island R.R. It was formerly a whaling port. It is now a summer resort, and has a fish hatchery and a school of biology.

Cold Storage, a method now generally employed for preserving perishable articles of food by the use of machines which reduce the temperature of the air. The same method is used extensively for preserving articles other than food which are destructible by high temperature. Refrigeration is often called ice-making, but in a cold-storage building the area

COLD STORAGE

kept at a certain temperature by the frozen liquid is small compared with that kept at a proper temperature by ammonia and other substitutes for ice. Perhaps no product ever came into common use more rapidly than air treated according to the cold-storage method, unless electricity or steam be excepted. It is now indispensable in connection with some of the largest business enterprises, which, without it, would soon cease to exist. One of the most important uses of cold storage is in the transportation of beef, fruit and vegetables, etc., from place to place and from one country to another, especially from the United States and South America to Europe.

The extensive systems employed in breweries, provision depots, dairies, and distilleries have familiarized the public with the use of cold air; and no modern hotel or apartment house on a large scale is constructed without a plant for producing it by some process. It is as much a portion of the mechanical equipment as the elevator motor, or the lighting and heating apparatus. It is also being introduced for cooling purposes in theatre and other auditoriums; it maintains a pleasant temperature during the heated term in the hospital ward, and several companies have been formed to distribute it in cities through mains, as water and gas are supplied to the consumer. In some of the largest packing-houses of Kansas City and Chicago, not a pound of ice is used in a year for preservative purposes, although every department where the products of the beef, sheep, and hog are stored any length of time, is required to be at a temperature near or below the freezing point. Plants are now being made in this country to generate cold air for butter and butterine factories, ice-cream factories, chemical works, sugar refineries, molasses factories, paraffine works, oil refineries, stearine factories, chocolate factories, morgues, office buildings, skating rinks, steel-tempering plants, blast-furnaces, laundries, glue works, dry-plate works, dynamite-works, paint factories, soap factories, fur storage, India-rubber works and plants for seasoning lumber—a list including some of the country's most important industries.

While an extensive variety of machinery is being manufactured for refrigeration under a score of patents, the aim of all the inventors is the same—to perfect the most economical process to remove the heat from a certain temperature level to a higher level, discharging it at this point. With one ton of coal, a cold-air equivalent of from 8 to 14 tons of ice has been produced, the quantity varying according to the process employed. In the United States the refrigerating machines use anhydrous ammonia as the agent for generating low temperatures, mostly in conjunction with brine made from chloride of calcium and water. The ammonia is circulated through a series of pipes in which it evaporates. Then, in its gaseous form, it is pumped by the machine into the condensers and liquefied. The brine-cooler consists of a double pipe-coil. A small quantity of ammonia is injected through a needle valve, which allows a very fine stream to pass into the space between two pipes, running in a coil approximately 300 feet long surrounding a pipe containing the brine. From this coil the ammonia gas is drawn to the machine. The gas is forced thence into other coils, called the ammonia

condensers, which have water circulating over them. It is now in a heated condition from the compression. The water running over these coils cools off the gas, and at the same time condenses it into liquid anhydrous ammonia. In this form the ammonia is conducted to a receiving tank, and from there it again passes through the needle-valve into the brine-cooler, going through the same circuit again and again. The brine-cooler represents the apparatus where the brine and ammonia systems are in conjunction, the brine being pumped through the cooler, and from there through coils of pipe in the room in which it is desired to reduce the temperatures. This is sometimes to 20° F. below zero for freezing fish, sometimes to 32° F. for preserving meat, and often to 50° F. for preserving fruits and other perishables. The temperature is easily adjusted to the required degree by controlling the brine-flow in the piping. By lessening or increasing the flow in a single pipe, a wide range of temperature can be produced. Thus the same room can be used either for freezing the articles it contains, or merely for chilling them.

The capacity of a refrigerating machine is based upon the weight of ammonia in the gaseous form which it can discharge in 24 hours, each pound of gas representing a certain quantity of heat-absorbing power. The unit of capacity is the refrigeration which would be accomplished by the use of one ton of ice. Such a quantity will lower the temperature of 28,400 pounds of water 10 degrees. Therefore, if a "one-ton" machine is employed, it will cool 197½ pounds of water to the extent of one degree a minute. Tests made of the York type machines of this capacity show that one will keep the "curing" department of a packing-house containing 12,000 cubic feet of space, at a temperature of 40° F. or 1,500 cubic feet at zero. In other words, it is sufficient to keep 10 beeves or 25 hogs chilled at the former temperature. As a single plant used in the large packing-houses and breweries may represent 500 tons capacity, it will be seen that the cold storage compartments are maintained on a very elaborate scale, a single one containing thousands of carcasses. The horse-power required for one of these large machines aggregates 625. The air-compressors are built in various designs, and are known as single and double acting.

In large cold-storage warehouses the floors are not over eight or nine feet high. The pipe is attached to the walls, and in wide rooms to the sides of posts running through the middle of the room, so that an equal temperature can be maintained in all portions. In others, like fish-freezing rooms, the pipes are even used as shelves to hold the tins filled with fish, which are frozen into bricks and piled away in another compartment. Poultry and game are also kept in a frozen state, and the meat remains almost as hard as stone while in the cold room. Butter also is kept at a temperature near zero, which is said to preserve the flavor contained in its volatile oil, so that it is equal to fresh butter. Eggs are preserved sometimes from two to six months, but require particular care. The air in the room should be neither too moist nor too dry, and the chamber should be neither without ventilation nor supplied with too much, as then the eggs would lose in weight on account of their liability to evaporate through the shell.

COLD WAVE — COLDEN

Eggs, butter, and milk are also liable to be tainted by any smell arising from the woodwork, or articles stored in the neighborhood, and the rooms have to be constructed and arranged with this point in view.

The above, it may be said, have been problems for the cold-storage experts to solve by practical experiments; but food products can be preserved in properly constructed houses with as little difficulty as any other articles. In the preservation of meat, from the time that the beef, sheep, or hog is killed, it is kept in cold storage or "chill" rooms, until the time that it is taken from the refrigerator to be prepared for the table. The "chill" rooms are used to take the animal heat out of the meat, and reduce its temperature from about 98° F. to cold-storage temperature, that is, from 32° F. to 40° F. For this purpose the meat is hung on rails in rooms which have chambers in the upper part over the rails for ammonia or brine piping, which reduces the temperature to a point near freezing before the meat is put in. After the meat is put in, the animal heat it still contains raises the temperature in the room, but this is again gradually lowered, in the course of 24 to 48 hours, to the proper degree for refrigeration. This length of time is required in order to chill the meat thoroughly. Should it become chilled on the outside and remain warm in the centre, the centre part of the meat would be spoiled. From the "chill" room the meat is run into the cold-storage rooms and hung on rails, where it is kept until such time as it is to be shipped. The choicest pieces are kept at least four weeks in cold storage, as the quality is thus improved, and, if the rooms are kept clean, these pieces will taste better than meat which has been recently slaughtered. For this reason, not only slaughter-houses, but depots of packers and other buildings where meat is kept in cold storage, even to small butcher establishments, are preferably cooled by refrigerating machinery, owing to its dryness and cleanliness.

In some of the large hotels refrigerators cooled by machinery are even placed close to the ovens or ranges where the viands are prepared for consumption, the refrigeration being maintained at the proper standard despite the outside temperature. High temperature is also the rule in candy factories, but manufacturers of chocolate candy have been using refrigerating machines for some time. They are forced to do this, as the compound is apt to become soft in hot weather, which, of course, would spoil the appearance of the goods for the market. The arrangement of the refrigerating piping for chocolate factories has been made in various ways. In some instances a large refrigerator is cooled in the centre of the workroom with the piping inside of it, this refrigerator being of such length that endless belting carrying tins with chocolate enters it on one side and brings them out chilled on the other. In other workrooms a series of pipe coils are simply placed along the ceiling, and the cold air coming down chills the confectionery as it is made by the employees in the same room. The chocolate is then stored in refrigerators, apart from the workroom, and there properly packed at a low temperature. After being packed it can be sent out, and ordinarily will keep for an indefinite length of time.

One of the most interesting applications of cold storage, however, and one which has become very extensive, is for preserving furs and woollens, which are kept at a temperature of not over 20° F. to keep the moths from destroying them. These rooms have a very interesting appearance, as among the trunks, boxes, and drawers of clothing there appear figures of bears, tigers, and other stuffed animals in threatening attitudes, put away through the hot season by their owners and taken out in the fall. Sometimes furs are left in storage continuously for several years, yet at the end of the time they are invariably found in perfect condition. Many of the trust companies in the larger cities have such cold storage compartments. In these fur and clothing rooms, where valuable carpets and rugs are also stored, the air is generally cooled outside of the room and circulated through it by means of fans.

The cold storage building erected by the United States government at Manila is probably unexcelled in scientific construction. It has a storage capacity for 1,200 tons of beef, 200 tons of mutton, 50 tons of butter, 100 tons of potatoes, and 100 tons of bacon; or, in other words, sufficient food to feed an army of 10,000 men for three months. In addition to the ordinary freezing apparatus it has an ice plant with a daily output of 40 tons. The elevator, with its 2,400 pound lifting capacity, as well as most of the other appliances in the building, are operated by electricity. Connecting with the elevator is an overhead tracking system extending four miles, and the mechanism is so complete that a ship landing at a near-by pier has only to open her hatches and her cargo is transported to the storage almost automatically. The power in the building is furnished by three 200-horsepower engines.

Cold Wave, a term commonly used in the United States to denote a fall of at least 20° in temperature in 24 hours, bringing the temperature below the freezing point. It is due to steady winds from the northwest, which bring with them the chill conditions of the great west Canadian plains. This chill seems due to anti-cyclonic conditions which bring down to the surface the cold air of the upper atmosphere, and cause it to flow out over the southern and eastern United States.

Colden, kōl'dën, **Cadwallader**, American scientist and colonial official: b. Dunse, Scotland, 17 Feb. 1688; d. Long Island, N. Y., 28 Sept. 1776. He was graduated from the University of Edinburgh in 1705, and emigrated to the American colonies in 1708. He devoted himself to botany and astronomy and also to public affairs, becoming surveyor-general of New York and president of the council. He sided with the crown in the contest over the stamp act. Among his correspondents were Franklin and Linnaeus, and he wrote 'Cause of Gravitation' and 'History of the Five Indian Nations.'

Colden, **Cadwallader David**, American lawyer: b. near Flushing, L. I., 4 April 1769; d. Jersey City, N. J., 7 Feb. 1834. He studied law in England and the United States; began practice in New York in 1791, where he soon attained high rank in his profession. He was a member of the legislature and mayor of New

COLDSTREAM — COLE

York (1818), a member of Congress (1821), and of the State senate (1824-7). He was an earnest advocate of the system of internal improvements that was an important political issue early in the 19th century. He wrote: 'Life of Robert Fulton' (1817); 'Memoir of the Celebration of the Completion of the New York Canals' (1825); 'Vindication of the Steamboat Right Granted by New York State' (1819).

Cold'stream, Scotland, a town in Berwickshire, on the northern bank of the Tweed, which is here crossed by a bridge (erected by Smeaton in 1766) that unites the two kingdoms, and forms a well-frequented thoroughfare. The ford of Coldstream was a favorite point with the invading armies of England and Scotland when they passed alternately into each other's country. Pop. 1,535.

Coldstream Guards, a regiment in the Foot Guards or Household Brigade, the oldest in the British army except the First Foot, now called the Royal Scots. Raised in 1660 by Gen. Monk at Coldstream, it was at first called "Monk's Regiment." but when Parliament consented to give a brigade of guards to Charles II., this corps, under the name of Coldstream Guards, was included in it.

Coldwater, Mich., a city and county-seat of Branch County. It is in the southern tier of counties, 153 miles east of Chicago and 126 miles west-southwest of Detroit, on the Coldwater River and the Lake Shore & Mich. Southern Railway. Coldwater was first settled in 1830 by Hugh Campbell, became a borough in 1837 and a city in 1862. It is governed by a mayor and a common council of eight members, four members of which are elected yearly for a term of two years. The city has three banks, churches of all denominations, is in the centre of a rich farming community, has cement, shoe, wagon, milling and other industries, and owns and controls its waterworks and electric-light plant. Pop. (1903) 7,000.

Cole, Asahel N., American agriculturist and editor: b. 1821; d. Wellsville, N. Y., 14 July 1889. He was educated in the public schools of western New York State, and when 21 entered politics. He figured prominently as a Republican in the party's early days, and in 1852 he founded the 'Genesee Valley Free Press,' the pioneer Republican paper. He was no less noted as an agriculturist, being widely known as the father of subsurface irrigation.

Cole, Grenville Arthur James, English geologist: b. London 21 Oct. 1859. He was educated at the City of London School and the Royal School of Mines, and has been professor of geology at the Royal College of Science for Ireland since 1890. He has published: 'Aids in Practical Geology' (1891, 4th ed. 1902); 'The Gypsy Road' (1894); 'Open Air Studies' (1895); 'As We Ride' (with Blanche Cole) (1902).

Cole, Joseph Foxcroft, American landscape painter: b. Jay, Maine, 9 Nov. 1837; d. Boston, Mass., 2 May 1892. He studied in Paris under Lambinet and Jacque, and exhibited at the Centennial Exhibition in Philadelphia, 'Twilight,' 'Melrose Highlands,' and 'Coast Scene in Normany,' for which he was awarded

a gold medal. His work was somewhat impressionistic in character.

Cole, King, a legendary British king, described as a "merry old soul," fond of his pipe, and fond of his "bowl," and fond of his "fiddlers three." Colchester is said to have been his residence.

Cole, Samuel Winkley, American musician: b. Meriden, N. H., 24 Dec. 1848. He began his professional career at Portsmouth, N. H., 1877, was organist of the Clarendon Street Baptist Church, Boston, Mass., 1882-94, and teacher of sight singing in the New England Conservatory of Music since 1883. Since 1884 he has been supervisor of music in Brookline, Mass., and in Dedham, Mass., since 1886. In 1890 he produced Haydn's 'Creation' with the Dedham high school, and in 1891 Handel's 'Messiah,' being probably the first successful attempt in the United States to produce a complete oratorio with high school pupils. He has written: 'Child's First Studies in Music'; 'Course in General Sight-Reading'; 'New England Conservatory Course in Sight Singing.'

Cole, Thomas, American landscape painter: b. Bolton-le-Moors, Lancashire, England, 1 Feb. 1801; d. Catskill, N. Y., 11 Feb. 1848. His father, a woolen manufacturer, came to the United States when Thomas was 18 years old, and settled in Steubenville, Ohio. The son worked in his father's shop for two years, but the coming of a portrait painter to the village made him wish to be an artist. After a few lessons he set to work to paint pictures, and traveled for a while painting portraits and landscapes, but often had to paint chairs and japanned ware for a living. At last he went to New York, and by hard work succeeded in making himself one of the foremost landscape painters in this country. Among the best of his pictures are five called 'The Course of Empire,' and four called 'The Voyage of Life.' The last, showing childhood, youth, manhood, and old age, are very popular, and are well known through engravings. He was one of the founders of the National Academy, New York.

Cole, Timothy, American engraver: b. London, Eng., 1852. He emigrated to America in 1857; was burned out by the Chicago fire in 1871, and returned to New York penniless. In 1875 he entered the employ of the 'Century Magazine' (then 'Scribner's Monthly'), and in 1883 was sent to Europe to engrave pictures by the old masters. The first Italian series was finished in 1892, the Dutch and Flemish series in 1896, the English series, 1900, and he has of late been at work on a Spanish series. He stands easily at the head of living wood-engravers. His notes and short papers to accompany his engravings in the 'Century' have been published separately. He received a first class medal at the Paris Exposition, 1900.

Cole, Vicat, English landscape artist: b. Portsmouth, Eng., 1833; d. London 6 April 1893. He was a pupil of his father, George Cole (1810-83), a landscape painter also, and painted many studies from nature in Surrey, 'The Heart of Surrey' being one of his most noted works.

Cole, William Morse, American teacher: b. Boston, Mass., 10 Feb. 1866. He graduated at Harvard in 1890, and was instructor in political economy there 1890-3, and since 1900. From 1894 to 1898 he was a university extension lecturer, and secretary of the Massachusetts Commission on the Unemployed. He is the author of 'An Old Man's Romance' (1895), under the pseudonym of "Christopher Craigie."

Colebrook, Henry Thomas, English Sanskrit scholar: b. London 15 June 1765; d. there 10 March 1837. In 1782 his father's influence procured him a writership in the Bengal service. His duties as revenue officer at Tirhut led him to make a minute study of the state of husbandry in Bengal; his legal functions led him to study Indian law and learn Sanskrit; and he began in 1794 publishing essays on Indian religion, poetry, and science in the 'Asiatic Researches' of the Asiatic Society of Calcutta. His removal in 1795 to the magistracy of Mirzapur gave him the opportunity of cultivating the acquaintance of the learned men of the neighboring Sanskrit college at Benares, and with this advantage he brought out his 'Digest of Hindu Law on Contracts and Successions.' A mission to Nagpur (1799-1801) interrupted his work, and on his return he was appointed a judge of the new court of appeals at Calcutta, and at the same time honorary professor of Hindu Law and Sanskrit at the college of Fort William. Yet he contrived during this busy period to publish the first (and only) volume of his 'Sanskrit Grammar' (1805), based upon Pānini and the native commentators, to write his famous articles on the Vedas and on the sect of Jains, besides many other valuable essays for 'Asiatic Researches,' and also to supplement his 'Digest' by 'Two Treatises on the Hindu Law of Inheritance' (1810).

Coleman, Arthur Philemon, Canadian educator: b. Lachute, Quebec, 4 April 1852. He was educated at Victoria University and at the University of Breslau, and after some years of scientific work he became professor of geology and natural history in Victoria University, and in 1891 professor of assaying and metallurgy in the School of Practical Science, Toronto.

Coleman, John, American clergyman: b. Baltimore, Md., 11 Feb. 1803; d. St. Louis, Mo., 16 Sept. 1869. Until 1834 he was a Methodist. He entered the Protestant Episcopal ministry in 1836, and for 20 years was rector of Trinity Church, Philadelphia. He edited the religious paper Banner of the Cross (Philadelphia); and also edited Faber's 'Difficulties of Romanism' (1840); and Wilmer's 'Episcopal Manual' (1841).

Coleman, Leighton, American Protestant Episcopal bishop: b. Philadelphia 3 May 1837. He was graduated at the General Theological Seminary in 1861, was ordained to the Episcopal ministry in 1862, and after holding important rectorships, was consecrated bishop of Delaware in 1888. He has written 'The Church in America.'

Coleman, Lyman, American clergyman and scholar: b. Middlefield, Mass., 14 June 1796; d. Easton, Pa., 16 March 1882. He grad-

uated at Yale 1817; taught in Hartford, Conn., 1817-20; was tutor in Yale 1820-5, studying theology at the same time. He was pastor of the Congregational Church in Belchertown, Mass., for seven years, when he again took up teaching. He studied in Germany 1842-3, where he formed a close friendship with Neander, and returning, taught German at Princeton and Amherst 1845-6. In 1856 he traveled extensively through the Orient. He was professor of Latin and Greek in Lafayette College from 1861 to 1868, when he was transferred to the chair of Latin, which he held until his death. His writings, which were highly praised and regarded in their day, are: 'Antiquities of the Christian Church' (1841), translated from the German; 'The Apostolical and Primitive Church' (1844); 'Historical Geography of the Bible' (1850); 'Ancient Christianity' (1852); 'Historical Text-Book and Atlas of Biblical Geography' (rev. ed. 1859); 'Prelacy and Ritualism' (1869); and 'Genealogy of the Lyman Family in Great Britain and America' (1872).

Coleman, William Tell, American pioneer: b. Cynthiana, Ky., 29 Feb. 1824; d. San Francisco, Cal., 22 Nov. 1893. In 1849 he made the overland trip to California, and opened several stores for the sale of mining supplies. When in 1851 the famous Vigilance Committee of San Francisco was formed to rid the city of its formidable criminal element, Coleman became one of the most active members. In 1856 the committee was revived in consequence of the murder of James King, an editor of William, Cal. Coleman took charge of the trials, resisted official pressure against interfering with "the people," directed the execution of Casey and the other murderers, and carefully avoided any clash with the United States authorities. From 1857 to 1864 he directed his business from New York, aided in suppressing the draft riot, and contributed liberally to patriotic benefactions. In 1877-8, at the request of the citizens of San Francisco, he organized the Committee of Safety, to fight Dennis Kearney and his sandlots mob, and in this was highly successful. In 1888 his firm failed with liabilities of \$2,000,000, but in 1892 he personally paid off his entire indebtedness, more than he was legally bound to pay, with interest.

Colenso, John William, English clergyman, bishop of Natal: b. Saint Austell, Cornwall, 24 Jan. 1814; d. Bishopstowe, Natal, 20 June 1883. He was educated at St. John's College, Cambridge; was assistant-master at Harrow 1838-42; resided at St. John's College 1842-6, when he was preferred to the rectory of Fornsett, St. Mary, Norfolk, and on 20 November 1853 was appointed the first bishop of Natal. His numerous writings extend over a wide field. His treatises on arithmetic and algebra have become text-books in schools and universities. In 1853 he published a collection of 'Village Sermons'; in 1855 'Ten Weeks in Natal' and an edition of the 'Communion Service with Selections from the Writings of the Rev. F. D. Maurice'; in 1861 a 'Translation of the Epistle to the Romans Commented on from a Missionary Point of View.' In the following year public attention was widely attracted by the first part of his work on 'The Pentateuch and Book of Joshua Critically Examined,' in which the historical accuracy and

COLEOPTERA — COLERIDGE

Mosaic authorship of those books were called in question. This work was condemned as heretical by slight majorities in both Houses of Convocation of the province of Canterbury in 1864, and Colenso was declared to be deposed from his see by his metropolitan, the bishop of Cape Town. The deposition was, however, declared null and void on appeal to the privy council in March 1865. Notwithstanding this decision the prelates forming the council of the Colonial Bishops Fund refused to pay him his income, and he appealed to the court of chancery. The master of the rolls delivered judgment on 6 Oct. 1866, ordering the payment in future of his income, with all arrears and interest, but declaring that if his accusers had refused payment on the ground of heretical teaching he should have felt it his duty to try that issue, an offer which they declined to accept. One of the results of this ecclesiastical quarrel was that the Anglican community of the Cape was divided into two hostile parties; Colenso still remained the only bishop of the Church of England in Natal, but the Rev. W. K. Macrorie was consecrated bishop of Maritzburg for the Church of the province of South Africa 25 June 1869. About the end of 1874 Colenso visited England, and during this visit he pleaded before the secretary for the colonies and other members of the government the cause of Langalibalele, a Zulu chief who had been dispossessed of his territory and imprisoned at Cape Town. From that time forward the humane bishop was foremost in advocating the cause of the aboriginals against the oppression of the Boers and the encroaching policy of the Cape officials supported by Sir Bartie Frere. The captive Cetewayo (see ZULULAND) appealed to Colenso to place his case before the English people, and it was mainly owing to the bishop's efforts that the Zulu king was allowed to go to England to plead his own case with the ministry. In the meantime Colenso continued his literary labors. 'The New Bible Commentary by the Bishops and Other Clergy of the Anglican Church Critically Examined' was published in 1871, the seventh and last part of his work on the Pentateuch in 1879, and 'Lectures on the Pentateuch and Moabite Stone' in 1873. Consult Cox, 'Life of Bishop Colenso' (1888).

Coleop'tera (Gr. *koleos*, a sheath and *pteron*, a wing), an order of insects the species of which are commonly known by the name of beetles. The insects which constitute the order *Coleoptera* may be characterized as having four wings, of which the two superior are not suited to flight, but form a covering and protection to the two inferior, and are of a hard and horny or parchment-like nature, and when closed their inner margins, which are straight, touch, and form a longitudinal suture. The inferior wings, when not in use, are folded transversely under the superior, and are membranous. The appendages of the mouth are well adapted for cutting, and the metamorphosis is complete.

Coler, Bird Sim, American politician: b. Illinois 1868. He removed to New York, and with his father, established the stock-broking firm of W. N. Coler & Company. He became active in Democratic municipal and State politics was elected comptroller in the first administration of Greater New York under the

new city charter (1900-1), and was Democratic candidate for governor of the State in 1902. In 1905 he was elected President of the Borough of Brooklyn on the Municipal Ownership platform. He has written 'Municipal Government, as Illustrated by the Charter, Finances, and Public Charities of New York' (1900).

Coleraine, kōl-rān', Ireland, a town in the county of Londonderry, situated on both sides of the river Bann, about four miles from its mouth, and 47 miles northwest of Belfast. It has long been celebrated for its fine linens. Its trade, chiefly in agricultural produce, and provisions, is considerable; and it has a valuable salmon fishery. Pop. 6,800.

Coleridge, kōl'rīj, Christabel Rose, English novelist: b. Chelsea, England, 1843. She is a daughter of Derwent Coleridge (q.v.), and for many years assisted Miss Charlotte Mary Yonge (q.v.) in editing 'The Monthly Packet.' She has published: 'Lady Betty' (1869); 'Hanbury Mills' (1872); 'Hugh Crichton's Romance' (1873); 'The Face of Carlyon and Other Stories' (1875); 'The Constant Prince' (1878); 'Kingsworth' (1881); 'An English Squire' (1881); 'The Girls of Flaxby' (1882); 'A Near Relation' (1886); 'A Plunge Into Troubled Waters' (1888); 'Reuben Everett' (1888); 'Amethyst' (1891); 'Waynflete' (1893); 'The Tender Mercies of the Good' (1895); 'The Main Chance' (1897); 'The Thought Rope' (1898); 'Tricks and Trials' (1899); 'The Winds of Cathrigg' (1901); 'Fifty Pounds'; 'The Green Girls of Greythorpe'; 'Life and Letters of Charlotte Mary Yonge' (1903).

Coleridge, Derwent, English clergyman and author: b. Keswick, England, 14 Sept. 1800; d. Torquay, Devonshire, 2 April 1883. He was a son of Samuel Taylor Coleridge (q.v.). He took orders in the Established Church, and engaging in teaching was master of the grammar school in Helston, Cornwall, 1825-40; and principal of Saint Mark's College, Chelsea, 1841-64. He was rector of Hanwell, Middlesex, 1864-80. He published 'The Scriptural Character of the English Church' (1839).

Coleridge, Ernest Hartley, English literary editor: b. 8 Dec. 1846. He is a son of Derwent Coleridge (q.v.) and was educated at Balliol College, Oxford. He engaged in tutoring 1872-93, and besides editing the 'Letters of Samuel Taylor Coleridge' (1895); 'Animæ Poetæ,' selections from unpublished notebooks of S. T. Coleridge (1895), and the 'Poetical Works of Lord Byron' (1898-1902), has published a volume of 'Poems' (1898).

Coleridge, Hartley, English poet: b. Clevedon, near Bristol, 19 Sept. 1796; d. Rydal, Westmoreland, 6 Jan. 1849. He was the eldest son of S. T. Coleridge (q.v.), and upon the elder Coleridge taking up his residence in the Lake district, Hartley and his brother Derwent were placed as day scholars under the charge of a clergyman at Ambleside. In 1815 he became a student at Merton College, Oxford, and having inherited his father's conversational talents, was soon in great request at the wine parties and other festivities of the undergraduates. An unfortunate propensity was thus formed for drinking, which proved even more ruinous than his father's craving for opium. He obtained a fellowship at Oriel College, but

COLEOPTERA.

COLERIDGE

forfeited it for intemperance before the close of his probationary year. He then left Oxford and resided for two years in London, contributing occasionally to the 'London Magazine,' in which his first sonnets appeared. His friends induced him against his will to settle at Ambleside for the reception of pupils, but this scheme, as might have been expected, failed. He continued, however, to reside in the Lake country, and during this period enjoyed the friendship and good offices of Wordsworth, who had taken a paternal interest in him from a child. He likewise employed himself extensively in study and literary composition, contributing to 'Blackwood's Magazine,' and producing a volume of 'Poems,' and 'Worthies of Yorkshire and Lancashire.' Many of his sonnets will rank with the finest in the English language, while the charming vivacity of his biographies leave only room for regret that he had not accomplished more as a prose writer. In 1839 he wrote a life of Massinger for an edition of his works published by Moxon. He was buried in Grasmere churchyard, adjoining the spot where Wordsworth was laid a few months afterward. A memoir, with a collection of poems written by him in his later years, was published after his death by his brother Derwent.

Coleridge, Henry Nelson, English writer: b. Ottery Saint Mary, 19 Sept. 1796; d. 26 Jan. 1843. He was a nephew of S. T. Coleridge (q.v.) and was educated at Eton and King's College, Cambridge. Having accompanied, in 1825, his uncle, the Bishop of Barbadoes, on a voyage to that island, on his return he published an account of his sojourn, under the title of 'Six Months in the West Indies.' He was called to the bar in 1826, and shortly afterward married his cousin Sara, only daughter of Samuel Taylor, and sister to Hartley Coleridge. In 1830 he published an 'Introduction to the Study of the Greek Classic Poets,' and after his uncle's death set himself to the task of committing to writing the reminiscences of Coleridge's conversation, which were published under the title of 'Specimens of the Table-talk of the late Samuel Taylor Coleridge.' He also edited the posthumous writings of his uncle, including three volumes of 'Literary Remains,' published in 1836 and 1838, and 'Confessions of an Inquiring Spirit,' in 1840.

Coleridge, Herbert, English philologist: b. Hampstead, Eng., 7 Oct. 1830; d. London 23 April 1861. He was a son of Henry Nelson Coleridge (q.v.), and was one of the original planners of the dictionary outlined by the Philological Society and which in subsequent years has expanded into the 'New English Dictionary on Historical Principles' in process of preparation from 1884.

Coleridge, John Duke Coleridge, LORD, Lord Chief Justice of England: b. London 3 Dec. 1820; d. 14 June 1894. He was the eldest son of Sir John Taylor Coleridge (q.v.), judge, a nephew of Samuel Taylor Coleridge. He was educated at Eton and Balliol College, Oxford, and was called to the bar at the Middle Temple in 1846. In 1855 he was appointed to the recordership of Portsmouth, six years later he became a queen's counsel, and soon afterward was chosen a bencher of the Middle Temple. From 1865 till 1873 he represented Exeter in the House of Commons as a Liberal, and in

1868 he became solicitor-general under Mr. Gladstone, being knighted at the same time. Three years later he became attorney-general, and in 1873 he was appointed chief justice of the court of common pleas. In the same year he was raised to the peerage as Baron Coleridge of Ottery St. Mary, and in 1880 succeeded Sir Alexander Cockburn as lord chief justice of England. Lord Coleridge distinguished himself very highly when acting as chief counsel for the Tichborne family in the famous trial of 1871-2. He was the first lord chief justice who was granted the office with his present title, instead of the older one of lord chief justice of the court of queen's bench.

Coleridge, Sir John Taylor, English jurist: b. Tiverton, Eng., 1790; d. Ottery Saint Mary 11 Feb. 1876. He was educated at Oxford, and was called to the bar of the Middle Temple in 1819. In 1835 he was appointed justice of the king's bench, and was sworn of the privy council in 1858. As a literary critic he took high rank, and besides editing an edition of 'Blackstone's Commentaries' (1825), published a 'Life of John Keble' (1869).

Coleridge, Miss M. E., English novelist: She has published 'The Seven Sleepers of Ephesus' (1893); 'The King With Two Faces' (1897); 'Non Sequitur' (1900); 'The Fiery Dawn' (1901).

Coleridge, Samuel Taylor, English poet and critic: b. Ottery Saint Mary, near Exeter, in Devonshire, England, 21 Oct. 1772; d. Highgate, London, 25 July 1834. It is customary to divide Coleridge's life into three periods, according to the prevailing interest of each; most of his poetry was written before the close of 1798; from that year till 1818, he was chiefly interested in criticism; and the last 16 years of his life were given mainly to metaphysical studies. As in the case of De Quincey, the first part of his life usually receives by far the more attention, and the interest of the last period resolves itself into an account of his writings.

He was the son of the Rev. John Coleridge, vicar of Ottery Saint Mary, a man inclined to mysticism and transcendentalism but also a pretty successful school teacher, and his second wife, Anne Bowden, a competent woman of much common-sense. Coleridge, the youngest of ten by this marriage, was the precocious one of the family and was regarded as a prodigy for his early attainments. His amusements were reading and dreaming and he early showed a marked liking for mysterious and spiritual things. In 1782, after schooling at his native place, he was sent to Christ's Hospital for eight years, where he was subjected to a rigorous intellectual discipline at the hands of the Rev. James Boyer, of whose methods he spoke with respect in 'Biographia Literaria' At school he left a tradition, preserved by Lamb, of his intellectual and spiritual attainments. At Jesus College, Cambridge, which he entered in 1791 with a view to taking orders, he gained some distinction as a writer of Latin and Greek, read a great deal, particularly in the philosophers Berkeley and Hartley, and absorbed and advocated the doctrines of the French Revolution. This last brought him such notoriety

COLERIDGE

that, in the fall of 1793, he ran away incognito to London, and enlisted in a company of dragoons, but, weary of his experiment, obtained his release the following spring. The following summer he tramped about in England and Wales, made the acquaintance of Southey (q.v.), with whom he devised the "Pantisocracy" scheme for a social settlement on the banks of the Susquehanna, became engaged to Sarah Fricker, the sister of Southey's fiancée, and definitely terminated his university career. The year was an active and somewhat critical one. It was followed by his addresses on political subjects "Conciones ad Populum, or Addresses to the People" (1795), which preached liberty, praised revolutionary doctrines, and condemned government; by his marriage (1795); his editorial venture on the *Watchman* (March to May 1796), in which he tried to expound true opinions on such subjects as the principles of the French Revolution, Godwin's ideas, and the like, and, more important, by his settlement in Nether Stowey, Somerset, in 1797, where he came in contact with Wordsworth.

The meeting had important results in English literature, for it led, in 1798, to the publication of the 'Lyrical Ballads' (see WORDSWORTH). Coleridge's own contribution to this volume, designed by its authors to change poetical taste, was his masterpiece 'The Ancient Mariner.' The year practically marks the end of his poetical production, though the famous 'Christabel' was not finished till two years later, and remained unpublished till 1816. Coleridge had previously written many poems; many of these were published in 1796 and 1797, under the title 'Poems on Various Subjects,' and he had also tried his hand at several dramas. Aside from the masterly 'Ancient Mariner,' 'Christabel' and 'Kubla Khan,' on which, together with a few others, his fame as a poet rests, the poems are chiefly interesting as showing the tenor of Coleridge's mind. In substance they are what is generally termed romantic, and are almost always treated with a view to expressing some underlying mystery. In style they might be called accumulative, in that they progress by the piling up of a great number of images, and in many respects they imitate the epithetical manner of Gray, but are less successful and less restrained. The great poems named are, of course, among the most original in the language. 1797-98 was the poet's golden year.

The middle period of Coleridge's life is marked by great desultoriness. It opened with much promise. After a journey to Germany (Sept. 1798 to Sept. 1799), in company with Wordsworth, he returned to England, where his first work was his brilliant translation of Schiller's 'Wallenstein,' usually regarded as one of the masterpieces of English translation. That same year and the following year he wrote a number of able articles for the *Morning Post* condemning, on the one hand, the policy of Pitt and, with equal zeal for the cause of liberty, the aggressions of Bonaparte. The impulse was short-lived. Failing health and growing restlessness caused him to go to Malta in 1804. It is known that at this period he was taking opium, but whether strictly for the alleviation of his pain, or whether the opium

was the cause of his failing health, is not definitely known. He made the acquaintance of the drug nearly ten years before and the severest of his critics, Mr. Robertson, maintains that all his most brilliant poems were written under its influence, but the whole matter is in some uncertainty, except for the fact that for a matter of 12 years he was, except at rare intervals, incapacitated from doing sustained work. From 1804 to 1816 he lived in great depression. A residence of two years and a half at Malta, where he was secretary to the governor, Sir Alexander Ball, was of no benefit to his health, and on the whole showed a weakening of purpose, as was natural to a man of weak will when removed from the guiding influence of friends. On his return his life was desultory and nomadic and he found himself in hard circumstances. Gradually becoming estranged from his friends and his family, he finally separated from his wife, and in 1810 left the Lake region for good. From that year till 1816, he lived at Hammersmith, London, and at Calne, in Wiltshire, with an old friend, John Morgan, by whom he was treated with the utmost kindness. Early in 1816, however, the Morgans, owing to loss of property, were obliged to give up the task, and, moreover, Coleridge, to whom the six years had been the most futile of his life, felt obliged to take some more energetic measures to redeem himself. Accordingly, in April 1816, a home was found for him with Dr. Gillman, in Highgate, London, where his health might be watched with care and firmness, and here he remained the rest of his life.

Up to 1818, as has been said, Coleridge was chiefly interested in criticism, but his work was, naturally, of a desultory nature. His first public utterances, after the articles in the *Morning Post*, were a series of 18 lectures on 'Poetry and the Fine Arts,' delivered at the Royal Institution in London, from January to May 1808. He had previously projected a course of lectures on the same subject, but they had come to nothing. The lectures of 1808 were very poorly given and were unsuccessful; DeQuincey has a vivid picture of the miserable figure that Coleridge presented as he faced his audience. Three courses in the winter of 1811-12 chiefly on Shakespeare and Milton, had a better fate, and, from accounts, must have made a great impression. These courses were recast into two which were badly delivered at Bristol in the winter of 1813-14. In 1818, Coleridge closed his career as a lecturer with a course on the history of literature which added much to his reputation. These various talks were published for the first time in 1836, in vols. I. and II. of Coleridge's 'Literary Remains.' In their present shape they are fragmentary; some are pretty complete, others merely marginal jottings, and others exist only in name.

Considered as a whole, these lectures attempted to define poetry, to trace in some detail the course of literature, to exalt to an unprecedented height the name and fame of Shakespeare, and to give his readers material for a sound critical judgment. Concerning the last of these points he said, for example, in the course of 1818, that he desired "To convey, in a form best fitted to render them impressive at the time, and remembered afterwards, rules and

COLERIDGE

principles of sound judgment, with a kind and degree of connected information such as the hearers cannot generally be supposed likely to form, collect, and arrange for themselves by their own unassisted studies," and he added, "I hope to satisfy many an ingenious mind, seriously interested in its own development and cultivation, how moderate a number of volumes, if only they be judiciously chosen, will suffice for the attainment of every wise and desirable purpose: that is, in addition to those which he studies for specific and professional purposes." Among the many great names which he chose to illustrate this oft-repeated idea, Shakespeare, in all the courses of lectures, occupied the chief place. His chief thesis, that Shakespeare is a poet of consummate poetical power and that his judgment is equal to his genius, he illustrated and illuminated with copious analysis and criticism, chiefly by running interpretation of the different plays and by pregnant statements of the fundamental differences in dramatic interest in the different types of play. Generally speaking his point of view is that of a man interested in works that express the soul, the reason, and the imagination, rather than outward situation, intelligence, fancy, or wit. More narrowly, it is the criticism of a man who gloried in the superiority of the literature of his own country, and of the moralist who abhorred the quality of the 'Decameron' and the misanthropy of Swift, and who praised the moral lessons of 'Robinson Crusoe' and 'Macbeth.' Nearly all his criticism in these lectures shows a love of fundamental distinctions, as, for example, the chivalric spirit of Spenser as compared with the universal, impersonal spirit of Shakespeare; or the distinctions between the witty, the droll, the odd, the humorous, etc., as illustrated by Rabelais, Swift, Sterne, and others. This idea of drawing fundamental distinctions has had a great influence on succeeding criticism.

Even more characteristic of the Coleridge of this period was the series of essays called 'The Friend.' This he intended to issue in Jan. 1809, but he characteristically put it off until the midsummer. Thence it ran till March 1810. He attempted to publish it himself as a weekly periodical from the Lake district, but his practical mismanagement was such that it rarely came out on time, and the scheme came to an end with the 27th number, long before he had reached his main point. The work was re-issued in 1818 with additions. The plan of the periodical, as well as Coleridge's conduct of it, foredoomed it to failure. Without regard to the work of his predecessors in the essay field, he attempted to treat philosophical questions and inflicted them on his readers with little variety and much diffuseness. The volume as it stands to-day contains three main parts dealing respectively with the laws of right thinking for the individual as an individual, the principles of political knowledge, and the "grounds of morals and religion and the discipline of the mind requisite for the understanding of the same." These are separated by essays in a lighter vein entitled 'Landing Places.' In spite, however, of the total lack of adaptation of the subjects to the tastes of his readers and to the periodical form, and his own unbusinesslike ways, the book as it now stands is regarded as

containing much of Coleridge's most stimulating work, his best flashes of insight, and is, in particular, replete with those famous distinctions, like that between reason and understanding, truth and veracity, which have proved stimulating to the spirits of succeeding generations. Much of its value lies in its point of view, which is that of an idealist who believes that motives are more important than results and that right thinking on all questions is better than action directed by mere prudence; and it lies also in his persuasive and winning style.

More important than 'The Friend,' indeed his most valuable work, is the 'Biographia Literaria.' This he projected and in a measure composed in 1815, but the happy results of his change to the Gillman's probably allowed him to improve the form of the book for its publication in 1817. His specific purpose, characteristically enunciated after the book was well under way, was to give voice to miscellaneous reflections suggested by particular events, to state his views on politics, religion, philosophy, poetry, and criticism, and to settle, on principle, the controversy that had grown up about the 'Lyrical Ballads.' On the philosophical side, the book amounts to a protest against materialist views of the origin of ideas, and it is notable for his digressions and distinctions, as that important one, which he borrowed largely from Schelling, between the objective facts of the world and a self-sustaining and self-regulating consciousness, independent and indestructible. The critical ideas, brought out most vigorously in his classic criticism of Wordsworth, are more important, and are among the most influential ever enunciated by any English critic. Abandoning the formalism of preceding English critics, and eschewing the oracular dogmatism of contemporary reviewers, such as Jeffrey, he rested his critical case on (1) a theory of poetry deduced, not from authority, but from philosophy, logic, psychology, and what he called "the nature of man"; (2) on the actual phenomena as presented by the actual vogue of an author, a complete, rather than a partial, view of an author's production, the purpose of the author as revealed in the interpretation of his meaning, and an analysis of the qualities of his style; and (3), in a wholly impressionistic way, on a feeling for what is good in poetry—which last, indeed, is really his ultimate test. So far as can be seen by a comparison with such earlier critics as Dryden, Addison, and Johnson, he pushed to a further degree than his distinguished predecessors his dependence on a theory of art and on philosophy, his reliance on analysis of qualities, and his personal feeling for what is good; and he is practically original among English critics up to his time in taking into account as necessary points of departure, the vogue of an author and his purpose. He differs from such contemporary critics as Lamb and Hazlitt in not trusting, at least ostensibly, to feeling alone, and from DeQuincey, in that the latter usually lays chief stress on what might be termed the intellectual contribution of an author. The more strictly autobiographical parts of 'Biographia Literaria' deal for the most part with Coleridge's intellectual experiences and the influences to which he was subject.

COLERIDGE

The remaining literary work of this period is of less importance. It comprises some desultory and comparatively colorless articles for the *Courier* in 1808 and 1811, chiefly against Bonaparte, the recasting and acting (1813) with some success of his drama 'Remorse' and the writing of the pastoral play 'Zapolya' (1817), 'The Statesman's Manual' (1816), a challenge to "all the critical benches of infidelity to point out any one important truth, any one efficient practical direction or warning, which did not pre-exist (and for the most part in a sounder, more intelligible, and more comprehensive form) in the Bible," and "A lay sermon addressed to the higher and middle classes on the existing distresses and discontents" (1817), an earnest and eloquent appeal to his readers to live by reason and wisdom and to refer conduct to ultimate principles.

The last named titles anticipate the chief subject of the so-called last period of Coleridge's career—his interest in theology and metaphysics. His writings on those subjects are embraced in three chief titles—'Aids to Reflection' (1825), 'On the Constitution of the Church and State' (1830), and the posthumous 'Confessions of an Enquiring Spirit' (1840, written between 1824 and 1834). Though these writings probably did more than any other of the author's to give him the great reputation which he had in the contemporary and succeeding generation, they add little to our knowledge of the great principles which dominated Coleridge's intellectual life. The 'Aids to Reflection,' his most important spiritual work, is a series of aphorisms designed to help the reader to think and feel rightly, that is in an orthodox, Anglican way, on spiritual matters. In his own words, he aimed "to direct the reader's attention to the value and science of words—to establish the distinct characters of prudence, morality, and religion—to substantiate and set forth at large the momentous distinction between reason and understanding—to exhibit a full and consistent scheme of the Christian Dispensation, and more largely of all the peculiar doctrines of the Christian Faith." His point of view is characteristically theoretical, introspective, and mystical, rather than objective and historical, and his exposition is, as usual, fragmentary and unsystematic. 'On the Constitution of the Church and State,' a more regularly sustained thesis, contains much the same premises, and is a piece of special pleading, ostensibly designed to show the people of England how to think and vote rightly on the question of Catholic emancipation. It is substantially an argument in favor of the national church. The 'Confessions' is one of the most striking expressions of a well-known doctrine of the 19th century that the Bible, the only sufficient rule of faith and practice, is nevertheless not to be taken literally but in what Arnold later called a literary way and Coleridge here called "according to reason." The demonstration of its truth is internal, not dogmatic. To this period also belongs Coleridge's 'Table Talk,' published after his death from the notes made by H. N. Coleridge between 1822 and 1834, and containing a rich and varied array of observations, chiefly philosophic in character, from the most brilliant talker of the time.

Critics of Coleridge are pretty well united in calling him one of the great sources of intellectual stimulus of his generation. His supporters, like Mill, point out the fundamental fact of his vast influence in fecundating the mind of his contemporaries. His detractors, like J. M. Robertson, lay stress on his desultory habits of mind, his weakness of character, and his vast plagiarism "unparalleled in literary history." The truth is probably that he so keenly and genuinely desired to find fundamental principles and sanctions for belief and action that he did not mind where he got his principles so long as they impressed him. Setting aside the question of his influence, his work (aside from his poetry) is, as it stands, remarkable for its avoidance of history in all its forms, of science as we know the term, and for its confinement to the fields of philosophy, metaphysics, theology, and criticism. In these fields it is almost wholly introspective, it consists of an examination of the contents of his mind, and is noteworthy for an almost complete lack of sense for external fact. Within these limits, few writers have scattered broadcast so many stimulating ideas; his apothegms and pregnant sayings are enormous in number, as well as recurrent. Added to this is an acute logical sense for detecting flaws in the arguments of an opposing view, a feeling for axiomatic proof, and a style, which, though desultory and essentially a monologue, is often marked by grandeur and charm.

Bibliography.—The standard edition of the works is that edited by Shedd (1853) in 7 vols., which is complete except for some of the articles from the *Morning Post* and the *Watchman*, and as yet unpublished marginalia. Separate editions of the poems and certain of the prose writings are numerous. There are lives by H. D. Traill in the 'English Men of Letters,' Professor Alois Brandl (trans. by Lady Eastlake), and Leslie Stephen in the 'Dictionary of National Biography.' Hall Caine in 'Great Writers Series,' and J. D. Campbell. Representative essays of diverse views are those of J. S. Mill ('Dissertations and Discussions,' vol. 2), Leslie Stephen ('Hours in a Library,' vol. 3), Walter Pater ('Appreciations'), G. E. Woodberry ('The Makers of Literature'), and J. M. Robertson ('New Essays Toward a Critical Method').

WILLIAM T. BREWSTER,

Professor of English, Columbia University.

Coleridge, Sara, English poet: b. Keswick 22 Dec. 1802; d. London 3 May 1852. She was the daughter of S. T. Coleridge (q.v.), and was married to Henry Nelson Coleridge in 1829. She is best known by the romance 'Phantasmion,' and her editions of 'Aids to Reflection,' and other works. She was also author of 'Pretty Lessons for Little Children.' Her 'Memoirs and Letters' appeared in 1873.

Coleridge, Stephen, English author and artist: b. 31 May 1854. He was educated at Bradfield College, and Trinity College, Cambridge. He has exhibited pictures at Birmingham, Leeds, and elsewhere, is honorary secretary of the National Anti-vivisection Society, and has published 'Demetrius' (1887); 'The Sanctity of Confession' (1890); 'Gloria' (1903).

COLES — COLGATE UNIVERSITY

Coles, kōlz, Abraham, American prose-writer and poet: b. Scotch Plains, N. J., 26 Dec. 1813; d. Monterey, Cal., 3 May 1891. In 1835 he graduated from Jefferson Medical College, Philadelphia. He published 13 original translations of the celebrated hymn 'Dies Iræ' (1859); 'Old Gems in New Settings' (1866); 'The Microcosm'; and 'The Light of the World' (1884).

Coles, Edward, American political leader: b. Albemarle County, Va., 15 Dec. 1786; d. Philadelphia, Pa., 7 July 1868. He was graduated from William and Mary College in 1807. He was Madison's private secretary from 1810 to 1816, and in 1817 was sent on a diplomatic mission to Russia. Shortly after his return to the United States he removed to Illinois; while living in Virginia he had owned slaves, but took them with him and liberated them, and soon became prominently identified with the anti-slavery party in Illinois. In 1822 he was elected governor of the State, holding that office till 1826. During his administration an attempt was made to amend the State constitution in favor of slavery, but under his leadership the anti-slavery party carried on a vigorous campaign in opposition to the proposed amendment and decisively defeated it. After 1833 he lived in Philadelphia. Consult Washburne, 'Sketch of Edward Coles.'

Colet, kōl'ēt, John, English divine, founder of St. Paul's School, London: b. London 1466; d. there 16 Sept. 1519. His father, Sir Henry Colet, was twice lord mayor of London. About 1493 he set out to make a continental tour, and became acquainted with several of the most eminent men of the time, and more especially with Erasmus. While on the continent, he studied Greek, canon, and civil law, and the writings of the fathers. In 1496 he returned to England, and in the following year he was ordained, took up his residence in Oxford, and lectured in Latin on St. Paul's Epistle to the Romans. He was an ardent advocate of the new learning and an admirable Biblical scholar. Erasmus was one of his audience at a later series of lectures on the First Epistle to the Corinthians, and from this time (1498) the two became warm personal friends. In 1505 Colet was appointed dean of St. Paul's. With Sir Thomas More and others he urgently advocated the reform of certain ecclesiastical abuses, but it is an utter mistake to suppose that he held anything in common with the spirit of the Protestant Reformation. St. Paul's School was founded and endowed in 1512, the earliest school in England in which Greek was a regular part of the curriculum. His writings are not numerous, but gave good evidence of his learning and piety. In 1867-76, J. H. Lupton produced an edition of those of Colet's works not published during the 16th and 17th centuries. The most recent biography is that by Lupton (1887).

Colet, Louise Révoil, loo-ēz rā-vwāl kō-lā, French poet and novelist: b. Aix, France, 15 Sept. 1810; d. Paris 8 March 1876. Four times between 1839 and 1855, poems of hers were crowned by the French Academy. She was a graceful lyrist, and often struck the chord of deep passion with effect. Of her verses, poured forth with marvelous facility, 'The Woman's Poem' is perhaps her best after the four offered to the Academy. Among her

numerous novels, 'Bruised Hearts' (1843) may be mentioned. She also wrote several narratives of travel.

Colewort, kōl'wért, a common name for several cultivated varieties of cabbage (q.v.).

Col'fax, Schuyler, American statesman: b. New York 23 March 1823; d. Mankato, Minn., 13 Jan. 1885. He removed in 1836 to Indiana, where in 1845 he acquired a newspaper at South Bend, which he made the most influential Whig journal in the district. He was a delegate to the Whig conventions of 1848 and 1852; was elected to Congress in 1854 by the newly formed Republican party, and re-elected until 1869, being thrice chosen speaker; and in 1868 he was elected vice-president of the United States, in Grant's first term. Implicated, unjustly, as he and his friends claimed, in the Credit Mobilier charges of 1873, he spent the remainder of his life in political retirement, making public appearances only on the lecture platform. He was the founder of the Daughters of Rebekah branch of American Odd Fellowship.

Colfax, Wash., city, county-seat of Whitman County. It is situated on the Palouse River, the line of the Oregon Railroad and Navigation Company, and 80 miles south of Spokane. It is a trade centre for the products of the fertile, surrounding country; grains, lumber, and live stock are the chief exports. Manufactures are increasing. The waterworks are owned by the city. Pop. 2,300.

Col'gate, James Boorman, American philanthropist: b. New York 4 March 1818; d. Yonkers, N. Y., 7 Feb. 1904. He was for some years a member of the dry goods firm of Colgate & Abbe in New York, and in 1852 formed a partnership with J. B. Trevor as dealers in stocks and securities. To Colgate University (q.v.) he gave several buildings and an endowment of \$1,000,000, called the Dodge Memorial Fund, and also gave to other institutions.

Colgate, Samuel, American manufacturer: b. New York 22 March 1822; d. Orange, N. J., 23 April 1897. He was a son of William Colgate, founder of the soap and perfumery house of Colgate & Company. Samuel Colgate succeeded his father as head of the firm, and continued his father's generous benefactions to religious, educational, and charitable enterprises. With his brother, he erected Colgate Academy building in Hamilton, N. Y., at a cost of \$60,000, and in recognition of their munificent gifts to Madison University, in the same place, the name of that institution was changed to Colgate University. He was a contributor to every charity in Orange, N. J., and at his death bequeathed to Colgate University his valuable collection of Baptist reports and literature, numbering 40,000 titles, in several languages.

Colgate University, an educational institution at Hamilton, N. Y., founded in 1819 as a school for the education of Baptist ministers. The collegiate and preparatory departments were later added. The name was originally Madison University, and was changed in 1890 in honor of the principal benefactors, the Colgate family. Soon afterward James B. Colgate established an endowment fund of \$1,000,000 in memory of Ebenezer Dodge, who was president for over 20 years. The theological seminary, which was at first a separate corporation,

COLIC — COLIMA

was incorporated with the university, the professors being members of the university faculty; the preparatory department (Colgate Academy) is also a part of the university, and its principal a member of the faculty. The college has two distinct courses, leading to the degrees of A.B. and B.S., and provision is made for graduate work for the corresponding masters' degrees. The theological course (three years) leads to the degree of B.D. The library numbers nearly 35,000 bound volumes; besides this there is in the library building the Baptist Historical Collection, of about 60,000 volumes and pamphlets, the bequest of Mr. Samuel Colgate. At the end of 1905 the university reported 37 professors and instructors, 413 students (228 in the college); value of property over \$2,200,000; president, George E. Merrill, D.D.

Colic, in pathology, a painful affection of the intestines, especially of the large bowel or colon, whence the name. The pain is due to spasmodic and irregular contractions of the colon, and is felt chiefly in the region of the navel. It is of a severe twisting character, and comes on in paroxysms, occasionally so severe that the patient rolls and twists about, usually doubled up and grasping his abdomen, and not seldom groaning or crying. Constipation of the bowels usually accompanies colic, and the pain may give rise to vomiting. Often, however, severe colicky pains are the forerunner of looseness of the bowels, caused by some food which has disagreed. The pain may be caused by wind, the discharge of which affords great relief. There is no fever with the attack, but the pulse is usually lowered, and the face pale and anxious-looking. In this respect colic differs from inflammatory attacks of the bowels. Pressure on the abdomen generally gives relief in cases of colic, but in cases of inflammation the patient cannot endure pressure. Whether the attack be one of colic or not may readily be learned from the attitude of the sufferer and the fact of his exerting or avoiding pressure. Treatment consists in applying hot cloths or bags of hot salt across the abdomen. Doses of medicine, such as castor-oil, should also be administered, and a large injection of water at a gentle warmth will probably bring relief. In the case of an adult patient 30 drops of laudanum may be given along with the castor-oil, or shortly after it. Magnesia and dill-water are also used as remedies for colic in young children. What is called biliary or renal colic is caused by the passage of gall-stones or kidney stones toward the bowel or bladder respectively. It occurs oftener in women than in men.

Coligny, kō-lēn-yē, **Gaspard de**, French soldier: b. Châtillon-sur-Loing 16 Feb. 1517; d. Paris 24 Aug. 1572. After a brilliant military career he was made in 1552 admiral of France. He was distinguished for valor in battle, for strict discipline, and for his conquests over the Spaniards, in particular for his defense of St. Quentin. When St. Quentin was taken by storm, the admiral was made prisoner. After the death of Henry II., the intrigues of Catharine de Medici induced him to place himself at the head of the Calvinists against the Guises. He formed so powerful a party that the Catholic religion in France seemed to be in danger. Condé was more ambitious, enterpris-

ing, active; Coligny more considerate, prudent, and more fit to be the leader of a party; equally unfortunate in war with Condé, but skilled in remedying even what appeared irretrievable losses, and more to be feared after a defeat than his enemies after a victory. The first battle between the Huguenots and Catholics (1562, at Dreux) was lost by the admiral, but he saved his army. When the Duke of Guise was murdered at the siege of Orleans, he was accused of being the author of the murder. The civil war re-commenced with increased fury in 1567. Coligny and Condé encountered the Constable Montmorency at St. Denis. This indecisive action was followed by the battle of Jarnac in 1569, which was fatal to the Calvinists. Condé fell, and the whole burden of command devolved on Coligny. An advantageous peace seemingly put a stop to this contest in 1570. Coligny appeared at court, and was, with his adherents, loaded with favors. Charles IX. gave him 100,000 francs as an indemnification for his injuries, together with a seat in the council. From all sides he was warned not to trust to these caresses. As the admiral was leaving the Louvre 22 Aug. 1572 his right hand and left arm were wounded by a shot from a window. One Maurenal had fired at him from a building belonging to the monastery of St. Germain l'Auxerrois, according to the plan of Catharine de Medici, probably with the knowledge of the Duke of Guise. Charles testified the deepest sorrow, caused search to be made for the assassin, and said to Coligny, "My father, you have the wounds, but I the pain." This he said at the moment when the massacre of the Protestants was already prepared. The slaughter began on the night of St. Bartholomew's, 24 Aug. 1572. The Duke of Guise hastened with a numerous suite to the house of the admiral. One Behme, or Besme, at their head, entered with his drawn sword into the chamber of the old man, pierced him with several stabs and threw the body out of the window into the courtyard.

Coliidae. See MOUSEBIRD.

Colima, kō-lē'mä, Mexico, a state in the southwest of the United States of Mexico. It includes the four desert islands, Socorro, Rosa Partida, San Benedicto, and Clarion, which form the Revillagigedo group. The northern section of the state is occupied by the slopes of the Colima volcanoes. The Armeria River flows through the state, and the Coahuayana is on the boundary. There are two lakes, Cuyuthan and Alcuzaque. The climate, except in the mountainous region, is hot and unhealthy. Rainfall is abundant, and malaria prevails. Salt, silver, gold, sulphur, and copper are found; about 170 species of trees, including fruit, and trees, the parts of which are useful for tanning, dyeing, clothing, food, and medicine. The chief products are coffee, cacao, tobacco, rice, cotton, indigo, sugarcane, cereal, and leguminous plants. The principal industries are agriculture, stock-raising, and working in the salt sections. Much of the trade is with the other states of Mexico, especially those along the coast, but it has a growing trade with Germany, Hawaii, and the United States cities on the Pacific. Exports are: rice, coffee, rubber, fruits, cabinet and dye woods, corn, hides and skins, and minerals. Imports are: woolen, linen, and silk

COLIMA — COLLARS AND CUFFS

goods, foodstuffs, wines and liquors, glass-ware, firearms and ammunition. The Pacific Mail, Red Line, Izaquirre, and the Sinaloa and Durango Railway Company's steamers connect the port of Manzanillo with other ports, foreign and domestic.

Colima, Mexico, capital of the state of Colima. It is situated in a fertile valley, which is irrigated by the Colima River. The principal buildings are the city hall, cathedral, theatre, the station of the Mexican N. R.R., and a new market. It has an electric-lighting system, a street-car line, etc. (See COLIMA, THE STATE OF.) Pop. 18,977.

Colin Clout, *kōl'in klowt*, a satire by John Skelton. It was a vigorous pre-Reformation protest against the clergy's lack of learning and piety.

Colise'um, more properly **Colosseum**, a gigantic ruin in Rome, the greatest amphitheatre which Roman magnificence ever erected. It was commenced by Vespasian (reigned 69-79 A.D.), and practically finished by Titus about the year 80 A.D., who dedicated it with shows in which 5,000 animals were killed. It was built to furnish a place for amusements for the Roman people; such as gladiatorial combats, fights with wild beasts, and less harmless athletic sports. In the early days of Christianity it was the scene of the martyrdom of a number of the Christians. It is said to have held 100,000 spectators, of whom about 87,000 were seated. For the greater part it consists of travertine, is elliptical in shape, 1,680 feet in circumference, and 157 feet high, and has three rows of columns, one above the other: the lowest is of the Doric, the second the Ionic, and the highest the Corinthian order. The diameter of the arena from side to side was 182 feet, from end to end 285 feet. Down to the 6th century this monument of ancient grandeur remained almost uninjured, when Theodoric, king of the Goths, caused material to be taken from it for the construction of various buildings; afterward Pope Paul II. took all the stones from it, which were used for the construction of the palace of St. Mark, and in later times some other palaces were erected from its fragments.

Colitis, *kō-lī'tis*, a general term indicating a disorder of the large intestine or colon. Disease or disorders of the colon may be due to a large variety of causes. A simple diarrhoea may persist, becoming chronic, or an enterocolitis (q.v.), or the initial process may have been dysenteric in character and, persisting, may have become a chronic colitis (see DYSENTERY).

Col'lamer, Jacob, American senator: b. Troy, N. Y., 8 Jan. 1791; d. Woodstock, Vt., 9 Nov. 1865. He graduated at the University of Vermont 1810, studied law at Saint Albans, and was admitted to the bar 1813. He became associate justice of the Vermont supreme court 1833-42; representative in Congress 1843-7; was appointed postmaster-general in 1849, but resigned upon the death of President Taylor; was again elected judge of the Vermont supreme court and held that office until 1854, when he was elected United States senator and remained such until his death.

Collar-bone. See CLAVICLE.

Collars and Cuffs, Manufacture of. The collar trade, a distinct and important branch of the "gent's furnishing" industry, originated at Troy, N. Y., about 1825, when the wife of a blacksmith conceived the idea of making the first detachable collar. Prior to that time shirts had always been made with the collars and cuffs attached to them, and no one seems to have thought that they might possibly be detached until the day her scissors cut the first pattern from a strip of paper. It is unfortunate, from the point of view of the historian, that the name of this clever woman should have been lost, and it is to be hoped that her inventive genius was financially rewarded. That she must have reaped some benefit from the innovation there can be but little doubt, for the detachable collar soon became extremely popular, and, in 1829, Rev. Ebenezer Brown, who had retired from the Methodist ministry to establish a dry goods store in Troy, opened a small factory that he might manufacture such collars in greater quantities.

As this branch of Mr. Brown's business increased very rapidly it was not long before he had several imitators. Somewhat prior to 1834 Orlando Montague and Austin Granger, who were then in business under the firm name of Montague & Granger, erected a still larger factory and devoted it to this industry. About a year later Independence Stark began to make collars in quantities, and, about 1837, he opened an establishment for the laundering of collars, both his own and other manufacturer's make. As this was undoubtedly the first "Troy Laundry," a name which is now known from one end of the land to the other, it is interesting to note that the inauguration of this independent industry was so largely the effect of the invention of the detachable collar. In these days, collars were known as "String Collars," because they were then tied around the neck by means of a string attached to each end. They were worn with the old-fashioned stock tie.

The manufacture of detachable cuffs did not begin until 1845, and, as in the making of cuffs, everything was then done by hand. In fact it was not until the latter part of 1851 that anybody had considered it possible to manufacture such a product by machinery, and, when Nathaniel Wheeler, of the firm of Wheeler & Wilson, attempted to introduce his new sewing machine, the collar and cuff makers laughed at him for his presumption in declaring that his invention would enable them to produce as good a collar or cuff at a cheaper cost than any human agency could sew it. Among all the Troy manufacturers only one, Jefferson Gardner, was willing to give the machine a trial, but his experiences were so satisfactory that, within twelve months, the other factories were not only supplied with similar machines, but one of the manufacturers, W. O. Edson, of the firm of Bennett & Edson, was also operating them by means of steam power.

The second great invention to which the amazing growth of the collar and cuff industry is so largely due was the introduction of the button-hole sewing machine, in 1875. If it had not been for this timely discovery the makers of collars and cuffs in the United States would never have been able to supply the demands of

COLLATION — COLLEGE

the market. At the present time, for example, they are required to make over 500,000,000 button-holes per annum, and to have found a sufficient number of human hands to have made these button-holes would have been a practical impossibility.

Those who are unacquainted with the manufacture of collars and cuffs would be surprised if they could see the almost infinite detail with which the making of these common articles of wearing apparel is attended. A single collar, for example, will often pass through as many as twenty-five different operations, each of which requires the attention of a workman who is an expert in his particular line of the trade. The designing of patterns is also expert work, as there are sometimes many patterns for a single collar, each ply being cut to a different measure.

It is an extremely difficult matter to secure anything like reliable statistics relating to the collar and cuff industry, because, as an industry, it is of such recent origin that it was not honored with a separate classification in any United States census report prior to that of 1900. Moreover, as the making of collars and cuffs is carried on conjointly with the making of shirts by many of the big manufacturers, it is not easy to make a satisfactory arrangement of such data as may be obtainable. Of all the statistics ever published, however, those of the census bureau have met with the most favorable reception from all.

According to these figures, the total value of the collar and cuff product of the United States for the year ending June, 1900, was \$9,077,700, of which amount \$8,073,271, or 89½ per cent., was made at Troy, and 99.4 per cent. in the State of New York. During the same year no less than 10,086,045 dozen collars and cuffs were made in the United States, of which number 8,881,400 dozen were made in Troy, while of the 17,115 workmen who depended upon this industry for their support the 14,822 who resided in Troy draw \$4,956,427 in wages out of the total amount of wages paid in this industry in the United States, \$5,658,969. The importance of the industry to the city of Troy is further indicated by the fact that, according to the same census reports, of the 21,564 wage earners who made that city their home during that year, no less than 14,822, or fully 68.7 per cent., were employed in the collar and cuff factories.

Colla'tion. 1. In the canon law of the Anglican Church, the act of a bishop in appointing a clergyman to a benefice (whether rectory, vicarage, canonry, or prebend) when the living is in his own gift through lapse or otherwise. In such a case the combination of the act of presentation and admission or institution constitutes collation. In the Roman Catholic Church the word has much the same meaning when applied to the conferring of a benefice, except that some benefices are conferred by the bishop or some delegated ecclesiastic; others, and in a few cases only by special grant of the Pope, a king or an abbeſs. In several countries of Europe the right of conferring the higher ecclesiastical dignities is regulated by a concordat between the Holy See and the respective governments.

2. Collation, the name given to the restricted meal, sometimes permitted on fast days, usu-

ally food to the amount of about eight ounces or one fourth of an ordinary meal.

Col'lect (*Collecta*) in ecclesiastical language means a collection, as of alms, taken up during the church service; this is of apostolic origin, and St. Paul mentions the collections for the saints taken up on the first day of the week. Used in still another meaning it signified what collect still does in English, a brief prayer pronounced by the priest in celebrating Mass after the Gloria.

Collect or **Collect Pond**, a small lake in old New York. See **NEW YORK**.

Collec'tivism, a plan of social organization in which the means of production and distribution in a community would belong to the people collectively. The term is also applied to the theory that society should be so organized. In the collectivist commonwealth the people cooperatively organized would have full control of production and distribution. Collectivism does not involve the abolition of all private property, but only of private property in the means of production. Collectivism is considered by Socialists as the natural successor to the present social system, and is the form of organization which they seek to establish; hence the term collectivism is often used as synonymous with Socialism (q.v.).

Collector of the Port. See **CUSTOMS**.

Colleen Bawn, kōl'ēn bân, **The**, a noted play by Dion Boucicault. It was based on Gerald Griffin's novel 'The Collegians' (1828) and was first played 10 Sept. 1860. The novel was republished in 1861 as 'Colleen Bawn or the Collegian's Wife.'

College (Latin, *collegium*), in its primary sense, a body of colleagues, a corporation or society of persons invested with certain powers and rights, performing certain duties, or engaged in some common employment. In Great Britain and America some societies of physicians are called colleges. So, also, there are colleges of surgeons, a college of heralds, etc. Colleges of these kinds are usually incorporated or established by the supreme power of the state. The most familiar application of the term college in English is to a society of persons engaged in the pursuits of literature or science, including both professors and students. At first the students of the universities had no common bond of union, except that of study and discipline, and were lodged where they could find it convenient. Then hostels or boarding-houses were provided (principally by the religious orders, for the benefit of those of their own fraternity), in which the scholars lived under a certain superintendence. Charitable persons subsequently endowed these hostels that poor scholars might have free lodgings. The colleges of Oxford and Cambridge are academical institutions of this kind, each endowed with revenues of its own, and having fellows, students, and tutors, who live together under a head, in particular buildings. Each college is regulated by laws framed by its founder, with such modifications as have been deemed necessary to introduce from time to time. According to these laws, the head (variously styled master, principal, warden, rector, etc.), is either chosen by the fellows from their own number, or appointed

COLLEGE

by the crown or other authority. The fellows are graduates who receive special emoluments for a term of years, and are generally elected to the position on account of special scholarship; while the scholars, admitted as undergraduates, are either chosen from particular localities, schools, etc., or elected according to merit after free competition. There are also a number of ordinary students, all as a rule occupying chambers belonging to the college. The undergraduates receive their instruction chiefly from tutors, who are generally resident fellows. The colleges are subordinate to the university, and it is the university that confers degrees, and institutes and carries out the necessary examinations. Generally speaking, the term college implies an institution inferior to a university, so far at least as the right of conferring degrees is concerned; but in Scotland, Germany, and elsewhere there are no colleges such as those of Oxford and Cambridge, and the college or colleges in Scotland are simply edifices in which the teaching is carried on. Some modern colleges are called university colleges, either because equipped similarly to a university, or because connected with a university, and able to train students for degrees to be obtained from that university. Institutions for teaching theology are often called colleges, and some schools that train pupils for the universities, or give a good secondary education, are also so called.

In France there are university colleges or *facultés* in all large towns, besides *lycées*, corresponding to what are called, in Germany, *gymnasias*. Other institutions of a similar kind, that is, schools for secondary education, are called *colléges communaux*. These are public establishments aided by the communes, and subject to the direction of the public authorities. Besides these, there is the *Collège de France*, which deserves the name of a university. It was instituted in 1529 by Francis I., and here numerous professors, among whom there are always some of the most distinguished men, lecture publicly and gratuitously.

College, The American. *Its Place and Importance.*—The American college has no exact counterpart in the educational system of any other country, although its elements are derived from European systems, and in particular from Great Britain. And while it is true that the primary form of organization in our earliest colleges, such as Harvard, Yale, and Princeton, was inherited from the English University of Cambridge, still it was subjected to modification at the very beginning, to adapt the college to its community, and afterward it was progressively modified to assure close sympathy with the character of the growing American nation. The result is an institution with derived elements of composition, and in less degree of form, which has developed for itself an organization notably different from the old-world schools.

So the college, from the nature of its development, holds the central place in the historic growth of American higher education. It remains to-day the one repository and shelter of liberal education as distinguished from technical or commercial training, the only available foundation for the erection of universities containing faculties devoted to the maintenance of pure

learning, and the only institution which can furnish the preparation which is always desired, even though it is not yet generally exacted, by professional schools. Singularly enough, the relation of directive influence sustained to-day by our colleges to the university problem is not unlike the relation held in the Middle Ages by the inferior faculty of arts at the University of Paris to the affairs of the university as a whole. In both cases the college, or faculty of arts, appears as the preliminary instructor in the essentials of liberal education; this earlier education is recognized as the proper requisite for later study in the professional faculties; and in both cases the inferior faculty contains the germ of the higher university faculty of pure learning, the faculty of arts, sciences, and philosophy. The reason for this similarity is that the American college in this respect perpetuates and develops a fundamental tradition of liberal learning, which found its way from Paris through Oxford to Cambridge, and then from Cambridge to our shores. The parallel of our college history with the old-world history holds good in other important respects. Still, in order to understand the precise nature and unique influence of the college in American education, it is not necessary to trace the story of its development, for in its various forms of present organization it reveals the normal type which has been evolved, survivals of past stages of development, instances of variation and even of degeneration from the type, and interesting present experiments which foreshadow the future.

The Old-fashioned College.—The three commonly accepted divisions of education into primary, secondary and higher stages, while fully recognized in America, are not followed rigorously in organization. Primary education is more clearly separable from secondary than secondary from the higher or university stage. The chief cause for this partial blending of the secondary and higher stages is the college. However illogical and indefensible such a mixture may appear the historical outworking of this partial blending has been compelled by the exigencies of our history and has been fruitful in good results.

The American college, then, as contrasted with European schools, is a composite thing—partly secondary and partly higher in its organization. It consists regularly of a four-year course of study leading to the bachelor's degree. Up to the close of the Civil War (1861-5) it was mainly an institution of secondary education, with some anticipations of university studies toward the end of the course, which, however, were usually taught as rounding out the course of disciplinary education, rather than as subjects of free investigation. The average age of graduation was about 20. The maximum course of preparation in secondary schools was four years. In the better schools they studied Latin and Greek grammar, four books of Cæsar, six books of Virgil's *Æneid*, six orations of Cicero, three books of Xenophon's *Anabasis* and two of Homer's *Iliad*, together with arithmetic, plane geometry (not always complete) and algebra to, or at most through, quadratic equations. This the stronger colleges required for entrance; but many weaker ones were compelled to teach some of these preparatory studies in the first two years of the college course. With few

COLLEGE

and unimportant exceptions the four-year course consisted of prescribed studies, including English literature and rhetoric, Latin, Greek, mathematics, natural philosophy, chemistry, the elements of deductive logic, moral philosophy, and political economy, and often a little psychology and metaphysics. Perhaps some ancient or general history was added. French and German were sometimes scantily taught. At graduation the student received the degree of bachelor of arts, and then entered some professional school, or went into business or into teaching in the primary or secondary schools.

The College of To-day.—At the present time things are very different. The old four-year course, consisting entirely of a single set of prescribed studies leading to the one degree of bachelor of arts, has grown and branched in many ways. The better preparation now given in thousands of schools has enabled colleges to ask for somewhat higher entrance requirements and to exact them. The age of entrance has increased. In some quarters the increasing age of the students is shortening the course to three years, in order that young men may not be kept back too long from entering upon their professional studies. A generation ago a young man graduated at 20 or earlier without difficulty, and after two or three years in studying law or medicine he began to earn his living at 22 or 23. But to-day a college student is 22 years old at graduation, and if he studies law or medicine he must wait until he is 25 to begin earning his living. Accordingly boys are now passing in considerable numbers directly from secondary schools, which do not really complete their secondary education, to the professional schools. The problem is an economic one, and it is affecting college courses of study. One solution, to shorten the course to three years, has been advanced by President Eliot of Harvard, and three years is the length of the course in the undergraduate college established in connection with the Johns Hopkins University. Another proposal is to keep the four-year course and allow professional studies in the last year, thus enabling the student to save one year in the professional school. This experiment is being tried at Columbia. A third proposal is to keep the college course free from professional studies, but to give opportunities in the last year or the last two years to pursue liberal courses clearly underlying professional training, thus saving a year of professional study. This is the trend of recent experiments in Yale and Princeton. The one common consideration in favor of all these proposals is that a year is saved. Against the three-year course, it is argued that there is no need to abolish the four-year course in order to save a year. Against the admission of professional studies it is argued that work done in a professional school ought not to count toward two degrees representing two radically different things. Against the proposal to allow the liberal studies which most closely underlie the professions, it is argued that this is a half-way measure, after all.

Alterations in the Course.—The four-year course, however, no longer leads solely to the degree of bachelor of arts, and this old degree has been modified. With the founding of schools of science, aiming to give a modern form of liberal education based mainly on the

physical and natural sciences, the degree of bachelor of science came into use. Then intermediate courses were constituted, resting on Latin, the modern languages, history, philosophy, mathematics, and science, and thus the degree of bachelor of letters or bachelor of philosophy came into use. Sometimes the various courses in engineering were made four-year undergraduate courses with their degrees virtually rated as bachelor's degrees. Still other degrees of lesser importance came into vogue here and there to mark the completion of a four-year college course. The dispersing pressure of the newer studies and the practical demands of American life proved too strong to be held in form or to be kept out by the barriers of the old course of purely liberal studies with its single and definite degree, and new degrees were added to represent the attempted organization of newer tendencies. Compared with the old course such courses lack definiteness of structure. They aimed to realize new and imperfectly understood conceptions of education, and were composed of studies whose inner content was changing rapidly, or else were "half-and-half" forms of education, difficult to arrange in a system that promised stability, as in the case of studies leading to the bachelor of letters or bachelor of philosophy. A graver source of trouble was the admission of various engineering and other technical studies as parallel undergraduate courses. This tended to confuse in the minds of students the radical distinction between liberal and utilitarian ideals in education, and by the attractiveness of the "bread-and-butter" courses, to diminish the strength of the liberal studies. When in addition it is remembered that the newer courses, whether liberal, semi-liberal, or technical, exacted less from preparatory schools in actual quantity of school work necessary for entrance into college, it will be seen that the level of preparation for college was really lowered.

The present drift of opinion and action in colleges which offer more than one bachelor's degree is more reassuring than it was some 20 years ago. There is a noticeable and growing tendency to draw a sharp line between liberal and technical education and to retain undergraduate college education in liberal studies as the best foundation for technical studies, thus elevating the latter to a professional dignity comparable with law, medicine, and divinity. The more this conception prevails, the more will college courses in engineering be converted into graduate, or at least partially graduate courses. Independent schools of technology may continue to offer their courses to young students of college age, but where such schools have been associated as parts of colleges or universities the tendency to a clearer separation of technical from liberal studies seems likely to prevail.

Another hopeful tendency gradually gathering strength is to give the various bachelor's degrees more definite significance by making them stand for distinct types of liberal or semi-liberal education. First comes the academic course, attempting a general liberal education, consisting of classical and modern literatures, mathematics, and science, with historical, political and philosophical studies, and leading to the bachelor of arts degree. The second aims to represent a strictly modern culture predomi-

COLLEGE

nantly scientific in character, and culminating in the degree of bachelor of science. In this course technical aspects of the sciences taught tended to create a demand for strictly technological instruction. So schools of science do little save produce experts in the various mechanical and chemical arts and industries. Conscious of this difficulty, many schools of science have been giving larger place in the curriculum to some of the more available humanistic studies, especially French, German, and English. Economics, modern history, and even the elements of philosophy have found place. Some improvement has also been effected by increasing the entrance requirements in quantity of school work. But the course still suffers from an inner antagonism between technical and liberal impulses, and until it settles into a strictly technical form, or else comes to represent a strictly modern liberal culture, its stability cannot be regarded as assured. In the independent scientific schools, unassociated with colleges, it seems probable the course will keep or assume a highly technical form. But wherever it exists side by side with other bachelor's courses as a proposed representative of some form of liberal education, it will almost inevitably tend toward the ideal of a modern culture mainly scientific. But the process promises to be slow and difficult. For there is not only a financial risk, but a serious theoretical difficulty in realizing this form of liberal education. The antagonism between the technical and liberal impulses in the course seems very difficult to eliminate completely. For the utilitarian instinct of the time militates against devotion to the intellectual value of modern studies and tends more and more toward technical standards.

The third type of liberal college education is the intermediate course labeled with the degree of bachelor of letters or bachelor of philosophy. It differs from the other courses mainly in its treatment of the classical languages. To placate the practical spirit it drops Greek, but retains Latin both as an aid to general culture and as a help in learning the modern languages. Although indeterminate and intermediate, it serves a valuable end by providing many students, who do not care for the classical languages in their entirety, with a sufficiently liberal form of education to be of great service. Judged from the standpoint of the historical bachelor of arts course, it is a less general but still valuable culture. Judged from the standpoint of the bachelor of science course, it appears to escape the unhappy conflict between the technical and liberal impulses.

But some colleges, following the example of Harvard, have dealt with the bachelor degree very differently. The meaning of the degree has been radically altered, so as to represent the free selections made by the students themselves out of the range of liberal studies. In these colleges it no longer stands for the completion of a definite curriculum composed of a few clearly related central studies constituting a positive type. What it does stand for is not easy to define, because of the variation of practice in different colleges and the wide diversity of selection on the part of the student. In the undergraduate college connected with the Johns Hopkins University at Baltimore choice is regulated by prescribing moderately elastic groups of cognate studies, the student

being required to say which group he will choose. In Harvard College the student is allowed to choose what he prefers, subject to such limitations as the priority of elementary to advanced courses in any subject, and the coincidence in time of various courses. A Columbia student in his senior year may pursue his first year's course in law or medicine, and at the same time receive double credit for this work, both toward the degree of bachelor of arts and toward the professional degree of doctor of medicine or bachelor of laws.

Other Phases of Change.—To what extent the undergraduate collegian has become a university student is the real question around which a controversy of vital importance is raging.

The profound change indicated by external symptoms has been in progress since the Civil War, and is still working along toward its consummation. The difficult thing in analyzing this change is not merely to understand the change from a uniform to a multiform mode of life and organization, but to understand what is changing the old-fashioned American college. But even the old-fashioned colleges, while aiming to follow out a single course of study ending in a single degree of single meaning, did not succeed in exhibiting such close individual resemblance to each other as is to be found among the lycées of France, the public schools of England or the gymnasias of Germany. Many colleges really served as preparatory schools for larger and stronger colleges, and many so-called universities did not attain and in fact do not yet attain to the real, though less pretentious dignity of the better colleges. For the sake of simplicity then we discard from our consideration all except the better colleges which, when taken together, exhibit the dominant tendency.

How, then, have these better colleges changed? Speaking generally, they have changed in a way which reflects the diversified progress of the country, and yet they have had an important influence in leading and organizing the national progress. Then, too, the change is not merely a change of form, but of spirit. In the older days scarcely any college had as many as 400 or 500 students, and the range of studies was limited. The faculty of the college exercised a strong paternal anxiety and oversight on behalf of the morals and religion, as well as over the studies of the students. The authority of the president was almost patriarchal in character. Not highly developed insight into the problems of education, but plain common sense in governing students was the condition of a successful presidency. The range of studies has increased. With the strengthening of preparatory courses, the school preparation of students has improved, and at the same time their average age at entrance has risen. The number of professors has multiplied. The old-fashioned college professor, the man of moderate general scholarship and of austere yet kindly interest in the personal welfare of those he taught, still remains; but at his side has appeared the newer type of American college professor, the man of high special learning in some one subject or branch, who considers it his primary duty to investigate, his next duty to teach, and his least duty to exercise a personal care for the individual students. Perhaps the old type will be replaced

COLLEGE

by the new. Such a result, however, would not be an unmixed gain, and our finest college professors to-day endeavor to combine high special attainments as scholars with deep interest in the personal well-being of their students. The authority of the faculty is still sufficient, but is exercised differently. Student self-government is the order of the day, and the more this prevails the less is exercise of faculty authority found to be necessary. The presidents of our larger colleges, and even of many of the smaller, are becoming more and more administrative officers and less and less teachers. It is no doubt something of a loss that the students should not have the intimate personal acquaintance with the president enjoyed by students a generation ago, but mere numbers frequently make this impossible. Out-door sports have also entered to modify and improve the spirit of our academic life. They have developed their own evils, but at the same time have done wonders for the physical health of the students, the diminution of student disorders and the fostering of an intense *esprit de corps*. In the reaction from the asceticism of early college life there is little doubt athletics have gone too far. But the abuses of college athletics can be corrected, and are to some extent self-correcting.

Nearly all our colleges are avowedly or impliedly Christian. A respectable minority of them are Roman Catholic. The large majority are under Protestant influences, which are seldom denominational. The student is expected to attend certain religious exercises, such as morning prayers; but often all such attendance is voluntary. The religious life of the undergraduates finds its expression in various societies, which endeavor to promote the Christian fellowship and life of their members. While moral and religious convictions are freer and sometimes laxer than of old the Christian life in our colleges is real and pervasive.

As a rule the student is so absorbed by the scholastic, athletic, and miscellaneous activities of his college that he sees little outside social life. This is particularly true in colleges which enjoy truly academic seclusion amid rural surroundings, for here more than anywhere else is to be seen the natural unperturbed outworking of the undergraduate spirit.

Development of Elective Courses.—The non-scholastic aspects of our present college life are important in that they give tone to the whole picture, but they do not account for the great transformation which has been wrought, for that transformation is distinctly scholastic. It is caused by the increase of students, their better preparation and their greater age. The studies which made up the curriculum leading to the old bachelor of arts degree are now being completed before the end, sometimes by the middle of the college course. There is to-day no reason why a young man of 20 should not know as much as his father knew at 20. But at 20 his father had graduated with the bachelor of arts degree, whereas at 20 the son is only half way through his college course. As this fact forced itself upon the older and stronger colleges, experiments were made in granting a limited amount of elective freedom to students in the latter part of their course; first in the senior year and then in the junior year, until in some instances the whole four-

year course is now elective. In some colleges a student may obtain the bachelor of arts degree without studying any science, or he may omit his classics, or he may know nothing of philosophy. To-day the problem of the relation of prescribed to elective studies is a question of constant interest and perpetual readjustment. The solutions offered are many.

The first proposal, which has now scarcely an advocate, is plainly an impossible one. It is to insist on the old-fashioned four-year prescribed course. But the old-fashioned course cannot be restored, because it no longer suits our age. Young men will not go to college and remain there until the age of 22 years without some opportunity to exercise freedom of choice in their studies.

The second proposal is to constitute the undergraduate course entirely, or almost entirely, of elective studies. It is argued that when a young man is 18 or 19 years of age, he is old enough to choose his liberal studies, and that his own choice will be better for him individually than any prescription the wisest college faculty may make. The advocates of this view admit its dangers. They see the perils of incoherency and discontinuity in the choice of studies. They see that many students are influenced, not by the intrinsic value of the studies, but by their liking for this or that instructor, or the companionship of certain students, or for the easiness of certain crowded courses. Yet they argue that the college student must be free at some time, that his sense of responsibility will be developed the sooner he is compelled to choose for himself, and that he will have the stimulating and sobering consciousness that what he does is his own act and not the prescription of others for him. Those who oppose this view argue that the academic freedom here proposed belongs to university rather than to college students; that the American freshman is not a university student in the sense in which that term has been commonly understood in the educated world, because of his much shorter preparatory training, and his mental immaturity as compared with the English and Continental student. If, therefore, he is to be as well educated as they are, some of his time in college, the first two years at least, should be spent in perfecting his properly secondary education before entering upon that elective freedom which has a place, and a large place, in our present undergraduate courses.

A third proposal is a conservative modification of the one just mentioned. It is to prescribe groups of cognate studies with the object of concentrating attention on related subjects in that field which the student may prefer. The advantage claimed for this mode is that it allows the student to choose the field of study he likes, and then safeguards him against incoherency by requiring him to pursue a group of well-related courses in that field. The advocates of wider freedom object to this as fettering spontaneity of choice, as not recognizing the fact that there are many students for whom it is advantageous to choose a study here and there at will, as a piece of side work outside the chosen field of their activity. The objection to this plan of restricted groups and also to the plan of practically unrestricted freedom, is that it offers temptations to pre-

COLLEGE

mature specialization at the expense of liberal education.

Still another proposal remains to be considered. Its followers urge that the best type of liberal education is to be found in the historic academic course, which has been the centre and strength of American college life. They concede that other bachelor's courses may give a valuable education to many, provided these courses are consistently organized according to their own ideals. They hold that it is possible to ascertain with sufficient exactness just what studies ought to be prescribed as integral parts of these courses, and that the preliminary training given in these prescribed studies develops maturity in the young student and enables him to choose intelligently his later elective studies. At the present time, in their view, it is not wise to introduce elective studies until about the middle of the college course. These studies should be organized and related in a system, and connected with the underlying system of prescribed studies. The principle of freedom should be introduced gradually, not suddenly. A form of this view which finds a good deal of support is that elective studies should be introduced first of all in the form of extensions of subjects already studied by the student, in order that he may make his first experiment of choice in an area where he is most familiar. According to this view the second stage of elective studies should be the introduction of large general courses in leading subjects, accompanied by special courses for students of exceptional ability in special directions, and finally leading to as high a degree of specialization as the resources of the college will allow.

Modes of Instruction.—Instruction is still mainly conducted by recitation and lecture, the recitation finding its chief place in the earlier and the lecture in the later part of the course. For purposes of recitation the classes are divided into sections of 25 or 30 students, and the exercise is usually based on a definitely allotted portion of some standard text-book. Much has been done to improve the character of this exercise. The correction of mistakes, the attempt to lead the student to discover the cause of his mistakes, and the endeavor to teach the entire class through the performance of each individual, is the aim of the more skillful instructors. The professors most skilled in the art of conducting recitations, rather than those who depend wholly on lectures, leave the most abiding impression. While instruction by recitation continues with effectiveness in the latter part of the course, especially with smaller groups of students, yet instruction by lecture is the rule. The lecturer may have to face a class which enrolls as many students as the whole college contained a generation ago. He delivers his lecture, while those before him take notes, or as they listen, read a printed syllabus prepared for the use of the class, and add such jottings as may seem desirable. In many lecture courses the recitation is employed as an effective auxiliary.

But other forms of instruction find place. In all except elementary courses in science the laboratory plays a most important part, and even in lectures in introductory courses in physics, chemistry, or biology full experimental illustration is the rule. The library serves as a sort of laboratory for the humanistic studies.

Students are encouraged to learn the use of the college library as auxiliary to the regular exercises of the curriculum. Certain books are appointed as collateral reading, and the written examination at the end of the term often takes account of this outside reading. That prolonged reading, which gives such wide and assuring acquaintance with the important literature of any subject, is as yet unattempted in a really adequate degree.

The academic year is divided into two (sometimes three) terms. At the end of each term the student is required to pass a fairly rigorous set of written examinations. Oral examinations have largely disappeared. Very rarely a high record of attainment in recitations during the term entitles a student to exemption from examination. In awarding honors the old academic college confined itself almost entirely to general honors. Honors for general eminence still remain in most colleges. The rank list of the class at graduation either arranges the students in ordinal position (in which case the first honor-man still appears) or else divides the class into a series of groups arranged in order of general scholarly merit. In such cases the old first honor-man is one of the select few who constitute the highest group in the class. But special honors in particular studies, while not unknown in the past, are really a development of our time. Undoubtedly they have tended to increase the interest of abler students in their favorite studies. A student trying for special honors is, of course, specializing in some sense, though he is not ordinarily pursuing original research. He is rather enlarging and deepening his acquaintance with some one important subject, such as history or mathematics.

Student Life.—At 18 the typical student of the older eastern college has completed a four-year course in some secondary school. He finds near at hand a local entrance examination conducted by a representative of his intended college. The days and exact hours of examination and the examination papers are the same as for the examination held at the college. His answers are sent on to be marked and estimated. In a week or two he receives notice of his admission to the freshman class.

Having passed his entrance examinations, he is now entitled to secure rooms in one of the dormitories, or else to find quarters outside the college campus in town. In the following autumn his name is enrolled in the matriculation book and his student career begins. His newness and strangeness naturally pick him out for a good deal of notice on the part of the older students, especially those of the sophomore class. But these annoyances soon cease unless he be vain or "very fresh." The daily round of college exercises demands his attention, and in the class room he begins to pass through a process of attrition more beneficent in its spirit. Under the steady measuring gaze of the instructor, and the unuttered but very real judgment of his classmates who sit about him, he begins to measure himself and to be measured by college standards. He is learning something not down in the books! and what he is thus discovering is well pictured in the words of Prof. Hibben: "There is a fair field to all and no favor. Wealth does not make for a man nor the lack of it against him. The students live their lives

COLLEGE

upon one social level. There is a deep-seated intolerance of all snobbishness and pretension. The dictum of the 'varsity field, 'No grandstand playing!' obtains in all quarters of the undergraduate life. It signifies no cant in religion; no pedantry in scholarship; no affectation in manners; no pretense in friendship. This is the first and enduring lesson which the freshman must learn. He learns and he forgets many other lessons, but this must be held in lively remembrance until it has become a second nature." His college comradeship continues and constitutes his social world. Day after day, term after term, they are thrown together in all the relationships of student life. Truly the American collegian is brimful of the "gregarious instinct."

In addition to this ever-present gregarious comradeship which environs and inspires him, our entering freshman finds the deeper intimacies of close individual friendship. As a matter of course he has some one most intimate friend, generally his room-mate or "chum." Side by side they mingle with their fellows. They stand together and, it may be, they fall together, and then rise together. And thus the class is paired off, and yet not to the lessening of the deep class fellowship. Here indeed is a form of communism, temporary and local, but most intense. They freely use things in common, not excepting the property of the college. They are welcome to enter each others' rooms at pleasure and use their friends' tobacco and stationery, or to borrow such articles of furniture and bric-a-brac as will brighten their own rooms for some special occasion. Money, however, stands on a different basis from other valuables. It is freely loaned for an indefinite time, but is strictly repaid. A student who lends his fellow money at interest cannot live in a college community.

Our student, unless he is an unusual recluse, takes some part in athletics. If he is not able to win a place on the football team or baseball nine or crew, which represents his *alma mater* in intercollegiate contests, he is very likely to be found playing ball in some organization improvised for the day, or trying his hand at tennis or golf. The bicycle is a necessity of his life, and on it he rides to recitations and lectures, to his meals and to the athletic field.

He has still other interests outside the curriculum. He may be a member of the voluntary religious society of the students. Perhaps he gets a place on the glee club or dramatic club. He may become one of the editors of the daily college paper or of the monthly literary magazine. Perhaps he is manager or assistant business manager for one or another undergraduate organization. Then there are the whist clubs and time-consuming chess clubs. There are also circles for outside reading and discussion springing up around the course of study, as well as the societies which train in speaking and debating. Perhaps he may win the distinction of representing his college in an intercollegiate debate, and success in intercollegiate debating is highly coveted. The contestants are greatly honored, for debating and athletics form the principal bond of union between the different colleges and give to their participants intercollegiate distinction.

Until the student passes out of freshman

year, he is not always free to choose what kind of clothes he will wear. In some colleges freshmen are not allowed to wear the colors, except on rare occasions. But as soon as he becomes a sophomore he is free to do as he likes. Then he and his classmates suddenly appear wearing various hats, picturesque and often grotesque in appearance, and revel particularly in golfing suits. Toward the close of the course their daily dress becomes more conventional, though the universal interest in athletics continues to affect the student mode to the end. He has other amusements besides athletics, and these again are found in the student circle. His briarwood pipe goes with him almost everywhere. In the evening, when the work of the scholastic day is done, he sits with his comrades at an unconventional "smoker," or else they may gather round the table of some restaurant with pipe and "stein"; for the American student who drinks at all prefers beer to either wine or whiskey. At such evening sessions the different phases of student politics are discussed again and again. College songs are sung, the air being carried in that sonorous baritone which is the dominant sound in all our student music. Tales and jests fill out the hour. At the end the college cheer is given as the men start strolling homeward, singing as they go. Arrived on the campus they disperse, and their good-night calls echo from the doors and windows of the different dormitories. And so the day ends where it began; within that closed circle where every student lives in "shouting distance" of the others.

Our former freshman is getting on bravely toward the end of his course. The closing months of senior year pass swiftly. His class procession is preparing to march out into the world, and there take its place as a higher order of freshmen in the long file of the classes of alumni advancing with their thinning ranks toward middle manhood and beyond,—and when commencement is over his undergraduate life is ended.

What has he acquired in the four years? At least some insight into the terms and commonplaces of liberal learning and some discipline in the central categories of knowledge, some moral training acquired in the punctual performance of perhaps unwelcome daily duty and some reverence for things intellectual and spiritual. He is not only a very different man from what he was when he entered, but very different from what he could have become had he not entered. He is wiser socially. He is becoming cosmopolitan. Awkwardness, personal eccentricity, conceit, diffidence, and all that is callow or forward or perverse have been taken from him, so far as the ceaseless attrition of his fellow-students and professors has touched him. He has been unconsciously developed into the genuine collegian. He is still frank and unconventional. But he has become more tolerant, better balanced, more cultivated, and more open-minded, and thus better able to direct himself and others. It is little wonder his student affiliations last. As he goes out to take his place among the thousands of his fellow alumni it is natural that his and their filial devotion to their academic mother should last through life. No matter what university he may subsequently attend, here or abroad, his college allegiance

COLLEGE

remains unshaken. It is this which explains the active interest shown by our alumni. In the best sense they advertise their college to the public, and it is to their exertions the recent rapid advancement of many of our colleges is largely due.

Organisation and Administration. — The form of government is simple. A college corporation, legally considered, consists of a body of men who have obtained the charter and who hold and administer the property. Where a particular State has established a college or even a university, which regularly includes a college, the members of the corporation are commonly styled regents, and are appointed by the State to hold office for a limited term of years. But most colleges have been established as private corporations. In this case the title is vested in a board of trustees, sometimes composed of members who hold office for life, or else composed of these associated with others who are elected for a term of years. Boards of trustees holding office for life usually constitute a close corporation, electing their own successors as vacancies occur. The two chief functions of such governing bodies, whether known as regents or trustees or by any other name, are to safeguard the intent of the charter and to manage the property. They give stability to our college system. To carry out the main purpose for which the charter was obtained they create a faculty of professors and instructors and entrust the general headship to a president. The president and professors usually hold office for life. In some places provision is made for the retirement of professors on pensions as they grow old. Instructors and sometimes assistant professors are appointed for a limited time, such appointments being subject to renewal or promotion. In the larger colleges the president is assisted in his administrative work by one or more deans. By immemorial tradition the president and faculty are charged with the conduct of the entire instruction and discipline. They have the power to admit and dismiss students. The conferring of degrees belongs to the corporation, but this power is almost invariably exercised according to recommendations made by the faculty. Honorary degrees, however, are sometimes given by the trustees or regents on their own initiative.

In State colleges the income is derived from taxation; in others from endowments, often supplemented by annual subscriptions for special purposes. But the private colleges are cut off from dependence on the State, and have to rely on private gifts. This stream of private liberality flows almost unceasingly. The fact that many colleges are integral parts of real or so-called universities makes it difficult to say how much the specifically collegiate endowments and incomes amount to. But a few significant facts may be mentioned. No college president, unless he is at the same time the president of a university, receives as high a salary as \$10,000 annually. He is more likely to receive \$4,000, \$5,000, or \$6,000. While \$2,000 is considered a good professor's salary in small colleges, \$3,000 is a usual salary in the larger colleges, while few professors receive more than \$4,000.

The expenses of individual students vary greatly. In some places there is no charge for tuition; in others they must pay as much as

\$100 or \$150. In little country colleges the total cost for a year often falls within \$300; in the larger old eastern colleges, drawing patronage from all parts of the land, the student who must pay all his bills and receives no aid in the form of a scholarship can hardly get along with less than \$600 or \$700, exclusive of his expenses in the summer vacation. The average expenses in some of the oldest colleges, according to tables prepared by successive senior classes, is higher than this, running up to \$800 or \$900, or even more. But these institutions afford the student of limited means multiplied opportunities for self-help. Moreover many colleges possess scholarships which are open to able students who need temporary pecuniary help. The young American of narrow means, if he be of fair ability and industry, can almost always manage to find his way through college.

The College is American.—The college lies very close to the people. Distinctions of caste may manifest themselves occasionally, and yet the college is stoutly and we believe permanently democratic. Its relation to the better side of our national life has been profoundly intimate from the beginning. The graduates of Harvard and Yale in New England, of Princeton and Columbia in the Middle States, and of the College of William and Mary in Virginia contributed powerfully to the formation of our republic. Edmund Burke attributed the "intractable spirit" of the Americans to "their education," and by this he meant the college education. "The colleges," wrote President Stiles, of Yale shortly after the Revolution, "have been of signal advantage in the present day. When Great Britain withdrew all her wisdom from America this revolution found above 2,000 in New England only, who had been educated in the colonies, intermingling with the people and communicating knowledge among them." John Adams of Harvard delighted to find in President Witherspoon of Princeton "as high a son of liberty as any in America." Hampden-Sidney College in Virginia, founded about the time of the Revolution, incorporated in its charter the following clause: "In order to preserve in the minds of the students that sacred love and attachment which they should ever bear to the principles of the ever-glorious Revolution, the greatest care and caution shall be used in selecting such professors and masters, to the end that no person shall be so elected unless the uniform tenor of his conduct manifest to the world his sincere affection for the liberty and independence of the United States of America." And from that day to this the collegiate spirit and the national spirit have been at one. Rightly, indeed, did our appreciative French visitor, Baron Pierre de Coubertin, perceive that the place to find "the true Americans" is in our college halls; "*les vrais Americains, la base de la nation, l'espoir de l'avenir.*" Scarcely one in a hundred of our white male youth of college age has gone to college. But this scanty contingent has furnished one half of all the presidents of the United States, most of the justices of the supreme court, not far from one half of the Cabinet and of the national Senate, and almost a third of the House of Representatives. No other single class of equal numbers has been so potent in our national life.

ANDREW FLEMING WEST,
Professor of Latin, Princeton University.

COLLEGE PARK — COLLEGES FOR TEACHERS

College Park, Md., a village in Prince George County, on the Baltimore & O. R.R., about nine miles northeast of Washington, D. C. It is a favorite suburb of Washington, and contains an experiment station and the Maryland Agricultural College. Pop. 325.

College of the City of New York, The, originally entitled the Free Academy, was established in 1848, for boys, by the board of education of New York City. In 1854 the legislature of the State passed a law endowing the school with collegiate powers and privileges; and in 1866 the name was changed to that of "The College of the City of New York." The institute possesses all the powers and privileges of a college pursuant to the revised statutes of the State of New York relative to colleges, visitation of regents of the university, granting of degrees, etc. Prior to 1882 one condition for admission was attendance for at least one year at the public schools of the city. In the year 1882 the legislature repealed so much of the statute as related to this condition, and now the college is open to all young men of the city of proper age and preparation. Instruction, the use of text-books, and apparatus are free. The courses of study extend over seven years, three academic or preparatory and four collegiate years. The number of students in attendance in 1903, 2,200; number of graduates, 200; volumes in library, 36,876. Purchases of books are made with the income of the Seth M. Grosvenor fund of \$30,000 and the Ephraim Holbrook fund of \$5,000. In 1903 plans were perfected for the removal of the institution from 23d Street and Lexington Avenue to Washington Heights, in the upper part of the city. The new buildings will eclipse any in the United States, if not in the world.

Collège de France, kōl-lāzh dè frāns, a celebrated institution founded by Francis I. in 1530, originally a *Collège de Trois Langues* or a college in which would be taught Greek, Hebrew, and Latin, is a very important educational institution, now giving instruction over a very wide field of literature, history, and science. It is independent of the University of France, is under the direct supervision of the minister of public instruction, and is supported by the government. As in the Sorbonne, the lectures are gratuitous, and for the most part are designed to attract auditors older than ordinary university students. The college comprises two faculties, one literary, one scientific; each has about 20 professors. Among the professors have been some of the most distinguished scholars and scientists in France, such as Laboulaye, Gaston de Paris, Saint-Hilaire, Ramus, Rollin, and others.

College Fraternities. See GREEK LETTER SOCIETIES.

Colleges, Land Grant, colleges established and maintained in whole or in part by the Land Grant Act of 2 July 1862. Justin S. Morrill, a representative from Vermont, introduced in Congress the first bill asking that grants of government land be donated for the purpose of aiding in the education of the people, in scientific and technical subjects. This bill, introduced in the lower House 14 Dec. 1857, authorized the establishment of colleges of agriculture and mechanical arts in all States, and provided for the support of said colleges, 20,000

acres of land for each senator and representative. The bill passed both Houses but was vetoed by President Buchanan. In December 1861 Mr. Morrill introduced a new bill, bestowing 30,000 acres of land for each member of Congress for the establishment and maintenance of industrial colleges. Ben Wade, of Ohio, introduced the bill in the Senate. The House committee on public lands made an adverse report, but the bill passed both Houses and was approved by President Lincoln 2 July 1862. This act gave to the cause of industrial education 30,000 acres of land for each senator and representative in Congress to which the States were entitled by apportionment of the census of 1860, or in all, about 13,000,000 acres of land for educational purposes. The act was entitled "An act donating public lands to the several States and Territories who may provide colleges for the benefit of agriculture and mechanical arts." The object of the act is expressed as follows:

"The endowment, support and maintenance of at least one college where the leading objects shall be, without excluding other scientific and classical studies, and including military tactics, to teach such branches of learning as are related to agriculture and mechanic arts, in such manner as the legislatures of the States may respectively prescribe, in order to promote the liberal and practical education of the industrial classes in the several pursuits and professions of life."

In 1889 Mr. Morrill and others began to form plans to secure another appropriation, and Mr. Morrill introduced another bill in Congress, providing that there shall be appropriated annually to each State out of the funds arising from the sale of public lands, the sum of \$15,000 for the year ending 30 June 1890, and an annual increase by the additional sum of \$1,000 to such appropriation for 10 years thereafter until the appropriation shall become \$25,000, at which figure it shall remain fixed.

The bill passed both Houses and was approved by President Harrison 30 Aug. 1890. The act says that this appropriation shall be applied "only to instruction in agriculture, the mechanic arts, the English language, and the various branches of mathematical, physical, natural and economic science, with special reference to their applications to the industries of life, and to the facilities for such instruction." Provision was made at this time for separate institutions for white and colored students in such States as desired to make this arrangement.

The reports for the year ending 30 June 1901, received by the Commissioner of Education from the presidents of the land grant colleges, show that the States have received 10,320,843 acres of land, of which 1,030,572 acres remain unsold. The invested funds from the sale of the land amount to \$10,806,780, yielding an income of 6.3 per cent. Unsold lands are held by 17 States.

The total number of students in the agricultural and mechanical departments was 29,950, of which number 23,872 were men and 6,978 women. (For information in detail about each land grant college, consult 'Report of Commissioner of Education,' Vol. II. 1901.)

Colleges for Teachers, or colleges in which are special departments for the study of the history of education, psychology as applied

COLLEGES FOR TEACHERS

to teaching, pedagogy, and all subjects bearing upon methods of instruction.

To the English schoolmaster, Richard Mulcaster, is given the credit of being one of the first, if not the first, to propose a college for the training of teachers. He classified his chief reasons for desiring the establishment of such a school under four heads: (1) Importance of the work, it will make or mar the State; (2) The great numbers who are to teach and be taught; (3) Need of the profession of teaching, professors must be trained; (4) That teachers may acquire wisdom in arranging and presenting subjects, in economizing time, and that they may attain staidness of demeanor.

Instruction in the science and art of teaching was included in the university scheme that was proposed for Columbia College in 1858, but then without avail. Again President Barnard urged the same plan, which he now worked out much more fully, upon the trustees of the same college in 1881 and 1882. The next step forward was the organization in New York, in 1888, of Teachers' College, which was chartered the following year. While this college was organized outside of the Columbia system, it was still under the control, in great part, of Columbia men, and was loosely affiliated with the college. The last step in the evolution came in 1898, when Teachers' College was made an integral part of the educational system of Columbia University. The president of Columbia is president also of the college, and the university professors of philosophy and education and of psychology are members of its faculty, while the college is represented in the university council by its dean and an elected representative. The college, however, continues its own separate organization, having its own independent board of trustees, which is charged with the sole financial responsibility of its management.

Teachers' College is the professional school of Columbia University for the study of education and the training of teachers, ranking with the schools of law, medicine, and applied science. The university accepts courses in education as part of the requirement for the degrees of A.B., A.M., and Ph.D.; while graduate students who prefer to devote their entire time to professional study may become candidates for the higher diploma of the college. The college diploma is conferred upon students who have successfully completed some one of the general courses, and a departmental diploma upon those who have fitted themselves for particular branches of school work. Undergraduate students of Columbia and Barnard colleges may, if they desire, obtain the diploma of Teachers' College at the same time that they receive the degree of bachelor of arts. The Horace Mann school, fully equipped with kindergarten, elementary, and secondary classes, is maintained by Teachers' College as a school of observation and practice.

These are the undergraduate courses: Secondary course leading to the degree of A.B. and the college diploma; general course leading to the college diploma in elementary teaching; general course leading to the college diploma in kindergarten teaching. Then there are several courses leading to the college diploma in art, domestic art, domestic science, and manual training. Candi-

dates for the first of these courses must be either college graduates or candidates for the degree of A.B. in Columbia University. There is a combined course of study prescribed for the degree of A.B. in Columbia University and the diploma of Teachers' College; but particulars must here be omitted. Graduate work is also well developed. For the year 1898-9 the teaching staff counted more than 60 persons.

New York University School of Pedagogy, established in 1890, aims to furnish graduate work equal in range to other professional schools. The school is an organic part of the university, having its own dean and faculty. More definitely, its aim is declared to be to furnish thorough and complete professional training for teachers. The plan of the school places it upon the same basis as that of the best schools of law, medicine, and theology. The work is of distinctively university grade, and graduates of colleges and normal schools, and others of equal experience and maturity, may find in this school opportunity for the thorough study of higher pedagogy. In 1898-9, the instruction was distributed in four major and eight minor courses, namely, history of education; physiological and experimental psychology; analytical psychology; history of philosophy; physiological pedagogics; elements of pedagogy; comparative study of national school systems; æsthetics in relation to education; sociology in relation to education; institutes of pedagogy, ethics, school organization, management, and administration. Special facilities for research are offered to the seminaries. The degree of master of pedagogy is conferred upon candidates who have completed five of the foregoing courses, three of them majors; the degree of doctor of pedagogy, upon candidates who have completed the four major and five of the minor courses. The school does not attempt undergraduate work. There is no practice teaching, but opportunity is given for the critical observation of selected schools. The staff includes 10 persons.

Clark University, opened in 1889, has given much attention to education from the first, and the subject has now been made a sub-department in the department of psychology, in which a minor may be taken for the degree of doctor of philosophy. The work is intended to meet the needs of those intending to teach some other specialty than education, but who wish a general survey of the history, present state, methods, and recent advances in the field of university, professional, and technical education, and of those who desire to become professors of pedagogy, or heads of instruction in normal schools, superintendents, or to become professional experts in the work of education. The program for the year 1899 included (1) child study, educational psychology, and school hygiene; (2) principles of education, history of education and reforms, methods, devices, apparatus, etc.; (3) organization of schools in different countries, typical schools and special foundations, motor education, including manual training, physical education, etc., moral education, and ideals. Great stress is placed on original investigation. The president, Dr. G. Stanley Hall, has been from the first the leader of the child study movement in the United States. 'The Pedagogical Seminary,' edited

COLLEGES FOR WOMEN

by him, is the organ of the educational department of the university. It is an international record of educational research and literature, institutions, and progress, and is devoted to the highest interests of education of all grades. One of its most valuable features is its digests of meritorious contributions to educational literature.

The department of pedagogy in the University of Chicago has as its primary aim to train competent specialists for the broad and scientific treatment of educational problems. The courses fall under three heads: Psychology and related work, educational theory, and the best methods of teaching the various branches. Stress is laid upon the relation of pedagogy to other subjects, and courses are offered in the proper departments in which the methodology of such subjects is employed. For the year 1898-9 such courses were offered in history, sociology, and anthropology, in the English, German, and Latin languages and literatures, in mathematics, and in geology. The courses in educational theory are preceded by the introductory courses in psychology, ethics, and logic, given in the department of philosophy.

The University of Chicago has also established a college for teachers on a somewhat novel plan. This institution, which was founded in October 1898, is an outgrowth of the class study department of the extension division of the university. It is a "downtown" college, and aims to provide instruction of high grade for busy people; or, more definitely, "for any and all persons qualified to do the work, who are so engaged by other imperative duties as to make continuous attendance at the other colleges of the university impracticable." The work of the new college is of the same grades as that of the other colleges of the university. Students may take much or little, according to their ability and wishes, but when the requirements have been met, the work is crowned with a degree. The school aims at scientific, cultural, and disciplinary results. It distinctly denies that it is in any sense a normal school. Moreover, while it is not exclusively a teachers' school, the college, nevertheless, emphasizes instruction suitable to the special needs of teachers sufficiently to justify its name. The distinctively pedagogical teaching, like all the teaching, looks to knowledge and scientific training rather than to practical applications. At the close of its first year of life the outlook is an encouraging one. See UNIVERSITY OF CHICAGO.

The University of Wisconsin school of education is an expansion of the former department of education. The four main lines of instruction are the history, the philosophy, the science, and the practice of education. The school aims to afford practical and healthful instruction to intending teachers, professors, principals, and superintendents, and to those students who desire to pursue studies and investigations in the science of education.

Colleges for Women. Three types of the collegiate education for women in the United States prevail. The first in time and in popularity is known as coeducation; the second, as separate education; and the third, as co-ordination in education. Under the first form, men and women are educated together under identical

conditions; under the second, women are educated by colleges founded and administered for them as women; under the third, there are established in the same university two colleges, one for men and one for women. The third form is subject, however, to considerable varieties in administration.

The first college founded for both men and women was Oberlin. Its charter was granted in 1834. The college was the result of the philanthropic and missionary movements of the first decades of the last century. The town and the Institute, as the college was called for about a score of years, were closely allied. In the first circular published regarding the institution, it was said that among its great objects was the extending of the benefits of the most useful education to "both sexes." "The elevation of female character" was also noted as a purpose. The giving of a college education to both men and women together was not a primary thought. The primary thought was to offer the best education to women. The conditions obliged the giving of the education to both sexes upon equal terms. In the first year of the college, 40 women were enrolled. Few of them were fitted, however, to pursue college studies. A preparatory department was formed. In 1837 four women offered themselves as candidates for college rank. Their classification was more or less irregular. At the commencement of 1841 three women received a degree, the first women to receive a degree in arts in the United States. For about a score of years Oberlin alone received women into its classes on the same terms, substantially, as those on which it received men.

The second step in the education of men and women together was taken 20 years after the beginning was made at Oberlin in another Ohio town. Antioch College, in Yellow Springs, was founded by Horace Mann in 1852. In his inaugural address Horace Mann declared himself heartily in favor of what is now known as coeducation. He affirms that coeducation is the only method to be pursued, at least for many years, on the ground of its relative inexpensiveness. He believes that social intercourse between young men and women will prove advantageous to each, preventing manners from becoming rude and sentiments coarse. He believes that the peril of forming undesirable attachments is less under academic than under ordinary social conditions.

The beginning thus made in two Ohio colleges advanced rapidly. Its chief field of growth lay in the universities founded by the various States. In 1856 Iowa, in 1866 Kansas, in 1868 Minnesota, in 1871 Nebraska, founded universities for both men and women. The University of Indiana, founded in 1820, was in 1868 opened to women. The University of Michigan, of Illinois, of California, of Missouri, were open to women in 1870, and the Ohio State University three years after. In 1874 Wisconsin adopted complete coeducation. At the present time every State university, excepting Virginia, Georgia, and Louisiana, is open to women.

The older parts of the country approached the question of the education of women through the establishment of new colleges for them. It was easier to found colleges for women than to adjust colleges already organized for men, and

COLLEGES FOR WOMEN

whose conditions and traditions were established, to the admission of women. Yet Middlebury, Colby, and other colleges, were opened to them; and Boston University, Bates in Maine, and Cornell in New York were coeducational either in the beginning or soon after. The founders of the four more eminent colleges for women in the seventh and eighth decades of the 19th century were moved by the same purpose. They desired to establish institutions which should give to women an education as good as the older colleges were giving to men. The purposes of Matthew Vassar, of Sophia Smith, of Henry J. Durant, the founder of Wellesley, and of Dr. Joseph W. Taylor, the founder of Bryn Mawr, were alike slow in fruition. In the year 1845, at the age of 53, Matthew Vassar decided to devote a large portion of his estate to some benevolent purpose. It was not until 20 years after that Vassar College was opened to students. In the year that Vassar received its act of incorporation Sophia Smith began to think of the establishing of a college for women. The college was incorporated in 1871 and opened for students in 1875. In 1864 Henry J. Durant, losing by death an only son, determined to use a part of his estate in philanthropy. In 1870 the institution was incorporated as the Wellesley Female Seminary; three years after the name was changed to Wellesley College, and in 1877 the college was authorized to grant degrees. For many years Dr. Joseph W. Taylor considered the question of devoting his estate to the education of women.

In these endeavors for the higher education of women help was derived from a foundation laid at Elmira in the year 1855. But the foundation was not adequate for offering the training which women were desirous of receiving. Its chief value, therefore, lay in the incentive it gave rather than in its actual educational achievement.

The general purpose and conditions under which all these foundations were laid are well indicated in an address given by Matthew Vassar to the trustees of his college in June 1864 at the time when the question of the election of professors was being discussed.

"It is my hope—it was my only hope and desire—indeed, it has been the main incentive to all I have already done, or may hereafter do, or hope to do, to inaugurate a new era in the history and life of woman. The attempt you are to aid me in making fails wholly of its point if it be not an advance, and a decided advance. I wish to give one sex all the advantages too long monopolized by the other. Ours is, and is to be, an institution for women—not men. In all its labors, positions, rewards, and hopes, the idea is the development and exposition, and the marshaling to the front and the preferment of women—of their powers on every side, demonstrative of their equality with men—demonstrative, indeed, of such capacities as in certain fixed directions surpass those of men. This, I conceive, may be fully accomplished within the rational limits of true womanliness, and without the slightest hazard to the attractiveness of her character. We are indeed already defeated before we commence if such development be in the least dangerous to the dearest attributes of her sex. We are not the less defeated if it be hazardous for her to avail herself of her highest educated powers when

that point is gained. We are defeated if we start upon the assumption that she has no powers save those she may derive, or imitate, from the other sex. We are defeated if we recognize the idea that she may not, with every propriety, contribute to the world the benefits of matured faculties which education evokes. We are especially defeated if we fail to express, by our acts, our practical belief in her pre-eminent powers as an instructor of her own sex."*

The third type of the collegiate education of women is known as co-ordination. It represents the inclusion in, or the alliance of, a college for women with a college for men. Certain communities, in their desire to promote the education of women, and in their unwillingness to duplicate educational equipment, have established colleges for women as an annex to, or as institutions parallel with, the institutions founded at an earlier date for men. This method represents the English tradition. Girton, at Cambridge, existed nine years before the foundation of the Society for the Collegiate Instruction of Women, organized in Cambridge in 1879. The more conspicuous of these colleges are Radcliffe, affiliated with Harvard; Barnard, affiliated with Columbia; the Woman's College of Brown University, the College for Women of Western Reserve University of Cleveland, and the H. Sophia Newcomb College, affiliated with Tulane University. The intramural administration of these colleges differs from each other. In Radcliffe, Barnard, and Brown the larger part of the instruction is given by members of the faculty of the older college for men. In the College for Women of Western Reserve University a distinct faculty is established which is co-ordinate with the faculty of the college for men—Adelbert—of the same university.

Colleges of each of these three types have special advantages, and are subject to special disadvantages. Each apparently has come to occupy a permanent place in American education. Coeducation, however, is by far the more popular. About nine tenths of all colleges are coeducational institutions. The number of degrees conferred on women in all American colleges in the last year was about 3,700. The more common degrees are A.B., Ph.B., B.L., and B.S., of which A.B. is conferred on about five eighths of all candidates.

CHARLES F. THWING,
*President of Western Reserve University,
Cleveland.*

Collegeville, Minn., village in Stearns County, on the Great N. R.R., nine miles northwest of St. Cloud. St. John's Abbey and St. John's University, in charge of members of the order of St. Benedict, are the chief parts of the village. The university was opened in 1867. The number of students is greater than the number of inhabitants of the village.

Collegeville, Pa., a borough in Montgomery County. It is situated on the Perkimon River, the Philadelphia & R. R.R., and is 27 miles northwest of Philadelphia. Ursinus College, established in 1870, is an institution belonging to the German Reformed Church. The manufactures are iron machinery and boiler-making. Pop. 700.

* 'Vassar College and Its Founder,' p. 100.

COLLEGIATE ATHLETICS — COLLIER

Collegiate Athletics. See EDUCATIONAL ATHLETICS.

Colles, kōlz, Christopher, American philosophic adventurer: b. Ireland about 1738; d. New York 1821. In 1765 he set out, a wanderer from his native land, and we find him in Philadelphia in 1772, delivering illustrated lectures upon pneumatics. He is reported to have been the first individual who undertook to build a steam engine in this country. In April 1774 he proposed to erect a reservoir for the purpose of conveying water through the several streets of the city of New York. His proposals were "read and referred." In 1775 he delivered lectures on gunnery, and was further employed in giving instruction to the artillery department of the American army in the principles of projectiles. Colles was the first person who suggested canals and improvements to connect Lake Ontario with the Hudson. According to the records of the assembly of New York, in November 1784 he presented a memorial on the subject, and in April following a favorable report was made thereon. In 1808 Colles published an elaborate pamphlet on the interests of the United New York, and in 1789 published a book of roads through New York.

Col'lie, the domestic sheep-tending dog developed in Scotland, and for a long time bred there exclusively, but now known in all parts of the world. It is one of the most beautiful, and perhaps the most intelligent of all dogs, and many anecdotes are told illustrative of its sagacity. Collies have for hundreds of years aided the Scotch shepherds in caring for their flocks, under all conditions and in all sorts of weather. To meet the inclemency of stormy days and cold nights, these dogs have acquired an outer coat of thick, rough hair, black or black-and-tan in color. It has an undercoat so close and soft that, even when it is parted, one can scarcely see the dog's skin. The chief points of these dogs are: long, sharp heads; bright, keen eyes, set rather close together; small ears, drooping at the tips; a full ruff of hair around the neck; strong, wiry frames; and rounded feet. Their intelligence is remarkable—almost human; and their affection so constant that they have been known to die of grief after the death of a master.

The collie measures from 22 to 24 inches at the shoulder, and weighs generally from 45 to 60 pounds. He is as alert as a fox, and as fleet as a deer. In fact, no dog, except the greyhound can excel him in speed and grace of movement, and it is safe to state that no dog is so faithful and trustworthy a companion to man, for the collie gives implicit obedience and unfaltering loyalty to his master, and will yield his life rather than desert his master's charge. This it is that makes him invaluable as a sheep-dog. Detailed information in regard to the collie may be found in most books relating to dogs (q.v.), and special books treating of him from the point of view of both the shepherd and the fancier are accessible. Consult Lee, 'Collie or Sheep-Dog'; and Wickham, 'Practical Training of the Shepherd Dog.'

Collier, kōl'yēr, Ada Langworthy, American writer of verse: b. Iowa 1843. Her principal work is 'Lilith, the Legend of the First Woman' (1885).

Collier, Arthur, English philosopher: b. Langford Steeple, Wiltshire, 12 Oct. 1680; d. there 1732. He was educated at Pembroke and Balliol colleges, Oxford, and in 1704 became rector of Langford, a living which had belonged successively to his great-grandfather, grandfather, and father, and which he retained till his death. In 1713 he published a work entitled 'Clavis Universalis,' in which he maintained both the non-existence and the impossibility of the existence of any objects external to the mind. Berkeley had three years before advanced incidentally his theory of the negation of an external world, but the two philosophers appear to have had no knowledge of each other, and it is certain that Collier meditated upon his opinion for 10 years before promulgating it. Though they developed simultaneously the first systematic scheme of absolute idealism, and though Collier was inferior to his contemporary rather in the graces of composition than in acuteness or method, yet the 'Clavis Universalis' attracted not the slightest attention in England. In Germany a copious and able abstract of its contents was given in 1717, in a supplemental volume of the 'Acta Eruditorum,' and it was quoted by Wolf, Bilfinger, and others. In 1756 a complete translation of it into German was made by Eschenbach. Thus rendered accessible in Germany, Collier has enjoyed among the thinkers of that country high repute for talent and originality, and the best comparative view of his doctrines and those of Berkeley is that given by Tennemann. Other publications of Collier were the 'Specimen of True Philosophy' (1713); and 'Logology' (1732). In religion he was an Arian, and also a high churchman on grounds which his associates could not understand.

Collier, H. Price, American writer: b. 25 May 1860. He is a son of R. L. Collier (q.v.) and was educated at Harvard. Entering the Unitarian ministry, he was for nine years in charge of churches in Hingham, Mass., and elsewhere, and during the Spanish-American war served as a naval officer. He has published 'Essays'; 'Mr. Picket Pin and His Friends'; 'America and the Americans from a French Point of View,' issued at first anonymously.

Collier, Jeremy, English bishop: b. Stow Qui, Cambridgeshire, 23 Sept. 1650; d. London 26 April 1726. He was educated at Caius College, Cambridge, entered the Anglican Church in 1677, and was rector of Ampton, Suffolk in 1679. The revolution of 1688 found in him a most zealous opponent, and he not only refused to take the oaths to the government of William and Mary, but came boldly forward in defense of his nonjuring principles, and subjected himself to repeated imprisonment, both for writings and other overt acts, which a more tyrannical government might easily have construed into treason. His political writings have almost been forgotten; but he wrote two other works, which have preserved his name, and prove him to have been a writer of distinguished ability. The one entitled 'Essays Upon Several Moral Subjects' (1697), is distinguished by learning and wit, and an easy flowing style; the other, entitled 'Short View of the Immorality and Profaneness of the English Stage' (1698), is unquestionably a masterpiece, and is still perhaps the best work written on

the subject. It enjoyed great popularity, notwithstanding the fierce opposition it encountered, especially from Congreve and Vanbrugh, and is said to have had the effect of greatly purifying both the sentiments and the language of the theatre. The only other work of Collier deserving of special notice is his 'Ecclesiastical History of Great Britain to the End of the Reign of Charles II.' (1708 and 1714). It cost him many years of labor, and displays much ability, but is strongly tinged with his nonjuring views.

Collier, John Payne, Shakespearean critic: b. London 11 Jan. 1789; d. Maidenhead 17 Sept. 1883. He wrote many critical articles in periodicals, published in 1820 his 'Poetical Decameron,' and thenceforward continued his editions of poems and plays, notably those of the less-known Elizabethan writers. His 'History of English Dramatic Poetry' appeared in 1831. He took great interest in and edited many publications for the Camden, Percy, and Shakespeare societies, and completed in 1844 an eight-volume edition of Shakespeare. In 1852 he professed to have discovered, on the margins of a copy of the second folio Shakespeare, bought from a second-hand bookseller, manuscript notes and emendations written in a 17th century hand. When these notes and emendations were published they became the subject of eager discussion by the critics, the best of whom were not disposed to set a high value on them, and in 1859 an examination of the volume convinced the British Museum authorities that the marginal notes were forgeries. Collier published a weak and inconclusive reply, in which he maintained their genuineness, and thenceforward he maintained complete silence on the matter. He continued to produce editions of English writers, among them Spenser, and also critical and autobiographical works. Among his papers were found indisputable proofs of a long series of literary forgeries. As a consequence suspicion has rested on all his work, and has obscured the real services he indisputably did to English literature.

Collier, Robert Laird, American Unitarian clergyman and writer: b. Salisbury, Md., 7 Aug. 1837; d. near Salisbury, England, 27 July, 1890. Starting in life as an itinerant Methodist preacher, he held prominent Unitarian pulpits in Chicago and Boston, and became noted as a preacher and lecturer. In later life he was London correspondent of the *New York Herald*. Besides religious writings he published 'Henry Irving, a Sketch and a Criticism'; 'English Home Life' (1885).

Collima'tion, Line of. In a measuring telescope there is placed at the focus of the eyepiece a system of spider-threads. In a transit instrument there are several vertical and two horizontal "wires," as shown in the diagram. In taking an observation the time at which the star passes behind each wire is noted. Taking the mean of these times, we obtain what is called the time for the "mean wire," an imaginary wire which would, if the adjustments were perfect, coincide with the middle vertical wire. The mean of these observations gives a better result than if only one central wire were used. The line of collimation is defined to be the straight line that joins the centre of the object-glass with the point of this imaginary vertical wire midway between the two horizontal wires. A

definition similar to that here given applies in other cases, in the case of the mural circle, for example, and in the case of instruments for terrestrial surveying.

Spider-lines.

The proper adjustment of the line of collimation of these instruments is one of the most important of the adjustments. In the case of the transit instrument, for instance, in observing the passage of a star, what is noted is practically the instant, according to the observatory clock, when the line joining the star and its image coincides with the line of collimation. The following is one of the conditions to be satisfied when the instrument is in perfect adjustment. The line of collimation must be perpendicular to the geometrical axis on which the telescope revolves, and will then describe a great circle. The framework that carries the spider-lines admits of several small movements for their adjustment. After the adjustment has been carefully made, however, there always remains a slight error, which is determined and allowed for in calculations under the name of the collimation error. Adjustments and corrections are similarly made in the other telescopes for measuring.

Collin, Heinrich Joseph von, hīn'řĭh yō'sēf fōn kōl'līn, Austrian dramatist and lyricist: b. Vienna 1771; d. 1811. He wrote several tragedies, mostly on antique themes; of these 'Regulus,' the first of the series, is the best. His powerful 'Songs for the Militia' (1809) gave him a high rank among the balladists of the war of liberation. Of his historical ballads, 'Kaiser Max on the Walls of St. Martin's' is best known.

Collin, Louis Joseph Raphael, loo ē zhō zēf rā-fā-ēl kōl lān, French figure and portrait painter: b. Paris. He studied under Cabanel, obtained a second-class medal in the Paris Salon in 1873, and the medal of the Legion of Honor in 1884. His 'Idyl' is one of his most admired works.

Collin d'Harleville, Jean François, zhōn frān-swā kōl lān dārl-vēl, French dramatist: b. 30 May 1755; d. 24 Feb. 1806. He worked a genuine vein of comedy, yet never slighted the moral side of conduct, and some of his plays still keep the stage. Notable among his works are 'The Old Bachelor,' his masterpiece (1793); and 'Castles in Spain' (1806).

Collingwood, Cuthbert, LORD, English admiral: b. Newcastle-upon-Tyne 26 Sept. 1750; d. at sea near Minorca 7 March 1810. He entered the royal navy in 1761, gradually rose in service, and became a close friend of Nelson. In 1799 he was made rear-admiral of the white. His most distinguished service was the part he bore in the great victory of Trafalgar, in which his gallant manner of bringing his ship (the 'Royal Sovereign') into action, and the skill and resolution with which he fought her, excited the personal admiration of Nelson himself, upon whose fall the command of the fleet devolved upon Collingwood as senior offi-

COLLINGWOOD—COLLINS

cer. He was promoted to be vice-admiral of the red, continued in his command of the fleet, and elevated to the peerage with the title of Baron Collingwood.

Collingwood, William Gershom, English writer and artist: b. 1854. He was educated at Liverpool College, and University College, Oxford. He first exhibited at the Royal Academy in 1880, while from 1881 to 1890 he was secretary to John Ruskin. He has published 'Limestone Alps of Savoy'; 'Art Teaching of Ruskin'; 'Life of Ruskin'; 'Thorstein of the Mere'; 'The Bondwoman'; 'Book of Coniston'; 'Saga-steads of Iceland'; 'Coniston Tales'; 'Early Sculptured Monuments of the Diocese of Carlisle'; 'The Lake Counties'; 'The Life and Death of Cormac the Skald'; 'King William the Wanderer,' etc.

Col'ingwood, Canada, port of entry and county-seat of Simcoe County, Ontario; on Georgian Bay, Lake Huron, and the Grand Trunk Ry., 95 miles northwest of Toronto. It is an important commercial port, the terminus of steamship lines to Owen Sound, Sault Ste. Marie, Fort William, Duluth, and other ports of the great lakes, and has a large trade in lumber, grain, produce, iron ore, etc. It is the seat of a United States consulate. It has tanneries, breweries, flour mills, sash, door, blind and pump factories; schools, churches, hotels, banks and weekly newspapers; and is lighted by gas and electricity. Pop. (1901) 5,755.

Col'lins, Anthony, English theologian: b. Heston, Middlesex, 21 June 1676; d. London 13 Dec. 1729. He was educated at Eton and at Cambridge, and devoted himself to general literature. During the years 1703-4 a correspondence was carried on between him and Locke, who regarded him as having "as much of the love of truth for truth's sake as he had ever met with in anybody." Among his numerous writings, all published anonymously, the one most commonly associated with his name is entitled a 'Discourse on Freethinking.' It attracted considerable notice at the time, and was answered, among others, by Bentley, under the assumed name of *Phileleutherus Lipsiensis*. Another work, entitled 'Philosophical Inquiry Concerning Liberty and Necessity,' was answered by Samuel Clarke. He also wrote 'Essay Concerning the Use of Human Reason' (1707); 'Priestcraft in Perfection' (1709); 'Historical and Critical Essays on the Thirty-Nine Articles' (1724); 'Deience of the Divine Attributes' (1710); 'Grounds and Reasons of the Christian Religion' (1724); 'Literal Scheme of Prophecy'; 'A Letter to the Rev. Dr. Rogers on Occasion of His Eight Sermons on the Necessity of Revelation and the Truth of Christianity' (1727). His benevolent and tolerant spirit gained the respect of many who widely differed from him on theological questions.

Collins, Edward K., American ship-owner: b. Truro, Mass., 5 Aug. 1802; d. New York 22 Jan. 1878. He early entered the shipping business, and after serving as superintendent of a packet line, established in 1836 the Dramatic Packet Line, from New York to Liverpool. In 1849 the Collins line between the same ports was inaugurated. The Arctic and the Pacific

of this line are memorable in the history of marine disasters. The government having withdrawn mail subsidies, the line ceased operations in 1858.

Collins, John, English poet and actor: b. Bath 1742; d. Birmingham 2 May 1808. He was a stay-maker, turned actor; and his poetic fame rests upon 'Scrapscrapologia,' a collection of poems, among which 'To-morrow' is especially readable.

Collins, John Churton, English author, editor, and educator: b. Bourton-on-the-Water, Gloucestershire, 26 March 1848. He was educated at King Edward's School, Birmingham, and Balliol College, Oxford, whence he was graduated in 1872. Since that time he has been engaged in journalism, education, and in public lecturing, especially pleading, both in his writings and lectures, for the study of literature as distinct from philology. Since 1904 he has been professor of English literature at the University of Birmingham. Among his publications are 'Sir Joshua Reynolds as a Portrait Painter' (1874); 'Bolingbroke' and 'Voltaire in England' (1886); 'Study of English Literature' (1891); 'Illustrations of Tennyson' (1891); 'Dean Swift, a Biographical and Critical Study' (1893); 'Essays and Studies' (1895); 'Ephemera Critica' (1901); 'Studies in Shakespeare' (1903); 'Essays in Poetry and Criticism' (1905); etc. He has also edited 'Plays and Poems of Cyril Tourneur' (1878); 'Poems of Lord Herbert of Cherburg' (1881); 'Plays and Poems of Robert Greene' (1899); Dryden's 'Satires'; Pope's 'Essay on Criticism'; Tennyson's 'Poems' (1901); Tennyson's 'In Memoriam, Maud and Princess' (1902); More's 'Utopia' (1904); Matthew Arnold's 'Merope'; 'A Treasury of Minor British Poetry'; etc., and is also general editor of the series 'Shakespeare for Schools' and 'British Classics for Schools.'

Collins, Joseph William, American ichthyologist: b. Isleboro, Maine, 8 Aug. 1839; d. 1904. His boyhood was spent on fishing schooners and he was entirely self-taught. He made the statistical inquiry into New England fisheries for the 10th United States census 1879-80, and for the United States Fish Commission, with which he remained connected until 1892. He was an official of the International Fisheries Expositions at Berlin 1880; London 1883; chief of the Fish and Fisheries department at the Chicago World's Fair 1893; and organized the section of Naval Architecture in the United States National Museum. He was a contributor to the 'Century Dictionary'; edited the 'Fishing Gazette' 1893-4; and wrote many papers and reports on his specialty.

Collins, Mabel. See COOK, MABEL COLLINS.

Collins, Mortimer, English man of letters: b. Plymouth, England, 29 June 1827; d. Knowl Hill, 28 July 1876. His father, who was a solicitor, published a volume of verse and seems to have been a good mathematician. His mother was connected with the Mortimers of Dorset. While at school, the boy wrote verse and prose for local newspapers; and began to contribute to *Fraser's* and *Punch*. At the age of 22 he married, and settled at Guernsey as mathematical master of Queen Elizabeth's Col-

COLLINS

lege. This position, which interfered with his literary work, he resigned in 1856, the year after the appearance of his first volume of poems, 'Idyls and Rhymes.' During the next 10 years, he edited several provincial newspapers and contributed extensively to the London press. A strong Tory in politics, he was accounted one of the best at political squibs. His lyrics and epigrams in the *Owl* were especially well received. In 1860 appeared 'Summer Songs' and in 1865 his first novel, 'Who is the Heir?' By 1862, he was settled at Knowl Hill, Berkshire, some 30 miles from London, where he passed the rest of his life in unremitting industry. He wrote novels, reviews, sketches of travel, and an enormous amount of verse. 'The Marquis and the Merchant' (1871) was regarded as his best novel. 'The Secret of Long Life' (1871), a collection of essays, including a notable one on laziness, ran through several editions. Collins was a "well-made man, over six feet in height, with a handsome face and well-shaped head." Among his numerous friends were Edmund Yates and R. D. Blackmore. His first wife died in 1867. The next year he married Frances Cotton, who collaborated with him in fiction and published on her own account a novel called a 'Broken Lily' (1882).

Bibliography.—Consult: 'Mortimer Collins; His Letters and Friendships' (2 vols. London 1877), a scrappy but interesting biography by his widow. To 'Pen Sketches by a Vanished Hand from the Papers of the Late Mortimer Collins' (London 1879) Tom Taylor prefixed a memoir. For some of his best pieces, consult also 'Thoughts in my Garden' (London 1885), collected and edited by E. Yates, and 'Attic Salt' (1880), a selection of Collins's epigrams, by F. Kerlake.

WILBUR L. CROSS,

Professor of English, Yale University.

Collins, Patrick Andrew, American politician: b. Fermoy, Ireland, 12 March 1844; d. Hot Springs, Va., 14 Sept. 1905. He came to the United States when four years old, went to the public schools until he was 16, became an upholsterer, saved money, and graduated at Harvard Law School in 1871. He served in the Massachusetts Legislature from 1869 to 1871, and was a delegate to the Democratic national conventions of 1876, 1880, 1884, 1888, and 1892. From 1882 to 1888 he sat in Congress and from 1893 to 1897 was consul-general at London. He was prominent in the Fenian movement, the Land League, and other Irish organizations. He was mayor of Boston 1902-5.

Collins, William, English poet: b. Chichester, England, 25 Dec. 1721; d. there 12 June 1759. He was educated at Winchester school and at Oxford, and while at college wrote his 'Oriental Eclogues,' printed in 1742. Their success was moderate, and in 1744 the author went to London as a literary adventurer. In 1746 he gave his 'Odes, Descriptive and Allegorical,' to the public; but the sale did not pay for the printing, and the poet burned all the unsold copies. These he was enabled to buy back from the publisher Millar through the generosity of an uncle who bequeathed him a small legacy. They were never widely read and their

musical verse, lyric fervor, and exquisite imagery remained unappreciated by the public for many years. Yet among these odes were many pieces which at present rank with the finest lyrics in the language. His head was always full of schemes though few of them matured with any degree of success to him and finding it more difficult to win fame than he had anticipated, he soon became dissipated and extravagant, exhausting his slender means. Yet during these times he planned works entirely beyond his power of execution and even advertised one, 'Proposals for a History of the Revival of Learning,' but did not write it. He subsequently began several tragedies but his indolence and irresolution retarded his progress and the tragedies rarely advanced beyond the preliminary stage of devising the plot. Constantly in debt and in fear of the bailiff, he finally persuaded a bookseller to advance money to leave London, in return for which he was to translate Aristotle's 'Poetics' and write a commentary, but he probably did not fulfill his agreement. Collins was always weak in body and when still a young man was affected by a mental disease. Originally too laxly strung, his nervous system was disorganized by disappointment, distress, and irregularity. Months of despondency were followed by periods of madness until he was finally taken to Chichester and cared for by a sister. His best known poems are 'The Ode on the Passions,' those to Mercy and Evening, 'The Dirge in Cymbeline,' and the famous 'How Sleep the Brave.' His odes are now almost universally regarded as among the best productions of the kind in English for vigor of conception, boldness and variety of personification, and genuine warmth of feeling. Of his 'Ode to the Evening' Hazlitt has said that "the sounds steal slowly over the ear like the gradual coming on of evening itself." Swinburne said, in speaking of the 'Ode to the Passions,' "its grace and vigor, its vivid and pliant dexterity of touch, are worthy of their long inheritance of praise." His 'Works' have been edited by J. Langhorne (1765), Mrs. Barbauld (1797), A. Dyce (1827), etc., and his 'Poems' by Bronson (Boston 1898).

Collins, William, English painter of landscapes and domestic scenes: b. London 18 Sept. 1787; d. there 17 Feb. 1847. His picture of the 'Young Fifer,' exhibited in 1811, was purchased for 80 guineas, and in 1813 he at once raised himself to a position of eminence by his 'Sale of the Pet Lamb,' so well known by engravings. In 1820 he was elected a Royal Academician. For his picture of the 'Fisherman's Departure,' painted in 1826, he received 350 guineas. Other noted works of his are 'Rustic Hospitality,' 'Sunday Morning,' and 'Happy as a King.' Two sacred pictures, 'Our Saviour with the Doctors in the Temple,' and 'The Two Disciples at Emmaus,' were exhibited in 1840 and 1841.

Collins, Sir William Job, English surgeon: b. London 9 May 1859. His medical training was obtained at Saint Bartholomew's Hospital, London, and he has since held various professional positions of importance. He was elected to the London County Council for West Saint Pancras in 1892, 1895, 1898, 1901, and 1904, and also contested that electorate for Parliament 1895 and the University of London in 1900. He

COLLINS—COLLISION

has published 'Specificity and Evolution in Disease' (1884-90); 'Pathology of Cataract' (1897); 'Spinoza' (1889); 'Rationalism in Medicine' (1890); 'The Man v. the Microbe' (1903); 'Physic and Metaphysic' (1905); etc. He was raised to knighthood in 1902.

Collins, William Wilkie, English novelist: b. London 8 Jan. 1824; d. there 23 Sept. 1889. The eldest son of William Collins, the landscape and portrait painter, he also bore the name of David Wilkie, the distinguished academician. Among his friends and in letters he was always known as Wilkie Collins. Educated privately, he passed two years (1836-38) with his father in Italy, where he became greatly interested in Italian art, scenery, and history. In 1841 he obtained a clerkship in a London firm of tea-merchants with a view to a business career. After five years of this, he began the study of law, and was called to the bar in 1851. While thus hesitating between law and business, he had shown for some time a bent towards art and literature. For landscape especially, he possessed talent. His first book to be printed was a memoir (1848) of his father who died in 1847; but he had written, long before this, 'Antonina, or the Fall of Rome,' an historical romance of the Bulwer-Lytton type. It was given to the public in 1850. The next year he published an account of a summer in southwest England under the title, 'Rambles beyond Railways.' Both books were well received. He now met Dickens, and at once became a man of letters. Thereafter the two novelists lived in the most delightful friendship. They frequently collaborated on novels, and Collins contributed largely to Dickens's 'Household Words' and 'All the Year Round.' The new influence upon Collins—Dickens in place of Bulwer-Lytton—was at once manifest in 'Basil' (1852), which dealt realistically with contemporary life in London. From history his descent was quick to a clerk and a linendraper's daughter. Then followed 'Hide and Seek' (1854), 'The Dead Secret' (1857) and numerous short stories like the clever series of ghost tales called 'After Dark' (1856).

In this early work Collins sometimes displayed great skill in concentrating attention upon a dominant *motif* which engrossed the reader as well as himself. In his view, the novel was a twin sister of the drama. But he first discovered his extraordinary talent in 'The Woman in White' (1860), which nobody left unread. It was absolutely a new type, depending in no wise upon the interest in character nor in adventure or incident as such, but upon the adroit manipulation of incident for first concealing and then revealing a secret. Collins is the father of the detective story. His first great success was repeated in 'The Moonstone' (1868). In other novels of the period he usually moulded his plot to a distinct didactic purpose. This is particularly true of 'No Name' (1862), 'Armadale' (1866), 'Man and Wife' (1870), and 'The New Magdalen' (1873), all of which are among the most interesting novels of their kind. In 1873-4, Collins visited the United States, where he gave readings from 'The Frozen Deep' and other stories which he had just written. Several of

his novels, dramatized either by himself or by others, were popular on the stage both in England and in the United States. He was buried at Kensal Green.

Bibliography.—Notable appreciations of Collins have been written by Swinburne, 'Studies in Prose and Poetry' (London 1894); Quilter, *Contemporary Review* for April, 1888; and Lang, *Contemporary Review* for January, 1890.

WILBUR L. CROSS,

Professor of English, Yale University.

Col'linson, Peter, English botanist: b. Hugall Hall, Westmoreland, 1693; d. 1768. A merchant in London, he yet found time for studies in natural history, which gained him the acquaintance of the most eminent naturalists of the time. He gave especial attention to botany, and to the naturalization of plants and trees in regions remote from their original habitats. He sent over to Maryland, Pennsylvania, and other Atlantic States, many foreign ornamental shrubs, which found in America a congenial soil and climate; and he introduced into England many American forest trees. He was one of the first to suggest the culture of the grape in Virginia. A genus of labiate plants is named *Collinsonia* from him.

Colli'sion, in navigation, the shock of two ships coming into violent contact, whereby one or both may suffer more or less injury. The American rules in regard to the prevention of such accidents are based upon the same principles as the British, with which they are substantially identical. The leading doctrines of the English law on this subject are thus stated by Lord Stowell: "In the first place, collision may happen without blame being imputable to either party, as where the loss is occasioned by a storm or any other *vis major*, in which case the misfortune must be borne by the party on whom it happens to light. Secondly, a misfortune of this kind may arise where both parties are to blame—where there has been a want of due diligence or skill on both sides; in such case the loss must be apportioned between them, as having been occasioned by the fault of both of them. Thirdly, it may happen by the misconduct of the suffering party only, and then the rule is that the sufferer must bear his own burden. Lastly, it may have been the fault of the ship which ran the other down, and in that case the injured party would be entitled to an entire compensation from the other. In a court of common law the same rule holds in the first, third, and fourth cases; but in the second (where both parties are to blame) the rule is, that if the negligence of both substantially contributed to the mishap, neither has an action against the other; but if one of them, by exercising ordinary care, might have avoided the consequence of the other's negligence, the former is liable for any injury sustained by the latter." In pursuance of the Merchant Shipping Amendment Act (1862), orders were issued in 1863, 1879, 1884, and 1885, giving regulations for preventing collisions. These contain rules concerning lights and fog-signals, and sailing and steering rules. With respect to lights it is enacted that steamers shall, when under way, carry a white mast-head light, on the star-board side a green, and on the port a red light; when towing other vessels they must

COLLODION — COLLOT

carry two mast-head lights, placed vertically. Sailing vessels shall carry only the side lights; fishing and other open boats are not required to carry side lights, but may use a lantern with a red slide on the one side and a green slide on the other, and such lantern must be exhibited in sufficient time to prevent collision, and so that the green light shall not be seen on the port side nor the red light on the starboard side. Ships at anchor in a roadstead must exhibit a white light where it can best be seen, but not 20 feet above the hull, in a globular lantern eight inches in diameter, showing at a distance of a mile all round. The sailing and steering rules demand that if two sailing ships are approaching each other end on, or nearly so, the helms of both must be put to port, so that each may pass on the port side of the other; in crossing so as to involve risk of collision the sailing ship with the wind on the port side shall keep out of the way of the ship with the wind on the starboard, but if they have both the wind on the same side the ship which is to windward shall keep out of the way of the one that has it to leeward. If a steamship and a sailing ship are approaching so as to involve collision, the former must keep out of the way of the latter. The rules for two steamships passing or crossing are nearly the same as for sailing ships. If one vessel is overtaking another she must keep out of the way of the last-named vessel. When, according to the rules, one of the ships keeps out of the other's way, that other shall generally be understood to keep her course. See NAVIGATION LAWS; RULES OF THE ROAD.

Collo'dion (Gr. *κολλώδης*, "like glue"), a solution, in mixed alcohol and ether, of soluble pyroxyline (or "gun-cotton"). It is colorless, and very inflammable. The gun-cotton that is used in its manufacture is commonly prepared by the action of a mixture of nitric and sulphuric acids upon cotton-wool that has been boiled in a solution of sodium carbonate (to remove all greasy and resinous matters), and afterward thoroughly washed and dried. The following details are recommended for the subsequent operations: Three fluid ounces of strong nitric acid are diluted with two fluid ounces of water, and nine fluid ounces of strong sulphuric acid are added. When the mixture has cooled to about 140° F., 100 grains of the cotton-wool are added in tufts weighing about 10 grains each. At the end of 8 or 10 minutes the acid is poured off, and the cotton is subjected to gentle pressure to expel the greater part of the fluid that its fibres have retained. The cotton is next thoroughly washed with water (or weak solution of sodium carbonate) until the acid has been entirely eliminated, after which it is allowed to dry. The product is "soluble gun-cotton." It does not differ materially, in appearance, from the original cotton; but if the operations to which it has been subjected have been correctly carried out, it will be found that the cotton has become soluble in a mixture of equal parts of alcohol and ether. Commercial collodion contains about 60 grains of gun-cotton to each 10 ounces of the solvent. Before the advent of the dry-plate process, collodion was greatly used in photography for the preparation of sensitive plates; and at the present day it is used to some extent in this way, especially in certain branches of photo-engraving. In the preparation of these plates the col-

lodion is first iodized or brominized by the addition of the iodides and bromides of cadmium and ammonium, and is then poured over a carefully cleansed glass plate. The volatile solvent evaporates rapidly, leaving a film of iodized gun-cotton upon the glass. Immediately before the exposure is made, the coated plate is immersed in a solution of nitrate of silver, with the result that a deposit of iodide and bromide of silver, sensitive to light, is formed in the gun-cotton layer. The plate is next exposed in the camera, and afterward developed in the usual way. Collodion is used in the place of adhesive plaster, in the case of trivial injuries, to afford protection from the air, and from pyogenic and other objectionable germs. When applied to the injured spot it quickly dries, leaving a tough, elastic coating which is impervious to moisture. It was first employed in surgery by Dr. J. Parker Maynard, of Boston, Mass., in 1847. It is also medicated in various ways, one of the best-known varieties of this sort being blistering collodion, which contains cantharides, and is applied to the skin for the purpose of producing a blister. Medicated collodion is also largely used in chiropody.

Col'loids (Gr. *κολλώδης*, "glue-like"), substances, such as albumin and silicic acid, which, when combined with water in certain proportions, exhibit a gelatinous consistency. The word does not imply that there is any chemical resemblance among the bodies to which it is applied, the distinction between colloids and non-colloids being wholly physical. The term "colloid" was proposed by Thomas Graham, in 1861, to designate substances that are practically incapable of diffusion through porous membranes. Substances such as salt, sugar, and the mineral acids, which diffuse readily through such membranes, were called by him "crystalloids." The distinction is a convenient one, and has been universally adopted by chemists and physicists. It is probable that colloidal substances do not combine with water to produce true solutions. Quincke, for example, says:

I believe gelatinous substances, such as glue and other jellies, should be regarded as fluids in which there are numerous invisible thin partitions of firm or fluid lamellæ,—the structure of a colloidal substance being likened by him, in other words, to that of a sponge filled with water.

Similar views have also been held by other competent authorities. For a discussion of the phenomena exhibited by colloids and crystalloids in solution (or apparent solution) see DIFFUSION.

Colloph'anite (Gr. *κόλλα*, "glue" + *φαίνειν*, "to appear" = "glue-like"), a native amorphous phosphate of calcium, having the formula $\text{Ca}_3\text{P}_2\text{O}_7 + \text{H}_2\text{O}$, and found principally on the island of Sombbrero, the phosphoric acid that it contains being derived from the guano deposits there. Collophanite is white or nearly so, with a specific gravity of 2.7 and a hardness of from 2 to 2.5. The name is given on account of the glue-like appearance of the mineral.

Collop Monday, the Monday after Quinquagesima Sunday and preceding Shrove Tuesday. It was so named because on that day the faithful ceased eating flesh, meat, or collops.

Collot, d'Herbois, Jean Marie, zhōn mā rē kō-lō dār-bwä, French revolutionary leader:

COLLOTYPE PROCESS

b. Paris 1750; d. Cayenne, South America, 8 Jan. 1796. He was an actor, who adopted the name of D'Herbois. On the breaking out of the French Revolution he zealously espoused the views of the ultra-party, and published his 'Almanach du Père Gérard,' which gave him much influence with the most violent revolutionists. After the events of 10 August he became a member of the Municipal Council of Paris, and a few days after the horrors of September was chosen deputy to the national assembly. He afterward became an active leader of the Mountain against the Girondists. He was sent by Robespierre along with Fouché to Lyons, in 1793, with almost unlimited powers, and was guilty of the most flagrant enormities. Declaring that he found the guillotine too tedious and formal, he introduced the method of executing wholesale by the sword and by discharges of musketry. On his return from Paris he became a determined opponent of Robespierre, and being chosen president of the convention (19 July 1794), contributed powerfully to his fall. A few weeks after his own downfall followed. On the motion of Merlin he was expelled from the assembly and banished to Cayenne.

Col'lotype Process, a method of reproducing engravings, photographs, etc., allied to photolithography (q.v.). It is worked universally, and is known by a variety of names: the Germans call it "Lichtdruck," the French "Phototypie," the Americans "Phototype," and the English have given it the titles of "Photoprint," "Heliochrome," "Autotype," "Photophane," "Photo-mezzo-type," "Graphotone," etc.

The process is based on the well-known action of light on bichromatized gelatine. It differs from photo-lithography in that in collotype the exposed image in gelatine is employed for the actual printing surface, and not only can line subjects be printed from it, but copies of photographs, paintings, and drawings. It renders half-tones so accurately that when prints by collotype process are made on highly glazed paper with a suitable ink there is scarcely any perceptible difference between them and ordinary silver prints; platinotype and bromide prints can also be closely imitated. The process is largely used for the production of view books, fac-simile copies of engravings, copies of paintings, portrait work, and for commercial illustrations. When a film of bichromate mixed with gelatine is exposed to light under a negative, then washed and dried, it will when treated like a lithographic stone absorb water where the gelatine film was protected from light by the dense portions of the negative, and will take ink and form a printing surface in the places where light has obtained access to the film through the negative. A collotype plate will not only take ink where absolutely clear glass occurs in the negative, but it will take ink in the half-tone in exact gradations corresponding to the amount of light passing through the negative. This property is most valuable, and, as a matter of fact, constitutes the process.

The preparation of collotype plates is not difficult. The printing plate is formed of a piece of plate glass of about half an inch in thickness, ground on the printing side to give a better hold to the gelatine. In order that the film may

withstand the heavy pressure of the printing press, it is found necessary to coat the plates first with a substance containing albumen, water-glass, and water. This solution is spread over the cleaned glass in a thin coating and dried. The sensitizing solution for collotype printing is composed of Coignet's gelatine, 3 ounces; albumen, 1 ounce; water, 25 ounces; and bichromate of potash, $\frac{1}{2}$ ounce. The exact proportions are not arbitrary, and different operators modify their solution as experience guides. The sensitizing solution is carefully filtered through flannel, and, while warm, is poured over the surface of the "substratumed" glass plate in a fairly thick film; the coated plate is then placed on accurately leveled supports in a drying-chamber or box, and heat is applied to the bottom of the box, which is made of sheet iron. Considerable heat is required to dry the plates, and the grain or texture of the plate is affected by the speed of the drying; about four hours is the usual time occupied. When the plate is dry and cool it is ready for exposure under the negative; the qualities necessary in a collotype negative are that it must be reversed, and be of full printing strength. A negative that would render a full rich print by any silver printing process is the proper standard for collotype. The margins of the negative are masked with thin opaque paper or tinfoil, so as to permit of the picture being printed with a clean edge on paper with proper margins. The time required for the exposure under ordinary conditions as regards light is from 20 minutes to half an hour, but this is a matter which can only be fixed by experience. The image on the plate cannot be examined during exposure, and an actinometer scale is used for gauging the amount of light. After exposure the plate is taken into a room lighted a dull or yellow light, and washed in running water for about half an hour in order that all the soluble unacted-upon bichromate may be removed from the film, after which the plate is allowed to dry spontaneously, when it is ready for printing.

The printing may be performed in an ordinary press used for letterpress printing, or in a lithographic press. For rapid printing, or for long runs, special steam-driven presses are constructed, with cylinder pressure, on which it is possible to print two or three hundred copies per hour.

When the plate is fixed in position in the press, it is first wetted all over with a sponge and water, or with a solution of common salt, glycerine, and water, which, after being allowed to act on the gelatine for 10 or 15 minutes, is sponged off, and the plate is rolled up with ink. If the printing is being done on a hand press, a coating of ink is applied first with a leather roller, which inks up the shadows and stronger parts of the picture. This inking is then followed by another with a gelatine roller, which inks up the half-tones and details of the subject. A sheet of ordinary printing paper is now placed over the inked surface, and pressure applied. The result is a permanent ink print on paper of the negative used. If the printing is done on a steam press, the operations are, of course, more mechanical, but the finished result is practically the same. Large plates can be successfully dealt with, and pictures on paper up to 40 by 30 inches can be printed.

COLLUSION — COLOCYNTH

The collotype process has had a long and successful career, and the beauty and delicacy of its results, when properly printed, are fully equal to that of any other photo-mechanical process, but of late years the advances made in half-tone blocks, and more especially in the machinery constructed for printing them, has to some extent covered the ground hitherto occupied by collotype illustrations alone; and though the half-tone block can never oust or replace collotype for many kinds of illustration, yet it is sufficiently a rival to restrict its expansion and scope from a commercial point of view.

Collusion, kōl-lū'zhōn (Lat. *collusio*, "a playing together"), a secret agreement between opposing litigants to obtain a particular judicial decision on a preconcerted statement of facts, whether true or false, to the injury of a third party. Collusion, when proved to exist, nullifies the judgment obtained through it.

Collyer, kōl'yēr, **Robert**, American clergyman: b. Keighley, Yorkshire, Eng., 8 Dec. 1823. He came to the United States in 1849, being then a Wesleyan preacher and a blacksmith, but became a Unitarian, and preached some years in Chicago, where he founded Unity Church in 1860 and was its pastor 1860-79. He was made pastor of the Church of the Messiah, New York, in September 1879, and pastor emeritus in 1896. Included in his publications are: 'Nature and Life' (1864); 'The Life That Now Is' (1871); 'The Simple Truth' (1878); 'A History of the Town and Parish of Ikley' (England, 1886, written with Horsefall Turner); 'Talks to Young Men' (1888); 'Things New and Old' (1893); 'A Man in Earnest.'

Collyridians, kōl-ī-rīd'ī-anz (Gr. *kollyridia*, "little cakes"), a sect toward the close of the fourth century, so denominated from the little cakes which they offered to the Virgin Mary. The sect consisted chiefly of Arabian women, who, out of an extravagant devotion to the Virgin, met on a certain day of the year to celebrate a solemn feast, and to render divine honors to her as to a goddess, eating the cakes which they offered in her name. It is said that the members of this sect were not native Arabs, but immigrants from Thrace and Scythia. While pagans they had been accustomed to offer similar cakes to Venus or Astarte.

Colman, kōl'man, **Benjamin**, American clergyman: b. Boston, Mass., 19 Oct. 1673; d. there 29 Aug. 1747. He graduated at Harvard in 1692, began preaching, sailed for England 1695, was captured by a French privateer, and after a short imprisonment, reached England. He received ordination in London, and returned to take charge of the Brattle Street Church, Boston, remaining with that society until his death. He was for many years one of the leading clergymen of New England, exerting a strong influence on civil affairs that frequently drew censure upon him. He procured considerable benefactions for Harvard and Yale, and was offered, but declined, the presidency of the former, in 1724. His collected sermons were printed at Boston 1707-22, and his 'Life' was written by his son-in-law, Rev. E. Turell (1749).

Colman, **George** ("THE ELDER"), English dramatist: b. Florence 28 April 1733; d. London 14 Aug. 1794. He wrote in 1760-1 the

comedies of 'Polly Honeycombe' and the 'Jealous Wife.' 'The Clandestine Marriage' we owe to him and Garrick. This was left unfinished, and it has never been ascertained to which of the authors most credit is due for one of the best pieces in our theatrical repertory. 'The English Merchant,' the 'Oxonian in Town,' and other pieces, followed the foregoing. In 1777 he purchased the little theatre in the Haymarket, and continued in the personal superintendence of it till the year 1790.

Colman, **George** ("THE YOUNGER"), English dramatist, son of the preceding: b. London 21 Oct. 1762; d. there 26 Oct. 1836. He was entered as a student in the Temple, but soon left legal studies for dramatic and general literature. He assisted his father as director of the Haymarket Theatre, and succeeded him as its patentee. After selling his interest in the theatre he was appointed examiner of plays, the duties of which he performed with a severe purism, hardly to have been expected in a man who wrote with almost licentious freedom himself. Most of his dramas were well received, and some of them still keep the stage; as 'John Bull'; the 'Heir-at-law'; 'Poor Gentleman'; and 'Love Laughs at Locksmiths.'

Colman, **Norman J.**, American office holder: b. Richfield Springs, N. Y., 16 May 1827. He settled in St. Louis, Mo., and adopted the legal profession. In 1874 he was elected lieutenant-governor, and was commissioner of agriculture in President Cleveland's first administration 1885-9. Shortly before his term of office ended, Congress enacted the law raising the Department of Agriculture to the rank of an executive department, with its chief a Cabinet officer, 11 Feb. 1889.

Colman, **Samuel**, American landscape painter: b. Portland, Maine, 4 March 1832. He studied in Europe 1860-2; was elected a member of the National Academy in 1862; and first president (1866-71) of the American Society of Painters in Water Colors. He has traveled extensively, and his pictures include scenes from Algeria, Germany, France, Italy, and Holland.

Colmar. See KOLMAR.

Colne, kōln, England, a municipal borough in the county of Lancaster, and 31 miles south-east of the town of Lancaster. The most remarkable edifice is the Piece Hall, in the Elizabethan style. The chief manufactures are cotton goods. Colne was one of the earliest seats of the woolen and cotton manufacture in England, but woolens are no longer made there. Pop. (1901) 23,000.

Colocasia. See COCCO.

Colocollo, kō-lō-kōl'lō, a wild cat (*Felis colocollo*) found in Guiana and Chile. It is somewhat larger than the domestic cat, is whitish-gray in color, with elongated black markings on the back and sides.

Colocynth, kōl'ō-sīnth, the fruit of *Citrullus Colocynthus*, deprived of its rind. The plant, one of the *Cucurbitaceæ*, or melon family, is widely distributed over waste lands in Arabia and adjacent countries, the Mediterranean islands, Cape of Good Hope, Java, southern Spain, and Europe. It is also extensively cultivated. It is collected when the fruit is nearly ripe and peeled while fresh. The fruit subse-

COLOGNE — COLOGNE YELLOW

quently contracts somewhat, is whitish in lustre, and very porous and light. As found in the market colocynth occurs as light, yellowish white balls, from one to three inches in diameter, that are very porous and fragile. It contains a large number of whitish seeds in six compartments. On breaking, the fruit splits irregularly, although there may be a tendency to dehisce in threes. The active principles are a resin and a bitter glycoside, colocynthin ($C_{56}H_{42}O_{23}$ Walz). Colocynth is an active drastic purgative and is rarely administered alone because of its harsh action, but in small doses in combination with other drugs, it is widely used as a laxative and purge. The compound cathartic pill and the vegetable pill are the chief vehicles that contain colocynth. The compound extract, made of colocynth, aloes, scammony, soap, and cardamom, is widely employed in other preparations. Colocynthin is recommended as a rectal cathartic in doses of $\frac{1}{8}$ to $\frac{1}{2}$ grain. Colocynth itself can be given in doses up to five grains.

Cologne, kō-lōn' (German, *Köln*), Germany, a strongly fortified city of Prussia, in the Rhine province, on the left bank of the Rhine. It stands upon the river in the form of a crescent, and is connected with Deutz, on the opposite side and forming part of it, by a bridge of boats and an iron bridge. Till recently it was surrounded by fortifications dating from the Middle Ages, but these have been cleared away, their site built upon, and a wider circuit of works constructed. Until the middle of the 19th century a great part of the city bore the impress of the Middle Ages, the streets being dark, narrow, and filthy; but now the municipality has paid great attention to the appearance and sanitary condition of the town generally by opening up thoroughfares, widening and paving the streets, etc. Among the principal buildings are the townhouse, a remarkably fine Gothic building, partly of the 14th century; the Gürzenich (1441-52), a splendid Gothic building, used for public festivities, and also accommodating the exchange; the Tempelhaus, a fine Romanesque building of the 12th or 13th century, occupied as the Chamber of Commerce; the government buildings, courthouse, postoffice, Imperial Bank, and railway station. But the object of greatest interest in the town is the cathedral, begun in 1248, one of the finest and purest Gothic monuments in Europe. It is in the form of a cross; its entire length is 490 feet; its breadth, 231 feet; the roof rests on 100 columns, of which the four centre ones are 30 feet in circumference. The choir was long the only part finished; it is 161 feet high, and, with its pillars, arches, chapels, and its superb painted glass windows, presents one of the finest sights conceivable. In 1842 the completion of this magnificent edifice was begun, after designs by Zwirner; the works were vigorously prosecuted from that time onward, and were completed in 1880. The two western towers are each 511 feet high, and are among the highest edifices in the world. The other remarkable churches are those of St. Peter, in which is an altar-piece of the crucifixion of that saint, by Rubens, who presented it to this church, in which he was baptized; St. Mary, on the capitol, occupying the site of the capitol of the ancient Roman city, and dating from about the year 1,000, with some good stained glass windows; the Apostles' church, in the

Neumarkt, built about the year 1200, a perfect specimen of the Romanesque style, having a singularly elegant and picturesque exterior; the church of St. Ursula, filled with the bones of the 11,000 British virgins, who, according to the legend, were destroyed here on their return to Britain, under the guidance of St. Ursula; the church of the Jesuits, or Maria Himmelfahrt, dating from 1636, overloaded with gorgeous decorations of marble sculpture, etc.; and St. Gereon's, which, like the church of St. Ursula, is lined with bones, not, however, of virgins, but of the Theban legion of martyrs, slain, according to tradition, during the reign of Diocletian; this is one of the finest and oldest churches in the city. The city contains several gymnasia and other high-class institutions; a technical school; an observatory, and botanical garden; a normal school, a public library, a theatre, several hospitals, a school of design, a museum, etc. The manufactures are very extensive and varied, embracing sugar, chocolate, tobacco and cigars, glue, liqueurs, mineral waters, starch, vinegar, soap, candles, velvet, silk, woolen and cotton goods, India-rubber, and gutta-percha wares, machinery and metal goods, etc., and the celebrated eau de Cologne, of which there are a great many different manufacturers. Its commerce is considerable; it has a good port on the Rhine, and an extensive railway communication with the interior of Germany and with Belgium and Holland. It is the principal entrepôt of the corn, wine, and oil trade on the river, and has active commercial relations with the Netherlands, Germany, Belgium, and Switzerland.

Cologne is of ancient origin, and was originally called *Oppidum Ubiorum*, being the chief town of the Ubii, a German nation. The Romans made it a colony 51 A.D., and called it *Colonia Agrippina*. It was annexed to the German empire in 870, and became one of the most powerful and wealthy cities of the Hanseatic league, its population then amounting to 150,000. As early as the 11th century Cologne carried on an extensive trade with foreign countries, including England, in the produce of the country—wine, corn, flour, malt, beer, etc. The arts and sciences also flourished, and its university was one of the most famous in Germany. Intestine divisions, and other causes, finally effected its ruin, and in 1792 it ceased to be a free city. It was taken by the French in 1794, ceded to them by the Treaty of Luneville in 1801, and restored to Prussia in 1814. Duns Scotus died in Cologne in 1308, and was interred in the chapel of the Minorites; and Rubens was born here in 1577, in the same house in which Mary of Medicis died, in 1642. Pop. (1900) 372,229.

Cologne, Eau de. See EAU DE COLOGNE.

Cologne Earth, a kind of ochre, of a deep-brown color, transparent, and especially valuable in water-color painting because of its durability. It is an earthy variety of lignite or partially fossilized wood.

Cologne Yellow, a pigment consisting of two parts yellow chromate of lead, one of sulphate of lead, and seven of sulphate of lime or gypsum. It is prepared by precipitating a mixture of nitrate of lead and nitrate of lime with sulphate of soda and chromate of potash.

COLOMB — COLOMBIA

Colomb, kō-lōm', SIR **John Charles Ready**, English military writer. He was educated at the Royal Naval College and entered the Royal Marine Artillery in 1854, retiring in 1869 with the rank of captain. He was member of Parliament for Bow and Bromley 1886-90, and was knighted in 1888. He has published 'Protection of Commerce in War' (1867); 'Imperial Strategy' (1868); 'The Distribution of Our War Forces' (1869); 'Colonial Defense and Colonial Opinions' (1873); 'The Defense of Great and Greater Britain' (1879); 'Naval Intelligence and Protection of Commerce' (1881); 'The Use and Application of Marine Forces' (1883); 'Imperial Federation: Naval and Military' (1886); 'British Defense' (1900); 'British Dangers'; 'Our Ships, Colonies, and Commerce in War' (1902).

Colomba, kō-lōn-bä, a romance by Prosper Mérimée, published 1830. It is the story of a Corsican vendetta, followed up to the end by the heroine, with a wild ferocity tempered with a strange piety. The story has an ethical significance of a rather unfortunate kind, for the author's belief in the dogma of fatalism underlies the whole of it,—that circumstances control the human will, and whether a man is a brigand or a philanthropist depends purely on chance, crime and virtue being mere accidents.

Colombia, The Republic of, a country of South America; bounded on the north and northwest by the Caribbean Sea and the Republic of Panama; on the east by Venezuela and Brazil; on the south by Brazil, Peru, and Ecuador; on the west by the Pacific Ocean. Its area cannot be stated precisely, estimates ranging between 424,000 and 482,000 square miles; official estimate, 472,202 square miles. The boundary lines between it and three of the neighboring countries are in dispute. The republic is divided into eight departments as follows: Two on the Caribbean coast, Bolivar, and Magdalena; one with coasts upon both oceans, Cauca; and five in the interior, Tolima, Antioquia, Boyacá, Cundinamarca, and Santander. The capital and largest city of the country is Bogotá (q.v.). Others of importance are: Vélez, Bucaramanga, San José de Cúcuta, Neiva, Medellín, Manizales, Pasto, Cali, Cartagena (q.v.) Barranquilla, and La Mesa.

Physical Features.—The Andes of Colombia are divided into three ranges—the Cordillera Oriental, Cordillera Central, and Cordillera Occidental—with intervening uplands of great extent, which are habitable and fertile, but as yet rather inaccessible. Of the three ranges mentioned, the western Cordillera is the least impressive, though it extends farther toward the north than the others. The central Cordillera has the greatest number of snow-clad summits. Some of the altitudes are: Sierra Nevada, estimated 23,779 feet; Alto del Viejo, 12,965 feet; Boca del Monte, 12,735 feet. The highest snow-peak of the central Cordillera is the volcano called Huila. The volcanos of Sotará (extinct), Pasto, Chiles, Puracé, and Azufral are well known, but the ordinary demonstrations of volcanic energy are earthquakes. See CORDILLERAS. There are four river systems in the republic: (1) The western system, comprising the streams which flow from the western Cordillera into the Pacific Ocean; (2) the river Cauca and its affluents; (3) the Magdalena

River with its affluents; (4) the streams of the eastern slope of the eastern Cordillera, including the upper Orinoco and upper Amazon, and some of the tributaries of those great rivers. Important harbors on the Caribbean coast are: El Portete of Rio Hacha, Santa Marta, Sabanilla (the active port of Barranquilla), Cartagena, etc. On the Pacific coast line are the Bay of Malaga, with the harbors of Guapi and Izcundé; the bays of Pasacaballos and Buenaventura; the harbors of Tumaco and Trinidad, and the gulfs of Montijo, David, and Dulce.

Climate.—The coast and some interior valleys are intensely hot and insalubrious. On the elevated plateaus the temperature is that of perpetual spring. The lowest average temperature in any inhabited part of the mountainous country is 20° F. The peaks of the Cordilleras are covered with snow always. In spite of the equatorial situation of Colombia, the Andes make temperature merely a question of altitude. At Bogotá the thermometer ranges from 55° to 70 F. Alternating periods of dry weather and rainy weather, each generally of three months' duration, are Colombia's "summer" and "winter."

Resources, Flora and Fauna.—Gold is found in Antioquia; in the Chocó region, department of Cauca; in Santander and Tolima, etc. Silver mines are especially productive in Antioquia, Cauca, and Tolima. Aggregate annual output of these metals, about \$4,100,000. Iron is found in Cundinamarca and Antioquia; copper in Boyacá and Magdalena; platinum, sulphur, salt, emeralds, lime, nitre, chalk, marble, petroleum, asphaltum, alum, magnesia, amethysts, lead, tin, manganese, mercury, and cinabar in various parts of the country. Emeralds valued at \$100,000 were produced annually at the Muzo and Coscuez mines up to 1899. The low and torrid regions (coasts and valleys) produce coffee, sugarcane, bananas, cacao, yucca, cotton, tobacco, indigo, vanilla, rice, and many kinds of tropical fruits. The temperate middle region of the Andes is suited to the cultivation of wheat, barley, etc., but these grains are not produced in very large quantities, owing to the lack of means of transportation. Vast tracts of forest remain to be explored. It is assumed that rare botanical treasures will be found in their recesses; and with good reason, since the known varieties of Colombian flora are of exceptional interest. Building, cabinet, and dye-woods are plentiful; the rubber-tree, the cinchona, wax-palms, cedar, balsam of tolu, lignum vitæ, and mahogany flourish especially. In the southeast are great plains suitable for grazing, but as yet unappropriated. The total number of cattle in the republic is only about 3,500,000, with an equal number of sheep, goats, and swine. There are some excellent horses and mules of Andalusian stock. Wild animals of the intertropical or higher regions are: the puma, bear (two species), jagua, alligator, sloth, armadillo, tapir, deer, cavy, opossum, guagua, and 17 distinct species of monkeys. Serpents (the boa constrictor, yaruma, etc.), are not found at a greater height than about 5,000 feet above the sea, though they are very numerous in the lowlands. Characteristic birds are: parrots (many varieties), paroquets, cockatoos, lorries, cranes, storks, the condor, and sol-y-luna.

COLOMBIA

Commerce, etc.—The average export trade of Colombia before the secession of Panamá, amounted to about \$15,000,000 annually. Imports during the five years immediately preceding the outbreak of hostilities in 1899 averaged about 14,000,000 pesos (gold). Exports to the United States during the fiscal year ending 30 June 1901 were valued at \$3,230,625, as against \$4,307,814 in 1900. Imports from the United States were valued at \$3,142,052 for 1901, as against \$2,710,688 for the preceding 12 months. The United States took about 27 per cent in value of Colombia's total exports; Great Britain 25 per cent; France 17 per cent; Germany 16 per cent. The articles exported are: coffee, quinine, emeralds, cacao, sarsaparilla, tobacco, indigo, ivory nuts, dyes, balsams, resins, straw hats, orchids, cattle, hides and skins, rubber, gold, and silver. The principal imports are: cloths of wool, cotton, linen, and silk, shoes, ready-made clothing, furniture, paper, machines, haberdashery, watches, drugs, books, flour, liquors, pottery, and iron. Duties are levied on exports as well as on imports.

Manufactures.—Sugar, molasses, articles of iron, ordinary cotton and woolen cloths, sole-leather, saddles, shoes, furniture, hats, jewels, books, pottery, varnishes, mats, bags, cigars, cigarettes, liquors, carpets of maguey thread, hammocks, hempen sacks, and household utensils are manufactured on a very small scale, partially supplying home consumption.

Transportation and Communication.—At the beginning of the year 1901, according to official information, there were in the republic 605 kilometres (376 miles) of railways; and before the events of November, 1903, eleven lines of steamships plied between the ports of Colombia and those of Europe and the United States. England had five lines, France two, Germany two, Italy one, and Spain one. There was not a single line of American steamers running to Colombian ports at that time. Inland traffic on the Magdalena River employs 42 small steamers. In some recent years the post-office has carried only about 2,600,000 letters, postal cards, newspapers, and parcels. The telegraph system has suffered especially. The total length of its lines in 1898 was given as 8,600 miles; the principal cities being connected with each other, and with the systems of Venezuela and Ecuador, as well as (by cable) with the United States. All the telegraph lines are owned by the government.

Coins.—Silver is the standard; the peso (value in United States gold or silver, \$0.361) is the unit. The gold coins are the condor (\$9.647) and double condor; silver coins, the peso and divisions. Paper money was issued during the war in such quantities that it became practically valueless.

Weights and Measures.—The kilogram (kilo), equivalent to 2.2046 pounds avoirdupois; carga = 125 kilos; quintal = 50 kilos; arroba (dry) = 12½ kilos; libra = 1.102 pounds avoirdupois. In liquid measure the French litre is the standard. Measure of length, the vara = 80 centimeters.

Federal Government.—The president is chosen (by electoral colleges) for a term of six years. His cabinet, though nominally composed of six secretaries, in recent practice has been limited to four, namely, state and interior, war, finance, and foreign affairs. As in Chile, the

secretaries are responsible to congress. A council of state (7 members) is also prescribed by the constitution for the assistance of the executive branch. When for any reason the president ceases to exercise the functions of his office, temporarily or finally, during his term, the vice-president takes his place; failing both, the vacancy is filled by a substitute elected by congress for a term of two years. In time of peace congress meets at Bogotá every two years on 20 July. It is composed of the senate (27 members; 3 from each department) and the house of representatives (one member for every 50,000 inhabitants; term, 4 years; elected directly by citizens—whereas the senators are chosen by departmental assemblies). Judicial authority is exercised by the supreme court (seven magistrates), the district courts, circuit judges, and municipal judges.

Revenue and Debt.—The revenue of the government is mainly derived from the customs, as may be exemplified, thus: Estimated government revenue for 1901–2 (in paper pesos), 28,983,640; estimated amount of customs duties in the same years, 21,450,640 paper pesos. Minor sources of revenue are the government monopolies—the salt mines near Bogotá, the slaughtering of cattle, and the sale of meat. Estimated expenditures for 1901–2 exceeded the estimated revenues for the same years by more than 11,000,000 paper pesos. In 1901 the government offered for sale or lease its emerald mines (Muzo and Coscuez). The exploitation of coal mines and other deposits of minerals in the republic was undertaken in the same year by Swiss capitalists and a mining company organized in the United States. The sale of monopolies supplies the departmental governments with a large portion of their revenues. The total external debt of the nation in 1901 amounted to more than \$14,000,000, the arrears of interest being about \$506,000. The internal debt, two months before the war began, had reached a total of 11,359,074 pesos.

Army and Navy.—In time of war the president's powers are so greatly enlarged by constitutional provision that they become those of a dictator. He has then, among other privileges, the right to claim the military service of every able-bodied male citizen, the age limits being disregarded in practice. In time of peace congress determines the strength of the army at each biennial session. The regular army in former years was usually maintained on a peace footing of 5,500, the reserve being estimated at 120,000 men. The government maintains only two or three small war vessels.

Population and Classes.—Uncivilized Indians to the number of 150,000 or more are found in the territories or districts outside of the departmental limits. Largely mixed with the whites of the lower classes are the numerous descendants of the aborigines in Cundinamarca, Cauca, and Boyacá. Negroes abound in Bolívar, and the Cauca valley, but are rare in the interior departments. The population of Antioquia (570,000) is chiefly white. Members of the ruling class, almost exclusively of European descent, preserve the language and literary traditions of Spain. The total population was about 4,000,000 when the war of 1899–1902 began.

Education.—Primary education is not compulsory, but public schools and colleges maintained at the expense of the departments were

COLOMBIA

attended in 1897 by 143,076 pupils. The federal government maintains a national university that has faculties of philosophy and letters, jurisprudence, medicine and natural sciences, and mathematics and engineering. Between 1,500 and 1,600 students are usually enrolled at this institution. Schools of secondary education, normal schools, an artisans' institute, an academy of music, and an institute of the fine arts are also supported by the nation. In addition to these there are many private schools, and several colleges relying wholly upon their own revenues. Before the civil war of 1899 an increase was noted in the provision for the free instruction of the people.

Local Government.—In each of the departments there is a legislative body, known as the departmental assembly, composed of deputies elected directly by the citizens in the ratio of one deputy for each 12,000 inhabitants. These assemblies regulate local affairs and expenditures, and choose members of the national senate. Governors of departments, being appointed by the president, and removed at his discretion, are regarded as local agents of the national administration, and at the same time chiefs of the departmental administrations. The municipal districts are controlled by alcaldes who are agents of the governors.

History.—The earliest voyages to the Colombian coast are mentioned in DISCOVERIES. In 1508 the Spanish crown granted to Ojeda the district between Cape Vela and the Gulf of Darien, and to Nicuesa the country from the Gulf of Darien to Cape Gracias á Dios. The two territories were united in 1514. Balboa's discovery of the "Southern Sea" was followed by the removal of colonists to the Pacific coast and the founding of the city of Panamá. (See BALBOA, DABAIBA, DARIEN, EL DORADO, and DAVILA.) Starting from Santa Marta 6 Aug. 1536, Gonzalo Jiménez de Quesada led 700 infantry and 80 horsemen into the mountains of New Granada (now Colombia), and took the Indian capital. Colonies were established in the table-lands and along the coasts. The city of Medina was founded in 1670 by Fray Alonso Ronquillo of the order of Preaching Friars. In 1719 the natives destroyed the Spanish colonies on the Pacific slope. New Granada became a viceroyalty in 1740, having been administered previously as a simple presidency, except in 1718-19. In 1810 an insurrection against the government of Spain began. In 1819 New Granada and Venezuela were united, Ecuador joining the union two years later. The country thus formed was called the Republic of Colombia. (See BOLIVAR.) The efforts of Spain to retain these colonies ceased in 1824. Six years later the Colombian union was dissolved, Venezuela and Ecuador having withdrawn; and the republic of New Granada was established in 1831, its territory corresponding to that of the present republic of Colombia.

New Granada was at first divided into five departments, namely: Boyacá, Cauca, Cundinamarca, the Isthmus, and Magdalena. Lack of coherence caused a civil war in 1840; Panamá and Veragua unsuccessfully sought independence in 1841. From 1849 to 1857 the Liberal party controlled the government. In 1853 the right was granted to the departments to elect their governors by popular vote, and the powers of the provincial legislative bodies were increased. New political divisions were organized soon

afterward — Panamá, etc. These claimed, and taught the older departments to claim, the privileges of semi-independent states. A civil war, beginning in 1859, resulted in a triumph for the liberal (States' Rights) party. Under the constitution of 1863 the name Colombia was reverted to, the official title being United States of Colombia. Nine sovereign states were formed, each authorized to maintain its own military forces without restriction, and to nullify the federal laws. Insurrections made steady progress impossible until a reasonable degree of federal control was asserted. In 1880, Rafael Nuñez became president. His influence secured to the national government the right to use its forces for the suppression of insurrections in the several states. A national (government) bank was incorporated; diplomatic relations were established with Spain; the question of the boundary between Colombia and Venezuela was submitted to arbitration. Nuñez held the same office, which he made important, again in 1884 and 1886. In 1891 he was elected for the fourth time, but allowed Vice-President Caro to assume his duties.

A new constitution, which is still in force, was adopted in 1886. By this the states were reduced to departments, with governors appointed by the president of the republic, and legislative assemblies elected by the people. The president's term of office was extended from two to six years. Colombia passed from the extreme of a loose federation to that of a centralized republic. Subsequent revolutions have shown the desire of the Liberals to return to the old irresponsibility. In 1892 subsidies were granted for the construction of several important railways, and new cable lines along the coast and telegraph lines in the interior were authorized. Two years later a law was passed providing for the free coinage of gold and the redemption of the paper currency. Very little progress was made, however; on the contrary the means of communication and transportation, as well as the medium of exchange, have gone from bad to worse in the last few years. The rebellion of 1895 was suppressed in 45 days, but a civil war which broke out 17 Oct. 1899, proved to be more ruinous than any preceding conflict. The Liberals attempted by force of arms to drive the Conservatives from power. An issue which, in a republic, should be settled at the polls, cost the lives of 50,000 soldiers, while among the wretched non-combatants the number of deaths from privation and disease was vastly greater. As usual, the department of Panamá was a centre of disturbance. American marines were landed to guard the stations and railway at Colón and Panamá, in accordance with the treaty of 1846 between the United States and New Granada, by the terms of which the United States guaranteed the neutrality of the isthmus and assumed the obligation to protect free transit between the ports mentioned.

Toward the end of 1902 the flame of civil war finally went out. The government was almost destitute of money; it could neither pay interest on the national debt nor meet current expenses. Congressional elections were held throughout the country. The most important matter to come before that Congress was the question of ratifying a convention concluded at Washington 22 Jan. 1903, between the secretary of state of the United States of America and the chargé d'affaires of Colombia, for the con-

COLOMBO — COLÓN

struction of a ship canal to connect the Atlantic and Pacific oceans. The French Panama Company, formed in 1881, had suspended operations in 1889, and in 1894 a new company had been organized, securing a concession for 10 years, which term was subsequently extended by six years. (See ISTHMIAN CANALS, AMERICAN.) The board of this company had offered (4 Jan. 1902) to sell all its property and rights to the United States for \$40,000,000. The Panamá route had been approved by the United States Isthmian Canal Commission. After a long discussion in the United States Senate, the convention was submitted to the Colombian Congress, the Constitution of 1886 providing that ratification by both Houses is requisite for the validity of such an agreement as that relating to the Panamá Canal.

The convention just referred to, commonly known as the Hay-Herrán treaty, was defeated at Bogotá, 24 members of the Senate voting on 12 Aug. 1903 to reject it. A counter-proposition prepared by a commission (29 Aug.) was debated for a while, but not adopted. The adjournment of the Colombian Congress on 31 Oct. was followed almost immediately by the outbreak of a carefully planned "Separatist" movement in Panamá. Independence was proclaimed 3 Nov., and the Colombian army and navy officers in the principal city of that department were imprisoned. A provisional government was organized. American warships were ordered to the Isthmus; marines landed at Colón; and the Colombian troops withdrew from that town. On 6 Nov. the government of the United States entered into relations with the government of the Republic of Panamá, and on 13 Nov. M. Philippe Bunau-Varilla was formally received by President Roosevelt as minister of the new country. At that time hostile demonstrations against the Colombian government occurred at Bogotá, and another revolution seemed imminent.

Arbitration.—While political factions have continued to resort to arms for the settlement of differences of opinion within the nation's boundaries, the better sentiment of an increasing class of educated people has begun to make itself felt in the disputes with neighboring republics touching the location of those boundaries. Arbitration has repeatedly been chosen in place of foreign wars. The award by the queen regent of Spain, 16 March 1891, defined the frontier on the Venezuelan side. An agreement was made 15 Dec. 1894 for submitting to arbitration the question as to the southern line between Colombia and Ecuador and Peru. President Loubet of France acted as arbitrator of the boundary dispute with Costa Rica, rendering a decision 11 Sept. 1900.

MARRION WILCOX.

Colombo, kō-lōm'bō, Ceylon, the capital, a seaport on the southwest coast, near the mouth of the Kelani River, and about 70 miles southwest of Kandy, the principal place on the island. It is a handsome town, and a portion of it, comprising most of the best houses, is within the walls of its very extensive fort, which occupies a projecting point of land, and embraces a circumference of nearly one and a fourth miles. The houses of the Europeans outside the town are very beautifully situated, especially those near the sea. There are several bazaars or market-places. The public buildings comprise the government offices, government house, hall of the supreme court, the valuable museum, etc. Some of the noted buildings are an old Dutch church, Presbyterian, Anglican, and Roman Catholic churches, hotels, orphan asylum, military hospital, and barracks, the town-hall, the railway station, the Colombo Royal College, St. Thomas' College, and Wesley college. The Moors have two handsome mosques with minarets; the Hindus also have their temples, rudely sculptured. Water is brought from a distance of 30 miles to the town, and there are extensive gas-works. The harbor was formerly capable of receiving small vessels only, and large ships had to cast anchor upward of a mile from the shore, exposed to the southwest monsoon; but a breakwater now gives complete shelter, and Colombo is the regular calling station for the large steamers bound for Bombay, Madras, Calcutta, the Straits, China, Australia, etc. It is the chief port of Ceylon, its exports and imports including the great bulk of the goods sent from and brought to the island. Pop. (1901) 154,556.

Colon, sometimes called **Aspinwall**, Panamá, a town of 5,000 inhabitants on the northern side of the Isthmus of Panamá, connected with the city of Panamá by a railway 49 miles in length. During the civil war in 1885 it was partly burned, but has been rebuilt. It stands upon an island which divides an inlet of the sea into the ports called Manzanillo and Naos, or Newbay. American marines and sailors were landed there during the revolutions which began in 1885, 1899, and 1903, in accordance with the treaty by which the United States guarantees to preserve from interruption free transit across the isthmus.

Colón, kō-lōn', Cuba, a town and district of the province of Matanzas. Area of the district 114 square miles. Area cultivated, 245.03 caballerias. (This was 498.91 caballerias in 1895.) Races, occupation, etc., for the district: Native whites, 5,706; foreign whites, 824; negroes, 2,856; mixed, 2,432; Chinese, 377; persons 10 years of age or over who can neither read nor write, 5,467; engaged in agriculture or mining, 2,741; in trade and transportation, 600; manufacturing and mechanical industries, 576; professional service, 61; domestic and personal service, 984; without gainful occupation, 7,233; number of occupied dwellings, 2,199; number of families, 2,624; persons to a family, 4.7. The following statistics are from the United States War Department census of 1899: Population of the town, 7,175; of the district, 12,195 in 1899, as against 16,679 in 1887.

COLON — COLONIAL ANIMALS

Colón, Venezuela, a federal territory embracing the Venezuelan islands in the Caribbean Sea, except those belonging to the state of Rivas. The islands forming the territory are: Blanquilla, Los Hermanos, Frailes, Sola, Testigos, Venados, Esmeraldas, Caracas, Picudas, Chimanas, Borracha, Arapos, Monos, Píritu, Farallón, Ocumare, Orchila, Los Roques, Aves, Los Monjes, and several smaller ones. The natural products are phosphate of lime, guano, lime, woods, and fish. Large quantities of the plant called orchila are exported for industrial purposes. There are salt deposits in Los Roques. Gran Roque is the capital. Nearly all of the islands are uninhabited. The territory is directly dependent upon the national government, and, like the territory of Amazonas, is governed by special laws.

Co'lon, that part of the intestine that extends from the ileo-cæcal valve to the rectum, practically the entire large intestine. Its position in the abdomen is at first vertical, on the right side,—the ascending colon; then horizontal, the transverse colon, situated just beneath and behind the liver and stomach, going from right to left. It then descends, on the left side, to the sigmoid flexure in the left flank, and then bends abruptly inward and backward to end in the rectum, just in front of the spinal column. It is about four feet in length, and two inches in diameter, is made up of the same kinds of tissue as the intestine, but is rougher and more sacculated. In the large intestine the fecal matter loses its surplus water, and is molded slowly into form for final discharge through the rectum and anus. See ABDOMEN; INTESTINE.

Colon Bacillus, a very common bacterium (*Bacillus coli communis*), of the intestinal canal of many animals, including man, in which place it seems to serve some useful functions in the breaking down of food-stuffs, although, for lower animals at least, it is not indispensable for proper digestive processes. It is a short motile bacillus and closely resembles the typhoid organism, from which it is separated only by careful bacterial technic. While a normal inhabitant of the intestines of man, it may in abnormal situations be a cause of disease-processes. Its presence or absence in potable waters is of service in determining the presence of contamination of a water supply by animal fecal matter. See TYPHOID BACILLUS.

Colonel, kër-nël, the commander of a regiment, whether of horse, foot, or artillery. Any rank above a colonel constitutes the bearer of it a general officer. In the British service the rank of colonel is honorary, and is usually bestowed upon officers of superior rank and princes of the blood, who receive the emoluments of it in addition to those of their regular rank. The actual commander of the regiment is the lieutenant-colonel. In some of the Continental armies also the colonelcy is an honorary post held by persons of rank in the army or the state. In the United States army and the State militias the title of colonel is not honorary, but entails actual service as commander of his regiment.

Colonia Bolívar, kō-lōn'-yā bō-lē'vār, Venezuela, in the Sucre district of the old state of Miranda, about 30 miles from Caracas and five miles from Guatire. It is one of the two

colonies which were established in 1874 with the design of encouraging immigration. The main products are coffee and starch. The principal town is Araitha. The Araitha River and several other streams irrigate the soil.

Colonia Catalana, kā-tā-lā'nā, Paraguay, situated in the department of Villa del Rosario. Cultivated area, 58 cuabras.

Colonia Cosme, kōz'mā, Paraguay, in the department of Caazapá, a colony recently founded by Australians, who have already a school, several stores, a carpenter shop, a shoe factory, a saw-mill, a tannery, and 65 cuabras under cultivation.

Colonia Independencia, ēn''dā-pān-dān''-sē-ā, Venezuela, in the Altigracia district of the old state of Miranda, about 70 miles from Caracas. Its area is 555 square kilometers; its altitude 5,400 feet above sea-level; Taguacita is its principal town, and its agricultural products are coffee, sugarcane, yucca, and cacao. There are extensive forests and two rivers. The colony was founded in 1874. See COLONIA BOLIVAR.

Colonia Nacional, nā-thē-ō-nāl', Paraguay, formerly called "President Gonzalez's Colony," situated in the department of Caazapá. It covers an area of 12 square leagues, crossed by the railway from Asunción to Villa Encarnación. The ground is hilly, well watered, and covered with fine timber. Maize (harvested as often as three times a year), sugarcane, tobacco, wheat, potatoes, coffee, vines, rice, and lucerne, all grow readily in the valleys or on the hill-sides. The export trade in 1901 was valued at \$245,971. Pop. 847. For other colonies, see PARAGUAY.

Colonia, Uruguay, a department on the Plata, below the Uruguay River. The uplands are barren, but in the fertile valleys and plains are numerous European colonies, engaged in agriculture and stock raising. The capital, Colonia del Sacramento, on the Plata, about 100 miles above Montevideo, has a good harbor, a dock for vessels of 1,000 tons, ruined fortifications, and some 1,500 inhabitants. Area of the department 2,192 square miles; pop. 50,300.

Colonial, or **Compound Animals**, organisms which cannot be fairly regarded as unities, but consist of numerous more or less similar individuals united in a common life. Among the usually single-celled simplest animals or *Protozoa*, loose colonies not unfrequently occur, and are of not a little importance as suggestions of the bridge between the single-celled and many-celled animals. Such colonies arise when the original cell instead of reproducing discontinuously, retains its daughter-cells in union with itself or with one another, much like the segments of the egg-cell of a higher animal. By sacrifice of individuality at the time of reproduction, a higher unity is formed. In the same way a simple cup-shaped sponge, by continuous budding, forms a colony of similar forms, which may possess more or less distinct individuality. The common fresh-water *Hydra*, to mount a step higher, buds off daughter *Hydræ*, which remain for a while connected with the parent organism, and make it temporarily colonial.

Many marine hydroids retain their polyps permanently as constituents of such a complex organism, and, as a differentiation of these into

COLONIAL DAMES OF AMERICA—COLONIAL WARS IN AMERICA

nutritive and reproductive, and often into still other kinds, takes place, a higher order of more complex individuality arises; the polyp life is in part subordinated to the colony life. Among the most perfectly organized of such colonies are the floating *Siphonophora* (such as the Portuguese man-of-war), in which five or six perfectly differentiated and specialized kinds of zooids act together in mutual interdependence to support the whole. In most cases such zooids are incapable of performing any but the one function, or set of functions, to which they are adapted, and consequently cannot sustain independent life. This is one way of approaching the questions of individuality and of organization of the higher *Metazoa*. See COMPARATIVE ANATOMY.

For social communities or colonies composed of numerous free individuals all working together for mutual benefit, and how new colonies are founded, see ANT; BEE; WASP; TERMITES, etc.

Colonial Dames of America, The National Society of, an ancestral and patriotic organization of American women, founded 19 May 1892; and composed of one Colonial Society from each of the 13 original States, one society from the District of Columbia, and one associate society from each of the non-colonial States. The objects of the National Society are: to preserve colonial history, traditions, manuscripts, records, relics, and buildings; to perpetuate the brave deeds, and glorious memory of the colonists, and to engender and encourage patriotism. To be eligible to membership, a woman must be descended from some worthy ancestor, who rendered valuable service to the colonies, and who became a resident of America previous to 1750. Memberships are obtained only upon invitation from those already enrolled, and must be procured through admittance into the Colonial Society, of the ancestral State, where the service of the ancestor was rendered. The work of the society has been patriotic. During the Cuban war nurses and supplies for the sick were supplied; at the close of the war a splendid monument, in Arlington cemetery, Washington, D. C., "to the memory of the soldiers and sailors, who gave up their lives in the late war with Spain," was erected by the society "in the name of the Women of the Nation." One of the most valuable and interesting collections of colonial relics and furnishings is under the control of the New York Society at the old Van Cortlandt manor house in Van Cortlandt Park. Churches and colonial houses of historical importance have been restored; historical sites marked with tablets; prizes awarded for essays on patriotic and historical subjects, to pupils of public schools and colleges. A complete list of the soldiers and sailors, who fell in the Cuban campaign, form the contents of a Record Book, compiled by the society. Great credit is due this organization for preserving many historical places which otherwise might have been destroyed. The society numbers (1903) 4,000 members.

Colonial Office, the English government office where business connected with the government of the colonies is carried on. A secretary of state for the colonies was first appointed in 1768. In 1782 the title was abolished again and

the colonies were placed under the home secretary. In 1801 the jurisdiction was transferred to the secretary for war. In 1854 the original arrangement was reverted to, and there have been colonial secretaries ever since.

Colonial System. See COLONIES AND COLONIZATION.

Colonial Wars in America. A résumé of the colonial wars in America must of necessity omit many local disturbances which were of importance historically and which the student can find graphically described in many of the volumes included in the bibliography at the close of this article. Some of the most important are here chronologically presented.

1607. Jamestown, Va.—Although Capt. Gabriel Archer and a sailor were severely wounded by arrows tipped with deer's-horn and sharp stones, the night the English landed in Virginia, the first real conflict in American colonial history came two weeks after the Jamestown settlement, at the end of May, 1607, 200 Indians being repulsed by the settlers under Capt. Edward-Maria Wingfield. English casualties, one killed; 11 wounded. From this encounter to the battle of Lexington (q.v.), April 19, 1775, scarcely a generation in the several colonies reached manhood, without knowing the horrors of war.

1620. Plymouth, Mass.—The Pilgrims of New England had their first encounter with the dusky Nausite tribe, whose arrows were headed with hart's-horn, eagle's-claws, and brass, Dec. 8, 1620, and for over half a century the warfare continued with exacerbations of varying ferocity.

1622. Virginia.—Two years later their kinspeople at Jamestown escaped annihilation by the warning of a converted Indian. March 22, at midday, 347 men, women, and children were slain, by supposedly friendly savages, among the scattered hamlets along both banks of the river.

1633-7. Pequot War.—The Pequot Indians, in 1633, killed several English traders who came to their Connecticut River territory; 1634 found the Pequots at war with the Narragansett tribe, and hostile to the Dutch as well. Then the New England colonists prepared for the inevitable encounter. Sassacus reigned as Pequot chief. About this time John Oldham and two young lads were slain by the savages at Block Island. Governor Endicott promptly sent a force which destroyed the major part of this band. The Pequots then tried to enlist the cooperation of the Narragansetts, but this failed, owing to the influence exerted by Roger Williams over this tribe. The murder of 30 men and women followed. Connecticut, in May, 1637, placed John Mason in command of troops contributed from Massachusetts and Plymouth under Capt. John Underhill, allies being Mohegans, Uncas their sachem, and 400 Narragansetts and Nyantics. The desperate battle of Pequot Hill, Groton, Conn., was fought May 26, 1637. Mason says: "Most courageously these Pequeats behaved themselves"; but, "such a dreadful Terror did the Almighty let fall upon their Spirits that they would fly from us and run into the very Flames, where many of them perished." Nearly 800 Indians were slain in an hour; only two English were killed, and 20 wounded. Activities ceased in August, and the

COLONIAL WARS IN AMERICA

next year a treaty was concluded between the colonies and the tribes.

1642-7. Ingle's Rebellion.—Indians began to molest Europeans in Maryland in 1642, and following these attacks came Ingle's Rebellion, July, 1643, aided by Clayborne, and which caused internal discord in the colony until peace was declared between contending parties in 1647.

1643-7. Kieft's War.—Kieft was appointed governor of New Netherlands in 1638. In the winter of 1643 he made war on the Mohawks, causing an outburst of hostilities among the Algonquin tribes. Massacres and conflagrations continued through the winter and following summer. John Underhill of Connecticut commanded the troops, and successfully routed the Long Island tribes. In March, 1644, Underhill, with 150 Dutch soldiers, landed at Greenwich, Conn., attacked an Indian village of 700, slew 180 in an hour, then set fire to the village, causing the death of 500 Indians by fire and sword. Kieft proclaimed a public thanksgiving for this victory. Nearly all Dutch farms and 1,600 Indians had been destroyed when Peter Stuyvesant succeeded Kieft in 1647, and peace was established.

1644. Virginia.—On Holy Thursday, 1644, Opechancanough and his warriors killed 500 white settlers in Virginia. Vigorous measures were taken by settlers, and the Indians were dispersed, their villages and the Powhatan confederacy (embracing nearly 50 petty tribes) destroyed, their chief captured and shot.

1648-56. New Sweden.—In April 1638 Peter Minuit, with his colony of Swedes, reached Delaware Bay. The colony was unusually prosperous, while Dutch interests there waned. Disputes arose as to titles of land; in 1648 the Dutch tried to erect a fort and houses on the Schuylkill, but were repulsed by the Swedes. Continued friction between the two races resulted, although Stuyvesant of New Netherlands and Printz of New Sweden agreed to be, and for three years were, allies. First one side would capture a fort, then the other; until, in 1656, after discussion by the States-General and Sweden (which came to naught), the city of Amsterdam bought the West India Company's interest on the South River (Delaware), and the colony of New Amstel was launched, while the authority of New Netherlands ceased.

1660. Bacon's Rebellion.—See BACON'S REBELLION.

1664-73. New Netherlands.—England seized New Netherlands Sept. 8, 1664, and war was formally declared in March, 1665. England suffered greatly at hands of Holland in 1666, but continued to hold her American conquests. August 8, 1673, a Dutch fleet of 23 vessels, with 1,600 men, arrived off Staten Island, and on the 9th anchored off the fort. The Dutch commander, Evertsen, at length opened fire, which the fort returned, but the fort surrendered and the Dutch flag was raised.

1666. French and Iroquois.—The French waged war with the Iroquois and other tribes for 60 years, coming down from Canada, invading and destroying their villages. As a result, peaceful white settlers suffered from Indian retaliation.

1675. King Philip's War.—John Sassamon or Sausaman, secretary and interpreter of the Wampanoags' chief (he had been a pupil of

the apostle Eliot) heard of plot to exterminate the English, and reported it to the Plymouth authorities. King Philip, second son of Massasoit, who had been chief sachem of tribes between Charles River and Narragansett Bay, was summoned and examined by the authorities. Learning of the informer, he caused his death, Jan. 29, 1675. His slayers were, in turn, executed by the authorities. Then followed a series of Indian retaliations; eight or nine whites were killed at Swansy; in June, companies from Massachusetts and Plymouth drove Pokanokets from Mount Hope; Philip fled to Nipmucks, who killed Capt. Hutchinson and 16 others; Brookfield was burned; Deerfield and Northfield attacked; Capt. Beers and 20 men from Hadley slain; Capt. Lathrop and 80 men killed at Bloody Brook, near Deerfield, which was then burned; and Springfield and Hatfield were attacked. War continued through the summer, and in October, fearing an attack from the Narragansetts, Governor Winslow with 1,000 men marched against them. All troops were assembled December 18, and on the 19th began the memorable battle, which ended in the complete rout of the once powerful Narragansetts. On Feb. 10, 1676, occurred the Lancaster massacre by the Nipmucks; and this, taken with the series of calamities at Medfield, Worcester, Marlborough, Mendon, Groton, Weymouth, Sudbury, Chelmsford, Springfield, Wrentham, Hatfield, Hadley, North Hampton, Andover, and Bridgewater, makes an appalling list of horrors. War was actively waged by Canonchet, son of Miantonomo, until his capture by Capt. Dennison and the Connecticut troops, and subsequent death at hands of Mohegans. August 12 King Philip was killed at Bristol and the war was at an end.

1680. Port Royal, S. C.—The Spaniards from Florida attacked the Scotch settlement at Port Royal, S. C., in 1680, completely destroying it. A force of 400 men was raised to retaliate, but this plan was forbidden by the proprietors, inasmuch as the colonists were supposed to be not wholly blameless.

1687-9. French and Senecas: Montreal.—The French waged war with Senecas 1687, defeating them. Indians then destroyed Fort Frontenac. In 1689 the Iroquois attacked Montreal causing great devastation and loss of about 1,000 French.

1689-91. Leisler's Rebellion.—See LEISLER'S REBELLION.

1690. First Intercolonial War: King William's War: Quebec.—War between England and France was declared in 1689. The French in Canada planned an attack on Boston and New York. They came down from Canada with Indian allies; attacked Schenectady Feb. 8, 1690; Salmon Falls, March 27; horrible massacres ensued, and the colonies were aroused. March 19 the General Court of Massachusetts proposed a congress, at which measures for their protection should be arranged. The several colonial bodies were notified. Representatives from Massachusetts, Plymouth, Connecticut, and New York met at New York. On May 1 they signed an agreement to send 855 men for the support of Albany and, "by the help of Almighty God, subduing the French and Indian Enemies." Attempts to conquer Acadia and so move on Quebec, together with a plan to secure Montreal *via* Lake Champlain,

COLONIAL WARS IN AMERICA

followed. Acadia and Port Royal were captured by New England men under Sir William Phipps; then the force pressed on to Quebec, but not securing the desired support of Major Fitz John Winthrop, their object was not accomplished.

1696. *Frontenac's Expedition*.—Frontenac's expedition against Iroquois, Oneida, and Onondaga tribes, occurred in 1696, when he was 74 years of age. The tribes were humbled by him, but not subdued.

1702-10. *Second Intercolonial War: Queen Anne's War*.—War was declared May 15, 1702. In August, 1703, the French and Indians attacked Wells, Saco, and Casco. Deerfield and Lancaster also suffered. In May, 1704, Col. Benjamin Church, with troops, sailed from Boston, against Acadian settlements. In 1705 French and Indians destroyed Petit Havre and St. John's, N. F. In 1709 Haverhill was attacked by French and Indians; Oct. 16, 1710, Port Royal captured by the English under Nicholson, and renamed Annapolis, in honor of the queen. Varying degrees of Indian hostility were experienced along the coast to the Kennebec River, until 1725, when peace prevailed.

1703-15. *Southern Wars: Charlestown*.—On Jan. 15, 1703, a battle was fought between Carolina troops under Col. Moore and the Spanish forces under Don Juan Mexia, and 800 of the latter were killed. In August, 1706, Charlestown was attacked by a Spanish fleet, with small loss to either side.

1711. *Tuscarora War*.—September 22, 1711, Tuscaroras and Corees slaughtered inhabitants along the Roanoke River and Pamlico Sound. During several days they killed the whites along Albemarle Sound. Col. John Barnwell, with South Carolina troops and Indian allies, guided an expedition which made several attempts to drive them away; finally captured 800 in a fort; fought a severe battle Jan. 28, 1712, and killed 400 warriors. The remaining hostile Tuscaroras migrated to Oneida Lake, joining the Iroquois confederacy.

1714-15. *Yemassee War*.—The Yemassee war was instigated, so it is claimed, by the Spaniards. A series of Indian outbreaks occurred in 1714-15, in one encounter 400 South Carolinians being killed. The Yemassees were driven out of Carolina into Florida, but disastrous warfare continued, hundreds suffering brutally at hands of savages.

1739-48. *War with Spaniards in Florida: War of Jenkins' Ear: Carthagena*.—The English South Sea Company, under the Treaty of Utrecht, was permitted to supply slaves to Spanish colonies. A smuggling-trade developed, which a Spanish fleet (*guarda costas*) tried to discourage. England and her colonies heard of terrible severities imposed by Spaniards on suspects captured. Runaway slaves from South Carolina made their way to Florida, were well received, protected, and given grants of land by the Spaniards, who declined to return slaves. In 1738 Oglethorpe, appointed military commander of Georgia and South Carolina, returned from England with a regiment. The same year, Capt. Jenkins, skipper of the ship *Rebecca*, was examined in the House of Commons. He described how, having unjustly accused him of smuggling, the Spaniards first hung him at the yardarm, then lowered him, and cut off his ear, telling him to take it to

his king. Public clamor caused Walpole to declare war Oct. 23, 1739. An English fleet under Admiral Vernon visited the Isthmus of Darien, and captured Porto Bello. Oglethorpe, having perfected a treaty with the Creek Indians, called on them and South Carolina for aid. Although an expedition captured Fort Picolata (thus preserving navigation of St. John's River, and preventing Spaniards communicating with posts at St. Mark's and Pensacola), Oglethorpe found the 1,200 men under his command unable to make any impression on St. Augustine, and gave up the siege of that place after heavy loss to his Highland regiment, and desertion of Indians and some Carolina troops. In the spring of 1741 Admiral Vernon, co-operating with land forces under Gen. Wentworth, failed in an assault on Carthagena. A fleet under Commodore Anson secured several valuable Spanish prizes. The Peruvian town of Paita was destroyed. In 1742 a Spanish fleet of 56 vessels, carrying 7,000 or 8,000 men, fitted out at Havana, and appeared off the Georgia coast at the end of June. Its attempts to capture the island of Amelia and forts at Frederica were frustrated by Gen. Oglethorpe. July 7, 1743, the Spaniards lost heavily at the battle of Bloody Marsh; July 24 Oglethorpe proclaimed a general thanksgiving for the end of the invasion.

The following reproduction of the governor's speech to the General Assembly of his Majesty's colony of New York is of interest. It is for the first time reproduced from the only known copy, in possession of the New York Historical Society, and bears upon this period of martial activity, giving an idea of the style of appeal from king to colonists.

JOURNAL OF THE NOTES AND PROCEEDINGS OF THE GENERAL ASSEMBLY OF HIS MAJESTY'S COLONY OF NEW YORK, 30TH DAY OF JUNE 1740.

Gentlemen: His Majesty having been called upon, by repeated Provocations, to declare War against Spain, and being determined, by God's Assistance in so just a Cause to Vindicate the Honor of His Imperial Crown, to Revenge the Injuries done to His Subjects, to Assert their undoubted Rights of Navigation, and by all possible Means, to Attack, Annoy, and Distress a Nation that has treated His People with such Insolence and Barbarity, has given Orders for the Equipping and setting forth an Expedition against the Territories of the Catholic King in the West-Indies, which will consist of a large Squadron of Ships of War, and of a considerable Body of Land Forces, with a suitable Train of Artillery, Store-ships, and all Things requisite: and has likewise given Orders to raise the Body of Troops in His Majesty's Colonies on the Continent of North America, to join those to be sent from England, at a particular Rendezvous. I have, in Obedience to His Majesty's Commands, taken the best Measures in my power, to invite and encourage in His Majesty's faithful Subjects in this Province, cheerfully to enlist in His Majesty's Service for this Expedition: But it is in your Power to do much more, by giving a Bounty to every Man who inlists in this Service. And I am perswaded it will be such as will shew the World, that you will not be behind the most Zealous of His Majesty's Subjects, in promoting this Glorious Enterprise. Now, although by the Success of this Expedition, the Commerce and Navigation of this Province, to and from the West-Indies, will not only be secured, but greatly increased by the large Possessions which, by the blessing of God on His Majesty's Arms, will fall into his Majesty's hands. And although by such acquisitions a Door will be opened for a larger Consumption of Provisions (the Staple of this Province) whereby the Farmer, as well as the Merchant, may be greatly enriched, Yet, it is but little that His Majesty expects from his Dutiful and Loyal Subjects of this Province, towards the Expense of this Expedition. And I am commanded by His Majesty, to Recommend it to you, in His Name, as I do most earnestly, That you provide Victuals, Transports, and all other Necessaries for the Troops

COLONIAL WARS IN AMERICA

to be raised in this Province, except Cloathes, Tents, Arms, Ammunition and Pay till their arrival at the general Rendezvous in the West-Indies from which Time the Said Transports are to enter into His Majesty's Pay. In the doing whereof, I hope you will loose no Time, that the Expedition may not be retarded. His Majesty's Expectations are so just and reasonable, and the Prospect of Advantage to the Province so clear, that I perswade myself, you will cheerfully and immediately provide for the Expence of what is recommended to you. These Things being Matter of the highest Importance, I will not now take off your Attention, by Recommending anything else to your Consideration, hoping you will give this Business the utmost Dispatch, wherein you will, in a very particular manner, Recommend yourselves and your Country to His Majesty, Whom God long Preserve.

GEORGE CLARK.

A bill covering the above passed the assembly July 10, 1740, and Cols. Morris and Philipse carried the same to the council for its concurrence. It was passed by the council July 11, and signed by the lieutenant-governor July 12.

1744-48. *Third Intercolonial War: King George's War.*—May 13, 1744, Governor Duquesnel of Cape Breton captured an English settlement at the island of Canso, near Nova Scotia; destroyed the fort, removing all prisoners to Louisburg; but was unsuccessful in an attempt against Annapolis, N. S., and Placentia, N. F. New England colonists declared war on Nova Scotia Indians, who attacked Annapolis and planned the capture of Louisburg. Men, money, and supplies were contributed by Pennsylvania, New Jersey, New York, Connecticut, Rhode Island, and New Hampshire, but the chief burden was imposed on Massachusetts. Command of the forces (some 4,000 men) was given to William Pepperell, who left Boston in April, 1745, Commodore Warren, commanding in the West Indies, furnishing ships of convoy. Five assaults were made on an island battery protecting the harbor before the French surrendered, June 17. For this success Pepperell was made a baronet. An expedition the following year proved unsuccessful, and Louisburg was returned to the French by the Treaty of Aix-la-Chapelle, Oct. 7, 1748.

1754. *Great Meadows.*—In December, 1753, George Washington carried a request from Gov. Dinwiddie of Virginia to the French commander of Forts Vernango (confluence of French Creek and Allegheny River, now Franklin, Pa.) and Le Bœuf (west fork of French Creek, now Waterford, Pa.) that he retire from territory claimed by the English; request was refused. Gov. Dinwiddie then ordered a fort constructed at the forks of the Ohio, and while work was in progress the French appeared and the English retired. A regiment organized under Col. Joshua Fry, with Washington second in command, pushed on with 150 men. May 28, 1754, when near Great Meadows, the French were met in a glen. In ensuing hostilities the French commander, Jumonville, was killed, and those under him captured. Washington retired to Great Meadows and threw up intrenchments, awaiting Col. Fry's force, which finally arrived. Col. Fry had died suddenly. Washington made a second advance, which proved ineffectual against a French force of 700, and he retired with the honors of war, July 3, 1754.

The same month Benjamin Franklin, Thomas Penn, and others assembled at Albany by request of the "Lords of Trade" (a standing

committee of England's privy council), hoping to make an agreement with the chiefs of the Six Nations for protection in the event of further hostilities with France. Franklin's plan was unanimously approved at this congress, but the several assemblies failed to ratify it. Had his plan been adopted, it is said, the several colonies would have been united and strong enough to withstand attacks from enemies without England's assistance and the later pretense for unjust taxation. Thus the Revolutionary struggle might have been averted.

1755-63. *Seven Years' War: French and Indian Wars: Braddock's Defeat.*—The English government, in 1755, placed Gen. Braddock over a force intended to drive the French from the Ohio Valley. Washington was on his staff. Braddock planned the capture of Fort Duquesne, at the confluence of the Allegheny and Monongahela rivers. Untrained in methods of frontier warfare, having seen no enemy on his tedious march (April 2 to July 9), Braddock scoffed at the employment of scouts as he approached the immediate vicinity of the enemy, with the result that when his command was attacked it was completely defeated; half his 1,600 men killed or wounded, and he himself died from a wound received in the onslaught. His papers were captured by the French, who found therein all the English plans.

1755. *Battle of Lake George.*—At a council of war, called by Gen. Johnson at early morning Sept. 8, 1755, it was proposed to send 500 men to Fort Edward. The noted Indian King Hendrick, when consulted about this number, said: "If they are to fight they are too few; if to be killed, they are too many." The force was doubled. Johnson then proposed dividing it into three parties. Hendrick took several arrows, handed one of them to Johnson, requesting that he break it, which the general did; Hendrick then placed three arrows in the general's hand, saying: "Put them together and you can't break them: take them one by one and you will break them easily." This argument was conclusive. Col. Ephraim Williams led; Lieut.-Col. Whiting had second division; King Hendrick, with 250 Mohawks, was in advance of the Provincials. Rocky Brook was reached; here the enemy was in ambush; but for friendly warning from Senecas, troops would have perished. Col. Williams and King Hendrick lost their lives; Gen. Johnson was wounded; Lieut.-Col. Whiting conducted a successful retreat, followed by the French and Indian allies. Lieut.-Col. Cole, with 300 men, came from Lake George; a brilliant dash was made on the enemy, driving them and capturing Baron Dieskau. Col. Blanchard advanced from Fort Edward, where the firing had been heard, with 250 men; discovered 300 Indians resting at Rocky Brook; slew most of them. Among 500 lost by the French was Le Gardeur de St. Pierre, whom Washington had met the year before at Great Meadows.

1756-7. *Forts Oswego, Ontario, George, and William Henry.*—England declared war against France May 18, 1756. Gov. Shirley was commander-in-chief of colonial forces; Marquis de Montcalm general of French. Shirley slowly matured plans of attack on Crown Point and Fort Duquesne; meanwhile Montcalm destroyed three forts, Oswego, Ontario, and George. This activity of the enemy cost Shirley his position;

COLONIAL WARS IN AMERICA

the Earl of Loudon taking his place, Gen. Abercrombie second in command. In 1757 Montcalm attacked Fort William Henry, at head of Lake George, garrisoned by 2,264 regulars, under Col. Munroe. The attack lasted from August 3 to August 9, when a capitulation was signed.

1758. *Louisburg: Ticonderoga: Crown Point: DuQuesne.*—Three expeditions were proposed for 1758: the first against Louisburg; the second against Ticonderoga and Crown Point; the third against Fort DuQuesne. May, 1758, found Admiral Boscawen at Halifax with a fleet of 157 vessels (23 ships of the line, 18 frigates and transports). There were 12,000 men under Jeffery Amherst to co-operate with him. The attack on Louisburg began June 9, and lasted until July 26, when the garrison capitulated, becoming prisoners of war. Vast quantities of ammunition and stores, 218 cannon, and 18 mortars fell into the hands of the English.

Gen. Abercrombie led a force of 15,000 men against Ticonderoga, embarking on Lake George July 5; advanced toward the fort; experienced many difficulties, including a skirmish in which Lord Howe was killed, and finally had to retreat. He lost about 2,000 men.

Lieut.-Col. John Bradstreet proposed an attack on Fort Frontenac (now Kingston, Canada); Abercrombie consented and gave him 3,000 men. This was successful toward the close of August; Bradstreet captured quantities of stores, ammunition, and cannon.

DuQuesne.—Early in July Gen. Forbes left Philadelphia en route to Fort DuQuesne, with Cherokee allies; Col. Bouquet was at Rays-town; in September Col. Washington joined Forbes; late in November Fort DuQuesne was in possession of colonial forces, receiving the name of Pittsburg in honor of the elder William Pitt.

1759. *Quebec.*—Maj.-Gen. James Wolfe was appointed to proceed against Quebec. He had ten battalions of infantry, six companies of rangers, artillery, engineers, and the Louisburg Grenadier Corps. Under Admiral Saunders were 22 ships of the line, 5 frigates, and several transports; Wolfe had, as brigadier-generals, Monckton, Townshend, and Murray; Col. Guy Carlton commanding the grenadiers, and Lieut.-Col. William Howe (brother of Lord Howe) the light infantry. At Quebec were more troops than the English had, under Montcalm, who placed them along the north shore, below the city, from St. Charles River to the Falls of Montmorency. Wolfe placed batteries within cannon-shot of Quebec at the west point of the Isle of Orleans, and at Point Levi. The lower town was destroyed; conflagrations occurring in the upper town by red-hot balls and shells. July 9 Wolfe crossed from the Isle of Orleans to the north branch of the St. Lawrence, camping below the Montmorency; July 18 he made a successful reconnoitre. His attack on redoubts at the ford was unsuccessful, with a loss of 400 men and two vessels. While ill, and awaiting the arrival of Gen. Amherst, he called a council of war; and it was decided to draw Montcalm into the open field. Camp was broken and the troops moved to Point Levi.

De Bourgainville, with 1,500 French, guarded the north shore to prevent landing. The English admiral deceived the French by moving his

vessels below the real landing-place (Wolfe's Cove, near Cape Diamond). Ascent was made to the Plains of Abraham; the memorable battle was fought, Wolfe and Montcalm both dying from wounds therein received; and the citadel surrendered September 17 to Gen. Townshend.

Fort Niagara.—Soldiers under Prideaux landed July 1, 1759, within six miles of Fort Niagara. A sally was made July 11. Prideaux was killed by a bursting shell July 19; Amherst appointed Gen. Gage to succeed him; until his arrival Gen. Johnson carried on a siege; the fort surrendered July 25.

Presqu' Isle: Venango: Le Bœuf: Ticonderoga.—Col. Bouquet captured with ease Presqu' Isle, Venango, and LeBœuf. Gen. Amherst had 11,000 men for an attack on Ticonderoga, which he took late in July (the French having withdrawn), only losing 75 men in a skirmish. He also took Crown Point. The English now fortified these places.

1759-60. *Cherokee War.*—While the above events were transpiring trouble arose with the Cherokees, who had accompanied Gen. Forbes against Fort DuQuesne the previous year. On the return of the Cherokees numerous instances of loss of life occurred between Indians, Virginians, and Carolinians. Gov. Littleton, with 1,500 men, marched against the Cherokees, demanding surrender of the murderers; he received 22 Indian hostages as security for peace, and retired from the field owing to disease and insubordination in his command. The Cherokees attempted to take Fort Prince George, at the head of the Savannah. Hostages were placed in irons through fear of an effort to release them; one of them wounded a soldier, and his friends promptly killed all the Indians. This enraged the Cherokees, and war-parties were sent out in every direction and laid siege to the fort; the South Carolina assembly offered £25 for each Indian scalp, and voted to raise 1,000 men. Gen. Amherst sent 1,000 Scotch Highlanders under Col. Montgomery, who raised the blockade at Fort Prince George, and met Indians in June 1760. Victory was claimed by both sides. Montgomery retired to Charlestown, prepared to return north, by order of Gen. Amherst. Lieut.-Gov. Bull now ordered 400 regulars for frontier protection. Upper Cherokees besieged Fort Loudon so successfully that the garrison lived on horse-flesh until it surrendered under promise of protection to the settlement; the promise was broken, many lives lost, and many taken prisoners. In June, 1761, the Highland regiment returned and defeated the Cherokees with great slaughter. They sued for peace, which eventually was concluded.

1760. *Quebec.*—The delay caused in rebuilding and strengthening Ticonderoga and Crown Point prevented Amherst from moving on Montreal. The French had time to rally under De Levis, who succeeded Montcalm, and planned retaking Quebec. The plan was put in operation April 17, 1760. De Levis, with 10,000 men went down the river to Quebec, where Murray was in control. De Levis camped three miles from the city. On April 28 an attack was made, in which Murray lost 1,000 men and a train of artillery. The French loss was estimated at 300. De Levis built trenches about the city, preparing for a long siege. May 15 Swanton arrived and destroyed all the French ships at Quebec. The siege was raised May 17,

COLONIAL WARS IN AMERICA

and on Sept. 8, 1760, the English flag was raised in Montreal.

1762. *Martinique: Havana.*—Gen. Robert Monckton sailed from New York late in 1761 with two line-of-battle ships, 100 transports, and 12,000 regulars and colonials; in February, 1762, he captured Martinique; next, Fort Royal, St. Pierre, St. Vincent, Grenada, and St. Lucia surrendered; the French fleet was destroyed; on Aug. 12, 1762, Havana was captured by forces under the Duke of Albemarle, after a fierce struggle of 44 days, and great loss of life.

1763-4. *Pontiac's War.*—Pontiac, chief of the Mohawks, posed as friend of the English after their victories; in secret he was plotting against them with Algonquins, Wyandots, Senecas, and others. He planned simultaneous attacks on western posts in the spring of 1763. Major Gladwin, commanding at Detroit, was forewarned, and when Pontiac and his 60 chiefs appeared on May 6, they found the garrison under arms. The fort was unsuccessfully attacked for two months; then relief came from Fort Niagara. Capt. Ecuyer at Fort Pitt (Pittsburg, Pa.) was also prepared. At the first attack, June 22, the Indians were repulsed. The second attack, July 26, lasted four days, and the Indians were defeated. Gen. Amherst sent Col. Bouquet with 500 men to its relief; while en route, 25 miles east of the fort, he fought a stiff battle with Indians at Bushy Run, coming off victorious. In September, 1764, Col. Bouquet was again at Fort Pitt. Toward the close of November the Delawares and Shawnees returned 200 captive whites. This border war had caused much distress, and the following forts had been lost before Sir William Johnson and Bradstreet successfully treated with 2,000 representatives of the Ottawas, Ojibways, Iroquois, and Wyandots at Fort Niagara, and Pontiac's war was over:

May 16, 1763, Fort Sandusky.

May 25, Fort St. Joseph (at the mouth of St. Joseph River, Mich.).

May 31, Fort Onatanon (on the Wabash, Lafayette, Ind.).

June 2, Fort Michillimackinac (Mackinaw, Mich.).

June 17, Fort Presqu' Isle (Erie, Pa.).

June 18, Forts Le Bœuf (Erie County, Pa.), Venango (Venango County), and forts at Carlisle and Bedford, Pa.

1774. *Lord Dunmore's War.*—When Lord Dunmore was royal governor of Virginia in 1774, dissension as to boundary lines arose between Virginia and Pennsylvania, as well as to ways and means of dealing with Indians. Virginia wished to possess their lands; Pennsylvania desired their trade; as whites encroached more and more on lands, Indians became angered; outrages followed, perpetrated by Shawnees, Mingos, Cherokees, Wyandots, and Delawares. In the spring of 1774 a ruffian borderer, Greathouse, killed nine kinsmen of the Iroquois Logan. This caused continued hostilities until the battle of Great Kanawha, or battle of Point Pleasant, in October. The effect of this battle kept the northwest Indians submissive during the early years of the Revolution, and at the same time permitted settlement of the Kentucky region.

Colonial Wars, Society of. The Society of Colonial Wars in the State of New York was incorporated 18 Oct. 1892. It is essentially a patriotic organization, keenly alive to the necessity, in these modern days of whirl and rush, of perpetuating the names and valor of those participating in the warfare of American colonial history. Eligibility to membership consists in the applicant being 21 years of age, of good moral standing, and having a line of descent from an ancestor: (1) who served as a military or naval officer, or as a soldier, sailor, or marine, or as privateersman, under authority of the colonies which afterward formed the United States, or in the forces of Great Britain which participated with those of the said colonies in any wars in which the said colonies were engaged, or in which they enrolled men, from the settlement of Jamestown 13 May 1607, to the battle of Lexington 19 April 1775; or (2) who held office in any of the colonies between the dates above mentioned, either as (a) director-general, vice-director-general, or member of the council, in the colony of New Netherlands; (b) governor, lieutenant or deputy governor, lord proprietor, member of the king's or governor's council, in the colonies of New York, New Jersey, Virginia, Pennsylvania, and Delaware; (c) lord proprietor, governor, deputy governor, or a member of the council, in Maryland and the Carolinas; (d) governor, deputy governor, governor's assistant, or commissioner to the United Colonies of New England, or body of assistants in any of the New England colonies.

Membership is hereditary in the male line of the present members of the society and of those who may hereafter be elected, up to the limit that the society may hereafter determine upon, subject to the vote of the council upon the moral qualification of the person who may be the heir at any time to such membership. The membership in the New York Society is limited to 1,000, exclusive of descendants of members, members of State societies who may be transferred to this society, and members of the army and navy and marine corps on active service.

In 1903 there were 26 co-ordinate State societies united in the general society, with a membership approaching 6,000. In New York "business courts" are held in March and November; a "general court," for the annual election of officers, in December. At these courts papers are read dealing with the colonial period. An annual banquet is held in honor of the founding of New Amsterdam. A "general assembly" of the general society meets once in three years at such time and place as the preceding assembly designated. These general assemblies are composed of the members of the general council, together with five delegates chosen by each of the State councils.

The society has erected commemorative bronze tablets at Fort Oswego and Ticonderoga,

and one of marble to Gen. Forbes. An oil portrait of Gen. Bouquet has been presented to the city of Philadelphia, and adorns Independence Hall. Many members of the society participated actively, either in the army or the navy, during the Spanish-American war, many thousands of dollars being contributed by the several State societies, from Maine to California, in equipping State regiments, caring for the sick and wounded, and for hospital supplies, flags, band instruments, etc. The year-books of the society contain valuable historical and genealogical data.

SYDNEY H. CARNEY, JR., M.D.,

Historian Soc. of Colonial Wars, New York.

Colonies and Colonization. In the older and stricter sense, a colony is a body of people who, having migrated and settled beyond the borders of their native country, retain a political connection with the parent state. Since, however, the colonists may be mingled in any proportion with the natives, it is impossible to maintain a firm distinction between colony and dependency. It has therefore become customary to apply the term "colony" to an outlying possession of a national state the administration of which is carried on under a system distinct from but subordinate to, the government of the national territory. According as the dominant feature is the exploitation of a dependent population, the settlement of immigrants from the mother country, or the investment of capital, colonies may be divided into possessions, settlement colonies, and investment colonies.

The Greek colony was formed in a natural way by the swarming off of surplus population, and was usually independent from the beginning. The bond between the mother state and the colony was sentimental, not political, and the former seldom expected any advantage from the founding of the colony save relief from the pressure of population. The Roman colonies formed part of an elaborate scheme for extending Roman dominion. They were instituted by the state, and were its chief instrument in confirming its conquests. In their origin they were little more than garrisons in conquered, fortified places, where land was allotted to the soldiers instead of pay and provisions.

When the discovery of America occurred, Europe was not overpeopled, and there was for a long time little spontaneous outflow of substantial elements to create new communities. The conquest of large and industrious populations, settled upon rich lands, tempted the cupidity of rulers, and gave rise to the conception of the colony as a possession, an estate to be mined or worked by the state or its favorites for purposes of revenue. Says Seeley: "A native population reduced to serfdom, in some parts driven to compulsory labor by caciques turned into state officials, in other parts exterminated by overwork and then replaced by negroes; an imperious mother country drawing from the colony a steady revenue and ruling it through an artful mechanism of division, by which the settlers were held in check by the priesthood, and by a serf population treated paternally, that it might be available for that purpose; such was the typical colonial system."

The exploitation of subject populations by such means as tribute, serfdom, forced labor on public works and government plantations, or

COLONIES AND COLONIZATION

the maintenance of crown or company monopolies, has come to be generally recognized as short-sighted, and no longer commends itself to enlightened nations. The old, harsh policy has, moreover, become more difficult with every step toward popular government in the dominant country, and every increase in the power of public opinion. The idea that the dependency is an estate, to be worked for the benefit of the owner, is, however, by no means dead. A disguised and slanting exploitation is still effected by tariff discriminations which insure the dominant country a monopoly of colonial trade, by the granting to favored citizens of lucrative concessions and contracts, by the imposition of a highly paid civil service from which the natives are excluded, and by the saddling of colonial taxes upon the natives while the proceeds are expended in the neighborhood and for the benefit of the European settlements.

Entirely different from the type just described is the settlement colony, which grows up in desirable temperate regions, vacant or sparsely peopled by savages. Although the love of adventure, the crusading spirit, and the desire to escape political, religious, or racial oppression are by no means to be overlooked, it is chiefly the economic motive that leads to the founding of settlement colonies. A stationary population enjoying rapid industrial expansion yields few colonists, but a clogged labor market, a narrowing circle of opportunities, and a darkening prospect stimulate large numbers to face the unknown in the hope of bettering their condition. Not only is a population stimulated to its utmost capacity, provided it remains in vitalizing touch with the mother country, but the mixture of races results frequently in a beneficial crossing of stocks, and the severe struggle in a new and untamed environment accelerates the improvement of the race by natural selection. The growth of numbers, changing constantly the relation between population and opportunities, carries a colony through well-defined stages. First comes the appropriation of natural wealth, hunting, trapping, and mining; then follows pastoralism; then agriculture, to which in time is added manufacturing. During the earlier stages, when the colony is complementary to the mother country, each finds in the other a convenient vent for its surplus products. The volume of exchanges is relatively large, and their trade reaches its maximum importance. But as population thickens and wealth accumulates, the colony, acquiring home manufactures and home markets, becomes an integral, self-sufficing community, and evinces a growing disposition to assert its independence of the mother country, formerly its complement, but now its competitor.

The granting of large entailed estates may lend a colony a semi-feudal character. But if the land system is popular, landed property will be diffused, the proceeds of labor will go to the producer, and the colony will contain few persons living on incomes derived exclusively from ownership. Moreover, being more favorable to production than to consumption, the colony will draw to itself adult males from the industrial population of the mother country, but will attract few members of the less active classes. Since the reward of industry is greater than in older societies, and the community is but little differentiated, economically or socially.

manhood rather than property controls the body politic, the temper is individualistic and liberty-loving, and the conditions favor the germination and rootage of democratic ideas. Despite its social and political radicalism, the colonial society is conservative in its moral and religious ideals. Unless non-economic motives have presided over the beginnings of the colony, the pursuit of wealth is the chief interest of the settlers, and there is little room for speculative thought. The lack of cities, of intercourse, and of leisure is unfavorable to the cultivation of the sciences or the fine arts. During the early life of the colony the preoccupation with private affairs leaves little margin for public life. If the mother country is wise enough to establish security without interfering vexatiously with private interests, the administration of affairs of general concern is turned over to it without regret. A dependence upon the richer and riper culture of the parent state may indeed cause the political connection to continue long after the colony is ready for self-government. Lands thickly peopled by non-European races, and tropical regions where the climate is such that white men will not settle there with their families, do not develop into settlement colonies. Unfit to serve as an outlet for the surplus population of the temperate zone, they can be legitimately utilized by the more advanced races only as a field for the employment of commercial or industrial capital.

The commercial type of the investment colony is best seen in the early establishments of Portugal, Holland, and England, for trade with the East Indian and African peoples. When colonial enterprise is dominated by the commercial motive, penetration of the interior of a new region is not required. Trade is conducted from the decks of merchantmen, from hulks anchored at the mouth of streams, or from fortified stations situated on the seacoast or on the banks of navigable rivers. Settlements of traders and soldiers spring up, but there is little motive to extend political control over large inland regions. A chartered commercial company has at first no occasion to clash with the natives. Its armament is chiefly directed against envious rivals, eager to share in its lucrative trade. Later, when in its eagerness for an exorbitant profit, it attempts to dictate to the natives or limit their production of the staples of trade, it comes to blows with them, and squanders its resources in profitless wars. The earlier commercial colony was valued as a source of tropical products, such as sugar, coffee, and spices, which could be resold in Europe at a large advance. Since the advent of machine industry, however, the commercial colony is valued rather as a market for surplus manufactures. The recent revival of protective tariffs accentuates the struggle for outlets, and impels each of the industrial countries to extend, so far as possible, its control over Oriental and tropical populations, in order to develop in them a taste for its own goods and thus build up an important trade. The old maxim that "trade follows the flag" has taken on a new significance since protectionist nations have adopted the policy of extending their own tariff walls about their territorial acquisitions so as to exclude their commercial rivals.

The chief means of relieving the superabundance of capital that threatens to lower the rate

COLONIES AND COLONIZATION

of profits in the advanced countries is the application of capital in the industrial development of the more backward regions. Tropical lands under native systems are almost invariably under-exploited from the point of view of modern industry. The forest and mineral wealth is largely untouched, and even the area under intensive native cultivation, lacking as it does the best facilities for irrigation, tillage, and transportation, produces by no means the value it might yield. Owing to ignorance, to unstable conditions, or to the lack of accumulated wealth, industry is almost wholly deprived of the aid given by large applications of capital. Under these circumstances it is possible for the more civilized peoples, without in any way exploiting the native populations, without depriving them of their earnings or their patrimony, to apply capital and directive skill in such a manner as to reap a generous profit.

The example of Mexico and of certain countries of South America shows that backward regions may be developed by capital invested under the protection of local governments, and that no adequate reason exists for administering these countries from a distance. In other cases, however, a rapacious and unstable native rule paralyzes industry, and the utilization of natural resources is impossible until a responsible and equitable government has been instituted. It is necessary for some civilized power to suppress tribal and local warfare, to stamp out brigandage, and to establish an efficient police, a righteous administration of justice, and a rational system of taxation. When order and stability have thus been assured, the next step is the investment of development capital in the form of harbors, railways, highways, telegraphs, improved natural waterways, and irrigation works. As the means of communication are perfected, there follows naturally the employment of capital in the opening of mines, the cutting of forests, the clearing and planting of estates, and, possibly, the establishment of factories. The development of a tropical region by the aid of capital from abroad requires the presence of a small body of white men in the capacity of officials, traders, planters, and superintendents, representing in the midst of the less advanced population the superior power and intelligence of the civilized peoples.

The extension of modern forms of agricultural exploitation into climates where white men cannot endure heavy field-work creates special problems respecting the relations of capital and labor. Successful enterprise requires an abundant supply of suitable and reliable labor, and this can come only from the natives or from other colored races. In the old plantation colony the problem was solved by enslaving the local population, or by kidnapping negroes from Africa. Of late there is a tendency, in case the natives cannot be tempted or taxed to work, to draw upon the great reservoir of labor power in the East Indies and China. In the British colonies alone the numbers of coolies that have been imported under five-year contracts are approximately: In Guiana, 70,000; Trinidad, 70,000; Natal, 40,000; Jamaica, 13,000; Mauritius, 250,000. Owing partly to the racial inequality of employer and employee, and partly to the character of tropical agriculture, which cannot bear interruption, especially at harvest time, there is a strong tendency in all planting

colonies to compel the specific performance of the labor contract. Under the indentured labor system in the British colonies strikes are unlawful, and refusal to work can be punished; on the other hand, the government closely supervises the terms of the labor contract, suppresses all obnoxious features, and provides machinery for compelling the fulfilment of its provisions by the employer.

If the welfare of the colony is the first desideratum, the degree of control exercised by the mother country over the internal affairs of a settlement colony will be moderate at the beginning, and will tend constantly to diminish. The prosperity of the English colonies in America was largely due to the salutary neglect of the mother country. They revolted when she sought by a stricter control to make them subserve her economic interests. The home government, even with the best of intentions, is likely through sheer ignorance to press upon the colony institutions ill-adapted to local conditions. On the other hand, during the early life of the colony the settlers, preoccupied with private affairs, have little leisure for the study of the problems of administration and government. Their political life is unduly dominated by selfish, special interests, and there is danger that the first comers may monopolize or waste the natural wealth which ought to be reserved for later arrivals. As impartial umpire and as custodian of the interests of the future, the home government may wisely exercise a supervision which will diminish as the colonial society grows in mass, stability, and variety of interests. In the final stage of political connection, the colony is granted autonomy in all save external affairs, or even becomes with the mother state a member in a federal empire. On the other hand, this gradual ripening off the parent stem is by no means the normal course of a tropical colony, where there are two unmingling elements in the population—a colored race and an incoming European race. In the West Indies, for example, self-government means the rule of the one race or the other. There is either the domination of a large native population by a permanently resident European caste, cut off from the moral and political conditions which have produced European standards, or else the subjection of the white element to the uneducated and politically inefficient majority race. Here, the home government presents itself as a power superior to local prejudices and able to override the antagonistic class or race interests which otherwise might wreck the prosperity of the colony. For these reasons the system of self-government now enjoyed by the colonies of Canada and Australasia is not likely soon to be extended to the remaining 500,000,000 human beings in existing colonies, dependencies, and protectorates.

The method of direct administration—known as “the crown colony system”—while excellent as a means of balancing conflicting interests and protecting the native majority against oppression by the white minority, errs in trusting too much to the power of ordinance, and showing too little deference to the deeply ingrained customs and characteristics of the native population. The direct government of an alien race by European officials is, moreover, very expensive; and if it is sought to utilize natives as magistrates and police, the best among the

COLONIZATION SOCIETY OF AMERICA

native leaders will stand aloof, leaving often only the ruffraff to become the instruments of administration. Provided there exists an advanced civilization and a highly organized native society, the legitimate ends of European control over a tropical region can best be attained by preserving and working upon the native government through the instrumentality of a protectorate. By this method the natives continue to follow their natural leaders, and retain their time-hallowed laws and customs. Resident agents of the suzerain country supervise the native authorities and, by the exercise of personal influence, prevent misrule, suppress obnoxious practices, and introduce gradually the standards of civilized administration. Commercial and industrial development proceeds apace, while the local population is better safeguarded against exploitation.

The present age has seen a marked increase of political dependency. The strong nations evince a growing disposition to police and place under orderly administration all regions where potential wealth exists, in order to make safe and profitable the improvement of such re-

The table below prepared by the Bureau of Statistics of the United States Treasury Department shows the present area and population of the colonial possessions, protectorates, dependencies, and "spheres of influence" of each country given.

Colonization Society of America, The National, an association to colonize free negroes in Africa or elsewhere. The idea was evolved by friends of negro advancement and opponents of slavery; by Dr. Samuel Hopkins of Newport, R. I., in 1770, at once to Christianize and civilize Africa, and to assist emancipation here by providing a place to which free negroes could go; and by Jefferson during the Revolution, for the latter object. But about 1800 it was taken up by the slaveholding interest, for exactly the opposite purpose—to strengthen their system by deporting the free negroes, who made the slaves discontented and were considered otherwise objectionable. Virginia tried repeatedly to obtain a national grant for colonizing purposes, and failing this, in 1806 enacted that any slave thereafter freed should leave the State within a year or be again reduced to

sources by means of the capital and skill of their citizens. The investment motive is likely to become in the future even more imperious than now, and the increasing speed of communication favors the permanence of the colonial relation where once it is established. There is, in fact, every prospect that in the more advanced nations a larger and larger share of attention will be given to colonial affairs and problems.

Professor Sociology University of Nebraska.

slavery; and in 1816 the petition to Congress was renewed, to force some national action. On the first of January the society above was organized. The president (Judge Bushrod Washington), all the managers, and all but a small minority of the vice-presidents, were slaveholders; its constitution professed no purpose to benefit the blacks, and its ablest northern advocate denied that it had any. Support was asked for it in the North on the ground of its civilizing Africa and leading to gradual emancipation; in the South, on the ground of its contributing to the continuance and strengthening of slavery, augmenting the value of slave property, and providing an overflow for the excess of slaves beyond profitable employment. This impossible "straddle" of purposes ruined its chance of accomplishing much; though a number of the best northern philanthropists, and their southern peers like Birney, clung to it for some years and hoped for good from it. A great many State branches were organized, and vigorous public appeals made for it. Charles Carroll, James Madison, Henry Clay, and Latrobe the architect were its presidents. In 1820 a colony of a few hundreds was sent to Sherbro Island, West Africa, with tools and arms, and in 1822 another was sent to

COLONNA — COLONNA PALACE

found Liberia, with sincere hopes. But the perpetual vilification of the free negroes by the managers, advocates, and organs of the society, their anxiety to do nothing to antagonize the slaveholders, and their advocacy of the severest "black laws" to force the freedmen into desiring deportation as a refuge, alienated the anti-slavery element, who felt that they were being used as cats'-paws of the slave interest. Even Daniel Webster in 1825 refused to join it on that ground, though in 1822 he favored it. By 1830 the Tappans, Gerrit Smith, Birney, Lundy, Garrison, and others had withdrawn from it, and the last-named was openly denouncing it. In 1833 he went to England to expose it before the anti-slavery people there, and they united in a public protest against it. A similar society was organized there, but accomplished nothing. The American society maintained its organization even after the War, though its problem was altered, as well as the southern attitude toward it. An effort a few years since to promote a large negro emigration to Kansas or Oklahoma was met with strong objection from southern employers of labor. Consult: Wilson, 'Rise and Fall of the Slave Power in America,' Vol. I., chap. 15; Alexander, 'History of Colonization on the West Coast of Africa.'

Colonna, kō-lōn'nā, Aegidius de, Italian scholastic theologian: b. 1247; d. 1316. He was prior-general of the Augustine order, and an ardent realist and disciple of St. Thomas Aquinas, under whom he studied at Paris.

Colonna, Fabio, Italian botanist: b. Naples 1567; d. there about 1650. He published several botanical works and is classed as the founder of genera in botany.

Colonna, Fabrizio, fä-brēt'sē-ō, Italian general: d. Naples 1520. He was the cousin of Prospero Colonna (q.v.) and father of Vittoria, served in the army of Charles VII. of France in 1494; in that of Frederick, king of Naples, in 1497; and afterward in that of Ferdinand the Catholic, by whom he was made grand constable in 1507. Subsequently he served in the papal army under Julius II. In 1512 he was made prisoner at the battle of Ravenna by Alfonso d'Este, Duke of Ferrara, who treated him with distinction, and dismissed him without ransom. To show his gratitude he tried to reconcile Alfonso with the Pope, and gave him a safe conduct to come to Rome; but Julius kept him prisoner, and attacked his states. Colonna, indignant at this breach of faith, rescued Alfonso from the papal troops, and reconducted him to Ferrara.

Colonna, Marco Antonio, Italian commander: b. 1535; d. 1 Aug. 1584. He commanded the papal forces at the battle of Lepanto and was subsequently viceroy of Sicily.

Colonna, Ottone. See MARTIN V. POPE.

Colonna, Pompeo, pōm-pā'ō, Italian ecclesiastic, nephew of Prospero Colonna (q.v.): d. 1532. He was a restless and intriguing Roman cardinal who quarreled in succession with the Popes Julius II., Leo X., and Clement VII., and had part in all the troubles of the court of Rome. When Clement VII. was the prisoner of the Constable de Bourbon, Pompeo exerted his influence for his liberation. He at length became viceroy of Naples.

Colonna, Prospero, Italian general: b. 1452; d. 1523. On the invasion of Italy by Charles VIII. he took part with that prince, owing to his enmity against the Orsini family. He shortly afterward, however, abandoned the French cause, and bore arms in the Spanish interest. Among his most noted victories were those gained at Vicenza over the Venetians 1513; and at Bicoque over the French 1522. He also took Milan from the French in 1521, and Genoa in 1522. In 1523 he defended Milan successfully against Admiral Bonnivert.

Colonna, Stefano, Italian noble: d. 1347. He deserted the policy of his house, and became a supporter of the Guelf party. He was chosen a senator with Orsini, the hereditary enemy of his family. He was a leader of the nobles in opposition to Rienzi, to whose government he temporarily submitted, but was killed in an attempt to take the city by a *coup-de-main*.

Colonna, Vittoria, Italian poet: b. Marino 1490; d. Rome 25 Feb. 1547. She was the daughter of Fabrizio Colonna (q.v.), and when four years old was betrothed to a boy of the same age, Fernando d'Avalos, son of the Marchese di Pescara. At 17 they were married. After her husband's death in the battle of Pavia (1525), Vittoria found her chief consolation in solitude, and the cultivation of her poetical genius. For seven years she resided at Naples and Ischia, then removed to the convent of Orvieto and afterward to that of Viterbo. In her later years she left the convent and resided in Rome. Her earlier poems were chiefly devoted to the memory of her husband. Among her later verse the 'Rime Spirituali' (1548), is remarkable for truth of sentiment and enlightened piety. She was the friend of Michaelangelo, who wrote several poems to her. Consult Campori, 'Vittoria Colonna' (1878); Ramont, 'Vittoria Colonna, Leben Dichten, Glauhen in 16 Jahrhunderten' (1881); Mrs. Roscoe, 'Vittoria Colonna, Her Life and Poems' (1868).

Colonna, a village in the papal states, which gave its name to one of the most powerful and celebrated aristocratic Roman families. During the Middle Ages the family played an important part in the affairs of Europe, became allied to the greatest houses of Italy, Spain, and Germany, and furnished many celebrated warriors, Popes, and cardinals.

Colonna, Cape. See SUNIUM.

Colonna Palace (It. *palazzo Colonna*), a handsome and interesting structure at the foot of the Quirinal, belonging to the family from whom it is named, but occupied of late years by the French embassy. It was commenced by Pope Martin V. in the 15th century, and was the residence of Julius II. and of Cardinal Borromeo. It contains a picture gallery, open to the public every day except holidays, which in point of size and architecture ranks with the finest in Rome. The ceiling of the great hall, supported by handsome columns of *giallo antico*, is covered with frescoes illustrative of the history of the Colonnas, the central subject being the battle of Lepanto. The collection of paintings, formerly numbering 1,362 pieces, has been greatly reduced by division among branches of the family, but still embraces many magnificent works by Titian, Guido, Salvator Rosa, Guercino, Paul Veronese, Giulio Romano, Holbein, and lesser artists. Almost equally celebrated as the

COLONNADE — COLONY

picture gallery are the Colonna gardens, which extend behind the palace in terraces up the west slope of the Quirinal. They are planted with box, ilex, laurel, etc., and have long rows of straw houses in which the lemon is brought to rich perfection. There are some colossal ruins in the garden, supposed to belong to the temple of the sun erected by Aurelian, and to the baths of Constantine.

Colonnade, a range of columns. If the columns are four in number it is tetrastyle; if six in number, hexastyle; when there are eight, octastyle; when ten, decastyle, and so on according to the Greek numerals. When a colonnade is in front of a building it is called a portico; when surrounding a building, a peristyle; and when double or more, polystyle. The colonnade is, moreover, designated according to the nature of the intercolumniations introduced as follows: pycnostyle, when the space between the columns is one diameter and a half of the column; systyle, when it is of two diameters; eustyle, when of two diameters and a quarter; diastyle, when three; and aræostyle, when four or more. A colonnade differs from an arcade in this respect, that the columns of the former support straight architraves instead of arches.

Colonsay (kōl'ōn sā) and **Oronsay**, ō'rōn-sā, two islands off the west coast of Argyle, Scotland, united at low water, and at high water only about 100 yards apart; united length about 12 miles; breadth varying from 1 to 3 miles. Colonsay is much the larger, and has a diversified surface with fine rock and other scenery and beautiful sandy beaches. On Oronsay are the imposing ruins of an extensive priory, and near it a fine sculptured cross. Cattle and sheep are reared, and fishing is carried on. Visitors land at Scalasaig pier, on the island of Colonsay. The islands are named after St. Columba and St. Oran. Pop. in 1891, 381.

Colonus, in civil law, a freeman of inferior rank, corresponding with the Saxon *ceorl* and the German rural slaves. It has been held probable that many of the ceorls were descended from the *coloni* taken into Saxony by the Romans. The names of the *coloni* and their families were all recorded in the archives of the colony or district, from which fact they were known as *adscriptitii* also.

Colonus, kō-lō'nūs, an eminence near Athens, to which Œdipus retired during his banishment to Thebes, and from which Sophocles gave the title of "*Œdipus Coloneus*" to one of his finest tragedies. According to Pollux, there were two places at Athens known as Equestris and Agoræus Colonus.

Colony, a settlement formed in one country by the inhabitants of another. Colonies may either be formed in dependence on the mother country or in independence. In the latter case the name of colony is retained only in a historical sense. The motives which lead to the formation of colonies, and the manner of their formation, are various. The lust of territory; the requirements of commerce; the desire of increasing wealth, combined with the love of adventure; the necessity of relieving the pressure of redundant population; political dissensions; the convenience of removing to a distance persons likely to disturb the peace of the state, and especially the apparent ease with which a numerous criminal class may be got rid of by

expatriations, are among the chief motives which have influenced colonization. Colonization is only a more formal development of the migratory tendency; and a colony may be considered as an organized and permanent migration. Among ancient nations the principal promoters of colonization in the more formal sense were the Phœnicians, the Greeks, and the Romans, and the greatest colonizers in modern times have been the English and the Spaniards, next to whom may be reckoned the Portuguese, the Dutch, and the French. The Phœnician colonies, extending along the shores and throughout the islands of the Mediterranean, were mainly commercial. The most famous of them was Carthage, itself a great colonizing state. From the distance of the mother states, and the slowness of communication, many of them must have been practically independent from a very early period; but this was not the case with the colonies of Carthage, which wielded powerful armies and maintained great fleets, both for commerce and for conquest. The Greek colonies were widely spread, being numerous in Asia Minor, the Balkan peninsula, and the islands and coasts of the Mediterranean, in South Italy, and Sicily. They were commonly independent, and frequently soon surpassed the mother states in power and importance. Constantinople, Naples, Palermo, and Marseilles were all originally Greek colonies. The Greek civilization was largely based upon and highly favorable to individual liberty, and the independence of spirit which it fostered made political dissension a frequent cause of colonization. A still more pressing one was the limited extent of the Greek territories, and the inviting character of those by which they were surrounded. Rome was a state which left nothing to the individual. Its colonies were chiefly military, and while the empire lasted were all in strict subordination. As the Roman power declined the remains of them amalgamated with the peoples among whom they were placed, and contributed largely to the homogeneous growth of modern civilization.

Before America and the way by sea to the East Indies were discovered, the states of Europe in the Middle Ages, with the exception of the Genoese and the Venetians, had no foreign colonies. The intercourse and wars of the Portuguese with the Moors, then more advanced in civilization than most of the European nations, served to incite their rivalry and stimulate them to maritime enterprise, and they became the pioneers of Europe in maritime discovery. One of the chief names in this connection is that of Henry the Navigator, son of John I. of Portugal. The Portuguese in 1419 discovered Madeira; in 1431-60 the Azores; in 1487 Bartolomeo Diaz doubled the Cape of Good Hope; and on 20 May 1498, Vasco de Gama landed near Calicut on the Malabar coast, after a voyage round the south of Africa. The Moors had previously been in possession of the inland trade of India, and it was not without a struggle that the Portuguese succeeded in establishing settlements on the coast of Malabar. The first Portuguese colonies were garrisons placed along the coasts of the continents and islands they visited for the security of their commerce, as Mozambique, Sofala, and Melinda on the east coast of Africa, Ormuz and Muscat, in the Persian Gulf; Goa, Diu, and Damao, on the Malabar coast of India. Goa became the capital of their Indian do-

COLONY

minions. Colonies were established in Ceylon in 1505; in the Moluccas in 1510; Java, Sumatra, Celebes, and Borneo were also colonized, though the settlements there did not attain so great importance. The direction taken by the Portuguese navigators made them miss the discovery of America; but Brazil was discovered by Cabral in May 1500, a few months after Pinçon, and was colonized by the Portuguese about 1530. The splendid colonial empire of which the foundations were thus laid was not destined to last. As in the case of Spain the energy of the Portuguese was trammelled by climatic and other conditions, and this, together with a despotic colonial policy, had weakened the power of Portugal before she fell in 1580 under the dominion of Spain. The colonial possessions of Portugal were afterward assailed by the Dutch as enemies of the Spaniards, and when she recovered her independence in 1640, many of them were irretrievably lost. Brazil declared its independence in 1822. The colonial possessions of Portugal are now mostly in Africa; the whole of her possessions in that continent embracing an area of more than 5,000,000 square miles.

Soon after the Portuguese the Spaniards commenced the work of colonization. On 12 Oct. 1492, Columbus discovered the island of San Salvador. Hayti, or San Domingo, named by Columbus Española, was discovered in the course of the same voyage, December 1492, and immediately colonized. Porto Rico and Jamaica were colonized in 1509, Cuba in 1511. On the mainland a Spanish settlement was effected in Colombia (New Granada) in 1510. Mexico was conquered 1519-21; Ecuador, Venezuela, New Granada, Peru, and Chile, were occupied and subdued between 1524 and 1541; and Spain was raised to the first rank among the colonizing powers of Europe. The Spaniards regarded their new possessions in various aspects. Some, animated by a zeal for religion, considered the conversion of the natives as the great end which Heaven had assigned to them. Others were inspired by the love of glory or the passion for gain, and scrupled at no means by which it was possible to gratify their wishes. Owing to the degraded character of many of the first colonists, who were often mere adventurers and released criminals, the first settlements suffered much from internal strife and confusion. After many dissensions the government of the colonies, in its fundamental traits, was settled in 1532, during the reign of Charles V. A council of the Indies in Europe, viceroys, at first two, afterward four, together with eight independent captains-general in America, were the heads of the administration. Cities were founded, at first along the coasts, for the sake of commerce and as military posts; afterward also in the interior, especially in the vicinity of the mines; as Vera Cruz, Cumana, Porto Bello, Carthagena, Valencia, Caracas; Acapulco, and Panamá, on the coast of the Pacific; Lima, Concepcion, and Buenos Ayres. The whole ecclesiastical discipline of the mother country was transferred to the colonies, except that in them the Church was much more independent of the king. The intercourse with Spain was confined at first to the single port of Seville, afterward to that of Cadiz, from which two squadrons started annually. So, although commerce was not expressly granted by law to a society, it remained

nevertheless entirely in the hands of a few individuals. Spain took possession of the Philippine Islands in 1564, and a regular intercourse was maintained from 1572 by the South Sea galleons, between Acapulco and Manila; but owing to the great restrictions on commerce those islands, notwithstanding their advantageous situation, were an expense to the crown. Spain proved to be the foremost of the colonizing powers of Europe in respect to the formation of new states; the most unfortunate of all in regard to the retention of her possessions. The causes of the loss of her colonies differed from those which prevailed in the case of the Portuguese. European wars and the decline of her home power were the most important, but they did not so often lead to the colonies falling under other powers, as in the case of Portugal. They more frequently became the occasion of revolt, and the opportunity for declarations of independence on the part of the colonies themselves. Thus were formed the republics of Mexico, of Central America, of Venezuela, New Granada or Colombia, Ecuador, Peru, Bolivia, Chile, etc.; but as the weak government of the mother country served to promote this early defection, few of the states formed in this unfortunate school have yet attained the repose of settled government. An insurrection began in Cuba in 1895, and after Spain had in vain endeavored to suppress it the United States interfered. War followed, with the result that after a brief struggle not only Cuba, but also Porto Rico and the Philippine Islands were lost to Spain.

The Dutch, during the struggle for their independence, first became the formidable rivals of the Portuguese, then subject to the Spanish yoke. They had already for some time carried on the trade in East India merchandise between Lisbon and the rest of Europe, but their intercourse with Lisbon was prohibited by Philip II. in 1584. The prohibition was revived in 1594 with the utmost severity, and a number of Dutch vessels in the harbor were seized. Excluded from the European trade in the productions of India, they resolved to import directly from India the articles which were refused to them in Europe. Companies were formed, which were united into one by a charter granted 20 March 1602 to the Dutch East India Company, established in 1595. This charter, which was renewed afterward at different times, conferred not only the monopoly of the East India trade, but also sovereign powers over the conquests which the company should make, and the colonies which it should establish in India. An entirely new colonial policy was thus introduced, which instead of political or ecclesiastical aggrandizement, contemplated mercantile advantage as its main object. The Dutch colonies in the East Indies were thus commercial colonies; and the islands of the Malay Archipelago, being more easily defended than the continent of India, became the principal seat of the Dutch power. This was undoubtedly the chief cause of their colonies being so long in a flourishing condition, as they required only the dominion of the sea to maintain them. In 1619 the newly built Batavia was made the capital of the Dutch East Indies. About the middle of the 17th century the power of the Dutch reached its highest point. They effected the establishment of a colony at the Cape of Good Hope in 1650, which afforded an

COLONY

excellent bulwark for their East India possessions, and took Ceylon from the Portuguese, after a long and sanguinary struggle in 1658. All the Dutch colonies in the East Indies were under the governor-general of Batavia. In 1621 the Dutch also established a West India Company, which at first made extensive conquests in Brazil, but soon lost them entirely (1623-60). Their settlements on some of the smaller West India Islands, as San Eustatia, Curaçoa, Saba, and San Martin (1632-49), were more permanent. On the continent Surinam, Paramaribo, Essequibo, and Berbice were in the hands of the Dutch in 1667. In North America the Netherlands held the valley of the Hudson, and pushed south at the expense of the Swedes, winning the present States of New Jersey and Delaware, only to lose them to England. The decline of the Dutch colonial power, partly caused by European wars and partly by the successful rivalry of the English, continued from the end of the 17th century till the French Revolution. On the recovery of its independence, the commerce and the colonial importance of Holland somewhat revived, and though many of her colonies were lost, the value of the remainder was enhanced by improved administration. The Dutch still possess numerous colonial possessions in the East Indies, including Java, Sumatra, parts of Borneo, the Moluccas, and part of New Guinea; several small islands in the West Indies, and Surinam.

No colonizing power has had a career of such uniform prosperity as Great Britain. The freedom of her institutions, and the practical enterprise and self-reliance of her people peculiarly fitted her for the work of colonization, and it has steadily advanced with her equally in peace and in war. Her insular situation freeing her from the ambition of direct territorial aggrandizement, and giving her the command of the seas, enabled her in every war to strip her opponents of colonial possessions which were not unfrequently retained as the price of peace. The only break in a career of prosperity which has resulted in the formation of an empire greater in extent of territory and of population than any other known to history was the revolt of her American colonies, which resulted in the formation of a state destined ultimately to rival Great Britain herself in political and commercial importance and in the freedom of its institutions. This state, too, by the successful result of the war of 1898 with Spain, itself entered on a policy of colonial expansion.

The English made their appearance as a colonial power nearly at the same time with the Dutch, but at first with far inferior success. After many fruitless attempts to find a northeast or northwest passage to the East Indies, English vessels found their way round the Cape of Good Hope to the East Indies in 1591. In 1600 Elizabeth granted a charter to the East India Company. Its commerce with India, however, was not at first important. It established only single factories on the continent, and at the beginning of the 18th century the possessions of the English in the East were limited almost exclusively to Madras, Calcutta, and Bencoolen. The ruin of the Mogul empire in India, which commenced in internal disturbances after the death of Aurengzebe (1707), and was completed by the incursions of Nadir Shah (1739),

afforded the opportunity for the growth of British power, as the British and French were compelled to interfere in the contentions of the native princes and governors. The French, under Labourdonnaye and Dupleix, appeared at first likely to maintain the superiority; but the British succeeded in acquiring the ascendancy in the Carnatic; and in the middle of the 18th century they greatly extended their dominions under Clive. By the destruction of Pondicherry they secured their superiority on the coast of Coromandel; and the victory of Clive at Plassey, 26 June 1756, laid the foundation of their exclusive sovereignty in India. By the Treaty of Allahabad, 12 Aug. 1765, Bengal was surrendered to the British by the titular Great Mogul; and the fall of the empire of Mysore, the dominions of Hyder Ali and Tippoo Saib, may be considered as completely establishing the British supremacy in India. The Mahrattas, with whom the British waged war at intervals from 1774 to 1818, and the Sikhs, subdued in 1849, were the last formidable enemies of the company. With the exception of a few dependent states the British territory now embraced nearly the whole of India, and this vast territory was still under the government of a chartered mercantile company, exercising many of the most important functions of an independent sovereignty. On the suppression of the Indian mutiny (1857-8) this state of things was deemed too hazardous to last, and the government of India was transferred to the crown by act of Parliament in 1858. Ceylon was first occupied in 1795-6.

The discoveries of the Cabots, following soon after the voyages of Columbus, gave the English crown a claim to North America, which in the reign of Elizabeth led to colonization on a large scale. In 1606 James I. divided the territory claimed by England into two parts — South Virginia, extending from Cape Fear to the Potomac; and North Virginia, from the mouth of the Hudson to Newfoundland. Two companies were formed for the colonization of America — the London Company, to which was granted South Virginia; and the Plymouth Company, to which was granted North Virginia. The region between the Potomac and the Hudson was neutral ground. The London Company in 1607 founded the commonwealth of Virginia by building Jamestown on the James River, so called in honor of the king. A House of Burgesses for the new colony met for the first time on 19 June 1619, and thus was constituted the beginning of representative government in the British colonies of America. In 1614 Capt. John Smith, having examined the coast from the Penobscot to Cape Cod, named the country here New England. The next permanent settlement on the North American coast was effected in this district by the body of Puritans, known as the Pilgrim Fathers, who sailed from England 6 Sept. 1620, in the Mayflower, and arrived 9 November in Massachusetts Bay. The government of this colony was that of a religious oligarchy. Another colony was established in New Hampshire in 1623, and in the same year Maine, which had previously been colonized by the French, received its first permanent English settlement. New Jersey was colonized in 1634. Connecticut was colonized in 1635 by emigrants from Massachusetts. Rhode Island was settled in 1636. Samuel Champlain, the French navi-

COLONY

gator, was the first European who entered the region now forming the State of New York (1609). In the same year Henry Hudson, an Englishman in the service of the Dutch East India Company, discovered the river to which his name has been given, where Dutch settlements were effected and gradually spread. The English, who claimed this territory as included in Cabot's discoveries, finally seized the Dutch colony of New Amsterdam by force in 1664, giving it the name of New York in honor of James, Duke of York (James II.), to whom Charles II. had made a grant of the province. In 1681 the territory west of the Delaware was granted to William Penn, who colonized it with Quakers, and founded Pennsylvania in 1682. The first settlement in Maryland was made in 1631 by a party from Virginia. In 1633 a colony of Roman Catholics arrived here from Great Britain. The country south of Virginia was permanently settled in 1670 by a party of English colonists who landed at Port Royal and afterward removed to Charleston. The colony was called Carolina. Georgia, originally a part of Carolina, was granted by George II., after whom it was named, to a colony from England in 1732.

Colonies were early established in the West India Islands, including Barbados, half of St. Christopher's (1625), and soon after many smaller islands. Yet the West India possessions did not become important as plantations until the sugarcane was introduced into Barbados in 1641 and into Jamaica in 1660. This island had been taken from the Spaniards in 1655. The cultivation of coffee was introduced into the West India Islands in 1732. Newfoundland was taken possession of by the English in 1583, and colonized in 1621 and 1633. Canada was surrendered by France to Great Britain at the Peace of Paris in 1763 (see section on French colonies below). In 1764 began the dispute between Great Britain and its North American colonies, on the question whether the former had the right to impose taxes on the colonies when they were not represented in the British Parliament; and on 19 April 1775 commenced the war which terminated with the acknowledgment of the independence of the 13 provinces. Though the United States thus entered on their independent career, Canada still remains as a great and flourishing British dependency.

Australia was discovered in the beginning of the 17th century. The first Australasian settlements of Great Britain were penal colonies. New South Wales, discovered in 1770, was established as a penal colony in 1788; Tasmania (Van Diemen's Land), discovered by Tasman in 1742, followed in 1803. West Australia, for some time a penal settlement, was founded as a free colony in 1829; Victoria (Port Phillip) was colonized in 1835, and made an independent colony in 1851; South Australia was settled in 1836; Queensland became a separate colony in 1859; New Zealand, discovered by Tasman in 1742, began to be used in connection with the whale fishery about 1790, was settled in 1839, and made a colony in 1840. In 1851 gold was discovered to be plentiful in Victoria. This gave a great impetus to the prosperity of the Australian colonies, and the influx of population it caused has largely contributed to promote their general development. A federal union of the

British colonies in Australia was proclaimed 1 Jan. 1901, with the title of the Commonwealth of Australia. The Fiji Islands became a colony in 1874, and other islands in the Pacific have been acquired since, as well as part of New Guinea and part of Borneo.

The acquisition of the South African colonies dates from the Napoleonic period, the Cape Colony and Mauritius being both secured to Great Britain in 1814. Natal was proclaimed a British colony in 1843. The Guinea Coast settlements date from the 17th century. Extensive spheres of influence have been recently acquired, being partly developed by chartered companies.

In Europe Great Britain has only two possessions of the nature of colonies, acquired for military reasons: Gibraltar in 1704; Malta and Gozo, 1800.

It is estimated that the existing British colonies and dependencies embrace fully one fifth of the land surface of the globe, and a rather larger proportion of its population. The whole of the British colonial possessions have been grouped in about 40 administrative divisions, and they are situated in every quarter of the globe. See GREAT BRITAIN.

According to their governmental relations with the crown the colonies are arranged under three heads: (1) Crown colonies, in which the crown has the entire control of legislation, while the administration is carried on by public officers under the control of the home government; (2) colonies possessing representative institutions, but not responsible government, in which the crown has no more than a veto on legislation, but the home government retains the control of public officers; (3) colonies possessing representative institutions and responsible government, in which the crown has only a veto on legislation, and the home government has no control over any officer except the governor. All colonies are, however, disabled from such acts of independent sovereignty as the initiative in war, alliances, and diplomacy generally.

France was somewhat late of entering fully upon a colonial career, being retarded by internal dissensions and religious wars. Between 1627 and 1636 Pierre Belain d'Esnambuc colonized St. Christopher's, Guadeloupe, and Martinique. Champlain was the pioneer of the French in the exploration of the North American continent, where they soon had considerable possessions, including Canada—in which they had settlements as early as 1604-5, and where Champlain founded Quebec in 1608—and Louisiana, colonized in 1699. Commercial companies were then deemed essential in colonizing, and a West India Company and an East India Company were established by Colbert in 1664. He purchased on several West India Islands, as Martinique, Guadeloupe, St. Lucia, Grenada, and others, settlements already formed by private persons, and sent out colonists in 1664 to Cayenne. But the settlements in part of St. Domingo, by the buccaneers, became of more importance than those effected by the government. The West India Company survived only 10 years. The East India Company, after fruitless attempts to form a colony in Madagascar, founded Pondicherry on the Coromandel coast in 1670. This became the capital of extensive French possessions in the East Indies. The French also acquired the Isle de France (Mauritius) and Bourbon (Réunion), occupied in 1720.

COLOPHON

At the beginning of the 18th century France had attained an important position as a colonial power. In North America her settlements extended from Canada to California, particularly along the Great Lakes and the Mississippi River, embracing many districts which have since become of the highest importance. Nova Scotia (Acadie) and Newfoundland (Terre Neuve), which had been disputed with Great Britain, were then in her possession. Her West India Islands were more flourishing than those of England, and she still had a prosperous career before her in India. The superiority of the fleet of England gave that power a great advantage in colonial contests, and many of the French colonies subsequently fell under the power of Great Britain. The struggle for the supremacy in India, though France was finally unsuccessful, was long and gallantly maintained, and more than once seemed to promise a different issue. The North American colonies were partly lost by conquest and partly suffered to fall into decay. Of the West India possessions several were taken by Great Britain, and finally ceded to her. Canada was finally ceded to England in 1763; Louisiana, after being surrendered to Spain, to prevent it from falling into the hands of the English, was sold by Napoleon to the United States in 1803. At the general pacification of 1815 France recovered some remains of her colonial possessions, and since then she has acquired extensive regions beyond sea, some of them highly valuable. She occupied in 1830 and begun in 1833 to colonize Algeria, a country whose irregular and lawless government had exposed her as well as other European states to frequent annoyance. Tunis, Senegambia, great tracts of the Sahara, Sudan, and Congo regions, the islands of Madagascar and Réunion, are all comprised in France's African possessions, while in Asia she possesses a large portion of the Indo-Chinese peninsula, and in America French Guiana. Some of the French colonies are represented in the National Assembly by members chosen for the purpose.

Denmark established an East India Company in 1618 with a view to enter on the colonial trade; and other companies were afterward formed. In the same year with the formation of the first company, the colony of Tranquebar was founded on the Coromandel coast. Its success was fluctuating, like that of the companies formed to manage it, and at last, in 1845, it was sold to the East India Company. St. Thomas in the West Indies was settled by the Danes in 1672; St. John and some of the smaller islands in the same group (the Virgin Islands) were also occupied by them. The island of Santa Cruz was purchased from France in 1733. The United States tried to buy these islands in 1902. Sweden established an East India Company in 1741. She acquired the island of St. Bartholomew from France in 1785, but restored it in 1878, and has now no colonies.

Germany has recently been making some attempts at establishing colonies in different parts of the world, and in this way acquired considerable tracts in southwest Africa, east Africa, between the Portuguese and British possessions, Camerun, Togo, New Guinea, etc. Italy has also shown the same ambition, and has established a colony on the African side of the Red Sea, between it and Abyssinia, and in Somaliland.

The colonial policy of paternalistic countries as Spain and Portugal naturally differed from that of commercial and industrial nations like England and Holland. In the former the expense and risk of colonizing was borne by the government, who retained direct control over the colonies and their productions; but in the latter the work, being too much for individual enterprise, was entrusted to companies, whose charters conferred on them not only exclusive privileges in regard to trading, but also extensive powers of conquest and administration. In respect to trade a very exclusive and jealous policy long prevailed, but since the adoption of a free-trade policy in Great Britain, the whole trade of her colonies has been thrown open without reserve, as far as the privileges of the mother country are concerned, to the competition of foreign nations. Other countries, while not following her commercial policy entirely, have relaxed more or less the stringency of the regulations affecting their colonial trade. Consult: Leroy-Beaulieu, 'De la colonisation chez les peuples modernes' (Paris, 3d ed. 1887).

Col'ophon, kōl'ō-fōn, an inscription at the "Finis" of a book, giving the printer's name and date and place of printing; in the early days of printing nearly all books had colophons. The printers followed the usage of their predecessors. The copyists, who almost invariably appended to the works they transcribed their own names, often with date and not unusually with some pious ejaculation. Not a few of the early printers adhered to the custom of the pious ejaculation, but usually the fraternity seized the opportunity of the colophon to magnify themselves and their art and in particular their own proficiency in the art. A collection of colophons of books printed in the first half century of typography would make a highly interesting and amusing chapter in the history of the Art Preservative of Arts. Usually they are ludicrous in the extravagant claims the printers make for the unapproachable excellence of their handwork; but some are modest and dignified, while a few are pathetic, showing the hard struggle made by masters of the noble craft for a bare subsistence. It was quite usual to compose the colophons of Latin classic works in heroic or in elegiac verses. Udalricus Gallus, for example—thus does Ulrich Hahn latinize his German name—in the colophon of his Virgil (Rome 1472) makes a pun with his Latin patronymic Gallus and the Latin name for a native of Gaul, which is also Gallus. In Latin, the noun gallus, as in German hahn, means cock. In the four elegiac couplets which constitute his colophon Ulrich apostrophizes the goose, which, by its cries, notified the Romans of the approach of the Gauls: "O Goose, keeper of Jove's Tarpeian abode, why flap your wings? The Gaul (Gallus) has fallen; the avenger is here, Udalricus Gallus; he has shown that there is no further call for your quills; in a day he prints more than is penned in a year." The two German printers, Conrad Schweynheim and Arnold Pannartz, who produced the *editio princeps* of the same poet in 1469, express in the colophon the hope that their artistic work may make amend for their harsh Teutonic names, unknown to the Muses:

Aspera ridebis cognomina teutona; forsā
Mitiget ars musis inscia verba virum;

COLOPHON — COLOR

which names, however, they contrive to squeeze into a Latin hexameter, thus:

Conradus Suueynheim Arnoldus Pannartzque magistri.

How graceful, modest and dignified is the tetrastich appended by the celebrated French printer, Nicolas Jenson, to his edition of Suetonius: I, Nicolas Jenson, a Frenchman, printed this book; who shall deny it to be a work of art? But while you peruse Suetonius do, I pray thee, love the artist's name —

Artificis nomen fac, oro, lector ames.

Posterity has confirmed that printer's estimate of his work, for his typography has ever since been regarded as a standard of elegance. Vindelin of Spire, the elder printed at Venice in 1470, in the colophon of his Virgil, an elegiac octastich celebrating himself and his typography and boldly challenging comparison with the Grecian masters of form:

Laudent ergo alii Polycletos Parrhasiosve
Et quosvis alios id genus artifices —

let others praise the Polycletuses or the Parrhasiuses, and the rest of that class of artists: Vindelin shall have the highest praise of all.

And Adam Rot, another German printer at Venice, in his Virgil (1471) in 12 hexameter verses, challenges Solomon and Hiram and the Sibyl, and Greece with all her sages, and Rome, mighty in arms and equal to the gods, to show forth such an art as he is master of. In a like spirit Bartolomæus of Cremona in a hexastich colophon to Virgil (Venice 1472) augurs for his natal town undying fame, insured to her by this work of her alumnus, which is more enduring than the Athene of Pheidias —

Phidiacum hinc superat Bartholomæus ebur.

But Christopher Valdarf (? Waldorf) is content with styling himself in the colophon of his Virgil (Venice 1471) the glory of Ratisbon, his native town:

Ratisponensis gloria Christophore.

Colophon, an ancient Ionian (Greek) city of Asia Minor situated at a short distance from the coast and about eight miles north of Ephesus. Its inhabitants were removed by Lysimachus after the death of Alexander the Great. Colophon was one of the places that claimed to be the birthplace of Homer. It was the native city of Mimnermus and other poets. Its site was discovered in 1887 by the German explorers, Schuchhardt and Wolters. Proverbially Colophon came to mean "a finishing stroke" because of the many instances in which the city's cavalry carried the day. The word took this proverbial meaning in Latin and was used by early printers as the imprint at the close of a volume; commonly used before the introduction of the title page.

Colophonium. See ROSIN.

Col'ophony, a name formerly used for common rosin (q.v.), but now found only in books.

Coloquintida. See COLOCYNTH.

Color, the impression given to the eye by lights of various rates of vibration. The optic nerves are excited by vibrations of the light-bearing ether when the rapidity of the vibrations

is not greater than or less than two limits, which perhaps vary slightly with different eyes, just as some ears cannot hear intensely shrill sounds or dull sounds that are perceived by others. Every vibration between these limits is recognized as light; its intensity or brightness is observed; but, besides this, the eye is differently affected by light of different times of vibration, in a way that it is not possible to describe. It is to this variation in the sensation that the name color is given. The word color is also applied to the properties of bodies that cause them to emit the light that thus affects our senses.

In considering the subject we must remark in the first place that ordinary white light, the light which comes from an incandescent solid or liquid, consists, as Newton showed by his celebrated experiment of passing it through a triangular glass prism, of a large number of colored lights, which, meeting the eye together, produce the sensation of white light. The colors of the spectrum are usually said to be seven — red, orange, yellow, green, blue, indigo, violet; although in reality there is an enormous if not an infinite number of distinct colors in it. These colors are frequently called the primary colors, and other tints and shades are producible by mixing them; but in a stricter sense the primary colors are three in number, namely, red, green, and violet (or blue). These three colors or kinds of light cannot be resolved into any others, while a yellow ray, for instance, can be resolved into a red and green, or can be produced by the mingling of red and green light, consequently yellow is not now regarded by scientific men as a primary color. Inasmuch, however, as a yellow and a blue pigment will always produce a green when mixed, red, yellow, and blue may still in a sense be regarded as primary. In the scientific sense of the word white and black are not considered colors, a white body reflecting and a black body absorbing all the rays of light without separating them, whereas the colors proper are due to separation of the rays of light by partial absorption and reflection or by refraction. That the colors of the spectrum may be recombined so as to make white light, the following experiment shows. Let a disk be painted as nearly as possible with the primary colors of the spectrum in sectors. If this painted circle be made to whirl rapidly round its centre all the colors will practically be seen simultaneously at each point, owing to the persistence of the impression on the retina of the eye, and the effect will be that the circle will appear white. If the proportions of the colored sectors be altered, or if any of them be cut or covered with white or black paper, various colors or shades of color are producible. If one complete sector be removed, and the wheel whirled round, the color produced is the complementary color to the removed sector. By complementary color is meant the color or colors which, with any color or colors mentioned, together make white; thus any of the primary colors is complementary to the other two, and a secondary color is complementary to the remaining primary.

The color resulting from the mixture of two or more lights is the color which is seen when they fall on the same part of the retina. There are various methods of mixing lights, such as, (1) by combining reflected and transmitted light; (2) by causing two or more spectra to overlap; and (3) by employing a rotating disk

COLOR.

DIAGRAM ILLUSTRATING THE PRIMARY, SOLAR SPECTRUM OR RAINBOW COLORS AND LAW OF THE COMPLEMENTARY COLORS.

DIAGRAM ILLUSTRATING THE PRIMARY COLORS AND THEIR COMBINATIONS OR TINTS.

COLOR

composed of differently colored sectors, as shown above. Colored disks of paper, each having a radial slit, are very convenient for this purpose, as any moderate number of such disks can be combined, and the sizes of the sectors exhibited can be varied at pleasure. The mixed color obtained by the rotating disk is to be regarded as a mean of the colors of the several sectors,—a mean in which each of these colors is assigned a weight proportional to the size of its sector. Thus if the 360 degrees which compose the entire disk consist of 100° of red paper, 100° of green, and 160° of blue, the intensity of the light received from the red when the disk is rotating will only be $\frac{10}{36}$ of that which would be received from the red sector when seen at rest; and the total effect on the retina is represented by $\frac{10}{36}$ of the intensity of the red, plus $\frac{10}{36}$ of the intensity of the green, plus $\frac{16}{36}$ of the intensity of the blue; so that the resultant color may be called the mean of 10 parts of red, 10 of green, and 16 of blue. All the results of mixing colors can be represented geometrically by means of a cone or pyramid within which all possible colors will have their definite places. The vertex will represent total blackness, or the complete absence of light; and colors situated on the same line passing through the vertex will differ only in intensity of light. Any cross-section of the cone will contain all colors, except so far as intensity is concerned, and the colors residing on its perimeter will be the colors of the spectrum ranged in order, with purple to fill up the interval between violet and red. It would seem that the true form of the cross-section is approximately triangular, with red, green, and violet at the three corners. When all the colors have been assigned their proper places in the cone, a straight line joining any two of them passes through colors which are means of these two; and if two lines are drawn from the vertex to any two colors, the parallelogram constructed on these two lines will have at its farther corner the color which is the sum of these two colors. A certain axial line of the cone will contain white or gray at all points of its length, and is called the line of white. It is convenient to distinguish three qualities of color, which may be called hue, depth, and brightness. Brightness or intensity of light is represented by distance from the vertex of the cone. Depth depends upon angular distance from the line of white, and is the same for all points on the same line through the vertex. Paleness or lightness is the opposite of depth, and is measured by angular nearness to the line of white. Hue or tint is that which is often *par excellence* termed color.

All authorities are now agreed in accepting the doctrine, first propounded by Dr. Thomas Young, that there are three elements of color sensation, or three distinct physiological actions, which by their various combinations produce our various sensations of color. Each is excitable by light of various wave-lengths lying within a wide range, but has a maximum of excitability for a particular wave-length, and is affected only to a slight degree by light of wave-length very different from this. The complete diagram of all color is theoretically a triangular pyramid, having for its three edges the colors which correspond to these wave-lengths; but it is probable that we cannot obtain one of the three elementary color sensations quite free from admixture of the other two, and the edges of the pyramid

are thus practically rounded off. One of these sensations is excited in its greatest purity by the green, another by the extreme red, and a third by the extreme violet. These three actions are ascribed to three distinct sets of nerves, having their terminations in different parts of the thickness of the retina, a supposition which aids in accounting for the approximate achromatism of the eye, for the three sets of nerve terminations may thus be at the proper distances for receiving distinct images of red, green, and violet respectively, the focal length of a lens being shorter for violet than for red. As it is completely established that the difference between the colors of the spectrum is a difference of vibration-frequency, there is an obvious analogy between color and musical pitch. Attempts have been made to compare the successive colors of the spectrum with the notes of the gamut; but forcing is necessary, as in almost all details the relations between colors are strikingly different from the relations between sounds.

When white light falls on the various objects that surround us, it is not always reflected back to our eye as white light. The bodies are illuminated by it, but they have the power of so altering it that they appear to us colored. The reason of the natural colors of bodies is a difficult subject, and one that is scarcely yet understood. It is usual to say that the surfaces of bodies have the power of absorbing certain parts of the white light and reflecting the remainder back, and that what we see is the complementary color to that which is absorbed. This is generally the case with light passing through a transparent colored body. But there is good reason for thinking that this is not really the case always. Experiment, in fact, seems to show that the light which comes from colored bodies is frequently generated by the bodies themselves by a kind of luminous resonance, as it has been called; just as a harp with two or three strings will send out a sound by resonance when a loud noise of any kind is made near to it, but the sound emitted by the harp will be only that belonging to its two or three strings, and not a clash like that which set it in vibration. The subject is one of much difficulty, as we know nothing of the molecular construction of the surfaces of bodies.

Lastly, we have to speak of the colored lights produced by ignited gases. The lights themselves are often far less complicated than white light, though we have spoken of them last. Incandescent gases, instead of giving out white light, as incandescent solids and liquids do, give out light of colors depending on the nature of the gas or vapor. Seen by the eye the flame is colored, and examined by the spectroscope it is found to be in many cases a very simple light indeed. Thus sodium vapor gives a yellow light, and on looking at a flame containing nothing but sodium it is seen to consist of two particular yellow lights shown by two bright yellow lines in its spectrum. Thallium, another metal, gives a simple green light. Hydrogen gas also gives a pale-blue flame when burning, and shows some five or six bright lines. So also do other gases. These colored flames are taken advantage of by the pyrotechnist, who mixes the powder for his fireworks with various bodies which give colored flames. See LIGHT; SPECTRUM.

COLOR-BLINDNESS — COLOR PHOTOGRAPHY

Color-blindness, a singular affection, producing an inability to distinguish one color from another, and in certain rare cases to discern color at all, the eye perceiving only light and shade, or black and white. Almost no attention appears to have been paid to this subject till the end of the 18th century, when the famous chemist, Dr. Dalton, brought it into notice by publishing in 1794 an account of his own case as marked by this peculiarity. More recently, Dr. George Wilson of Edinburgh also examined minutely into this phenomenon, and collected many striking instances. From the result of these investigations it would appear that color-blindness is much more common among men than among women, and that of the former one in 20 is unable to discern the nicer shades of color, and one in 50 to distinguish certain primary colors from one another. The colors most liable to be confounded are red and brown with green, purple and green with blue, red with black, light hues of all sorts with white, and dark shades with black. Many of the instances adduced by Dr. Wilson are exceedingly curious and amusing. An undertaker covered a coffin with bright scarlet instead of black; a chemical lecturer had always to ask the colors of his compounds; a physician never met with scarlet fever in the course of his practice; a gentleman meeting a lady in a green dress condoled with her on the bereavement which he imagined she had sustained; and a quaker purchased a bottle-green coat for himself and a scarlet merino gown for his wife. The cause of this remarkable affection in almost every case which has been carefully investigated has been found to be seated in the sensorium, not in the visual apparatus, and to consist in the absence of the elementary sensation corresponding to red. To persons thus affected, the solar spectrum appears to consist of two decidedly distinct colors, with white or gray at their place of junction. One of these two colors is doubtless nearly identical with the normal sensation of blue or violet. The other color extends a considerable distance into what to normal eyes is the red portion of the spectrum. The scarlet of the spectrum is thus visible to the color-blind, not as scarlet but as a deep dark color, perhaps a kind of dark green, orange and yellow as brighter shades of the same color, while bluish-green appears nearly white. The eyes of persons so constituted present in general nothing abnormal either internally or externally, while their power of vision is equal to, and in many cases even superior to, that of persons in whom no such peculiarity exists. The colors most easily distinguished by the color-blind are yellow and blue, the latter color, if pure and well-illuminated, being the one many of the color-blind see best, and which is rarely mistaken for other colors. The use of yellow spectacles has accordingly proved advantageous in some cases. It is a curious fact that the substitution of artificial light for daylight often enables persons affected in this manner to discern colors.

Color Photography. From the earliest days of photography, efforts have been made to reproduce by it alone the colors of nature. It was found as long ago as 1801 by Ritter, of Jena, that the various rays of the spectrum differed considerably in their action on silver chloride, and in 1810 Seebeck, also of Jena, ob-

tained a reproduction of the spectrum, in some approach to natural colors, on paper coated with silver chloride. These images could not, however, be fixed.

Various other experimenters have from time to time endeavored to obtain the desired result by the use of different materials and methods, but without effecting a complete solution of the problem.

In 1891 Lippman laid the foundation of the process known by his name, it being based on the theory of Zenker and work of Wiener, with due acknowledgment to both. This is distinguished as an "interference" process, the effect being produced by decomposition of the light.

The apparatus employed for the production of the picture is very simple, differing but little from that used for ordinary photography. Any transparent sensitive film answers as the photographic surface. This film is exposed in a camera of the usual type, with the difference in arrangement that the plate is backed by a layer of mercury, which layer, of course, acts as a mirror. The arrangement is effected by using a slide so arranged that mercury can be allowed to flow into a space back of the plate after the plate has been placed in the slide. After exposure the mercury is allowed to flow out, and the plate is then developed in the usual way.

The materials on the finished plate are the same as those on an ordinary negative, but a difference exists in the structure of the deposit, by which it is enabled to decompose the light by which it is illuminated and reflect those portions of it which correspond to the natural colors of the object from which the picture was taken.

The reason for the formation of this structure as formulated by Lippman is that the light waves, as they rush through a plate as ordinarily arranged, impress the plate more or less strongly, and thus leave a design of different intensities of the image, but in this rapid passage they leave no record of their own forms. Each ray of light of a certain color has a certain structure; it is made up of waves which have a certain wave-length. If there be a mirror behind the plate, the light, says Lippman, is reflected back on itself; the light rushes in and rushes out again with the same velocity; the entering and issuing rays interfere, and the effect of the interference is that vibration takes place; but the effects of propagation are stopped, and instead of having propagated waves we get stationary waves; that is, the waves now rise and fall, each in its own place; they pause, therefore, in the interior of the film and impress their form upon it.

On looking through a film obtained by the Lippman method it appears like an ordinary negative; its color effect is obtained only when viewed by reflected light, different portions of the plate reflecting different colors according to the light-waves by which it had been impressed. In order that the interference colors may be seen so that they are true to nature, the plate must be viewed by vertical incidence, which is inconvenient. They may be projected by an arrangement devised for the purpose.

In 1861 Prof. Maxwell showed at a lecture at the Royal Institution that by taking photographs of a colored ribbon through three solutions colored to represent the primary colors, and then projecting these photographs so that their

COLOR PHOTOGRAPHY

images were superposed, a colored image of the ribbon was given, which was faulty, however, from lack of photographic materials more sensitive to the less refrangible rays. In 1873 Prof. Vogel announced that dyes would influence the distribution of color-sensitiveness in plates.

On these facts are based the process of Ives, brought out in 1892. In his process three negatives are obtained through color-filters; from these positive transparencies are made (in monotone), which are placed in a special viewing instrument called the "kromskop," each in combination with its properly adjusted color-screen; these being then combined, the images are seen in the original colors of nature.

The next development in this method was the introduction of the process worked out by Prof. Joly in 1894. This differs considerably from the Ives method in the manner of working, but in principle it is very similar. Only one negative, instead of three, is required, but this is taken through a transparent lined screen, ruled very finely and closely with parallel alternate lines of orange, yellowish-green, and blue. After development a positive transparency is made from the negative, which, when mounted accurately and in close contact with a viewing-screen similarly ruled with parallel lines of red, green, and violet, the image is seen in its original colors. These mounted positives are usually viewed as lantern-slides, but are somewhat marred by the obtusiveness of the lines when seen too closely.

To go back to the underlying principle of the three-color process—the "filtering" out of certain rays in taking the different plates—we should explain that the primary colors from which white light is formed are now set down as a particular shade of red, a particular green, and a particular blue-violet. The primary pigmentary colors, it may be added, are red, yellow, and blue, as has always been taught. If we obtain three negatives from an object, each taken through a color-filter or screen adjusted for the red, the green, and the blue-violet respectively, these plates will present negative images of the object in the negative values of the colors named. When from each of these negatives we produce a positive in the complementary color, and combine these positives in accurate registration, we shall, if the operations have been correctly performed, obtain a reproduction of the original object in the exact colors of nature. The ordinary photographic plate, as is well known, is not sensitive to all the rays. If, however, the addition of certain colored substances, chiefly analine compounds, be made to the emulsion, these apparently combine with the haloid silver salt to form an organic compound of silver which is sensitive to the light reflected from various colors according to the particular dye employed; and in this way it is possible to obtain a plate which will be sensitive to the light reflected from all the colors of the spectrum, though for convenience in working, the extreme red is generally excluded, or otherwise the plate could be made and handled only in complete darkness.

The processes of Lumière and others are essentially the same as that of Ives, varying in the details of working.

In the working of the three-color process the negatives are taken through color-screens of red, green, and blue-violet, adjusted for use

with the Cadett spectrum plate. By means of a repeating back used in connection with a frame containing the screens, these may all be taken upon one plate; that is when the size of the picture required is small, such as is suitable for a lantern-slide. The length of exposure varies with each of the screens, an ordinary ratio being, say, 55, 13, 4 for the red, green and blue-violet respectively; but on account of unavoidable variations in different batches of emulsion, largely due to the difficulty in obtaining gelatin of uniform quality, these ratio exposures are liable to differ, but can be readjusted without great difficulty by making a trial exposure upon some subject with well-marked high lights and half-tones, such as a crumpled piece of white blotting-paper, which should appear equal in all three negatives. The length of the exposure through the red screen may be gauged by a fraction tint actinometer, by timing to a certain tint; from the time thus obtained the remaining two exposures can then be calculated from the ratio numbers.

There is a special form of camera in which the exposure for the three negatives can be made simultaneously by means of mirrors.

The plate must be developed either in darkness or by a special "safe" light supplied for use with such a plate, and a developer of the rapid type used, yielding a soft negative of good gradation without stain. Correctness of exposure is essential, forcing development being almost certain to result in failure. Intensification and reduction can be effected only at great risk of interfering with the gradation of the image, and should never be resorted to unless it is impossible to make another exposure. The best intensifying re-agent is said to be mercuric iodide with sodium sulphite.

The next step is the production from the negatives of the three positives, and first we produce a blue—or rather greenish-blue—positive from the negative obtained through the red color-filter. This, in the Sanger-Shepherd process, is done by first making a lantern-slide positive in the ordinary way by contact, taking care to secure one of good quality and well representing all the detail and gradation in the negative clear and free from fog, for the density and detail of the finished slide will largely depend upon the blue positive. This, after fixing and washing, is treated with a solution of potassium ferri-cyanide, again well washed, then immersed in a solution of ferric salt, rinsed, and replaced in the fixing solution, and finally again washed to free from hyposulphite. The effect of this is to convert the deposit of silver into one of Prussian blue. When dry this plate should be varnished, preferably with a solution of celluloid.

The remaining two positives, the pink and the yellow, are produced by modifications of the carbon process. A celluloid film coated with an emulsion of silver bromide in soft and soluble gelatin is employed. This is sensitized by immersion in a solution of potassium or ammonium bichromate, and, when dry, printed in contact with the two other negatives, care being taken to place the celluloid side next the film side of the negative. The necessary exposure varies from 1 to 10 minutes, according to the light, and should be gauged by means of the fraction tint actinometer. The silver bromide takes no part in the formation of the image, its func-

COLOR PRINTING

tions being to afford some guide in the exposure and development by giving a faintly visible image, and to assist in the more rapid disintegration of the gelatin in the warm water used for the development. The water used should be of a temperature of from 90° to 100° F., as in the carbon process, and when all the soluble portions which have not been acted upon by light are removed, the silver bromide is dissolved out by a solution of hyposulphite, leaving the almost invisible photographic image in relief in clear gelatin. The positive thus obtained from the negative taken through the green filter is then immersed in a dye-bath of a pinkish-red color, and that from the negative taken from the blue-violet filter in one of a yellow color, and they are stained to the required depth, comparing the result by holding in approximate position occasionally with the blue positive, without touching each other. It is usually better to overstain these positives and then wash down in water to the required depth of color.

The blue positive may be obtained in similar manner upon a thin celluloid support, using a weak solution of methylene blue as the stain, and this method is preferred by some workers. The advantage, however, rests with the prussiate process, in that a positive is produced of maximum sharpness, being printed in actual contact, without the necessity for the interposition of the celluloid, this being more essential in the case of the blue print, which forms the foundation of the finished slide, for however slight the diffusion may be, it must necessarily be more apparent if it exists in each of the three monochromes.

In the method of working recommended by Messrs. Lumière the three stained positives are produced upon a mica support. The mica has the great advantage of rigidity, but the still greater disadvantage of frequently failing to retain the gelatin film, which will sometimes float off, even in the bichromate sensitizing solution.

The pink and yellow positives, having been dried, are placed in register with the blue, and any preponderance or inequality in coloring noted. This can be corrected by careful reduction, in cold water, of either the pink or yellow films. The greens are usually the best guide, as, if these are correct, the other colors will usually be bound to follow. If the blue be at fault, it will be found better to make another rather than attempt to alter it. When finally adjusted and dry, the two celluloid films are varnished with a special transparency varnish, in order to prevent the colors from running. The three positives may now be placed in accurate register and bound up with a cover glass as usual, but the transparency and unity of the complete positive will be much improved by mounting in Canada balsam. This is effected by first fixing the two celluloid positives on one edge of the blue plate, by trimming first the pink, so that when it is in register there is a margin of at least one eighth of an inch of the blue extending beyond it, then the yellow, so that the pink extends beyond it for the same distance. The three can then be fixed down by a piece of lantern binding strip, or better and more securely, by a thin strip of paper firmly fastened down with fish-glue, as the gum of the binder does not always adhere securely

to the celluloid. The three positives and the cover glass are then made warm; the Canada balsam, thinned by heating in a beaker, poured in a sufficient quantity between each of the positives and also under the cover glass, and the excess pressed out; the whole being then placed between strong spring clips till set; after which the slide can be cleaned with alcohol and masked and bound up as usual. Should any separation or bubbles occur, these may generally be remedied by again warming the slide and replacing it in the clips for a few hours.

The three-color process has assumed much importance as a means of producing colored prints. To do this, the process is modified to produce three half-tone plates, the negatives being taken through filters of the complementary colors, and from these the prints are made by the use of suitable inks, the impressions being made accurately one over the other. Here the primary colors are represented by pigments of red, yellow, and blue (as before noted) and the colors overlapping and mingling produce, approximately at least, the various tints required.

It has been recently reported that Prof. A. B. Leckenby has devised a new method of color photography, the details of which have not yet been made known. The method is said to be the same as the old system of photography up to the making of the print. The difference lies in the emulsion of the sensitive paper. The slight differences in the shades on the negative plate are just enough to act in different ways on the paper during printing, and produce the several colors. One fault has been found with the pictures; they are not all the same shade. A red rose may show pink at one time, and with the next toning and fixing, a dark crimson. In either case the color will still be red, but the shades will be decidedly different. Even this objection, which is not in itself very serious, Dr. Leckenby thinks will be remedied, and he has worked out a method which will have the effect of bringing the various prints to a more even tone.

Color Printing, the art of producing pictures, designs, cards, etc., in various colors by means of lithography, printing from metal blocks, etc. The ordinary methods are: (1) The chromo-lithographic, in which a tracing of the original picture, or the like, is first made, and a copy transferred to as many stones as there are colors in the original, every color requiring a fresh stone. The drawing on each stone is made to fit in, or register, with the preceding one, and as the paper passes through the machine an additional color is added every time, and thus the picture is built up, color upon color (each being allowed to dry before the next is put on), until it is completed. Some chromos or oleographs may have as many as 25 or 30 printings or colors. (2) Block or surface color-printing is specially adapted for book illustrations, or work where nicety of detail or rapidity is required. As in chromo-lithography, various printings are necessary; but these are reduced in number by printing several tints of the same color at one operation. Each block, which is usually of zinc and prepared in the usual way, is capable of producing three or more gradations of the same color; the darkest shade from the normal surface, lighter shades being

COLORADO

got from parts which have been bitten or corroded in an almost imperceptible degree—the deeper corrosions giving the lightest shade. When the tints of one color are thus printed from one block and at one operation, a second block with gradations, in the same way, is used, registering as in chromo-lithography, and so on till the picture is finished.

Colorado, kŏl-ŏ-ră'do, the "Centennial State" (admission to the Union planned for 4 July 1876, consummated 1 August), is bounded north by Wyoming and western Nebraska, south by New Mexico and western Oklahoma, east by Kansas and Nebraska, west by Utah. Capital, Denver. Area, 103,925 square miles (280 of it water). Pop. (1900) 539,700, (1907) 700,000.

Topography.—Eastern Colorado, one-third the total area, is the westernmost portion of the great treeless plains that continue the Kansas prairies. Near the abrupt rocky faces of the mountains, they rise in low sharp-ridged foothills, called "hog-backs," composed of an extensive series of fresh water and marine formations (remnants of the junction of sedimentary with primary rock). The remainder of the State belongs entirely to the Rocky Mountain system. The Front Range connects the plains with the main range of the system. The western portions fall in minor slopes toward the Pacific. Colorado contains the greatest mass of high land in the United States, if not on the continent.

The main mass of the Rockies crosses Colorado in two principal lines of elevation. The eastern or more recent line, is composed of the Medicine Bow Range, which extends into Wyoming; the Front Range, the one first encountered by the early emigrants and still crossed by the main line of transmontane travel, the Sangre de Cristo and the Culebra. The western, or main line, is composed of the Park Range from the north and the Sawatch Range, which is a continuation of the Sierra Madre of Mexico. West of these main lines lies a complicated series of broken ranges and plateaus, parallel, lateral, and oblique, but with a general trend northwest and southeast. Of these the principal ones are the Roan, or Book, north of the Grand River in the extreme west; the Uncompahgre parallel to the Gunnison River on the south; the San Miguel further south; the San Juan to the east; and the Elk near the centre obliquely to the Sawatch (incorrectly spelled Sogauche). The Elk is a very notable range about 30 miles long, geologically interesting from the extraordinary displacement of strata, with a number of lofty and rugged summits; Castle Peak, 14,259 feet; Maroon, 14,003 feet; Snow Mass, etc.

The best-known peaks in the State, Longs (14,271) and Pikes (14,108), noted landmarks of the emigrant trail, are in Front Range, which also contains Audubon, Arapahoe, James, Rosalie, Grays (14,341), Torreys (14,336), and Evans (14,330). The loftiest range, as a whole, is the Sawatch, a granite mass over 13,000 feet high for many miles together and from 15 to 20 miles wide. Its peaks are Harvard (14,375), Princeton (14,196), Yale (14,187), and others. After a depression of 18 miles, the range rises in the Mountain of the Holy Cross, where a deep ravine and a transverse fissure outline a

gigantic cross in the snow. The highest point in the State is Mount Massive (14,424).

The great passes are far higher than any mountain summits east of the Rockies. There are 15 over 10,000 feet above sea level. Alpine (13,550), Cottonwood (13,500), Argentine (13,286), Marshall (10,841), Tennessee (10,418), and Fremont (11,313).

Lying between the two parallel elevations are four great parks which are separated from each other by cross ranges. By far the largest is San Luis Park, which extends into New Mexico and has an altitude of about 7,000 feet and lies between the Sangre de Cristo and Culebra ranges on the east and the Sawatch on the west and is more nearly level than the plains. It is nearly the size of Massachusetts. It is drained by the Rio Grande through the southern centre, while the mountain streams of the north flow into the San Luis Lake, the largest lake in Colorado. North of San Luis Park is South Park, between Front and Mosquito ranges, 8,000 to 12,000 feet high, and about the size of Rhode Island. Further north is Middle Park, still more elevated and somewhat larger. Lying between Medicine Bow and Park ranges is North Park, the second in size. There are many smaller parks, the most famous of which are Monument Park and the Garden of the Gods near Colorado Springs, in the latter "rise towers and pinnacles consisting of the vertical strata of the white Dakota sandstone and of the red triassic sandstone below. Some of these huge masses rise vertically for 200 or 300 feet, and serve as examples of erosion of steeply upturned strata of varying consistency. Lower white ridges of Jurassic gypsum or Cretaceous limestone afford strong contrast in color when compared with the red sandstone."

River Systems.—The main Rocky Mountains must obviously be the greatest of American watersheds; and chief source of river systems, except Minnesota; they contain the continental divide between the waters flowing to the Atlantic and those flowing to the Pacific. One part of it is the southern boundary of North Park, the streams of which flow north to the Platte-Missouri-Atlantic system, those south of it feed the Grand-Colorado-Pacific; another is between Creede and Ouray, separating the headwaters of the Rio Grande from those of the Gunnison and Uncompahgre of the Colorado system. The eastern plains are divided chiefly between the two great systems of the Arkansas and the South Platte; the former occupies more than one half their area in the State, the southern portion; the South Platte, the larger portion of the northern half; between them on the east is a section draining into the Republican River, an affluent of the Kansas. The South Platte rises in South Park; the Arkansas in the mountains west of it, Leadville lying on one of its head creeks. Except for these and the Rio Grande in San Luis Park, the mountain section is almost entirely drained by the Colorado River system; the Yampa (or Bear) and the White, in the northwest, flowing to the Green; the Grand through the centre, with its chief affluent the Gunnison from the south; and the Dolores in the southwest.

Of equal fame with the giant peaks and even greater beauty, are the stupendous mountain cañons through which its rivers cut their way.

COLORADO

Western Colorado forms the eastern edge of what Major Powell has called the Plateau Province; and all the wonders and beauties of this remarkable region are found in Colorado. There are the terraced platforms, ending in rock faces dropping sheer upon other platforms hundreds of feet below, and ending in vertical gorges from 1,000 feet to a mile in depth, where the sand-laden currents with a steep fall have cut their channels through countless strata of brilliantly variegated sedimentary rock; here are barren mesas, and cool grassy forested levels and slopes above the plane of perpetual drouth where the mountains bar off the vapors; rock headlands around curves or junctions of streams or gullies, fantastically carved in striking likeness to the work of human architects. The cañon of the Grand, the Black Cañon of the Gunnison, the Royal Gorge, a part of the Grand Cañon of the Arkansas, are famed for their beauty and their grandeur.

Climate and Rainfall.—The dry, cool, thin air of mountain Colorado makes its accessible eastern portions, especially the parks, widely famed as sanatoriums for patients with asthmatic or pulmonary diseases. Colorado Springs, the Rocky Mountain Saratoga, is built up by eastern invalids. The summer days are sometimes hot, but the dry air and bare rocks cause so rapid a radiation that the nights are always cool and dewless. There is little severe winter cold, zero being rare; the frost season is short, and the snows, seldom deep, soon melt, except on the mountains. The January mean temperature for the leading places is about 28.5°F.; the July 72° to 74°F. The average rainfall is 14.8 inches, fairly even through the State, though naturally much heavier on the higher levels, varying from nearly 30 inches at Pikes Peak to 12 inches at Las Animas in the Arkansas plains. Hence, agriculture can be carried on without irrigation in many mountain regions, though better with it.

Surface, Farming, Stock Raising, and Irrigation.—There are about 16,000 square miles of forested land in the State, the trees being mostly conifers, with cottonwoods along the eastern streams. Of the 40,000 square miles of plain and parks, about one-third is arable, the rest being grazing-ground, to which, however, must be added many thousand miles of grassy mountain slope. The pasturage in many parts lasts through the winter; and the plains are covered with gorgeous wild flowers. The soil of the plains is mostly sandy loam, with some clay. Along the water-courses the soil is rich, but the rainfall is not sufficient, and irrigation is needed; but is scarcely feasible there except along a few large streams, or near the mountains. But the system of dry-farming promises to extend largely the area farmed. But there is an estimated irrigable area of 4,800,000 acres, or 7,500 square miles, in the State; and in recent years an immense amount of energy has been turned to utilizing its possibilities. The land within reach of mountain streams had been so improved thereby that in 1900 Colorado was first in the United States in extent of land irrigated, and was surpassed only by California in number of irrigators and value of crops raised by irrigation. The average size of farms is much larger than in California. But of all the land under cultivation in 1900, 70.9 per cent.,

or 1,611,271 acres, was irrigated, against little over half that in 1890. Of this amount over one-third is in a solid block along the South Platte, at the northeast corner of the mountains in the State; the next greatest, nearly a fifth of the whole, in San Luis Park. There are lines along the South Platte and Arkansas; blocks on the Grand in Mesa County, on the Gunnison in Delta and Montrose, and again in Gunnison County; scattered sections on the White and Yampa, along the southern Arkansas tributaries, and indeed in every quarter of the State. There were 1,890 gravity irrigating systems in all, with 7,374 miles of main ditches; besides 277 artesian wells. Each mile of ditch had side ditches covering 390 acres; but only 218 were actually irrigated, from lack of water. The last census year was, however, one of abnormally small rainfall. The cost of construction per mile was \$1,569; per acre, \$7.21. In 1906, the length of main ditches was about 10,500 miles; of laterals, more than 7,000; total number of acres that can be irrigated under these main ditches 3,500,000, but not more than 2,350,000 are under cultivation. The State is divided by law into five irrigating divisions: the South Platte—the richest farming section of Colorado—irrigating 921,675 acres; the Arkansas, Rio Grande, Grand, and San Juan.

The most important single crop of Colorado is hay, now amounting to some \$20,000,000 a year in value. Two-thirds of this is alfalfa, whose great yield and nutritious qualities make irrigation worth while, and most of it is grown by means of irrigation. The next is wheat, 7,207,111 bushels in 1900. It had more than doubled in the decade, and it makes the highest priced flour on the market. Potatoes rank third; the soil is admirably adapted to them, and in 1900, 4,465,748 bushels were raised, against 383,123 in 1880. The sugar-beet industry has become of the first importance. There are 15 large beet-sugar factories in the State which in 1906-7 are estimated to have utilized a crop of 1,477,700 tons of beets harvested from 111,670 acres producing 310,317,000 pounds of sugar. Amount paid for beets and labor, \$9,399,500. Number of persons engaged in beet culture and sugar manufacture, 23,475. In it the State ranks second of the United States. The only other crops of first-rate importance were oats, 3,080,130 bushels; and corn, 1,275,680 bushels. (3,000,000 bushels in 1906). Others, however, are rapidly becoming valuable specialties. Barley is increasingly raised for brewing. With irrigation fruit-culture is assuming large proportions; especially the growing of apples, which has arisen from nearly nothing in 1890 (77,798 trees and some 10,000 bushels) to 2,004,595 trees and 257,563 bushels in 1900. Over 80,000 bushels of peaches, pears, and plums were also grown. In 1906, 85,000 acres were planted with fruit trees and vines which produced a crop worth \$8,000,000. Most of the fruit-raising is in Delta, Mesa, and Montrose counties, on the Grand and Gunnison, in Boulder County, on the South Platte, and in Fremont County, on the upper Arkansas. A valuable crop on the Arkansas is that of muskmelons, including the famed Rocky Ford cantaloupes.

Stock raising has increased with the production of feed, or vice versa. In 1900 the value

COLORADO

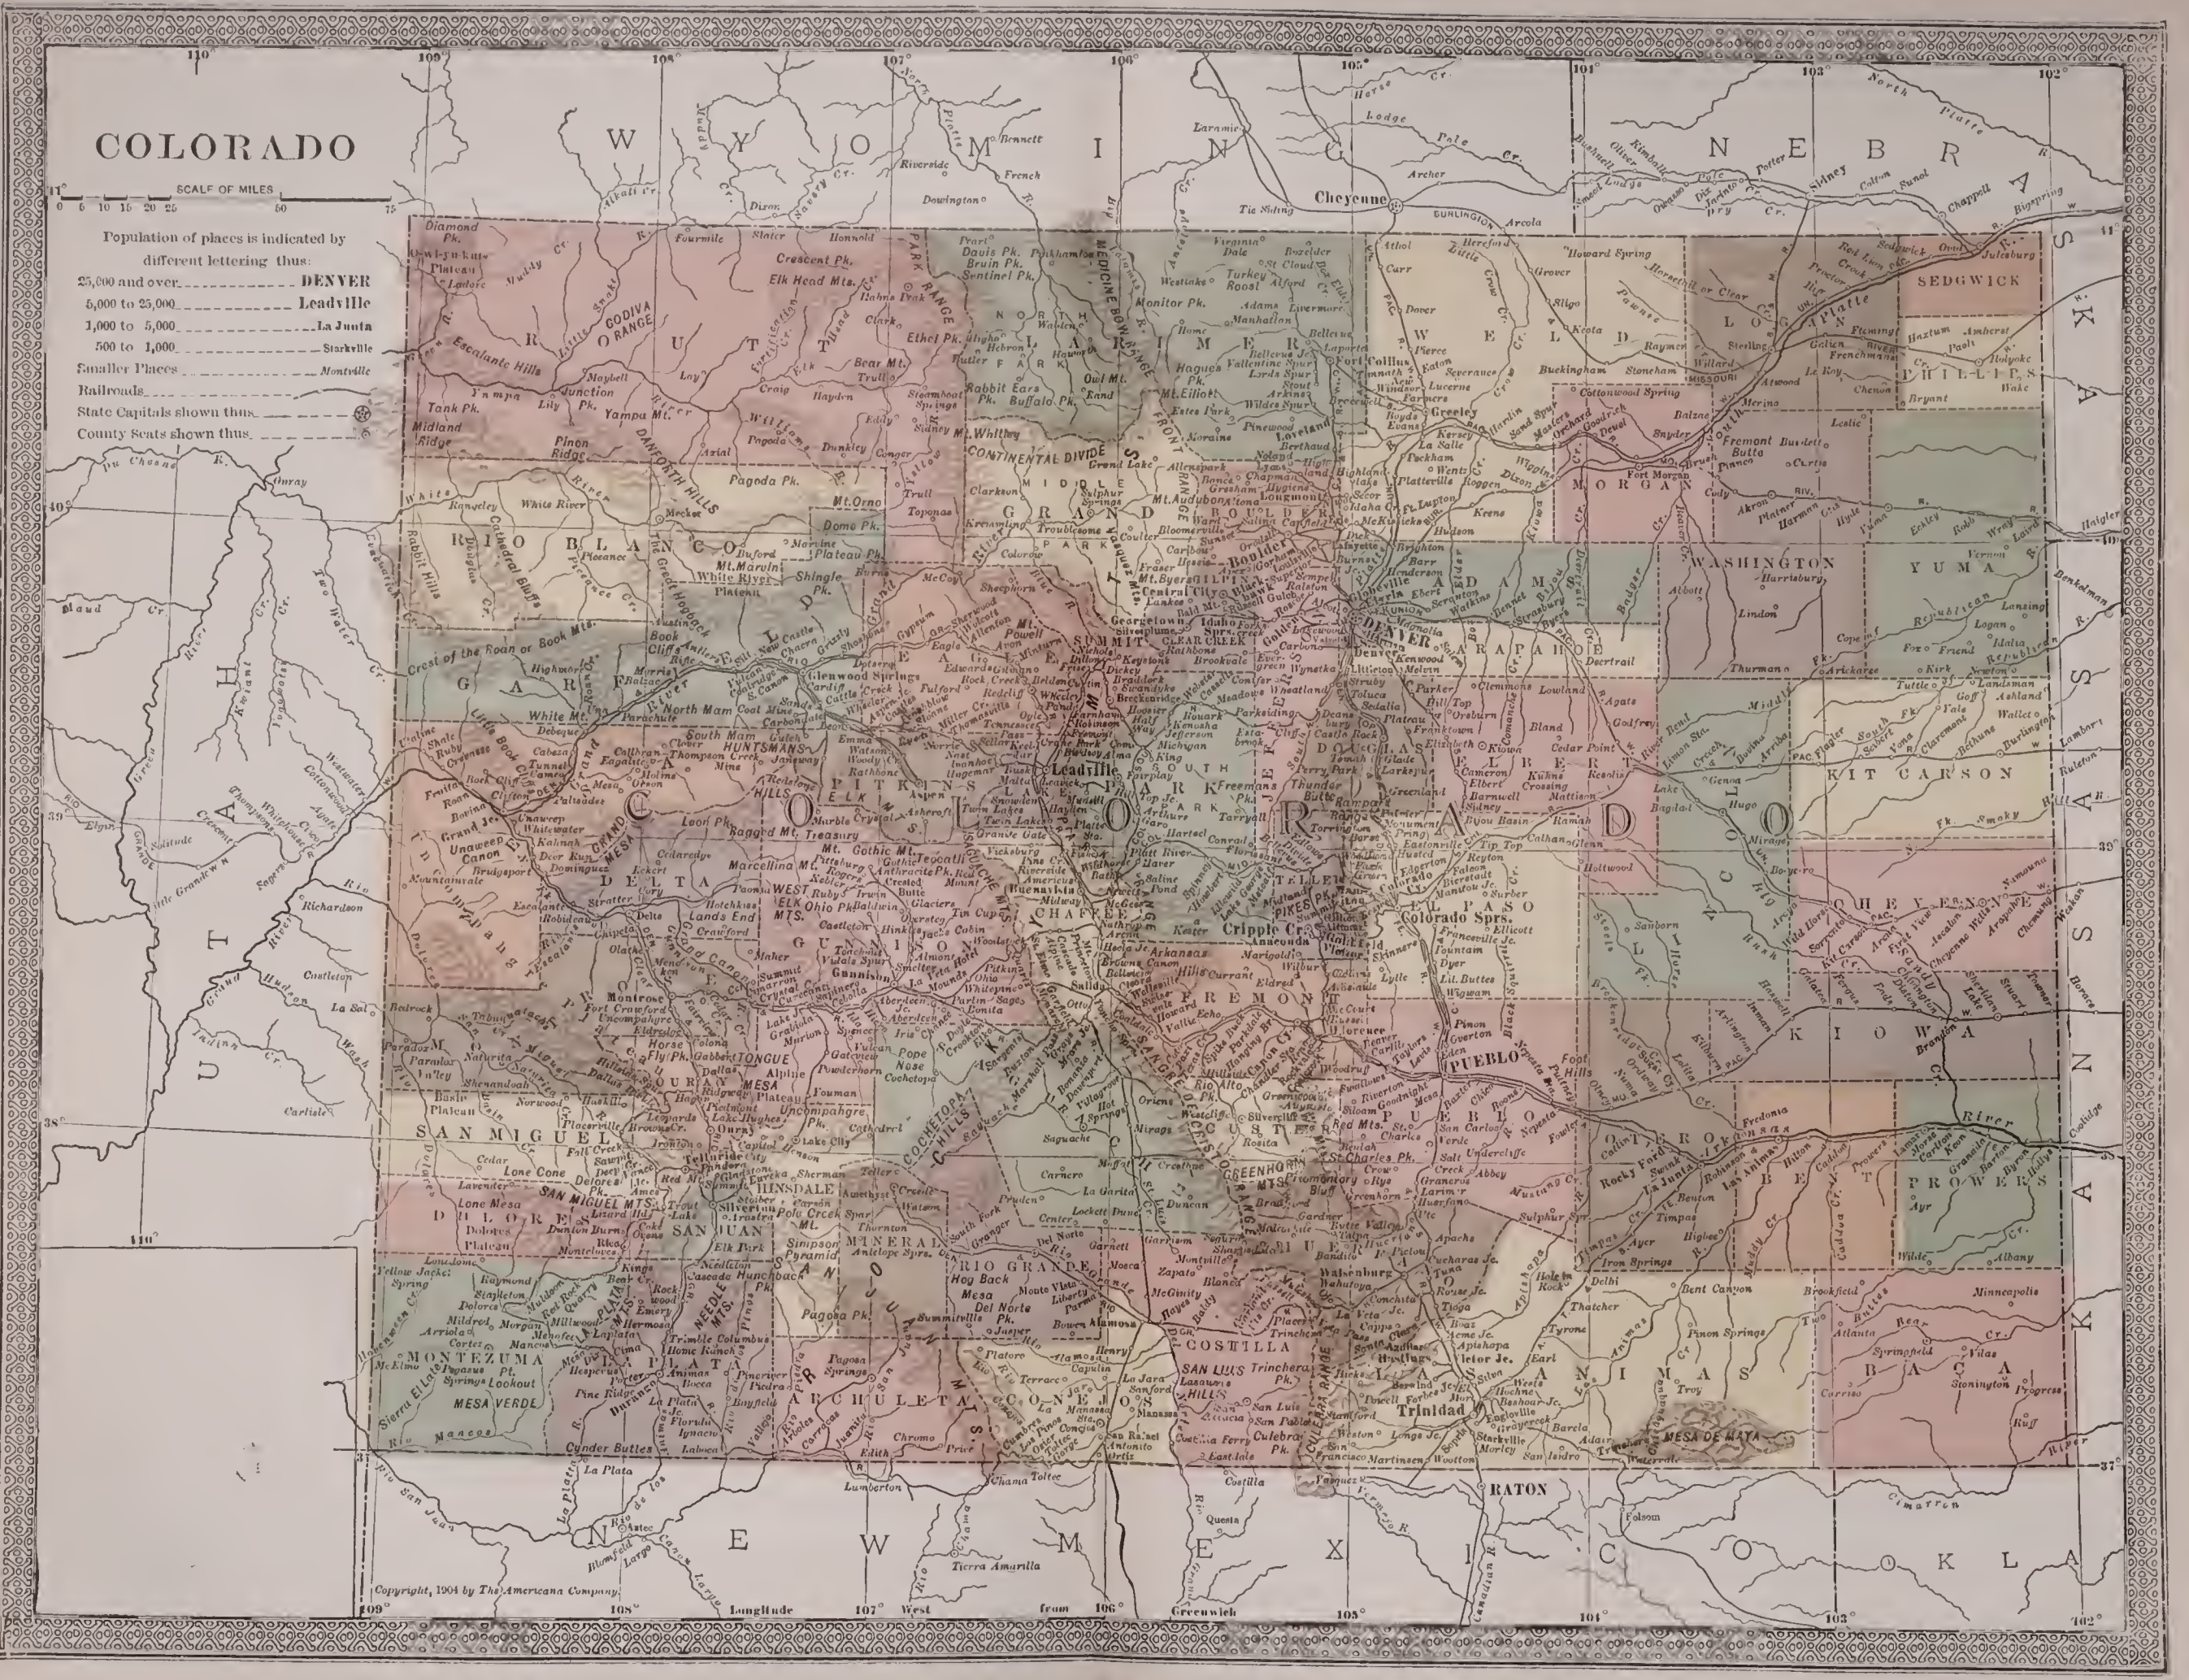

Population of places is indicated by different lettering thus:

- 25,000 and over ----- **DENVER**
- 5,000 to 25,000 ----- **Leadville**
- 1,000 to 5,000 ----- **La Junta**
- 500 to 1,000 ----- **Starkville**
- Smaller Places ----- **Montville**

Railroads -----

State Capitals shown thus

County Seats shown thus

COLORADO

of Colorado live stock was \$49,359,781; the number of neat cattle more than doubled in the decade (640,913), as it had done in each decade since 1870; and sheep, swine, and horses increased 50 to 75 per cent. The quality improved even faster than the quantity. Colorado ranchmen have been among the foremost to import blooded bulls to breed up the native stock, and in 1900 the average price of bulls was \$55.26, the highest in all the States save one (Wyoming), against \$34.49 for the whole country, and \$15.26 for the South Atlantic States. This breeding is displacing the Texas long-horn with blooded stock, and the average herd is smaller and better looked after. Dairying has increased by a third in the decade. There were 76 creameries and 27 cheese factories in the State in 1901, and a large condensed milk factory was built. Recently the tendency to consolidation has been marked and there are now not more than 36 creameries and 14 cheese factories. Sheep and wool form the wealth of several counties.

Stock feeding—a very important industry—has developed in the San Luis Valley where field-peas grow luxuriantly. Dry-farming is now attracting much attention. Many square miles of plain and hillside that were thought to be worthless are bearing valuable crops, thus increasing the tillable land by 12,500,000 acres.

Geology and Mining.—The main ranges, particularly the east range, have a core of schist and gneiss with an occasional area of granite. These main ranges are flanked on all sides with sedimentary rocks. In many cases, these rocks show practically all the geological epochs from Cambrian Quartzite to the Quaternary, while again the most recent is found resting on the most ancient. There are large areas of purely eruptive rock, such as the San Juan range in the southwest and the Spanish Peaks, near Walsenburg. The prairie land is so completely clothed with soil that it is difficult to follow the geological skeleton, but it is probable that nearly all geological periods are represented in its formation. Great coal deposits are found in the upper Cretaceous, and most of the metallic deposits are found in igneous formations.

Colorado leads the Western States in mineral production. Total output (1903) \$65,284,009; (1904) \$68,870,280; (1905) \$89,309,861; (1906 estimated) \$111,617,120. The output (1905) of leading minerals was as follows: gold, \$25,577,946; silver, \$7,743,718; lead, \$5,438,506; zinc ore, \$4,774,497; copper, \$1,536,266; clay products, \$1,663,231. The production of zinc (worth \$6,000,000 in 1906) is second to that of the Missouri-Kansas field. Most of the ore is shipped to Eastern smelters. Boulder County produces 80 per cent. of all the tungsten mined in the United States (\$250,000). Iron sulphides are mined at Creede and other places from which sulphur is obtained in paying quantities. Uranium and vanadium are found in large quantities. There is a vast quantity of oil shales in the northwest. The output of silver is steadily increasing. About three-fourths of the silver is from lead ores, and Colorado's lead product is one-sixth of that of the whole country. Lead is not only sold as a raw material, but is a most valuable flux for smelting gold and silver ores, therefore large quantities are imported from other states. The mines of

Cripple Creek and Leadville are among the best equipped in the country. Cripple Creek is the leading gold-producing section in the State and Leadville leads in the production of silver, lead, copper, and zinc.

As a coal-producing State, Colorado ranks sixth. There were mined in 1906, 11,240,000 tons, about one-half coming from Las Animas County in the south central part of the State. Marble, fuller's earth, potter's clay, fire clay, cement shales (the finest in the world), limestone and abrasives, petroleum and natural gas are valuable and abundant minerals. The Florence oil fields produce the finest oils in the world.

Manufactures.—The chief industries of Colorado could be predicted from a glance at its raw materials—precious metals, copper and lead, coal and iron, wood, cattle, and grain. These mean smelting, iron and steel and railroad work, lumber manufacture, meat-packing, flouring-mills and breweries. In 1905 there were 1,606 manufacturing establishments in the State; the capital invested amounted to \$107,663,500; there were 21,813 wage earners, whose wages aggregated \$15,100,365; the cost of materials used was \$63,114,397; and the value of the products was \$100,143,999. The 1905 census does not include separate figures for the leading industry of the State—smelting and refining—and those for 1900 are given. In that year the product of the works, smelting and refining lead ores or with lead, was valued at \$40,732,271, investment of capital \$22,569,715, wages paid \$2,390,383. Copper-smelting embraced about one tenth as much capital and product, and paid one eighth as much in wages. Iron and steel were second, with \$2,903,136 capital, \$6,108,295 product, and \$710,742 wages. The great advantage of Colorado in having its iron, coal, and flux close together has given it a practical monopoly of the market west of the Mississippi. Foundry and machine-shop products in 1905 were valued at \$4,107,986; wages \$1,061,882; and car-shop work is dependent on iron and lumber, \$5,259,183 product, \$2,264,859 wages. Flouring and grist-milling showed \$5,783,421 product, \$202,778 wages; wholesale slaughtering and meat-packing, \$3,323,503 product and \$175,419 wages; malt liquors, \$2,120,187 product, \$242,978 wages; lumber, timber, and planing-mill output, \$2,467,568 product, \$884,362 wages. Colorado industries pay about \$1,000,000 a year internal revenue tax.

Railroads.—Colorado has about 5,000 miles of main track of steam roads; besides well-developed electric systems, not only in cities, but between mining camps. A number of great trunk lines cross the State; while short lines pierce to the heart of its mountain districts, giving the best transportation service of any State along the Rocky Mountains. The chief systems are the Union Pacific, the Missouri Pacific; the Atchison, Topeka & Santa Fe, the Denver & Rio Grande, the Rock Island, the Colorado & Southern, the Colorado Midland, the Rio Grande Western, the Burlington, the Denver & Northwestern (the Moffat Railroad). Within the past few years two important branch lines have been built from Denver, connecting with the Burlington and the northwestern systems.

Finances.—In 1906 the assessed valuation

COLORADO

was about \$350,000,000 and the bonded debt was \$393,500. The tax for state purposes is \$4.00 per \$1,000.

Banks.—March 1907, there were in Colorado, national banks, 99; private banks, 76; state banks and trust companies, 86, with a total capital of \$14,647,950, and a total deposit of \$125,435,000, an increase of over 50 per cent. in four years.

Churches.—There are about 700 churches and 1,000 Sunday schools in the State. The Methodists, Presbyterians, Roman Catholics, Baptists, Congregationalists, and Disciples of Christ are the strongest denominations, while the Episcopalians, Lutherans, and other denominations have many churches throughout the State. The various denominations are very aggressive both in spiritual and secular affairs. The Jews are a very important element in Colorado civilization; they number not less than 10,000.

Education.—The school system, the efficiency of the teachers, and the equipment of the school-houses place Colorado with the States that lead in educational affairs. Of the 187,130 children of school age (1906), 144,007 were in attendance at the public schools, while many were in private schools; number of teachers, 4,600; amount paid in salaries, \$2,445,668; value of school property, \$9,513,458; total expenditure, \$4,486,226. The institutions of higher learning are The University of Denver (1864, M. E.), the pioneer institution of higher learning in the Rocky Mountains, with 170 professors and 1,392 graduates; Colorado College (1874, Congregational), 43 professors; University of Colorado (1877, State), 112 professors, 908 graduates; College of the Sacred Heart (1884, Jesuit), 18 professors and 82 graduates. The State supports the School of Mines at Golden, ranking among the best of the world, and a Normal School at Greeley, with a large efficient faculty and 965 graduates to its credit. The Universities of Colorado and Denver maintain medical schools. Many private schools are maintained; they are located in Denver, Boulder, Cañon City, Leadville, and other cities of the State. Two other institutions are in process of organization: The Colorado Woman's College (Baptist), and the Westminster University (Presbyterian), both located at Denver.

Charitable and Penal Institutions.—Each of these has a Board of Control, under general supervision of the State Board of Charities and Corrections. Besides the care of the poor by the counties and some city institutions, as elsewhere, there is a State insane asylum at Pueblo and a Soldiers' and Sailors' Home at Monte Vista. The State Prison is at Cañon City. The prisoners have been employed in purely institutional labor on the inside, and road-making in Fremont County on the outside. The session laws of 1907 provide that all prisoners in the penitentiary and reformatory shall be employed in working for the State, making articles needed at the various State institutions, or in road-building. The prisoners may receive compensation, graded by the warden. The money credit may be drawn on for the family of the prisoner. The balance becomes his on his absolute discharge. All able-bodied prisoners confined in any jail must be employed at hard labor, not less than eight hours each day. The indeterminate sentence is used. There is a State reformatory

and farm at Buena Vista, and an industrial school for juvenile offenders at Golden, where the inmates are not confined nor marked with penal badges; the appeal is to their honor. There is an industrial school for girls at Morrison, where girls may be detained until 21 years of age.

State Government.—The State constitution, which was largely modelled after that of Illinois, was ratified 1 July 1876. Colorado was admitted to the Union by proclamation of the President 1 Aug. 1876. A few important amendments have been made to the constitution. The most important are the one that provides optional home rule for certain cities and the one that gives women the right of suffrage. The suffrage amendment was voted in 1893. The women have full right to hold office. In the State the office of Superintendent of Public Instruction and in many counties the offices of County Superintendent of Schools are conceded to the women. It has been a number of years since any woman has been elected to the General Assembly.

Executive.—Executive officers, except members of the Railroad Commission, hold office for two years. The governor (salary \$5,000) may veto any bill and specific items in an appropriation bill. In either case the veto may be overruled by a two-thirds vote of each house. The Railroad Commissioners are appointed by the Governor to serve until 12 Jan. 1909. Their successors must be elected at the regular state election in 1908. The regular term is six years, salary \$3,000.

Legislative.—The General Assembly meets biennially, the 35 senators are elected for four years and the 65 representatives are elected for two years. The constitution limits the total membership of the two houses to 100 members.

Judiciary.—The Supreme Court consists of seven members, elected for 10 years. The court is divided into three departments. The Chief Justice, who is the Judge having the shortest term to serve, providing he has been elected for the full term, presides in each department. Constitutional questions must be heard by the full bench, other questions may be. There is no appeal from the decisions of a department. The district judges are elected for six years and the county judges for four years.

Militia.—The National Guard, a part of the militia of the State, consists of one regiment of infantry, one squadron of cavalry, one company of field artillery, one signal corps, one hospital corps. The complete organization contains 1,000 men.

Population and Divisions.—The first (Territorial) census, that of 1860, showed 34,277 people; 1870, 39,864; 1880, 194,327; 1890, 412,198. The census of 1900 showed a population of 539,700. The foreign-born numbered 91,155. Of these, 27,441 were from England, Scotland, and Canada; 14,606 were from Germany; 10,765 were from Sweden; 10,132 from Ireland; 6,818 from Italy; and 6,024 from Austria (probably in the main Hungarians and Slavs). Counting the north of Ireland English, probably a third of the foreign-born were English. The negroes numbered 10,654. The enormous predominance of males usual in a mining district had dwindled with the settled industries, and the males were under 55 per cent.

COLORADO AGRICULTURAL COLLEGE — COLORADO COLLEGE

There are 59 counties in the State, as follows, with their county-seats:

Adams, Brighton.	La Plata, Durango.
Archuleta, Pagosa Spr'gs.	Larimer, Fort Collins.
Arapahoe, Littleton.	Las Animas, Trinidad.
Baca, Springfield.	Lincoln, Hugo.
Bent, Las Animas.	Logan, Sterling.
Boulder, Boulder.	Mesa, Grand Junction.
Chaffee, Buena Vista.	Mineral, Creede.
Cheyenne, Cheyenne Wells.	Montezuma, Cortez.
Clear Creek, Georgetown.	Montrose, Montrose.
Conejos, Conejos.	Morgan, Fort Morgan.
Costilla, San Luis.	Otero, La Junta.
Custer, Silvercliff.	Ouray, Ouray.
Delta, Delta.	Park, Fairplay.
Denver, Denver.	Phillips, Holyoke.
Dolores, Rico.	Pitkin, Aspen.
Douglas, Castlerock.	Prowers, Lamar.
Eagle, Redcliff.	Pueblo, Pueblo.
Elbert, Kiowa.	Rio Blanco, Meeker.
El Paso, Colorado Spr'gs.	Rio Grande, Del Norte.
Fremont, Cañon City.	Routt, Hahns Peak.
Garfield, Glenwood Spr'gs.	Saguache, Saguache.
Gilpin, Central City.	San Juan, Silverton.
Grand, Sulphur Spr'gs.	San Miguel, Telluride.
Gunnison, Gunnison.	Sedgwick, Julesburg.
Hinsdale, Lake City.	Summit, Breckenridge.
Huerfano, Walsenburg.	Teller, Cripple Creek.
Jefferson, Golden.	Washington, Akron.
Kiowa, Sheridan Lake.	Weld, Greeley.
Kit Carson, Burlington	Yuma, Wray.
Lake, Leadville.	

There are 27 places in Colorado of over 2,000 people; 17 of over 3,000; and 8 of over 4,000. The metropolis is Denver (q.v.), on the east flank of the Rocky Mountains, north of the centre, with 133,859 inhabitants in 1900 (estimated in 1906 200,000) having nearly quadrupled in 20 years; the head of the Rocky Mountain trade, and chief United States market for ranching, prospecting, and mountaineering supplies. Pueblo with 28,157, and Colorado Springs with 21,085, are on the same front line of the mountains: the former a mining emporium; the latter the greatest sanatorium of the West. Leadville, 12,455, is the head of a great mining district on the upper Arkansas west of South Park; Cripple Creek, 10,147, is the centre of its rich mining region, west of Colorado Springs; Boulder, 6,150, in the mountains northwest of Denver, is a sanatorium with medicinal springs, also a manufacturing town; Trinidad, 5,345, in the extreme south, is the southernmost of the frontal towns, below Pueblo; Victor, 4,986, is one of the Cripple Creek settlements.

Colorado towns are growing so rapidly that the figures of the census of 1900 give a very inadequate idea of their population or importance.

History.—Colorado (Sp., pp. of verb *Colorar*, to color; colloquially used for red-colored) was named either from the river of that name or from the varied colors of the landscapes. Its territory is composed of three portions: one from the Louisiana Purchase; one from the Texas Cession; and the third from the Mexican Cession of 1848. The southwest portion was, in prehistoric times, inhabited by the Pueblos (the Cliff Dwellers). A few of the followers of De Soto and Coronado seem to have entered the territory of the State about 1541. It was explored in the southwest by Escalante in 1776, and its eastern mountain and plain regions by Zebulon Pike (1806) and Stephen H. Long (1820). Later John C. Fremont, led by Kit Carson, penetrated many portions of the Rocky Mountain region. Gold had been discovered in small quantities many times from 1806 to 1857

but the discoveries of 1858, near the confluence of Cherry Creek with the Platte, brought a large number of prospectors into the State. People from Georgia, Kansas, Missouri, and other Eastern States came in large numbers. Prospectors from Kansas and Georgia built Montana on the Platte near where Denver now stands; other towns followed; Auraria, St. Charles Town (now Denver), Golden, etc.

The discoveries of George A. Jackson at Idaho Springs on the south fork of Clear Creek and by J. H. Gregory on the north fork at Central City brought immigrants by the thousands. At once, local political organizations were made without regard to the territorial government of Kansas, of which Colorado was then a part. It was but a step from making laws for a mining camp to making laws for a whole district, from city building to State building. This step was soon taken. In 1859 delegates met and adopted a constitution for the State of Jefferson with an area somewhat larger than that of Colorado. The opposition to a State led to a second convention which, under the fiction of erecting a territory, established a new State and called it the "Territory of Jefferson." The constitution adopted by the first convention was ratified but never went into effect. The constitution adopted by the second convention was almost unanimously ratified 24 Oct. 1859, on which day a full complement of State officers was elected. R. W. Steele, who was elected governor, continued in office until 1861, when he surrendered his office to William Gilpin, first governor of the territory of Colorado.

Colorado was anxious for statehood, but it was not until party necessity compelled the majority party of Congress to turn to the west for more senators, that the enabling act was passed. The Constitutional Convention (in session 20 Dec. 1875—14 March 1876) provided that the territorial officers should become the State officers and serve until their successors were elected (at the regular election) and qualified.

Politics.—Colorado was admitted as a Republican State and is now (1907) Republican by a safe majority. It left the Republican ranks on the "money issue," but the improved methods of handling silver ore make silver smelting more profitable at present ruling prices than it was in 1896.

FRANK H. H. ROBERTS,
Professor of History, University of Denver.

Colorado Agricultural College, a coeducational institution at Fort Collins, Col., providing instruction in agriculture, mechanical engineering, veterinary science, etc., a four years' course leading to the degree of B.S. It was opened in 1879, and received a grant of 90,000 acres of land under the act of Congress of 1862. In 1904 there were 41 instructors and 433 students.

Colorado College, a coeducational non-sectarian institution in Colorado Springs, organized in 1874. It offers full collegiate courses and confers the degrees of A.B., B.S., and Ph.D. In 1906 the college reported 43 professors and instructors; 597 students; 39,800 volumes in the library; value of grounds and

COLORADO DESERT—COLORADO RIVER

buildings, \$500,000; annual income, \$41,000; president, William F. Slocum, LL.D.

Colorado Desert. See DESERT.

Colorado River, one of the chief streams of Texas. Rising in the high table-lands of Bexar, near the line of New Mexico, about lat. $32^{\circ} 30'$ N. and lon. 102° W., it flows southeast, receiving in its upper course the Conca, the San Saba, and the Lano on the south, and the Pecan from the north, and empties into Matagorda Bay. Austin, Bastrop, and Columbus are on its banks, and Matagorda near its mouth. For most of its course it flows through a fertile region, and has an average width of 250 feet. It is a clear stream; its name, meaning red, was originally applied to the Brazos, north and east, but the two were interchanged. The Colorado is some 900 miles long, and navigable to Austin or farther.

Colorado River, or Colorado of the West, a great river of the United States and Mexico, formed at about lat. 38° N. and lon. 110° W., by the junction of the Green and Grand rivers. The Green river rises in the Rocky Mountains in the west of Wyoming, receiving in its southwestern course the waters of the Bear, the White, the Uintah, and San Rafael. From Flaming Gorge, a point in the northwest of Colorado, where the Uintah Mountains rise, the Green River cleaves its way rapidly through cañons, the walls of which tower up to a height of nearly 1,500 feet. The Grand River rises in the Rocky Mountains, west of Denver, Col., receiving in its southwestern course the South Fork or Gunnison, the San Miguel, and Dolores. After the junction the Colorado flows southwest through Utah, joined on the east by the San Juan, on the west by the Dirty Devil and Escalante; southwest through the north of Arizona, till its waters are increased by the Colorado Chiquito, or Little Colorado of Arizona. Near the inflow of this tributary is the Marble Cañon, 3,600 feet deep and about one third the length of the greater cañon below.

From the mouth of the Little Colorado the river bends west and for more than 200 miles flows through the wonderful Grand Cañon. The successive divisions of the cañon are known as the Kaibab section, the Kanab section, the Uinkaret section, and the Sheavwitz section. The walls of this water-worn trench are often vertical, or nearly so, for a distance of thousands of feet at a time; sometimes they slope steeply, or constitute magnificent terraces. The cliffs or rock-walls attain a height of from 4,000 to 7,000 feet above the stream. (For heights of particular points, see CAÑON.) There are frequent whirlpools and waterfalls. Below the cañon the valley opens, and there is much fertile bottom-land on one or both sides of the river. Numerous tributaries pierce the high plateau on either side, the whole presenting a strangely intersected topography. Escaping from the Grand Cañon, the river flows southwest to the borders of Nevada, receiving from the west the Paria, Tapeat's River, the Kanat (of Arizona), and the Virgen (of Nevada).

Above Callville, Nev., the Colorado, as also its tributaries, again bores its way through deep cañons, the sides of which in some places present walls of solid rock nearly 7,000 feet high; the plateaus at the top of these rock masses, generally treeless, are again surmounted by ter-

aces 1,000 feet or more high. These lower and higher terraces are both piled with massive ruins, once the walled towns and cities of the Toltecs, as is supposed, a race said to be represented by the present Moqui Indians in the northeast of Arizona. Below Callville the river is again shut in by the last of the cañons, the Black Cañon, 25 miles long, and from 1,000 to 1,500 feet high. Shortly after receiving the Virgen, the Colorado takes a southerly course, severing Arizona and Sonora on the east from Nevada, California, and lower California on the west, and receiving on the east Bill Williams' Fork and the Gila. After absorbing the Gila the river sweeps round in a westerly direction for 7 or 8 miles, and soon expands to a width of 1,200 feet. Thence it pursues a tortuous course of 180 miles, the last portion being through Mexican territory, to its mouth in the Gulf of California. There is a vast delta or flood plain formed by the waste from rock erosion. From the sources of the Green River the Colorado measures a total length of about 2,000 miles. It is navigable for steamers as far as Callville, 612 miles from its mouth, and can be made navigable, it is thought, to the foot of the Grand Cañon, 57 miles higher. The first attempt to navigate the upper part of the Colorado was made in 1891. In 1893 the stream was proved navigable for 130 miles between Green River and Cataract Cañon.

The investigation of the geologists dispelled the theory once held that the Grand Cañon was a fracture of the earth's crust. It is now clear that a long period of erosion through plateaus successively uplifted has produced this remarkable gorge. At the bottom of the cañon throughout a considerable part of its course the Archæan system is laid bare. The Algonkian beds with their high coloring give brilliancy to that portion of the cañon where they can be traced. The Cambrian beds are found above the Algonkian, but in places rest directly on the Archæan. The thickness of the Cambrian (here known as the Tonto formation) is in places 1,000 feet. The upper part of the cañon walls consists of carboniferous formations (Red Wall formation below, Aubrey limestone and sandstone above). It has been estimated that all of the Eocene, Cretaceous, Jurassic, and perhaps Triassic beds and the greater part of the Permian were worn away from the plateau region during the period of erosion. The Marble Cañon platform, like that of the Grand Cañon consists of carboniferous strata with a considerable number of Permian remnants scattered over it.

In less than 50 years after the landing of Columbus, Spaniards explored the Colorado. In 1540 the river was visited by a detachment of Coronado's expedition and another of his exploring parties gave the first description of the Grand Cañon as seen by white men. About the same time Fernando Alarçon ascended the stream in boats for a long distance. Catholic missionaries subsequently traveled through these regions. For about 300 years, nothing more was learned concerning the Colorado. Much light was thrown on the subject by the investigations of Ives in 1858. In 1869 Powell explored the region and made the descent through the whole course of cañons to the mouth of the Rio Virgen, a distance of more than 1,000 miles.

COLORADO SPRINGS — COLORATION

Dutton made geological studies of the Grand Cañon in 1875. In 1889 the cañons were explored by a party of engineers sent out to make surveys.

Bibliography.—W. M. Davis, 'An Expedition to the Grand Cañon of the Colorado'; Dutton, 'Monograph II, U. S. Geol. Survey' (1882).

Colorado Springs, Col., a city and county-seat of El Paso County, on the Denver & R. G., the Denver T. & G., the Santa Fe R. I. & M. P., and the Colorado M. R.R.'s. It is situated on a plain at an elevation of 6,000 feet, near Pike's Peak and has a world-wide reputation as a health and pleasure resort. Colorado Springs is an attractive city and is the midway gate to the western section of the State. The celebrated mineral springs of Manitou attract many visitors.

Industries.—Colorado Springs was settled in 1870 and its wonderful growth since 1892 may be largely attributed to the development of the Cripple Creek gold mines, which are 30 miles distant on the opposite side of Pike's Peak. The gold output since the discovery of the district in 1891 has been \$136,000,000. A great part of this wealth flows into Colorado Springs, whose population has more than doubled in the past ten years, and whose bank deposits have increased 600 per cent. in the same period, and now amount to about \$10,000,000.

Buildings, Educational Institutions, Railways, Etc.—Colorado Springs boasts a handsome opera house and five clubs, one occupying an edifice worth \$80,000; 17 fine school buildings, Colorado College (q.v.), one of the oldest institutions of its kind in the State, with over 500 students, a State institution for the education of the blind and mute, sanitoriums, church edifices, 2 hospitals, and 6 trunk lines, 28 miles of electric railway and a modern telephone system.

Government, Etc.—The city is governed by a mayor, who is chosen biennially, and a city council. Colorado Springs has a water supply costing over \$1,000,000 and a sewerage system perfected at an expense of \$10,000,000. Pop. (1904) 24,000.

HENRY RUSSELL WRAY,
Secretary Chamber of Commerce.

Colorado Stage. The rocks of the Colorado Stage, one of the lower divisions of the upper Cretaceous Series, are all of marine origin and cover a great area, having been laid down in an interior sea that stretched from northern New Mexico, where it opened into what was then the Gulf of Mexico, to the Arctic Ocean. This sea at about the latitude of Duluth, Minn., was over 1,000 miles wide. The Colorado is separated into two sub-stages, the lower, or Fort Benton, clays, shales, and limestones, with a maximum thickness of 1,000 feet, and the upper or Niobrara, shales, sandstones, chalk, and chalky marls, with a maximum thickness of 2,000 feet. Along the northern border of what was the Gulf of Mexico, in Alabama and Mississippi the Colorado is represented by the rotten limestone 500 to 1,200 feet thick, and along the western shore of the gulf, across Texas into Mexico, by the Eagle Ford shales, 500 feet thick, and by part of the great chalk belt 300 to 600 feet thick, that stretches from Arkansas into northern Mexico. The Colorado Stage is of interest because of its marking the

time when more of North America was under water than since the Carboniferous Epoch, and because of the beds of chalk in South Dakota, Kansas, Arkansas, Texas, and Mexico. See CHALK; CRETACEOUS SERIES.

Colorado, University of, a coeducational institution at Boulder, Col., supported by the State. It was incorporated in 1861 by the Territorial legislature; when Colorado became a State in 1876, the Constitution provided that the university at Boulder should become the State University, thus giving it the advantage of the lands appropriated by the national Congress for such institutions. The University of Colorado commenced its work in September, 1877, with two departments, the collegiate and the preparatory. Since then the preparatory work has been gradually withdrawn from the university until the preparatory school has a separate organization; and the schools of medicine, law, and applied science have been added. The collegiate department offers courses leading to the degrees of A.B., Ph.B., and B.S. In 1903 there were over 500 students in the university proper, and nearly 400 in the preparatory school. The library numbers 26,000 volumes.

Coloration, Protective. The color of plants and animals is primarily due to the action of light, and is dependent on the pigment in the tissues of flowers, and in the skin, scales, hair, or feathers of animals. Plants are colored green by chlorophyll, so are caterpillars from eating plants; animals derive their colors from the waste matter of the blood. The "chromatic function" is that adaptation of color of the skin of the frog, chameleon, squid, fish, or crustacean, which rapidly changes so as to be assimilated to the tints of the objects on which they rest. In all animals the coloration is due to pigment-cells (see CHROMATOPHORES), which are more or less ramified, and which, under the stimulus of the prevailing color of the habitat, cause the animal to be assimilated in hue to the ground, or tree, or sea-bottom. In most animals the coloration is permanent, in a few it changes with the change of color of the immediate surroundings of the animal, as in the chameleon. In insects, fishes, and birds, where the variety of colors is almost endless, it is usually more or less protective, though, when the males are brightly colored this is the effect of sexual selection.

Pigment in Animals.—That this is primarily due to the action of light is proved by the fact that cave animals, or those living in darkness, are white or bleached out, so that the pigment cells become degenerate, the pigment losing its more or less dark color, while in insects the colors are either optical or natural; the pigments, when present, are formed in the cellular layer of the skin (*hypodermis*). The pigments are formed from the waste products of the blood which have not been carried away with the urinary excretions. These colors tend to fade after death, but when enclosed and preserved in air-tight sacs, such as the scales and hairs of butterflies, and the wing-covers of beetles, they remain bright for a longer time, though eventually fading when dried specimens are exposed to the light. It has been shown that red, yellow, brown, and black colors in the scales of certain butterflies are always due to pigments, while in a few cases greens, blues, violets, purples, and whites are due to

COLORATION

pigments in the scales themselves. Mayer finds that the pigments of the American silkworm moth (*telea polyphenmus*) are derived from the blood of the chrysalis. He has artificially produced several kinds of pigments from the blood, which are similar in color to various markings on the wings of the moth, and has found that chemical reagents have the same effects on their manufactured products as on similar pigments in the wings of the living moth.

Origin of Spots, Bands, or Stripes.—The markings of caterpillars, the stripes of the zebra, of many African antelopes, and of the tiger are supposed to be due to the direct effects of light and shade, to shadows cast in jungle-grass or in forests. The proofs of this are the experiments of Steinach, who glued strips of black paper to the skins of frogs which were kept in the dark; when they were exposed to the light, only the uncovered parts of their skins returned to a lighter hue, while the covered parts remained dark. The reflected green light in the case of frogs turning green when among leaves, appears to act directly upon the pigment cells. When the bottom of the vessel is covered with felt or with a wire net, the frogs become black, but recover their green color when a green branch is introduced into the vessel containing them. Those caterpillars living among pine needles are green, striped with white, yellow, and red, exactly harmonizing with the red and yellow or white portions of each needle; this seems due to the direct reflection of different shades of light on the moist skin of the caterpillar. In other caterpillars the longitudinal lines are broken up into spots, and if the process is carried on farther the spotting becomes transverse. Eyelike spots on certain caterpillars have been observed to be gradually formed at successive molts from what were originally continuous lines or stripes. It thus appears that the wonderful variety of colors and markings in animals is primarily due to the direct result of the environment, bringing about different results in animals of different groups and exposed to different environments. (For coloration due to changes of temperature see *Seasonal Dimorphism* under DIMORPHISM.)

General Protective Resemblance.—Cases in illustration are the white animals of the Arctic regions, where extreme cold and dryness have turned the hair of the polar bear, and the feathers of the snowy owl white. This applies to species, the individual ptarmigan, ermine, hare, fox, etc., turn white in winter, but of a russet hue in summer, due to the differing light reflected from the ground in summer and the snow in winter. The ptarmigan, grouse, prairie chicken, and the like, which build open nests, are protectively colored, while the conspicuously marked kingfisher, parrot, etc., build a nest which conceals the sitting bird.

The under side of the wings of certain butterflies, such as the species of *Polygonia*, *Suwanessa antiopa*, and the East Indian *Vallima* are assimilated in color, together with their often ragged outlines, to dead and tattered leaves; when the butterfly is resting on the ground or in bushes among the dead leaves, it is difficult to distinguish. On the other hand the upper side of the wings are conspicuously marked with reddish hues and conspicuous bars. Certain moths, when resting on the lichen-covered bark of trees, are wonderfully similar

to the surroundings, and are thus protected from the attacks of birds or lizards. In the Arctic regions and in Labrador certain butterflies and moths are of the color of lichen-covered rocks, so much so that when at rest they are difficult to detect.

Special Protective Resemblances.—The most striking examples are the measuring-worms, or geometrid caterpillars, which, when holding themselves out straight and stiff, resemble twigs, not only in shape, but in color and markings; and still more wonderful are those species whose bodies are provided with tubercles which in shape resemble the leaf-bud and other excrescences in the back of the twigs. How to account for the origin of such protuberances is a puzzle. The stick-insect is another example; though not common with us, and supposed to be well protected from the bills of birds, yet in the East Indian archipelago they are said to be the principal food of one kind of bird. Another example is the famous leaf-insect (*phyllium*) of Java, in which the wings are very broad, thin, and marked with veins like the mid-rib and side-ribs of a leaf.

Alluring Resemblances.—Such are the tentacles of the angler-fish or goose-fish, which, buried in the mud, waves its tentacles so as to deceive small fish. An Asiatic lizard (*phrynocephalus mystaceus*) is colored like sand, but is furnished with a red fold of skin at each angle of the mouth, which, says Marshall, is produced into a flower-like shape resembling a little red flower which grows in the sand. An Indian mantis (*Hymenopus bicornis*) devours insects which are attracted by its flower-like shape and pink color, which are like an orchid, the shape being due to the flattening of the tarsal joints of the legs, which radiate from the body like the petals of a flower.

Recognition Marks.—By Naller and others the stripes of the African antelopes, the upturned white tail of the rabbit and hare, and the bars and other conspicuous markings of birds that fly in flocks, are regarded as recognition marks, but others consider that this is rather fanciful and that they are protective alone.

Warning Colors.—Certain animals, of which the skunk affords an example, are so marked as to be easily distinguished by their enemies, which knowing by experience their offensive nature, pass them by. Hence the conspicuous stripes of the different species of these animals in the New World. There are many cases of brightly colored caterpillars which are avoided by birds and lizards which greedily devour green ones. The conspicuous red, blue, and purple spots and stripes are advertisement of their inedibility. In Nicaragua Belt observed that while ducks and fowl fed on ordinary green frogs, a small species gorgeously colored with red and blue, was avoided. On offering one to ducks and fowl they all refused to eat it, except one young duck, which took the frog in its mouth, only to drop it, going about jerking its head as if the taste of the frog was unpleasant. Although these striking markings are supposed to be the result of natural selection, Eisig's theory that the abundant secretion of pigment is the cause of the distastefulness, seems better grounded. Indeed a large number of cases of protective mimicry seem due to the direct action of light and warmth in

COLORIMETER — COLORING MATTERS

bringing about the varied hues of the pigment—moreover the range of primary colors is not very great, and the hues are apparently due to the action of the environment, so that we need not, in most cases at least, invoke the somewhat fanciful hypothesis of Wallace, Poulton, and others to account for these resemblances. As Eisig claims, the abundant secretion of pigment has caused the insects to be inedible, rather than that the bad taste has caused the production of bright colors as an advertisement or warning signal.

Color Preference.—It has been frequently noticed that house-flies will light on a dark dress in preference to a light one. They will settle down upon a dark red or brown dress in great numbers, and either avoid or rarely alight upon a pearl gray, lavender, or light or white dress or clothing of any kind. It is the same with the mosquito, which has the same color preference as the fly. In malarious countries this is a most important matter. The wearing of light yellow, drab, or white garments is an important means of protection against malaria. Houses in such regions should have light-colored walls to the rooms, especially in sleeping-apartments.

On the other hand, locusts are attracted by white or light-colored garments more than those of any other hue. White butterflies (*Pieris*) show a preference for white flowers; while in several cases yellow butterflies (*Colias, etc.*) prefer to visit yellow to white flowers.

Insects Attracted Rather by the Odors of Flowers than their Colors.—It has been argued by Lubbock and others that the colors of flowers attract insects, and that the gay lines and stripes leading down to the bottom of deep corollas are guides to the nectar. At present this view has been stoutly opposed by Plateau, after many observations, who thinks that the color of flowers has no connection with the visits of insects, but that they are attracted by the odor of the nectar. He finds that any flower is freely visited if it be nectariferous, no matter how colorless or inconspicuous it may be. Many gay flowers are wholly avoided by insects, but on placing nectar at the base of such flowers, insects were at once attracted. It appears from Plateau's observations that color is not a primary factor in attracting insects to flowers. Though bright blossoms are undoubtedly seen by insects from a distance, when they once reach the flowers it is a matter of indifference to them what their color is—blue, red, yellow, green, or white—if they differ from one another in no other respect. Consult: Wallace, 'Darwinism,' (New York 1889); Poulton, 'The Colors of Animals' (New York 1890); Beddard, 'Animal Coloration' (New York 1895); Newbigin, 'Color in Nature' (London 1898); also the writings of Lubbock, Plateau, Coste, Urech, Eimer, Hopkins, Weismann, Tenneck.

Colorimeter, kŭl''ō-rĭm'ē-tēr, an instrument for measuring the depth of color in a liquid by comparison with a standard liquid. In its usual form it consists of two long, narrow glass tubes placed side by side on a stand. The standard liquid and the one in question are poured in equal quantities, one into each tube; and water is then added to the darker till its tint becomes the same as the other. The

amount of water used is a measure of the depth of color in the given liquid.

Coloring, one of the essential parts of painting—namely, that part which relates to colors. Besides a knowledge of the art of preparing and mixing colors, and the whole mechanical process from the beginning to the finishing of a picture, which in the various kinds of painting varies according to the materials of each, coloring comprehends the knowledge of the laws of light and colors, and all the rules deducible from the observation of their effects in nature, for the use of the artist. This subject has been treated by Leonardo da Vinci in his work on painting; Lomazzo and Gérard Lairesse in books on the same subject; Mengs in his 'Praktischer Unterricht'; Goethe in his 'Farbenlehre'; etc. The skill of the painter presupposes a natural ability founded on superior sensibility—namely, the ability to image forth, and in the imitation to express with characteristic truth the peculiar substances and color of any object under the influences of the light and air. To make this imitation successful, an accurate attention to the local tones and tints is requisite. By local tones we understand the natural color of an object as it appears on the spot where it stands, or from the spot where the spectator is supposed to be stationed. In works of art the natural color of an object appears always as a local tone, because every object must be regarded from only one point of view, conformably to which the natural color is modified according to the supposed distance. By tints we understand, in a more restricted sense, the gradations of the clear and obscure which lights and shadows produce on the colored surface. In no object of art do these modifications and shades exist in greater delicacy and diversity than in the naked human body, which is consequently the most difficult subject for a painter. Coloring, in as far as it is an imitation of the color and character of flesh (the naked body), is called carnation (q.v.). If, in addition to the accurate coincidence of the natural colors, local tones, and tints of a painting with its original, the artist hits the expression of the peculiar character of the substance of which the object consists, the coloring is called true. But to truth should be joined beauty, which is attained by the harmonious union of all the tones of the painting into one leading tone. The coloring must conform to and promote the object of the painting as a work of art, and by the harmony of the colors and lights, as well as by the truth of the local colors, and of the individual parts of the subject, constitute one beautiful whole. In the choice of lights and the distribution of colors the artist should aim not only at clearness of representation, but at the same time at the production of a pleasing harmony, which should aid the general impression of the piece. Consequently harmony and chiaroscuro are comprehended in the idea of correct, beautiful coloring. We often see pictures in which the colors are true to nature, but which have little merit and are deficient in a harmonious union of excellences.

Coloring Matters. This name ought to include every substance, organic or inorganic, which is the cause of color in another, but in practice it is restricted to the natural coloring

COLORING MATTERS

matters of vegetables and animals, and to the dyes that are used for coloring fabrics. The reason of this restriction probably is that these coloring matters are distinctly different from the tissues or fluids which contain them, whereas the color of a mineral is not in general due to an isolable body, but is peculiar to the mineral itself. It is impossible, for instance, to take away the blue color of a copper compound, or the green or yellow of one of chromium. In the mineral world the analogy to the coloring of plants is found rather in rocks; for example, in a sandstone colored with oxide of iron, where the coloring matter may be removed without the rock mass being destroyed.

The organic coloring matters derived from vegetables are both important from their uses in the arts and interesting from their character and decompositions. They may be divided into two classes, those which exist ready formed in the plant, and those which are obtained by the spontaneous or artificial decomposition of some principle in the plant. Of those belonging to the first class, chlorophyll, the green coloring matter of the leaves, and the different colors in the flowers, are the most obvious. Those, however, which are used in the arts are not at first sight apparent, being contained in the seed, bark, stem, or roots, from which they can be extracted by water, alcohol, ether, dilute alkalies, etc. The second class includes bodies which result by oxidation or other chemical change from some usually colorless matters, to which the name "chromogens", color-producers, has been given; the question having been raised whether all coloring matters, even in plants, have not been produced from prior chromogens. The coloring matters have been subjected to investigation by numerous chemists, but, notwithstanding, very little is known about their real constitution. It is certain that many of the crude colors of commerce are mixtures, and it is highly probable that, when better known, their constituent principles will turn out to be diverse in constitution. Coloring matters are generally odorless, with a rough taste, soluble, some in water, others in alcohol. Indigo and alizarine can be sublimed, but most are decomposed by a slight elevation of temperature. They all consist of carbon, hydrogen, and oxygen, to which in some cases nitrogen is added. Some exhibit a weak acid tendency, combining with the oxides of lead, copper, and especially tin, iron, and aluminum, and forming insoluble colored compounds called "lakes." Some have the power of attaching themselves permanently to different vegetable and animal fibres, as silk, wool, cotton, and linen; others are unable to give a color which will not redissolve in water: in such cases the fibre is mordanted, that is, treated with one of the metallic oxides just mentioned, and then, when immersed in the color, the lake is precipitated in the fibre. The coloring matters are liable to change by exposure to daylight; they are also affected by a number of chemical reagents—certain blues, for example, are turned green by alkalies, and red by acids; they are destroyed by nitric acid, bleached by chlorine, decolorized, but not always permanently destroyed, by sulphurous acid, sulphuretted hydrogen, etc.

Of the coloring matters the yellows are the most abundant, and different varieties are got

from different plants: fustic, turmeric, quercitron, Persian berries, morindin, saffron, arnotto, purree, chrysophanic acid, and others; of the blues, indigo and litmus are the most familiar; and of the reds and purples, madder, logwood, Brazil-wood, safflower, and a few more. Most of these colors require complicated operations to separate them in the pure state.

The only green coloring matter known, of no importance as a dye, but indispensable to the life of the plant, is chlorophyll. It was formerly supposed that this is a single substance which could be obtained from an alcoholic extract of leaves by adding lime, then decomposing the lime-chlorophyll compound with an acid, and agitating with ether, from which the chlorophyll was got by evaporation. But by another process it was found that it could be separated into two bodies, one yellow, the other blue; and by the application of the spectroscope, Stokes showed that chlorophyll contains four coloring matters, two yellow and two green, differing in optical properties. By further study in the same direction Mr. Sorby thinks he has proved that besides the greens there are four or five distinct yellow coloring matters, to which he has given special names. It is quite obvious, if this be so, that our knowledge of the nature of chlorophyll is just beginning, for each coloring matter will become an object of chemical and physiological investigation, and not till then will it be possible to say how chlorophyll acts in a plant. Experiments have been recently tried to elucidate more precisely the fading of chlorophyll when exposed to light, a change which is accompanied by altered spectrum bands, but in their present state they are too incomplete for description here.

The chief animal coloring matters are those of the blood, the bile, the urine, the retina, of the muscle and of the skin. The blood's coloring matter is the well-known hemoglobin, while the pigments of the bile, bilimbim, and its oxidation product, biliverdin, are derived from the blood pigments. Biliprasin and fuscine, bilicyanin, bilipurpurin, and bilixanthin, are other bile pigments. They may be regarded as various products of oxidation and reduction of the initial bile pigments. Urochrome is the general name applied to the urinary pigments. Its exact composition is by no means definitely understood. In the retina there are a number of pigments or chromophenes. They are mostly lipochromes, or fatty pigments, and have been named rhodophane, chlorophane, and xanthophane, these being red, green, and yellow respectively. There is a further black pigment in the eye, fuscine, allied to the melanins of the skin and hair. The muscle pigments are identical with the blood pigments. The skin pigments belong to a group known as the melanins. It is questioned whether these are iron pigments or not.

The artificial coloring matters may be divided into two classes, those which exist ready formed in nature, as many of the common red and brown paints, or which are formed by the mechanical mixture of such naturally existing colors, and those which do not exist in nature, but are produced by chemical operations. The latter are of mineral or of organic origin, examples of the first class being afforded by

COLORS — COLOSSUS

Scheele's, Guignet's and other greens, artificial ultramarine, smalt, and many others, and of the latter by Prussian blue, and especially by the aniline colors. The artificial colors will be more particularly described in the articles DYEING and PIGMENTS; COAL-TAR COLORS.

Colors, in the army, the flags carried by each regiment. Each British regiment carries two colors, the royal or first color, and the regimental or second color; neither of these is now carried into battle. Each United States regiment carries the national color and the regimental color, the latter bearing the regiment's number; both are carried into action. In the navy the term colors is applied only to the national flag.

Colors. See COAL-TAR COLORS.

Colors of Thin Plates. See INTERFERENCE.

Colossæ, kō-lōs'ē, an ancient city in Phrygia, situated on the Lycus, a branch of the Mæander. Colossæ had disappeared by the Middle Ages, and it is uncertain whether it was superseded by the town of Chonæ in its neighborhood, or whether Chonæ was Colossæ with only a change of name. It was first mentioned by Herodotus, Xerxes passed through it on his march to Sardis, 481 B.C., and it was a place of considerable mercantile importance in the time of Strabo. One of Paul's epistles was addressed to the Colossians, from which it is known that Colossæ was the site of one of the early Christian churches.

Colossal Cavern, The. A large cave discovered in 1895, the entrance to which is about one and a half miles distant from the entrance to the Mammoth Cave, of Kentucky. It was not explored to any great extent until 1898, nor has it yet been thoroughly explored; and no scientific investigation was made of the interior until 1903. On account of its immense size and the varied character of its formations, which are preserved in all their pristine beauty, the Colossal Cavern is a most worthy rival of the Mammoth Cave. The Louisville & Nashville Railroad Company purchased the Cavern in 1896. As exploration was pushed in various directions, the company acquired the land under which its course was found to run, and large sums have been expended in widening narrow passageways, smoothing rough places, building stairways where desirable for comfort, and doing many other things to make exploration easy. There are four separate entrances to the Cavern, only one of which (an artificial entrance) is used by visitors, and over 14,000 linear feet in distance have been surveyed. Among the many attractions of the Cavern are, Colossal Dome, 135 feet high, which is the most symmetrical as well as one of the largest domes known; Vaughn's Dome, 78 feet in height, which is approached through a magnificent canyon, about 300 feet in length; the Twin Pits, 65 feet deep; the Lover's Gallery, 400 feet long; the Ruins of Carthage, 400 feet long and 100 feet wide; Pearly Pool; Pulpit Rock; Dining Room, etc. Taken as a whole, Colossal Cavern presents to lovers of subterranean beauty and grandeur, a field which is perhaps unequalled by any other known cavern. The Cavern is readily and comfortably accessible by wagon from the terminus of the Mammoth Cave R.R.

Colosseum. See COLISEUM.

Colossians, kō-lōsh'ī-anz, **Epistle to the**, accredited to Paul the Apostle, written to the faithful of Colossæ, a city of Phrygia, near Laodicea. The epistle does not show that Paul had been in Colossæ or that he had, by word of mouth, preached the doctrines of Jesus Christ to the people of that city. There are good reasons to believe that Epaphras, a disciple of the apostles, preached to the Colossians and converted them. From the epistle itself (i. 7, 8,) it would seem that the disciple Epaphras was one of Paul's assistants, that he gave to this apostle accounts of his work, and that such accounts had been pleasing to Paul.

Some critics and commentators writing on this epistle, claim that it was written by Paul when he was in prison, in Rome (iv. 10), and that he wrote epistles, at the same time, to the Ephesians and Philippians. Others hold that the epistle to the faithful in Colossæ was written while he was in prison in Cæsarea.

The epistle contains a summary of Christian doctrine and practices, an arraignment of the sins of the time and the temptations by which the new-born Christians were beset, and a series of practical exhortations to the people of Colossæ in particular, but which are applicable to Christians in general. The epistle itself seems to show clearly that it was addressed to a body of Christians in union with all the other Christian Churches and bodies of the day. The sins and crimes which are mentioned indicate the time and locality where lived the people to whom the epistle was addressed.

A distinctive mark of the Christians was their method of prayer. They saluted each other in the name of Jesus Christ and expressed honor and respect for him, and thus made a prayer of the very beginning of their conversations, discourses, or writings (i. 2). They praised and adored God (i. 16-20), they petitioned Him and returned thanks for all things (i. 9, 12), and they offered the Lord Jesus Christ as atonement for all their wrong doings (i. 14, 21, 22). Several of the early Christian missionaries are mentioned; as Epaphras, Onesimus, Aristarchus, Mark, Barnabas, Luke, Demas, and Tychicus. The epistle must have been written in 62 or 63 A.D. The union among the Christians is shown by the remarks about the faithful in Laodicea and Hierapolis.

The faithful of Colossæ are warned lest any man cheat them or deceive them (ii. 8); they are told that Jesus Christ died for all (iii. 11), and they are given a code of morals and told their duty as Christians in general and as husbands, wives, children, masters, and servants.

Colossus, kō-lōs'ūs, in sculpture, a statue of enormous magnitude, from which our adjective colossal is derived. The people of the East from the most ancient times have been celebrated for colossal sculpture. The pagodas of China and of India and the excavated caverns of the East abound with colossi of every description. The Asiatics, the Egyptians, and in particular, the Greeks, have excelled in these works. The celebrated colossus of Rhodes was reckoned one of the seven wonders of the world. It was raised by the Rhodians in honor of Apollo. Strabo, Pliny, and other ancient authors who

COLQUITT — COLUBRIDÆ

lived at the time that the colossus of Rhodes is said to have been in existence, have given its height at 70 cubits, or about 105 feet. Other authors who flourished since its destruction report its height at 80 cubits. The statue stood at the entrance of the harbor of Rhodes, but there is no authority for the statement that it bestrode the harbor mouth, and the Rhodian vessels could pass under its legs. Of other colossal statues of ancient times the most celebrated are the Olympian Zeus and the Athena of the Parthenon, both the work of Phidias. The virgin goddess was represented in a noble attitude, 26 cubits or 39 feet in height, erect, clothed in a tunic reaching to the feet. In her hand she brandished a spear, and at her feet lay her buckler and a dragon of admirable execution, supposed to represent Erichthonius. The statue of Zeus was 60 feet high. The earliest colossus recorded to have been sculptured in Rome was the statue of Jupiter Capitolinus, which Spurius Carvilius placed in the capitol after his victory over the Samnites.

Among modern works of this nature are the colossus of San Carlo Borromeo at Arona in the Milanese territory; the four colossal statues at Paris in front of the façade of the palace of the Chamber of Deputies, representing four of the greatest French legislators; and a statue of Germania, 34 feet high, on a pedestal over 81 feet high, erected near Rudesheim in commemoration of the unification of the German empire. In the United States a figure of "Liberty Enlightening the World," 151 feet high on a pedestal 155 feet high, has been erected in New York, overlooking the harbor and serving as a beacon. It was the work of the French sculptor Bartholdi, and was constructed mainly through the efforts of a French-American Union formed in 1874. In 1880 it was presented by France to the United States, and six years later it was placed on its present site, Bedloe's Island.

Col'quitt, Alfred Holt, American legislator: b. Walton County, Ga., 20 April 1824; d. Washington, D. C., 26 March 1894. He was graduated at the College of New Jersey in 1844, and settled in his native State as a lawyer. He served in the Mexican war, and was elected to Congress in 1852 as a Democrat. Upon the outbreak of the Civil War he entered the Confederate army as a captain. He was elected governor of Georgia in 1876 and United States senator in 1882 and in 1888.

Colquitt, Walter T., American lawyer: b. Halifax County, Va., 27 Dec. 1799; d. Macon, Ga., 7 May 1855. He was educated at Princeton, was admitted to the bar in 1820; became a district judge in 1826, holding the first court ever held in Columbus, Ga. He was a successful lawyer, and in criminal practice was without a rival in his State. He was a member of the Georgia State senate 1834, 1837; a representative in Congress 1839-43; a United States senator 1843-9; and a member of the Nashville Convention 1850.

Colt, Samuel, American inventor: b. Hartford, Conn., 19 July 1814; d. there 10 Jan. 1862. He had a common school education and was employed in his father's textile mill; but went to sea as a sailor when 15. His attention being drawn to firearms while at sea, he began to perfect a revolver and patented it in 1835. Its great success led to the erection by him at Hartford

of one of the most extensive weapon factories in the world.

Col'ton, Arthur Willis, American writer: b. Washington, Conn., 22 May 1868. He graduated at Yale 1890, held the Foote scholarship there 1890-3, and was instructor in English literature 1893-5. He has of late devoted himself to writing, and his stories have appeared in the 'Atlantic Monthly' (1899), 'Scribner's Magazine' (1899), and the 'Century' (1900). In book form he has published 'Bennie Ben Cree'; 'The Debatable Land' (1901); 'The Delectable Mountains' (1901); 'Tioba, and Other Tales' (1903); 'Belted Seas' (1905).

Colton, Charles Henry, American Roman Catholic prelate: b. New York, N. Y., 15 Oct. 1848. In the schools of that city he pursued his elementary studies, later attended the Latin school connected with Saint Stephen's Church, and in 1869 began a theological course at Saint Francis Xavier's College. After three years he repaired to Saint Joseph's Diocesan Seminary, Troy, N. Y., where he was ordained priest 10 June 1876. He was then made assistant pastor of Saint Stephen's Church, New York, and, in 1886, assumed charge of the Church of Our Lady of Mercy, Port Chester, N. Y. In 1887 he was recalled to New York to aid the Rev. A. J. Donnelly of Saint Stephen's. Father Colton was named administrator of the parish, and subsequently appointed rector. In 1896 Archbishop Corrigan appointed him chancellor of the New York diocese and upon Bishop Quigley's promotion to the archbishopric of Chicago, Ill., the Holy See chose Father Colton to succeed him as bishop of Buffalo. He was consecrated in New York by Archbishop Farley 24 Aug. 1903. According to the latest statistical report (1904) the diocese of Buffalo has a Catholic population of at least 197,000; 257 priests, 157 churches, 73 parochial schools, 2 seminaries, 5 orphan asylums, 2 hospitals; also other charitable and educational institutions.

Colton, Gardner Quincy, American scientist: b. Georgia, Vt., 7 Feb. 1814; d. Rotterdam, Holland, 11 Aug. 1898. He received a common school education and learned chair making, removing to New York in 1835, and taking up the study of medicine and science in 1842. Lecturing on chemistry and physics a few years later, accident led him to a discovery of the anæsthetic properties of nitrous oxide, or "laughing gas," credit for which is also given to Dr. Horace Wells. He perfected an electric motor in 1847, went to California in 1849, and resumed his scientific lectures in 1860.

Colton, Walter, American writer: b. Rutland, Vt., 9 May 1797; d. Philadelphia, Pa., 22 Jan. 1851. He became professor of moral philosophy and belles-lettres at Middletown Academy, Conn. (1825); in 1828-30 was editor of the 'American Spectator,' Washington. In 1845 he went to California, and in Monterey established the first newspaper of the State, called the Californian. He wrote several books of interest, including 'Visit to Athens and Constantinople' (1836), and 'Three Years in California' (1850); 'The Sea and Sailor' (1851).

Colūbridæ, kō-lū'brī-dē, a family of snakes, typified by the limited genus *Coluber* of Linnæus, and itself typical of the sub-order or super-family *Colubroidea* or *Colubrina*. As used

COLUGO — COLUMBÆ

by Cope the family contains non-venomous snakes only, but under Boulenger's system it embraces both the *Opisthoglypha* and *Proteroglypha*, which include the majority of poisonous snakes, especially those of the Old World, all, indeed, except the vipers and pit-vipers (qq.v.). Even in the limited sense, a vast majority of snakes, not less than 1,000 species, fall within the family. All are of relatively small size, only a few giants attaining a length of 10 feet and all have continuous rows of small teeth in both jaws, and none enlarged to serve as poison fangs. The head scales are large non-imbricate plates, but the body scales usually overlap, tile-like. They are oviparous or ovoviviparous, and feed on insects, small mammals, birds, etc., though a few, as the king-snake, habitually devour poisonous serpents. Most of them are terrestrial, but some are aquatic and others arboreal. Nearly cosmopolitan in their distribution, but very sensitive to the influence of cold, they are absent from the polar regions, and in temperate climes hibernate during the winter. Many species are found in North America. (See BLACK-SNAKE; CORNSNAKE; GARTERSNAKE; PINE-SNAKE; WATERSNAKE; etc.) Consult: Cope, 'Scaled Reptiles of North America'; Boulenger, 'Catalogue of Snakes of the British Museum,' where full references will be found.

Col'ugo, kō-loo'go, **Cobego**, kō-bā'gō, or **Kaguan**, kā'gwän, an East Indian insectivore of the typical genus of the family *Galeopithecidae*, as yet imperfectly known. It is a slender creature about 18 inches long, its body covered with peculiarly sleek fur, and provided with a parachute of membrane furred on both sides, and extending from the neck nearly to the tip of the tail, by which it is enabled to make long sailing leaps like a flying-squirrel, a feature which gives it its technical name, *Galeopithecus volitans*. Like the bat, which the colugo resembles in various actions, it is a creature of twilight, hanging suspended by its hind legs, from branches during the glare of day, and seldom venturing forth in the complete darkness of night. It feeds upon leaves, fruit, and insects. Consult: Moseley, 'Notes by a Naturalist on H. M. S. Challenger'; Wallace, 'Malay Archipelago.'

Columba, kō-lūm'ba, **Saint**, apostle of the Northern Picts of Caledonia and founder of numerous monasteries in the Hebrides and the Scottish mainland: b. 7 Dec. 521 in the territory of the Kinel-Conal, modern Donegal. He was a scion of the illustrious race of Conal, and was thus of kin to the northern princes of Ireland and of the Gaelic princes of Scotland. Whether his name, or surname, Columba, is Latin or a Latin modification of a Gaelic name cannot be determined; it appears also in the form Colm (whence the name Malcolm, servant or devotee of Columba); and the saint is also known as Columkillé (Columba of the churches, or *cellae*, the c in Gaelic being equal to k), because of the great number of churches and monasteries he founded both in Ireland and in Scotland and the isles. He became a monk in his youth in the monastery of Moville in Donegal, and at the age of 30 was a priest. Among the monastic establishments founded by him in Ireland are those of Daire-Calgaich (Calgach's oak grove), the site of the famous city of Derry or Londonderry; and Dair-mach

(oak of the plain) where now is Darrow. This was the greatest of all his Irish monasteries. It is worthy of note that after his migration to Scotland, he and his immediate successors in Iona exercised jurisdiction over these Irish monasteries. About the year 563, being then under excommunication for the part he had taken in the bloody battle of Cooldrevny, he set sail for North Britain with a band of his monks to preach the Christian religion to the still pagan Picts of northern Caledonia. He was entertained hospitably by his kinsman, Conal, king of the Scots in Argyll (Airer-Gædhill, land of the Gæl) who gave him for his residence the island in the Hebrides later called I, or Iona and I-Columkillé. Having established in Iona a monastery and training-school of missionaries, he crossed over to the country of the northern Picts—the southern Picts had already been converted to Christianity—and to them preached the gospel with such effect that their king Brude and the whole people embraced the faith. Before Columba's death all northern Caledonia was Christian and monasteries were very numerous whether on the mainland or in the islands. Iona was the mother house, and thence Columba and his successors, abbots of Iona, governed not only the monastic houses but the churches also; and though there were bishops for the special functions of the episcopate—the ordering of priests, for example, the administering of confirmation, the consecrating of churches, and the like—those bishops were subject to the authority of the abbot of Iona, though he was never more than a presbyter in ecclesiastical order. What time was at his disposal amid the many cares of his station, Columba devoted to study and to transcription of the Scriptures. On 8 June 597 he was employed in this labor, transcribing the psalm *Benedicamus Domino* (the 33d in the Septuagint and the Vulgate, but the 34th in the authorized English version); after penning the words "Inquirentes autem Dominum non minuentur omni bono"—they who seek the Lord shall want no manner of thing that is good. "Here," he said, "I must stop; what follows let Baithen write," and laid down the pen. At the midnight hour he was in choir for the office of Matins, having come to the church unaided and knelt at the altar; through sleep he in a few moments passed to death.

Columba, or **Columba Noachi**, nō-ā'kī (Lat. "Noah's dove"), a small constellation of stars south of Lepus and Canis Major, about the time of whose discovery there are different statements. It is generally believed that it was first named by Royer in 1679 or 1680. This is easily disproved by the fact, seldom noted, that Bayer in his 'Uranometria,' published in 1603, on the 37th map, just below Canis Major, pictures the dove flying with the olive-branch in its mouth. Dr. Gould states that it was mentioned by Petrus Plancius, an eminent Dutch geographer and teacher of Petrus Theodori. The latter died in 1596. The constellation is known to-day by the simple name of Columba, and is situated between Puppis, Pictor, Cælum, Lepus, and Canis Major.

Columbæ, kō-lūm'bē, an order of birds, also when somewhat extended, called *Pullastræ*, placed next to the *Gallinæ* near the summit of the series of schizognathous birds. It contains

COLUMBANUS — COLUMBIA

the various kinds of doves and pigeons. The order is not clearly circumscribed, but all typical forms may be distinguished from the *Galina*, with which they have most in common, by the tumid membrane or cere into which the nostrils open at the base of the beak, and by their feet. Their toes are four, namely, three before and one behind, the former not or very slightly united toward their base by a membrane; the hallux is well developed and on the same level as the other toes. The species are monogamous, and pair for life; lay generally but two eggs for a brood, but breed often, and feed their young with macerated food from their own crops. The young at birth are helpless and naked. Upward of 500 species of pigeons have been described from all parts of the world, including many strange forms. Three sub-orders, the *Didi*, *Pterocletes*, and *Peristeræ* are recognized. The first includes only the extinct dodo, family *Dididæ*; the second the *Pteroclidæ*, or sand-grouse, so called, of Asia and Africa; the third the families *Didunculidæ*, or tooth-billed pigeon, of the Samoan Islands; *Tieronidæ*, or fruit-eating tree-pigeons of the Australian and Malayan regions; *Calenadidæ*, or bony-gizzard pigeon of the Indian Archipelago; *Gouridæ*, or crowned pigeons of New Guinea; and finally the *Columbidæ* or true pigeons and doves, cosmopolitan group, and the only family represented in North America. Consult: Salvadori, 'Catalogue of Pigeons of the British Museum.'

Columbanus, kōl-ūm-bā'nūs, missionary and founder of a monastic order, that of the Columban monks, was born in Ireland about 545; died in his monastery of Bobbio, in the Apennines, Italy, 21 Nov. 615. The order founded by him, was for a while hardly inferior to the order of St. Benedict in number of monasteries or in the services it rendered to the Church. He was an alumnus of the great monastery of Benchor or Bangor, in Ulster, and thence in his 45th year he went to France as a missionary, accompanied by 12 young disciples. In France he founded the monasteries of Luxeuil and Fontenay, giving to the monks a rule identical with that of the Celtic monasteries of Ireland. He gave offense to the French bishops by the fashion of his tonsure and by his observance of Easter in accordance with the calculation of the eastern churches. And his apostolic outspokenness in rebuking the vices of the Burgundian court, the king (Thierry II.) and the queen mother (Brunehaut) led to his expulsion from that country. He now decided to cross the Alps and labor as a missionary in Italy. On his route thither he tarried a while among the Swiss, preaching the gospel on the shore of Lake Constance. One of his 12 companions, named Gallus, falling sick, was left behind when the missionary party resumed their travel: this Gallus afterward laid the foundations in Switzerland of a monastic institute which later was called by his name, St. Gall (Sankt Gallen) and which was one of the notable centres of monasticism in Europe. Columbanus, in 612, founded the great monastery of Bobbio in the Apennines, giving to the monks of that house, which soon was recognized as the mother-house of a multitude of abbeys and monasteries, a rule of great austerity. The keynote of it is implicit, unquestioning

obedience in all things to the abbot or superior. It prescribes perpetual silence save where speech is absolutely necessary. The use of animal food of all sorts is interdicted. The monks are allowed one meal daily, taken at eventide, and it consists of vegetables and bread. The monks of his monasteries, called Columbans, came under the Benedictine rule in the 8th century and the Columban order was merged in the Benedictine. Columbanus was a man of learning, acquainted not only with the Latin language current in his time, but with the classic Latin authors, as also with the Hebrew and Greek languages. He left a few writings, all in Latin; they have all been published more than once. They comprise his Monastic Rule (*Regula Cœnobialis*); a few poems of considerable merit; 16 brief sermons, and several letters of value for ecclesiastical history. A town in Lombardy, San Colombiano, perpetuates the memory of this Celtic missionary to Italy.

Colum'bia, the popular name of the United States; derived from Columbus, and applied to the greatest nation of the New World from a feeling of poetic justice to the memory of its great discoverer.

Columbia, British. See BRITISH COLUMBIA.

Columbia, District of. See DISTRICT OF COLUMBIA.

Columbia, Mo., a city and county-seat of Boone County, situated 10 miles north of the Missouri River, on the Wabash R.R. It was first settled in 1815 by Kentuckians and is governed by a mayor and a council of eight members, who are elected semi-annually. The city has four banks with a combined capital of \$370,000. Columbia has many public and educational institutions, including Missouri University, Missouri State Farm and Experiment Station, Parker Memorial Hospital, Stephens Baptist College for Women, Christian College for Women, Columbia Normal Academy, Columbia Business College, University Military Academy, and High School. Pop. (1904) 6,000.

Columbia, Pa., borough, in Lancaster County; on the Susquehanna River, and on the Pennsylvania and the Philadelphia & Reading R.R.'s; about 26 miles southeast of Harrisburg. The place, originally called Wright's Ferry, was founded in 1726 by Quakers from Chester County. Columbia was one of the places proposed, in 1789, for the capital of the United States. The bridge, which connected Columbia with Wrightsville, was burned in 1863, to prevent the Confederate forces from proceeding to Philadelphia. A fine bridge has taken the place of the old one. Columbia is an industrial and trade centre of considerable importance. The chief manufactures are foundry and machine-shop products, boilers and engines, flour, beer, wagons, shirts, silk, lace, and lumber. Pop. (1890) 10,199; (1900) 12,316.

Columbia, S. C., the State capital, and county-seat of Richland County, situated in the centre of the State, on the east bank of the Congaree River, at the head of navigation, two miles below the junction of the Broad and Saluda. It is on the Atlantic Coast Line, the Seaboard Air Line, the Southern, and the Columbia, N. & L. R.R.'s, 129 miles northwest

COLUMBIA

of Charleston, 82 miles northeast of Augusta, Ga., and 153 miles north of Savannah.

Columbia is one of the handsomest cities of its size in the country, and in a district noted for sanitariums. It is built on a sand-hill plateau which forms a bluff 100 feet high at the river, and sloping away on all sides, giving excellent drainage. The streets which are 100 feet wide are at right angles to each other, and there are four avenues 150 feet wide radiating from the capitol. All the chief streets are boulevards, with handsome shade-trees not only along the sides but in the centre. There is also a fine park. The business buildings are rapidly increasing in size and architectural beauty. The granite State-house, costing \$4,000,000 and modeled on the capitol at Washington, is one of the most imposing in the South and one of the handsomest in the country. Spacious grounds surround the capitol, and among the city's attractions are the monuments, which include a "Palmetto Tree" in bronze. The executive mansion, the government building, the county court-house, the city hall, the State insane asylum and State penitentiary are also noteworthy. The city is rich for its size in important educational institutions: South Carolina College, founded 1801; the Presbyterian Theological Seminary, also very old; Columbia Female College (Methodist Episcopal Church South), founded 1859; Allen University (African Methodist Episcopal), 1881; the College for Women (Presbyterian) 1890; and Benedict College (colored). It has also a well-attended public-school system, and two high schools.

Municipal Conditions.—The principal streets are asphalt; the roads are chiefly of sand and clay and are excellent. The city owns its waterworks, and has gas, electric light and power, and an electric railway system. The government is by the revised charter of 1894, with a two-years' mayor, and a council which has nearly all the appointing power.

Business Interests.—The city affords one of the most remarkable instances of manufacturing development in the country. It is in the heart of a fertile cotton district, and near forests of pine, oak, walnut, and maple; but its site is the key to an important future. A rocky shelf projecting for four miles from the junction of the Broad and Saluda forms the bed of the Congaree, 500 feet wide, which plunges down it in rapids, affording immense power, which is made available by a canal $2\frac{7}{8}$ miles long, 110 feet wide at bottom and 150 at top, with 31 feet fall, furnishing 14,000 horse-power, and operating dynamos which create electricity for manufacturing power, light, and street railways. But the greatest establishments are independent of this except as a resource, using steam dynamos,—for all Columbia's industries are run by electricity. In 1892, there was one cotton mill in the city employing 125 men. Now the great Whaley system of cotton mills includes four in Columbia, with 197,000 spindles, 4,840 looms, and \$3,100,000 invested capital. The Olympia mill, with nine to ten acres of floor space, and over 100,000 spindles, is the largest in the world operating under one roof; the Granby and Richland are also large and well-equipped mills; and the three, owned by one company and employing almost 3,000 hands, are the nucleus of a large village of 500 acres owned

by the company, with sewerage, fire department, electric street lighting, cottages wired and plumbed, churches, schools, etc. The Columbia Mills Company is also a great organization, capitalized at \$1,500,000, and turning out over 20,000 bales of cotton duck a year. Besides this predominant industry, there are growing hosiery works, glass works which utilize the fine sand found nearby, four quarries of fine granite, large lumber works starting up, and small miscellaneous industries. The vast beds of kaolin in the vicinity now supply outside potteries, but local works are contemplated. The rock ledge before mentioned extends two miles below the city with only four feet of water over it, dropping off to ten feet or more at Granby. Deep water is now to be brought up to Columbia, not by dredging, but by a floating dam 15 feet high, costing \$250,000, which will enable vessels of ten feet draft to come up to the city, instead of unloading and trucking up from Granby as heretofore. Two steel steamers run from Granby to Georgetown, which will start from Columbia when the dam is completed, and ultimately go to Charleston. This improvement makes Columbia the great distributing point for central and northern South Carolina.

History.—The town was settled about 1700, but remained farm land till 1786, when the people of the State demanded a capital more centrally located than Charleston, and Columbia village was laid out. The legislature first met there in 1790. In the Civil War it shared the general fortunes of the State, till Sherman's army entered it 17 Feb. 1865. The following night a fire broke out which lasted all the next day and laid over half the city in ashes, including a number of business blocks, private residences, schools, the railroad station, several churches, and a convent, and destroyed a great quantity of cotton. Its development since is part of the general industrial awakening of the South. Pop. (1860) 8,052; (1870) 9,298; (1880) 10,036; (1890) 15,353; (1900) 21,108, of which 11,244 were white. Several mill villages, chiefly that of the Whaley mills, with several thousand inhabitants, are outside the old city limits though close by, and 35,000 is a reasonable estimate of the population including these suburbs.

Columbia, Tenn., county-seat of Maury County, situated on the Duck River, and on the Louisville & N. and the Nashville, C. & St. L. R.R.'s. It is the trade centre of a fertile agricultural region, and has a stock yard, a grain elevator, and cotton and flouring mills. It is the seat of Jackson College and two seminaries for young women. It also has a United States arsenal. Pop. (1900) 6,052.

Columbia City, Ind., the county-seat of Whitley County, in the northeastern part of the State, situated on Blue Creek and on the Wabash and on the Pittsburg, Ft. W. & Ch. R.R.'s. It has lumber mills and a few other manufacturing interests. Pop. (1900) 2,975.

Columbia or Oregon River, after the Yukon the largest river on the western side of America; it rises in British Columbia, on the west slope of the Rocky Mountains, near Mounts Brown and Hooker, in about lat. 50° N.; has a very irregular course, generally southwest through Washington; forms the northern boundary of Oregon for about 350 miles; and enters

COLUMBIA SALMON — COLUMBIA UNIVERSITY

the Pacific by an estuary 35 miles long and from three to seven wide. Its estimated length is 1,400 miles. The area drained by this stream and its tributaries, of which the largest are Clarke's Fork and the Snake River (with very remarkable cañons), has been computed at 298,000 square miles. The river is broken by falls and rapids into separate portions, and formerly a bar across its mouth obstructed navigation. The construction of a jetty has provided a good harbor; and in Nov. 1896 the Government completed a canal and locks at the Cascades, at an expense of nearly \$4,000,000, and navigation is (1904) open to The Dalles. The Government is about to begin work to overcome the obstructions at The Dalles. The Columbia and its branches have 2,132 miles of navigable waters. The extraordinarily abundant salmon-fisheries have been largely developed. There are a number of canneries near the mouth of the river; the annual export of canned salmon exceeds 500,000 cans. Captain Gray of Boston was the first modern navigator to enter the river in 1792; and it was explored in 1805 by Lewis and Clark.

Columbia Salmon. See QUINNAT.

Columbia University, a seat of learning in New York. The design of establishing a college in New York was more than 50 years in contemplation before it was carried into effect. In 1746 provision was made by law for raising money by public lotteries. Five years later the proceeds of these lotteries amounted to about \$1,700 and were given to trustees. The fact that two thirds of these trustees were in communion with the Church of England, and that some of them were vestrymen of Trinity Church excited opposition to the proposal as a scheme to strengthen the Established Church and delayed the procurement of a royal charter. Friends of the enterprise proceeded, however, with the arrangement for opening the college and elected for their first president the Rev. Dr. Samuel Johnson, of Stratford, Conn., who assumed the office 17 July 1754, in the school house belonging to Trinity Church. There was a class of eight students.

The cosmopolitan character of the governing body of the college is due to its charter. To meet the objections that had been made, it was so drawn as to include in its board of governors, besides other ex-officio representatives, not only the rector of Trinity Church, but the senior minister of the Reformed Protestant Dutch, Ancient Lutheran, French, and Presbyterian churches. It is probably due to this circumstance that Columbia almost alone of all the pre-Revolutionary colleges in the United States has never had a theological faculty connected with it. The trustees, at present, are members of the Episcopal Church, and also of the Reformed, Presbyterian, and Roman Catholic churches, showing that this cosmopolitan character has never been lost. A prominent Hebrew rabbi was at one time a member of its councils.

The charter of King's College, the original name of Columbia, was granted by George II., and finally passed the seals on 31 Oct. 1754, from which day the college dates its existence. It received from Trinity Church, according to

a promise previously given, a portion of a grant of land known as "the King's Farm," upon the site of which its first building was erected. It was stipulated in the royal charter that its president should be a communicant of the Episcopal Church and that proper selections from the liturgy of that Church should be used in the religious services of the college. This caused much angry controversy, and after the Revolution it was stricken out of the charter, but remains as the condition of the deed of gift from Trinity Church. King's College played a conspicuous part in securing and confirming the independence of the United States. The Revolutionary War caused a suspension of the activities of the college, and in 1776 the college building was used as a military hospital. After eight years the college work was resumed by act of the legislature, 1 May 1784, under the name of Columbia College.

On 13 April 1787 the legislature revived the original charter with amendments, which abolished ex-officio membership of its governing body, canceled the requirement that the president should hold a certain form of religious belief or that a certain form of prayer should be used in the services of the college, and named a body of 29 trustees, which, when reduced to 24 members, was made a self-perpetuating body, under which government the college has remained. The medical faculty was organized in 1792 and a professorship of law was established in 1793.

The original site of the college was in what became later the block bounded by College Place, Barclay, Church, and Murray streets. In 1857 the college was moved to 49th and 50th streets and Madison Avenue, where it remained until 1897. In 1892, for \$2,000,000, purchase was made of 17½ acres of land lying between 116th and 120th streets, Amsterdam Avenue, and the boulevard. Here in 1897 the college was reorganized on the basis of a university.

Columbia University, in a technical sense, consists of the faculty of law, the first professor of which (1792), James Kent, during the period of his second appointment in 1823 delivered the courses of lectures which developed into the first two volumes of his famous 'Commentaries'; the faculties of medicine; philosophy, political science; pure science; and applied science. The College of Physicians and Surgeons, the outcome of the medical faculty, established in King's College in 1767, became in June 1860, the Medical College of Columbia. In 1891 it surrendered its separate charter and became an integral part of Columbia College. A peculiarity of the Columbia organization is the system by which seniors in Columbia College, who have entered the college not later than the beginning of the junior year, are allowed to select part or all of the courses necessary for the bachelor's degree from among those designated by the university faculties, professional or non-professional, as open to them. The object of this arrangement is to shorten the time necessary to the attainment of the higher, particularly of the professional, degrees. The degree of master of laws is conferred for advanced work in law done under the faculties of law and political science together. The faculties of law, medicine, and applied science, conduct respectively the schools of law, medicine, and mines, chemistry, engineering, and architecture, to which

COLUMBIA RIVER.

LIBRARY BUILDING.

COLUMBIAN COLLEGE—COLUMBINE

students are admitted as candidates for professional degrees on terms prescribed by the faculties concerned. The school of mines was due to the exertions of Thomas Egleston, who was made professor of mineralogy and metallurgy in 1864, and who opened the school of mines the same year in the basement of the old college building in 49th Street. There is also the school of chemistry, engineering, and architecture, set off from the school of mines in 1896. Out of the school of mines grew the school of pure science, established in 1892. Under President Barnard's influence, in April 1889, the trustees gave their official approval to the plan for founding Barnard College for women studying for Columbia degrees. It is financially a separate corporation, but educationally it is part of the system of the university. Teachers' College, a professional school for teachers, is also financially a separate corporation and educationally a part of the university. It was founded in 1888, chartered in 1889, and included in the university in 1898. (See COLLEGES FOR TEACHERS.) Some of these courses are accepted by Columbia University, and may be taken without extra charge, by students of the university in partial fulfilment of the requirements for the degrees of bachelor of arts, master of arts, and doctor of philosophy. In 1902-3 the university had a total of 5,134 students in all departments, and its library comprised 330,000 bound volumes. The new library building is a gift from ex-President Low, and cost over \$1,000,000.

The presidents of the University have been: Samuel Johnson (1754-63); Myles Cooper (1763-75); the Rev. Benjamin Moore (1775-6); William S. Johnson (1787-1800); Charles H. Wharton (1801); the Rt. Rev. Benjamin M. Moore (1801-11); William Harris (1811-29); William A. Duer (1829-42); Nathaniel Moore (1842-9); Charles King (1849-64); Frederick A. P. Barnard (1864-89); Henry Drisler, acting (1888-90); Seth Low (1890-1901); and Nicholas Murray Butler (inaugurated 1902).

SETH LOW,

Ex-President Columbia University.

Columbian College. Columbian College was originally organized in 1821 by special act of Congress, under the auspices of the Baptist denomination. In 1873, in accordance with the provisions of a donation given by William W. Corcoran of Washington, D. C., the charter was changed by special act of Congress, making it a university. By special acts of Congress in 1904 and 1905 the university was made non-sectarian, the name changed to The George Washington University, and authority given to organize, under the charter and in connection with the university, colleges desiring to carry on educational work in the arts, sciences, liberal and technical knowledge; the college to be non-degree-conferring, its faculty recommending students for the baccalaureate degrees only, the degrees being conferred by the university. Colleges may be organized by any society with the consent of the university, the charter providing the mode and manner of nominating and electing trustees. Under this amendatory act Columbian College was reorganized as an undergraduate college in connection with the university, continuing its affiliation and control with the Baptist denomination. See GEORGE WASHINGTON UNIVERSITY, THE.

Columbian Formation, a series of gravels, sands, and clays of Pleistocene age covering the coastal plain of the Atlantic slope from New Jersey southward, and typically developed in the District of Columbia. The formation in the north covers the plain up to elevations of 400 feet, and in the south up to 100 feet. It includes estuarine and delta deposits, and the fossils are recent marine species, indicating a submergence and re-elevation of the coast. The formation may correspond to the Champlain stage of the glaciated portion of the continent. See CHAMPLAIN STAGE; GLACIAL PERIOD.

Columbian University. See COLUMBIAN COLLEGE; GEORGE WASHINGTON UNIVERSITY.

Columbian World's Fair. See WORLD'S COLUMBIAN EXPOSITION.

Columbidæ, kō-lūm'bī-dē, the family of true pigeons, the typical one of the order *Columbæ*, of which it embraces the bulk of the known species, more than 400 belonging to this family. Over half of them are found in the Maylayan and Austro-Malayan Archipelago, and 75 in South and Central America, while all other parts of the world, except the polar regions, have their representative species in smaller numbers. Although our native species give but a faint idea of the richness of color and other peculiarities of adornment of the tropical pigeons, the structural features are remarkably constant and well exemplified in the domestic pigeon. The bill is moderate and compressed, having at its base a soft skin in which the nostrils are placed. The feet have three divided toes before and one behind, all of which are on the same level; the tarsi scutellate. The wings are rather long and exceptionally powerful; the plumage generally compact, and the feathers without aftershafts. One of the most variable features is the tail, which may be short and square or long and pointed, and its rectrices from 12 to 16. Although classed by Cuvier with the gallinaceous birds, the *Columbidæ* differ from them in structure and especially in habits, being monogamous and good flyers. Besides they are unlike the domestic fowl which is the type of the *Gallinæ*, in that the males assist in nest-building and incubation, and the young are not able to walk, and are nourished by the parent birds, which secrete in the double crop a milky fluid utilized to soften their food. Moreover the *Columbidæ* drink at a single draught. They eat seeds and berries, more rarely insects. See DOVE; PIGEON; etc.

Col'umbine, a popular name for *Aquilegia vulgaris* or other species of the genus *Aquilegia*. The common columbine has drooping purplish-blue flowers with five flat sepals; five petals, with long spurs, often curved; five follicles, the root-leaves twice or thrice ternate, the others singly ternate. The claim of the columbine to become the national flower of the United States has been pressed since 1896 by the Columbine Association with offices in Boston. This association urges that the flower is wild and commonly diffused, that it has decorative value, that its common name symbolizes the dove of peace and suggests Columbus, the discoverer; that its Latin name hints at the eagle of power, that the form of the short-spurred variety is strikingly like the Liberty Cap, and that its compound leaf exemplifies the Federal motto *E pluribus unum*.

COLUMBITE — COLUMBUS

Colum'bite, a mineral of variable composition, consisting of a compound niobate (columbate) and tantalate of iron and manganese. When niobium is present in large amount relatively to the tantalum, the mineral is called "columbite," and when the reverse is the case, it is called "tantalite"; the two minerals passing into each other, in nature, by insensible gradations. Typical columbite has a hardness of 6, and a specific gravity of from 5.4 to 5.8, the specific gravity increasing with the proportion of tantalum present. The crystals are short and prismatic, often tabular, and belong to the orthorhombic system. The mineral is black or brownish-black in color, and is often iridescent. In the United States columbite is known to occur in most of the States lying near the Appalachian Mountain system, and also in Colorado, South Dakota, and California. One crystalline mass of it, found in the Black Hills region, is said to have weighed about a ton. The existence of columbite in the United States was first made known through a specimen sent by Gov. Winthrop of Connecticut to Sir Hans Sloane, president of the Royal Society of Great Britain.

Colum'bium, a metallic element, better known as niobium (q.v.).

Columbo, the root of a climbing plant, *Jateorrhiza Columbo*, which grows in great profusion in the island of Mozambique. It is also called calumba. The root, sliced transversely into disks, is dried and is used in medicine in the form of an infusion as an appetizer, and tonic. It contains a bitter alkaloid *berberine*, and another bitter principle *columbin*. It is free from tannic acid, so, unlike most bitters, it may be mixed with the preparations of iron. It was formerly employed for diarrhœa, dysentery, and gas in the bowels, being carried to India, whence it is exported.

Columbus, Bartholomew (Sp. Bartolomeo Colon; It. Bartolommeo Colombo, his real name), Italian navigator, brother of Christopher Columbus: b. Genoa about 1432; d. San Domingo May 1515. The events of his early years are not on record. In 1470 we find him established at Lisbon as a mariner and constructor of maps—one of those adventurous navigators whom the patronage of the Portuguese princes had drawn to their capital. About 1486 he visited the Cape of Good Hope, probably with Bartholemi Diaz. It is not known how long he was absent when his brother sent him to England to seek the aid of Henry VII., but it appears certain that Christopher was ignorant of his fate, further than that he was captured by pirates. He did, however, attain the ear of the English monarch, and presented him with a map of the world, but it does not appear that he succeeded in securing English aid. On his return through France, he learned that his brother had already discovered the new world, and had sailed on a second voyage. Hastening to the Spanish court, he was received as became the brother of the admiral. Queen Isabella sent him in command of three store ships to the new colony of Hispaniola, where Christopher received him with joy, and appointed him adelantado or lieutenant-governor of the Indies. In this position Bartolommeo showed great bravery and decision. He shared his brother's imprisonment, and with him was liberated on reaching Spain, where the Spanish monarchs confirmed

his title, and gave him the lordship of the small island of Mona near St. Domingo, with 200 Indians as his personal body-guard. The fierce energy of his character, however, made them jealous of giving him too much latitude in public affairs. He died without issue.

Columbus, Christopher (Sp. Cristobal Colon; It. Cristoforo Colombo, his real name), Italian navigator, the discoverer of America: b. Genoa probably 1446; d. Valladolid, Spain, 20 or 21 May 1506. His father, Domenico Colombo, a poor wool-comber, gave him a careful education. He soon evinced a strong passion for geographical knowledge, and an irresistible inclination for the sea. The details of his early life are confused and unsatisfactory. He appears to have gone to sea at an early age, and to have navigated all parts of the Mediterranean and some of the coasts beyond the Strait of Gibraltar. In 1470 we find him at Lisbon, where he married the daughter of Bartolommeo de Palestrello, a distinguished navigator, who had founded a colony in Porto Santo, an island recently discovered and belonging to the Madeira group, and had left many charts and nautical instruments. Columbus made use of these materials, and his opinion that the other side of the globe contained land, belonging to eastern Asia and connected with India, which was, as yet, little known, became more and more fixed. While the Portuguese were seeking to reach India by a southeast course round Africa, he was convinced that there must be a shorter way by the west. He applied in vain to Genoa for assistance, and equally fruitless were his endeavors to interest John II. of Portugal in the enterprise. He also sent letters on the subject to Henry VII. of England, with the same ill success. He then determined to apply to the Spanish court, Ferdinand and Isabella being at this time the sovereigns of Spain, and after an eight years' struggle with the obstacles thrown in his way by ignorance and malice, he received three small vessels. These were named the Pinta, the Niña, and the Santa Maria; and according to Jal each of them was fully decked and had four masts and a crew of 90 men. The dignity of high-admiral and viceroy of all the countries he might discover was conferred on him, the former to be hereditary in his family. A certain share of the profits was secured to him by a written contract with the sovereigns.

It was early in the morning of Friday, on 3 Aug. 1492, that Columbus set sail from the port of Palos. Eighteen years had elapsed since he had first conceived the idea of this enterprise. The most of that time had been passed in almost hopeless solicitation, amidst poverty, neglect, and ridicule; the prime of his life wasted in the struggle. Nor should it be forgotten that it was to Isabella alone that he was finally indebted for the means of executing his project, which had been coldly rejected by the prudent Ferdinand. Having provided himself at the Canary Islands with fresh water, he sailed southwest into an ocean never before navigated. But when 21 days had elapsed without the sight of any land, the courage of his men began to sink. It was certain, they said, that they should perish, and their visionary commander ought to be forced to return. Some of them even proposed to throw him overboard; and Columbus had to exert all the powers of his daring and

CHRISTOPHER COLUMBUS.

COLUMBUS

commanding spirit to prevent an open rebellion. A phenomenon, which surprised even him, filled his pilots with consternation: the needle deviated a whole degree. But the sea appeared suddenly covered with grass, and again showed symptoms of shoals and rocks. Numbers of birds were also seen. Columbus sailed in the direction from which they flew. For some days the voyage was continued with revived courage, until at last the dissatisfaction of the crews began to break out into open violence; but Columbus, after endeavoring in vain to pacify his men by promises, finally assumed a different tone, and told them it was useless to murmur; that he was determined to persevere. Fully convinced that he must be near the land, he promised a reward to whosoever should first discover it. On the night of 11 and 12 October Columbus himself descried a light which sometimes flickered in the distance and sometimes disappeared, and at two o'clock on the morning of the 12th a cannon shot from the *Pinta* announced that a sailor belonging to that vessel had discovered land.

It was the island of Guanahani, which Columbus believed to belong to eastern Asia and to be connected with India, a belief which he carried with him to his grave. Hence the mistaken names of Indians applied to the natives of America, and that of West Indies applied to the group of islands of which Guanahani forms one. On landing Columbus threw himself upon his knees and kissed the earth, returning thanks to God. The natives collected round him in silent astonishment, and his men, ashamed of their disobedience and distrust, threw themselves at his feet, begging his forgiveness. Columbus, drawing his sword, planted the royal standard, and in the name of his sovereigns took possession of the country, which, in memory of his preservation, he called Saint Salvador. He then received the homage of his followers, as admiral and viceroy, and representative of the sovereigns. Being informed by the natives that there was a rich gold country toward the south, Columbus directed his course toward that region, and reached Cuba on 28 October, and Española (Hispaniola, Hayti), on 6 December; but as one of his vessels was wrecked, and the other separated from him, he resolved to carry the news of his success to Spain. Having built a wooden fort from the wreck of his vessel, he left in it 39 volunteers, and set out on his return, 4 Jan. 1493. The day after he left the island he met the *Pinta*, which had been missing. Both vessels were afterward nearly wrecked in a tremendous storm. Columbus, more interested for his discovery than for himself wrote an account of his voyage on a piece of parchment, which he secured in a cask, and threw the whole overboard, in the hope that it might be carried ashore. He had hardly finished his work when the gale subsided. On 15 March he re-entered the port of Palos amid the acclamations of the people, the thunder of cannon, and the ringing of bells. He hastened immediately to Barcelona, where the court then was, and entered the city in a triumphal procession, with the productions of the newly discovered countries carried before him. A chair was placed for him next to the throne, and, seating himself, he gave an account of his discoveries. He was created a grandee, and all the marks of royal favor were lavished upon him.

On 25 Sept. 1493, he set sail from Cadiz with 3 large ships of heavy burden and 14 caravels, carrying 1,500 men. On 3 November he discovered the island of Dominica, and afterward Mariegalante, Guadeloupe, and Porto Rico, and on the 22d arrived at Hispaniola. Finding the colony he had left destroyed, he built a fortified town, which he called, in honor of the queen, Isabella, and of which he appointed his brother Diego governor. He immediately left the island in order to make new discoveries, visited Jamaica, and returning after a voyage of five months, worn down with fatigue, found to his great joy that his brother Bartolommeo, who had escaped from his captivity, had arrived at Isabella with provisions and other supplies for the colony. Meanwhile a general dissatisfaction had broken out among his companions, who, instead of the expected treasures, had found hardships and labor. They set on foot many calumnies, and gave the most unfavorable description of the country and the viceroy. Columbus thought he could not better oppose these reports than by sending considerable treasures to his sovereigns, and for this purpose collected gold from the natives, which was not done without violence and some cruelty. Aguado, a personal enemy of Columbus, was sent as commissioner to investigate the complaints against the great discoverer, who, thinking it time to vindicate himself in the presence of his sovereigns, prepared to return to Spain. Having appointed his brother Bartolommeo adelantado or lieutenant-governor, he embarked for Spain in March 1496 with 225 Spaniards and 30 natives. In Spain calumny was silenced by his presence, and probably still more by his treasures. Yet his enemies were powerful enough to detain the supplies intended for the colony a whole year, and to retard the fitting out of a new expedition.

It was not till 30 May 1498, that he sailed with six vessels on his third voyage. To man these vessels criminals had unwisely been taken—a measure which Columbus himself had advised, and which had been taken up with great satisfaction by his enemies. Three of his vessels he sent direct to Hispaniola; with the three others he took a more southerly direction, for the purpose of discovering the mainland, which information derived from the natives induced him to suppose lay to the south of his former discoveries. He visited Trinidad and the continent of America, the coasts of Paria and Cumana, and returned to Hispaniola, convinced that he had reached a continent. His colony had been removed from Isabella, according to his orders, to the other side of the island, and a new fortress erected called St. Domingo. Columbus found the colony in a state of confusion. After having restored tranquillity by his prudent measures, in order to supply the deficiency of laborers he distributed the land and the inhabitants, subjecting the latter to the arbitrary will of their masters, and thus laying the foundation of that system of slavery which has lasted down to our time. His enemies, in the meantime, endeavored to convince his sovereigns that he had abused his power, and that his plan was to make himself independent, till at last even Isabella yielded to the wishes of Ferdinand, who had previously become convinced of the truth of the slanders. Francisco de Bobadilla was sent to Hispaniola with extensive powers to

COLUMBUS

call the viceroy to account. As soon as he reached the island he summoned Columbus to appear before him and put him in irons. His brothers were treated in the same manner. All three were sent to Spain, accompanied by a number of written charges, drawn up from the statements of the bitterest enemies of Columbus. Columbus endured this outrage with noble equanimity, and wrote, as soon as he had arrived in Cadiz, 25 Nov. 1500, to a lady of the court vindicating his conduct, and describing in eloquent and touching language the treatment he had received. The fetters with which he had been bound he kept to the day of his death, and his son Hernando states that he even ordered that they should be enclosed with him in his coffin. Orders were immediately sent directing him to be set at liberty, and inviting him to court, where his sovereigns received him with the same distinction as formerly. Isabella was moved to tears, and Columbus, overcome by his long-suppressed feelings, threw himself upon his knees, and for some time could not utter a word for the violence of his tears and sobbings. He then defended himself by a simple account of his conduct, and was re-instated to his dignities. Ferdinand even consented to dismiss Bobadilla, which was intended for the first step toward the promised restoration of the great discoverer in his dignities. But these dispositions in the monarchs were soon changed. There was much talk of great expeditions, and in the meantime Nicolas de Ovando y Lares was sent as governor to Hispaniola. Columbus still urged the fulfilment of the promises solemnly made to him; but after two years of delay he became convinced that there was no intention to do him justice.

But he had now learned to suffer, and he was principally desirous of completing his work. Supposing the continent which he had seen to be Asia, he did not doubt that he should find, through the Isthmus of Darien, a way to the East Indies, from which the first fleet of the Portuguese had just returned richly laden. In four slender vessels supplied by the court for this purpose Columbus sailed from Cadiz on his fourth and last voyage 9 May 1502, with his brother Bartolommeo and his son Hernando; arrived contrary to his original intention off St. Domingo 29 June, and was denied permission to enter the port for the purpose of refitting his vessels, and escaping an approaching storm. He succeeded, however, in anchoring his small squadron in a place of safety, and rode out the storm, while a fleet of 18 vessels, which had put to sea in spite of his warning, was almost entirely destroyed. He then continued his voyage to Darien, but without finding the expected passage. Two of his vessels were destroyed by a gale; the two others were wrecked off Jamaica, where he was scarcely able to save himself and his companions. Here the severest trials awaited the constancy of Columbus. Separated from the other part of the world, his destruction seemed to be certain. But he succeeded in procuring a few canoes from the natives, and prevailed on some of his boldest and best men to attempt a voyage to Hispaniola, in two canoes, in order to inform the governor of his situation. Several months elapsed without a glimpse of hope. Part of his companions, reduced to despair, rebelled, repeatedly threatened his life, separated from him, and settled

on another part of the island. Here they alienated the minds of the natives by their cruel treatment, so much that they ceased to bring them supplies. The death of all seemed inevitable; but Columbus, whose courage rose with the danger, preserved his men in this crisis. He had ascertained that a total eclipse of the moon was about to take place, and threatened the natives with the vengeance of his God if they should persist in their enmity. As a proof of his assertion the moon, he said, would lose its light, in token of the chastisement which awaited them. When they beheld his threat verified they hastened to bring him provisions, and implore his intercession with the Deity. But hostilities now broke out between him and the rebels, in which several of the latter were killed, and their leader was taken prisoner. After remaining a year on the island, relief at last appeared. The two canoes had reached Hispaniola in safety, but the messengers could not prevail on the governor to undertake the deliverance of the admiral. They finally bought a vessel themselves, and it was on board this ship that Columbus left Jamaica 28 June 1504. He went to St. Domingo, but only to repair his vessel, and then hastened back to Spain. He arrived in Spain ill and exhausted. The death of the queen soon followed, and he urged in vain on Ferdinand the fulfilment of his contract. After two years of illness, humiliations, and despondency, Columbus died at Valladolid. His remains were transported, according to his will, to the city of St. Domingo, but on the cession of Hispaniola to the French, they were removed in January 1796 with great pomp, to the Cathedral of Havana in Cuba. A splendid monument was erected to him, in a convent at Seville, where his body lay before being transferred to St. Domingo. In 1898 his remains were again removed to Spain, Cuba being no longer a Spanish possession since the war with the United States.

In the vigor of manhood Columbus was of an engaging presence, tall, well formed, and muscular, and of an elevated and dignified demeanor. His visage was long, his nose aquiline, his eyes light gray, and apt to enkindle. His whole countenance had an air of authority. Care and trouble had turned his hair white at thirty years of age. He was moderate and simple in diet and apparel, eloquent in discourse, engaging and affable with strangers, and of great amiability and suavity in domestic life. His temper was naturally irritable, but he subdued it by the benevolence and generosity of his heart. Throughout his life he was noted for a strict attention to the offices of religion; nor did his piety consist in mere forms, but partook of that lofty and solemn enthusiasm with which his whole character was strongly tinged. Of a great and inventive genius, a lofty and noble ambition, his conduct was characterized by the grandeur of his views and the magnanimity of his spirit. For further information respecting the life of Columbus various authorities are available to the inquirer. His son Ferdinand wrote a memoir, but the original is lost, though an early Italian version exists which has been translated into English and other languages. His own journal of his first voyage may also be read in English, both it and Major's 'Select Letters of Columbus' being published by the Hakluyt Society.

COLUMBUS

Bibliography.—Irving, 'History of the Life and Voyages of Columbus'; Winsor, 'Christopher Columbus' (1891); Fiske, 'The Discovery of America' (1891); Payne, 'History of the New World' (Vol. I. 1892); Markham, 'Christopher Columbus' (1892); Adams, 'Christopher Columbus' (1891); Harisse, 'Christoph Colomb' (1884); Cronau, 'Amerika: Seine Entdeckung' (1891-2); Thacher, 'Christopher Columbus' (1903); Prescott, 'Ferdinand and Isabella' (1838); Roselly de Lorques, 'Christophe Colombe' (1856).

Columbus, Diego, *dē-ā'gō* (It. Giacomo Colombojē), Italian voyager: b. Genoa about 1450; d. after 1509. He was a brother of Christopher Columbus, whom he accompanied on the second voyage to America, in 1493. He was sometimes left in command at the settlements of Isabella and Santo Domingo and returning to Spain in 1500, subsequently entered the priesthood.

Columbus, Diego (Sp. Colon, *kō-lōn'*): b. probably at Lisbon about 1476; d. Montalvan, near Toledo, Spain, 23 Feb. 1526. He was a son of Christopher Columbus (q.v.), and from 1492 till his father's death was a page at the Spanish court. He was confirmed admiral of the Indies and governor of Hispaniola in 1509, where he ruled with great pomp and splendor, but his opponents in the New World succeeded in curtailing his powers and he was recalled to Spain.

Columbus, Ferdinand (Sp. Ferdinando Colon, *fēr-dē-nān'dō kō-lōn'*), Spanish voyager: b. Cordova, Spain, 15 Aug. 1488; d. Seville 12 July 1539. He was a son of Christopher Columbus, whom he accompanied on his father's fourth voyage 1502-4. His library of 20,000 books was bequeathed to the cathedral chapter of Seville and was known as the "Columbina." But 4,000 of these now remain and the history of the Indies by him is also lost as well as the original Spanish of his life of his father, largely drawn upon by Las Casas. This is the basis of the majority of the lives of Columbus.

Columbus, Luis, *loo-ēs'* (Sp. Colon), Spanish noble: b. Santo Domingo 1521 or 1522; d. Oran, Africa, 3 Feb. 1572. He was a son of Diego Columbus 2d (q.v.), and a grandson of Christopher Columbus. He was given the title of admiral of the Indies, but in 1530 was obliged to relinquish the title of viceroy, receiving in exchange the island of Jamaica, an estate 25 leagues square in Veragua, a pension of 10,000 ducats and the titles of Duke of Veragua and Marquis of Jamaica. He was captain-general of Hispaniola 1542-51. Arrested in 1559 for having three wives, he was imprisoned for three years and then banished to Africa. Felipa, his daughter married her cousin, Diego, who then became Duke of Veragua, but dying childless in 1518 the family of Columbus then became extinct in the male line. The present Duke of Veragua (b. 1837), traces his descent from Columbus through Diego, Cristoval, Diego's son, and Francesca, the daughter of Cristoval and sister of Diego Columbus, who died in 1578.

Columbus, Ga., a city and county-seat of Muscogee County, situated on the east bank of the Chattahoochee River, at the head of navigation, and on the Central of Ga., the Southern,

the Seaboard A. L., and the Georgia F. & A. R.R.'s. It is also connected with Appalachicola, Fla., by three steamer lines. Columbus is in the centre of a fertile cotton and agricultural producing region, and near forests of conifers and hardwood, and deposits of coal and iron. It is also at the foot of the "Piedmont" region, where the rock ledges of the older geological formations give place to the coast plain; hence the Chattahoochee falls sharply for many miles over its rock bed to its new levels and deeper water, affording an immense head of power,—115 feet fall, with 42,500 horse-power, at average low water, within a mile of Columbus, and 368 feet with 134,000 net horse-power within 36 miles. Three large companies (the Columbus Power Company, the Coweta Company, and the Chattahoochee Falls Company) are making this power available by a series of dams, transmitting electric power from dynamos. Two great dams nearly 1,000 feet long, developing 28,866 horse-power, are already built; and five others, one with a fall of 52 feet, and all developing over 70,000 horse-power, are announced within a year or so. The Coweta Company owns 12 miles of river front to the north. This power implies a great future extension of industries; but the cotton manufacture is already so extensive as to give the city the name of "the Lowell of the South." There are now six large mills here, operating 154,000 spindles and 4,400 looms, employing about 4,000 hands, paying nearly \$1,000,000 a year in wages, and using toward 50,000 bales of cotton a year. The great Eagle and Phoenix mills were the pioneers of large manufacture; the Coweta Company has a mill of 35,000 spindles and a village (Bibb) of its own; the North Highlands mills represent an investment of \$500,000, and are second in the South in equipment and arrangement. There are also two cotton compressors and ginning works, among the largest in the South; cotton-seed oil mills, etc. Next to this, and equally old, is the iron industry, with two great concerns; the Columbus Iron Works, dating from 1853, which with their department, the Southern Plow Company, cover six acres, and are to be the largest in the South; and the Goldens Foundry and Machine Company. These manufacture all kinds of agricultural implements, cotton screws and compressors, engines and boilers, etc. One of the largest syrup and sugar refining works in the South has lately been erected; there are also a large wagon factory, a barrel factory, three show-case works, grist mills, etc. The trade of the city is large; it is the distributing centre of all southwest Georgia and a considerable part of central Georgia and Alabama. There are five cotton warehouses, and the total receipts of cotton are about 165,000 bales a year.

The city has broad handsome streets, which in the original plan were intended to be boulevards with parks down the centre. Steps are being taken to carry out the design. The business streets are being paved, and 35 miles of macadam roads are completed. There is an electric street railway system, and the city is connected with its suburb, Girard, Ala., by a bridge, which is crossed by the Central R.R. of Ga. There are some fine buildings, and the number is rapidly on the increase. The \$60,000 passenger station of the Central of Georgia is one; the Masonic Temple is one of the finest in

COLUMBUS

the South, and the Odd Fellows have planned an equal; the new Y. M. C. A. building, faced with the finest Georgia marble, is to be one of the most beautiful in the Southern States; and several of its 23 churches, embracing all denominations, are excellent specimens of architecture. The school system is justly famed: Columbus was the first city in the South to adopt graded schools and manual training. It has five large modern school buildings, and the system includes not only free kindergartens and a night school, but a primary industrial school for the children of the poorer wage-earners, with a unique provision for "little dinner carriers" (children carrying dinner to parents at work), regulating the hours to give them a longer nooning. The improvement of the condition of cotton-mill workers (all of the "poor white" class) has engaged the attention of the owners, who have not only provided excellent modern villages for them, but schools and other elevating influences. The Columbus Power Company proposes to build and partly maintain at Bibb a superior school for the operatives' children; and the Eagle and Phoenix Club for employees is a building with library, gymnasium, and all forms of amusement, built by the company, and then given over to the absolute control of the hands. There is also a public library in the city. The city government is by a mayor, elected for two years, and a council, elected on general ticket, the council appointing the other city officers.

History.—Columbus was laid out in 1828, on land taken partly from an Indian reservation. As early as 1845 it had a cotton mill and was a centre of the cotton trade; in 1846 it was nearly destroyed by fire. In 1853 the first iron foundry was built there. During the Civil War it was the reliance of the Southern armies for their clothing, shot and shell, and swords. In its streets and those of Girard was fought the last battle of the War east of the Mississippi, when on 16 April 1865 Wilson captured it. Pop. (1870) 7,401; (1880) 10,123; (1890) 17,303; (1900) 17,604 (10,337 whites); (1903) including suburbs, about 30,000.

Columbus, Ind., a city and county-seat of Bartholomew County, in the southern central part of the State, situated on a fork of the White River and on the Cleveland, C. Ch. & St. L. and the Pittsburg, C. Ch. & St. L. R.R.'s. It has large manufactories of cerealine, agricultural implements, and furniture, and starch- and flour-mills. Pop. (1900) 8,130.

Columbus, Kan., the county-seat of Cherokee County, in the southeastern part of the State, situated on the Kansas City, Ft. S. & M. and the St. Louis & S. F. R.R.'s. It is in an agricultural and mining district, coal and zinc being found in the neighborhood. Pop. (1900) 2,310.

Columbus, Miss., a city and county-seat of Lowndes County, situated on the Tombigbee River and on the Mobile & O. and the Southern R.R.'s., 150 miles southeast of Memphis and the same distance northeast of Jackson. It is the farming trade centre of the country, and has a large cotton-mill, machine shops and lumber-mills. It is the seat of the State Industrial Institute and College for girls and of Franklin Academy. Pop. (1900) 6,484.

Columbus, Neb., the county-seat of Platte County, in the eastern part of the State,

situated on the Loup River, near the Platte, and on the Union Pacific and the Burlington & M. R.R.'s. It has various manufacturing interests and is the seat of a Roman Catholic academy. Pop. (1900) 3,522.

Columbus, Ohio, the capital of the State and the county-seat of Franklin County, is located at the centre of the State and at the junction of the Scioto and Olentangy rivers, in lat. 39° 57' N., lon. 83° 3' W., on a slightly elevated alluvial plain, and is nearly equidistant from Cincinnati, southwest; Cleveland, northeast; Toledo, northwest; and Marietta, southeast, the average distance from these points being 115 miles.

Columbus was made the capital by the legislature in 1810, and became the permanent capital in 1816, the original Territorial and State capital having been Chillicothe. The first State buildings were of brick, and cost \$85,000. The present massive buildings and additions are of dressed native gray limestone, in the Doric style of architecture. They cover nearly three acres, and their total cost has been \$2,500,000.

As early as 1812 Columbus was surveyed in rectangular squares; it was incorporated as a village in 1816, and chartered as a city in 1834. In general outline the city resembles a Maltese cross. It extends eight miles north and south, and seven miles east and west on its arms of expansion. Its longest streets, High and Broad, bisect the city north and south and east and west respectively. The uniform width of the former is 100 feet, and the breadth of the latter is 120 feet. Broad Street is planted with four rows of shade-trees for its entire length east of the capitol square, where it penetrates the fashionable residence district. High Street is the leading business thoroughfare. Capitol square, a miniature park of 10 acres, is situated at the intersection of these streets, two squares east of the Scioto River. The residence portions of the city contain many beautiful homes and fine mansions. There are numerous apartment buildings; the houses of the average people are substantial and comfortable; the tenement districts are but ordinary of their class. On the business streets are many handsome, commodious blocks; many steel, brick, and stone office buildings from 8 to 14 stories high, as well as commodious railway buildings and stations. The streets are wide, well paved and lighted, and are kept in good condition.

The police and fire departments are excellent; the water supply is pure and ample, and the sewerage system good. Natural gas is the principal fuel for domestic use. Bituminous coal, in unlimited quantities, is found a few miles south.

The 40 or more church buildings of Columbus include those of the following religious denominations: Methodist Episcopal, United Presbyterian, Roman Catholic, Lutheran, Baptist, Disciples, Friends, Christian Scientist, Evangelical Jewish, Independent German Protestant, German Evangelical Protestant, African Methodist Episcopal, Seventh Day Adventists, and United Brethren. These churches have a total active church membership of 75,000. The newspapers and periodicals include four English and two German dailies, 21 secular weeklies, and 33 trade, professional, religious, fraternal, and other publications. There are 38 large public school

COLUMBUS, OHIO.

State Capitol (upper).

Looking North on East Broad Street (lower).

COLUMBUS — COLUMN

buildings, four being devoted to high school purposes. The schools have an average attendance of 18,500, the high schools having 2,300. Among institutions for higher education are the Ohio State University, Capital City University, and St. Mary's Academy. Professional schools include one dental and three medical colleges, and a law school; and there are also private and religious educational institutions. Here are 20 private hospitals; and Columbus is the location of a State hospital for the insane; State institutes for the education of deaf-mutes, blind, and imbecile youth; the Ohio Penitentiary; county, city, and memorial buildings; five opera houses; and a board of trade building. There are five public parks and a United States military post, Fort Columbus. This post, known also as Columbus Barracks, was originally an arsenal, and now has quarters for eight companies of infantry.

From Columbus 18 steam railroads radiate to all parts of the State, intersecting all through lines running east, west, northwest, northeast, and south; and eight interurban lines in operation, and as many more nearing completion, connect with a model street-railway system. Prominent business interests of the city are represented by 6 national and 20 private banks, trust companies, savings and building and loan associations, with a combined capital of \$25,000,000. There are 289 great and small manufacturing establishments, representing an investment of \$35,000,000, including steel plants, blast-furnaces, malleable iron works, and manufactories of various steel, iron, and wood products, beer and liquors, trucks, cars, cash registers, watches, furniture, agricultural implements, mine, mill, and farm supplies, shoes, cloth fabrics, gloves, hosiery, clothing, medicines, buggies, wagons and all kinds of vehicles, automobiles, novelties, specialties, and general merchandise, with an annual output approximating in value \$105,000,000. The mercantile trade is extensive, including all lines, and embracing 23 wholesale and hundreds of retail establishments.

The people of Columbus possess the characteristic push and enterprise of Western cities, and much of the culture and artistic taste of those in the East. The population is drawn from all the counties in the State, especially the 45 which are centrally located. Two thirds of the population are native-born. The largest foreign elements are German, Irish, Welsh, English, and Italian, in this order, and include scattered groups and individuals from almost every civilized and semi-civilized country in the world. Since 1880, when it had 41,215 inhabitants, Columbus has grown rapidly. In 1900 it had a population of 125,560, and that number has increased, according to the estimate of 1903, to about 150,000.

WILLIAM ALEXANDER TAYLOR.

Columbus, Texas, the county-seat of Colorado County, situated on the Colorado River and on the Southern P. R.R. Its chief industry is its cotton trade. It is the seat of Colorado College. Pop. (1900) 1,824.

Columbus Barracks. See COLUMBUS, OHIO.

Columella, kōl-ū-mēl'la, **Lucius Junius Moderatus**, Roman practical writer on agriculture: b. Cadiz, Spain. He flourished about the middle of the 1st century, and wrote 12 books on gardening ('De Re Rustica'), one of

which was a metrical combination of the Georgics of Vergil. He treats in this work of all the branches of agriculture. The earlier editions of this work contain also his treatise 'De Arboribus,' in one book. According to Pliny, Columella wrote a work on ancient sacrifices for obtaining the fruits of the earth, but this is lost. The *editio princeps*, printed in folio by Jenson at Venice, in 1472, and forming part of a collection of 'Rei Rusticæ Scriptores varii,' is very rare. The most complete edition is contained in the 'Scriptores Rei Rusticæ' of Schneider (1794-7).

Column (Latin, *columna*), in architecture, a round pillar. In the earliest times the column was merely a tree-trunk, or its imitation in stone, used to support the roof. The parts of a complete column are its base, on which it rests; its body, called the shaft; and its head, called the capital. Columns are used to support the entablature of an order, which has also its proper division. In the most ancient times columns of wood were most usual, as being most easily wrought. In countries like Egypt, where timber fit for construction is scarce and stone abundant, the latter became the principal material for columns, and those of Egypt are remarkable for the beauty of their workmanship and the durability of their materials. The Egyptian columns were numerous, close, short, and very large. They were generally without bases, and had a great variety of capitals, from a simple square block ornamented with hieroglyphics, or faces, to an elaborate composition of palm leaves, not unlike the Corinthian capital. The Greeks, for their columns, used marble of the finest kind, with which their country abounded; and other nations the stone or material of their country. The Greeks considered the column as an essential part of the architecture of their temples, and never used it as a mere decoration.

The manner of constructing the columns of all the orders rests on similar principles. They are all divided into three primary parts or divisions, the base, the shaft, and the capital, except the Doric order, which has no base. The lowest or thickest part of the shaft is used by architects as the universal scale or standard whence all the measures which regulate and determine heights and projections are taken; and this standard or scale must be understood before any architectural design can be commenced. The universal architectural scale is called a diameter, and is the diameter of the lowest or the largest part of the column; and, unlike the foot, inch, or yard, is as various as the size of columns. By the diameter, of course, is meant that of the circle which forms the bottom of the column. Half of this diameter, or the length of the radius which forms the circle, is called a module, and is used as well as the diameter as a primary standard of mensuration by some writers upon architecture. These measures of length are subdivided as follows, namely: the diameter into 60 parts, and the module into 30 parts, called a minute. The Doric column has no base. The Ionic column has one peculiar to itself called the Attic, which, with that of the Corinthian order, is described under the article ARCHITECTURE.

The shafts of the different orders differ in height and even in various examples of the same order. The capitals also are as various. Col-

COLUMN — COLVILLE

umns are either plain or fluted, and the flutes and manner of dividing them are different in the Doric and Corinthian orders. The Ionic flutes much resemble the Corinthian, and in many instances are exactly similar. Columns of all the orders taper gradually toward the top, but in the middle there is sometimes a slight swelling called an entasis. Roman architecture being derived from the Greek, Roman columns were either exactly similar to Greek ones or modifications of the latter. The principal modifications of the column made by the Romans were that form of the Ionic capital in which there were four pairs of diagonal volutes instead of two pairs of parallel ones, and that peculiar to the Composite order, in which the capital of the Corinthian column was combined with that of the diagonal or modern Ionic.

Columns are also often used for commemorative purposes as well as for architectural supports; like the Trajan and Antonine columns in Rome, and that called the Monument in London, which was erected in commemoration of the great conflagration of 1666, and is one of the loftiest, the best constructed, and the most beautiful. It is a Doric fluted column, 202 feet high from the bottom of the pedestal, which is ornamented with bas-reliefs of Charles II. and his court giving protection to the fallen city, and various inscriptions, to the top of the vase of flames, by which it is surmounted.

Column, in military tactics, a deep, solid mass of troops, formed by placing several bodies of men one behind another (sections, platoons, companies, squadrons, and even several battalions). The column is either open or close. When a battalion is formed in open column, room enough is left between the companies for them to wheel into line. When the distance left between the companies is very small, the battalion is said to be formed in close column. When the distance is intermediate between that in close and that in open column, it is said to be formed either for marching or for attack. On the march and in manœuvring the arrangement of troops in column is general and convenient, and this order is usually kept up till the actual fighting is about to begin; but it is as a rule unsafe to expose troops in column to the firearms of the present day. This formation consequently is retained in combat only when time and space do not allow of any other being adopted, or for some other special reason.

By dividing a large force into columns it becomes possible to march in places where it would be impracticable to move with unbroken lines. They also increase the force and steadiness of troops, both in attack and defense. The drawing up of the infantry in line is usually advisable where there is no obstacle in the ground to prevent advancing in this order. The order in mass may be preferred where a charge is intended, in which physical force, given by the depth of the column, is necessary and also where a charge, particularly of cavalry, is apprehended. Though a cannon ball, and still more a shell, in the midst of the mass, causes a greater havoc, the probability of being hit is diminished on account of the small front exposed.

An objection to columns, founded on the difficulty of moving so dense a mass, and of changing it into a line, has been removed in modern times by the practice of making the

columns consist of only one battalion, and by disposing these single battalions near each other in such a way as to support one another by their fire, instead of arranging them uselessly one directly behind another. By the usual way of forming the columns toward the centre, those have received such a mobility and facility of development that a line may be restored in two or three minutes. The charge in close columns, which has been especially common among the French, is of the greatest effect when it succeeds; but when it fails the whole body of assailants is exposed to annihilation or to rout, no orderly retreat being possible. The attack with columns at some distance from each other has this advantage, that the facility of manœuvring is much greater. This mode of attack has been frequently employed in assulting squares of infantry. Marching and fighting in lines, however, are the modes usually practised by cavalry. Column roads are such roads as may be passed with all kinds of arms; when the ordinary road is ruined, they are laid out across the fields and marked by poles with straw (*jalons*).

Column of July, a monument erected in Paris in 1840, on the site of the old Bastille in honor of the citizens killed in the revolution of 1830. It is a shaft of bronze on a marble base, capped with a gilded statue of the Genius of Liberty. It is 154 feet high and 13 feet in diameter.

Column of Saint Mark. See VENICE.

Column of Trajan, a monument erected in Rome in 114 A.D. in honor of the emperor. It is a Roman Doric column of white marble of 34 blocks, 23 composing the shaft, on which is carved representations of various scenes in Trajan's campaigns, containing 2,500 figures of men, each about two feet in height. The quadrilateral pedestal bears an inscription which can easily be read. It is 127½ feet high, exclusive of the statue of St. Peter, which now stands on the apex of the column, having taken the place of the colossal figure of Trajan in 1587.

Column Vendome, vōñ-dōm, a monument erected in the Place de Vendome, Paris, by Napoleon I., to commemorate the victories of the Grand Army over the Russians and Austrians in 1805. It is similar in design and ornamentation to the Column of Trajan, but is built of masonry encased in bronze taken from 1,200 captured guns, and capped by the statue of Napoleon. It is 142 feet high and 13 feet in diameter. It was overthrown in 1871 during the Commune but was restored in 1875.

Colure, kō-lūr', one of two imaginary great circles of the celestial sphere passing through the celestial poles; one passing through the equinoctial points of Aries and Libra and the pole of the equator; and the other through the solstitial points of Cancer and Capricorn, and the poles both of the ecliptic and equator. For this reason the first is called the equinoctial, and the second the solstitial colure. The name, meaning "docked" or "dock-tailed," is now rarely used; it was originally applied because a portion of these circles is always concealed under the horizon.

Col'ville, SIR Henry, English general: b. 10 July 1852. He was educated at Eton and entered the grenadier service in 1870. He

COLVIN — COMANCHE

served in Egypt, the Sudan, Uganda, and elsewhere, was knighted in 1885, and in 1897 was promoted major-general. He has published: 'A Ride in Petticoats and Slippers' (1879); 'The Accursed Land' (1884); 'History of the Sudan Campaign' (1887); 'The Land of the Nile Springs' (1895); 'The Work of the Ninth Division' (1901).

Colvin, kōl'vīn, Sidney, English critic: b. Norwood, Eng., 18 June 1845. He was professor of fine arts at Cambridge 1873-5, since when he has been keeper of prints and drawings at the British Museum. His writings include: 'Children in Italian and English Design' (1872); 'Life of Walter Savage Landor' (1881); 'Life of Keats' (1887); 'A Florentine Picture and Chronicle' (1898); 'Early History of Engraving in England' (1901).

Col'well, Stephen, American lawyer and writer: b. Brooke County, Va., 25 March 1800; d. Philadelphia 15 Jan. 1872. He graduated at Jefferson College, studied law, was admitted to the bar, and practised for some years in Pittsburgh. About 1830 he removed to Philadelphia, became an iron merchant, and amassed a fortune. He early developed a fondness for the study of finance, political economy, and social science, and frequently published the results of his studies on questions of current interest or debate. During the Civil War he aided the administration with pen, purse, and voice, and was a liberal supporter of the work of the sanitary commission. He was appointed by the government one of the commissioners to examine the whole internal revenue system and suggest improvements. He left his large and valuable library of works on political and social science to the University of Pennsylvania, where he also endowed a professorship of social science. Of his writings the following may be mentioned: 'Relative Position in Our Industry of Foreign Commerce, Domestic Production, and Internal Trade' (1850); 'New Themes for the Protestant Clergy' (1851); 'The South; . . . Effects of Disunion on Slavery' (1856); 'Ways and Means of Commercial Payment' (1858), his last and most important work.

Colymbidæ, kō-līm'bī-dē, a family of birds which includes the divers and grebes. See DIVER; GREBES.

Col'za Oil, or Rape Oil, an oil, familiar from its use as an illuminating agent in the moderator and other lamps, expressed from the seeds of several plants of the cabbage and turnip genus, the name being originally "kolzaad" (Dutch), that is kail- or cabbage-seed. It is yellowish brown, has a specific gravity of .92, and little or no smell, and dissolves in hot alcohol and in ether. It becomes thick and solid only at very low temperatures; when heated it volatilizes, but not completely, undergoing partial decomposition. It is purified for use by continued agitation with sulphuric acid, which destroys mucilaginous matter from the seed, and washing with water to remove all trace of the acid. The oil is largely used both in Great Britain and on the Continent in soap-making, tanning, fulling of cloth, lubricating machinery, and for burning. For the last it is so well adapted that it has been specially recommended for lighthouse purposes. It is brilliant and

steady, is managed with very little attention, and is cheap. In these respects it is said to be superior to spermaceti.

Coma, in medicine, a state of complete or almost complete insensibility, resulting from various diseases, as apoplexy; from narcotics, as opium; from accident or injury to the brain; or from excessive cold. In cases of coma the pulse is usually low and soft, but sometimes quick, the breathing is rarely stertorous, the pupils of the eyes are commonly more or less dilated, and the face is often swollen and livid. The patient is either altogether unconscious and incapable of replying to any question, or he makes incoherent and rambling statements. Stimulating agencies and blistering are sometimes used in the treatment of comatose cases, but generally the disease or injury producing the condition determines the remedy.

Coma Berenices, bër-ě-nī'sēz ("the Hair of Berenice"), a northern constellation, the name of which is due to the flattery of Alexandrine astronomers, who professed to see in the new constellation a lock of the beautiful hair of Berenice, wife of Ptolemy Euergetes. Callimachus in Greek and Catullus in Latin wrote poems descriptive of the apotheosis of the curl. Ptolemy did not introduce it into the *Almagest* as a distinct constellation, but called it *Plokamos* (Gr., "hair," or "curl"). Tycho Brahe restored it as a distinct constellation in his catalogue of 1602. It is formed of rather faint stars, none being brighter than the fourth magnitude. Baily, in the "B. A. C." in 1845, attached the first three letters of the Greek alphabet to three of the brighter stars. The constellation is surrounded by Ursa Major, Canes Venatici, Boötes, Virgo, and Leo.

Comacchio, kō-mä-chē'ō (ancient COMAC-TIUM, Italy, town in the province of Ferrara, in Emilia, about 20 miles north of Ravenna and 30 miles southeast of the city of Ferrara. The town is built on islands which are connected by bridges. The chief industries are fishing and manufacturing salt.

Coman, Katherine, American teacher: b. Ohio 1857. She has been professor of economics in Wellesley College (Mass.) since 1900. She has written: 'Growth of the English Nation' (1895); 'History of England' (1899); 'History of England for Beginners' (1901), and in collaboration with her colleague Katherine Lee Bates, 'English History Told by English Poets' (1902).

Comana, kō-mā'nā. 1. An ancient city of Cappadocia, supposed to be the modern Elbostan, on the river Sarus, celebrated in antiquity for its temple of Artemis Tauropolis, and for the great devotion of its inhabitants to the worship of that goddess. Over 6,000 persons were engaged in the service of the temple. The city was governed by the high priest, who was always a member of the reigning family, and took rank next to the king. 2. A city of Pontus, now Tokat, on the river Iris, and almost as famous for its devotion to Artemis as the other city of the same name.

Comanche, kō-män'chē (also **Camanche, Chouman, Comande**, a Spanish name; their own name is Nüm, "people"; the Sioux gave them one which the French turned into *Padouca*), a powerful and ferocious tribe of the

COMANCHE STAGE — COMBAT

widely distributed Shoshonean stock, speaking the same language as the Shoshoni of Wyoming, and traditionally their neighbors. When first made known to the whites by the French under Dutisné, they were located in eastern Colorado; they had already obtained horses from the Spaniards and become nomads and expert horsemen, and horse-breeders, for the French bought horses from them. In 1724 another French expedition made a treaty with them. They seem shortly after to have been pushed southward by the Sioux, and we find them later roving the plains of northwestern Texas, making plundering raids from Colorado through Texas, deep into Mexico, and westward to Santa Fe. They lived in skin wigwams, with few or no fixed villages except near the Spaniards, and were in eight bands, with a very loose organization. They probably numbered 5,000 warriors, and 25,000 in all, at their best estate; one village near the Spaniards had 800 warriors, and over 4,000 in all. They were at constant war, both with the Spaniards and the other Indian tribes, and in 1783 engaged in a wholesale war with the former; but Anza inflicted a crushing defeat on them, killing 30 of their chiefs, and there was peace for a time. In 1816 they are said to have lost 4,000 of their number by an epidemic of smallpox; but they were still estimated at 9,000; and in 1847 at 10,000 or 12,000, one fifth warriors. They recruited their numbers by kidnapping and adopting Mexican children, boys or girls. For all the years of immigration into those regions, down to 1875, they were the bloody and relentless scourge of the white settlers, and furnished a good part of the Indian horrors of the southwest. They were once placed on a reservation in Texas, but were driven off. In 1868 the bulk of them agreed to go on a reservation in western Oklahoma; but the Quahada or Staked Plain band refused, and kept up their murderous forays. They were sharply punished by Col. McKenzie at McClellan's Creek in 1872, in which year they were estimated at 3,218 on the reservation, with 1,000 more in roving bands. The last of these surrendered in 1875. In 1901 their reservation in Oklahoma was thrown open to settlement. At present they number about 1,400.

Comanche Stage, in American geology a great limestone formation of Lower Cretaceous age that covers much of northern Mexico, and parts of Texas, New Mexico, Indian Territory, and Kansas. The beds contain chalk in places and are mostly of marine origin. The thickness is 1,000 feet in central Texas and reaches a maximum of 20,000 feet in Mexico. See CRETACEOUS SYSTEM.

Comayagua, *kō-mä-yä'gwä*, or **Valladolid la Nueva**, Honduras, C. A., a town, capital of the department of the same name, situated on the southern border of the plain of Comayagua, on the Humuya River, 220 miles east of Guatemala. It is the seat of a bishopric, has a large and handsome cathedral, a richly endowed hospital, several convents, and a college. It was founded by Alonzo Caceres in 1540, and up to 1827 was a thriving place, with about 18,000 inhabitants. In that year, however, it was burned by the monarchical faction of Guatemala, and has never recovered. Pop. 3,100.

Comb (A.S. *camb*), an instrument to separate and adjust the hair, too well known to need description. We have no certain authority that either the Greek or the Etruscan women applied this useful article regularly to their hair in the operations of the toilet; although it was used by the Greek women, at least, to arrange their hair. The combs used by the Greeks were of boxwood, and had teeth on both sides, while those used by the Egyptians had teeth only on one side. The Romans also had combs of boxwood, and at a later time probably of ivory and other materials. In the work of Guasco Delle Ornatrici there are several representatives of ancient Roman combs. One of them is a long one of box, of which the handle is overlaid with ivory, and appears to have been ornamented with a small meander in gold. It has two rows of fine teeth, delicately wrought and well proportioned. In making combs the material is first cut to the form which the comb is to have, and the teeth are then made all at once by means of circular saws mounted on the same axle and placed at a suitable distance from one another. Large combs in horn or shell, with wide teeth, are sometimes made with a punch, which cuts in the piece the teeth of two combs by the same operation. The teeth are afterward finished with the file. Combs made of vulcanized india-rubber, which are now so common, are made by pressing the caoutchouc while soft into molds, and then bringing them to the desired degree of hardness by the process of vulcanization. Canova and other modern sculptors have made great use of the comb, placed in the heads of their women, to which they add much grace and elegance.

Comb, the wax cavities in which bees lodge their honey. The comb of a bee is composed of hexagonal cells, of which there are two tiers, the cells in which are placed end to end, so that the three plates of wax, which serve as the bottom of the cell in the one tier, constitute also that of the corresponding one in the other. The mathematical problem in "maxima and minima," how to construct the greatest number of cells within the smallest possible room, and with the least expenditure of material, is solved. This the natural theologians and the older naturalists were accustomed to adduce, as one of an infinite number of proofs, that design and a Designer were displayed in nature.

Combaconum, *kōm-ba-kō'nūm*, Madras, British India, town in the district of Tanjore. It is regarded by the Hindus as a place of peculiar sanctity, and is inhabited largely by the Brahmans. It contains numerous pagodas and tanks with water, supposed to come from the Ganges River. It is one of the strongholds of Brahmanism, but a considerable number of the inhabitants are Roman Catholics, and a Protestant mission has been successfully established. Pop. 54,307.

Combat, Single, a very ancient usage, evidenced by Goliath (1 Sam. xvii.), and by Ajax in the 'Iliad.' The Norse practice of principals going alone to a small holm or island, to be free from disturbance while settling their quarrels by strength and skill, gave rise to the Saxon term *Holm-Gang*. In the days of chivalry the single combat received the strong support of law and custom, and was resorted to both in civil and in criminal cases. The accuser

COMBE — COMBINATION

or plaintiff swore to the truth of his tale, the other gave him the lie, a gage of battle was thrown down and taken up, and they fought it out under rules before an assembly, the supposition being that God would give victory to the right. The barbarous practice survives in European countries, without its excuse of superstition, in the modern duel, which is legally prohibited in the United States. In England it was still a legal method of trial well into the 19th century, but was abolished by statute 59 George III., cap. 48.

Combe, kōm or koom, Andrew, Scottish physiologist: b. Edinburgh 27 Oct. 1797; d. there 9 Aug. 1847. He was educated for the medical profession, and in 1822 he commenced practice at Edinburgh, and had considerable success. In 1838 he was appointed one of the physicians extraordinary to the queen in Scotland. His chief works are: 'Observations on Mental Derangement' (1831); 'Principles of Physiology' (1834); 'Physiology of Digestion' (1836); 'A Treatise on the Physiological and Moral Management of Infancy' (1840). Like his brother George (q.v.), he was a zealous phrenologist.

Combe, George, Scottish phrenologist: b. Edinburgh 21 Oct. 1788; d. Moore Park, Surrey, 14 Aug. 1858. He was a brother of Andrew Combe (q.v.), was bred to the law, and in 1812 admitted a member of the Society of Writers to the Signet. He was the first to introduce the doctrines of phrenology into Great Britain; and visited Germany and America, lecturing on his favorite science. He was also a zealous promoter of the cause of popular education and social progress; and was among the first to advocate compulsory education and the establishment of a board of health. Besides the 'Constitution of Man' (1828), which has had an enormous circulation, he was the author of: 'A System of Phrenology' (1825); 'Lectures on Popular Education' (1833); 'Moral Philosophy' (1840); 'The Life and Correspondence of Dr. Andrew Combe' (1850); 'Principles of Criminal Legislation and Prison Discipline Investigated' (1854); 'Relation Between Science and Religion' (1857).

Combe, William, English writer: b. Bristol 1741; d. Lambeth 19 June 1823. His 'Tour of Dr. Syntax in Search of the Picturesque' (1812), was once very popular. Other works by him: 'The Diabolical,' a poem (1776); 'The Devil Upon Two Sticks in England' (1790). After 43 years within the rules of a debtor's prison, and previous fortunes from officer to cook, he died in Lambeth.

Combermere, kōm'- or kūm'bēr-mēr, SIR Stapleton Stapleton-Cotton, VISCOUNT, English general: b. Denbighshire 17 Nov. 1773; d. Clifton 21 Feb. 1865. He entered the army in 1790, served in Flanders and India, and with the rank of major-general accompanied the Duke of Wellington to the Peninsula in 1808. At Salamanca, in 1812, he headed the brilliant cavalry charge which greatly contributed to the decisiveness of that victory, and was subsequently present at the battles of the Pyrenees, Orthez, and Toulouse. Shortly after the last battle he was raised to the peerage with the title of Baron Combermere. From 1817 to 1820 he was governor of Barbadoes; and in 1825 was sent to India as commander-in-chief

of the forces there, to put down the usurper Doorjun Sal. After a siege of less than two months, Bhurtpore, the chief city of Doorjun, was taken by storm on 6 Feb. 1826, for which Combermere was raised to the rank of viscount. The remainder of his life was passed in England. In 1852 he was appointed constable of the tower; and in 1855 made a field-marshal.

Combes, koomz, Justin Louis Emile, French statesman: b. Roquecourbe, Tarn, France, 6 Sept. 1835. He was educated in a Roman Catholic seminary for the priesthood, but subsequently studied medicine, and began practice in Pons, where he filled various posts of responsibility, such as those of mayor and county councilor. In 1885 he was elected to the Senate, of which he was vice-president 1893-4, becoming minister of public instruction in 1895. He has been active in the re-organization of primary and secondary education. In June 1902 he succeeded Waldeck-Rousseau as President du Conseil des Ministres. In this capacity he has enforced the Association Act, abolishing liberty of teaching in France and aimed at the clergy. His opponents have claimed that this has been done with needless severity. It has caused widespread disturbances throughout the country. On his becoming prime minister M. Combes announced his intention to reduce the period of military service to two years, and to establish a general income tax.

Combination, in mathematics, the selection, from a given set of objects, of a stated number without regard to their arrangement. Each combination can, by varying the arrangement of the constituent objects, be made to give rise to several permutations. Thus, of the four letters, *a, b, c, d*, four combinations, three at a time, are possible; namely, *abc, abd, acd, bcd*. Each of these combinations, however, produces six permutations, according to the order of the letters. For example, the combination *abc* yields the six permutations *abc, acb, bca, bac, cab, cba*. Thus, of the four letters *a, b, c, d*, the number of permutations three at a time is 24. It is easy to prove that the number of permutations of *n* objects two at a time is $n(n-1)$; three at a time $n(n-1)(n-2)$; four at a time $n(n-1)(n-2)(n-3)$; and so on, the number when *r* at a time are taken being $n(n-1)(n-2).....(n-r+1)$. The number of permutations of *n* things *n* at a time is therefore $n(n-1)(n-2).....4, 3, 2, 1$, a product usually represented by $|n$ or $n!$, and read as "factorial *n*." The theory of permutations and combinations is of very great importance in higher mathematics, and may be studied in any text-book of algebra, such as those by Chrystal, Todhunter, and Smith.

Combination, a union of individuals, companies, or corporations formed for the purpose of accomplishing a particular object or purpose. At common-law combinations were unlawful, but in the United States a combination is not unlawful in itself, though it becomes so if it seeks to obtain its ends in an unlawful manner. Combinations may be divided into two general classes, those formed by employees or "labor," and those formed by employers or "capital." Combinations formed by employees, or labor, are generally designated unions. The

COMBUSTION

purpose of a union is to better the condition of its members in relation to the work in which they are engaged, by securing higher wages, less working hours, different methods of doing the work, and similar changes. A union generally tries to enforce its demands by striking, or threatening to strike. A strike is a combination effected by employees whereby at a pre-arranged time they all stop working unless their demands are granted. A strike is usually organized through a union.

A boycott is a combination to cause a loss to a particular person by restraining others from doing business with that person. It is often so conducted that the person is affected socially as well as in his business. When a boycott has been declared against a person, any one having either business or social relations with that person is also boycotted.

When the objects of such combinations are effected in a peaceful and lawful manner there is no legal means by which they can be interfered with; but it generally happens that when a number of working-people strike there is a breach of contract or a conspiracy, in which case there is a legal redress. The usual action is for the injured party to proceed in equity and ask for an injunction restraining the former employees from committing certain acts. Sometimes damages are asked for, and it makes no difference what the status is when the cause is heard, as damages can be recovered for acts committed during a strike, although the strike may have ended long before the demand for damages.

Combinations formed by employers, or capital, are usually known as trusts. Trusts are generally formed with the object of regulating the supply or price of a product, or both, or for the purpose of reducing expenses or competition.

It is very difficult to frame a law which will be effective against all the different arrangements under which a trust can do business. The State courts have no jurisdiction outside the limits of the State to which they belong, and it is very seldom that a trust would be formed whose business would be confined to any one State. The Federal government has passed several anti-trust laws, and up to the present time the most effective way of dealing with this class of combinations is by laws passed under the clause in the Federal Constitution (Art. I., § 8, cl. 3), which provides that Congress shall have power "to regulate commerce with foreign nations, and among the several States, and with the Indian tribes."

In recent years a great many combinations called trusts have been formed, and one of the most recent instances is that of the Northern Securities Company, which was decided by the United States circuit court of appeals in April 1903. In this case there were two parallel and competing railroad companies doing an interstate commerce business. These roads were controlled by a very few people, and they formed a corporation called the Northern Securities Company, which gave its stock in exchange for that of the competing railroads. The result was that the Northern Securities Company owned the two competing roads, and it naturally follows that the roads would be run as one line instead of, as formerly, competing lines. The court decided that the anti-trust

laws covered such a case, and granted an injunction, declaring that the stock of the Northern Pacific Railroad and the Great Northern Railway companies (the two competing roads), held by the Northern Securities Company, was acquired in view of a combination among the defendants in restraint of trade and commerce among the several States, such as the anti-trust law denounces as illegal, and restrained the Northern Securities Company from exercising any control over either of the parallel and competing railroads.

Combustion. In consequence of the combination of the carbon and hydrogen in fuel with the oxygen of the air being the universal method of getting heat and light, and as when the action takes place the fuel is said to burn or undergo combustion, the latter term has been extended to those cases in which other bodies than carbon—for example, phosphorus, sulphur, metals, etc.—burn in the air, or in other substances than air—for example, chlorine. It is therefore but a special case of chemical action which, partly on account of its frequency and importance, partly on account of its obviousness, has attracted greater attention than the more recondite but not less potent manifestations of the same force. It is besides of peculiar interest in the history of chemistry, because all along it was felt to be of great importance to understand in what combustibility actually consists. The older chemists ascribed to bodies a combustible principle which assumed different shapes at different epochs, but continued till Lavoisier, in the end of the 18th century, pointed out the part which oxygen gas performs in the combustion of a body. One result of this was that the idea of a combustible principle quickly disappeared from chemical theory, and there grew up in its place a separation of bodies into combustibles and supporters of combustion, which is still retained in common language. The distinction, however, is accidental, for, as it requires the concurrence of a member of both classes to produce burning, it is plain that each must be regarded as supporting the combustion of the other; and it is experimentally possible to reverse the ordinary conditions, and exhibit that body as the combustible which is usually defined as the supporter of combustion, and as a necessary consequence the other acting as the supporter, which is usually regarded as a combustible.

For many years subsequent to Lavoisier his views were dominant, but increase of facts led to most important modifications of them. By degrees, combustion and oxygen, which was the chief element concerned, have lost their theoretical predominance, and have merged in ideas which are not limited to one set of actions, but which will ultimately attempt to comprise all the manifestations of chemical action in a general theory. See HEAT; LAVOISIER; METAL; OXYGEN; PHLOGISTON.

Combustion, Spontaneous, the ignition of bodies by the internal development of heat without the application of an external flame. It not infrequently takes place among heaps of rags, cotton, and other substances strongly lubricated with oil, when, if the oil is freshly made, it is very ready to combine with the oxygen of the atmosphere and give out carbon and hydrogen. The heat thus developed, diffusing itself through

COMEDIÉ FRANCAISE — COMENIUS

a mass of highly inflammable substances, will in certain circumstances be sufficient to set them on fire. A remarkable instance of spontaneous combustion among hemp was afforded in June 1861, being the cause of the terrible conflagration in Tooley Street, London. Bituminous coal, piled up in heaps, is apt to ignite by the decomposition of the sulphuret of iron which it contains. In ships laden with coal impregnated with sulphur and iron in the form of bi-sulphuret of iron (pyrites), decomposition of this substance is sometimes occasioned by the access of moisture, and heat is evolved to such a degree as to cause the combustion of the coal, especially if air is admitted freely. Water poured upon the burning material only adds to the intensity of the action. The most singular instances, however, of spontaneous combustion are those of which human beings become the victims in their own persons—if we really can believe that such cases have occurred. Those whom it is alleged to have befallen have been individuals grossly addicted to intemperance, fat, and advanced in years. The chemical changes producing such a result are not well understood, and from the difficulties attending its explanation some eminent chemists, such as Liebig and others, have been led to reject the theory altogether as untenable, and maintain that none of the instances adduced are well authenticated. Among other hypotheses regarding the origin of this extraordinary phenomenon, it has been surmised to be owing to the development of phosphuretted hydrogen, which takes fire on coming into contact with atmospheric air, and might be formed and exhaled under certain conditions from the living body. The proximate cause of the ignition appears always to have been some burning substance, such as a candle, the fire, or a spark from a tobacco-pipe. The flame in cases of human combustion is described as having been of a bluish color, faint, and extinguished with difficulty by water. It is said to be the trunk which is first consumed, the extremities being the last to be destroyed. Dickens, in his 'Bleak House,' has introduced a gruesome case of spontaneous combustion.

Comédie Française, kō-mā-dē frān-sāz, the official name of the national theatre of France which is supported from public funds, for the purpose of advancing dramatic art. After Molière's death, in 1673, the rivalries existing between the two factions into which his company of actors had divided, caused the decree of Louis XIV. of 21 Oct. 1680, that made this a national institution. This decree has remained in force with but slight modifications down to the present.

Comédie Humaine, ü-mān, La, a series of novels by Balzac, so classified by their author, and intended to form a picture of the manners and morals of the period.

Comedietta, kō-mā-dī-ēt'ta, a dramatic composition of the comedy class, but not so much elaborated as a regular comedy, and generally consisting of one or at most two acts.

Comedones, kōm'ē-dōnz, a name applied to the little cylinders of sebaceous and epithelial substance which are apt to accumulate in the follicles of the skin and to appear on the surface as small round black spots. When squeezed out they have the appearance of mi-

nute maggots or grubs with black heads, and thence have derived their name. They are generally associated with a weak state of the skin as well as of the individual. Generous diet and tonic treatment with soap-and-water cleansing and friction will be useful; as an astringent to invigorate a debilitated skin, a lotion of corrosive sublimate (two grains) in emulsion of bitter almonds (one ounce) and dilute alcohol will be effective. See ACNE.

Com'edy, a dramatic representation of a light and amusing nature, in which are satirized pleasantly the weaknesses or manners of society and the ludicrous incidents of life. Comedy took its origin in the Dionysian festivals, with those who led the phallic songs of the band of revelers (Gr. *kōmos*) who, at the vintage festivals, gave expression to the exuberant joy and merriment by parading about, dressed up, and singing jovial songs in honor of Dionysus. These songs were frequently interspersed with extemporized jokes at the expense of the bystanders. Comedy first assumed a regular shape among the Dorians. The first attempts at it among the Athenians were made by Susarion, a native of Megara, about 578 B.C. Epicharmus first gave comedy a new form and introduced a regular plot. That branch of the Attic drama known as the Old Comedy begins properly with Cratinus. It lasted from 458 B.C. to 404 B.C. The later pieces of Aristophanes belong to the Middle Comedy. The chorus in a comedy consisted of 24. The Middle Comedy lasted from 404 B.C. to 340 B.C., and the New Comedy till 260 B.C. Middle Comedy found its materials in satirizing classes of people instead of individuals. New Comedy answers to the comedy of the present day. The most distinguished of Roman comic writers were Plautus and Terence, whose plots were mainly derived from the Greek. See DRAMA.

Comedy of Errors, The, a play by Shakespeare, first acted at Gray's Inn 28 Dec. 1594. It is one of the shortest of the Shakespearean plays, and one of the very earliest written. The main story is from the 'Menæchmi' of Plautus, and the plot turns upon a series of mistakes caused by the wonderful likeness between two sets of twin brothers: Antipholus of Ephesus and Antipholus of Syracuse, and their two servants, each named Dromio. In recent years two American actors, Robson and Crane, have frequently presented the play with great success, their roles being those of the two Dromios.

Comenius, kō-mē'nī-ūs (originally **Komensky**), **Johann** (yō hān) **Amos**, Moravian educational reformer: b. Nivnitz, Moravia, 28 March 1592; d. Amsterdam 15 Oct. 1671. In 1616 he received an appointment as teacher in Fulnek, on the plunder of which by the Spaniards after the battle of Prague, in 1620, he lost all that he possessed, including his books and manuscripts. He then went to Poland, where, in 1632, he was elected bishop of the Moravian and Bohemian Brethren in Lissa. In 1631 he published his 'Janua Linguarum reserata,' a work translated into many European languages, also into Persian, Arabian, and Mongolian. In this he laid down a new system for teaching languages to children by the use of visible signs in order to facilitate the learning of words. His 'Orbis Pictus,' or the 'Vis-

COMET

ible World,' an abridgment of the 'Janua Linguarum reserata,' with the addition of a large number of cuts, was published in 1657. In the latter part of his life he gave himself up to religious dreams, after the fashion of that time, and revered Bourignon as a prophetess. Comenius' place in the history of education is now generally recognized. Consult Laurie, 'John Amos Comenius' (1881); Payne, 'Lectures on the History of Education' (1892).

Comet (Greek, "hair," alluding to the luminous appendage or tail with which the brighter comets are always associated, and which formerly won for them the name of "hairy stars"). Comets may for convenience be divided into two classes, periodic and unexpected. From 2 to 3 of the former, and from 3 to 4 of the latter, appear on the average every year, but the number varies greatly. In 1898 as many as 10 were discovered, 5 being found in 12 days. Of the 10, 7 were unexpected.

Every comet, no matter how magnificent it may subsequently be, when first discovered, if remote from the sun, appears as a small, very faint, hazy ball. As it comes nearer it becomes brighter, and generally larger, although sometimes it contracts in size. If it is going to be a fine comet it gradually lengthens out, and develops a short tail. The tail rapidly brightens and lengthens as the comet approaches perihelion, as the point in its orbit is called when it is nearest the sun. If the earth is favorably situated the comet appears at its best a few days after the passage of perihelion, and then gradually fades out and disappears as it came. About one unexpected comet in five is visible to the naked eye. The periodic comets move in elliptical orbits about the sun in planes not in general greatly inclined to the ecliptic. The longest period so far definitely known, that of Halley's comet, is 76 years. The unexpected comets have still larger orbits, lying in all planes, with much longer periods. Many of them have a retrograde motion, and occasionally one visits the sun never again to return to it. When an unexpected comet arrives, its orbit is first computed from three observations made on different nights, on the assumption that it is moving in a parabolic orbit. If we are able to observe it through a long period we frequently find that its path differs slightly from a parabola. It is not likely that any comet moves in an exact parabola. If it moves a little slower than the parabolic velocity, its orbit is an ellipse, and the comet really becomes periodic, although it is not classed as such until it has been certainly identified at another return. If it moves a little faster than the parabolic velocity, its orbit is a hyperbola, and the comet will recede into space never to return.

Should a comet happen to pass near one of the larger planets, its orbit may be somewhat changed by the approach and its speed may be either increased or diminished. In this manner new members of the periodic class of comets are from time to time added to the list. On the other hand, its velocity may be so far accelerated as to change its orbit, or even drive it out of our system, never to return to it. In this way some of the members of our periodic family of comets are subject to change; others, however, have apparently come to stay for good. Out of 33 well-known periodic comets 24

have, or did have, periods lying between five and nine years. Many of these were doubtless brought into our system by the giant planet Jupiter. Some of them have already disappeared, owing to a change in their orbits, while some have lost a large part of their gaseous constituents and thus become invisible.

This last statement naturally brings us to the question, What is a comet? In early times they were supposed to be objects within our own atmosphere, presaging famines, wars, and the death of kings. It was first shown by Tycho Brahe that they were celestial bodies independent of the earth, and Newton proved that, excepting their tails, they were bodies subject to the law of gravitation. In the middle of the last century it was shown by H. A. Newton, Schiaparelli and others that our chief meteoric showers, those of 10 August and 14 November, were due to great swarms of meteoric bodies moving in elliptical orbits, practically coincident with the orbits of two well-known periodic comets, 1862, III. (Tuttle's), and 1866, I. (Tempel's).

In several instances two or more comets are known to be following practically the same path, and it was but a step from this to see that the head of a comet was only a concentrated swarm of meteors. It is only within the last few years, however, that we have begun to understand the nature of a comet's tail. That it is matter in a state of extreme tenuity is obvious, since, when millions of miles of it is interposed between us and the faintest stars, they are still visible and practically undimmed. What has puzzled astronomers since the time of Newton, however, is the fact that while all other bodies in the sidereal universe, as far as we are aware, obey the law of gravitation, comets' tails are clearly subject to some strong repulsive force, which drives the matter composing them away from the sun with enormously high velocities. The tail, therefore, always lies outside of the comet's orbit, being somewhat behind the comet when the latter is approaching the sun, and somewhat in advance of it when the comet is receding.

That the tail is gaseous is proved conclusively by the spectroscope, also that it is in an extremely rarified condition; but why the extremely small particles which constitute a gas should act in any way differently under the law of gravitation from the larger meteoric masses which constitute the head of the comet is not at first sight obvious. If, however, we consider the matter carefully, we shall see that if all objects are attracted to the sun in proportion to their mass, and repelled from it in proportion to their surface, then the attraction will vary as the cube of the diameter of the objects and the repulsion as the square. For objects of ordinary size the repulsion is so slight that we cannot detect it; but if the object becomes gradually smaller, the attraction of the mass will diminish much more rapidly than the repulsion on the surface, and a time will come when they will be equal, and if the particle becomes still smaller, the repulsion must exceed the attractive force. It therefore becomes evident that if such a repulsive force existed, and if the gaseous molecules were sufficiently small, we should have an effect exactly like that which we observe.

It has been shown by J. J. Thomson ('Proceeding of the Royal Society,' LVIII. No. 356)

THE COMET OF 1882.

COMET

that if hydrogen gas is electrified positively, the green line in its spectrum will be brighter than the red, and, on the other hand, if negatively charged, the red will be brighter than the green. In the case of the sun the red is the brighter line, so that we may infer that the solar surface is charged negatively.

It is a well-known fact that if the ultra-violet rays of the spectrum be allowed to fall upon a metallic body little corpuscles or electrons leave the atoms forming the metallic body and fly away from them with enormous velocity. These corpuscles either carry a negative charge of electricity, or what is perhaps more probable, constitute the negative electricity itself. The atoms lacking these corpuscles are as we usually express it positively charged.

Surrounding the meteor swarm and with it forming the comet's head is a mass of gas. When a flying corpuscle comes in contact with a molecule of this gas the two unite, the molecule becomes negatively charged, and both being repelled by the negatively charged sun, recede from it. The subject will be found treated in more detail by R. A. Fessenden, ('Astrophysical Journal,' III., 36. He there computes the potential of the sun's surface at about 15,000 volts. According to Arrhenius and Thomson the corpuscles which constantly deliver a negative charge to the earth, and would therefore also deliver it to a comet, proceed directly from the sun. The tail probably receives a charge from both these sources, but the latter would seem to be much the more effective of the two.

The question may now naturally be asked, since there is an abundance of extremely rarefied gas at an altitude of a few hundred miles above the earth's surface, and since we too are exposed to the flying corpuscles, why is not the earth itself provided with a comet-like tail? In answer we reply that at certain times it is. ('Annals of Harvard Observatory,' XXXII., 288. Our great auroras are indeed nothing else than the appearance of a small cometary tail. These great auroras, which exist at an altitude of several hundred miles, and envelope the whole earth, must not be confounded with the small but intensely brilliant local auroras always existing at low altitudes in the polar regions.

The reason that these great auroras only reach an altitude of a few hundred miles, instead of several millions, like the tail of a comet, is on account of the great mass of the earth, which does not permit the electrified gases to escape from it. The great auroras exhibit two notable characteristics. They appear only when the electro-magnetic condition of the sun is greatly perturbed, and they are most conspicuous at those times when the earth is approaching or receding most rapidly from it; that is, at the end of March and September. The same appears to be true of comets. The longest tails belong to those comets that approach closest to the sun's surface, and accordingly approach and recede from it with the greatest rapidity. Of the comets that do not approach remarkably close to the sun's surface, those which come during years of great solar activity are more likely to be provided with long tails than those coming when the solar surface is quiescent. Of the past 62 years during which sun spots have been recorded, 31 have been classed as of greater, and 31 as of less solar

activity. If the sun's activity had no influence upon a comet's tail, we should expect that an equal number of comets provided with long tails would have appeared in each of these intervals of 31 years. During the 62 years 10 comets have appeared that were furnished with long tails, and yet did not pass within 10,000,000 miles of the sun's surface. Of these, 7 came during the years of great solar activity, and only 3 during those of less. From this we see that comets' tails, like our auroras, other things being equal, appear to be more pronounced during years of great solar activity.

Since the electric current spreads out from the nucleus on all sides as it recedes from the sun, there must, by the well-known laws of currents, be a rotation produced by the magnetic force of the sun acting upon the current ('Annals of Harvard Observatory,' XXXII., 275). The tendency would be for the tail to revolve about its axis, in one direction, if located north of the sun's magnetic equator, and in the other direction if located south of it. Such a rotation has in fact been observed in the case of the bright comets of 1825 IV., 1835 III. (Halley's), and 1892 I. (Swift's).

Quite recently another explanation of comets' tails has been given by Arrhenius. He attributes the recession of the particles forming the tail, however, to the repulsion of light. It was first shown mathematically by Maxwell that light must exert a slight mechanical pressure upon all bodies above a certain size that are exposed to it. Gaseous molecules are too small to be affected by it. In the case of large bodies it would be concealed by the overwhelming attraction of gravitation. In order to be repelled from the sun, particles having the density of water must have diameters lying between 1-1000 and 1-14000 of a millimetre, or between 1-25000 and 1-350000 of an inch. For particles of greater specific gravity the dimensions will have narrower limits.

It is most likely that several causes combined produce the observed repulsion of the tail. Several of these are suggested by Nichols and Hull in their article describing their attempt to produce an artificial cometary tail ('Astrophysical Journal,' 1903, XVII. 352). It was shown in the 'Harvard Annals,' XXXII., 288, that the gaseous spectrum persisted in the tail of Swift's comet to a distance of 3,000,000 miles from the head. The presence of dust would be indicated by reflected light giving the solar spectrum. On account of the faintness of the tail we should hardly expect to distinguish the solar lines, but a distribution of photographic intensity in the spectrum similar to that which we find in the sun might be accepted as evidence of the presence of dust in the tail. Such a distribution was found in the case of the bright comet of 1881 III.

We may therefore say that the most probable explanation of a comet is that the head consists of a more or less concentrated swarm of meteors enveloped in gas and dust and that the tail is a current of gas and sometimes dust proceeding from the head, being most pronounced when the comet crosses the greatest number of electro-magnetic equipotential surfaces.

The shape and size of the tail enable us to compute the intensity of the repulsive force causing the tail to recede from the sun. This

COMET

was done by Bredichin, who divided all comets' tails into three classes according to the sharpness of their curvature, and suggested that the sharpness of the curve indicated the atomic weight and therefore the general chemical constitution of the matter forming the tail. This last suggestion is open to doubt.

More recently, by means of photography, we have been enabled to detect condensed areas in the tails of certain comets, and by comparing the photographs upon successive nights we have measured directly the speed of recession of the particles forming the tail from the head of the comet. Two comets so far have been measured in this manner that of 1892 I. (Swift's), by the writer, and that of 1893 II. (Rordame's), by Hussey. For the comet of 1892 the repulsive force was 39.5 times that of gravity. In the case of the comet of 1893, the repulsive force was 36 times as great ('Pub. Astron. Soc. Pac.,' VII., 185).

Since the gaseous particles receding from a comet's head can never again return to it, and since a comet is visible to us chiefly, and generally wholly, by the electrical illumination of this gaseous medium, it is clear that a comet must become less and less luminous after each return to the sun. But not only does it become less luminous on account of the loss of the material forming its tail, but the meteors composing its head likewise become more and more widely distributed along the course of its orbit. This is in part due to the positive charge left by the tail, which neutralizes the gravitation—or pull of the various portions of the comet's head for one another—and therefore permits those portions of the meteoric swarm which are nearest to the sun to move at a higher speed than those portions which are more remote.

In some cases, like our August meteors, the distribution extends throughout the orbit, with but one luminous condensation, known as the comet of 1862 III. In some cases there are two or more condensations. Thus Biela's comet was seen to split into two parts. Four distinct comets were found following in the track of the great comet of 1668.

We must now discuss the important question, what is the origin of comets? It is known that the sun, with its attendant planets, is traversing space in the direction of the constellation Lyra at a speed about 12 miles per second. If comets come from remote interstellar space, or from the other stars, it is obvious that we should meet more comets coming from Lyra than would overtake us coming from the opposite direction. Also that those comets we met would have a greater velocity relative to the sun than would those that might overtake us. Nothing of the sort is found, however—the distribution is uniform in all directions. There is but one conclusion to be drawn from this, and that is that all the comets that we have observed possess the same common speed as the sun, omitting relative motion, and travel in the same direction. In short, they are all of them parts of the same original gaseous mass from which the solar system condensed, being merely those portions which were originally left on the outside, before the great common rotation was established, and which now occasionally drop in toward the centre, and then fly back again to their original position on the outskirts of the system. The normal path of every comet is therefore an

ellipse. If the paths of some comets have become slightly hyperbolic through the action of some outside body, they can never again visit the sun. As we have just seen, a comet not belonging to our system would be most likely to approach us from the general direction of the constellation Lyra, with a high hyperbolic velocity. We are acquainted with the orbits of about 400 comets, but no such body is found among them.

From this point of view it is interesting to determine of what chemical elements comets are composed. To this the spectroscope gives a ready answer, and shows that by far the most common elements are hydrogen and carbon in chemical combination. This answer, however, is only a partial one, because most comets do not approach sufficiently near to the sun to enable their more refractory elements to be volatilized. The bright small comet of 1882 I. (Wells') approached so close to the solar surface that the distance at perihelion amounted to only about 5,000,000 miles. Some of its metallic constituents were accordingly vaporized, the most prominent of them being sodium. The great comet of 1882 III. approached within 300,000 miles of the sun's surface. This was so near that not only the sodium, but even some of the iron lines appeared in its spectrum. This is what we should have expected, judging by the chemical composition of most of the meteors that reach the earth's surface. We thus see that incidentally comets are able to give us information regarding the temperature that bodies would attain at different distances from the sun. When the metallic lines are present in the spectra of these comets the carbon bands vanish. This is precisely the effect that is produced in our laboratories when the cause of the illumination is an electric current. The current by preference selects the molecules which are the best conductors. If the illumination of the comet were due merely to heat, there is no reason why the carbon bands should have disappeared.

Few persons now living remember distinctly the great comet of 1843. It appeared suddenly in the northern hemisphere about the middle of March, and was not long visible. It was notable for the great length of its tail and its small perihelion distance,—the smallest on record. This amounted to only 511,000 miles. Its centre therefore came within 78,000, and the nearer side of its head within 32,000 miles of the sun's surface.

The great comet of 1858, known generally as Donati's, was a magnificent object. Not only was it a fine comet in itself, but it seems as if everything conspired to enable it to be well seen from the earth. It was a most conspicuous object in the northern sky during the early evenings in October, and was nearest us shortly after the passage of perihelion. Its tail reached a length of 60° and swept as a broad curved plume across the heavens. It was visible for several months, which enabled it to be carefully observed, and there is no doubt but that it moves in an elliptic orbit. Its period is about 2,000 years.

The great comet of 1861 was discovered by Tebbutt in Australia. It appeared suddenly in the northern hemisphere at the end of June and, according to Sir John Herschel, was the brightest comet of the century up to that time. It was not long visible.

COMET

The great comet of 1882 was remarkable on many accounts. In the first place it was shown to be one of a group of five comets all following nearly in the same orbit. The four others were those of 1668, 1843, 1880, and 1887. The last was comparatively inconspicuous, but the others were all notable. The nucleus of the comet of 1882 moreover showed a tendency to fall apart, five different condensations in it being visible at once. Schmidt, Barnard, and Brooks all noticed small companion nebulosities in the immediate vicinity of the comet and moving with it. It was visible for about nine months—an unusually long interval, and in this time it traversed 340° of its orbit. It clearly follows an elliptical path with a period which lies between 772 and 1,000 years. The tail was very extraordinary. It measured about 200,000,000 miles in length, and was strongly forked at the end. Moreover it was accompanied by a clearly seen but filmy sheath of light, extending 3° or 4° towards the sun. The whole comet was surrounded by an elliptical envelope of enormous dimensions and of a still more filmy nature. That this most remarkable object was not more generally observed by the public is due undoubtedly to the fact that it was visible only in the early morning hours. It was certainly the brightest comet of the century, and it was so bright that it was watched in perihelion passage until in contact with the sun's limb, when it suddenly disappeared, being of too filmy a nature to be detected upon the sun's surface. For three days it was visible to the naked eye with the sun above the horizon. There have been so far 14 different comets placed on record which were bright enough to be seen under these circumstances.

Turning now to the periodic comets; by far

appearance it was considered to be the precursor of the conquest of England by William of Normandy. It was a magnificent object in 1145, and again in 1223, when it was supposed to foretell the death of Philip Augustus of France. In 1456 it was a superb object appearing shortly after the Turks had taken Constantinople. In 1682 it was observed by Halley, who computed its orbit, and showed that it was identical with the great comets of 1531 and 1607, and predicted its return for the end of 1758 or the beginning of 1759. This is the first time that the return of a comet was ever predicted, and although Halley knew that he could not expect to live to see his prediction fulfilled (he was born in 1656), yet he left a somewhat plaintive appeal to posterity, that in case the comet should reappear, it should be remembered that this first prediction was made by an Englishman. The comet appeared Christmas day 1758. At its next appearance, in 1835, the comet was a fine object, but did not correspond in brilliancy to the descriptions of some of its earlier apparitions. This may perhaps be explained by the fact that it was but two years after a sun-spot minimum. Its next appearance is scheduled for 1911 or 1912, also unfortunately very near a sun-spot minimum. But very likely the chief reason for its relative faintness in 1835 is that the material which formed the tail has been largely used up by its frequent visits to the sun, and that it will thus never again present the brilliancy of its past appearances.

The following table of the elements of the orbits of the periodic comets has been condensed and brought up to date (1 Jan. 1904) from Holden's tables of periodic comets given in the 'Encyclopedia Britannica':

TABLE OF THE MOST IMPORTANT PERIODIC COMETS.

T				ω	Ω	i	q	a	U	e	
1901	II.	Sept.	15.....	184°	335°	13°	0.34	2.22	3.30	0.85	Encke.

1835	III.	Nov.	16.....	111	55	162	0.59	17.99	76.29	0.97	Halley.

the finest is Halley's. Our first record of it is in the year 11 B.C. Since then it has appeared regularly every 76 or 77 years, in all 25 times. We have a drawing of it as it appeared in 684, and another drawing of it in 1066. During its latter

The question is often asked the astronomer, what would happen if the earth should come into collision with a comet? As far as the tail is concerned, that is probably a frequent occurrence. It happened twice during the last

COMET — COMFORT

century, in the case of the comets of 1819 II. and 1861 II., but in neither case was it known until after the encounter had occurred. Should we come into contact with the head of a small comet there would undoubtedly be a fine meteoric display. That is in fact what probably happened in 1833, and also on a number of previous occasions, notably in 472, 902, 1029, 1202, and 1799, although the comet itself was not luminous. If the comet were moving rapidly with regard to the earth, as in these cases, the meteors would be consumed at a great altitude in our atmosphere, and no harm would be done. If the comet were moving in the same direction as ourselves, however, and at about the same speed, the matter would then become more serious, as many of the meteors might reach the earth's surface.

The self-luminous, and therefore visible comet, which has come nearest to the earth, as far as we are aware, was that of 1770 I. (Lexell's). It approached within 1,400,000 miles, or six times the distance of the moon. Its head appeared about four times the diameter of the moon, but its mass was imperceptibly small. Should the earth strike the nucleus of a great comet, like that, for instance, of 1858, it is impossible to foretell what would happen, but possibly the temperature and shock would be such that all life within several thousand miles of the point of contact would become extinct. Considering the vast recesses of celestial space, however, and the insignificant size of our earth, the probability of such an encounter may well be likened, as someone has suggested, to the chance that if a man should shut his eyes and fire a gun into the air, he would bring down a bird.

For a more detailed account of the individual peculiarities of the more interesting comets, see Clerke's 'History of Astronomy'; Chambers' 'Handbook of Astronomy.'

WILLIAM H. PICKERING,
Harvard College Observatory.

Comet, in ornithology, one of a group of humming-birds with long forked tails. One of the most imposing of all humming-birds is the Sappho comet (*Cometes Sappho*), or bar-tailed humming-bird, native to Bolivia, but migratory, and in the winter generally visiting eastern Peru. Specimens are secured only with great difficulty, owing to the rapidity of the complex evolutions of the bird when on the wing. Mounted examples, gorgeous as they are, do not convey an adequate idea of the brilliancy of the plumage. The Phaon comet (*Cometes Phaon*) is equally magnificent, but larger, inhabiting also Peru and Bolivia. It is distinguished from the Sappho comet by the fact that the tail is wholly crimson red, while that of the Sappho comet is ruddy brown at the base and is tipped with a black band. See HUMMING-BIRDS.

Comet-seeker (also called COMET-FINDER), a telescope of low power but optically so contrived as to have a wide field, used in searching for comets.

Cometas, called SCHOLASTICUS, Greek author, generally assigned to the 9th century A.D., although his time is doubtful. There are extant of his works a paraphrase of part of the eleventh chapter of Saint John's Gospel, in 57 hexameter verses, and six epigrams in the Greek Anthology. It appears from some of these epi-

grams that he made a new recension of the Homeric poems, effecting radical changes for the better in the punctuation. Clemens Alexandrinus refers to a Cometas of Crete as a commentator on Homer. By some he has been identified with the Cometas who was made professor of grammar at Constantinople in 856.

Comète, Pensées sur la, a work by Pierre Bayle, published in 1682, on the occasion of the appearance of the comet of 1680. It is a discussion of various questions of metaphysics, morals, theology, history, and politics, and is written with a boldness of thought unusual in those times. Its general thesis is that atheism is less to be feared than idolatry and superstition.

Comettant, Oscar, French musician, composer, and author: b. Bordeaux 18 April 1819; d. Montivilliers 1898. He was a pupil of Elwart and Carafa at the Conservatoire, and first became known as a pianist; he also wrote several works for the piano, duets for violin and piano, and choruses and songs. Among the piano compositions were 'Robert Bruce' and 'Le Juif Errant'; the vocal included 'L'Alboni' and 'L'Inde Révoltée.' For many years he was musical critic of the *Siècle*, and he was also a contributor to the 'Ménestrel,' the 'Gazette Musicalé,' and other journals of music. A great traveler, he visited the United States and wrote a book of impressions, 'Trois Ans aux Etats-Unis' (1857). Among his further works, most of which are marked by a humorous and brilliant style, are: 'Les Civilisations Inconnues' (1863); 'Le Danemark tel qu'il Est' (1865); 'La Musique, les Musiciens, et les Instruments de Musique' (1870); and 'Francis Planté' (1874).

Comez, or Comes, Juan Baptista, Spanish composer: b. province of Valencia about 1560. He was director of the music at Valencia in the Cathedral and in the Church del Patriarca. His reputation in Spain is very high. His compositions are preserved in manuscript at the Escorial and various churches. A two-volume collection of them appeared at Madrid in 1889.

Comfort, Samuel, American manufacturer: b. Morrisville, Bucks County, Pa., 5 May 1837. He enlisted for the Civil War in an independent cavalry company, subsequently recruited and equipped a cavalry company, and in 1865 was made major and mustered out. After the war he became interested in petroleum refining at Titusville, Pa., his business finally being merged with the Standard Oil Company. He was made representative of the company in western India, with headquarters at Bombay. In 1894-6 he was United States vice-consul, and in 1896-8 consul, at Bombay. He patented several mechanical devices.

Comfort, George Fisk, American scholar and educator: b. Berkshire, Tompkins County, N. Y., 20 Sept. 1833. Graduated from Wesleyan University in 1857, he studied archæology and the history of the fine arts in Europe, in 1865-8 was professor of modern languages and æsthetics in Allegheny College (Meadville, Pa.), and in 1868-72 lecturer on Christian art and archæology in the Drew Theological Seminary (Madison, N. J.). In 1872 he was appointed professor of modern languages and æsthetics in the newly-established Syracuse University, where he organ-

ized the college of fine arts, of which he was dean from 1873 to 1893. He organized the Syracuse Museum of Fine Arts in 1896, and became its director. He was also one of the chief organizers of the American Philological Association, and from 1869 to 1874 its secretary. From 1872 to 1893 he was editor of the art department of the 'Northern Christian Advocate.' He has also contributed extensively to periodicals, and published 'Art Museums in America'; 'Modern Languages in Education,' and other works.

Comfrey, kŭm'fri, the common name of the genus *Symphytum* of the natural order *Boraginaceæ* or *Borage* family. There are about 15 species, all natives of the Old World, where they are used in household medicine or for forage plants. Attempts have been made to naturalize them in America for commercial purposes, but the experiments have not given much promise of success. There is but one American species growing wild, *S. officinale*, naturalized from Europe or Asia. It is a coarse perennial weed, from two to three feet high, with flowers in long racemes. The roots are mucilaginous, and are supposed to have medicinal virtues as a cure for diarrhœa. It is known also as blackwort, bruisewort, and boneset. In England the leaves, gathered while young, are sometimes used as a substitute for spinach, and some people of unrefined taste eat the young shoots after blanching them by forcing them to grow through heaps of earth. Comfrey stewed in sugar, with a small amount of paregoric added, makes a highly prized domestic remedy for coughs and bronchial irritations.

Comines, kō-mēn, **Commines**, or **Comynes**, **Philippe de**, French statesman and historian: b. Comines near Lille 1445; d. Argenton 18 Oct. 1509. He stood high in the favor of Charles of Burgundy, afterward Charles the Bold, and on occasion of Louis XI.'s imprisonment by Charles at Péronne, succeeded in bringing about a treaty of peace between them. In 1472 he forsook the cause of the Duke of Burgundy and became councilor and chamberlain of Louis XI., who compensated him so amply for the loss of his property, which had been confiscated by Charles, that he soon became one of the most wealthy and influential noblemen in France. The death of Louis, however, proved fatal to his fortunes. He was no favorite with Anne de Beaujeu, the regent, and was imprisoned on a charge of conspiracy against her. On the accession of Charles VIII., however, he was again employed in the public service, but went into retirement after the advent of Louis XII., who seemed reluctant to favor him, although he left him in possession of a pension. The fame of Comines rests not only upon his astuteness as a statesman, but still more upon his 'Mémoires,' which give a complete view of the political affairs of his time, and present a vivid picture of the character of Louis XI. They have been frequently printed. Lenglet Dufresnoy's edition (London 1747), is still sought for, especially on account of its annotations; but the best are those published by Mlle. Dupont (Paris 1840-7); and Chantelauze (1881). Comines figures in Sir Walter Scott's romance of 'Quentin Durward.'

Coming Race, The, a story by Edward Bulwer-Lytton, published in 1871. It was a skit at certain assumptions of science; but its clever invention and brilliant treatment, added to the

craving wonder of humanity as to what its evolution is to be toward, gave it a large popularity.

Comitat, kōm'ī-tat (L. *comitatus*), which means county, the name given to administrative districts of some size into which Hungary and Transylvania are divided.

Comitia, kō-mīsh'ī-ā, with the Romans, the assemblies of the people in which the public business was transacted, and measures taken in conformity with the will of the majority. They existed even under the kings. In the time of the republic they were convoked by the consuls; in their absence often by the dictator, the tribunes, and in extraordinary cases even by the pontifex maximus. There were three comitia among the Romans, which were called *comitia curiata*, *comitia centuriata*, and *comitia tributa*. The oldest of these was the *comitia curiata*, so called because in it the people voted by *curiæ* or wards. It consisted exclusively of the patricians, the original ruling class at Rome, and the class to which the name of *populus* was at first restricted. They were divided into three tribes, the *Luceres*, *Rammes*, and *Tities*, each of which was divided into 10 *curiæ*, so that there were 30 *curiæ* who voted in the *comitia curiata*. The *comitia centuriata* was a mixed assembly of the patricians and plebeians, in which the people voted by centuries, as these had been formed by Servius Tullius. On the institution of this comitia the principal privileges of the *comitia curiata* were transferred to it, and in course of time the functions of the latter became a mere formality, so that even before the time of Cicero these were not performed by the *curiæ* themselves, but by 30 lictors representing them. The rights of the *comitia centuriata* were thus very important, comprising the right of electing the higher magistrates, the right of passing or rejecting laws proposed to them, the right of deciding upon war on the ground of a *senatus consultum* or decree of the senate, and the highest judicial power. This comitia could be held only on certain days, and it must be summoned 17 days before the day of meeting. On the day of the comitia itself the presiding magistrate, with an augur, went into a tent before the city in order to observe the auspices. If the augur declared them unexceptionable, the comitia was held; if not, it was postponed to another day. Before sunrise and after sunset no business was transacted in the comitia. The presiding magistrate, on his curule chair, opened the assembly by a prayer, which he repeated after the words of the augur. In earlier times, first the equites, then the centuries of the first class, etc., were called upon to vote. In later times lots were cast for the order of voting. The opinion of the century which first voted was usually followed by all the rest. In the earliest times every century voted verbally; in later times by ballot. What was concluded in each century by the majority, was proclaimed by the herald as the vote of this century. The comitia was interrupted if any one in the assembly was attacked by a fit of epilepsy (which was called for this reason *morbus comitialis*), or if a tribune of the people pronounced his veto, and under some other circumstances. The other comitia, the *comitia tributa*, which was also an institution of Servius Tullius, was essentially plebeian in its nature, for if the patricians were not, as some

COMITLAN — COMMANDITE

think, entirely excluded from it, they were in so small a minority that their influence was scarcely felt. It was based upon the division which Servius Tullius made of the whole Roman territory into 30 local tribes, which were afterward increased to 35. Its power was at first very limited, being merely local, but it gradually increased, so that it in the end it came to possess the right of exercising electoral, legislative and judicial functions, though not so extensive as those of the *comitia centuriata*. It had the right of electing only the inferior magistrates; legislatively, it was merely entitled to pass resolutions proposed by the tribunes, which before becoming law had to be sanctioned by the senate; judicially, it had the right of trying only those who had committed offenses against the majesty of the people, and the only punishment it could inflict was a fine. It might assemble either within or without the walls of the city, but not at a greater distance than 1,000 paces, which was the limit of the power of the tribunes. The *comitia centuriata*, on the other hand, always met in the Campus Martius. Sometimes the *comitia centuriata* was mixed with the *comitia tributa*, but in what manner it is not known. The emperors retained these assemblies for the sake of appearance, but used them only as instruments for the accomplishment of their purposes.

Comitlan, *kō-mēt-län'*, or **Comitan**, *kō-mē-tän'*, Mexico, a town in the state of Chiapas, on the Grijalva River, 35 miles south-east of Ciudad Real. It has a magnificent church, and is a place of considerable trade. It is supported chiefly by contraband trade, as the duties on foreign goods are excessive. Pop. 10,000.

Comitium, a square in the ancient city of Rome between the Curia and the Forum, where the *comitia curiata* (q.v.) met. It contained the original rostra or speakers' platform.

Com'ity of Nations (more frequently mentioned by its Latin equivalent, *comitas gentium*), the international courtesy by which effect is given to the laws of one State within the territory and against the citizens of another State. "In the silence of any positive rule," says Story, "affirming, or denying, or restraining the operation of foreign laws, courts of justice presume the tacit adoption of them by their own government, unless they are repugnant to its policy or prejudicial to its interests." Consult Story, 'Conflict of Laws.'

Comma, the stroke or mark used in writing and printing to separate from each other phrases and clauses in a sentence. The word is of Greek origin and is the noun of the verb *kopto*, to cut; hence literally comma is section, and in grammatical works written in Greek and Latin *comma* or its diminutive *kommation* means a clause in a period as well as the punctuation mark, and in prosody the *cæsura*. In German typography the punctuation mark comma is a downward short stroke from right to left (/).

Comma Bacillus. See CHOLERA.

Commagene, *kōm-a-jē'nē*, in ancient times a district in the north of Syria, bounded on the east by the Euphrates, on the north by Mount Amanus, and on the west by Cilicia, for some time attached to the kingdom of the Seleucidæ, but afterward for more than 100 years an independent state. It seems to have

become independent about 100 B.C., and on the death of its fifth king, Antiochus III., in 17 A.D., it was made a Roman province. It was again for a time allowed by the Romans to hold a position of nominal independence, but was reduced to a Roman province by Vespasian, 73 A.D.

Commander-in-Chief, the supreme commander of the united forces of any country. In the United States the President for the time being is commander-in-chief of the army and navy, and of the militia of the several States when the latter is in the national service and forms part of the national provisional army. In all other cases the governor of each State is the commander-in-chief of the State troops. In England he is officially called the officer commanding-in-chief. He is the head of a department of the military administration. He acts, under the secretary of state for war, as the head of the army, and when military operations are undertaken on a sufficiently large scale to require his presence, is charged with the duty of commanding the army in the field, though, as a matter of fact, this very rarely occurs.

Commander Islands, two islands belonging to Russia lying east of Kamchatka in Bering Sea. The larger, Bering Island (q.v.), lies nearest the coast; the other island of the group, Miedni, is nearly 30 miles long but narrow; it is sometimes called Copper Island, because copper is found there in small quantities. The climate is mild and there are a few inhabitants.

Commander of the Faithful, a title assumed by the Caliph Omar, and retained by his successors. See CALIPH.

Comman'dery. (1) Among the Knights Templar, Hospitallers, etc., a district under the administration and control of a member of the order, called the commander or preceptor, who received the income of the estates within that district, expending part for his own use, and accounting for the rest. In England more especially applied to a manor belonging to the Knights Hospitallers or Knights of St. John of Jerusalem. These establishments formed at the same time branches. . . . On the first creation of these (branch) establishments, they were denominated Preceptories; the superior being called the preceptor; but eventually the name became changed to that of commandery, by which they were always afterward known. The council reserved to themselves the power of at any time recalling a commander from his post, and substituting another in his place, at their pleasure; he being merely considered as the steward of their property. Time, however, gradually wrought a great change in the relative position which the commanders held to the council; and, eventually, a nomination to a commandery came to be considered in the light of a legal acquisition, subject only to the payment of a certain amount of annual tribute to the public treasury, which tribute received the name of Responsions. (2) A regular assembly of Knights Templar, which confers certain degrees. Consult 'History of Knights of Malta.'

Commandite, *kōm-mōn-det'*, a term used in France, primarily for a partnership or firm, in which one advances the funds, while another devotes his skill and assiduity; but by extension, a co-partnership *en commandite* oftener means a

COMMELIN — COMMENSALISM

company for manufacturing or trading, "with limited liability." In terms of French commercial law, those whom we would call the sleeping partners or silent partners in such associations are denominated *commanditaires*. Their names do not appear in the nominal title of the firm; they may assist it with their counsel, but they cannot order or sign for its behoof, nor act overtly for it in any way; on the other hand, they are not bound to incur a final loss in case of its failure, beyond that of the entire sum they have advanced, should indeed such be needed to satisfy the claims of agents and creditors. For all details on the rights and obligations of *commanditaires*, see the French 'Code de Commerce,' articles 23-28.

Commelin, kōm-lān, **Casper**, Dutch botanist; d. 1731. He was a nephew of Jan Commelin (q.v.).

Commelin, **Hieronimus**, hī-ē-rōn'ī-mūs. See COMMELIN, JEROME.

Commelin, **Isaac**, Dutch historian: b. Amsterdam 1598; d. there 1676. Among his works the history and description of Amsterdam is still much valued.

Commelin, **Jan**, yān, Dutch botanist: b. Amsterdam 1629; d. 1692. He was for many years a professor of botany in the university of his native city, where with his nephew, Casper, he founded the botanical gardens renowned throughout Europe.

Commelin, **Jerome**, Flemish printer: b. Douay; d. Heidelberg 1598. He was distinguished by his excellent editions of Greek and Latin classics. His emblem is a figure of Truth, and on many editions the words *Ex Officina Sanct. Andreana*.

Commelin, kōm'mě-lin, or day-flower, is a genus of the spiderwort family (*Commelinaceæ*). It contains about 95 species widely distributed in warm and temperate zones. There are about eight species found in the United States, along streams and in waste places, from New Jersey to Missouri, southward to Florida and Texas. It is also common in Asia and Africa. The fleshy rhizomes of the plant may be eaten when cooked, as they contain much starch and mucilage. In Asiatic countries some species are used for medicinal purposes. The plant receives its name from Jan and Casper Commelin, two noted Dutch botanists.

Commencement. In the colleges of the United States this term denotes the day when the students are made bachelors of arts, and the degree of master of arts and the degrees of doctors in the professions are also conferred at the same time. The term is given also to the closing exercises of secondary and even elementary schools.

Commendam, kōm-měn'dām (Lat. *commendare*, that is, to intrust), used in ecclesiastic law to denote the administrative or provisional management of a benefice during a vacancy. The person intrusted with the management is called *commendator*. The grant or benefice was sometimes converted into a regular fief and was then said to be in *perpetuam commendam*. The practice gave rise to great abuses, and is now almost unknown.

Commensal, kōm-měn'sal (Lat. *con*, together, and *mensa*, a table), literally, a messmate. This term is applied in zoology to animals which live on or in other animals for part or the whole of their life, simply sharing the food of their host without being parasitic on him: thus the pea-crabs live within the cavity of shell-fish, and find their food in the water introduced for the benefit of their host. There are various forms or degrees of commensalism. Sometimes the relation is more or less accidental, and of little, if any, use to either organism, or again it may be advantageous in a greater or less degree to one of the animals only, or yet again both host and guest may be benefited. In still higher cases the guest is, as it were, not only welcomed, but invited and induced to cling to a host. See SYMBIOSIS.

Commen'salism, the intimate connection or partnership between animals of quite different affinities; thus commensals, messmates, or fellow-boarders take up their abode together for their mutual benefit. A good example is a large sponge, whose canals and passages shelter innumerable worms, crustacea, etc., which lodge there without expense to their host. Floating jellyfish shelter certain pelagic crustaceans (*Hyperina*) and little fishes. The oyster-crab (*Pinnotheres*) is a typical case of commensalism; it does no harm to the oyster or mussel in whose shell it lives, and which protects it from danger; while, as the result of its sheltered life, its shell is soft and thin. The pearl-oyster, besides taking in a *Pinnotheres* as a boarder, admits a kind of shrimp. Certain small slender, eel-like fishes (*Fierasfer*) insinuate themselves into the body of holothurians, which also keeps open house for *Pinnotheres* and shrimps; hence a holothurian has been compared to a hotel with its *table d'hôte*. Other crustaceans board in different animals; thus a little crab (*Fabia chilensis*) lodges in the end of the intestine of a sea-urchin; another (*Porcellana*) lives on the Brazilian coast in a starfish. Polyps and corals shelter various species of crabs, snails, etc., all being of the same color, while a crinoid (*Comatula*) takes in as a permanent lodger a decapod crustacean (*Galathea*). Hermit crabs, taking up their abode in an empty snail-shell, are obliged to admit a variety of intruders who come to stay. Certain mollusks live in starfishes and other echinoderms and, as the result of their semi-parasitic life, become more or less modified and degenerate. Thus *Stylina* lives on a crinoid (*Comatula*); a species of *Stilifer* becomes encysted on the rays of a starfish (*Linckia*), and on the underside of the arms of the same *Linckia* lives a limpet-like snail (*Thyca*), while *S. astericola* lives in the body of a Bornean starfish, and so on with a number of similar cases. Ascidians throw their "front hall" (*atrium*) wide open to a variety of forms, such as small worms, polyps, mollusks, crustaceans of different orders, sea-spiders, brittle-stars. The "Venus flower-basket," a silicious sponge of the Philippine Islands, gives shelter to three different kinds of crustaceans: a prawn, a *Pinnotheres*, and an isopod.

Rising to the higher animals there occurs on an island off the New Zealand coast the case of the interesting lizard "tuatara," which shares its deep burrows with a petrel, though the latter

COMMENSURABLE — COMMERCE

may at times be the work of the bird. Each builds its nest on opposite sides of the chamber, the lizard almost invariably choosing the right, and the petrel the left side. The former sits with its head close to the entrance ready for any attack; it feeds partly on worms and beetles, and in part on the remains of fishes and crustaceans brought to their common table by the petrel.

By far the most numerous assemblage of messmates are the different kinds of beetles and other insects which live in ants' nests, the number of kinds of which amount to upward of 1,500. See ANT; COCKROACH; SYMBIOSIS.

Commen'surable, among geometricians, an appellation given to such quantities or magnitudes as can be measured by one and the same common measure. Commensurable numbers, whether integers or fractions, are such as can be measured or divided by some other number without any remainder; such are 12 and 18, as being measured by six or three.

Com'mentary, a term used (1) in the same sense as memoirs, for a narrative of particular transactions or events, as the 'Commentaries' of Cæsar. (2) A series or collection of comments or annotations. These may either be in the form of detached notes, or may be embodied in a series of remarks written and printed in a connected form.

Commentry, *kō-mān-trē*, France, a town in the department of Allier, eight miles south-east of Montluçon, in the midst of a vast coal field, to which the town owes its prosperity. There are important iron works in the vicinity. Pop. 9,200.

Commerce, a term which in its primary significance relates to an interchange of goods, merchandise or property of any kind. In its usual acceptance it relates to interchange of merchandise between countries or different parts of a country, distinguished respectively as "foreign commerce" and "internal commerce"; the commerce between the United States and other countries, for example, being of the class designated foreign commerce, that between the Atlantic seaboard and the Mississippi valley or the Pacific coast, internal commerce.

The earliest form of interchange was naturally that of man with his neighbor, the exchange of the products of the chase for those of the soil or of natural products for those ready for use; and when this was a mere exchange of article for article, and passed from hand to hand, it is more properly designated by the word "barter." But with the utilization of a common measure of value by which goods were purchased, usually to be sold again, the transactions are called commerce, especially when they occur between citizens of different localities. Among the early examples of commerce is that of the Phœnicians with the people and cities scattered along the coast of the Mediterranean, the caravans carrying the silks and spices of the far East to the Mediterranean countries, and later the markets and great fairs of the Middle Ages. With the introduction of a common and generally accepted measure of value, money, arose the class of middlemen, or merchants, who purchased the goods offered for sale and resold them. Following this came the establishment of trade centres, and when states or countries were formed and duties collected on goods entering or

leaving them, a record of the international commerce began to be established. In England there is a record of commerce as early as the year 1355, in which the imports are reported at 120,000 pounds sterling and the exports at 294,000 pounds sterling; in 1573, imports, 2,100,000 pounds sterling, and the exports, 1,180,000 pounds sterling; in 1701, imports, 5,900,000 pounds sterling, and exports, 6,900,000 pounds sterling. In France official returns date continuously from 1716, the annual average of imports for that year to 1720, being 65,000,000 francs, exports, 1,050,000,000 francs. Mulhall presents figures of the commerce of 12 European countries in 1720, making the total recorded commerce of Europe for that date 62,000,000 pounds sterling; that of Spanish-America, 10,000,000 pounds sterling; India, 9,000,000 pounds sterling; British colonies, 2,000,000 pounds sterling; and "various," 5,000,000 pounds sterling, thus making the total recorded commerce of the world at that date 88,000,000 pounds sterling, or \$428,252,000 of imports and exports combined. Accepting his figures as probably the best approximation possible for the earlier dates when official records of commerce of many of the countries were not available, the international commerce of the world from 1720 to 1900, including both imports and exports, may be stated as follows:

Year	Total Commerce	Year	Total Commerce
1720.....	\$ 428,000,000	1850.....	\$ 4,049,000,000
1750.....	681,000,000	1860.....	7,246,000,000
1780.....	905,000,000	1870.....	10,662,000,000
1800.....	1,470,000,000	1880.....	14,760,000,000
1820.....	1,660,000,000	1890.....	17,519,000,000
1830.....	1,980,000,000	1900.....	20,715,000,000
1840.....	2,788,000,000		

It will be seen from the above figures that by far the most rapid growth has occurred in the last half of the 19th century, the increase in the 80 years from 1720 to 1800 being, in round terms, but one billion dollars, and that of the 50 years from 1800 to 1850 but two and a half billions, while that of the 50 years from 1850 to 1900 was 16 billions. Meantime values of merchandise of all kinds have greatly decreased, so that the increase in the volume of merchandise exchanged is really much greater than that indicated by the mere figures of value. This increase is chiefly due to the facilities for transportation and communication which were developed in the later period. At the beginning of the 19th century there were no railroads to carry the products of the interior to the seaboard, no steam vessels to carry them from continent to continent, and no telegraphs for intercommunication. In 1850 there were but 24,000 miles of railway in the world, and this consisted of fragmentary lines not furnishing continuous communication for considerable distances; the steam vessels of the world had a tonnage of less than 1,000,000 tons; the land telegraph lines were but 5,000 miles in length, and the submarine cables of the world, 25 miles. In 1903 the railroads of the world are 500,000 miles in length, and have been brought into such relation that they furnish great through transportation systems from the interior of continents to the water's edge; the steam vessels of the world have a tonnage of 17,000,000 tons; the land telegraphs are 1,200,000 miles in length, and the submarine cables 200,000 miles. With this enormous increase in steam-carrying power on land and sea have come great reduction in charges

COMMERCE

for transportation, a great increase in the currency of the world, and such improvements in its financial systems as to greatly facilitate international commerce.

FOREIGN COMMERCE OF THE PRINCIPAL COUNTRIES
OF THE WORLD, 1900.

^a Exclusive of commerce between the Australasian colonies, but inclusive of precious metals.

^{dd} Including bullion and specie.

^e Except Australasia, Canada, and British India.

^f Includes imports and exports of precious metals, namely, \$2,618,000 and \$44,271,000, respectively.

^h Includes dependencies.

^g Figures for 30 June 1902.

^s Trade over the European frontier only.

With this increase of facilities for transporting the products of the interior to the seaboard and from continent to continent came a great increase in production and a reduction in cost of both production and transportation, and this reduction in cost to the consumer was followed by a great increase in the quantity and variety of the articles utilized by man, for food, clothing, and in household and business affairs. The per capita of the world's international commerce is

now about six times as great in value as a century ago, having been about \$2.35 per capita in 1800 and \$13.25 per capita in 1900, while the reduction in prices meantime indicates that the quantity represented by the per capita figures of 1900 is probably 20 times as great as that represented by those of 1800.

The commerce of the world at the latest available date, including all countries for which statistics are available, is given by the bureau of statistics of the treasury department in the table which follows, the figures being in most cases for the year 1901. It will be noted that, although the exports of one country always become the imports of some other country, the figures of total imports exceed those of total exports. This is accounted for in part by the fact that the cost of transportation is added in many cases to the stated value of the merchandise when it becomes an importation, while the fact that revenues are more generally collected on imports than on exports probably results in a more nearly complete record of the imports than of the exports.

United States Commerce.—The official record of the foreign commerce of the United States begins with the year 1790. During the existence of the Colonies the most of their commerce was with Great Britain, and during the period of confederation each State regulated its own commerce. It was not until the beginning of the present form of government that satisfactory statements of the foreign commerce of the United States became available. A record of the exports of the Colonies to Great Britain from 1697 to 1790, compiled by Mr. Charles H. Evans, shows a total of 279,852 pounds sterling, or \$1,362,000 of exports from all the Colonies to Great Britain in 1697; 415,650 pounds sterling, or \$2,023,000; in 1725, 814,766 pounds sterling, or \$3,965,000 in 1750; 1,105,170 pounds sterling, or \$5,403,000 in 1763; 1,373,846 pounds sterling, or \$6,685,000 in 1774. In 1790, the first record under the Constitution, the total imports of the United States were \$23,000,000, and the exports \$20,205,156. The period of wars in Europe which began during that decade increased the figures of the commerce of the United States greatly, by reason of the fact that merchandise from the British, French, and Dutch colonies, although subject to seizure under the blockades if passing from the colony to the mother country, was not subject to seizure if first brought to the United States by American vessels, entered as an import and then sent forward to its destination as an export from the United States. Goods from those countries destined for their colonies sometimes also evaded the blockades by a similar process. As a result, the figures of both imports and exports of the United States from 1769 to 1807 showed during that period exports of foreign merchandise actually in excess of exports of domestic merchandise, while exports of foreign merchandise are now less than 2 per cent of the total exports. The domestic exports, which were \$18,500,000 in 1791, never reached as much as \$50,000,000 until 1819, and did not reach \$100,000,000 until 1835. In 1854 they for the first time exceeded \$200,000,000, and in 1860 for the first time passed \$300,000,000. In 1871 they for the first time exceeded \$400,000,000, but from that time rapidly increased, being over \$800,000,000 in 1881, more than \$1,000,000,000 in 1892, and since 1897 have never been below the \$1,000,-

COMMERCE

000,000 limit, the highest figure reached being in 1901, \$1,460,462,806.

This rapid increase in exportations, beginning with 1870, was coincident with the opening up of the interior by railroads, and the development of the manufacturing industry. In 1870 there were 52,992 miles of railway in the country; the number of farms was 2,659,985, and the gold value of their products, \$1,958,030,927, while the value of the manufactures of the country was \$4,232,325,442, and the exports of manufactures but \$68,279,764. In 1880 the number of miles of railway was 93,262, having nearly doubled in 10 years; the number of farms, 4,008,907, and the value of their products, \$2,212,540,927; while the value of the manufactures was \$5,369,579,191. In 1890 the number of miles of railroad was 166,654, the number of farms 4,564,641, the value of farm products \$2,460,107,454, and the value of the manufactures \$9,373,437,283. In 1900 the number of miles of railroad was 194,321, the number of farms 5,739,657, and the value of their products \$3,764,177,706; while the value of manufactures had reached \$13,039,279,566. During this period of 30 years in which the number of miles of railroad nearly quadrupled, the value of farm products doubled, the value of manufactures more than trebled, the exports of agricultural products grew from \$361,188,483 in 1870 to \$835,858,123 in 1900, and those of manufactures grew from \$68,279,704 to \$433,851,759, manufactures forming but 15 per cent of the total exports in 1870 and 31 per cent in 1900. The result of this rapid growth in exports is that the United States, which in 1870 stood fourth in the list of the world's exporting nations, being surpassed by the United Kingdom, Germany, and France, was in 1901 at the head of the list, the domestic exports of the United States in that year exceeding those of any other country. The imports into the United States usually exceeded the exports prior to the great increase in exports which began with 1870. In 1874 the exports began to exceed the imports, and have so continued during nearly the entire period since that date. There was during that period, however, a comparatively slow but steady growth in imports, from \$436,000,000 in 1870 to \$668,000,000 in 1880, \$789,000,000 in 1890, and \$850,000,000 in 1900, and in 1902 they for the first time exceeded \$900,000,000. This growth is largely due to the increased demand for manufacturers' materials, the imports of which in 1870 amounted to \$120,000,000 and formed 28 per cent of the total imports, and in 1902 amounted to \$418,000,000 and formed 46 per cent of the total imports. This increase in manufacturers' materials imported is chiefly in articles not produced in the United States, such as raw silk, hemp, jute, rubber, tin, etc.

The foreign commerce is chiefly with Europe but is growing rapidly with other parts of the world. In 1880 55 per cent of the imports were from Europe, and 86 per cent of the exports went to Europe. In 1902 53 per cent of the imports were from Europe, and 73 per cent of the exports went to that continent. The exports to Asia and Oceanica have increased from \$14,000,000 in 1870 to \$116,000,000 in 1902, including in this statement the shipments to the Hawaiian Islands, which are not now stated as exports, but which should be so included in a comparative statement of this character. The commerce with the Hawaiian Islands, the Philippine Islands, and

Porto Rico has grown rapidly since their annexation to the United States, the total imports from those islands having increased from \$20,252,563 in 1897, to \$39,610,551 in 1902, and the exports to them, from \$6,733,530 in 1897, to \$34,971,311 in 1902.

The tables which follow show the annual average of imports and exports in each decade from 1790 to 1900, and the total imports and exports for each fiscal year from 1790 to 1902. They are from the annual publications of the Bureau of Statistics, and are thus the official record of the foreign commerce of the United States.

COMMERCE OF 1901 AND 1902 COMPARED WITH AVERAGE OF DECENNIAL PERIODS, 1790 TO 1900.

TEN-YEAR PERIODS	Annual Average of Ten-Year Periods of		Annual Average of Excess of

NOTE.— Figures include specie prior to 1821.

*Fiscal year ended 30 September prior to 1843; since that date 30 June.

In 1903 a Department of Commerce and Labor was created by the Congress of the United States, its chief officer to be a member of the cabinet, the province and duty of the department being to "foster and develop the foreign and domestic commerce, the mining, manufacturing, shipping, and fishery industries, the labor interests, and the transportation facilities of the United States." The Bureau of Statistics, Bureau of Navigation, Steamboat Inspection Ser-

vice, Light House Establishment, Coast and Geodetic Survey, Bureau of Standards, Bureau of Immigration, Department of Labor, Census Office, and Fish Commission were transferred from other departments to the Department of Commerce and Labor; also the Bureau of Foreign Commerce of the State Department, which was consolidated with the Bureau of Statistics; and two new bureaus, Bureau of Corporations and a Bureau of Manufactures, created as a part of the department. Hon. George B. Cortelyou, former secretary to the President, was nominated by the President and confirmed by the Senate as the secretary of Commerce and Labor. The other governments which have similar governmental organizations devoting their attention to commerce are Germany, France, Belgium, Austria-Hungary, Spain, Portugal, Italy, and the United Kingdom; the organization of the latter being designated the Board of Trade, its president, however, being a member of the cabinet.

OSCAR P. AUSTIN,

Treasury Dep't, Washington, D. C.

Commerce, a card game in which each player contributes an equal sum to the pool, and a full pack of cards is dealt to the players. The eldest hand, that is, the one who received the first card on the left of the dealer, then exchanges one of his cards with his left hand player, who, in turn, exchanges one with his left hand player, and so on, until some one finds that his hand consists entirely of cards of one suit, when he calls out "My Ship Sails." Aces count 11, court cards 10, the rest according to "pips." Each player, through all the exchanges, is aiming to hold a tricon, three cards alike; a sequence, three following each other in the same suit; or a point, the smallest number of pips on three cards. The winner of the pool is the player who has the highest tricon, or, if none is displayed, the highest sequence, or in its place the holder of the best point. See Cassell, 'Book of Pastimes.'

Commerce, Chambers of. See CHAMBERS OF COMMERCE.

Commerce, Interstate. The colonies, under the lead of Massachusetts, early attempted to provide roads; yet for more than two hundred years nothing existed in this country that by any stretch of the imagination could be called a postal service. The only carriers of commerce for nearly two hundred years after the first settlers sought these shores were the simple sailing vessels, that crossed the ocean only at the greatest hazard. Courageous attempts to navigate the ocean waters and the almost unknown rivers and lakes were numerous before 1800, and canals, even, were attempted. It can hardly be said, however, that anything deserving the name of interstate commerce existed in this country at the beginning of the 19th century, since at that time the total effects of the government were transported from Philadelphia to Washington in a frail sloop, and President John Adams and his wife lost their way, as tradition has it, in the woods beyond Baltimore, as they proceeded in their carriage toward the new capital. The Alleghanies constituted an almost impassable barrier between the East and the West, and such necessary products as the colonists could not obtain in their immediate neighborhoods were mostly brought from over seas.

COMMERCE

There was another difficulty in the way of trade. The high price of labor rendered it impossible to manufacture linen, cotton, or woolen cloth, except at a cost 20 to 50 per cent greater than the same stuffs could be turned out for in England. The trade of New Hampshire was principally in lumber and fish, which were exported. In Massachusetts a little wool and flax were worked into a coarse cloth, and a few hats were made, but it was cheaper to import them. In the province of New York the export of furs, whalebone, oil, pitch, tar, and provisions included everything. So it was in New Jersey. Virginia produced nothing for intercolonial trade. Tobacco was a permanent staple, but it became chiefly an export. The early colonists were inevitably sailors. Therefore a considerable coasting trade grew up, but there were no means of internal transportation except by wagons and the rude craft plying the natural waterways. In spite of this the Constitution, which went into operation 4 March 1789, embraced the right to regulate domestic commerce,—a right not conferred by the previous Articles of Confederation,—and from that year one may find exhibits of the tonnage employed in the coastwise trade. In 1789 this tonnage was 78,607; in 1812 it was 477,971.

The Americans of those early times had only a vague knowledge of the country west of the Allegheny mountains; yet the hardy settlers along the coast soon beat out for themselves paths to this unknown region. The act to provide for the Cumberland road was passed March 29, 1806, and the first stage-coach driven from Cumberland to Wheeling in 1818. The length of the line first opened was 130 miles, and its cost \$1,700,000. In those years, too, were tried the first experiments with steam-craft. Livingston and Fulton built the Clermont in 1807, and Fulton claimed under his patent a monopoly of transportation on the Hudson and other rivers. His claim was carried to the courts and defeated, so that after 1815 the rivers of the country were free to steam-vessels. In 1812 steamboats made their appearance on the western rivers. The first craft, the New Orleans, built at Pittsburg by Fulton at a cost of \$40,000, a stern-wheeler of between 300 and 400 tons, put out for New Orleans. Others followed, but none proved able to ascend the river, until 1815, when the Enterprise, a stern-wheeler of 70 tons, made the trip from New Orleans to Cincinnati in 28 days. It was later than this, again, that steamships came gradually to ply up and down the coast.

The first charter for canal building was granted to the James River Company by the legislature of Virginia in 1785. Another of these projects was the Dismal Swamp Canal, begun in 1787, under a joint charter from Virginia and North Carolina, and opened in 1794. The owners of its stock included George Washington and Patrick Henry, and it was originally designed to facilitate the movement of lumber out of the Dismal Swamp. The Chesapeake and Ohio Canal, the Delaware and Chesapeake Canal, and the Union Canal, of Pennsylvania, intended to connect the Delaware and Susquehanna rivers, were only forerunners of the Erie Canal, 363 miles long, completed in 1825. A canal from Lake Champlain to the Hudson River was completed in 1823. On the opening of the Erie Canal the cost of freight fell, according to its class, all the way in amount

from \$15 to \$25 per ton, and the time of transit from 20 to eight days. Wheat was worth \$33 per ton in western New York, and it did not pay to send it to market, down the Susquehanna to Baltimore. The canal changed all that. Indeed, it has been said that the Erie Canal added \$100,000,000 in value to the farms of New York State. It made New York city the commercial metropolis. Freight which had gone overland from Ohio to Pittsburg and Philadelphia, at a cost of \$120 per ton, now went to New York by way of the lakes, the great canal, and the Hudson. The opening of the Erie Canal excited also a fever of enterprise in canal building in Ohio, Pennsylvania, Massachusetts, Maryland, and Virginia.

The first voyagers on the Great Lakes, La Salle and Hennepin, set sail in 1678 in a schooner of 10 tons, which they had launched near the present city of Kingston, Ontario. From the mouth of the Niagara River they continued their journey by land, and in the following May launched the Griffin, the first sailing vessel to navigate the upper lakes. In September they reached their destination at Green Bay. From 1700 until 1756 the construction and navigation of sailing vessels on the lakes was largely confined to Lake Ontario. Then the English began to build and sail vessels upon Lake Erie and Lake Ontario, and the commerce of Lake Ontario increased so fast, that in 1800 it exceeded that of all the other lakes together. The first American vessel to sail Lake Erie was launched at Erie in 1798. The first steam-vessel that navigated the lakes was built at Sackett's Harbor in 1817, and measured 240 tons. The next year the first steamboat above Niagara Falls was launched at Black Rock, and made voyages between that place and Detroit. The schooner Illinois, 100 tons, was the first vessel to arrive at Chicago from the lower lakes. "This event," writes one, "occurred 12 July 1834, when all the male inhabitants of the village, amounting to nearly 100, assisted in dragging the craft across the bar."

Gibson and Linn, according to Ringwalt, in 1776, descended the Ohio and the Mississippi from Pittsburg to New Orleans, and brought back a cargo of 136 kegs of gunpowder for the use of the continental army. When they reached the falls of the Ohio River they were obliged to unload their boats and carry the cargo around the falls; but the success of their trip gave an impetus to the flatboat trade which has continued in one form or another up to the present time. The first regular packet line between Pittsburg and Cincinnati was established in 1794, and consisted of four keel-boats of 20 tons each. They were much like the modern canal-boats, and could be either propelled by sails, pushed by poles, or towed by horses. Freight charges were high, the following rates for steamboats on the Mississippi having been established by the legislature of Louisiana in 1812: From New Orleans to Louisville, four and one-half cents per pound for heavy goods, and six cents for light, averaging five cents per pound, or per ton \$112; from New Orleans to Natchez, three quarters of a cent per pound, or \$1.50 per barrel; and the same rate for all intermediate landings from New Orleans to Louisville. Passage, \$125 for the full trip, and \$30 to Natchez. Half-rates were allowed for tonnage going down the river.

COMMERCE

Hon. Levi Woodbury, who made a trip down the Mississippi in 1833, says: "At every village we find from 10 to 20 flat-bottom boats, which, besides corn on the ear, pork, bacon, flour, whiskey, cattle and fowls, have a great assortment of notions from Cincinnati and elsewhere. Among these are corn brooms, cabinet furniture, cider, apples, plows, cordage, etc. They remain in one place until all is sold out, if the demand be brisk; if not, they move further down. After all is sold out they dispose of their boat, and return with their crews by the steamers to their homes."

By 1856, however, the steam-tonnage of the Mississippi and its tributaries equaled the steam-tonnage of the whole of Great Britain. Until 1850 the boats measured from 200 to 400 tons; but the builders enlarged their vessels from year to year, until, in 1878, they attained the size of the transatlantic liners. The steam-tonnage of the inland and coast lines of the United States increased from 24,879 tons in 1823 to 1,172,372 tons in 1876, as follows:

INLAND AND COASTWISE FLEETS, 1876.

	Number of Vessels	Tonnage
Atlantic and Gulf coasts	2,081	665,879
Pacific coast.....	270	78,439
Northern lakes	921	201,742
Western rivers.....	1,048	226,312
Total	4,320	1,172,372

In 1891 there were on the Great Lakes 3,700 steam- and sail-vessels, with a net registered tonnage of 1,250,000 tons. In that year they carried 63,250,000 tons of freight, while in 1890 the ton-mileage carried by this fleet was 18,849,348 ton-miles, or 24.7 per cent of the ton-mileage of all the railroads of the United States. The tonnage of the lake marine more than doubled during the five years from 1887 to 1892. On the 16,000 miles of the navigable waters of the Mississippi River and its tributaries there were afloat, in 1890, 7,445 crafts of all kinds, with a registered tonnage of 3,400,000 tons. During the year this fleet carried 30,000,000 tons of freight and 11,000,000 passengers. The Hudson River had, in the same year, a traffic of 5,000,000 passengers and 15,000,000 tons of freight, exclusive of 3,500,000 tons that passed through the canals of New York by way of the Hudson River to tide-water. The total for these four divisions of waterways alone was 111,750,000 tons. The Mississippi Valley rivers furnish transportation facilities for 24 States, embracing an area of 1,240,000 square miles. In 1903 about 23,255 vessels of 5,198,569 tons were engaged in our domestic trade.

The average freight rate on wheat from Chicago to New York in 1902 was 5.3 cents per bushel by lake and canal, and 17½ cents per bushel by rail, the water cost being \$1.76 per ton, and the rail cost \$5.82 per ton. The Erie Canal is only a little over 300 miles long, yet Mr. Albert Fink says that it regulates the freight rates of all the railroads east of the Mississippi River, not only on those whose tracks run parallel with the canal, but upon those in every part of that territory.

The development of the railway system of the United States has been without a parallel. Time and distance have been overcome, and the products of the farmers, the lumbermen, the miners, and the artisans now reach in successful com-

petition the markets of the world. The railway had its inception less than 70 years ago in the little four-mile tramway constructed to the granite quarries in the town of Quincy, Mass., and operated by horses. The first really important railway was the Baltimore and Ohio, 14 miles of which were opened in 1830. In the same year the South Carolina Railway was begun; in 1833 it was completed for 136 miles, and was then the longest railway in the world. It was also the first railway to carry the United States mails. In 1834 the opening of the Philadelphia and Columbia Railroad, as part of the system of internal improvements of Pennsylvania, gave that State a continuous line of railways and canals from Philadelphia to Pittsburg. In 1835 the Washington branch of the Baltimore and Ohio road was opened. The completion of the Boston and Albany road in 1841, and a connecting-link composing the line from Albany to Buffalo in 1842, marked the opening of the first great railway line. The real beginning of interstate commerce in this country may be said to date from this time.

The total railway mileage of the United States in 1902 was above 200,000 miles, or nearly one half the railway mileage of the world. The total mileage of all tracks reaches 274,195.36 miles, representing a capital of nearly \$13,000,000,000—an amount equal to one sixth of the entire wealth of the country, and five times greater than the entire circulating currency of the United States. The annual gross earnings and other income of this capital is more than \$1,900,000,000—an amount more than three times the entire annual revenues of the government; and it operates lines having an annual traffic of nearly 650,000,000 passengers and more than 1,200,000,000 tons of freight. An idea of the magnitude of this single branch, concerned with the transportation of freight, may be conveyed when it is stated that 1,000,000,000 tons means that a train of cars long enough to reach more than six times around the earth would be required to transport it all at a single load. The average distance over which this freight was hauled by the railroads was about 128 miles. Set a single team to the task, and it would take it something like 1,400,000 years to move the same amount 25 miles.

The total number of tons of freight carried by the steamers and sailing vessels of the rivers, lakes, and coastwise transportation routes of the United States in 1902 may be reckoned one third that of the railways. Add to this amount the freight traffic of the railways during the year 1902, namely, 1,200,315,787 tons; this would make the total average tonnage of the railways and waterways of the country more than a billion and a half tons, or 20 tons for every inhabitant of our continental possessions.

As late as 1850 there seems to have been little conception of the influence which the railways were to wield in the development of the interstate traffic of this great country, and of the country itself. It was thought that they could not successfully compete with waterways and canals, except where a speedy carriage was essential. The solution of the problem of cheap transportation from Pittsburg, for example, was not reached until the railroads threatened to take away all traffic from the traders; so that Pittsburg coal can now be delivered in New Orleans for about \$2.60 per ton, although New

COMMERCE

Orleans is 2,000 miles away by river. Cow Island, on the upper Missouri, is 4,300 miles from Pittsburg; yet coal is carried to market there, a distance as great as from New York to the Baltic Sea. Not less than 20,000 miles of inland navigable waters are accessible to these Pennsylvania coal traders. The aggregate number of vessels engaged in this business is more than 4,000, and of the 13,000,000 tons of coal that were mined in 1893 in the counties near Pittsburg about 4,500,000 tons were carried to market by water. Yet let me illustrate further the growth of domestic trade in a part of our country which was only lately as remote and undeveloped as the westernmost provinces of Brazil. This growth, due to the transition from the pony express to the transcontinental steam-car, quickened the activities of California and of the whole Pacific slope like the inspiration of a new life. The assessed value of all property within California rose from \$260,563,886 in 1869 to \$584,578,036 in 1879. In 1889 shipments were made over the lines of the Southern Pacific system of 1,140,596,010 pounds from San Francisco, and of 1,571,347,605 to San Francisco. The probable duration of an overland journey from the Missouri River to California before the continental railways were constructed was about 110 days.

Chittenden in his early steamboat navigation on the Missouri River says the traffic reached high-water mark in 1867. That profits on a single voyage of a boat between Saint Louis and Fort Benton had reached as high as \$65,000.

Freight rates were 12 cents a pound in 1866, or \$240 a ton. Insurance rates 6½ cents on sidewheel and 8 cents on sternwheel steamers; a cabin passenger paying \$300, and the salary of a pilot whatever he might be pleased to ask, as high as \$1,200 per month being paid.

It is claimed that the practically unobstructed competition which has prevailed among railways has been a main cause of many consolidations of railway interests. On the other hand, in defense of consolidation and combination, it is asserted that these result in better and swifter service and lower rates. Whatever the cause or causes, rates generally are much lower than they were 10 years ago. On 30 June 1894, 44 railways, each with an operated mileage of over 1,000 miles, out of a total of 1,039 operating corporations, controlled and operated 56.30 per cent of the total railway mileage in the United States. Extend the classification to include all roads operating over 400 miles of line, and it appears that 90 corporations operate 72.90 per cent of our total railway mileage. In 1837 the superintendent of motive power of the Columbia and Philadelphia Railroad reported that the following charges were imposed on the railroads named:

FREIGHT RATES ON RAILROADS IN 1837.

Railroad	Per Ton per Mile Cents
Baltimore & Ohio.....	4½
Baltimore & Washington.....	4
Winchester & Potomac	7
Portsmouth & Roanoke.....	8
Boston & Providence.....	10
Boston & Lowell.....	7
Mohawk & Hudson.....	8
Petersburg.....	10

These rates seem preposterous when compared with the .757 of one cent per ton per mile, which was the average charge on all the rail-

roads of the United States during the year 1902.

The growth of lake commerce in this country is something marvelous. The increase of freight shipments through the Saint Mary's Canal, both east and west bound, was from 1,560,000 tons in 1881 to 28,403,065 tons in 1901. There was an increase in the valuation of this tonnage from \$28,965,612.92, in 1881, to \$290,000,000 in 1901. During the season of 225 days in 1901 in which this canal was open there passed through it 14,372 steamers and 4,482 sail-vessels—a total, with unregistered craft, of 20,041 vessels, or an average of about 90 per day during the entire season. The total registered tonnage for the season was 8,400,680. The freight which passed through the canal in 1900 was carried an average distance of about 825 miles, at a cost per mile per ton of 1.18 mills. The size of the vessels passing through the canal continues to increase. The average registered tonnage per vessel in 1867 was 626.3 tons, while in 1891 it was 962.1 tons, and in 1901 there were over 100 vessels, steam and sail, of from 5,000 to 8,000 tons and 10 above 8,000 tons. This freight-tonnage during the season of 1889 amounted to 19,717,860 tons. The tonnage passing through the same canal during the season of 1890, including the foreign and coastwise traffic, amounted to 21,888,472 tons, while the tonnage of all vessels of the Atlantic coast engaged in foreign trade during 1890 was but little more—22,497,817 tons. All the vessel-tonnage engaged in the foreign trade, entering and clearing at London, England, during the same year was 13,480,767 tons, and at Liverpool the same year it was 10,941,800 tons; so that the vessel-tonnage passing through the Saint Mary's Canal in 1890 was more than 8,000,000 more than that of London, about double that of Liverpool, and nearly equal to that of the two combined. Another comparison: The tonnage passing through the Suez Canal in 1900 was 13,699,237—less than one half of that passing through the Saint Mary's which was open for navigation during the season of 1890 only 228 days, while the Suez Canal was open during the entire year. The total tonnage, entrances, and clearances, of the foreign and coastwise trade of Chicago and Buffalo for the season of 1901, as compared with the total foreign trade tonnage of the four great British ports, was as follows:

CHICAGO AND BUFFALO TRADE.

	Tons
Chicago.....	13,831,882
Buffalo.....	10,455,032
London.....	17,275,645
Liverpool.....	12,636,225
Glasgow.....	3,825,890
Hull.....	4,425,356

Carrying the comparison still further, the volume of this inland trade is again shown in the figures giving the foreign trade of the following great commercial ports in 1901-2:

FOREIGN TRADE TABLE.

	Tons
New York.....	12,646,555
Hamburg.....	16,441,470
Antwerp.....	14,967,921
Marseilles.....	9,563,544
Havre.....	4,406,159
Bremen.....	4,377,824
Boston.....	4,498,785
Philadelphia.....	3,871,928
San Francisco.....	2,562,655

COMMERCE

It will be seen that the commerce of the two inland cities, Chicago and Buffalo, consisting almost wholly of a coastwise trade within the confines of the Great Lakes, compares most favorably with the tonnage movement of the great maritime cities of the world. In 1867 the average rate for carrying iron ore from Escanaba to Lake Erie was \$4.25 per ton; in 1870 the average rate was \$2.50 per ton; in 1891 the average rate was 82 cents per ton; and at one time in that year it was as low as 55 cents per ton.

The benefit of these great reductions in lake transportation rates appears very forcibly in the movements of the huge cargoes of coal that are sent from ports on Lake Erie to the harbors of the upper lakes. In 1887 the average rate per ton for lake transportation of coal from Buffalo to Chicago was \$1.05; in 1891 the average rate was 50 cents per ton; and from 10 Nov. 1891 to the close of navigation, coal was carried from Buffalo to Duluth, a distance of 1,000 miles, for 10 cents per ton. Using the common unit (cost per ton per mile) for comparison, and taking the official report of the movement of freight through the St. Mary's Falls Canal, the ton-mileage rate has decreased as follows: 1887, 2.3 mills; 1888, 1.5 mills; 1889, 1.5 mills; 1890, 1.3 mills. The average revenue per ton of freight per mile on all the railroads of the United States was given at 9.4 mills in 1890, or more than seven times as much as the cost of freight carriage through the St. Mary's Falls Canal.

The regulation of interstate commerce before the Declaration of Independence was by Parliament. Under the Articles of Confederation trade was controlled, where it was controlled at all, by the legislatures of 13 distinct sovereignties. It soon became evident that the several States would not unite in any general or fixed rule to govern commerce. Discriminations naturally followed, which resulted in confusion and discord among the different parts of the confederacy. Accordingly one of the reforms demanded under the old confederacy, and introduced in the Constitutional Convention, was that "Congress shall have power . . . to regulate commerce . . . among the several States." The dissatisfaction among the States in respect to the interchange of trade, and the urgent demand for a uniform and general principle controlling their commerce, were clearly shown in the debates of the Constitutional Convention. The following contemporaneous opinions are of interest:

"The want of authority in Congress, under the confederation, to regulate commerce had produced in foreign nations, particularly Great Britain, a monopolizing policy injurious to the trade of the United States. . . . The same want of a general power over commerce led to an exercise of the power, separately, by the States, which not only proved abortive, but engendered rival, conflicting, and angry regulations." (Madison Papers, Vol. V., p. 119.)

"The oppression of the uncommercial States was guarded against by the power to regulate trade between the States." (Mr. Sherman, Deb. on Fed. Cons., Mad. Pap., Vol. V., p. 434, 1787.)

"Mr. Carroll and Mr. L. Martin expressed their apprehensions, and the probable apprehensions of their constituents, that, under the power of regulating trade, the general legislature might favor the ports of particular States, by re-

quiring vessels destined to or from other States to enter thereat." (Ibid., p. 455.)

To cover this defect, Art. I., Sec. 9, Cl. 6, of the Constitution was enacted, to wit: "No preference shall be given by any regulation of commerce or revenue to the ports of one State over those of another, nor shall vessels bound to or from one State be obliged to enter, clear, or pay duties in another."

Gen. Washington, in a letter to a friend on the weakness of the confederation, and pleading for a stronger government, wrote: "We have abundant reason to be convinced that the spirit of trade which pervades these States is not to be repressed. It behooves us, then, to establish just principles, and this cannot, any more than other matters of national concern, be done by 13 heads differently constructed and organized. The necessity, therefore, of a controlling power is obvious, and why it should be withheld is beyond my comprehension."

Alexander Hamilton, in the 'Federalist,' Letter VII., wrote: "The competition of commerce would be another fruitful source of contention. The States less favorably circumstanced would be desirous of escaping from the disadvantages of local situation, and of sharing in the advantages of their more fortunate neighbors. Each State or separate confederacy would pursue a system of commercial probity peculiar to itself. This would occasion distinctions, preferences, and exclusions which would beget discontent. The habits of intercourse on the basis of equal privileges, to which we have been accustomed from the earliest settlement of the country, would give a keener edge to those causes of discontent than they would naturally have, independent of the circumstances." Also, in Letter XXII.: "The interfering and unneighborly regulations of some States, contrary to the true spirit of the Union, have, in different instances, given just cause of umbrage and complaint to others; and it is to be feared that examples of this nature, if not restrained by a national control, would be multiplied and extended till they became not less serious sources of animosity and discord than injurious impediments to the intercourse between the different parts of the confederacy."

In the debates of the Constitutional Convention, the clause regulating commerce, etc., was agreed to *nem. con.*, not even a yea-and-nay vote being taken. When the grant of this power to regulate commerce among the States was made by the Constitution, the traffic which might be controlled under it was quite insignificant. On the land there was nothing that could approach the dignity of interstate commerce, and its regulation, as also of that which was exclusively State traffic, was for the most part left to the rules of the common law. The exceptional regulations, if any seemed to be called for, were made by the State laws. For the regulation of commerce on the ocean and other navigable waters, Congress very promptly passed the necessary laws; but its jurisdiction within the limits of the States was not very clearly understood, and it was not until the celebrated case of *Gibbons v. Ogden*, decided in 1824, that it was authoritatively and finally determined that the waters of a State, when they constituted a highway for foreign and interstate commerce, are, so far as concerns such commerce, as much

COMMERCE

within the reach of Federal legislation as are the high seas, and consequently that exclusive right for their navigation cannot be granted by States whose limits embrace them. But while providing from time to time for the regulation of commerce by water, Congress still abstained from undertaking the regulation of commerce by land. The reasons were the same. The land commerce was insignificant, and the rules of the common law were in general found adequate for the settlement of any questions. When Congress provided for the construction of the Cumberland road, it was thought undesirable to regulate its use by national law, or to take national supervision of the commerce upon it; and it was left to the supervision and care of the States through or into which the road was built. With the application of steam as a motive power for propelling vessels, conditions were immediately changed. But even then the circumstances were favorable to a prolongation of State control. The first improved highways were turnpikes, the next in grade canals; but the highways by water, as well as the highways by land, were provided for by the States. It was not unnatural that they should be left in charge of the regulation of trade upon them, especially as no complaint was made that their regulations were unjust, or that they discriminated unfairly as against the citizens or the business of other States. When, in 1830, steam-power began to be applied to the propulsion of vehicles upon land, the same conditions continued to prevail. The power of the Federal government in the regulation of commerce between the States was put forth negatively rather than affirmatively; that is to say, it was put forth in restraint of excessive State power, instead of by way of affirmative national regulation.

The subject of the management of railways in respect to interstate commerce had been more or less discussed in Congress, when in March 1885, a resolution was adopted by the United States Senate empowering a select committee, known subsequently as the Cullom Committee, to investigate it. On 18 Jan. 1886, this committee submitted a report based upon testimony contained in more than 1,450 printed pages. On page 40 the committee says: "Unjust discrimination is the chief cause of complaint against the management of railroads in the conduct of business, and gives rise to much of the pressure upon Congress for regulating legislation."

In summing up the testimony, on pages 180-2 the committee says: "The complaints against the railroad systems of the United States expressed to the committee are based upon the following charges: (1) That local rates are unreasonably high, compared with through rates; (2) that both local and through rates are unreasonably high at non-competing points, either from absence of competition or in consequence of pooling agreements that restrict its operation; (3) that rates are established without apparent regard to the actual cost of the service performed, and are based largely upon what the traffic will bear; (4) that unjustifiable discriminations are constantly made between individuals in the rates charged for like service under similar circumstances; (5) that improper discriminations are made between articles of freight and branches of business of a like character, and between different quantities of the same class of freight; (6) that unreasonable dis-

criminations are made between localities similarly situated; (7) that the effect of the prevailing policy of railroad management is, by an elaborate system of secret special rates, rebates, drawbacks, and concessions, to foster monopoly, to enrich favored shippers, and to prevent free competition in many lines of trade in which the item of transportation is an important factor; (8) that such favoritism and secrecy introduce an element of uncertainty into legitimate business that greatly retards the development of our industries and commerce; (9) that the secret cutting of rates, and the sudden fluctuations that constantly take place, are demoralizing to all business except that of a purely speculative character, and frequently occasion great injustice and heavy losses; (10) that in the absence of national and uniform legislation the railroads are able, by various devices, to avoid their responsibility as carriers, especially on shipments over more than one road, or from one State to another, and that shippers find great difficulty in recovering damages for the loss of property or for injury thereto; (11) that railroads refuse to be bound by their own contracts, and arbitrarily collect large sums in the shape of overcharges, in addition to the rates agreed upon at the time of shipment; (12) that railroads often refuse to recognize or be responsible for the acts of dishonest agents acting under their authority; (13) that the common law fails to afford a remedy for such grievances, and that in case of dispute the shipper is compelled to submit to the decision of the railroad manager or pool commissioner, or run the risk of incurring further losses by greater discriminations; (14) that the differences in the classifications in use in various parts of the country, and sometimes for shipment over the same road in different directions, are a fruitful source of misunderstandings, and are often made a means of extortion; (15) that a privileged class is created by the granting of passes, and that the cost of the passenger service is largely increased by the extent of this abuse; (16) that the capitalization and bonded indebtedness of the roads largely exceed the actual cost of their construction or their present value, and that unreasonable rates are charged in the efforts to pay dividends on watered stock and interest on bonds improperly issued; (17) that railroad corporations have improperly engaged in lines of business entirely distinct from that of transportation, and that undue advantages have been afforded to business enterprises in which railroad officials are interested; (18) that the management of the railroad business is extravagant and wasteful, and that a needless tax is imposed upon the shipping and traveling public by the unnecessary expenditure of large sums in the maintenance of a costly force of agents engaged in a reckless strife for competitive business."

The report of Senator Cullom's committee formed the basis of the law commonly known as the Interstate Commerce Act, which became effective 3 April 1887. The supreme court in the case of the Union Pacific Railway Company against Goodridge, October term, 1892, in speaking of a similar act of the State of Colorado, said: "This act was intended to apply to interstate traffic the same wholesome rules and regulations which Congress two years thereafter applied to commerce between the States, and to

COMMERCIAL COURTS

cut up by the roots the entire system of rebates and discriminations in favor of particular localities, special enterprises, or favored corporations, and to put all shippers on an absolute equality."

The statute recognizes the fact that it is no proper business for a common carrier to foster particular enterprises or to build up new industries; but, deriving its franchise from the legislature, and depending upon the will of the people for its very existence, it is bound to deal fairly with the public, to extend reasonable facilities for the transportation of persons and property, and to put all its patrons upon an absolute equality. The laws making the giving of transportation privileges a criminal offense are at present difficult of enforcement. Public opinion has not yet been roused to the energetic condemnation which is necessary to make these special favors as completely unknown as they are at the post-office window, where the value of every stamp must be paid.

At the head of all the vast machinery employed in moving interstate commerce are men of integrity, and of ability rarely developed in other walks of life, broad-gauged men, to whom the public is indebted for the efficiency with which they carry on their stupendous enterprises. Under the railway presidents are the traffic managers, the passenger and freight agents. The feeling of these men that they must serve solely the corporations which employ them has grown to be a second nature with them. Their duty to the government and to the public, therefore, is sometimes obscured, and it is hard for them to realize that many practices which they have come to regard as ordinary business methods are wrong. So also the shipper and the merchant find it hard to realize that the push and barter and dicker that have made them successful must be abandoned when they ship their merchandise; that it is no longer to be bargained for, and cannot be carried except at a rate open to every competitor.

On 4 Feb. 1887, the Act of Congress creating the Interstate Commerce Commission, and investing it with authority to regulate certain matters with respect to commerce which were detrimental to the public interest, and with authority to require annual reports from all carriers engaged in carrying interstate commerce, was passed. This act, being in the nature of experimental legislation, has not accomplished all that its framers hoped or intended, but that great good has been accomplished cannot be denied. Various defects in its practical application have from time to time been brought to the attention of Congress, and amendments to remedy some of them have been adopted. The statistics compiled from the reports required under the provisions of this act have marked a new era in railway statistics in this country. Being compiled from sworn reports made up on a uniform plan and for a uniform period, in compliance with a requirement of law, and published as official documents of the government, they are accepted as authority, and eagerly sought after by the public and by railway officers.

I may observe in closing that within the last two or three years the courts have taken advanced ground in asserting the power of the Federal government over interstate commerce. It was held by the supreme court in the case of Debs that "the government of the United States

is one having jurisdiction over every foot of soil within its territory, and acting directly upon each citizen; that while it is a government of enumerated powers, it has within the limits of those powers all the attributes of sovereignty; that to it is committed power over interstate commerce and the transmission of the mail; that the powers thus conferred upon the national government are not dormant, but have been assumed and put into practical exercise by the legal action of Congress; that in the exercise of those powers it is competent for the nation to remove all obstructions upon highways, natural or artificial, to the passage of interstate commerce or the carrying of mail; that while it may be competent for the government (through the executive branch, and in the use of the entire executive power of the nation) to forcibly remove all such obstructions, it is equally within its competency to appeal to the civil courts for an inquiry and determination as to the existence and character of any alleged obstructions, and if such are found to exist, or threaten to occur, to invoke the powers of those courts to remove or restrain such obstructions." In this case the extent and nature of the power of the Federal government over interstate commerce, and the methods by which that power can be applied, were discussed. It was decided that the United States circuit court, sitting as a court of equity, has power to enjoin, at the instance of the attorney-general of the United States, acts of obstruction to interstate commerce, notwithstanding that the acts enjoined, or some of them, might amount to offenses against the criminal law of the United States.

While it is clearly the fact that, under our form of government, the national authority has no excuse for interfering with the relations existing between employer and employee in ordinary business transactions, it is maintained by many that as the government has control of the agencies engaged in interstate commerce, those who are employed by such agencies are also engaged in the public service, and for that reason an obligation exists on the part of Congress to enact such legislation as will tend to settle differences which may arise between railroads and their employees without causing inconvenience to the public.

EDW. A. MOSELEY,

Secretary Interstate Commerce Commission.

Commercial Courts are tribunals distinct from the ordinary civil courts, and in some countries are established in various commercial towns, or within certain districts, to settle disputes with regard to rights and obligations between persons engaged in trade, with the assistance of experienced merchants, by a brief process, according to equitable principles. The general introduction of tribunals of this sort began in the Middle Ages. The first was probably that established at Pisa, in the 11th century, and the basis of its decisions was the code of maritime laws of Pisa, confirmed by Pope Gregory VII. in 1075. At first the commercial tribunals were not so much courts established by government as arbiters of disputes, freely chosen by the merchants and confirmed by the governments. Under the name of commercial consuls such committees of arbitration were appointed in all the great commercial cities of Europe; and in the

COMMERCIAL EDUCATION

course of time they really became tribunals of justice, and were, in part at least, administered by men of legal learning and experience. Pope Paul III. confirmed the commercial consuls in Rome. Francis II. in 1560 granted to the Parisian merchants particular arbiters for the adjustment of commercial disputes; and in 1563 was established the Parisian Court of Commerce, consisting of a judge and four consuls. The same thing soon followed in all the important commercial towns of France. In London Henry VII. appointed particular commercial judges. The president of the commercial tribunal for the Hanse towns, established in 1447, bore the name of alderman. At Nuremberg, in 1621, a similar tribunal was instituted under the name of inspectors of the markets. The diets of the empire even called upon the German princes and commercial cities to follow this example, as the decrees of the empire in 1654 and 1668, and the decree of the imperial commission of 10 Oct. 1663, show. In many of these cities, as in Frankfort-on-the-Main, and in Leipsic, they were not so much independent authorities as delegates from the city councils. When commercial courts take cognizance particularly or solely of disputes relating to maritime affairs, they may be called courts of admiralty. Such a court was erected in Hamburg in 1623. The internal regulations of commercial courts commonly require that a part of the members, or at least the presidents, should be lawyers; the rest are for the most part experienced merchants, who are better adapted than regular judges to give counsel on commercial affairs, with which they are more acquainted, and which very often are not to be reduced to simple principles of law, but are to be decided according to commercial practice. Their jurisdiction commonly extends over all commercial disputes, matters of exchange, insurance, freight, bottomry, average, etc.; and further, over bankrupts, the hiring of shops and stores, clerks, and apprentices; the debts of those who receive goods from merchants upon credit; and all natives and foreigners who traffic in the place, and are found there; all shipowners, contractors for transporting goods, brokers, factors, etc., are obliged to submit to their decisions. They do as much as possible by oral investigation; and the intention of their institution is that they shall avoid the long and formal process of other courts. But when the difficulty and confusion of the matters in dispute occasion the necessity of an investigation in writing, recourse is had thereto. The greater despatch of these courts consists principally in this—that the defendant is orally summoned, once or several times, to appear before them at an early day, and if he fails to come, he can be brought by force. The complaint is then made orally, both parties are heard, and sentence is given, if possible, immediately after. But as this can seldom be done, and most cases require reference to written documents, a day not far distant is appointed for the answer to the complaint and for the evidence on both sides, and the time is seldom or never prolonged. The remedies against a sentence must be sought from the same judges, and are not easily obtained. Appeals are only allowed in very important cases, and upon the deposit of a large sum as a pledge that the final decision shall be obeyed without delay. The principal features of this process form the basis of most commercial

codes. From the sentence of these tribunals appeal is made to the court of appeal within whose jurisdiction they happen to be. The other countries where these tribunals exist are Belgium, Spain, Portugal, and Italy. See COMMERCIAL LAW.

Commercial Education. It is not known when commercial education was begun in the United States, and the facts about its subsequent development are difficult to ascertain. The opportunities for formal school preparation for a business career which are now offered in the United States may be roughly divided into four classes. First: The "commercial college" of the well-known type. Second: The business courses of the public high school. Third: Private endowed schools, more or less technical in character. This class might include business courses in the unclassifiable, but increasingly important and popular correspondence schools. Fourth: College and university courses.

The "commercial college" is the best known and almost the only well-known method of business training. Its almost spontaneous origin, its rapid and wide diffusion, its rough adaptation of primitive material to the satisfying of immediate and pressing needs, its utter disregard of all save the direct answer to current demand, its gradual recognition of present inadequacy, and its determination toward broader, fuller usefulness, mark it as a product of a young, eager and gradually maturing people. It is claimed that Bartlett of Cincinnati was the first American to assume for his undertaking the name of business "college," and he was unquestionably one of the earliest and most successful workers in this field. He gave commercial instruction to private pupils in the forties. About the middle of the fifties there were not more than a dozen commercial schools scattered in the large cities from Boston and Philadelphia to Chicago and St. Louis. They had arisen with the idea of facilitating the entrance of young men into minor positions as clerks and bookkeepers. The instruction offered was very meagre,—commercial arithmetic, a little practice in keeping accounts, and a certain amount of ornamental penmanship made up the total. A school of this kind did not require a large force of teachers,—in many cases the entire instruction was given by one man. The equipment was not elaborate and the fees were low, \$40 being an average charge, not for one term or for one year, but for an indefinite or life scholarship, and often valid at any of a large number of schools, embraced in single "chain." In those early days there were no text-books for the "commercial colleges"; and arithmetic and bookkeeping were taught by manuscript prepared by actual accountants engaged in business. The students also came primarily from business houses, a fact which necessitated the institution of evening classes. The average time spent in a business college was not more than three months. Poor as such education was, it filled a need, for commercial colleges thrived and multiplied and with success became still more successful. Increased popularity led to higher fees and longer courses, to the preparation of printed texts; life and interchangeable scholarships were abolished; the teaching force was increased; day classes largely took the place of evening instruction; school equip-

COMMERCIAL EDUCATION

ment improved and gradually these institutions grew into the apparently permanent place in public favor which they enjoy to-day.

But apart from mere numerical increase, considerations of the lengthened course of study, improved teaching, and better average preliminary preparation, there is evidence of broadening views and sounder conceptions among the business college teachers. Of course, even in the limited field of preparing for subordinate mechanical labor, good work may be done and the business college accomplished excellent results. But to-day the directors of commercial schools realize that for clerical positions more technical instruction is necessary; that a broader education pays, even if no higher position is ever won; and that the business college can equip the student through liberal and fundamental studies for subsequent promotion. These ideas produce their logical outcome, a course of study which is at once broader and more technical. The process is slow, but evidences of advance are apparent in the printed announcements of various schools, in the discussions of business teachers' conventions, and in the periodicals, weekly and monthly, issued in the interests of business education. Secondly, the necessity of pedagogical training has been recently forced upon the consciousness of business school directors. So that to-day there is a growing proportion of men and women of collegiate or other special preparation in this work. A third favorable influence on the work of the business college has been the recent and marked growth of a new form of competition, that of the public high school, a rivalry which can only prove to the advantage of each. It is not too hazardous to predict that the commercial college may hereafter be glad to see much of its work go over to the system of public education, thus giving it better equipped students and freedom to evolve a still higher course of instruction. The probability of this further evolution of the business college into a supplementary educational instrument of a somewhat better type is foreshadowed in a fourth fact favorable to commercial training, its formal recognition as a factor in public education by the University of the State of New York, whose regents trusted that this standard would create a demand for higher qualifications and lead to a repetition of the experience with the professional schools of medicine and law, when similar actions led to a large increase in the attendance at secondary schools. Conditions of recognition of a business school are in brief: Instruction by at least six teachers giving all their time to the work; an equipment worth not less than \$5,000, exclusive of buildings and fixtures; and a satisfactory one-year course, supplementary to the high school and consisting of at least 500 hours of actual instruction, in preparation for the State business diploma. Out of 30 schools in the State reported by the bureau of education, the regents granted full recognition to 11 and provisional registration to 13. Besides granting registration to business schools on these conditions, the university decided to issue business credentials, including a State business diploma and a State stenographer's diploma and corresponding certificates. The distinction between the two is the requirement of graduation from a registered high school in

the case of the diploma, but not of the certificate. To obtain the diploma, candidates must be certified as having completed also a full one-year registered business course, and must pass regents' examinations in advanced bookkeeping, commercial law, business English, arithmetic, practice, and office methods, commercial geography, and the history of commerce. If the high school course previously taken did not include United States history, civics, and economics, the regents' examination in these subjects must be passed. The requirements in general are much higher than for the corresponding subjects in the high school course, and require a higher degree of theoretical and practical knowledge.

The annual tuition fee varies in the better commercial colleges from \$50 to \$150 and even \$200 for a school year of 10 months. It is perfectly safe to say that in the quality of the work which they do, and in the equipment for this particular work, the American commercial colleges have no rivals, largely because they are engaged in the mechanical work in which Americans excel the rest of the world. They are not educational institutions in any broad sense of the term at all, but trade schools pure and simple. They train for facilities. That hundreds of the students of the colleges have been successful business men of initiative and independent enterprise simply proves that they had native ability for that sort of thing; not that this sort of training was especially helpful, though it is only fair to say that many of these men trace their start in business to the technical skill in bookkeeping, etc., which they acquired in the schools.

The Packard Commercial College opened in New York, in the spring of 1858, as a link in the Bryant and Stratton chain of business colleges, and may be considered a type of these colleges. In 1867 Mr. Packard bought the interest of his partners, Bryant & Stratton, and changed the name from Bryant, Stratton & Packard's business college to Packard's business college. The most important result of the change of proprietorship was in doing away with the life-scholarship plan under which the "chain" had been conducted, and putting an end to the interchangeability of tuition. Mr. Packard's lead was followed by the other schools, and thus the foundation was laid for individual,—if not competitive work, which has done so much to advance the character of business education in this country. In the first years of the existence of the school, Mr. Packard wrote text-books on bookkeeping for the use of Bryant & Stratton schools, which in revised form are still used. The school was first located in two small rooms in the Cooper Union building, of which it was the first tenant. In the fall of 1863 it was removed to the Mortimer block, corner of Broadway and 22d Street and Fifth Avenue, and in the spring of 1870 to the Methodist building, corner of Broadway and 11th Street, occupying the entire fourth story of the structure. Here it remained for 17 years, until it outgrew its accommodations, and moved to its present quarters. In 1865 commercial law was added to the course, and later practical English and civics. In 1872 stenography was first taught, in classes only. A very small proportion of students studied this branch, and always in connection with the commercial course. The following year the

COMMERCIAL EDUCATION

typewriter was introduced. This was the first school to teach stenography or typewriting. At the present an important feature of the work, from which no student is excused, is public speaking without any attempt at elocution. Another feature is the character record, a brief history of the student's career from the beginning to the end of his course, showing not only progress in study, but also comments by his various teachers on any special characteristics or performance that is deemed worthy of comment. It has proved not only efficacious as discipline, but is useful as reference after the student has passed out from the school and refers to it for recommendation in business. This record is never destroyed. A specimen of the student's work is also preserved. The commercial course now covers about a year and a half, or 15 months, the students entering at any time and being graduated not in classes, but as they finish the course, in greater or less time, according to their ability. The instruction is largely individual. The school graduates yearly about 150 pupils, the number in recent years being almost equally divided between the stenographic and commercial departments.

The career of Thomas May Pierce, of Philadelphia, illustrates in a similar way the growth of this department of our educational system. Starting in 1865 with the meagre curriculum then offered, he increased the scope of the work, improved the equipment, introduced regularity and system into the instruction until, when he died in 1896, he had built up what might fairly be called a typical school of the better sort. He employed some 25 instructors, and occupied quarters in one of the best office buildings in Philadelphia, where he used 15 rooms containing 10,000 feet of actual floor space. The charge for tuition was \$15 per month, or \$100 for a course of seven months.

Commercial instruction in the American public school system is only beginning to attract general attention, despite the fact that a certain amount of this work has been carried on for many years. A commercial course was not infrequently announced, although it differed from other courses in the same school only by the inclusion of a little typewriting, bookkeeping, and possibly stenography. Of late years a considerable change has come about, and high schools which had offered some business training have improved the course of study. Commercial instruction has been introduced for the first time into many schools, and gradually distinct and separate courses are being established in connection with city systems to give opportunities for the future business man, comparable to the aid already furnished to those looking forward to higher studies of a professional or technical kind. The natural order of development in this matter can be seen in a glance at the course of high school study in some typical cities. Omaha represents one stage, presenting a commercial course in which commercial arithmetic is substituted for elementary science and botany in the 9th grade of the regular English course, bookkeeping for zoology and mediæval history in the 10th, commercial law and bookkeeping for chemistry and French history in the 11th, and stenography and typewriting for American history and political economy in the 12th grade. Some question might arise as to the

advisability of the substitution in one case or another, yet there remains a fairly liberal plan of study, covering four years. Even if the aggregate of special preparation for business does not exceed the ordinary work of the year, it is preferable from an educational point of view at any rate either to place this late in the high school programme or to distribute it as indicated above. Boston with a two years' commercial course and little special business training, Pittsburg with one year's work in place of the second high school year, and Washington with a two years' course, are all in an early stage of development in this direction. Possibly Washington with a distinct business high school, even though the course of study covers only two years, is nearer the final form than Milwaukee with its new four-year commercial course. The evolution of a real secondary business school may come more easily through the addition of successive years to the course than through the gradual specializing of an ordinary high school curriculum. Indeed this view is borne out by the experience of the Hillhouse high school in New Haven with an admirably outlined three years' course and by the development in Paterson, N. J., of a commercial department in the city high school into practically a distinct school operated in a separate building by an entirely independent faculty, with a special course of two years, requiring one year of secondary study for admission. What is desirable seems perfectly clear. First of all the course of study should be at least four years. We cannot successfully defend commercial instruction in the public high school unless the work is as broadly educational as any other of the secondary courses. Secondly, the course should be thoroughly outlined as distinctly commercial. A mere substitution of a few business studies in the usual English course does not make for commercial training and such action is not only an inadequate provision for present needs, but it is destructive of future possibilities. A separate building is strongly desirable, not only on the ground of superior adaptability for the uses of a commercial school, but for absolute independence in fact, and full differentiation in the public thought. When a few such independent schools have solved the problem of commercial instruction, the ordinary schools will have a better basis for "commercial courses." With these considerations in view, we can readily say that between the two-year, strictly commercial course of Washington, for example, and the four-year course slightly specialized, of some other cities, the choice should be made not on the basis of what is offered now, but of approximation to the real type, namely, a well-planned, fully-specialized scheme of commercial training covering at least four years of secondary grade. This standard of secondary commercial training has been more nearly approximated in Philadelphia than in any other American city. In 1898 a department of commerce was established in connection with the Central high school. For reasons of expedience and economy, the department was housed in the new high school building, and much of the instruction given by the regular teaching force. Under a special director, however, the work promises to grow into an entirely differentiated institution, which may parallel the success of the

COMMERCIAL EDUCATION

manual training high schools of that city. The commercial department in the Pittsburg high school was organized in 1872 for the benefit of those who could not spend four years in the high school and yet desired some scholastic training in addition to that given in an elementary school, and especially such training as will best prepare for business positions. Its commercial studies are essentially those of a so-called commercial college, at the same time it undertakes to give general training. The curriculum is two years, one given up chiefly to general studies, the second to bookkeeping, typewriting, stenography. Almost one third of the students of the high school were enrolled in the commercial course and of these 50 per cent were girls. The commercial course in the Boston high schools is likewise only two years long. Commercial arithmetic, bookkeeping, and stenography are begun in the first year, occupying about one half of the time, while the rest is devoted to general studies like English, history, drawing, music, etc. The second year is much like the first; about one half the time is given to the study of commercial subjects. In the Hillhouse high school, New Haven, Conn., while all the other courses are four years each, the commercial course is three years. About five hours a week, approximately one third of the time, is given to strictly commercial subjects, the rest are of a general nature. Students who do the regular work well are permitted to take stenography and typewriting extra.

The work in the commercial courses of other high schools is along one or the other of the lines indicated above. It is at present a concession to a popular demand. It does not grow out of a conviction on the part of high school principals and teachers, that it is an essential part of the high school system. It will undoubtedly continue to grow and after a few good commercial high schools have formulated and solved the purpose of this kind of instruction, the average high school, profiting by their experience, will be able to organize commercial courses which will be better than those thus far elaborated. In the opinion of the writer the technical work of the commercial courses in high schools is not as well done as in the better commercial colleges.

The third division of business courses is the private secondary schools with the usual wide variation in what is offered, and a total registration of nearly 20,000. The influence of this form of competition upon the ordinary business college has been already mentioned. How widely it may be felt can, perhaps, best be seen through an outline of what is open to business students in one of the best endowed secondary schools of the country, the Drexel Institute of Philadelphia. Special departments of such schools and new endowments by private or semi-public bodies will, we may expect, play a large part in the work of business training in the United States, if the experience of other countries be a good basis for prophecy.

The Drexel Institute of arts, science, and industry at Philadelphia was founded and endowed by Anthony J. Drexel of that city. It included from the beginning in the scope of its instruction courses in commerce and finance. As the school is well endowed and independent of

State control, one may see from an examination of its work in this department a type, and, indeed, a very good type, of the best work which such institutions can do in the field of commercial education. The departments of commerce and finance consist of three special departments: (1) The course in commerce and finance; (2) the office course; (3) the evening course. The course in commerce and finance in its general features resembles the commercial schools of Europe, and is intended to place commercial education in its proper relation to other departments of educational work. The object of the course is to train the young men to do business rather than simply to record business. It has been organized with a view of meeting these conditions. It provides a liberal, and at the same time, thoroughly practical course of study, including two years' training in the knowledge of the world's industries and markets, the law of trade and finance, and the mechanisms and customs of business. The first special department gives a fundamental training including: (1) the production, manufacture, sale, and transportation of articles of commerce; (2) management of stock companies and corporations; (3) buying and selling of securities; (4) importing and exporting of merchandise; (5) borrowing and lending of money and credit; (6) advertising of commercial concerns; (7) keeping of business records. The work of this course is divided into two years. In addition to the general course in commerce and finance, described above, and requiring two years for its completion, three distinct office courses are offered. The bookkeeping course occupies one year and includes the following subjects: Bookkeeping, business forms and customs, typewriting, commercial arithmetic, English and penmanship. Another office course trains stenographers and typewriter operators. It includes stenography, typewriting, English, business forms, and office practice. The private secretary's course has been organized in response to applications that have been made to the institute for clerks fitted to do work of a different character from that required in a purely business office. The subjects included in the course are as follows: Stenography, typewriting, penmanship, English, correspondence, accounts, office practice, and business printing. Applicants for admission must show by examination, or otherwise, that they are prepared to meet the requirements of the course. The course occupies one year, divided into two terms. The department of evening classes is fully organized, and includes the following courses: (1) Beginners' course in bookkeeping and arithmetic. (2) Accountants' commercial course. (3) Office course in stenography and typewriting. The fee for each of the courses, for the entire season of six months, \$5. In the course in commerce and finance, the fee is \$25 for each of the two terms; and there is the same charge in the office courses.

The work done in the Drexel Institute is paralleled to a greater or less extent by similar work done in many private institutions, such as the Heffley School, formerly of Pratt Institute of Brooklyn, the Armour Institute of Chicago, and other schools founded by private initiative. Many of these schools have the advantage of ample funds, so that they are not as dependent

COMMERCIAL EDUCATION

upon the whims of individual students as are the commercial schools described in previous paragraphs, and on the other hand they are independent of the injurious influences at work elsewhere. I think it is not too much to say that the two years' course offered in the Drexel Institute forms in its way a model, and furnishes the basis for the elaboration of a curriculum which will compare favorably with the best of the European commercial schools of the same grade. The work done in the evening course of this institution corresponds more closely to the work of the ordinary business college as described above. The business courses of the "correspondence schools," although classified with the privately endowed schools, correspond more closely to the "commercial colleges," especially in their attention to the individual, their over-technical and practical purpose, their lack of the ideal of educational value in their work, and their freedom from the bondage of definite curriculum or class-room work. The "correspondence schools" are a factor of growing importance, but from the nature of the case their methods admit of little analysis or examination.

In the fourth class of institutions of commercial instruction, namely, the colleges and universities, the movement for instruction is of comparatively recent origin, and has affected few of these institutions. It is also a matter of interest that the attitude of these higher institutions of learning toward this subject is a radically different one from that of the other classes of institutions which we have been discussing. It has been very difficult indeed in this whole development to get the so-called commercial colleges, the high schools and other commercial courses of the various institutes in their departments of commerce to give any instruction, whatever, except in the so-called practical subjects, and of any kind whatever except of the most immediate, technical, special sort. In the colleges and universities on the other hand, even where they have been willing to accord a certain recognition to the necessity of higher education in commercial and business matters, it has been difficult to get them to give any attention, whatever, to the more practical sides of the work. While the commercial colleges have felt that political economy, commercial geography, and similar subjects were too remote and impracticable to make it worth while for them to admit these subjects into their curricula, the colleges have felt that accounting, commercial arithmetic, and similar subjects were too elementary to deserve any attention, whatever, from higher institutions of learning. The colleges and universities, moreover, have seen scores and hundreds of young men complete the old-fashioned classical courses of study, and enter the ranks of business men with ability and success. They have felt, therefore, that in a certain sense every man who wished to go into business, would find it worth his while to take the old-fashioned course. And they were very slow, indeed, to recognize that there were scores and hundreds of young men in the community who would take a higher education if an emphasis were laid upon subjects in which they were interested and which had to do with their future careers, who could not be persuaded to follow out an old-fashioned classical curriculum.

Four institutions in the United States, the University of Pennsylvania, in Philadelphia; the University of Chicago, in Chicago; the University of California, in Berkeley, Cal.; and Columbia University in the city of New York, deserve special mention for their connection with this subject of higher commercial education. Some other institutions, notably, New York University and the University of Vermont (where a department of commerce and economics opened in 1900), have important commercial schools.

In 1881 Joseph Wharton, Esq., a manufacturer of Philadelphia, gave to the University of Pennsylvania the sum of \$100,000 in order to establish a department in that institution for higher commercial training. The Wharton school of finance and economy had a curriculum two years in length and made up largely of political economy, political science, accounting, mercantile law and practice, etc. A bachelor's degree was conferred upon the graduates from this school. To enter as a regular student the candidate must have completed the first two years of the regular four years' college course. After some 10 years' experience it was decided to enlarge the course by extending it downward into the first two years of the college course, and at present the course in finance and economy covers four years and is included together with the other courses in arts and science in the so-called school of arts. The requirements for admission are the same as for other departments and represent the ordinary requirements of first-class American colleges. The faculty is composed of some 13 members. The nucleus of the course is in the study of economics and politics, supplemented by practical courses in accounting, business law, and business practice.

The growing demand for higher instruction in commercial subjects, combined with the success of the experiments in the University of Pennsylvania, turned the attention of several institutions toward the subject about the same time.

The University of Chicago, which opened its doors in October 1892, had included within its plan of work from the beginning a college of practical affairs. But it was not found practicable to undertake the organization of such a department until the year 1898, and students were enrolled in this college for the first time on 1 July of that year. The new department received the title of the college of commerce and politics, and was organized as a co-ordinate department with the other colleges of arts and literature and science. The purpose of the new college, like that of those already existing in the university, is two-fold. First, it aims at the attainment of general culture; in the second place the weight of work is put in the lines of the courses offered in certain specified departments. In the new college those departments include political economy, political science, history, and sociology. It is by no means a technical school, but is intended to give a kind of knowledge and training which may enable those who enter commerce, politics, journalism, or diplomacy to begin their work with a certain degree of equipment. The course of study covers four years. The first two years, however, are essentially the same as the first two years in one or another of the

COMMERCIAL EDUCATION

liberal courses, political economy, or political science being the only subject in these two years having a specific relation to the special work of the college. The other studies of the first two years are history, French or German, English, mathematics, science, and a small proportion of the time (about one sixth) is given to any other subject which the student may desire to pursue from among the courses offered in the university. The admission to the course covers about the curriculum of the typical four years' high school course, including at least four years' work in Latin, two in mathematics, and the usual time devoted to English history, physics, and German or French. It is during the last two years of the work that the special character of the college becomes apparent. The work of the last two years is divided into three groups: Commerce, politics, journalism and diplomacy. In the first group, commerce, there are four special sub-groups: (a) Railways; (b) banking; (c) trade and industry; (d) insurance. The student must elect, at the beginning of the third year's work in this college, one of these groups to which he wishes to devote his time. One third of the course for the next two years must be selected from within the group chosen. Another third may be selected by the student from a list of specified courses. The remaining third may be chosen by the student from any course offered by the departments of political economy, political science, history, or sociology. It will be seen that in this work the nucleus consists of economics and politics, using those terms in a large sense. But the University of Chicago has not added special technical courses in accounting, business law, business practice, etc., which forms a characteristic feature of the Wharton school.

About the same time that the University of Chicago determined to adopt a scheme of higher commercial training, a report was made to the board of trustees of the University of California, by one of its members, urging the adoption of a similar course there. After an elaborate discussion, it was decided to erect an additional college in the university, to be known as the college of commerce. The course extends over four years, similar to that of the other colleges in the university. The requirements for admission are essentially the same, and correspond to graduation from the typical high schools with the four years' course. In the first annual report of the president, after work was begun, it was stated that many details were yet to be determined, among others, the question of what degree should be conferred upon students who completed the course. In the same report the following statement is contained as to the scope of the new college: "It is the intention of the authorities of the university to place the course in commerce upon a high scientific plane, otherwise it is not justified in claiming a place in the university curriculum beside those advanced scientific, philosophical and literary courses which have already won recognition." The student will be encouraged to acquire a knowledge of them elsewhere possibly, before entering college. Thus the college of commerce will supplement, not compete with, the work of the older business commercial schools. The courses of the college of commerce of the University of California fall into the general divi-

sions: Economic studies, economic history, legal, political, historical, and geographical studies, technical studies of transportation, and of the materials of commerce, and mathematical, linguistic and philosophic studies related to commerce.

On 3 Nov. 1898, the Chamber of Commerce of the State of New York adopted the report of a committee which had been previously appointed by that body on the subject of commercial education. This report, after strongly commending the establishment of a department of sounder commercial education, both in secondary schools and in higher institutions of learning in this country, advised the appointment of a special committee by the president of the Chamber of Commerce for the further consideration of the subject of commercial education. This committee was appointed and, after various sessions and conferences with authorities of Columbia University, a report was submitted to the Chamber of Commerce recommending that the chamber assist Columbia University in the establishment of a collegiate course in commerce by the grant of certain funds. This report presents in a certain way the most complete scheme of higher commercial instruction which has thus far been submitted for the consideration of the public. It unites the practical elements in the course of the Wharton school with the wider range of the courses and subjects offered at California and Chicago. It was framed upon the plan of utilizing as largely as possible the existing courses of instruction in Columbia University, and supplementing and adding to such courses the subjects necessary to offer a complete and well-rounded scheme of higher commercial instruction. It planned a college course of commerce covering 4 years of 15 hours a week. It presupposes graduation from a secondary school, public or private, in which English, mathematics, history and natural science, and one modern language will have been systematically studied to the extent now required for admission to the college department of Columbia University. In form and in content it is adapted to students of college age, namely, 16 to 20 years. In addition to the training provided in commercial subjects, the course includes two years in writing English, two years in a modern European language, two years in European and American history, and three years in political economy and social science. It offers opportunities for the study of industrial chemistry, of a selection of three modern languages and literature, if any of these be desired.

Of the 60 hours required (4 years of 15 hours each) 4 hours are devoted to instruction in writing English; 6 hours to European and American history; 6 hours to the modern European languages; 10 hours to political economy and social sciences, and 34 hours to the study of commerce itself in its various phases. It will be observed that this curriculum comprises fundamental courses in the principles governing business combined with a detailed course in practice. It is intended that many of these latter courses, as well as some of the former, shall be given by men having an intimate personal acquaintance with actual business life. Among such courses would be those in accounting and transportation, technique of trade and commerce, commercial ethics, com-

COMMERCIAL LAW

mercial credits, insurance and commercial business. Aside from the general subjects included in liberal courses we note a course of three hours per week for one year in accounting and a similar course in economic geography; a course of two hours a week following a course in chemistry on the study of commercial products; a course of three hours a week upon the technique of trade and commerce, such as weights and measures, currency, and banking system, customs regulations, markets, fairs, etc. There are also courses in banking, accounting, commercial geography, railroad and public accounting, history of commercial theory and merchant shipping and trade routes, commercial treaties and insurance. No degree is given for this course, but a certificate of graduation testifying that the candidate has completed the work of the four years will be given to all students who pass the requisite examinations after attending the courses.

It is plain from the foregoing account that instruction in commercial subjects is to be introduced into all higher institutions of learning upon a broader scale than ever before. It cannot be maintained, however, up to the present, that our experience has been large enough to afford any accurate indication of what the ultimate form or purpose of such instruction will be. We have as yet established no independent college of commerce in the United States upon an adequate foundation. We have not even established any institution which may be fairly called a commercial high school, that is, a school with an adequate equipment, with a differentiated curriculum and with an opportunity under favorable conditions to show what it can accomplish in an educational and a technical way. None of our colleges and universities have as yet been willing to give such departments a fair opportunity to show what they might accomplish in the same directions. But with every passing year the demand for better facilities on the part of young people who desire to prepare themselves for business careers will force those who have charge of public education to give a larger space in our secondary schools to this branch of work; will lead the managers of our private secondary schools to offer better facilities, and will finally compel our colleges and universities to do something for the education of the future business man which may be compared with what they are doing for the future engineer, or lawyer, or physician, so far as the peculiarities of a business career may render such a scheme feasible. See TRADE SCHOOLS.

EDMUND J. JAMES,

President University of Illinois, Urbana.

Commercial Law, or Law Merchant, that branch of law which relates to trade, navigation, maritime contracts (such as those of insurance, bottomry, bills of lading, charter-parties, seamen's wages), bills of exchange, bills of credit, factors, and agents. Lord Mansfield describes it as a branch of the public law, and applied to its universal adoption the language of Cicero respecting the great principles of morals and eternal justice—"Nec erit alia lex Romæ, alia Athenis" ("Nor shall there be one law at Rome, another at Athens"). The body of rules constituting this law is substantially the same in the United States and Europe, the rules, treatises, and decisions of one country and one age being

in general applicable to the questions arising in any other. The reason is obvious why this law should be common to different nations, for it regulates those contracts and transactions in which they come in contact, being a sort of neutral ground between their hostile interests, institutions, customs, and prejudices. International law, which regulates the conduct of different nations toward each other, is distinguished from maritime law, by which private contracts between individuals are regulated.

The first known collection of marine laws was that of Rhodes, of which some fragments have come down to us in the 'Digest' of Justinian, in the title ('De Lege Rhodia de Jactu'); the collection under the title of 'Rhodian Laws,' published at Basel in 1561, and at Frankfurt in 1596, being generally considered as spurious. This title and that ('De Nautico Fœnore') recognize the first broad principles on the subject of jettison and maritime law. The law ('De Exercitoria Actione,' in the 'Digest,') also transmits to us their principles as to the liability of the owners for the acts and contracts of the master of a vessel. The remaining rules and principles by which the commercial transactions of the ancients in the Mediterranean were governed have for the most part passed into oblivion. The reason of so small a space being assigned to this branch of jurisprudence in the Roman laws may be the low estimation in which trade was held by the Romans, who prohibited men of birth and rank from engaging in commerce, of which the Code (4, 63, 3) speaks contemptuously; and Cicero says it was not fitting that the same people should be both the porters and the masters of the world. The Greeks adopted the Rhodian laws with modifications. The Athenian law on the subject of maritime loans is stated particularly in Boeckh's 'Economy of Athens' (b. i. § 23), from which it appears that the rules on this subject were very definitely settled. The laws of trade naturally followed the trade which they were designed to regulate. Accordingly we find them first revived in the Middle Ages, on the shores of the same sea, in one of the islands of which they had their origin; a collection of them being made at Amalfi, in Italy, at one time a great center of Mediterranean trade, about the time of the first crusade toward the close of the 11th century, called the Amalfitan Table, the authority of which was acknowledged throughout Italy.

The origin of the compilation of sea laws which passes under the title of 'Consolato del Mare,' though involved in some obscurity, is most generally assigned to the city of Barcelona in Spain. Some writers, however, and particularly Azuni, claim the honor of this collection also for Italy. But Casaregis, a profound commercial jurist, who published an edition of it in Italian at Venice in 1737; and M. Boucher, who published a French translation in 1808, from what he considers the original edition of Barcelona of 1494, both admit the Spanish claim. These laws are supposed by M. Boucher to have been adopted and in use as early as the 9th century, and their authority was acknowledged in all the maritime countries of Europe, and some of the articles of this collection form a part of the present commercial law of all civilized nations. It has been translated into German also, but no entire English translation has yet

COMMERCIAL ORGANIZATIONS

been made. It is an ill-arranged, confused compilation; and, though it is interesting as a historical record of the marine laws and customs of the Middle Ages, a large proportion of its provisions do not apply to the modes of transacting business and making contracts in modern times. The 'Jugemens d'Oleron' ('Laws of Oleron'), are supposed to have been compiled about the time of Richard I.; and the honor of this collection, like that of the 'Consolato,' from which it is partly borrowed, is in dispute being claimed for the French by Valin, Emerigon, and Cleirac, who say it was made by order of Queen Eleanor, Duchess of Guienne, for the use of that province, and adopted by her son Richard I., Duke of Guienne. But Selden Coke and Blackstone assert that it is an English work published by Richard I. in his character of king of England. The maritime codes of Wisby and the Hanse Towns are also of historical celebrity, and constitute a part of the legal antiquities of this branch of jurisprudence. These were the principal marine codes down to 1673, the date of the French ordinance of commerce, which treated largely of bills of exchange and negotiable paper. In 1681 was published also the French 'Ordinance of the Marine,' one of the most glorious monuments of the reign of Louis XIV. It was framed under the influence of Colbert, and merits all its celebrity, being comprehensive and including provisions, not only on many of the subjects of commercial law as we have defined its limits, but also ample regulations on the subject of prizes. These ordinances are the foundation of the present system of marine law in Europe and America. Valin's 'Commentary upon the Ordinance of the Marine,' published in 1760, is a profound, original, comprehensive, learned, and accurate work. In 1763 he also published his commentaries on the provisions of the ordinance in relation to prizes. About 20 years afterward (1782) Emerigon published his masterly treatise on insurance. The two ordinances, with the commentary of Valin and the treatise of Emerigon, made the commercial law a science, of which the principles were now settled, and their application also traced out into a great number of examples. It was now in the power of jurists, judges, and legislators to make every new question and case that should arise only a confirmation and extension, in application of doctrines which had been established upon conclusive reasons and made parts of a harmonious system; and all the commercial nations have adopted the system thus formed. It forms the basis of the French code of commerce and appears everywhere in the British, American, and continental treatises and decisions. The other French writers of greatest celebrity on this branch of law are Pothier, Cleirac, and Boucher. M. Jacobsen, a jurisconsult of Altona, has published a useful work on the subject of sea laws. The earlier English writers on commercial law were Malynes (a merchant), Molloy (a lawyer), Beawes (a merchant), Postlethwaite, Magens (a *dispatcheur*, or adjuster of marine losses, originally of Hamburg, afterward of London), and Wiskett (a merchant). But the marine law cannot be considered as having become a branch of the general science of jurisprudence in Britain until the time of Lord Mansfield, who appears to have had some considerable acquaintance with the treatise of Valin, from which

he drew principles and reasons and incorporated them into the reluctant common law. By degrees during his judicial career this branch of jurisprudence gained popularity, and from that time has occupied an important part of the British legal administration, though very few legislative enactments have either disturbed or promoted its progress. Though the maritime law in Great Britain continued in a very rude and undigested state long after it was arranged into an admirable system in France, yet the assiduity with which it has been cultivated since its introduction, and the splendid talents which have been brought to its illustration, have contributed to advance it with a rapid progress. Among the ornaments of this branch of law was Lord Stowell, judge of the British high court of admiralty. Lord Tenterden, chief justice of the court of king's bench, by his learned and well-arranged 'Law Relative to Merchant Ships and Seamen,' contributed very materially to the present advanced state of British commercial jurisprudence. The other principal writers on this law are Millar, Park, Marshall, Bayley, Chitty, Levi, Smith, Tudor, etc. Nor have the Americans been idle spectators of this improvement in a branch of law in which their industry and prosperity are so deeply interested. Though they have supplied but few original systematic treatises and digests, yet in the numerous, important, and interesting questions that have been brought under discussion before the legal tribunals, the research, comprehensive views, and logical power displayed by both the counsel and the courts, will support a comparison with those of their European contemporaries, who might derive very useful additions to their own adjudications, particularly on the subjects of merchants' shipping and insurance, from the American reports. Among the most eminent of those who have contributed to the elucidation of the commercial law are Chief Justice Marshall and Justices Washington, Story, and Blatchford, of the **Supreme Court** of the United States, and Chancellor Kent, of New York.

Commercial Organizations. The idea that is responsible for the institution of the commercial organization is of ancient origin, for it was prior to the close of the 14th century that the first French Chamber of Commerce was founded at Marseilles. For many years this was the only organization of the kind, however, and it was not until the latter years of the 17th century that a similar organization was instituted at Dunkirk, but, from that day, the idea spread so widely that such societies were founded in many parts of Europe. In 1700, one was instituted in Paris; in 1702, another in Lyons; two were founded in 1703, one at Rouen, the other at Toulouse; in 1704, one at Montpellier, and, in 1705, another at Bordeaux.

The first English Board of Trade was instituted in 1660, but it was not until a quarter of a century later that the present department was established in council, this being nothing less than a permanent committee of the privy council appointed to consider all matters in any way relating to trade and the colonies, its functions being partly ministerial and partly judicial. At the beginning of the 19th century, therefore, there were about fourteen institutions which exercised any marked in-

COMMERCIAL ORGANIZATIONS

fluence upon the home and foreign commerce of the several nations of the world. Of these there were 3 in Great Britain, 7 in France, and 4 in the United States. The Great Britain organizations included the Glasgow Chamber of Commerce, which was instituted in 1783, and the Chamber of Commerce of Edinburgh, instituted in 1785, and incorporated by royal grant in 1786.

In the United States the history of the commercial organization dates from 1768, when the first chamber of commerce was established by the merchants of New York city. Two years later, in 1770, this association was incorporated by royal charter, and during the next few years similar organizations were founded at New Haven, Conn., Charleston, S. C., and Philadelphia, Penn. The only association in the country that bore any resemblance to these institutions was a New York board of brokers, which, since their organization, about 1792, had erected the Tontine Coffee-house, where they were accustomed to meet the out-of-town merchants to discuss all questions of mercantile or semi-commercial interest. As this association was chiefly devoted to sociability and to affairs of mutual interest, and never exercised any material influence in the settlement of questions of national or international importance, it might very properly be omitted from a list of the early commercial organizations of the country.

To discover the object for which such commercial associations were founded it is only necessary to refer to the original words used in the formal organization of the New York Chamber of Commerce, this society being in many respects not only the fore-runner, but also the model upon which similar institutions in other cities of the land were afterward constructed. In reciting the terms under which it was organized, it refers to its probable field of usefulness as follows:

"Whereas, Mercantile societies have been found very useful in trading cities for promoting and encouraging commerce, supporting industry, adjusting disputes relative to trade and navigation, and procuring such laws and regulations as may be found necessary for the benefit of trades in general. . . ."

From such a statement of purposes it may be seen that the commercial organization as originally founded differed greatly from all other institutions. Not only did it interest itself in matters of local welfare, but it was so broadly national in its sympathies and work that it was able to exert a guardian's constant watchfulness over the diversified and ever multiplying commercial and industrial interests of the young republic.

The first meeting of the New York Chamber of Commerce was held at a house situated on the corner of Pearl and Broad streets. This building, which is still standing, is now known as "Fraunces' Tavern."

One of the first matters that called for the attention of the new chamber was the question of finding a suitable meeting place, and, for a time, as its records show, the members congregated in the "great room of the building commonly called the 'Exchange,' at the lower end of the street called Broad." In

1779 they removed to the "Merchants' Coffee-house," at the southeast corner of Wall and Water streets, and, in 1817, to the "Tontine Coffee-house," on the opposite corner of the same streets. In 1817, a room was set apart for their use in the original Merchants' Exchange, and, when that building was destroyed by fire, in 1835, they met temporarily in the director's room of the Merchants' Bank, on Wall street, and their later establishment, at the corner of William and Cedar streets, remained their permanent home until they finally removed to their present commodious quarters on Nassau street. From the year following its organization the Chamber of Commerce had acted under the authority of the charter granted by the king, so, at the close of the Revolutionary War, or on 13 April 1784, an act was passed by the legislature of the State of New York "to remove doubts concerning the corporation of the Chamber of Commerce, and to confirm the rights and privileges thereof." It was under this statute that the title of the organization was changed from the "Chamber of Commerce" to the "Chamber of Commerce of the State of New York."

To trace the history of the Chamber of Commerce of the State of New York is to record the development of the nation itself. Thus, for example, more than a century ago, when the government formed its code of commercial laws and regulations, it was the members of the Chamber of Commerce who determined and bound themselves reciprocally to do all in their power to prevent "the scandalous practice of smuggling." Again, about two years after the evacuation of the city of New York by the British forces several members of the new legislature determined to force the adoption of a plan to issue paper money that should, by authority of such law, be made a legal tender in the transaction of business. This matter was immediately taken up by the Chamber of Commerce, and it was largely due to its efforts and to the memorial which it drafted, in which it set forth in forcible terms the evils and immorality of such a system, that the measure was finally defeated. It was also due to the sound judgment and persistent efforts of the members of this organization that the general government, at this perilous period in its history, adopted the measures which so successfully maintained the credit of the nation. It was also the Chamber of Commerce which, in January, 1786, adopted a resolution requesting the State legislature to create a fund to be used in connecting the city of New York with the great lakes by means of an artificial waterway, a movement which finally culminated in the construction of the Erie Canal, and it was but a few years later that the members of this association gave their approval to a project for a ship-canal around Niagara Falls, and a railroad to connect Lake Erie with the Hudson River. In fact, there have been few matters for the improvement of transportation that have not met with at least the tacit recommendation of this chamber. At several periods during the history of the country the members considered the question of the insti-

COMMERCIAL ORGANIZATIONS

tution of tribunals of commerce, but, although the matter met with the approval of the association the State legislature was so largely composed of persons who were not friendly to this innovation in commercial jurisprudence that it was not until 1874 that the act was passed providing for the court of arbitration which now considers such questions. Another matter that had occupied the attention of the Chamber of Commerce from time to time was the question of the pilot laws of the States of New York and New Jersey, and it was to their efforts that the present excellent system was mainly due.

As early as 1848, at the annual meeting in that year, the members adopted formal measures pledging their aid in the organization of a savings bank for the benefit of "merchants' clerks and others" who might desire to take advantage of such opportunities for the safe deposit of their savings, and the first charter granted by the legislature for an institution of that character was clearly the result of this action. A year later the Chamber of Commerce gave its unqualified approval to Whitney's project for the construction of a transcontinental railroad from the Pacific, even memorializing Congress upon the subject; it was largely through its efforts that the National Government consented to widen the passage through Hell Gate by removing the dangerous sunken rocks from the channel, and, again and again, as the position has demanded, it has maintained its position in opposition to privateering. In 1852, when the question of the relations between the United States and Canada came prominently to the front, the action of the chamber was in favor of a reciprocal agreement with the North American provinces which should provide for the free interchange of natural productions between the two countries, embracing, as well, the rights of joint participation in the fishing and navigation privileges of the St. Lawrence River. The successful efforts of Commodore Perry to perfect treaty negotiations between the United States and Japan were made a matter of public appreciation by the chamber, a gift of a service of silver plate being the members' method of showing their recognition of the importance of that officer's services, and when the transatlantic telegraph cable had been laid, and the New and Old World had at last been connected, the members of the Chamber of Commerce appropriated the sum of \$10,000 to be applied to the purchase of gold medals to be presented to such persons in England and America who had been most prominent in the successful conduct of the great international enterprise. When the matter of a Pacific line of steamships was suggested, in 1860, a meeting of the Chamber was held on 6 September, at which the following resolution was adopted:

"Resolved, That in the judgment of this chamber an urgent necessity exists for the establishment, at an early date, of mail facilities between the city of San Francisco, in California, and Shanghai, in China, with connection at such intermediate ports as the interests of commerce may indicate."

Persistent as the members of the Chamber

of Commerce had been in their efforts to further the best interests of the United States along every possible line of national enterprise, it was not until that remarkable period in which the Southern States combined in a revolt against the Federal Government that this association was really given an opportunity to prove its loyalty to the nation. At this epoch, at a time when the business affairs of the country were in an almost inextricable tangle, the chamber, at a large and enthusiastic meeting held on 19 April 1861, responded to the President's appeal for troops by raising a sum that proved to be amply sufficient to send two regiments of the State National Guard to the defense of the National capital without delay, and to organize the several regiments of volunteers that left within a short time for the seat of war. In fact, the patriotic enthusiasm shown at this meeting was so great that when it was announced that a portion of the loan for which the Government had advertised still remained untaken, a special committee was at once appointed to see that the balance should be subscribed for without further delay, and the Treasury Department was accordingly notified that the chamber could be drawn upon for that sum at once. The entire balance, therefore, a sum amounting to fully \$8,000,000 was soon in the hands of the proper officials at Washington.

It is impossible, within the limits of space of a single article, even to give passing reference to the various occasions upon which the Chamber of Commerce has shown that its highest wishes were in sympathy with the best interests of the Government. Of one incident, however, it is necessary to speak:

In 1872, when the Senate was "hanging fire" in regard to the ratification of the Treaty of Washington, which would result in the arbitration of the difficulties existing between Great Britain and the United States, the members of the Chamber of Commerce held a special meeting on 15 May, to urge upon Congress the necessity for immediate action, both regarding the treaty itself, and the additional article thereto which had been proposed by Minister Schenck. At this meeting, after a long discussion, the following preamble and resolutions were adopted.

WHEREAS, The Treaty of Washington, referring the differences between this country and Great Britain to arbitration, has justly been regarded as a measure of great importance to the interests of civilization and peace, and the honor of proposing it belongs to this country; and

WHEREAS, Differences of opinion have arisen between the governments of the two countries respecting the proper construction of the treaty in regard to the claims for indirect damages, and a supplemental article for settlement of those differences has been proposed by the government of Great Britain, and by the President laid before the Senate for its advice, which article appears to this chamber to be sound in principle, binding the two governments to the adoption of a beneficent rule for the future, and especially beneficial to the United States and its commerce; and

WHEREAS, The failure of the treaty would be a great public calamity; therefore,

Resolved, That this chamber, without meaning thereby to imply that our government has at all erred in its construction of the treaty, and believing that the supplemental article is more than an equivalent for the claims of our government as originally presented, and feeling the importance of removing all obstacles in the way of the execution of the treaty, earnestly recom-

COMMERCIAL ORGANIZATIONS

mends the adoption of the supplemental article, and prays the Senate to ratify it.

As the sequel showed, the action of the chamber, at a time like that, when anything except war between the two countries seemed impossible, was the weight that was sufficient to throw the balance in favor of the ratification of the Treaty, and the Geneva award arbitration was the historic result.

Closely as the career of the New York Chamber of Commerce follows the history of the political, commercial, financial, and industrial development of this country, it was not the only commercial organization that was sufficiently patriotic to be able to promote the general welfare of the country. It is true that, prior to the War of 1812 there were comparatively few organizations of this character in the United States, but, soon after 1815, other cities began to institute such associations of merchants and men of affairs. Among these organizations there are many that still exist, the strongest and most successful being those that were founded by persons interested in a special trade or calling, such as that of cotton in New Orleans, leather or wool in Boston, the iron trade in Philadelphia, paper in Holyoke, the print cloth markets of Fall River and Providence, or the crockery trade of Trenton. While such associations have naturally played a part in promoting the interests of the country, their most important work has been confined to the development of the particular trade and industry in which the majority of its members are most interested. Such an organization is the Chicago Board of Trade, a body which came into existence 13 March 1848, although its active business history did not begin until 2 May 1850. From its earliest days it has been an important medium in the buying and selling of grain, animal food products, and lumber, but neither this Board, nor the similar organizations in Detroit, St. Louis, Milwaukee, Cincinnati, Toledo, Minneapolis, and several other western cities have ever devoted much effort to the general interests of the nation, valuable as they may have proved themselves from a local point of view.

In fact, the most representative body among the strictly business associations in this country, next to the New York Chamber of Commerce, is the Associated Board of Trade of Boston. Unlike most associations of this character, the Boston Board of Trade is not a promiscuous grouping of such business men as may have chanced to come together through individual inclination. Instead, it is composed of delegates regularly elected by the organized trade associations of the city. Thus, when they speak and act, they not only express their own opinions but all their actions represent the wishes of the various associations which elected them as delegates to this central body. Although the idea upon which this board is founded is a new one, the past few years of its existence have proved its practicability and usefulness.

In view of the fact that New York is the commercial metropolis of the United States it is quite logical that this city should be the home of a variety of organizations founded

to aid the merchants in their dealings, not only in home products, but in the products of all other countries with whom they hold commercial relations. Of course, with such an extensive commercial interest, an interest so diversified in its character that it extends from one end of the world to the other and embraces the products of every land, it would be impossible to imagine any single organization that should be sufficiently wide in scope to include so many and such varied interests. To facilitate the operations of this great concentration of business, therefore, it has been found necessary to organize many separate exchanges, some of which have become great commercial organizations. To describe all of them would be impossible at such a time as this, for there are more than 70 of them. First in influence, perhaps, is the New York Stock Exchange, whose dealings are confined to stocks and bonds and similar securities of this and other countries. The New York Produce Exchange, an organization of fully 3,000 members, deals in such commodities as grain, flour, provisions, lard, tallow, etc. The Cotton Exchange deals so extensively in that staple that it actually buys and sells more cotton for future delivery than any similar organization in the world. The old Petroleum Exchange once devoted its attention almost exclusively to its dealings in petroleum and mineral oils, but, as it changed both its name and its character when it became the Consolidated Exchange, it now devotes its interests more closely to its stock transactions, and has become to some extent a competitor of the New York Stock Exchange. The Mercantile Exchange confines its operations exclusively to farm products, buying and selling such quantities of butter, cheese, eggs, poultry, etc., that the aggregate of its transactions represents an enormous sum of money. So, too, the Coffee Exchange has attained such prominence that the volume of its business now exceeds that of any similar association in Europe, while such other organizations as the Wool Exchange, the Coal Exchange, the Fruit Exchange, the Metal Exchange, the Maritime Exchange, the Board of Trade and Transportation, and the many others that have come into existence in response to ever-increasing trade necessities, represent the modern expansion of the old commercial association.

In the beginning of the 19th century there were but four commercial organizations in the United States. To-day, from one end of the country to the other, there are not less than 2,000, while the following list of the principal cities of the Union and their commercial associations will be of interest, as an indication of the wide influence which such commercial bodies now exert upon the trade of the nation. For example, Boston now has no less than 48 organizations; Philadelphia has 20; Baltimore, 21; Pittsburgh, 11; San Francisco, 15; New Orleans, 11; Minneapolis, 12; St. Louis, 26; Buffalo, 16; Cincinnati, 17; Milwaukee, 10; Kansas City, 9; Cleveland, 9; Omaha, 9; Louisville, 9; and Indianapolis, 8.

COMMERCIAL TERMS

Commercial Terms. The following list is practically a short dictionary of the terms used in commercial or business life. As it is manifestly impossible to include all the terms applied in this relation, care has been taken, as far as possible, to omit those that may be ordinarily regarded as self-explanatory. Some of the more important terms are defined more fully under their respective headings.

ABANDONMENT.—Used in the customs when an importer abandons his property to avoid paying duties upon it.

ABBROCHMENT.—The act of controlling the market by monopolizing goods.

ACCEPTANCE.—An engagement to meet a bill of exchange. To make it legally correct the person against whom the bill is drawn must write his name across its face. Sometimes the word "Accepted" written above the name, is also insisted upon.

ACCEPTOR SUPRA PROTEST.—A person who, while not a party to a bill of exchange, engages to pay it if the drawee does not.

ACCESSORY CONTRACT.—An engagement made to secure the observance of a prior contract; sometimes by the same parties; sometimes by others, as in the case of suretyship, etc.

ACCESSORY OBLIGATION.—An obligation that is subordinate to another obligation, as when a mortgage is made to secure the payment of a bond.

ACCOMMODATION.—A term usually used to denote pecuniary aid in time of emergency.

ACCOMMODATION BILL.—A note, or bill of exchange, not founded upon a prior debt, but indorsed by one or more responsible parties that others may obtain credit on it.

ACCOUNT.—(a) A record of money transactions, as with a bank; (b) in business, the statement of debits and credits, with balance on hand, or due; (c) on the stock-exchange, a transaction to be settled on the regular settling-day.

ACCOUNT CURRENT.—A detailed account of business dealings still continuing between specified parties. Sometimes called an open account.

ACCOUNT SALES.—An account rendered by a broker to his principal, specifying the goods sold, prices obtained, and the net result after the deduction of commissions, expenses, etc.

ACCOUNTABLE RECEIPT.—The form of receipt given when the money or goods received are to be accounted for.

ACTIVE.—A term used to denote brisk, or lively trading, as: an active market.

ADULTERATION.—The act of debasing goods by admixture with other substances. When performed to meet the tastes and demands of the public it is called "conventional" adulteration; when done with intent to deceive it is "fraudulent" adulteration; when through carelessness it is known as "accidental" adulteration.

AD VALOREM.—According to value. Usually applied to duties levied by the customs.

ADVANTAGE.—Another term for usury; (b) the thirteenth article added to make what is commonly known as the baker's dozen.

ADVENTURE.—A speculation in goods sent abroad; a hazard.

ADVISES.—A notification respecting mercantile transactions especially in the despatching of goods.

AFFREIGHTMENT.—The act of hiring a ship in which to transport goods.

AGAINST.—Used in commerce in reference to a balance, as when an exporter draws against the merchandise he has shipped.

ALLONGE.—Sometimes called a rider. A paper attached to a note, or bill of exchange to receive indorsements for which there may be no room on the back of the bill.

ALLOTMENT.—The act of dividing a ship's cargo into separate portions that they may be assigned by lot to different purchasers.

ALLOTMENT CERTIFICATE.—The memorandum issued to an applicant for stock, showing the number of shares allotted, etc., as well as the dates on which the payments are to be made.

AMORTIZATION.—A term used chiefly to denote the extinction of a debt by a sinking fund.

APPRAISEMENT.—Chiefly used to denote the value placed upon special articles by disinterested person.

ARBITRAGE.—A branch of the Stock Exchange business, its transactions being based upon the temporary difference in the price of securities in two markets, the purchases being made in the cheaper, the sales simultaneously in the dearer market.

ARTICLES OF ASSOCIATION.—The document containing

the internal regulations of an incorporated company with all the laws by which its affairs are conducted.

ASSESSMENT.—Used on the stock exchange to denote the sum charged against stockholders to pay debts of a corporation.

ASSETS.—The property, either real or personal, that may be devoted to paying the debts of the person or corporation.

ASSIGNMENT.—The transfer of title or interest in property; chiefly used when the transfer is made for the benefit of creditors. The term is applied both to the action and to the document making said transfer.

ATTACHMENT.—A legal process directing that the person or estate of a person be taken to secure a debt, or demand, etc.

AUDIT.—Official verification of accounts and claims made to prevent fraud on the part of the person keeping the books.

AVERAGE.—The charges, over and above freight charges, paid to the master of the ship for his personal attention to the care of the goods. The small charges paid by the master for pilotage, towage, etc., are specified as "petty average."

AVERAGE ADJUSTER.—When a loss is to be divided between several interested parties the expert accountant who ascertains and states the sum to be paid by each person is called the average-adjuster, or average-stater.

BALANCE.—The difference between the liabilities and assets in an undertaking.

BALANCE OF TRADE.—The difference shown between the total value of a country's annual exports and imports.

BANK BILL.—A bill or note drawn by one bank upon another and payable according to specifications.

BANK CREDIT.—An arrangement by which, upon the giving of proper security, a person is permitted to draw to a specified extent upon the bank's funds.

BANK NOTE.—A promissory note by which the bank of issue agrees to pay its face value to bearer on demand. In the United States and Canada, where these notes are issued only by banks authorized by law, such paper passes as currency.

BANKRUPT.—A person who, having become insolvent, or unable to pay his debts in full, is adjudged a bankrupt by the court, either upon his own application or on that of his creditors.

BAR.—Commercially a bar is an ingot, or lump of gold or silver, run in a mold, but still unwrought.

BEAR.—In the stock exchange the term denotes a person who sells stocks or shares that he does not possess for future delivery in the hope that he will be able to buy them, in the meantime, at a lower rate.

BILL.—A written statement of goods delivered or services rendered with the amount of money charged for the same.

BILL-BOOK.—A book in which the merchant keeps the detailed record of promissory notes, bills of exchange, etc.

BILL OF ADVENTURE.—A document by which a master or ship-owner shows that the goods shipped on a vessel are at the venture of another person, he being responsible only for their delivery.

BILL OR LETTER OF CREDIT.—A letter requesting that credit in goods or money be given to the bearer.

BILL OF ENTRY.—A written statement of goods entered at the custom-house.

BILL OF EXCHANGE.—A written order to pay on demand, or at some specified time, a certain sum of money to a specified person, or his order.

BILL OF HEALTH.—An official certificate showing the condition of a ship's company at the time of her clearing port. Such bills are termed "clean," "suspected," or "foul," according to conditions prevailing, both on the ship and at the place from which she cleared.

BILL OF LADING.—A receipt for goods delivered to a common carrier for transportation. Usually applied to goods delivered on board ship.

BILL OF PARCELS.—Another term for Invoice.

BILL OF SALE.—A contract by which an absolute or conditional transfer of goods is made; often given as a security for debt.

BILL OF SIGHT.—A custom-house entry which permits the importer to inspect goods before they are officially accepted.

BILL OF STORES.—A license granted by customs officials by which merchant vessels are permitted to carry stores and provisions for their voyage free of duty.

BILL OF SUFFERANCE.—A license authorizing coasting vessels to trade from port to port without the payment of customs duties. Under such license all goods must be loaded and landed at sufferance wharfs.

BILLS PAYABLE AND RECEIVABLE.—Bill of exchange promissory note, or other commercial paper. The

COMMERCIAL TERMS

- person who is to pay it terms it a "bill payable," the person who is to be paid holds it as a "bill receivable."
- BOARDING-OFFICER.**—A custom-house official whose duty it is to board ships upon their arrival, to examine papers and prevent smuggling.
- BOND.**—(a) An instrument by which the maker binds himself to perform a specified act; (b) a surety; (c) goods or merchandise left in charge of custom-house or excise officers.
- BOND DEBT.**—An obligation contracted under a bond.
- BONDED WAREHOUSE.**—Often called "public" or "bonded stores." A building in which goods or merchandise is stored pending the payment of customs duties or excise tax.
- BONUS.**—(a) A premium for a loan; (b) an extra dividend or allowance paid out of accumulated profits; (c) an honorarium, or extra sum paid voluntarily as a reward for successful efforts or as a stimulus to extra exertions.
- BOOK-ACCOUNT.**—In double-entry bookkeeping, an account showing transactions in some particular commodity, without reference to the individual with whom they may have been effected.
- BOOTHAGE.**—The sum charged for the right to erect booths at fairs or in market places.
- BOUGHT AND SOLD NOTES.**—Contracts issued between brokers at the conclusion of arrangements for sales or purchases. Also called "Contract notes."
- BOUNTY.**—A premium or reward offered by a government to encourage some particular branch of industry.
- BOURSE.**—The name applied to the stock exchanges, or money markets of Continental Europe.
- BROKER.**—The middleman who negotiates the purchase or sale of stocks, commodities, etc., for others, accepting a commission, called "brokerage," in return for his efforts. There are many classes of brokers, the following being examples: Bill-brokers, insurance brokers, cotton brokers, stock exchange brokers, curb brokers, ship brokers, etc.
- BROKER'S NOTE.**—A voucher containing the particulars of a transaction delivered by a broker to his principal.
- BUCKET SHOP.**—While nominally established for the conduct of a stock exchange business, the fact that there are neither transfers nor deliveries of the stocks or commodities dealt in has led the courts to determine that its transactions are nothing more than gambling wagers.
- BULL.**—On the stock exchange, one who purchases stock for future delivery, hoping to sell at a higher price before the time of settlement.
- BULLION.**—Chiefly used to denote uncoined gold and silver in bars and other forms.
- BY-BIDDER.**—A person employed to increase the bids upon goods sold at auction.
- CALL.**—(a) A privilege secured by contract and a consideration, of claiming and receiving either a certain number of shares of some particular stock at a stated price and within a given period, or the difference in value between the date of the demand and the date of the contract. (b) A notice of withdrawal of bonds, upon receipt of which holders must present them and receive payment of the principal and whatever interest may be due. (c) An assessment upon stockholders to pay installments or losses.
- CALL LOAN, or CALL MONEY.**—Money loaned on condition that it may be recalled at any time.
- CAMARAGE.**—The rental paid for a storage house.
- CANCEL.**—A bill, or bond becomes void when the word "Cancelled" has been written across it.
- CARRIER.**—One who conveys goods or persons for hire. A "common" carrier carries as a business; a "private" or "special" carrier, by special agreement.
- CASH.**—A term ordinarily applied to coin, and other currency, although readily negotiable securities are sometimes included. The term "hard cash" is also frequently applied to money actually in hand.
- CASH ACCOUNT.**—An account of money transactions: receipts, payments and balance on hand; (b) a term used in banking to denote the credit given to depositors on receipt of a properly secured bond for the repayment of the amount advanced with interest.
- CHAMBER OF COMMERCE.**—A local association composed of men interested in commerce and organized for the protection of trade interests.
- CHARGE.**—(a) To fix as a price; (b) to set down at a price; (c) to enter on the debit account.
- CHARTER.**—(a) A document given in evidence of a government grant conferring privileges on the fulfillment of specified conditions; (b) the hiring of a ship by special contract.
- CHARTER PARTY.**—The written agreement under which a vessel is leased.
- CHECK.**—To all intents a check is practically a bill of exchange, being a written order for money drawn on a banker.
- CHEST.**—The box-shaped case in which such goods as tea and indigo are packed for shipment is commercially known as a "chest."
- CIRCULAR LETTER.**—A communication conveying the same information or instructions to a number of interested persons.
- CIRCULAR NOTE.**—A letter of credit issued on foreign firms by bankers to travelers.
- CIRCULATING MEDIUM.**—The recognized means of making payments.
- CLEARING.**—A term used in several branches of trade, and usually to denote different actions. A vessel is "cleared" when it has furnished all particulars about its crew and cargo when about to leave port. In importations goods are "cleared" when all duties and dues have been paid. In banking, "clearing" is a term applied to a plan by which checks and bills are exchanged daily.
- CLEARING HOUSE.**—An institution where local banks meet daily to settle their mutual claims. Its certificates of deposit are negotiable only between members of the association.
- COLLATERAL SECURITY.**—Any property given to secure the performance of a contract and that is to be surrendered upon the performance of the latter.
- COMMERCIAL PAPER.**—Drafts, bills of exchange, and other negotiable paper given in the course of business.
- COMMISSION.**—The allowance given to the agent, or person delegated to buy or sell goods in the interests of another.
- COMMUTATIVE CONTRACT.**—A contract in which each of the parties interested gives and receives an equivalent.
- COMPOSITION.**—The sum, or rate agreed upon in compounding with creditors. When a contract is signed by which the creditors agree not to molest their debtor the document is termed a "composition deed."
- COMPOUND INTEREST.**—Interest paid not only on the principal but on the interest that accrues thereon, the latter being added to the original amount.
- CONCESSION.**—A grant or privilege made by governments to individuals to encourage them in carrying out undertakings that promise to be mutually beneficial.
- CONDITION OF SALE.**—A written statement of the particular terms under which property may be sold at auction.
- CONSIGNMENT.**—Goods sent for sale or delivery according to agreement. The sender is called the "Consignor;" the recipient, the "Consignee."
- CONTENT.**—A term used in the customs to denote the paper given by the master of a vessel before she clears outward. It details the vessel's destination, describes goods shipped, etc.
- CORNER.**—Commercially the term is used to denote the fact that some person or clique has purchased so largely of a certain stock or commodity for immediate and future delivery that nearly the whole available supply has been monopolized.
- CONTRABAND.**—Goods exported or imported contrary to the law of a country.
- CORPORATION.**—A company of individuals whose acts are recognized by law as those of a single person. A corporation which fills its own vacancies is known as a "close" corporation.
- COUPON.**—A warrant for the payment of interest or dividends that may be detached from bonds and presented for collection when such payments fall due.
- COVERING SHORTS.**—The term "to cover shorts" is used in the stock exchange to denote the fact that some person has bought in such stocks as he had previously sold short to enable him to meet his engagements or to protect himself against loss.
- CREDIT.**—A term applied when goods are sold upon the understanding that they are to be paid for at a future date. The time given for such payment denotes whether the accommodation shall be known as a "long" or a "short" credit.
- CURRENCY.**—The legal coinage, or that which is current as a medium of exchange.
- CUSTOMS DUTIES.**—The tax, or duty imposed by law upon the exportation or importation of merchandise.
- DAYS OF GRACE.**—The number of days which may expire after payment is due before said payment may be demanded. In the United States and Canada 3 days of grace are usually allowed, except on "demand" or "sight" paper, although some States, like New York, have abolished all grace in the payment of obligations.
- DEAD-PLEDGE.**—Lands or goods pawned, or pledged.
- DEBENTURE.**—(a) A deed given by a corporation as an evidence of debt which may be negotiated like any other investment paper; (b) in the customs the term is used to denote a certificate of drawback indicating that the holder is entitled to a refunding from the

COMMERCIAL TERMS

- government on the re-exportation of goods upon which the duties have been paid.
- DEBIT.**—That which is entered upon an account as a debt.
- DEL CREDERE.**—An additional commission paid to a factor, or agent when he binds himself to be responsible for the transaction of business, but also to guarantee the solvency of those with whom he contracts.
- DEFERRED BONDS AND SHARES.**—Bonds entitling the holder to draw interest at a gradually increasing rate to a specified point at which they assume the character of ordinary active bonds. Holders of "Deferred shares" do not participate in the profits until the expiration of a specified time.
- DELEGATION.**—A term used in banking to denote a non-negotiable letter employed by bankers in transferring a debt or credit.
- DEMURRAGE.**—A charge made as compensation for the detention of a freighter in loading or unloading.
- DEPOSIT.**—(a) A sum of money placed with bankers under agreed conditions; (b) partial payment on goods before delivery as a security for the order.
- DISCOUNT.**—Allowance made on bills paid before they are due. The term "At a discount" implies that an investment is below par. "Discount day" in banking is the day set apart for the discounting of bills or notes.
- DISHONOR.**—When an acceptor fails to pay a bill when due it is said to be "dishonored."
- DIVIDEND.**—(a) An individual share of profit due upon an investment. (b) The payment made by a bankrupt to creditors in adjusting the difference between his assets and liabilities.
- DOCUMENT BILL.**—A bill of exchange accompanied by such security as a bill of lading, an insurance policy, etc., given in return for an advance in money.
- DRAFT.**—A term used in many connections, but usually as a bill of exchange.
- DRAWBACK.**—Duty paid on imported goods refunded because of re-exportation.
- EARNEST MONEY.**—Money paid to bind a bargain.
- EMBARGO.**—An official seizure of ship or merchandise to prevent its removal from port.
- EXCHANGE.**—(a) To part with in return for an equivalent; (b) a place where merchants, brokers, etc., meet daily to transact business.
- EXCISE.**—The tax imposed upon certain articles of home production. Also called the "Internal Revenue tax."
- FISCAL.**—Pertaining to financial matters, as the "fiscal agent," the "fiscal year," etc.
- FIDUCIARY CAPACITY.**—A relation of trust and confidence. Thus a "fiduciary loan" denotes a loan granted without other security than confidence in the borrower's honor.
- FLOATING CAPITAL.**—A sum ready to be used as occasion may demand.
- FLOATING DEBT.**—An unfunded debt.
- FLOTSAM.**—Goods from a wreck that are found floating.
- FORCE MAJEURE.**—Circumstances that are beyond human control.
- FORECLOSE.**—To deprive a mortgagor of his right to redeem the property mortgaged.
- FORESTALL.**—To corner the market.
- FORWARDING NOTE.**—A descriptive note sent by the consignor with goods conveyed by carrier.
- FRAUGHT MONEY.**—Money paid for transportation of goods.
- FUNDS.**—The accumulation of money, or its equivalent, devoted to, or available for the maintenance of some business or institution, or for some other specific purpose.
- GOODWILL.**—The value supposed to attach to an established business connection.
- GROSS.**—(a) Weight and amount without deduction for any purpose; (b) twelve dozen, or 144 articles.
- GUARANTEE.**—An engagement to fulfill another person's obligations providing he may fail to do so.
- HONOR.**—To meet a claim, or obligation at the time when it is due.
- HYPOTHECATION.**—(a) The act of pledging, by delivery or otherwise, stocks, bonds, etc., as security for obligations; (b) the mortgage of a vessel or her cargo.
- IMPOST.**—A tax or duty laid on goods imported.
- INDENTURE.**—A sealed agreement between two or more parties.
- INSOLVENT.**—A person whose assets are insufficient to enable him to meet his liabilities.
- INTEREST.**—The sum paid for the use of money or the profit derived from the employment of capital.
- INVESTMENT.**—A sum of money expended with the hope of making profit.
- INVOICE.**—An account sent to the buyer of goods in which the seller gives all necessary details respecting quantity and price.
- JETSAM.**—That part of a ship's cargo that sinks in time of wreck.
- JOINT STOCK COMPANY.**—An association the member-
- ship in which is attained by the purchase of stock which is issued in shares.
- JUDGMENT NOTE.**—A promissory note to which a power of attorney to appear and confess judgment for the sum named has been attached.
- LAMB.**—A slang term used in the stock exchange to denote a person who has been deceived into making losing investments.
- LAY-DAYS.**—The stipulated number of days allowed to a charterer for the shipping or unloading of a vessel.
- LEASE.**—The grant of temporary possession, as of lands or tenements, for a fixed compensation, and a specified length of time. The person granting this right is called the "Lessor;" the person accepting the grant is the "Lessee," or "Leaseholder."
- LETTER OF CREDIT.**—A document, usually issued by bankers, authorizing their agents to pay a sum of money to the bearer.
- LIGHTERAGE.**—The sum paid for unloading a ship's cargo by means of a lighter, or barges.
- LIMITATION.**—Many statutes fix a period after which debts cannot be collected. This period of limitation ranges from 6 to 20 years.
- LIMITED LIABILITY COMPANY.**—A concern the shareholders in which cannot be held responsible for more than the nominal value of their own shares.
- LIQUIDATION.**—The act of winding up a business.
- LOCUM TENENS.**—One who temporarily holds the place of another.
- MANIFEST.**—A statement giving full details of a cargo which must be prepared before the sailing of a ship.
- MATURITY.**—The time when notes, drafts, etc., become due.
- MEASUREMENT GOODS.**—Light goods which are charged for carriage by bulk instead of weight.
- MEMORANDUM SALE.**—The act of sending goods to a proposing buyer subject to his approval, title vesting in the intending seller until they have been accepted.
- MORTGAGE.**—A method of pledging property for debt in which the lender may foreclose upon the security if the interest agreed upon is not maintained.
- NEGOTIABLE PAPER.**—An evidence of debt which can be transferred by indorsement to another.
- NET.**—The sum remaining after the deductions for expenses, etc., have been made.
- PAR.**—The face value of shares or bonds.
- PASS BOOK.**—A small book issued by bankers in which to show the receipts and payments made on a customer's account.
- PERMIT.**—The written authority to remove goods on which duty has been paid from the custom-house is called the revenue officer's "permit."
- POST-DATE, To.**—To date ahead of the actual date.
- PREMIUM.**—When shares or bonds are quoted above par they are said to be "at a premium."
- PRICE CURRENT.**—A list published by a merchant showing the prices at which goods are to be sold for a fixed period.
- PRIME COST.**—The first, or original cost of an article.
- PRICE OF MONEY.**—The rate of discount at which money may be borrowed.
- PROCURATOR.**—The person who is empowered to act for another.
- PROCURATION-FEE.**—The sum taken for effecting loans of money.
- PRO FORMA INVOICE.**—A statement issued in the form of an invoice to be presented in lieu of a formal invoice at the custom-house, where, if duly verified, it is accepted as a substitute.
- PROMISSORY NOTE.**—A written agreement to pay a specified sum of money at a certain time.
- PROOF IN BANKRUPTCY.**—An affidavit in which a creditor declares that his claim to bankrupt's estate is correctly stated.
- PRO RATA.**—To distribute proportionally.
- PROTEST.**—A note or check is said to have gone to "protest" where there were no funds to meet it.
- PROXY.**—A term applied both to the person who acts for another and to the document that gives him the power to act.
- PUTS.**—An option to deliver, or not deliver, at a future date. A term used in stock exchange speculation.
- QUOTATION.**—The prices at which goods are offered.
- RATE OF EXCHANGE.**—The sum given in one country's currency for the currency of another country. Rates of exchange fluctuate widely, being subject to many influences.
- REBATE.**—A discount given by bankers in return for ready-money payments.
- RESERVE.**—The sums kept for the purpose of enabling the holder to meet special contingencies.
- SALVAGE.**—A term applied both to the goods rescued and to the money paid for their rescue from damage or loss, especially at sea.
- SCRIP.**—A provisional certificate, or receipt for money paid as installments for shares to be exchanged for a

COMMERCIAL TREATIES — COMMERSON

more formal certificate when conditions agreed upon have been complied with.

SECURITIES.—Documents given as an evidence of debt.

SET-OFF.—The balancing of one debt by another.

SHARE.—The unit, or one of the entire number of equal parts into which the capital stock of a company or corporation has been divided.

SILENT PARTNER.—A person who maintains an interest in a business enterprise but who takes no active part in its management.

SINKING FUND.—A fund constituted for a special purpose; usually for the redemption of bonds.

STOCK.—(a) The accumulation of merchandise. (b) The share capital of a corporation.

SUPERCARGO.—The person who has charge of a ship's cargo.

SUSPENSION OF PAYMENT.—The act of discontinuing the payment of debts because of insolvency.

TARE.—A deduction made from the gross weight of goods to allow for the weight of the box, or package containing them.

TENDER.—An offer, in writing, to perform some specific service or to supply certain articles at a specified rate and upon stipulated conditions.

TONTINE.—An annuity, in which the subscribers to the loan share under the benefit of survivorship, the share of each increasing as other subscribers die until the whole reverts to the last-living subscriber.

TRET.—A now almost obsolete custom of making an allowance to purchasers who were compelled to transport their own goods.

TRUCK SYSTEM.—The system of paying employees partly or wholly in goods instead of money.

TRUSTEE.—A person entrusted with the management of the affairs and property of others.

ULLAGE.—The estimated measure of the empty portion of a cask.

UNBALANCED BID.—A bid for the performance of work in which the rates specified for each of the various kinds of labor or material required have been based upon an erroneous estimate of the quantities of each, thus making a high bid appear as a low estimate.

UNEARNED INCREMENT.—The increase in the value of land resulting from such general causes as the increase of population, etc., as distinguished from the increase due to the efforts of its individual owner.

USANCE.—The time allowed for the payment of bills of exchange drawn on foreign countries. The term is also used as another word for interest.

VOUCHER.—A written document in proof of money transactions.

Commercial Treaties, compacts between countries for the purpose of improving and extending their commercial relations; each country engaging to abolish or to reduce to an agreed rate or otherwise modify the duties on articles of production and manufacture imported from the one country into the other. They are usually for a limited period, but may be renewed and modified according to changing conditions. In these treaties the phrase, "most favored nation," implies concessions equal to the most favorable ones granted under similar treaty. The first treaty of commerce made by England with any foreign nation was entered into with the Flemings in 1272; the second was with Portugal and Spain in 1308. The first commercial treaty made by the United States with China was entered into in 1844, and among other things provided that "If additional advantages and privileges of whatever description be conceded hereafter by China to any other nation, the United States and the citizens thereof shall be entitled thereupon to complete, equal, and impartial participation in the same." This provision has substantially been repeated in all subsequent treaties between the United States and China, and forms the basis on which the United States demanded of the Powers of Europe a recognition of the "open-door policy" in their spheres of influence in China.

The commercial treaties of the United States have been based almost wholly upon the prin-

ciple of reciprocity. Among the most noteworthy of recent years are the following:

Country	Date	Subject
Brazil	1891	Manufactures.
San Domingo	1891	Foods, manufactures.
Salvador	1891	Foods, merchandise.
Germany	1892	Foods, raw materials.
Great Britain	1892	Manufactures, etc.
Nicaragua	1892	Foods, implements.
Guatemala	1892	Manufactures, etc.
Austria	1892	Cotton goods, etc.
Spain	1892	Miscellaneous.
France	1898	Miscellaneous.
Portugal	1899	
Italy	1900	Miscellaneous.
Germany	1900	Food products, etc.

and several others of wider scope which require confirmation by the Senate.

Commercial treaties have also been concluded with Colombia, Honduras, and Venezuela. The terms upon which the United States negotiates treaties of this character have been twice indicated in tariff bills (1890 and 1897), the last one being known as the Dingley Act; but under the Constitution the President and Senate have full right to make such treaties. Concessions to foreign governments in respect to duties are authorized by the Dingley Act upon certain specific conditions, of a reciprocal character, to be ascertained by diplomatic negotiation. The great expansion of the commerce of the United States in recent years has led the government to extend the application of commercial reciprocity wherever practicable. The last tariff bill provided certain commercial arrangements by the President alone, and for treaties under certain limitations which required approval by Congress. To execute this law the President appointed a special commission plenipotentiary, in whose charge the negotiation of such treaties was placed. John A. Kasson was appointed the first reciprocity commissioner. As a further means of promoting the foreign trade of the country, a movement was inaugurated during the congressional session of 1899-1900 for the creation of a separate executive department to have charge of the purely commercial affairs of the nation. In 1903 a new department of "commerce and labor" was created, and a secretary of commerce and labor was added to the President's Cabinet.

JOHN A. KASSON,

United States Reciprocity Commissioner.

Commercy, kō-mār-sē, France, a town in the department Meuse, on the left bank of the Meuse River, about 180 miles east of Paris. In its ancient castle the Cardinal de Retz wrote his memoirs. The town is tolerably well built, and has tanneries and breweries. The cavalry barrack was once the residence of King Stanislas of Poland. Pop. 7,000.

Commere, Léon François, lā-ôn frän-swä kō-mār, French genre and portrait painter: b. Trelon, France, 10 Oct. 1850. He studied under Cabanel and obtained the Grand Prix de Rome in 1875. His famous portrait of a ballet dancer, called 'A Star' (1882), is owned in the United States.

Commerson, kō-mār-sōñ, Philibert, French botanist: b. Chatillon-les-Dombes 18 Nov. 1727; d. Mauritius 1773. At the request of Linnæus he composed a treatise on the 'Fishes of the Mediterranean,' the most important ichthyological work that had as yet appeared. In 1767, at the command of the king of France, he ac-

COMMINATION — COMMITTEE

accompanied Bougainville on his voyage round the world. He died on the Isle de France (Mauritius), after residing there for about four years. He wrote, among other things, a botanical martyrology — a biography of those who have fallen victims to their efforts in the cause of botany. He left his plants, drawings, and papers to the royal cabinet at Paris. *Commeronia*, a genus of the family *Sterculiaceæ*, was named in his honor.

Communa'tion, an office in the liturgy of the Church of England, appointed to be read on Ash Wednesday (the first day of Lent), containing a recital of God's anger and threatenings toward sinners.

Communes, kō-mēn, or **Comines**, France and Belgium, towns on opposite sides of the Lys, eight miles north of Lille. The one on the right bank is in the department of the Nord, France, and communicates by a drawbridge with the other, which is in the province of West Flanders, Belgium. Anciently they formed a single town, which was fortified and had a castle, in which the celebrated historian, Philip de Commines, was born. The manufactures are chiefly ribbons and cotton goods. Pop. of French Communes, 6,000; of Belgian Communes, 5,829.

Commissariat, kōm-mīs-sār-ī-āt, that department of an army which provides provisions, forage, camp equipage, and all the daily necessities other than those connected with actual fighting. In the United States army the provisioning, etc., is in the care of the Department of Subsistence, presided over by a commissary-general, assisted by 5 assistant commissary-generals, ranking as colonels and lieutenant-colonels; 9 commissaries of subsistence, ranking as majors, 8 as captains, and 200 commissary sergeants. There are also regimental commissaries of the rank of captain. The transportation of supplies belongs to the quartermaster-general's department. In the British army the duties of the commissariat have been managed by different bodies at different times, and at present there is no department so named. The commissariat duties now partly fall on the Army Service Corps, while there is also an ordnance store department for the supply of warlike stores. It is only in the latter body that there are officers designated commissaries.

Commissary, an officer of a bishop who exercises spiritual jurisdiction in remote parts of a diocese, or one entrusted with the performance of duties in the bishop's absence. For this term in its military sense, see **COMMIS-SARIAT**.

Commission. (1) Formal act of trust; a warrant by which any trust is held or authority exercised. (2) A written document investing a person with an office or certain authority. (3) A certificate issued by authority by which a military officer is constituted; as, a captain's commission. (4) A body of persons joined in an office of trust, or their appointment; as, a building commission. (5) Brokerage, allowance, or compensation made to a factor, agent, etc., for transacting the business of another; as one per cent commission on sales. (6) A warship is said to be "in commission" when she is fitted out for service and her commanding officer has taken charge under his commission (see

definition 3, above). (7) In an official sense, a commission is a legally created body of persons invested with limited but well-defined jurisdiction, as the Interstate Commerce Commission, the Civil Service Commission, the Anthracite Coal Commission, etc.

Commission of Bankruptcy.—A commission appointed to investigate the facts relative to an alleged bankruptcy and to secure all available assets and effects for the creditors concerned.

Commission Merchant.—One who sells goods on behalf of another, being paid by a certain percentage which is called his commission.

Commissionaire, kōm-mīs-sē-ō-nār, the attendant attached to continental hotels, who waits the arrival of the trains to secure customers, to look after their luggage, etc. They may also be employed as guides or otherwise. In London, Edinburgh, and elsewhere, bodies of commissionaires have been established, the men being drawn from the ranks of military pensioners of undoubted character.

Commis'sioner, a member of a commission. See **COMMISSION**.

Com'missure, an anatomical term applied to nervous connections between adjacent parts of the nervous system. Though it is not always used in quite the same way, the general signification of the term, and the physiological import of the structure, is that of a uniting bridge.

Commit'tee, one or more persons elected or deputed to examine, consider, and report on any matter of business.

Large deliberative assemblies, with a great variety of business coming before them from time to time, are unable, when sitting as a whole, sufficiently to discuss and investigate many subjects on which they are obliged to act. Committees, therefore, are appointed to examine and report to the assembly from which they are selected. In the legislative bodies of the United States, and in the British Parliament, in fact, in all legislative bodies in representative governments, there are committees for various purposes. What are known as "standing committees" and "grand committees" are regularly appointed at the beginning of every session, and have a definite class of subjects with which to deal, the object being to divide the work of the assembly among several bodies, and so facilitate the progress of legislation. In the British Parliament there were formerly four grand committees — of Religion, of Grievances, of Courts of Justice, and of Trade, but they fell into disuse, and were discontinued in 1832. Another ancient committee is that of Privileges, which is still appointed at the beginning of every session, but has seldom any work to do, questions of privilege being generally laid before a select committee specially appointed. Two grand committees have again been constituted since 1882, to deal respectively with Law and Courts of Justice, and with Trade. In the United States Congress the standing committees are very numerous. Among the most important of them in both Senate and House (though each House has not the same committees) are those on Appropriations, Commerce, Elections, Foreign Affairs, Judiciary, Military and Naval Affairs, Rules, and Ways and Means. (See **CONGRESS, UNITED STATES**.) "Select committees" are appointed by both Houses of the British Parlia-

COMMITTEE OF PUBLIC SAFETY

ment and of the United States Congress to take up special questions and investigate them previous to legislation. In these witnesses may be examined upon oath, and evidence of all kinds brought forward, the proceedings being such as could not be carried on before the whole House. When their reports are given in, measures may be based upon them and passed into laws. What is known as a Committee of the Whole House can only be regarded as a committee in so far as its procedure is concerned, since it consists of all the members who are present. Matters of great concernment (as supply, ways and means, etc.) are usually referred to a committee of the whole House, in which bills, resolutions, etc., are debated and amended till they take a shape which meets the approbation of the majority. The sense of the whole assembly is better taken in this way, because in all committees every one speaks as often as he pleases. When, in the British Parliament, the House is in committee, the chair is regularly taken by the chairman of committees, a member who receives a salary and holds the post during the duration of the Parliament, acting as deputy speaker. (See PARLIAMENT.) When the House is desirous of forming itself into committee, the speaker, on motion, puts the question whether the House will resolve itself into a committee of the whole, to take into consideration such a matter, naming it. The previous question cannot be put in committee; nor can the House in committee adjourn, as ordinary committees may, but, if the business is unfinished, must hold an entirely new sitting. If the business is finished, the chairman reports, either immediately, or, if the House wish, at a later period.

In law, a committee is a guardian appointed to take charge of the person or estate of one who has been found to be of unsound mind, or who is laboring under some other disability. The next of kin is usually selected, but the appointment rests in the discretion of the court. It is the duty of the person appointed to take care of the incompetent.

Committee of Public Safety (*Comité du Salut Public*), a body elected by the French Convention, 6 April 1793, from among its own members, at first having limited power conferred upon it—that of supervising the executive and of accelerating its actions. Later, its powers became extended; all the executive authority passed into its hands, and the ministers became merely its scribes. At first composed of nine, it was increased to 12 members—Robespierre, Danton, Couthon, St.-Just, Prieur, Robert-Lindet, Héroult de Séchelles, Jean-Bon St.-André, Barrère, Carnot, Collot d'Herbois, and Billaud Varennes. In the terms of its constitution the members should have been elected only for one month, but all the above-mentioned held their seats for a whole year. The prevailing party acted on the ground that France, threatened from within and without, could not be governed as if at peace, but could only be saved by desperate measures, as in times of the greatest danger. But after the downfall of the Girondists, 1 and 2 June 1793, when the Mountain, on the recommendation of the Committee of Safety, declared that the population of France consisted of but two parties—patriots and enemies of the Revolution—and consigned the latter to the persecution of all good citizens, terror took the place of law. From

this time the committee governed the Mountain party, and through it the Convention. As the sole rule of his conduct Robespierre declared that the mainspring of a popular government in a state of revolution was *la vertu et la terreur!* Carnot confined himself to the direction of the armies, and left to his colleagues the affairs of the interior. At the motion of these men the new constitution was suspended for a time, and the revolutionary government conferred on the Committee of Safety by a decree of the Convention of 4 Dec. 1793. The committee now instituted in all the communes of the republic, as judges of the suspected, revolutionary committees, composed of the most furious zealots: the number of these new tribunals was as great as 20,000. The last remaining forms of regular process were abolished; their place was supplied by violence, and often by avarice and folly. In this time of internal revolutions, and danger from without, it was not in the power of man to restrain the exasperated fury which probably alone prevented France from being conquered. Finally Danton, who had absented himself for a time from the committee on account of the influence of Robespierre, declared himself against the system of bloodshed; and Robespierre himself acquiesced in the condemnation of the ring-leaders of the Paris mob (24 March 1794), among whom was Hébert; but soon after (5 April) Danton, with Héroult de Séchelles, was himself overthrown by Robespierre. Till 28 July 1794 the latter now remained master of the lives of 30,000,000 of men. He appointed Fouquier-Tinville public accuser. Prisons were multiplied and crowded; the prisoners were cruelly treated, betrayed by spies, and condemned without being allowed the privilege of defense; the property of all imprisoned on suspicion was confiscated, and the guillotine remained *en permanence*. The same violence was practised in the provinces by some of the delegates of the committee. Among the numberless victims of the system were the noble Malesherbes and the celebrated Lavoisier. The members of the Committee of Public Safety and of the *comité de sûreté générale* at last disagreed among themselves. Each committee contained three parties. These, and not Tallien, were the real causes of the 9th Thermidor (27 July). In the committee of public safety Robespierre, Couthon, and St.-Just (*gens de la hautemain*) formed one party; Barrère, Billaud, and Collot d'Herbois (*les gens révolutionnaires*) another; and Carnot, Prieur, and Lindet (*les gens d'examen*) a third. In the *comité de sûreté générale* one party comprised Vadier, Amor, Jagot, Louis (*du bas Rhin*), and Voulland (the *gens d'expédition*); to a second belonged Danton and Lebas (*écouters*); to the third Moise Bayle, Lavi-comterie, Elie Lacoste, Dubarran (*les gens de contrepoids*). Robespierre attempted to remove the unyielding Carnot from the Committee of Safety. On the other hand Billaud Varennes labored to effect Robespierre's downfall. Couthon, St.-Just, the Jacobins, and the commune of Paris alone adhered to Robespierre. But when St.-Just actually proposed in the committee a dictatorship for the safety of the state an opposition was raised against Robespierre in the National Convention by Vadier, Collot d'Herbois, Billaud Varennes, and especially by Tallien and Fréron; the dictator and his faction were proscribed, and the victory of Barras (q.v.)

COMMITTEES OF CORRESPONDENCE — COMMITTEES OF SAFETY

on the 9th Thermidor brought Robespierre, his brother, St.-Just, Couthon, and others, 105 in all, to the scaffold, 28 July. The Convention now recovered its authority; the Jacobins and the partisans of terrorism (*le queue de Robespierre*) were completely overthrown; at the same time the Convention gave the Committee of Safety and the revolutionary tribunal a more limited power and jurisdiction. The bloody despotism ceased; and when a new constitution introduced (28 Oct. 1794) a directorial government (see DIRECTORY), the Convention was dissolved, and with it sank into its grave the revolutionary government, the reign of terror, and the Committee of Public Safety.

Committees of Correspondence, in American history, public functionaries of a type first appearing in England, created by the parliamentary party of the 17th century in their struggles with the Stuarts. In 1763, when the English government attempted to enforce the trade and navigation acts on America after the Peace of Paris, the colonial leaders advised the merchants to hold meetings and appoint committees to memorialize the legislature and correspond with each other to forward a union of interests. This was done in Massachusetts, Rhode Island, and New York 1763-4. On 13 June 1764 the Massachusetts General Court appointed a committee to communicate to other colonial governments its instructions to its agent in London, to protest against the Sugar Act and the proposed Stamp Act. When the latter was passed in 1765, the Sons of Liberty formed committees of correspondence to organize resistance. Samuel Adams, during the decade 1764-74, constantly urged the adoption of this plan by the patriots of every town and county in each colony, and moved the general court to that effect in 1770-1. A few public bodies in the country appointed such committees, but there was no general concert. The payment of judges' salaries by the royal government in 1772 was seized upon by Adams as a fresh incitement, at first with scant effect, but on 21 November a slender town meeting at Faneuil Hall, Boston, appointed a correspondence committee of 21 to communicate with other Massachusetts towns concerning infringements of popular rights. It consisted of the foremost popular leaders—Adams, Otis, Warren, Quincy, etc.—and until late in 1774 (see COMMITTEES OF SAFETY) remained the real executive of the town and largely of the province. A report of its first meeting was printed and sent to all the towns and to other provinces, and in a few weeks 80 Massachusetts towns had appointed similar committees, many more doing so in a short time. No fresh places in other colonies joined, though the report was printed in their newspapers. But the royal commission to investigate the burning of the Gaspee in Rhode Island and send the culprits to England for trial effected Adams' purpose—curiously, not in Rhode Island itself, but in Virginia, where the House of Burgesses, on 12 March 1773, appointed a committee of 11 to communicate with other colonies on the doings of the administration, especially in Rhode Island, and report. The plans were characteristically different, the Massachusetts being by the town voters, the Virginia by the legislature, but the latter was immediately effective in eliciting response. Committees were appointed by Rhode

Island 7 May, Connecticut 21 May, New Hampshire 27 May, Massachusetts 28 May, South Carolina 8 July. This threat of united opposition daunted the government; the Gaspee prosecutions were not pressed, and the commission found adversely to its commander. There being nothing more to do, the legislative committees stopped for the time, after exchanging proceedings. The Boston committee alone continued its political activities, and the tea question (see BOSTON TEA-PARTY) soon revived the others. The Boston committee, followed by that of Connecticut, sent out circulars urging the defeat of British purposes; and the former, by legal town-meeting, was made the executive of Boston. It called the committees of five surrounding towns into consultation, and sat "like a little Senate," Hutchinson said. Under its direction the tea was thrown into the harbor. The Tea Act roused the remaining colonies: Georgia in September, Maryland and Delaware in October, North Carolina in December, New York and New Jersey in February, chose legislative committees of correspondence; and new municipalities joined the movement—several in New Hampshire and Rhode Island and the city of New York. After the Boston Port Bill came into effect the Boston committee invited those of eight other towns to meet in Faneuil Hall, and the meeting sent circulars to the other colonies recommending suspension of trade with Great Britain, while the legislative committee was directed by the House to send copies of the Port Bill to other colonies, and call attention to it as an attempt to suppress American liberty. The organization of the committees was at once enormously extended; almost every town, city, or county had one, though a few dismissed theirs in fear of the coming storm. The Boston opposition attempted this, but were crushingly defeated. In the middle and southern colonies the committees were empowered, by the terms of their appointment, to elect deputies to meet with those of other committees, to consult on measures for the public good. The history of the committees from this time on is the history of the preliminaries of the Revolution. Consult Frothingham, 'Rise of the Republic' (1872).

Committees of Safety, in American history, these were a later outcome of the committees of correspondence (q.v.). In Massachusetts, as affairs drew toward a crisis, it became usual for towns to appoint three committees of correspondence, of inspection, and of safety. The first was to keep the community informed of dangers either legislative or executive, and concert measures of public good; the second to watch for violations of non-importation agreements, or attempts of loyalists to evade them; the third to act as general executive while the legal authority was in abeyance. In February 1776 these were regularly legalized by the General Court; but consolidated into one, called the "Committee of Correspondence, Inspection, and Safety," to be elected annually by the towns. This possessed all the powers of the other three, but in addition was empowered to notify the proper authorities of all violation of any of the acts, resolves, or recommendations of the legislature; also to send for persons and papers, call out the militia, take charge of confiscated property and prisoners of war, and carry out

COMMODORE — COMMON CARRIERS

the laws against Tories. An appeal lay from them to the legislature, but was not often thought judicious. Previous to this, however, in October 1774, the first Provincial Congress of Massachusetts had appointed a provincial committee of safety, with 11 members, to act as the general executive of the province; and in the next few weeks it made arrangements to raise and support an army. On 9 Feb. 1775 the second Provincial Congress constituted five members a permanent executive, and instructed it to "alarum, muster, and cause to be assembled with the utmost expedition, and completely armed, accoutred, and supplied, such and so many of the militia of the province as they shall judge necessary," such levy to be made when the committee thought a forcible attempt was to be made to carry out the Boston Port Bill. It was this committee's decision to take possession of Charlestown and Dorchester Heights, on the rumor that Gage was to have heavy reinforcements and occupy them, which led to the battle of Bunker Hill. New York had also a committee of safety, of 100 men, but it is characteristic of the undeveloped politics of the time that several of these were conservatives who afterward joined the British side. Partly from this, and partly from the unwieldy size of the committee, an inner committee was formed consisting entirely of Sons of Liberty, and directed its operations. At the news of the battle of Lexington, they called a public meeting in New York at the city hall, and secured the arms and ammunition in the arsenal. John Lamb and Isaac Sears led the action, arrested all British vessels about to sail for Boston, locked up the custom-house, and discharged the cargo of a vessel detained by British authorities as loaded with supplies for the patriots, formed a military company, armed it from the arsenal, surprised and captured the chief depot of British stores at Turtle Bay, and when the British commander ordered his men to join the army in Boston, refused to allow them to take any arms but those in their hands. Otherwise they were to be allowed to embark unmolested. The more ardent members were displeased at this, but kept the letter of the promise and no more. The muskets being carried in wagons, they confiscated them as not "in the hands," the soldiers declaring that they should not be used against their brethren in Boston. Consult the functions of the committees, Sparks, 'Life of Gouverneur Morris,' Vol. I., chap. 2.

Commodore, in the United States navy, formerly an officer ranking next above a captain, and commanding a few ships when they were detached for any purpose from the rest of the fleet. The grade was abolished by Congress in 1899, when all commodores became rear-admirals.

The word is also a title given in courtesy to the president of a yachting club, or to the senior captain of a line of merchant vessels.

Commodus, kōm mō-dūs, **Lucius Aelius Aurelius**, Roman emperor: b. 161 A.D.; d. 31 Dec. 192. He was the son of Marcus Aurelius and gave early proofs of his cruel and voluptuous character. On the death of Marcus Aurelius, 180 A.D., Commodus ascended the throne, and showed himself a more execrable monster than even Caligula, Nero, or Domitian. For his amusement he cut asunder persons

whom he met, put out their eyes, mutilated their noses, ears, etc. He was endowed with extraordinary strength, and often appeared in imitation of Hercules, dressed in a lion's skin, and armed with a club. To fill the treasury, exhausted by his extravagances, he imposed unusual taxes upon the people, sold governments and offices to the highest bidder, and pardoned criminals for money. To display his strength and skill in arms he appeared publicly in the amphitheatre. He is said to have fought in this way 735 times, and as his opponents were armed with weapons of tin or lead, while he was encased in impenetrable armor, he had naturally an easy victory on every occasion. In his combats with wild beasts he was securely protected by a screen of network, through which he hurled his darts or shot his arrows. A part of the city having been consumed by fire, and the people reduced to despair by famine, disturbances broke out, and the emperor was obliged to consent to the death of his minister, Cleander, who was charged with being the author of these calamities. Commodus was strangled by the gladiator Narcissus, and on the news of his death, which was reported to be the consequence of an apoplexy, the senate declared him an enemy of the state, ordered his statues to be broken to pieces, and his name to be erased from all public inscriptions. Rome was indebted to him for her handsomest baths — the *Thermæ Antoninianæ*. He established also an African fleet, in addition to the Egyptian one, for the purpose of supplying the city with corn.

Common, that which belongs as a privilege or right equally to more than one, to many, or to the public at large; free to all; general; universal; public; having no separate owner; as, the common weal.

In logic the word is applied to terms or names, in opposition to individual, singular, or proper. "Common terms, therefore, are called 'predicables' (namely, affirmatively predicable), from their capability of being affirmed of others; a singular term, on the contrary, may be the subject of a proposition, but never the predicate unless it be of a negative proposition (as for example, the first-born of Isaac was not Jacob); or, unless the subject and predicate be only two expressions for the same individual object, as in some of the above instances."

The word is also applied to an open and (generally) unenclosed space, the use of which is not restricted to any individual, but is free to the public or to a certain number. In most of the cities and towns in the United States there are considerable tracts of land appropriated to public use. These commons were generally laid out with the cities or towns where they are found, either by the original proprietors or by the early inhabitants.

Common Carriers, such as carry goods for hire indifferently for all persons. The term includes carriers by land and by water. On the one hand they comprise stage-coach proprietors, railway companies, truckmen, wagoners and teamsters, carmen, porters, and express companies, whether such persons undertake to convey goods from one portion of the same city to another, or through the whole extent of the country, or even from one country to another; and on the other hand they include the owners and masters of every kind of vessel or water-

COMMON COUNCIL — COMMON-TIME

craft, who undertake to carry freight of any kind for all who choose to employ them, whether the extent of their navigation be from one continent to another or only in the coasting trade, or whether employed in lading or unlading goods or in ferrying, with whatever motive power they may adopt. (Story, Bailments, §§484-496.) Common carriers are liable for all damage or loss during the transportation from any cause, except the act of God or the public enemy. Common carriers both by land or water, when they undertake the general business of carrying every kind of goods, are obliged to carry all which offer, and if they refuse without just excuse, they are liable to an action. Common carriers may qualify their common-law responsibility by special contract. The bill of lading is usually the written evidence of the contract between the parties. The responsibility of the carrier begins on receipt of the goods from the owner. Carriers of passengers are not held responsible as insurers of the safety of those whom they transport, as common carriers of goods are. They are, however, bound to a high degree of care in the selection of appliances, employees, etc., in order to secure the safety of their passengers. See **COMMERCE, INTERSTATE**.

Common Council, the council of a city or corporate town, empowered to make by-laws for the government of the citizens. In American cities the city council is generally composed of two branches, called, respectively, select and common. They are elected by the people.

Common Law in America. See **LAW, COMMON, IN AMERICA**.

Common Life, Brethren of the, or The Common Lot, a religious institute founded about 1376 by Geert or Gerhart Groot at Deventer, in the Low Countries. Groot on a visit to the noted mystic Ruysbroek was so impressed by the spectacle of peace and joyful co-operation shown in the community of Austin friars over which Ruysbroek presided that he resolved to form a society embracing both clerics and laymen who, without taking the monastic vows, should lead an austere Christian life in common. One of the aims of the brotherhood was to conduct schools for the religious and moral education of children, and their labors in that field were so successful and so highly appreciated that their school at Hertogenbosch had 1,200 pupils and another school even a larger number. Establishments of the brotherhood were founded in Italy, Sicily, and Portugal, and in 1430 there were in existence 130 societies of the institute. At the same time there was formed a similar institute for women: here the superior of each society was styled the Martha. Among the eminent characters who were members of the brotherhood or alumni of their schools were Thomas à Kempis, Nicolaus Cusanus and Erasmus. Many of the "obscurantist" letters in the 'Epistolæ Obscurorum Virorum' purported to be written by members of the Deventer Brotherhood, who are made to appear as irredeemable blockheads.

Common Pleas, Court of. See **COURT**.

Common Prayer, Book of, the book which contains the public form of prayer prescribed by the Church of England to be used in all churches and chapels, and which the clergy are to use under a certain penalty. The Book of Common Prayer is used also by the English

speaking Episcopal Churches in Scotland, Ireland, America, and the colonies, as well as by some non-Episcopal bodies, with or without certain alterations. It dates from the reign of Edward VI.; was published in 1549, and again with some changes in 1552. Some slight alterations were made in it when it was adopted in the reign of Elizabeth. In the reign of James I., and finally soon after the Restoration, it was revised.

Common Schools, schools for the common people or the people in general; in the United States the term means schools to which all persons within certain ages, except criminals and those with contagious diseases, may attend. The common schools in nearly all the States and Territories are supported by public funds. At first the term was confined to elementary and secondary schools, but there is a growing tendency to include in the common schools of the United States all grades and degrees from the kindergarten to the university. At present (1903) laws relating to compulsory education have been enacted by 31 States, one Territory, and the District of Columbia. There are enrolled in the elementary and secondary common schools 17,299,230 persons or over 22 per cent of those of school age, namely, between the ages of 5 and 21 years. There are about 420,000 teachers employed in about 300,000 school houses. The common school system in general use in the United States is now being extended into Porto Rico, Hawaii, and the Philippine Islands. Cuba has adopted the same system. See **EDUCATION IN THE UNITED STATES; EDUCATION, ELEMENTARY, SECONDARY**, etc.

Common Sense, the philosophy of the so-called Scotch school of philosophy founded by Thomas Reid (1710-96), who aimed to establish a series of fundamental truths indisputable as primitive facts of consciousness. He taught that the general consent of mankind as to the existence of an external world, as to the difference between substance and qualities, between thought and the mind that thinks, is sufficient to establish the reality of a permanent world apart from ourselves; and he maintains that sensations are not the objects of our perception, but signs which introduce us to the knowledge of real objects.

The name is applied in colloquial language to that power of mind which arrives at correct conclusions, even if the thinker has no knowledge of laws of thought.

Common-time, time with two beats in a bar or any multiple of two beats in a bar. The beats may be of the value of any note or rest or compound of notes and rests, providing the sum required by the time sign be exactly contained in each bar. Common-time is of two kinds, simple and compound. Simple common-time is that which includes four beats in a bar, or any division of that number, or square of the number of its divisions. The signs used to express simple common-time are the following: $\frac{2}{1}$, $\frac{2}{2}$, $\frac{2}{4}$, $\frac{4}{4}$, $\frac{4}{8}$, and the characters C and \mathcal{C} . In these signs the upper figure denotes the quantity of notes required in the bar, and the lower figure the quality of the notes. Compound common-time is expressed by the signs $\frac{6}{4}$, $\frac{6}{8}$, $\frac{12}{8}$, such signs meaning two or four beats of three crotchets or quavers to each beat.

COMMONS — COMMUNICATIO

Commons, John Rogers, American economist: b. Darke County, Ohio, 13 Oct. 1862. He graduated at Oberlin College 1888, studied at Johns Hopkins University 1888-90, and became professor of sociology in Syracuse University, resigning in 1899 to become director of the Bureau of Economic Research. He is the author of many articles on wealth, social reform, representation, municipal government, etc., which have appeared in the leading American journals devoted to those subjects, and of 'Social Reform and the Church,' 'Proportional Representation,' 'The Distribution of Wealth,' etc.

Commons. The commons of Great Britain, in a general sense, consist of all such men in the kingdom as have not seats in the House of Lords, and every one of whom has a voice in Parliament, either personally or by his representatives. Commons in Parliament are the lower house, consisting of representatives elected by the counties or divisions of counties, and by the cities and boroughs. In the election of representatives anciently all the people had votes; but in the 8th and 10th of King Henry VI., for avoiding tumults, it was enacted that in counties none should vote but such as were freeholders, did reside in the county, and had 40s yearly revenue, equivalent to nearly £20 a year of the present money; the persons elected for counties to be *militēs notabiles*, at least esquires or gentlemen fit for knighthood; native Englishmen, or at least naturalized, and 21 years of age; no judge, sheriff, or ecclesiastical person to sit in the House for county, city, or borough. The House of Commons, in Fortescue's time, who wrote during the reign of Henry VI., consisted of upward of 300 members: in Sir Edward Coke's time their number amounted to 493. At the time of the union with Scotland, in 1707, there were 513 members for England and Wales, to which 45 representatives for Scotland were added; so that the whole number of members amounted to 558. In consequence of the union with Ireland, in 1801, 100 members were added for that country; and the whole House of Commons therefore consisted of 658 members. By the reform bill of 1832 the number of members was altered as follows: 500 for England and Wales, 53 for Scotland, and 105 for Ireland. The reform acts of 1867 and 1868 introduced a further alteration, the numbers being 493 for England and Wales, 60 for Scotland, and 105 for Ireland; by the act of 1885 they became respectively 495, 72 and 103. See PARLIAMENT.

Commonwealth, the state or prosperity of a country without any reference to the form of government under which it may be at the time. Owing to the semi-independent position of the States of the American Union the term commonwealth is of frequent application to the various members of the great Federal government, which itself is spoken of as the National or Federal Commonwealth in contradistinction from its constituent autonomies. In many of the States the legal proceedings against criminals, etc., are instituted in the name of the (for example) "Commonwealth of — v. John Doe."

The word is also applied to the period in the history of England during which the parliamentary army and the Protector Oliver Crom-

well exercised the power of government. King Charles I. was beheaded on 30 Jan. 1649; but if the beginning of the commonwealth be deferred to the time when Oliver Cromwell became Protector, then its beginning was not till 16 Dec. 1653. It received an all but fatal blow by the death of its great chief, 3 Sept. 1658. On 22 April 1659, Richard Cromwell, his incompetent son and successor, resigned, and on 29 May 1660, Charles II. was restored to the throne.

Communalism, *kōm'mū-nał-izm*, the theory of government by communes or corporations of towns and districts, adopted by the advanced republicans of France and elsewhere. The doctrine is that every commune, or at least every important city commune, as Paris, Marseilles, Lyons, etc., should be a kind of independent state in itself, and France merely a federation of such states. This system must not be confounded with "Communism" (q.v.), with which, however, it is naturally and historically allied, though the two are perfectly distinct in principle.

Commune, *kōm'mūn*, the unit or lowest division in the administration of France, corresponding in the rural districts to the English parish or township, and in towns to the English municipality. In France there are about 36,000 communes, with a considerable measure of self-government, with the power of holding property, etc. Each commune has a council elected by universal suffrage, and the council is presided over by a *maire* and one or more *adjoints* or assistants. In the larger communes the *maire* is selected by the central government out of the members of the council; in others he is appointed by the prefect of the department. The central government, through its officials, exercises generally a very large control over the affairs of the commune.

The rising of the Commune of Paris in 1871 should not be confounded with "communism" (q.v.). It was a revolutionary assertion of the autonomy of Paris; that is, of the right of self-government through its commune or municipality. The theory of the rising was that every commune should have a real autonomy, the central government being merely a federation of communes. The movement was based on discontent at Paris, where the people found themselves in possession of arms after the siege of the Germans. The rising began on 18 March 1871, and was only suppressed 10 weeks later after long and bloody fighting between the forces of the commune and a large army of the central government; 6,500 Communists having fallen during 20-30 May, and 38,578 being taken prisoners.

Communicatio, *kōm-mū-nē-kā'shī-c*, or **Communio**, **Idiomatum**, *īd-ī-ō-mā'tūm*, a term or phrase hardly capable of translation into English, which is used to signify the appropriation mutually of divine attributes to Christ as man, and of human attributes or human affections to Christ as God: this because of the hypostatic union of the divine nature and the human nature in Christ: thus, we say "God died for us," and the mother of Jesus is *theotokos*, *deipara*, mother of God. *Idioma*, plur. *idiomata*, is Greek equivalent to Latin *proprietās*, and means that which belongs to one, an attribute: the theological phrase in Greek is *antidosis idiomaton*.

COMMUNION--COMMUNISM

Communion, the reception of the Eucharist. In the Roman Catholic Church the Eucharist is administered to the faithful only in one kind, the species of bread: only the priest who performs the act of consecration receives the sacrament in both kinds: in the Protestant churches the laity receive the sacrament in both kinds, and the usage of the Greek and Oriental churches is the same. The withholding of the cup from the laity was not required by the laws of the Latin Church till the Council of Constance ordered it in 1414, though by that time usage had made it an almost universal custom. Yet down to the 11th century communion under both species was universal, and as late as the middle of the 13th century St. Thomas Aquinas notes the communion under one kind as the usage only of "some churches." As it is purely a Church regulation, the Church can and does dispense from it, or the Church can abrogate it and bring back the original usage of communion in both kinds. Even in the earliest times communion under one kind was the rule when the sacrament was to be administered to the sick and infirm in their homes: in that case the one kind was under the species of bread; but in the same early period it was customary to administer the Eucharist to infants immediately after baptism, but only under the one species of wine.

Communism. Although aiming at the abolition of private property, communism must not be understood as including at all times an equal division of all property. In its limited application it may mean the common management of industry and the sharing of the fruits of some of these in common. Socialism is not communism, though some socialistic schools are communistic, that of Edward Bellamy's 'Looking Backward' being purely so.

Communism, or the sharing of things in common, is, in a limited form, practised by every civilized community. There is to-day common management of parks, schools, and other utilities, and practical communism in water, which is supplied free to the poorest inhabitant of our cities. In the case of commodities which are plentiful and cheap, as, for example, matches, there is a kind of communism prevailing among individuals. But perfect communism as a social theory finds few adherents, and practical experiments in the past in such directions have been, save for limited periods, unsuccessful. Even where the communism of certain societies or settlements has succeeded temporarily it has done so largely by their trading with or manufacturing for the greater world of capital and labor that touches them from without. Few of such communities that have remained entirely isolated have attained even a measurable degree of success.

It is not too much to say that in primitive times property was in common, and that individual ownership arose as a natural development out of communism. The Cretans and the Spartans possessed communistic societies, and there seems to be little doubt that communism as a supernatural ideal was practised among the early Christians. That it was successful for a time in the primitive state of society then prevailing among the disciples of Jesus also seems highly probable. The communistic societies that have since been formed have been successful in the measure of

religious devotion that inspired sacrifice, and have declined as this religious ardor subsided, or became corrupted by other elements. But whatever their temporary success may have been among the early Christians, the experiments were soon utterly abandoned, and the principle of individual ownership of property finally and fully asserted itself. That even the early Christians adopted without qualification the theory of communism may be doubted. Certainly authorities are disagreed, so that even here we are without the necessary data to conclude that perfect communism was temporarily successful. During the Middle Ages many of the religious orders, notably those that strove to preserve the apostolic simplicity of the early Church, the Franciscans, the Brothers of the Common Lot, and others, taught and practised communism.

The communities that have been formed in the United States, mostly in New England and the West, have nearly all died out, or exist in a moribund condition. We need not speculate upon the reasons, though it would seem that the desire of individual ownership, with the incentive to action which such ownership inspires, is indestructible and therefore fatal to perfect communism. The most famous of all American communistic or semi-communistic societies that arose as a result of the teachings of Charles Fourier (q.v.), was that of Brook Farm (q.v.) because of the intellectual and literary eminence of its founders. Horace Greeley (q.v.) was a warm friend of the Fourierite movement from the first, advocated it powerfully in the *New York Tribune*, and was vice-president of the North American Phalanx, in Monmouth County, N. J., one of the most successful of the Fourierite communities, for it lasted over 12 years, dying in 1856. It was intended as the model of its kind, and at the beginning it prospered. Perhaps no similar movement has ever received anything like the influential support accorded to Fourierism. The teachings of this remarkable man, the insight and value of much that he wrote, as well as the warmth that suffused his prophecies, enlisted the enthusiasm and aid of some of the most eminent men of the time. But feuds and inharmony set in, and slowly the movement began to disintegrate. The noble dreams of Fourierism were either founded upon mistaken generalizations, or were too early anticipations of the industrial and social development of mankind. It was only at a late period of its career that Brook Farm came to be modeled on the Fourier plan, and its simple life became perhaps too systematized. Work was in common, and at the most menial occupations men who became the glory of American letters, and women of the highest New England culture cheerfully took their turns. But with the ebbing of the tide of Fourierism the Brook Farm experiment came to an end. The North American Phalanx outlived it for a short period, but with the death of that settlement a movement which embodied one of the most pretentious and sweeping philosophies of social regeneration perished from the American continent. Fourierism, which in France had died for lack of funds, had received in America as fair and adequate a trial as was ever accorded to any mooted social reform. For years its disciples had taught and experimented, only to end with failure. When

COMMUNISTIC SOCIETIES — COMMUTATOR

The New York *Tribune* abandoned its advocacy it ceased even to be a topic of general discussion, and in 1856 came its final collapse.

In connection with early attempts in the last century to found communistic settlements in this country the name of Robert Owen (q.v.) is conspicuous. This English manufacturer, an enthusiastic communist, having seen his efforts in Great Britain fail of fruition, visited this country and founded a number of communities, the best known of which was that of New Harmony, Ind. Most of the others were short-lived, and that of New Harmony, born in 1825, expired in 1827. Among the communities that owe their origin to religious fervor, and which still survive at Mount Lebanon, N. Y., Union Village, Ohio, Watervliet, N. Y., and elsewhere are those of the Shakers (q.v.). Their founder, Ann Lee (q.v.), landed in New York in 1774, with eight followers from England. They had fled to escape the persecution which had followed her bold assertion of divine revelation. The Shakers are celibates, and thus their communities have not grown very rapidly, yet 15 are said to exist to-day. The Oneida Community, another of the very few survivals of that communistic spirit which swept over the country in the middle forties, was established in 1848. It ignored the regulation of marriage, founding the union of the sexes purely on the mutual consent of the man and woman. It was because of this that the Oneida Community fell into evil repute, and this reputation extended in many cases to communities less deserving of the stigma. The union of one man with one woman the community expressly discouraged as an "exclusive and idolatrous attachment." When a man and woman were brought together, and showed a tendency to "fall in love," everything was done by the society to discourage such relationship, even to the extent of forcing them apart by publicly expressed condemnation. A more extraordinary view of sex relationship has probably never suggested itself among all the confused and eccentric beliefs of mankind. The Oneida Community was founded by John Humphrey Noyes, in Madison County, N. Y. They practised communism, and a change of occupation (a Fourierite principle). They have, it is said, forbidden the admission of new members.

The Harmony Society, which was succeeded in 1825 by New Harmony, Robert Owen having purchased the land of that settlement from George Rapp (q.v.) and his followers, was a notable experiment. Rapp's notions were queer enough, but he had great influence with his followers, who regarded him as possessed of supernatural powers. They practised communism and celibacy from 1805, the date of the founding of the community in Butler County, Pa., where they remained until 1814, when they changed their location to the Wabash valley. Here the settlement flourished until the purchase of the lands by Robert Owen. The Amana Community, still surviving, was formed in 1842 by emigrants from Germany and Switzerland, who originally belonged to the peasant class. They settled in New York State, near Buffalo, and later removed to Iowa. They were spiritualists who regarded themselves as the subjects of special revelation. This religio-communistic settlement is probably the earliest in origin in this country, for it traces the beginnings of its

creed as far back as the early part of the 18th century. Their rules of life are rigid and forbidding; amusements are prohibited; and much that ministers to innocent pleasure is banished as sinful.

To mention even the names of all the communities that exist or have existed in the United States would take more space than can be given to the subject. The appended bibliography will guide to all the information of which the reader may be in search. But special mention ought not to be omitted of the Icarian Community, remarkable as owing its origin to a book, 'A Voyage to Icaria,' by Etienne Cabot (born 1788), who had been a member of the French legislature and a leader of the Carbonari. He sailed in 1848 with a number of his followers from France, and established the community in Illinois in accordance with the ideas contained in his work. They numbered as many as 1,500 at one time. Later they were compelled to seek other settlement in Iowa. This community was peculiar in that it came nearer to the ideal of democratic communism; the rigid regulations of other communities were absent, the point aimed at being to let every one do as he pleased. A settlement in which no community of property save that of land obtains, and in which the government is nearly as purely democratic, is that of Fairhope, Ala., founded a few years ago by a handful of the disciples of Henry George. It is organized as a corporation, by which its real estate is administered. The annual value of the land is taken for communal purposes. It numbers about 300 members, and up to the present time is prosperous.

All these experiments which have been reviewed have failed to demonstrate the feasibility of communal life. Existence within its confines is, for the most part, meagre and unsatisfying. Though these communities sometimes grow rich, progress in its finer sense there is none; they do not rise in culture and intelligence above their original level. Yet some things they have demonstrated, among which are the possibilities of a more peaceful industry, more unselfish lives, together with a fuller leisure, and freedom from the harassing fear of want. Abnormal as they seem, they are really protests against what in our civilization is abnormal. Clothed, as the most successful of them are, in religious guise, the fact that they are impulses, even when most eccentric, of the more profound and imperishable nature of man, is vastly significant.

Com'mutator, a piece of apparatus used in connection with many electrical instruments for reversing the current from the battery. There are various forms, which will generally be found described with their proper instruments. See DYNAMO.

COMNENI — COMONFORT

Comneni, kŏm-nē'nī, an extinct family of sovereigns, according to an unsupported tradition, of Italian origin, which numbered, on the throne of Constantinople (1057 to 1204) and on that of Trebizond (from 1204 to 1461), 18 emperors, besides 19 kings and numerous independent princes. When the Crusaders had overturned the throne of the Comneni in Constantinople, and established the Latin empire there in 1204, a prince of the ancient house of the Comneni founded an independent state at Trebizond in Asia Minor, where he was governor. The last sovereign of this house was David Comnenus. From him, it is said, was descended Demetrius Comnenus, a French captain of dragoons, who died without children at Paris in 1821, with the title of *maréchal de camp*. But his descent cannot be historically traced. Ducange asserts without hesitation that Mohammed II., the conqueror of Constantinople, after he had obtained the empire of Trebizond, so called (which was scarcely as large as a French department), from the Emperor David, by a treaty, sent for this prince and his seven children to Constantinople. In order to get possession of the income which had been secured to the Greek prince he ordered him to be put to death, with all his children, at Adrianople in 1462, under pretence of a conspiracy. This is confirmed, according to Ducange, by all contemporary writers — Chalcondylas, Ducas, Phranzes. A remarkable member of the family was the Princess Anna Comnena, daughter of the Emperor Alexius I., who flourished in the first half of the 12th century.

Como, kŏ'mō (anciently COMUM), Italy, capital of the province of Como, in Lombardy, 24 miles northwest of Milan in a delightful valley at the foot of Lake Como. It is a bishop's see. The city contains some antiquities, a splendid marble cathedral dating from the 14th century, and 12 beautiful churches; also a cabinet of natural history and natural philosophy. During the 11th and 12th centuries Como was at the head of the Ghibelline party, and the rival of Milan. Here was born Pliny the Younger and Volta and Giovio, writers, also the popes Clement XIII. and Innocent XI. A number of the inhabitants travel about with small-wares, such as mirrors, spectacles, little pictures. Even in the time of the Roman emperors this taste for emigration manifested itself. The inhabitants of Como were then to be found in all parts of Italy in the capacity of masons. Silk and knit wear are manufactured. The province of Como has an area of 1,049 square miles and a population of 515,134. It has fine pastures, and yields grain, olives, wine, and silk. Population of the commune 25,800.

Como, Lake (LAGO DI COMO, lä' gō dē kŏ'mo, anciently LAC LACUS LARIUS), a lake in the north of Italy, at the foot of the Alps. Toward the middle it is divided into two branches by the point on which is situated Bellagio. The branch extending toward the southwest to the city of Como goes under the same name; that which turns to the southeast to Lecco takes the name of Lake Lecco. The length of the lake to Bellagio is 16 miles, that of the southwest branch 19 miles, and that of the southeast branch 12½ miles. The greatest width is two and a half miles. More than 60 rivers and rivulets flow into it, and the Adda passes through it. It is

about 700 feet above the level of the sea, and about 190 feet above Milan. Lake Como, the most delightful of all the lakes in Upper Italy, is surrounded by mountains 3,000 or 4,000, or even 7,000, feet high, which descend toward the lake, and in many parts are clothed with woods. It is bordered by delightful gardens and country seats. Fish, particularly trout, are caught in the lake. The neighboring country is rich in minerals — iron, copper, and lead.

Como Stage, a thin mass of shales and sandstones representing clays and sands deposited in a fresh-water lake that covered southern Wyoming and extended into Colorado. The exact age of the beds is still in dispute; they have been assigned to the top of the Jurassic, though there are good reasons for placing them at the base of the Cretaceous. The beds are remarkably rich in fossils of land reptiles and mammals, including such giant saurians as *Atlantosaurus*, and are typically developed near Como, Wyo. See CRETACEOUS SERIES; JURASSIC SERIES.

Comonfort, Ygnacio, ĩg-nä'sē-o kŏ-mŏn-fŏrt', Mexican general: b. Pueblo 12 March 1812; d. 13 Nov. 1863. He became a captain of cavalry in 1832, in 1834 was made prefect and military governor of the district of Tlapa, and in 1842 he was elected member of the National Congress. This Congress was soon dissolved, and Comonfort resumed his functions in Tlapa, displaying great energy in repelling the aggressions of hostile Indians. Appointed 3d alcalde of the capital, and afterward prefect of western Mexico, he relinquished these positions to engage in the war with the United States; and on Santa Anna's dissolving the army and leaving the capital open for the Americans, Comonfort commenced organizing guerrillas, when he was summoned to the Congress of Queretaro, where a treaty of peace was concluded with the United States. He was now chosen senator by his native state, and served in this capacity until 1851. In 1852-3 he was the representative in Congress of the newly created state of Guerrero, and acted as custom-house director of Acapulco and other places until Santa Anna's return to power, when he was dismissed from office. He now joined Alvarez, raised the standard of rebellion, proclaimed the plan of Ayutla, 11 March 1854, and compelled Santa Anna, who endeavored to seize that town, to retreat. At the end of the campaign in 1855, Santa Anna was finally compelled to abdicate. Alvarez assumed the supreme government, but shortly afterward delegated his authority to Comonfort, who became provisional president of Mexico, 11 Dec. 1855. He soon met, however, with the most strenuous opposition on the part of the clergy, the army, and the large body of the Conservative party. The junta of Zacapoastla declared itself on 19 December against the president, and a little later the seat of revolution was transferred to the city of Puebla. Over 5,000 men assembled there in February 1856. Comonfort marched against them, forced the rebels to surrender on 20 March, promulgated on 31 March a decree ordering the confiscation of the property of the Church, followed on 28 June by another decree forbidding the clergy to hold landed estate. At the same time he sent a Mexican envoy to Rome to settle with the holy see the questions raised by these measures; but the Mexican clergy made

COMORIN — COMPANY

all possible effort to prevent his reception, while at home they labored to undermine the government. Congress, which was opened by the president, 5 Feb. 1857, assembled under very inauspicious circumstances. It proceeded, however, to draw up a new constitution, which vested the legislative power and the control over religious and military affairs exclusively in Congress. The president, finding it impossible to meet the difficulties which agitated the country under such restrictions, was eventually constrained, on October 1857, to apply for extraordinary powers. These were granted by Congress on 4 November and he was proclaimed constitutional president on 1 December. His position, however, became more and more critical. Opposed by the clergy and the army, he found himself isolated, and could only depend upon the brigade of Gen. Zuloaga, which was attached to him personally. By a pronunciamiento at Tacubaya, 17 December, this brigade, too, declared itself against the new constitution, but appointed Comonfort chief of a new government. By a new pronunciamiento, however, of 11 Jan. 1858, they discarded him altogether, and the insurrection which broke out on that day in the capital led to a fierce struggle of several days. Appointing Juarez, president of the supreme court, provisional president, Comonfort attempted to regain his authority by force of arms, but in vain. On the morning of 21 January the capital was in the hands of the rebels. The House of Representatives, convoked on the same day by Zuloaga, appointed that general provisional president, while Juarez convened a congress at Guanajuato, to guard the rights of Comonfort. The latter in the meantime, deserted by his soldiers, and unable any longer to maintain his power, repaired to the United States. He returned in 1862 and was minister of war in the Juarez cabinet.

Comorin. See CAPE COMORIN.

Com'oro Islands, a volcanic group in the Indian Ocean, between the northern extremity of Madagascar and the continent of Africa. They are four in number — Angareja (called also *Comoro*), Mohilla, Johanna, and Mayotta. In 1843 France took possession of the last-mentioned island, and the others were taken under the protection of the same country, by treaty, in 1886. They are extremely fertile, well stocked with cattle, sheep, hogs, and birds of various kinds. They produce, likewise, sweet and sour oranges, citrons, bananas, honey, sugar-canes, rice, ginger, coconuts, etc. The people are chiefly engaged in rearing cattle, and in the manufacture of coarse cloths, jewelry, and small arms. They are professed Mohammedans, but fetish worship is customary. Pop, Arabs and negroes, 70,000.

Compagnie des Indes, *koñ-pan-yē dā zard* ("Company of the Indias"), an organization which owned Louisiana for several years. See MISSISSIPPI BUBBLE.

Company (Old Fr. *compagnie*, from Lat. *companire*, "mess," from *com-*, "with," and *panis*, "bread"), an association of individuals formed for some purpose of mutual advantage, especially for business purposes. The commercial use of the word which bulks most largely now has two separate uses: in general of a firm or corporation; and particularly of the silent members of a business house whose names do not appear in its style but are comprehended by

the affix "and Company." Historically the earliest occurrence of the term in connection with business enterprise dates in England back to the 14th century, when the Merchant Adventurers of England about 1359 began trade. English commerce and empire are equally indebted to the efforts of the companies formed in the early part of the 17th century. The Eastland Company, the Muscovy Company, and the Turkey Company carried English trade into eastern Europe. The East India Company won the major part of the Asiatic trade for England, and gained possession of India and administered that country until the middle of the 19th century. The Virginia Company and the Massachusetts Bay Company prepared the way for English colonization in America, but never flourished. The history of the Hudson Bay Company is another interesting episode because of the combination of territorial and trading grants which it long held and because it still enjoys trading privileges. England still employs the same method of opening up trade, and the North Borneo Company, the British East Africa Company, and the famous South Africa Company were formed between 1880 and 1890. Germany with her new imperial policy fosters the formation of such associations, and in 1884 the German East Africa Company was started, with the object of extending trade and colonization. The London City companies also are historically important as outgrowths of the mediæval guilds and because for many years membership in them was a necessary preliminary to political privilege of any sort; their authority was curtailed in 1725 and by the reform bills of the 19th century, but members of the companies are still the only electors for civic offices.

In modern commerce companies may be most conveniently divided into the simple firm or partnership, which is a mere mutual agreement, and the stock company, which, by reason of its complex character and quasi-public nature, comes under State control and has displaced to a great degree the simpler method. In the stock company, instead of a private agreement, the members, under State authorization, make a company with a fixed capitalization divided into a certain number of shares, possession of which carries the right to vote, proportionally to holdings, on matters of business policy. State regulations require in all cases that one of the contracting parties be a resident of the State in which the company is incorporated, and that an office of the concern be located in the State. Other requirements vary in different States, especially in the matter of fees, which some of the western States have reduced to a minimum for the sake of attracting business to the State, and replenishing its treasury; and in the breadth and range of powers granted by the charter. The corporation laws of the State of New Jersey, together with its convenient situation near New York, have drawn a tremendous volume of this business to it. See CORPORATIONS; TRUSTS.

A particularly American class of stock company is the industrial, which is especially adapted to mine-exploiting or the development of agricultural business. In mode of government it differs from the usual share-holder controlled company, as it is largely managed by a promoter. The capitalization of American industrial com-

COMPARISON — COMPASS

panies in 1903 is estimated at \$150,000,000,000, of which a large fraction is paid in in cash.

In military nomenclature a company is regularly an integral part of a regiment or battalion and consists of 100 men. A looser and typically American use of the word applies it to any small body of soldiers or uniformed men, especially as independent of a State or national soldiery. These independent companies, numbering something like 25,000 in the United States, form a valuable supplement to army and State militia, as was evidenced by their service in the Spanish war.

Compar'ison, Degrees of, in grammar, inflexions of adjectives denoting the degree in which a quality is possessed by a substance, either generally or in reference to other substances. The positive can scarcely be considered as a degree, as it denotes the quality generally without comparison. The comparative compares two things only, the superlative compares one thing with any number of others. In English the comparative is generally formed by the addition of *er*, the superlative by the addition of *est*, to the positive or monosyllabic adjectives and dissyllabic adjectives ending in *y*, or by the use of the words *more* and *most*, *less* and *least*, when the adjective is of more than one syllable and does not end in *y*. Adverbs are nearly always compared by the latter method. There are some adjectives, such as *good*, *better*, *best*; *little*, *less*, *least*, that do not form their degrees of comparison in the regular manner.

Compass, Mariner's, a form of compass specially adapted for use at sea. A thin circular sheet of mica is supported so as to turn with great freedom in a horizontal plane about its centre. This is called the compass-card. The bearing usually consists of a small plate of agate let into the card, and has a conical hole at the

probably still something to be learned on this question. The compass-card is marked with a star of 32 rays, which are called the rhumbs, or the points of the compass. A line joining two of these points diametrically opposite is or ought to be exactly parallel with the magnetic axis of the arrangement below; and at the extremities of these points are marked *n.* (north) and *s.* (south). *e.* (east) and *w.* (west) are marked at the extremities of another diametral line at right angles to the first. The other points have also names; and to repeat these from memory in order, beginning at north and going

Ship's Compass.

a b, Needle. *c c*, Box. *d d*, Inner gimbal. *f f*, Outer gimbal. *i*, Pivot upon which the card is placed. *m*, Reflector. *r r*, Card. *t t, u u*, Supporting pivots.

Compass Card.

centre, and this rests on a fine needle-point of hard steel. This arrangement gives very little friction. To the under surface of the compass-card a magnet is attached, or often in the best instruments several parallel magnets. Many experiments have been made to find the best arrangement for the magnets, but there is

round the whole circle, is what sailors call "boxing the compass."

The card is supported, as we have said, on a steel point, which is attached either to a hemispherical bowl of thick copper, or to a thick copper ring when the compass is to be used for night-sailing, in which case a lamp placed below the ring shines up through the mica card and makes the markings on it visible. This thick copper bowl or ring is called the compass-box. Its use is to damp the vibrations of the needle; for it is found that the presence of a large mass of copper properly placed damps the vibrations of a freely suspended magnet rapidly, while it does not at all prevent it from coming to rest in the proper position. The compass-box is suspended on gimbals, which are two concentric copper rings. The larger turns on a horizontal axis, whose extremities rest on the inside of the case that contains the compass. The smaller ring turns on a horizontal axis

COMPASS PLANT—COMPETITION

at right angles to the former, and resting on the outer ring. The compass-box is attached to the inner ring, and its weight tends to keep both horizontal. Thus supported, the compass-box and card always remain horizontal however the ship rolls or pitches. The chief difficulty in making use of the compass arises from the magnetism of the ship itself. In iron ships particularly, the magnetism of the ship greatly interferes with its indications. The effect of the ship's magnetism is determined by swinging the ship, and determining a correction to be applied for every position. This, however, is liable to some uncertainty, for it is found that rough weather and other circumstances alter the magnetism of the ship, and therefore its effect on the compass. It is usual to place a compass at the mast-head of large ships, and from time to time to compare the deck compass with it.

The origin of this instrument cannot be traced with anything like certainty. There is reason to believe that the Chinese knew something about the polaric property of loadstone more than 2,000 years before the Christian era. In the year 1242 A.D. Bailak Kibdjaki gave an explicit description of a primitive kind of compass in common use on the Syrian coast; and it is said that on the return of Marco Polo from Cathay, in 1260, he brought a knowledge of this as well as several other Chinese inventions with him. The Italians ascribe the invention of the compass to Flavio Gioja, a native of Amalfi, giving the dates 1300-20, but it is obvious from the dates given above that he can be credited only with some important improvement of the instrument. The discovery of the variation of the needle has been generally attributed to Columbus, but is now supposed to have been known much earlier.

Bibliography.—Cornwell, 'Compass Disturbance in Iron Ships'; Bowditch, 'The American Practical Navigator'; Capt. F. J. Evans and Archibald Smith, 'The Admiralty Manual for the Deviations of the Compass.'

Compass Plant (*Silphium laciniatum*), a tall composite yellow-flowered plant growing on the prairies of the Mississippi Valley, and remarkable from the fact that its erect radical leaves stand so that their edges point almost exactly north and south, especially in midsummer. This is said to be due to the action of light, and to depend on the leaves having an equal number of stomata on either face. The plant is known in some localities as "resinweed," because it contains such an amount of resinous matter. A European species of lettuce (*Lactuca scariola*) has received the same name.

Com'passes, a mathematical instrument used for describing circles, measuring lines, etc. They consist simply of two pointed legs movable on a point or pivot. For describing circles the lower end of one of the legs is removed and its place supplied by a holder for a pencil or pen. Hair compasses are compasses having a spring tending to keep the legs apart, and a finely threaded screw by which the spring can be compressed or relaxed with the utmost nicety, and the distance of the legs regulated to a hair's-breadth. Bow compasses are compasses having the two legs united by a bow passing through one of them, the distance between the legs being adjusted by means of a screw and nut. Propor-

tional compasses are compasses used for reducing or enlarging drawings, having the legs crossing so as to present a pair on each side of a common pivot. By means of a slit in the legs, and the movable pivot, the relative distances between the points at the respective ends may be adjusted at pleasure in the required proportion. Beam compasses are used where greater lengths are needed than can be secured by the ordinary pivot compasses. Points are arranged on a sliding bar so they can be clamped at certain distances from each other. Triangular compasses, having three legs, are used when it is desired to transfer the vertices of a triangle. Club compasses, called also bullet compasses, are constructed with a ball instead of one of the points of the ordinary compasses; the ball being arranged so as to turn in a hole or socket.

Compensa'tion, that which is given or received as an equivalent for services rendered, losses sustained, sufferings endured, or in payment of a debt; amends, remuneration, payment, recompense. When one is sued for a debt, it is competent for him, partially or wholly, to bar the claim by alleging that he is the plaintiff's creditor for services rendered or money lent. If the sum claimed from the plaintiff is found to be the exact equivalent of that for which he sues, the two are held to compensate or balance each other; if, on the contrary, it be less, it diminishes by so much the prosecutor's claim. If, however, the defendant feels that he owes the plaintiff more than that individual is indebted to him, he is required at the outset to pay into court the smaller sum for which he admits himself to be responsible.

Compensatio injuriarum is a defense against actions for damages claimed for slander, false accusations, and like causes.

Compensation Balance, a balance-wheel for a watch or chronometer, so constructed as to make isochronal (equal time) beats, notwithstanding changes of temperature. This effect is usually attained by having the balance-wheel cut into two segments, the arcs being fixed at one end each. This allows space for the expansion and contraction to counteract the varying strength of the spring. See CHRONOMETER.

Compensation Pendulum, a pendulum constructed of two different metals, as brass and iron, which so work against each other, that the expansion of the one downward is counteracted by that of the other upward. By this arrangement the pendulum does not vary in length, and consequently in frequency of vibration, whatever the temperature may be. Arnold's compensation balance-wheel for chronometers and watches is constructed on a similar principle.

Competition, a term nearly equivalent to the phrase "struggle for existence." Lamarck was the first to point out definitely the fact of competition in the cases of man and the sloth, but it was not until a half-century later that Darwin and Wallace emphasized its far-reaching importance as a biological agent in evolution. Competition may be most strikingly illustrated by a case in which it is entirely absent. The Great Salt Lake of Utah is inhabited by the brine shrimp (*Artemia fertilis*), which abounds in enormous numbers in the dense briny waters; hundreds may be dipped up in a dish of water and thousands captured by a few sweeps of the tow-net. As the water is so

COMPIÈGNE — COMPLETE ANGLER

salt that no other animal can live in it except a maggot near shore, it has absolutely not an enemy, and there is no other form to compete with it. Its food is a floating green alga (*Polycystis packardii*). It is absolutely harmless and without means of defense, and lays but few eggs; yet its success in point of numbers is beyond all precedent. Another case is that of a fly (*Ephydra gracilis*) whose larva abounds at the margin of the same lake. These two cases illustrate how a species may abound in profusion, though not crowding out other forms, since there are no competitions.

A familiar example of the crowding out of native species by those introduced from foreign countries in the struggle for existence among plants is the ox-eye daisy, which was introduced from Europe, first appearing in Leicester, Mass., in 1740. Many years ago what were once throughout New England green fields of grass became white with its flowers; it drove out even the grasses introduced. On the other hand, in central Europe, throughout France, the Pyrenees, and the Alps, as recently observed, it grows sparsely, never in extensive patches. Other examples are the introduced European injurious insects, the gipsy moth, the scale insects, and many others, whose numbers in the Old World are kept within due limits by ichneumon parasites, but which in the United States and Canada, owing to the absence of their natural enemies, breed in unlimited numbers. Another case is that of the Colorado potato-beetle, which spread eastward from comparatively limited tracts in the Rocky Mountain region, and invaded the eastern States to the shores of the Atlantic. The English sparrow, introduced during a period from 1850 to 1870 has become, owing to the lack of competition, a grievous pest, driving out the native birds. The periwinkle (*Littorina littorea*) of the European coast, introduced on our shores, about 1855, has multiplied to such an extent that it lives between tide-marks in millions, to one of our native species of the same genus. Such cases as these throw light upon the subject and prove that there is a silent but unceasing struggle for existence going on over nearly all the earth's surface. Yet in the case of desert plants which grow sparsely, separated by barren spaces, there is, as Henslow has observed, no struggle for existence.

Nowhere is the agency of competition more marked than in human society. In the lower savage races, as in the black race of Africa or the natives of Australia, the scattered tribes have confined their contests to simple raids, and no single people or sub-race has gained marked pre-eminence over another, with the exception of the Hottentots and Bushmen, who were largely exterminated by negro tribes from the north. But as we ascend to the higher or white race, to the Semitic, the western Asiatic and European peoples, we have examples of the sudden rise to power and pre-eminence of vast hordes of barbarian peoples under Tamerlane, the Grand Mogul, Attila, and other conquerors, which have swept over vast territories and crushed the weaker, more peaceful, or even civilized but less resistant nations. The rapidity with which the Arabs overran and still dominate northern Africa in language, social customs and religion; the Mongolian movements eastward into China, and westward to the bor-

ders of Europe; the successive rise and irresistible waves of migratory hordes from eastern to northern Europe, throughout prehistoric and historic times; the colonizing and expansion of the powers of Greece, of Rome, of the Norsemen, Anglo-Saxon, the Spanish, French, and German peoples; the success of the white race in the struggle for pre-eminence; the disappearance of the lower, weaker races, less favored intellectually and morally, some of which had become fossilized, or semi-fossilized, and practically inept and unfit,—all these phenomena, which are historic facts, are of a piece with what we witness, though in a less distinct and marked way, in the plant and brute realms. The results are in the long run beneficent, though the injustice, moral degeneration, suffering, and evils which attend human progress are pitiful and deplorable. Consult: Darwin, 'Origin of Species'; Wallace, 'Darwinism'; Fredericq, 'La Lutte puer l'existence chez les Animaux Marins.'

Compiègne, kôn-pē-ān'yŭ, France, a town in the department of Oise, and on the left bank of the river Oise, 45 miles north-northeast of Paris. It has a tribunal of commerce, a communal college, a public library, a theatre, manufactures of muslin, hosiery, and cordage, besides a trade in wood and grain. The splendid chateau, surrounded by its extensive and beautiful park, bordering on the celebrated forest of Compiègne, was a favorite autumnal residence of Napoleon III. Charles VI. took this town from the Duke of Burgundy in 1415. In 1430 Joan of Arc was taken prisoner here by the English. Pop. (1902) 14,106.

Complaint, in Law, the name given in some States to the written statement on which the plaintiff's case is founded. In criminal law, an allegation made to a proper officer that a designated offense has been committed, accompanied by an offer to prove, and a request that the offender be punished.

Complement, that which fills up to a certain unit. Thus the complement of an angle is the angle which would, by addition, make the given angle a right angle; and the complement of a number is a number which would, by addition, make the given number equal to the next higher unit, or the next higher power of 10.

In medicine the complement or the complementary body is supposed to be a substance in the blood serum that is necessary for its antibacterial or bacteriolytic action. In order to bring about a lysogenic action (*Pfeiffer phenomenon*), two bodies seem to be necessary in the blood serum. One known as the immune serum is developed during the process of immunization. It alone cannot however cause bacteriolysis. There must be present in the blood serum another body, the complement. Also called alexine or cytase. See IMMUNITY.

Complete Angler, The, a famous book by Izaak Walton, first published in 1653. It was designed primarily by its author to teach the art of angling, of which long experience with hook and line had made him master. It is written in dialogue form, and is filled with conversations touching the theme in question, which are carried on by an angler, a hunter, a falconer, a milkmaid, and others. The book is filled with descriptions of rural scenery and interspersed with many charming lyrics, old songs and ballads.

COMPLEX VARIABLE

The 'Angler' is not alone devoted to sport, but is filled with precepts which recommend the practice of religion and the exercise of patience, humility, contentment, and other virtues. Whether considered as a treatise on the art of angling, or as a delightful pastoral filled with charming descriptions of rural scenery, 'The Complete Angler' ranks among English classics. In 1676, when Walton was preparing a fifth edition for the press, Charles Cotton, also a famous angler, and an adopted son of Walton, wrote a second part for the book, which is a valuable supplement. Walton, though an expert angler, knew but little of fly-fishing, and so welcomed Cotton's supplement, which has since that time been received as a part of his book.

Complex Variable, Theory of Functions of a

1. *Function*.—The Theory of Functions of a Complex Variable deals with ordinary complex numbers, $z = x + yi$, when x and y are real, and i denotes the pure imaginary number $\sqrt{-1}$. Just as real numbers are represented by points on a line, e.g., the points of the axis of x in analytic geometry, so complex numbers are represented by points in a plane, called the *complex plane*, z corresponding to that point whose Cartesian coordinates are (x, y) . The distance $\sqrt{x^2 + y^2}$ of z from the point $z = 0$ is called the *absolute value* of z and is written $|z|$. Let S denote a region of the plane bounded by one or more closed curves. To every point z of S let one or more numbers w , real or complex, be assigned according to some definite law. Then w is said to be a single- or multiple-valued *function* of z : $w = f(z)$. For the present we shall restrict ourselves to single-valued functions.

2. *Continuity and Limits*.—The function $w = f(z)$ is *continuous* in the region S if, when z describes any continuous curve in S , the image w of z describes a continuous curve in the w -plane. The variable $f(z)$ is said to *approach* b as its *limit*, if, when z approaches a along an arbitrary path, the corresponding point $w = f(z)$ approaches the point $w = b$; in symbols,

$$\lim_{z \rightarrow a} f(z) = b.$$

A complex variable z is said to *become infinite*: $\lim z = \infty$, if its absolute value becomes infinite; i.e., if the corresponding point of the complex plane recedes indefinitely, no matter in what direction.

3. *Derivative*.—The function $w = f(z)$ has a *derivative*, $f'(z)$, if the quotient $\Delta w / \Delta z$ approaches a limit, when Δz approaches 0:

$$\lim_{\Delta z \rightarrow 0} \frac{f(z + \Delta z) - f(z)}{\Delta z} = f'(z) = D_z w.$$

When z is the independent variable,

$$dw = D_z w \Delta z;$$

and it is shown, as in the Diff. Calc., that

$$dz = \Delta z \quad \text{and} \quad dw = D_z w dz,$$

the latter relation holding no matter what the independent variable may be. The general rules for differentiation apply here, e.g.,

$$d(U + V) = dU + dV, \quad \text{etc.}$$

Moreover, we have

$$\frac{d(z^n)}{dz} = n z^{n-1}, \quad n = \text{pos. integer.}$$

Hence it follows that all rational integral functions, i.e., polynomials in z , and all other rational functions of z , can be differentiated according to the same rules as reals.

Theorem: The necessary and sufficient condition that the function

$$w = u + vi = f(x + yi)$$

have a continuous derivative is that the real functions u and v of the real variables x and y have continuous first partial derivatives satisfying the *Cauchy-Riemann Differential Equations*:

$$\frac{\partial u}{\partial x} = \frac{\partial v}{\partial y}, \quad \frac{\partial u}{\partial y} = -\frac{\partial v}{\partial x}. \quad (1)$$

The condition is necessary. For since we shall always get one and the same limit, no matter along what path Δz may approach 0, let Δz pass first only through real values: $\Delta z = \Delta x$; thus

$$\lim_{\Delta x \rightarrow 0} \frac{\Delta w}{\Delta x} = \frac{\partial w}{\partial x} = D_z w.$$

Secondly, let Δz be pure imaginary: $\Delta z = i \Delta y$; then

$$\lim_{\Delta y \rightarrow 0} \frac{\Delta w}{i \Delta y} = \frac{1}{i} \frac{\partial w}{\partial y} = D_z w.$$

Hence

$$\frac{\partial w}{\partial x} = \frac{1}{i} \frac{\partial w}{\partial y},$$

and it remains only to separate the real and the pure imaginary terms. We omit the proof of the sufficiency of the condition.

Two functions which satisfy relations (1) are called *conjugate functions*.

Example: Let

$$w = e^x (\cos y + i \sin y).$$

Then

$$\frac{\partial u}{\partial x} = e^x \cos y = \frac{\partial v}{\partial y},$$

$$\frac{\partial u}{\partial y} = -e^x \sin y = -\frac{\partial v}{\partial x}.$$

Hence w has a derivative, and furthermore

$$\frac{dw}{dz} = w.$$

A function which is single-valued throughout a region S and has a continuous derivative in S is said to be *analytic in S* . The terms *holomorphic*, *monogenic*, and *synectic* are also sometimes used in this sense.

4. *Conformal Mapping*.—Given any two functions

$$u = \phi(x, y), \quad v = \psi(x, y), \quad (2)$$

we may interpret them geometrically as transforming the points of one plane into the points (u, v) of a second plane. Thus a region S of the first plane will be *mapped*, if certain further conditions are fulfilled, in a one-to-one manner and continuously on a region Σ of the (u, v) -plane. For example, let

$$u = x^2 - y^2, \quad v = 2xy.$$

Here the first quadrant of the (x, y) -plane is mapped on the upper half of the (u, v) -plane, the family of lines $u = \text{const.}$ going over into the

family of equilateral hyperbolas whose axes lie in the coordinate axes, and the family of

FIG. 1.

lines $v = \text{const.}$ going over into the orthogonal family, whose asymptotes are these axes.

If u and v have continuous first partial derivatives and if their Jacobian

$$J = \begin{vmatrix} \frac{\partial u}{\partial x} & \frac{\partial u}{\partial y} \\ \frac{\partial v}{\partial x} & \frac{\partial v}{\partial y} \end{vmatrix}$$

does not vanish, then, at least for a restricted region S_0 about a point (x_0, y_0) , the equations (2) will always define a one-to-one map of S_0 on a region Σ_0 including the point (u_0, v_0) . This map will represent approximately (*i.e.*, to infinitesimals of higher order than the first) a projection of the immediate neighborhood of (x_0, y_0) on that of (u_0, v_0) ; in other words, *strain*—a small circle about (x_0, y_0) going approximately into an ellipse about (u_0, v_0) . If, however, u and v are conjugate functions, the ellipse becomes a circle, and the angle under which two curves intersect in the (x, y) -plane is preserved in the (u, v) -plane. Thus the shapes of small figures are but slightly distorted. Such a map is called *conformal* or *isogonal*. The elements of corresponding infinitesimal arcs in the two planes are connected by the relation

$$dS = M ds,$$

where M is a positive function of x and y , and does not depend on ds , dS . The Jacobian here has the value

$$J = \left(\frac{\partial u}{\partial x}\right)^2 + \left(\frac{\partial v}{\partial x}\right)^2.$$

Referring to the developments of § 3 we see that the theorem just stated is coextensive with the following.

Theorem: If $w = f(z)$ is single-valued and analytic in the region S , then this function maps the neighborhood of any point z_0 of S , in which $f'(z_0) \neq 0$, in a one-to-one manner and conformally on the neighborhood of the point $w_0 = f(z_0)$.

The problem of conformal mapping first studied was that of making a map of the earth such that the shapes of small regions should be but slightly distorted. The two principal solutions that presented themselves were (a) *Ptolemy's Projection*, known in mathematics as *stereographic projection*, which consists in passing a variable ray through a fixed point of the sphere, which we will think of as the north pole. Let P and Q be respectively the variable intersections of this ray with the sphere and with the plane of the equator, or a parallel plane, taken as the plane of the projection. Then Q is the projection of P . (b) *Mercator's Chart*.

By a *simply connected region* is meant a region bounded by a single curve. Any simply connected region can be mapped in a one-to-one manner and conformally on the interior of a circle, and hence any two such regions can be mapped conformally on each other (Riemann, 1851).

5. *The Elementary Functions.*—(a) The Exponential Function. For real values of x the function e^x can be expanded by Taylor's Theorem into the series

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \dots$$

Substituting formally for x a pure imaginary value and operating with the infinite series as if it were a polynomial, we get

$$1 - \frac{y^2}{2!} + \frac{y^4}{4!} - \frac{y^6}{6!} \dots + i \left(y - \frac{y^3}{3!} + \frac{y^5}{5!} - \frac{y^7}{7!} \dots \right) \\ = \cos y + i \sin y.$$

This formal work suggests a *definition* of e^x for a pure imaginary value of the argument, namely:

$$e^{yi} = \cos y + i \sin y, \quad (3)$$

and it is this definition that we shall adopt, setting at the same time more generally

$$e^z = e^{x+yi} = e^x (\cos y + i \sin y).$$

The function e^z thus obtained is a true generalization of e^x , for it is single-valued and analytic for all values of z , reduces to e^x when z is real, and satisfies the same functional relations as e^x :

$$e^{z_1} e^{z_2} = e^{z_1+z_2}, \quad \frac{de^z}{dz} = e^z.$$

(b) The Trigonometric Functions. When x is real, we have from (3)

$$\sin x = \frac{e^{xi} - e^{-xi}}{2i}, \quad \cos x = \frac{e^{xi} + e^{-xi}}{2}.$$

The right-hand sides of these equations have a meaning for complex values of the argument. By means of them we define the functions $\sin z$, $\cos z$:

$$\sin z = \frac{e^{zi} - e^{-zi}}{2i}, \quad \cos z = \frac{e^{zi} + e^{-zi}}{2}.$$

These generalized functions are single-valued and analytic for all values of z and satisfy the same functional relations as $\sin x$, $\cos x$; *e.g.*,

$$\sin(z_1 + z_2) = \sin z_1 \cos z_2 + \cos z_1 \sin z_2.$$

The $\tan z$ is defined as $\sin z / \cos z$, etc.

(c) The Inverse Functions. The function $\log z$ shall be defined as the inverse of the exponential function:

$$e^w = z, \quad w = \log z.$$

Setting $w = u + vi$, $z = r(\cos \phi + i \sin \phi)$, we have

$$e^u (\cos v + i \sin v) = r(\cos \phi + i \sin \phi).$$

Hence $u = \log r$, $v = \phi + 2k\pi$, and

$$\log z = \log |z| + (\phi + 2k\pi)i.$$

Thus it appears that the logarithm is no longer single-valued when complex numbers are admitted to consideration. For example,

$$\log z = .693 \dots + 2k\pi i.$$

COMPLEX VARIABLE

In a similar way each of the other inverse functions is defined. We find

$$\begin{aligned}\cos^{-1}z &= i \log(z + \sqrt{z^2 - 1}), \\ \tan^{-1}z &= \frac{i}{2} \log \frac{i+z}{i-z}.\end{aligned}$$

From the foregoing it appears that in the domain of complex quantities the trigonometric functions can be expressed in simple form in terms of the exponential function and conversely; while the inverse trigonometric functions express themselves in terms of the logarithm. Thus the formulas of integration:

$$\int \frac{dx}{a+bx^2} = \begin{cases} \frac{1}{\sqrt{ab}} \tan^{-1}\left(x\sqrt{\frac{b}{a}}\right), & ab > 0; \\ \frac{1}{2\sqrt{-ab}} \log \frac{\sqrt{a}+x\sqrt{-b}}{\sqrt{a}-x\sqrt{-b}}, & ab < 0, \end{cases}$$

apparently in no wise akin, are seen to be equivalent in the complex domain.

6. *Laplace's Equation.*—(a) Flow of Heat or Electricity. Let the points of the boundary of a homogeneous (or more properly isotropic) conducting substance be maintained at given temperatures (for example, a steam-pipe, the interior being kept at 100° and the exterior at 0°). Then a flow of heat ensues within the conductor and the temperature at any given point approaches a limiting value, u , as time goes on. In fact, if each point were brought to this limiting temperature, it would continue there so long as the boundary conditions are maintained and we should have a steady flow. The corresponding temperature u satisfies Laplace's Equation in three dimensions:

$$\Delta u = \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} = 0.$$

If in particular the solid be bounded by cylindrical surfaces whose elements are parallel to the z -axis, and if the given temperature be constant along each element, then u will evidently be constant along any line parallel to the z -axis, and we shall have in substance a two-dimensional flow, for which

$$\Delta u \equiv \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0.$$

We may conceive the solid itself in which the flow takes place as two-dimensional if we think of a thin section as cut out of the above solid by two planes parallel to the (x, y) -plane and very near together. The flat faces of this slab are then to be thought of as coated with some adiabatic substance, so that no heat can enter or leave the slab across these faces.

The electrical problem is mathematically identical with the heat problem, u being interpreted as *potential* instead of temperature. As conductor consider for example a piece of tin-foil whose edge is connected with a thick piece of copper. Let one pole of a battery be attached to the copper and the other to the tin-foil at an interior point. We thus have a point source.

The curves $u = \text{const.}$ are called *isothermals* or *equipotential curves*. The curves $v = \text{const.}$ are the *lines of flow*. Every solution of a two-dimensional problem in steady flow leads to the solution of a second such problem, in which u and v are interchanged; for if u satisfies Laplace's Equation, then it follows from (1) that v does also.

(b) Flow of an Incompressible Fluid. Consider the flow of an incompressible fluid constrained to move between two parallel planes, the particles which lie in any line perpendicular to the planes at any moment always remaining in that line. If there be a function u whose partial derivatives with regard to x and y give the components of the velocity of each particle of the fluid along the axes, then u is called the velocity potential. If u does not depend on t , we have a steady flow with velocity potential, and u here satisfies Laplace's Equation.

Conversely, let u be any *harmonic function*, i.e., a solution of Laplace's Equation, in two dimensions. Then this function defines a steady flow of heat, electricity, or an incompressible fluid with velocity potential.

Let us turn now to analytic functions of a complex variable:

$$w = u + vi = f(x + yi).$$

Differentiating the first of the equations (1) with regard to x , the second with regard to y , and adding, we see that v satisfies Laplace's Equation. Hence

Theorem: Every analytic function of a complex variable defines a steady flow of heat, electricity, or an incompressible fluid.

The converse is also true. Let us first recall the condition that

$$P dx + Q dy$$

be an exact differential, namely,

$$\frac{\partial P}{\partial y} = \frac{\partial Q}{\partial x}.$$

If this condition is fulfilled throughout a finite region S , then

$$\int P dx + Q dy$$

taken over the complete boundary of S will vanish. Furthermore, if S has but a single boundary,

$$\int_{(a,b)}^{(x,y)} P dx + Q dy$$

will be a function of the upper limit (x, y) alone, not of the path of integration; cf. Goursat, ('Cours d'analyse,' vol. I, § 152.

Returning now to the main question, let u be any solution of Laplace's Equation, and form the function

$$v = \int_{(a,b)}^{(x,y)} -\frac{\partial u}{\partial y} dx + \frac{\partial u}{\partial x} dy + C.$$

Then the value of the integral will be independent of the path of integration,—at least if we confine ourselves to a finite region S with a single boundary. The derivatives of this function have the values

$$\frac{\partial v}{\partial x} = -\frac{\partial u}{\partial y}, \quad \frac{\partial v}{\partial y} = \frac{\partial u}{\partial x},$$

and thus satisfy (1). Hence u and v are conjugate functions, and $u + vi$ is an analytic function of $x + yi$.

The relation here pointed out between the theory of functions of a complex variable and certain problems of mathematical physics was employed by Riemann (1851–1866) as a means of investigation in the former subject, and his

COMPLEX VARIABLE

method has been further developed by Klein (since 1881) and others.

7. *Cauchy's Theorem.*—Let $f(z)$ be single-valued and continuous throughout a region S , and let C be a curve lying in S . The integral of $f(z)$ taken along C is defined much as a curvilinear integral is in the calculus. Let C be divided by the points $z_0 = a, z_1, \dots, z_n = b$ into n arcs; set $z_{k+1} - z_k = \Delta z_k$. Then if, as n increases, the lengths of all the arcs approach 0,

$$\lim_{n \rightarrow \infty} \sum_{k=0}^{n-1} f(z_k) \Delta z_k = \int_a^b f(z) dz.$$

The following theorem, due to Cauchy (1825), is fundamental.

Cauchy's Integral Theorem. Let $f(z)$ be single-valued and continuous throughout a finite region S , inclusive of the boundary, and let $f(z)$ be analytic within S . Then the integral of $f(z)$, extended over the entire boundary C of S , has the value 0:

$$\int_C f(z) dz = 0.$$

Writing $f(z) = u + vi$, $z = x + yi$, we have

$$\int_C f(z) dz = \int_C (u dx - v dy) + i \int_C (v dx + u dy).$$

But each of these latter integrands is an exact differential (§ 6), since u and v are conjugate functions. Hence, by the theorem of § 6, each integral vanishes.

By means of this theorem many real definite integrals may be computed. In fact, it was through the attempt to obtain a rigorous deduction of such formulas that Cauchy was led to his theorem (memoir of 1814). We will give one example: Consider the integral of e^{-z^2} extended along the boundary of the region indicated. Its value is 0. Hence

$$\left(\int_{OA} + \int_{AB} + \int_{BO} \right) f(z) dz = 0.$$

Now let $OA = R$ increase without limit. The

FIG. 2.

first integral thus becomes the well-known integral of the Theory of Probability:

$$\int_0^{\infty} e^{-x^2} dx = \frac{\sqrt{\pi}}{2}.$$

The second integral can readily be shown to approach the limit 0. In the third,

$$z = r(\cos 45^\circ + i \sin 45^\circ) = \frac{1}{\sqrt{2}}(1 + i)r.$$

Hence

$$\frac{\sqrt{\pi}}{2} + \frac{1}{\sqrt{2}}(1 + i) \int_0^{\infty} e^{-r^2 i} dr = 0.$$

Setting $e^{-r^2 i} = \cos r^2 + i \sin r^2$ and separating

reals and pure imaginaries, we obtain the evaluation of the Fresnel integrals:

$$\int_0^{\infty} \sin r^2 dr = \int_0^{\infty} \cos r^2 dr = \frac{1}{2} \sqrt{\frac{\pi}{2}}.$$

The *residuum* of a function $f(z)$ in a point a in whose neighborhood, with the exception of the point a itself, the function is single-valued and analytic, is defined as

$$\frac{1}{2\pi i} \int_C f(z) dz,$$

the path of integration C being a closed path surrounding the point a and containing no other singularity of the function. If $f(z)$ is single-valued and analytic in a finite region S except at a finite number of points lying within the region, then the sum of the residues of $f(z)$ at these points is given by

$$\frac{1}{2\pi i} \int_C f(z) dz,$$

where C refers to the boundary of S .

8. *Development into a Taylor's Series.*—In 1831 Cauchy extended Taylor's Theorem to functions of a complex variable and at the same

FIG. 3.

time discovered a simple test for the range of values of the variable for which the series converges. Let $f(z)$ be single-valued and analytic in a region S , and let a be an interior point of S . Let K be the largest circle that can be drawn in S with a as centre so as to include in its interior no point of the boundary of S . Then, for all points z within this circle, $f(z)$ can be represented by the series

$$f(z) = c_0 + c_1(z-a) + c_2(z-a)^2 + \dots,$$

where
$$c_n = \frac{1}{2\pi i} \int_C \frac{f(t) dt}{(t-a)^{n+1}} = \frac{f^{(n)}(a)}{n!},$$

and
$$|c_n| < Mr^{-n},$$

where M denotes the maximum value of $|f(z)|$ on the circumference of the circle $|z-a| = r$.

Example. Let $f(z) = (1 - 2\mu z + z^2)^{-\frac{1}{2}}$, where μ is a real constant numerically less than 1. Here either value of the function is continuous and analytic except where the radicand vanishes:

$$1 - 2\mu z + z^2 = 0, \quad z = \mu \pm i\sqrt{1 - \mu^2},$$

i.e., at two points on the unit circle about $z=0$. Hence we can develop either value of the radical into a Taylor's series:

$$\frac{1}{\sqrt{1 - 2\mu z + z^2}} = P_0 + P_1 z + P_2 z^2 + \dots,$$

where the coefficients P_n depend on μ alone, and the series will converge for all values of z within the unit circle.

COMPLEX VARIABLE

The proof of the theorem is based on Cauchy's Integral Formula, by means of which the value of the function $f(z)$ at any interior point of S can be expressed solely in terms of the value of $f(z)$ along the boundary, C , of S :

$$f(z) = \frac{1}{2\pi i} \int_C \frac{f(t) dt}{t-z}.$$

This formula is deduced directly from Cauchy's Integral Theorem, and is analogous to the theorem in the Theory of the Potential by which the value of a harmonic function u at any point within a region is expressed in terms of its value $U(s)$ on the boundary, and of a function peculiar to the shape of the region, namely, the Green's Function G :

$$u = \frac{1}{2\pi} \int_C U \frac{\partial G}{\partial n} ds.$$

In fact, each formula can be deduced from the other one. The whole theory of functions of a complex variable can be based on Cauchy's Integral Formula as well as on the Taylor's development.

Conversely, let

$$c_0 + c_1 z + c_2 z^2 + \dots \quad (4)$$

be any power series converging for values of $z \neq 0$. Then it can be shown that this series converges within a certain circle of radius R and (excepting the special but important case that it converges for all values of z and thus represents a so-called *integral transcendental* function of z) diverges outside of the circle. Within this circle, called the *true circle of convergence*, the series represents an analytic function and forms in fact the Taylor's (or Maclaurin's) development of this function about the point $z = a = 0$.

9. *Other Series.*—(a) *Laurent's Series.* If $f(z)$ is single-valued and analytic within a circular ring of radii r_1 and r_2 about the point a , then $f(z)$ can be developed into a Laurent's Series:

$$f(z) = \sum_{n=-\infty}^{\infty} c_n (z-a)^n,$$

convergent for all values of z within this ring: $r_1 < |z-a| < r_2$. Here

$$c_n = \frac{1}{2\pi i} \int_C \frac{f(t) dt}{(t-a)^{n+1}}, \quad |c_n| \leq M r^{-n},$$

where C denotes a closed curve lying within the ring and encircling the point a , and M, r have the same meaning as in § 8.

(b) *Lagrange's Series.* Kepler's problem of developing a root w of the equation

$$w = a + z \sin w$$

(or more generally a function $\Phi(w)$ of this root) according to powers of z led Lagrange to formulate the following problem: To develop a root w of the equation

$$w = a + z f(w),$$

or more generally a function $\Phi(w)$ of this root, according to powers of z . He thus obtained the series that bears his name:

$$\Phi(w) = \Phi(a) + z \Phi'(a) f(a) + \sum_{n=2}^{\infty} \frac{z^n}{n!} \frac{d^{n-1}}{da^{n-1}} [\Phi'(a) f(a)^n].$$

Example: Let $f(w) = \frac{1}{2}(w^2 - 1)$,

$$w = \frac{1 - \sqrt{1 - 2az + z^2}}{z}.$$

Then $\partial w / \partial a = (1 - 2az + z^2)^{-\frac{1}{2}}$ and

$$\frac{1}{\sqrt{1 - 2az + z^2}} = 1 + \sum_{n=1}^{\infty} \frac{z^n}{n!} \frac{d^n}{da^n} \left[\frac{(a^2 - 1)^n}{2^n} \right].$$

Thus the form of the coefficients P_n in the example of § 8 is determined:

$$P_n(\mu) = \frac{1}{n!} \frac{d^n}{d\mu^n} \left[\frac{(\mu^2 - 1)^n}{2^n} \right].$$

These functions are known as Zonal Harmonics.

10. *Roots and Singular Points.*—A function $f(z)$ is said to have a *root* or *zero* at an interior point a of the region S of § 8 if $f(a) = 0$. It follows that $f(z)$ can then be written in the form

$$f(z) = (z-a)^m [c_m + c_{m+1}(z-a) + \dots],$$

where m is a positive integer and $c_m \neq 0$ (unless $f(z) \equiv 0$). The point a is called a *root* or *zero* of *order* m ; $f(z)$ is sometimes said to have m roots in $z = a$. A circle of definite radius can always be drawn about the point a containing no further root of $f(z)$.

If $f(z)$ is single-valued and analytic throughout the neighborhood of a point a with the exception of this point itself, and if $f(z)$ becomes infinite no matter how z approaches a , then a is called a *pole* of $f(z)$. Since $1/f(z)$ then has a zero in a , $f(z)$ can be written in the form

$$f(z) = \frac{\phi(z)}{(z-a)^m},$$

where m is a positive integer and $\phi(z)$ remains finite and different from 0 at a ; $f(z)$ is said to have a pole of *order* m , or to have m (simple) poles in $z = a$.

If, however, $f(z)$ does not approach a limit when z approaches a , and does not have a pole there either, a is called an *essential singularity*. In the neighborhood of such a point Weierstrass has shown that the function comes as near as one pleases to any arbitrary preassigned value.

11. *Linear Transformations.*—The linear transformation

$$Z = \frac{az + b}{cz + d}, \quad ad - bc \neq 0,$$

plays an important rôle in the theory of functions. If $c = 0$, we have an *integral linear transformation*. Interpreted geometrically as a transformation of the plane into itself, it comprises as special cases:

- (a) $Z = z + b$, *i.e.*, a translation;
- (b) $Z = e^{ai} z$, " a rotation;
- (c) $Z = Az$, $A > 0$, " a stretching.

The general integral linear transformation can be generated by a succession of these transformations.

If, however, $c \neq 0$, we need to consider one further transformation:

$$(d) \quad Z = \frac{1}{z}.$$

This corresponds to an inversion in the unit circle: $R = 1/r$, followed by a reflection in the axis of reals: $Y = -y$.

The general linear transformation carries circles over into circles, straight lines being regarded, as in the geometry of inversion, as circles with infinite radii. The infinite region of the plane is considered as a *point* (not, as in

COMPLEX VARIABLE

projective geometry, as a line), and this is the convention which it is desirable, for reasons that cannot be named here, to make in the theory of functions. We speak of *the point* $z = \infty$.—Cf. an article by F. N. Cole, 'Linear Functions of a Complex Variable,' *Annals of Math.*, ser. 1, vol. 5 (1890), p. 121.

12. *Multiple-Valued Functions*.—When in the definition of § 1 more than one value is assigned to each point of S , the first thing to be done is to group these values in such a way that they form several single-valued functions. Consider for example the function \sqrt{z} . Setting

$$w = Re^{\phi i}, \quad z = re^{\phi i},$$

we have

$$R = \sqrt{r}, \quad \Phi = \frac{1}{2}\phi, \quad \frac{1}{2}\phi + \pi.$$

If now we sever the plane along a line running from $z=0$ to $z=\infty$, say along the positive axis of reals, we can then spread out two single-valued functions each analytic in this region, namely,

$$w_1 = \sqrt{r}e^{\frac{\phi i}{2}} \quad \text{and} \quad w_2 = -\sqrt{r}e^{\frac{\phi i}{2}},$$

and these two functions together just exhaust the values of the multiple-valued function \sqrt{z} . Let us, therefore, consider two planes instead of one, each severed along the cut in question and lying one above the other like the leaves of a book, and assign the values w_1 to the points of the one plane, w_2 to those of the other. We observe, furthermore, that the values of w_1 along the upper side of the cut in its leaf and those of w_2 along the lower side of the cut in the second leaf agree with each other. Let these two edges be united, so that z , moving continuously in the surface thus formed, will pass from leaf I to leaf II without interruption when it crosses the positive axis of reals from the upper side. Similarly the values of w_1 along the lower edge of the cut in leaf I and those of w_2 along the upper edge of the cut in leaf II correspond. Hence we shall unite these two edges. The final result is a closed surface of two sheets in which the function \sqrt{z} is single-valued. The sheets cut through each other along a line; but the point z in crossing this line is not at liberty to pass into either sheet. z has not come to a fork in the road, but to a switch which has already been set, and its further course is definitely determined.

The point $z=0$ is called a *branch-point*, the cut a *junction-line*.

More generally, let

$$G(w, z) = A_0(z)w^m + A_1(z)w^{m-1} + \dots + A_m(z) = 0$$

be an algebraic equation. Then to each value of z correspond in general m distinct values w_1, \dots, w_m . Mark the points a_1, \dots, a_k (finite in number) for which this is not the case. Draw a curve C , not cutting itself, through these points and continue C from the last point to $z=\infty$. Then spread out m leaves over the z -plane and cut each leaf along C . The m values w_1, \dots, w_m of the function can now be assigned to the points of these leaves so as to form m single-valued functions analytic throughout these regions. Finally, corresponding edges of the leaves are to be connected along each of the segments into which C is divided by the points a_1, \dots, a_k, ∞ . The result is a closed surface

on which w is a single-valued function of z . If $G(w, z)$ is irreducible, the surface will consist of a single piece, and conversely. A branch-point in which μ leaves are connected in cycle is said to be of order $\mu - 1$.

The surfaces here described are due to Riemann (Göttingen, thesis for the doctorate, 1851) and are known as *Riemann's Surfaces*. Corresponding to any given analytic function there can always be constructed a Riemann's surface on which the function becomes single-valued. In all ordinary cases the leaves are joined together in cycle in branch-points, and they always pass over into each other along junction lines, never merely at isolated points.

13. *Analytic Continuation*.—If a function $f(z)$ be single-valued and analytic in a region S , it may happen that the function can be defined

FIG. 4.

in an adjacent region S_1 in such a way that the extended function is analytic throughout the enlarged region (S, S_1) . In this case $f(z)$ is said to be *continued analytically* beyond the region S into the region S_1 . There can never be two distinct analytic continuations of $f(z)$ into S_1 . If S_1 overlaps S , it will in general be necessary to introduce a Riemann's surface for the extended function.

Consider, for example, a function given by the power series (4). Let $z_0 \neq 0$ be an interior point of the circle of convergence K . Develop the function by Taylor's Theorem about the point z_0 . The new power series, which proceeds according to powers of $z - z_0$, will surely converge within a circle tangent internally to K , and it may converge throughout a larger circle K_1 . In the latter case analytic continuation is possible, the region S_1 corresponding to the part of K_1 exterior to K .

We are now in a position to complete the definition, according to Weierstrass, of an analytic function. Let $f(z)$ be analytic in a given region S . Continue $f(z)$, if possible, analytically beyond S . Repeat this step so long as it is possible to do so. The most extended function that can thus be generated out of the given function is known as the *monogenic analytic function* $f(z)$. It is uniquely determined by the values of $f(z)$ in S . Weierstrass employed the method of overlapping circles and power series for obtaining the successive analytic continuations. The function is completely defined as soon as any one of these power series, called *elements*, is known.

The rational functions and the elementary functions e^z , $\log z$, etc., are examples of monogenic analytic functions. By an *algebraic function* is meant any monogenic analytic function which satisfies an algebraic equation, $G(w, z) = 0$, where G denotes a polynomial. Every irreducible algebraic equation in w and z defines such a function.

Two analytic functions which agree in value with each other along an arc of a curve, however short, lying wholly within their domain of defi-

COMPLEX VARIABLE

dition, are identical throughout their whole extent.

It may happen that the singular points of an analytic function are not isolated, but fill a curve (for example an arc or the whole circumference of a circle, the latter being the case with the function defined by the series

$$\sum_{n=1}^{\infty} z^n!$$

throughout the interior of the unit circle $|z| < 1$), so that the function is analytic up to the curve, but cannot be extended beyond it. Such a curve is called a *natural boundary*. A region of the plane into which a given function cannot be continued analytically is called a *lacunary space*.

14. *Reflection in Analytic Curves*.—A curve which can be represented by the equations

$$x = f(t), \quad y = \phi(t), \quad a \leq t \leq b,$$

where f and ϕ are both developable by Taylor's Theorem about every point t_0 of the above interval and where, furthermore, $f'(t)$ and $\phi'(t)$ never vanish simultaneously in the interval, is called an *analytic curve*.

Let S be a region bounded in part or wholly by an analytic curve Γ having no multiple point. If

$$u + vi = f(z)$$

is analytic in S and takes on real boundary values along Γ , then $f(z)$ can always be continued analytically across Γ . In particular, let Γ be an arc of a circle. Then the analytic continuation is effected by inverting S in this circle and assigning to $f(z)$ in the transformed points values conjugate to those in the original points. The method is fundamental in the study of minimum surfaces, and of the elliptic modular and the automorphic functions.

15. *Dirichlet's Principle*.—In order to show that a simply connected region S can be mapped in a one-to-one manner and conformally on a circle (§ 4), it is necessary to establish the existence of a function u which (a) is single-valued and continuous in S , (b) satisfies Laplace's Equation (§ 6) throughout the interior of S , and (c) takes on preassigned values along the boundary of S . In similar cases in mathematical physics Gauss, Thomson, and Dirichlet had attempted to give a proof of the existence of such a function by making connections with a skilfully constructed corresponding problem of the Calculus of Variations. Riemann adopted this method in order to obtain his existence proofs, both for the present problem and for the case of algebraic functions corresponding to a preassigned Riemann's surface. The problem of the Calculus of Variations which matches the present problem is as follows: To find a function u which is continuous in S , together with its first derivatives, takes on the prescribed boundary values, and makes the integral

$$\int_S \int \left[\left(\frac{\partial u}{\partial x} \right)^2 + \left(\frac{\partial u}{\partial y} \right)^2 \right] dS$$

a minimum. If such a function exists and if, furthermore, it has continuous second derivatives, then it will satisfy Laplace's Equation within S and thus yield the desired solution. It was assumed by the mathematicians named above that the problem of the Calculus of Varia-

tions necessarily has a solution. This method of proof is known as *Dirichlet's Principle*. Weierstrass pointed out the insufficiency of the reasoning involved in the assumption to which we have just called attention. Other methods of proof were then devised by Schwarz and Neumann. Recently Hilbert has, with considerable labor, partially filled the gap in the original method.

16. *Weierstrass's and Mittag-Leffler's Theorems*.—It is always possible to form a polynomial which has n roots situated arbitrarily in the complex plane. The question presents itself as to whether this theorem can be extended to transcendental integral functions. This question Weierstrass answered in 1876 as follows: Let a_0, a_1, \dots be any set of points in the complex plane such that $\lim a_n = \infty$ when $n = \infty$. Then there exists an integral transcendental function $G(z)$ which has in each of the points a_n a zero of arbitrarily preassigned order, and does not vanish for any other value of z . The most general such function is given by the formula

$$G(z) = e^{\Gamma(z)} \mathfrak{G}(z),$$

where \mathfrak{G} denotes a particular function of the class in question and Γ is a rational or transcendental integral function. This theorem has formed the point of departure for many recent researches, chiefly of French mathematicians.

Mittag-Leffler's Theorem: Let a_0, a_1, \dots be any set of points in the complex plane such that $\lim a_n = \infty$ when $n = \infty$. In each of these points let an arbitrary polynomial in $1/(z - a_n)$:

$$f_n(z) = \frac{A_1^{(n)}}{z - a_n} + \frac{A_2^{(n)}}{(z - a_n)^2} + \dots + \frac{A_\kappa^{(n)}}{(z - a_n)^\kappa},$$

be chosen. Then there exists a single-valued function $F(z)$ analytic throughout the whole plane except at the points a_n and behaving in each of these points like $f_n(z)$; *i.e.*, the difference

$$F(z) - f_n(z)$$

has no singularity in the point a_n . The most general such function is given by the formula

$$F(z) = \mathfrak{F}(z) + G(z),$$

where \mathfrak{F} denotes a particular function of the class in question and G is an integral function, rational or transcendental.

17. *Elliptic and Abelian Integrals*.—The motion of a simple pendulum and the length of the arc of an ellipse lead respectively to the elliptic integrals

$$\int_0^x \frac{dx}{y}, \quad \int_0^x \frac{y dx}{1 - x^2},$$

where $y^2 = (1 - x^2)(1 - k^2 x^2)$, $0 < k < 1$.

If we set the first of these integrals equal to w and let x take on complex values z , then the inverse function z :

$$w = \int_0^z \frac{dz}{\sqrt{(1 - z^2)(1 - k^2 z^2)}}, \quad z = \sin \operatorname{am} w,$$

turns out to be a single-valued function of its argument w having two linearly independent periods (§ 18) and being analytic throughout the whole w -plane except for poles.

A generalization which now presents itself is the following: The integrand in each of the foregoing cases is a rational function of x and y ,

and these variables are connected by an algebraic equation. Consider, therefore, generally an algebraic equation

$$G(w, z) = 0,$$

where G denotes an irreducible polynomial in w and z , and construct the Riemann's surface corresponding to it. Let $R(w, z)$ be any rational function of w and z . Then, setting w equal to the algebraic function of z defined by the foregoing equation, we have in $R(w, z)$ a function which is single-valued and in general continuous on the above surface. If now we extend the definite integral

$$\int_{(w_0, z_0)}^{(w, z)} R(w, z) dz$$

along an arbitrary path on the surface, we have before us an *Abelian Integral*. It is obvious that the logarithm and the inverse trigonometric functions, e.g.,

$$\sin^{-1} z = \int_0^z \frac{dz}{w}, \quad z^2 + w^2 = 1,$$

are special cases of Abelian integrals. When the equation $G = 0$ is of the form

$$w^2 = f(z),$$

where $f(z)$ denotes a polynomial in z of degree > 4 having all distinct linear factors (or can be thrown into this form by means of birational transformations), the integral is called a *hyper-elliptic integral*.

The only Abelian integrals whose inverse function is single-valued are those which lead to the exponential (including trigonometric) and the elliptic functions. The *Abelian Functions* are single-valued periodic functions, not of a single argument, but of p independent variables, where p denotes the deficiency of the corresponding Riemann's surface $G(w, z) = 0$. They have $2p$ periods. These functions arise as the inverse functions $z_\kappa(w_1, \dots, w_p)$, ($\kappa = 1, \dots, p$) of a system of p equations:

$$w_\kappa = \int_{a_1}^{z_1} \phi_\kappa dz_1 + \dots + \int_{a_p}^{z_p} \phi_\kappa dz_p,$$

where the integrals $\int \phi_\kappa dz$ are p linearly independent Abelian integrals on the Riemann's surface for $G(w, z) = 0$.

18. *Automorphic Functions*.—A function $f(z)$ is said to admit a linear transformation into itself if

$$f\left(\frac{\alpha z + \beta}{\gamma z + \delta}\right) = f(z),$$

where α, \dots, δ are constants and $\alpha\delta - \beta\gamma \neq 0$. A familiar class of such functions are the *periodic functions*. Here the transformation reduces to a translation:

$$f(z + \omega) = f(z).$$

The most general single-valued periodic functions of a single variable z , which are in general analytic, are the *simply* and *doubly periodic functions*, i.e., those functions whose periods can all be expressed as integral multiples $n\omega$ of a single primitive period ω , or else in the form $n\omega + n'\omega'$, where ω and ω' form a primitive pair of periods. In the latter case ω/ω' cannot be a real quantity.

If the coefficients are integers and $\alpha\delta - \beta\gamma = \pm 1$, we have the *elliptic modular functions*. More generally the coefficients may have non-integral values, being restricted only in such a way that the transformations form a "discrete group." These most general functions, including the special cases above mentioned, are known as the *automorphic functions*.

19. *Definite Integrals*.—The Γ -function may be defined by the definite integral

$$\Gamma(z) = \int_0^\infty t^{z-1} e^{-t} dt,$$

the variable of integration t being real and positive. This integral converges only for values of z which lie to the right of the axis of pure imaginaries: $z = x + yi$, $x > 0$. A new definite integral can be formed as follows which converges for all values of $z \neq -n$, where n denotes a positive integer, namely,

$$\int_C t^{z-1} e^{-t} dt,$$

extended over the loop indicated in the figure.

FIG. 5.

It is readily shown that the second integral is equal to the first multiplied by $1 - e^{2\pi iz}$ for all values of z for which the first integral converges. Hence we have generally

$$\Gamma(z) = \frac{1}{1 - e^{2\pi iz}} \int_C t^{z-1} e^{-t} dt.$$

By means of this integral the Γ -function has been systematically treated.

The above is an example of a *loop integral*, i.e., a definite integral extended over a certain *loop-circuit*. Such integrals have been generalized, being extended over *double circuits*, and these latter integrals are an aid in the study of the solutions of certain linear differential equations.

20. *Functions of Several Variables*.—In each of n complex planes let a region S_1, \dots, S_n be given, and let z_κ be an arbitrary point of S_κ . Then the set of values (z_1, \dots, z_n) is called from analogy with the case $n = 1$ a *point*. The totality of these points constitutes the *region* (S). In every point of S let a function $f(z_1, \dots, z_n)$ be uniquely defined. The idea of the limit and of continuity can be extended at once to such a function. $f(z_1, \dots, z_n)$ is said to be *analytic in* (S) if it is continuous in (S) and if, furthermore, when all the z_κ but one, — z_m , let us say, — are held fast, f is then analytic in S_m ; this condition to be satisfied for $m = 1, \dots, n$. For brevity let $n = 2$. Cauchy's Integral Formula becomes

$$f(z_1, z_2) = \frac{1}{(2\pi i)^2} \int_{C_1} \frac{dt_1}{t_1 - z_1} \int_{C_2} \frac{f(t_1, t_2) dt_2}{t_2 - z_2}.$$

The function can furthermore be developed by Taylor's Theorem as follows: Let (a_1, a_2) be an interior point of (S), and let K_κ be the largest circle that can be drawn in S_κ about a_κ as centre, containing in its interior no boundary point of S_κ . Then

$$f(z_1, z_2) = \sum_{l=0}^{\infty} \sum_{m=0}^{\infty} c_{lm} (z_1 - a_1)^l (z_2 - a_2)^m,$$

where

$$c_{lm} = \frac{1}{l! m!} \left. \frac{\partial^{l+m} f(z_1, z_2)}{\partial z_1^l \partial z_2^m} \right|_{(a_1, a_2)}$$

$$= \frac{1}{(2\pi i)^2} \int_{C_1} \frac{dt_1}{(t_1 - a_1)^{l+1}} \int_{C_2} \frac{f(t_1, t_2) dt_2}{(t_2 - a_2)^{m+1}},$$

and z_κ is an arbitrary interior point of the circle K_κ . We have, as in the case $n = 1$,

$$|c_{lm}| \leq M r_1^{-l} r_2^{-m},$$

where $|z_1 - a_1| = r_1$, $|z_2 - a_2| = r_2$.

The idea and the method of analytic continuation can be extended without difficulty to functions of several variables, and thus the *monogenic analytic function* is completely defined. For implicit functions and analytic configurations lying in hyperspace the reader is referred to the author's report in the *Encyklopädie*, §§ 44 and 47 (see below).

The following theorem is due to Weierstrass: Let (b, a_1, \dots, a_n) be an interior point of a region (S) in which $f(w, z_1, \dots, z_n)$ is analytic. Let f vanish at this point; but $f(w, a_1, \dots, a_n)$ shall not vanish identically. Then

$$f(w, z_1, \dots, z_n) = \{w^m + A_1 w^{m-1} + \dots + A_m\} \Phi,$$

where $\Phi(w, z_1, \dots, z_n)$ is analytic throughout a certain neighborhood of the point (b, a_1, \dots, a_n) and does not vanish there, while each of the coefficients $A_1(z_1, \dots, z_n), \dots, A_m(z_1, \dots, z_n)$ is single-valued and analytic throughout a region including the point (a_1, \dots, a_n) in its interior. The excluded case $f(w, a_1, \dots, a_n) \equiv 0$ is also treated by Weierstrass.

II, B. 1.

WILLIAM F. OSGOOD,

Professor of Mathematics, Harvard University.

Complex'ion, the term generally used to signify the special color or hue of a person's skin. The human skin, till the time of Malpighi, was supposed to consist only of two parts—the epidermis or outer skin, and the cutis or true skin; but that anatomist, about the middle of the 17th century, discovered between these a cellular texture, soft and gelatinous, to which the names of rete mucosum, rete Malpighi, or Malpighian tissue, have been given. He demonstrated the existence of this membrane at first in the tongue and in the inner parts of the hands and feet; but by his subsequent labors, and also by those of Ruysch and other anatomists, it was proved to exist, between the epidermis and cutis, in all parts of the human body. Malpighi, on the discovery of this membrane, offered a conjecture respecting the cause of the color of negroes. He supposed that this membrane contained a juice or fluid of a black color,

from which their blackness arose. The actual existence of a black pigment has been since ascertained. The rete mucosum is of very different colors in different nations; and the difference of its color so completely agrees with the difference of their complexions, that there can be no doubt that it is the sole, or, at least, the principal seat of the color of the human complexion. Its thickness varies in different parts of the body; and the depth of its color, for the most part, is in proportion to its thickness. It is now, however, not regarded as altogether a distinct tissue, being considered rather as the innermost and newest layer of the epidermis or cuticle. The black color of the negroes is destroyed by whatever destroys the rete mucosum, as wounds, burns, etc.; the scar remaining white ever afterward. The greatest contrast in complexion is between the fair white peoples of northern Europe and the ebony colored negro of Africa.

The nature and color of the hair seem closely connected with the complexion. In proportion to the thinness of the skin and the fairness of the complexion the hair is soft, fine, and of a white color; this observation holds good not only in the great varieties of the human race, but also in albinos. Next to them in fairness of complexion is the Teutonic race, the *rutilæ comæ* (fair locks) of whom were a distinguishing characteristic even in the time of the Romans. The Celtic people are not so fair as the Teutonic, and their hair is darker and less inclined to curl; but it is perhaps more difficult than in the case of the Teutons to be sure of unmixed blood. But though the color of the hair is evidently connected with the complexion, yet its tendency to curl does not appear to be so. Many brown complexion Celts have curled hair; the Mongolian and American races, of a much darker complexion, have hair of a darker color, but long and straight. Among that portion of the Malay race which inhabits some of the South Sea Islands, soft and curled hair is said to be met with. The color of the eye is also connected with the complexion. In the Africans, Prof. Sommering remarks that the white of the eye is not so resplendently white as in Europeans, but rather of a yellowish brown, something similar to what occurs in the jaundice. The iris in the negroes, in general, is of a very dark color; but the iris in the Congo negro is said to be frequently of a bluish tinge. The Teutonic tribes are not more distinguished by their fair complexion than by their blue eyes, —*cærulei oculi*, while the iris of the darker colored Finn is brown, and that of the still darker Laplander black. The color of the eyes also follows, in a great degree, in its changes, the variations produced by age in the complexion. The most singular class of people in point of complexion are the albinos, but albinism is not confined to the human race. An intermediate complexion is produced where children are born from parents of different races. If the offspring of the darkest African and the fairest European intermarry successively with Europeans, in the fourth generation they become white; when the circumstances are reversed, the result is reversed also. Along with the successive changes of complexion is also produced a change in the nature and color of the hair; though, in some instances, the woolly hair remains when the complexion has become nearly

COMPLEXION

as fair as that of brown people in Europe. It does not, however, always happen that the offspring is the intermediate color between that of the respective races to which the father and mother belong; it sometimes resembles one parent only, while, perhaps, in the second or third generation, the color of the other parent makes its appearance. An instance has been given of a negress who had twins by an Englishman: one was perfectly black; its hair was short, woolly, and curled: the other was white, with hair resembling that of a European. In another case the child of a black man and an English woman was quite black; and still more remarkable: a black married a white woman, who bore him a daughter, resembling the mother in features, and as fair in all respects, except that the right buttock and thigh were as black as the father's.

The generally received opinion concerning the varieties of complexion which are found in the different races of man throughout the globe is, that they are caused entirely by the influence of climate. Respecting the primary color of man the supporters of this opinion are not agreed. The opinion that climate alone will account for the various complexions of mankind is very plausible, and supported by the well-known facts that in Europe the complexion grows darker as the climate becomes warmer; that the complexion of the French is darker than that of the Germans, while the natives of the south of France and Germany are darker than those of the north; that the Italians and Spaniards are darker than the French, and the natives of the south of Italy and Spain darker than those in the north. The complexion also of the people of Africa and the East Indies is brought forward in support of this opinion; and from these and similar facts the broad and general conclusion is drawn, that the complexion varies in darkness as the heat of the climate increases; and that, therefore, climate alone has produced this variety. But it can be shown that the exceptions to this general rule are very numerous; that people of dark complexions are found in the coldest climates, people of fair complexions in warm climates, people of the same complexion throughout a great diversity of climate, and races differing materially in complexion dwelling near together.

1. In the coldest climates of Europe, Asia, and America we find races of a very dark complexion. The Laplanders have short, black, coarse hair; their skins are swarthy, and the irides of their eyes are black. According to Crantz the Greenlanders have small, black eyes; their body is dark gray all over; their face brown or olive; and their hair coal-black.

The complexion of the Samoiedes and other tribes who inhabit the north of Asia is very similar to that of the Laplanders and Greenlanders, who are Eskimos by race. Humboldt's observations on the South American Indians illustrate and confirm the same fact. If climate rendered the complexion of such of these Indians as live under the torrid zone, in the warm and sheltered valleys, of a dark hue, it ought also to render or preserve fair the complexion of such as inhabit the mountainous part of that country; for certainly, in point of climate, there must be as much difference between the heat of the valleys and of the mountains in South America as there is between the tempera-

ture of southern and northern Europe; and yet this author expressly assures us that "the Indians of the torrid zone, who inhabit the most elevated plains of the Cordillera of the Andes, and those who, under the 45th degree of south latitude, live by fishing among the islands of the archipelago of Chonos, have as coppery a complexion as those who, under a burning climate, cultivate bananas in the narrowest and deepest valleys of the equinoctial region." He adds, indeed, that the Indians of the mountains are clothed, but he never could observe that those parts which were covered were less dark than those which were exposed to the air. The inhabitants also of Tierra del Fuego, one of the coldest climates in the world, have dark complexions and hair.

2. Fair complexioned races are found in hot climates. Ulloa informs us that the heat of Guayaquil is greater than at Carthagená; and by experiment he ascertained the heat of the latter place to be greater than the heat of the hottest day at Paris; and yet in Guayaquil, "notwithstanding the heat of the climate, its natives are not tawny"; indeed they are "so fresh-colored, and so finely featured, as justly to be styled the handsomest, both in the province of Quito and even in all Peru." According to a statement of Humboldt, in the forests of Guiana, especially near the sources of the Orinoco, "are several tribes of a whitish complexion of whom several robust individuals, exhibiting no symptom of the asthenical malady which characterizes albinos, have the appearance of true Mestizos. Yet these tribes have never mingled with Europeans, and are surrounded with other tribes of a dark brown hue." The inhabitants of Boroa, a tribe in the heart of Araucania, are white, and in their features and complexion very like Europeans. Even in Africa darkness of complexion does not increase with the heat of the climate in all instances; the existence of comparatively fair races in this quarter of the globe is noticed by Ebn Haukal, an Arabian traveler of the 10th century, and has been confirmed by subsequent travelers.

3. The same complexion is found over immense tracts of country, comprehending all possible varieties of climate. The most striking and decisive instance of this is on the continent of America, all the inhabitants of which, with the exception of the Eskimo, exhibit the copper-colored skin and the long and straight black hair. Australia is an instance of a similar nature, though on a less extensive scale: over the whole of the island, even in the comparatively cool climate of the southern parts, the complexion of its inhabitants is of a deep black, and their hair is curled like that of negroes.

4. Different complexions are found under the same physical latitude, and among the same people. Illustrations and proofs of this have already been given. The physical latitude in which the Norwegians, the Icelanders, the Finns, and the Laplanders live scarcely differs; and yet their complexion, and the color of their eyes and hair, are widely different. There is a great diversity of color and features among the Morlachs, who inhabit Dalmatia. The inhabitants of Kotar, and of the plains of Seigu and Knin, have fair blue eyes, broad face, and flat nose. Those of Duare and Vergoraz, on the contrary, have dark-colored hair; their face is long, their complexion tawny, and their stature tall. M.

COMPLEXION

Sauche, who traveled among the Tartars in the southern provinces of Russia, describes a race or tribe as having countenances as white and fresh as any in Europe, with large black eyes. In the south of Africa we find the **Kafirs**, who are of a brown or iron-gray color, and the Hottentots of a yellow color. In the island of Madagascar, according to Mr. Sibree, the observer "finds almost every shade of color from a very light olive, not darker than is seen in the peoples of southern Europe, down through all gradations of brown to a tint which although not black is certainly very dark. In the quality of the hair, too, there is a good deal of difference; the lighter-colored people having usually long, black, and straight hair, while the darker tribes have, as a rule, shorter and more frizzly hair."

Besides a Malayan olive-colored race, people with the negro complexion and features are found in the Philippine Islands; and in Java, the Hindu, and Malay character may be clearly traced in the complexion and features of the two classes of inhabitants which are found in that island. In several of the Moluccas is a race of men who are blacker than the rest, with woolly hair, inhabiting the interior, hilly parts of the country. The shores of these islands are peopled by another nation, whose inhabitants are swarthy, with curled, long hair. In the interior hilly parts of Formosa the inhabitants are brown, frizzle-haired, and broad-faced; while the Chinese occupy the shores.

It is observed that there are two great varieties of people in the Pacific islands; the one more fair, the other blacker, with their hair just beginning to be woolly and crisp. The first race inhabits Tahiti and other of the Society Islands, the Marquesas, the Friendly Isles, Easter Island, and New Zealand; the second race peoples New Caledonia, Tanna, and the New Hebrides, especially Mallicolo. If we examine the relative situation and latitudes of these islands on a map, we shall be convinced not only that darker complexioned people are found where the climate is comparatively colder, but that the same complexion is found under very different latitudes. It is not meant to be denied that a burning climate will render the complexion very dark, and that a climate of less extreme heat will bronze the complexion of the fairest European; but there are some material points in which the dark complexion of the Caucasian, or naturally fair-skinned variety of mankind, caused by climate, differs from the dark complexion of all the other varieties of the human race.

1. The offspring of the Caucasian variety is born fair; the offspring of the other varieties is born of the respective complexion of their parents. Ulloa informs us that the children born in Guayaquil of Spanish parents are very fair. The same is the case in the West Indies. Long, in his history of Jamaica, expressly affirms "that the children born in England have not, in general, lovelier or more transparent skins than the offspring of white parents in Jamaica." But it may be urged that this is not the case with respect to the other nations of the Caucasian variety, who have been settled in warm climates from time immemorial, and that the question ought to be decided by the Moors, Arabians, etc. Their children, however, are also born fair complexioned, as fair as the children of Europeans who live under a cold climate. Russell

informs us that the inhabitants of the country round Aleppo are naturally of a fair complexion, and that women of condition, with proper care, preserve their fair complexion to the last. The children of the Moors, according to Shaw, have the finest complexions of any nation whatsoever; and the testimony of Poiret is directly to the same effect. "The Moors are not naturally black, but are born fair, and when not exposed to the heat of the sun remain fair during their lives."

2. Individuals belonging to the Caucasian variety, that inhabit warm countries, preserve their native fairness of complexion if they are not exposed to the influence of the climate; while there is a uniform black color over all the parts of a negro's body. The hue which Europeans assume is the same, though the tinge may be lighter or darker, whether they settle in Africa, the East Indies, or South America. They do not become, like the natives of those countries, black, olive-colored, or copper-colored; their complexion merely resembles that of a tanned person in this country, only of a darker tinge. The negroes that are settled in the West Indies or America do not assume the copper color of the Indians, even though a milder climate may have some effect on the darkness of their complexions. The children of Europeans, of negroes, and of Indians are all born, in America, of the same reddish hue; but in a few days those of the negro begin to assume the black complexion of their parents, those of the Indian the copper complexion, while those of the European either continue fair, if kept from the influence of the sun, or become tanned; not black like the negro, or copper-colored like the Indian, if exposed to its influence. Europeans who settle in Canada, or in the northern parts of America, where the climate resembles that of their native country, do not assume the complexion of the Indians, but continue fair like their ancestors. The same observation may be made respecting the Russians who are settled among the Mongolian variety, in those parts of the Russian empire in Asia, the climate of which resembles the middle or northern parts of European Russia. Indeed the wide extent of country over which the Mongolian variety is spread, including the extreme cold of Lapland and the north of Asia, the mild temperature of the middle parts of that continent, and the warmth of the southern parts of China, is in itself a proof that dark complexion does not arise either from the influence of heat or cold.

Lastly, radical varieties of complexion are always accompanied with radical varieties of features. We do not find the olive color of the Mongolian variety with the features of the Malay; nor the brown color of the Malay with the features of the Mongolian; nor the black skin of the Ethiopian variety, or the red color of the American, united with any set of features but those which characterize their respective varieties. It, however, by no means follows that the hypotheses of different races having been originally formed must be adopted, because climate is not adequate to the production of the radical varieties of complexion which are found among mankind. Man, as well as animals, has a propensity to form natural varieties; and the variations may in process of time involve all the tissues so as to yield permanent differences in color and quality of hair, color of skin, size

COMPLINE — COMPOSING-MACHINES

and form of bones, especially those of the skull and limbs. See EPIDERMIS; HISTOLOGY; MALPIGHI; RUYSCH.

Com'pline, the last or seventh of the daily canonical hours in the Roman Catholic breviary; the complement of the Vespers or evening office. St. Benedict, in the 6th century, added Compline to the hours, thus making the number seven, answering to the praises of which the psalmist speaks of "seven times a day." Matins and lauds were classed as one hour.

Complutensian (kōm-ploo-těn'sī-an) **Polyglot**, a polyglot made by seven scholars under the auspices and at the expense of Cardinal Ximenes. It was begun in 1502, and finished in 1517, but was not actually published till 1522. It consists of six folio volumes. In the Old Testament, on the left hand page, are the Hebrew original, the Latin Vulgate, and the Greek Septuagint; and on the right hand page, the Vulgate, the Septuagint, with Latin translation above, and the Hebrew, with primitives belonging to that language on the outer margin. At the lower part of the page are two columns used for a Chaldee paraphrase, and a Latin translation. The Greek Testament, constituting part of the Complutensian Polyglot, was the first complete edition of that part of Scripture printed.

Composing-machines, a general title for all classes of machines that compose or set either type or matrices, arranging them in lines and columns for printing. There are four prominent types of these: (1) Those that set matrices in line and cast therefrom a solid line or slug, as the linotype, monoline, and typograph; (2) those that cast and set type, as the monotype and graphotype; (3) those that set and distribute ordinary foundry type, these being the only ones properly styled type-setting machines, as the Simplex (modernized Thorne), Empire, Dow, Fraser, Kastenbein, etc.; and (4) those that impress male dies into soft material and cast lines from these impressions.

Historically, the type-setting machine comes first, William Church, of Connecticut, devising a machine which was patented in England in 1822, that was the first practical effort in this direction. He employed a keyboard, and stored the type in channels. From 1842 to 1872 there were 57 United States patents granted on composing machines, and from 1822 to 1872 a like number were patented in Great Britain. The most noteworthy of these were the Mitchell and the Alden machines in the United States, and the Kastenbein, Hattersley and Fraser machines in England. These machines all came into use during the period between 1853 and 1872, and a few may still be found in operation in England. The difficulty with all of them seems to have been that they required several persons to operate each machine, and that the consequent cost was very nearly the same as for composition by hand. From 1872 up to 1880 there were invented or constructed over 50 different machines designed to supersede the compositor, practically all of which failed of commercial success. During the period between 1880 and 1890 the Thorne type-setting machine, originating in Connecticut, came into considerable use, being employed by many newspapers throughout the United States,

and beginning to find a market abroad. During this period the Burr and McMillan machines also found some sale in the United States, and the Fraser, Hattersley, and Kastenbein in England and Germany. In 1898 the Thorne was remodeled and renamed the Simplex.

Of all the machines devised for setting foundry type, the Simplex is the best in use. The types are contained in 90 channels, set radially in the periphery of an upright cylinder. As the operator fingers the keys, the types called for are pushed out of the lower ends of the channels and carried around on a circular race-way to the point where they are brought into line. This line extends to a considerable length, without any reference to the length of line in which the matter set up is to appear finally. A second operator draws to him from the composed type thus emerging enough to form a line of the desired length. This he puts in the gal-

The Simplex.

ley and justifies, or spaces out to length, by hand. The leads, or spaces between lines, are also inserted by this operator.

After type set on the Simplex machine has been printed from, or molded for electrotyping, it is taken by a boy, who puts the type, a galley at a time, into a holder, which feeds it, a line at a time, into a short cylinder superimposed over the type-cylinder previously mentioned, from which it passes to the lower cylinder ready for composition again. Distribution and composition proceed simultaneously. Specially nicked type and combinations of wards or lips at the magazine entrances accomplish the distribution. The arrangements are such that the keyboard operator can also do the justifying (by hand), or two operators can be employed, as suits the convenience of the user. The Simplex machine has enjoyed a larger sale than any other composing-machine except the linotype.

The Empire machine, first known as the Burr, is a modification of the Kastenbein. It was produced in New York, and, like the Kastenbein machine, requires three operators. The distributor is a separate machine, that, when loaded with pages of type, separates them one

COMPOSING-MACHINES

by one and pushes them into the channels of a magazine. This magazine is placed on the top of the setting-machine, which is supplied with a keyboard. The operator releases the lower type from the channels by manipulating the keys, and the lines are justified by a second operator by hand. The builders of this machine have been for many years experimenting with an automatic justifying mechanism to do away with the labor of one operator.

The Kastenbein machine, which has had some sale in Europe, is very similar to the Empire, and does not require a separate description. Both employ nicked type in distributing.

The McMillan machine, developed in Ilion, N. Y., was provided with automatic justification, thus dispensing with the labor of one operator. When a line of type was composed, it was taken up automatically by a carrier and transferred to a point where the spaces between the words were exchanged for a size larger spaces; if the line was not then filled to measure, it was carried on to a third and a fourth stage, until large enough spaces were supplied to spread it to the width of the column. This justifying mechanism was very ingenious, but complicated, and only a few of the machines were built and sold. The distributor was a separate machine, operating quite simply at a speed of about 10,000 ems an hour.

The Cox type-setting machine attracted considerable notice in the printing trade in Chicago and New York in 1897. It was purchased by the Unitype Company of New York, manufacturers of the Simplex, or improved Thorne machine. The most unique feature of Cox's machine was the employment of crimped or corrugated spaces made of lead. The line was overset in length, and then squeezed down to measure by compressing the corrugations. This justification was satisfactory in some respects, but the crimped spaces created difficulty in many others, and its use was abandoned.

The Calendoli type-setting machine, developed in France by a priest of that name, has attracted much attention because of the wonderful claims made for its speed. Though exploited for several years, it has not yet (1905) been perfected for the market. It employs short types grooved so as to slide on rails, and the keyboard has numerous combinations to enable the operator to strike whole words or syllables at a single motion of the hand.

There was exhibited at the Pan-American Exposition in Buffalo, in 1901, a one-man type-setting machine that appeared to work successfully. It is the invention of Alexander Dow, and is the latest machine handling founders' type that is adapted to handle the several sizes in one machine. The justification or spacing out of the lines is entirely automatic, requiring no thought by the operator. The machine measures the line, calculates the proper size and number of spaces, and, discarding the dummy spaces inserted during the original setting, substitutes the proper sizes and pushes the type into the galley. It is in many respects a counterpart of the abandoned Paige machine. A distributor adapted to supply this machine has been constructed with a capacity for supplying three setting-machines.

Among other composing-machines that have been built in the United States, and attracted the attention of the printing trade at one time

or another, are the Converse, projected about 1894, which did good work, but was obstructed by previous patents; the Paige, on whose development nearly \$2,000,000 was spent, and which proved too costly to construct for the general market, the two machines built being now stored with Cornell and Columbia universities as mechanical curiosities; the St. John typobar, consisting of cold-pressed metal clamped on a steel base, to form a line; the Lagerman typotheter or Chadwick, a little machine for enabling a compositor to set type with both hands; the Johnson, which justified the lines by sawing a space of the required width; the composite type-bar machine, in which short, notched type were transformed into a line or type-bar by casting metal around their bases and between them; the Sears, in which dies were impressed in a block of wood, and a slug cast from the matrix thus formed; the Risley and Lake, in which the type were impressed in a soft sheet like blotting paper, and a stereotype taken after a quantity had been thus impressed, and the Heath matrix typograph, of the same class.

Many other type-setting machines might be mentioned that have been built and used somewhat, but practically all of them have been dropped by their owners, because automatic justification has not yet been practically achieved and the labor involved in operating them is much greater than with the linotype, which is a one-man machine,—that is, a machine delivering a full product with the labor of one operator. Many inventors have labored to produce a one-man type-setting machine handling single type, because such a machine is available for some purposes that a linotype machine is not. No such machine is yet on the market.

About 1890 the linotype became a commercial machine and began to take the market, and since that time has far outsold all others combined, there being at this writing (1905) about 10,000 in use as against probably 1,500 of all other makes.

The linotype is the invention of Ottmar Mergenthaler, who spent nearly 15 years of his life in Baltimore perfecting the machine which has largely revolutionized methods of type-setting. For a full description see LINOTYPE.

The Scudder monoline machine produces a slug like that of the linotype, and has been barred out of the United States as an infringing machine. It is being manufactured in Canada, and has been supplied to a considerable number of printing-offices there and in Europe. It is much smaller than the linotype and does a more restricted class of work. Twelve characters are carried on a single matrix, and the position as to height in the line determines which of the 12 shall be used. Eight kinds of matrices thus serve to give a total of 96 characters, and because there are so few matrices the mechanism for distributing them after using becomes very simple. The matrices have hooks on top which engage wires leading to their magazines, and readily slide back to position.

The Lanston monotype is the leading machine of the class that both casts and sets type. It employs first a keyboard, the operation of whose keys results in punching holes in a paper tape. The combinations of holes represent the different type characters. This tape is carried to a type-casting machine and fed in; as it passes

Copyright, 1903, by the Scientific American.

BATTERY OF LINOTYPE COMPOSING MACHINES.

COMPOSITÆ

along, it controls the positioning of the dies before the mold, so that the characters are cast and assembled into lines and columns in the proper order for printing. The keyboard machine or

Lanston No. 1.

perforator is entirely separate from the casting mechanism. It includes 225 characters and a set of justifying-keys. The operator, having decided on the size and face of type and width of column, adjusts certain gauges and proceeds

Lanston No. 2.

to manipulate the keys. As he approaches the end of a line, a pointer on a dial indicates to him what justifying-keys he should strike to make the line of proper length. These perforations are made at the end of each line. Any errors made are repeated in the casting-machine,

and must be corrected later by hand. The product of his machine is a paper tape about two and a half inches wide, with rows of holes, each row representing a type character.

The tape is taken to a type-casting machine and fed in backward, so that the space casting arrangement is first adjusted before casting a line, so that the thickness of spaces required to justify that line accurately may be produced as required. The tape is fed in with a step-by-step motion and as each pair of holes is presented to the proper part of the machine, a blast of air which passes through the holes, serves to set in position the proper parts to produce whatever type character is called for. The casting-machine is automatic, but, being delicate and complicated, requires one attendant to two machines. The matrices are made separately, but are locked together in a frame that jumps from point to point, in order to bring the required letter to the face of the mold for casting. By changing the matrices and mold, any size or face of type within certain limitations can be produced from the one machine. A width of seven inches is also provided for, being the greatest on any composing-machine.

The Goodson graphotype machine operates on principles very similar to those of the monotype just described. Its mechanism is electrical, however, and both perforator and caster are much smaller machines. The number of characters on the keyboard is limited to 100, so that italics and small capitals cannot be produced with the full complement of other characters.

For further information on this subject consult: 'Wonders of Modern Mechanism,' 'The History of Composing Machines' and the files of 'The Inland Printer.'

JOHN S. THOMPSON,
Author of 'The History of Composing Machines.'

Compositæ (Lat. "compound," "put together"), a family of dicotyledonous plants, the greatest order in the vegetable kingdom, usually herbaceous in temperate and colder climates and shrubby in dry and hot regions, and seldom, apparently only in tropical zones, growing as trees. The leaves are never accompanied by stipules; they most commonly are alternately arranged, and sometimes opposite or whorled. But the true mark of the order is the compound flower, from which it gets its name and which makes it one of the simplest orders to identify, the daisy or aster being the commonest type and the name aster family or sun-flower family being sometimes used. The true blossom is a head made up of many florets, flat as in the aster or approaching a conical shape as in the black-eyed-susan. This head is set in an involucre of leafy bracts, which to the lay observer resemble petals and give the compound flower the appearance of a single bloom. The calyx, joined to the ovaries, crowns them, save in a few cases, with the pappus, which is usually hairy, toothed, or bristly, and coming to maturity at the time of fruition frequently furnishes the seed with a sort of wing facilitating dispersion by the wind. The corolla, tubular, ligulate or labiate, divides into five lobes at the summit. The anthers are united in a tube by which the five stamens are also joined into one. The ovules at fruition dry up and become

COMPOSITE ORDER—COMPOUND AMMONIAS

achenes (q.v.). Among the florets, which naturally fall into two classes, the fertile ones of the disk and the sterile ones of the ray, grow bracts called paleæ or chaff, except where the receptacle is naked. The classification of the order *Compositæ* is difficult, if for no other reason because it contains about 11,000 genera and more than 1,000 species, that is about one-tenth of the higher vegetable forms. The simplest division is into *Liguliflora*, with all florets ligulate or strap-shaped, and *Tubulifloræ*, with disk florets not ligulate. The latter class is by far the larger. The *Ligulifloræ* contains only the one tribe, *Cichoriæ*, of which the food-plants, lettuce, salsify, and chicory, are the best known members. In the other sub-order the *Tubulifloræ* are 12 tribes: *Vernoniæ*, with 41 genera, iron-weed being a common member; *Eupatoriæ*, with 35 genera, including the medicinal plants, ayapana, bitterbush, boneset and hemp agrimony; *Astereæ*, including the typical asters, dahlias, etc.; *Helianthæ*, with the artichokes and other tuberous plants; *Inuleæ*, of which elecampane may be mentioned as an example; *Heleniæ*, sneezeweed being an American member; *Anthemideæ*, including the different varieties of camomile, the chrysanthemum and the marguerite; *Senecionæ*, with four sub-tribes, and the old-fashioned foliage plant called dusty miller; *Calendulaceæ*, including the marigolds; *Arctotideæ*, with only one genus, occurring in South Africa and Australia; *Mutiseæ*, another scantily diffused tribe; and *Cynareæ*, including the thistles.

The *Compositæ* may be regarded, especially from a consideration of their flowers, as the highest order in a scale of vegetable evolution. Their peculiarly efficacious methods of pollination, this process being simplified by the close set florets which permit of insect-fertilization or wind pollination, and by a peculiar action of the style which in the individual flower pushes itself in the way of wind or insect. Dissemination also is highly developed, there being three prominent types, the plumose pappus, as in dandelion and thistle, which is wind-sown; the hooked achenes, as in the burdock and tickseed, which fastens to passing animals, and the gummy seeds of other plants, which are dispersal adaptations. On the order in general consult Bentham, 'On the Classification, History, and Geographical Distribution of the *Compositæ*' (1873).

Composite Order, a term denoting the last of the five orders of architecture. As its name implies, it is composed of two orders, the Corinthian and the Ionic. Its capital is a vase with two tiers of acanthus leaves, like the Corinthian; but, instead of stalks, the shoots appear small, and adhere to the vase, bending round toward the middle of the face of the capital; the vase is terminated by a fillet, over which is an astragal crowned by an ovolo. The volutes roll themselves over the ovolo, to meet the tops or the upper row of leaves, whereon they seem to rest. The corners of the abacus are supported by an acanthus leaf bent upward; and the abacus itself resembles that of the Corinthian capital. In detail, the Composite is richer than the Corinthian, but it is less light and delicate in its proportions. Its architrave has only two fasciæ, and the cornice varies from the Corinthian in having double modillions. The column is 10 diameters high. The principal ancient

examples of this order are the temple of Bacchus at Rome, the arch of Septimius Severus.

Composition, in Law, an agreement between debtor and creditor or creditors, by which the latter accepts part of the debt due in satisfaction of the whole.

Composition of Forces and Motions. See MECHANICS.

Com'post, any mixture of decomposed organic matter with earth, used as a fertilizing compound. They are most frequently made by alternating layers of sods and stable manure in piles three or four feet thick and sprinkling them with lime, kainit, and some potash salt, such as the sulphate or muriate. After several weeks, during which they are kept moist by applications of water or, better, liquid manure, they are cut with a spade and turned over to form a new heap in which the various substances are mixed as much as possible. They may be turned several times to insure the decay of the various organic materials. By varying the proportions of manure and fertilizer to soil and organic matter composts may be obtained suitable for various purposes; rich ones for succulent crops and less rich for plants that must be kept stocky. In a general way the term compost is also used for any heap of decaying vegetable or animal matter which is to be used as a manure. Thus stable manure and litter become compost heaps; also the piles of leaves, etc., from which leaf mold is obtained for greenhouse use. Directions for making composts for particular kinds of plants may be found in all books on gardening, floriculture, etc., and many of the works dealing with manures and manuring also devote space to composting.

Compostella, kōm-pōs-tā'la, **Order of St. James** of, an order of Spanish knights formed in the 12th century to protect the Christian pilgrims who had flocked in vast numbers to Santiago de Compostella, in Spain, where the relics of St. James the Great were preserved. At first there were but 13 members of the order, but it grew rapidly in numbers, and they became not only strong defenders of the relics of their patron, but defenders of Christianity against the invasion of the Moors. In time this order attained great wealth, thereby exciting the jealousy of the crown, which succeeded in securing the grand-mastership in 1522, after which the order rapidly declined.

Compound Alcohol, rectified spirits to which has been added one or more flavoring ingredients. They are called also compounds. The chief compounds are gin, British rum, British brandy, and some grades of American whiskey, cordials, and liqueurs, such as curaçao, lovage, cherry brandy, noyau, rum shrub, etc., are also denominated compounds. These are prepared by adding to clean rectified spirits various essences or oils, and sweetening with sugar or syrup. Sweetened compounds usually contain from 20 to 35 per cent of proof spirit.

Compound Ammonias, or **Amines**, a large and very important class of bodies derived from ammonia by replacement of the hydrogen with an organic radical. They are termed primary, secondary, or tertiary, according as one third, two thirds, or the whole of the hydrogen is replaced by an organic radical.

COMPOUND ANIMAL—COMPRESSED AIR

They are all basic in function, combining with acids to form crystalline salts. They have an alkaline reaction, and some are volatile and pungent. They are of great importance in the investigation of the constitution of various organic bodies.

Compound Animal. See COLONIAL ANIMALS.

Compound Steam-engine, a form of steam-engine originally patented by Hornblower in 1781, in which steam at a relatively greater pressure was allowed to expand in a small cylinder, and then, escaping into a larger cylinder, to expand itself against a larger piston. Compound engines are of two classes, which may be called compound and independent compound engines. The former are those in which the cylinders are near each other, and the pistons commence their respective strokes simultaneously, or nearly so, the steam expanding from one cylinder direct to the other through as small a passage as convenient. To this class belong most land engines, and the compound marine-engines with cranks at about 130° . See STEAM AND STEAM ENGINES.

Compounding a Felony, the act of accepting from a felon, by the person aggrieved, a return of the goods, a consideration, or a reward, on the express condition that he will not prosecute the felon. The mere failure to prosecute a person committing a crime is not, even if the goods are returned, compounding a felony; but the essence of the action is the agreement not to prosecute, for a consideration of any kind,—and the return of the goods is a sufficient consideration. The person aiding the felon is an accessory to the crime and can be prosecuted, although the person committing the crime has never been tried. In English law, to advertise a reward for the return of stolen goods renders the advertiser liable to a fine of \$250.

Compressed Air. Historical.—The use of compressed air as a power dates back to the beginnings of recorded history. Leaving out of the question the use of wind power for the propulsion of vessels, air compressed in some degree must have been used in the earliest ages. The reduction of metals from their ores antedates the Christian Era by thousands of years; and the blast furnace in primitive form was the basis of this process. Some of these crude devices are in use to-day among savage tribes, doubtless little changed from the forms used centuries ago when mankind was young. Among them may be mentioned the wind-bag trodden by the feet, and the wooden cylinder and piston.

On the sculptured and painted walls of the oldest civilizations appear figures indicating the use of air under pressure for some of the processes of those times. The bellows in some form is doubtless the original of modern air compressors, and it may have had a place at the fireside of primeval homes.

Among the earliest records of the use of compressed air must be placed the 'Spiritualia' of Heron of Alexandria. The notes of this old philosopher show conclusively that the use of compressed air in a pump was familiar to the scientists (so-called) of those days. Heron himself—or Hero—must have had some means of producing air pressures higher than those furnished by the bellows, in operating the well-known "Hero's Fountain."

There is no doubt that many of the "supernatural" phenomena with which the priests of ancient Egypt awed the credulous people were the results of air pressure secretly applied. The vocal statue of Memnon at Thebes owed its divine powers to the expansion and contraction of air under heat and cold. The famous moving statue of the god Serapis was operated by crude pneumatic devices. Much of the famous altar magic of the priesthood was the effect of compressed air action. For instance, the automatic opening of the temple doors when the altar fire was kindled was caused by the expansion of air in a closed chamber under the heat of the fire. As early as 350 B.C., the diving bell in primitive form was in use. It is mentioned by writers of that period as known to the Greeks and Phœnicians. Heron knew of a means of compressing air by the fall of water in a tube and Pliny mentions the use of this early precursor of the modern hydraulic compressor.

Coming to a later date, the "wind guns" of Ctesibius of Alexandria, 120 B.C., prove the existence of some means of securing a pressure high enough for the discharge of projectiles. This is the only instance in ancient history of what may be called "high pressure" compression.

Compressed air seems then to have been lost in the darkness of the early Christian Era and the Middle Ages. Then the diving bell appears again in Spain and is mentioned in the writings of Bacon. A little later Halley in England introduced the submarine diving armor and Smeaton and Brunel, about 1780, used compressors for supplying fresh air to the diver. In 1600 and 1656 the pneumatic gun reappeared in France and Germany.

Von Guericke of Nuremburg introduced improvements in vacuum pumps and air compressors. The development of the iron industry brought about improvements in blowers for blast furnaces. About 1653 the first attempt was made by Papin to transmit power by compressed air. His original scheme contemplated the compression of air in a pump driven by water wheels and its use in a tube for transmission to a distance. His attempts failed for lack of a correct understanding of the physical properties of air. This same inventor experimented with a parcel delivery in pneumatic tubes.

In the last years of the 18th century and the early part of the 19th, Medhurst in England experimented along general pneumatic lines. He succeeded in attaining pressures above 200 lbs.; he transmitted these pressures and applied them in a motor; he developed a pneumatic despatch system for parcels and persons; and he otherwise contributed to compressed air development. His was the first pneumatic automobile, brought out in 1800. Wright in England a little later used air storage tanks on cars with air motors and applied a reheater to increase the expansive force. He also produced the first crude air brake, with an axle-driven compressor for furnishing pressure.

Compressed air as a distinct and accepted branch of engineering may be said to date from the first of the 19th century. Its safety, adaptability and general utility then began to be recognized and the great variety of the uses to which it was applied foreshadowed its countless applications to-day. Compressed air locomotives and pneumatic motor-carriages were built and operated. Pneumatic tube systems were developed

COMPRESSED AIR

and achieved a practical success in London in 1845. Dr. Gorrie, in New Orleans, built the first refrigerating plant, in 1850, and the modern systems of refrigeration by expansion of compressed gases follow the lines laid down by him.

The development of the air compressor was slow and spasmodic. Mann, in 1829, first suggested and patented a system of stage or compound compression in several cylinders with intercooling. But the tremendous importance of this system was not realized and it lay dormant for almost half a century. The *trompe*, or primitive water compressor, was in use as late as 1870, but it was not economical. Only in recent years has this principle in modified form received a degree of recognition in the hydraulic compressors of Taylor. The great Alpine tunnels—Mont Cenis and St. Gothard—brought compressed air appliances into prominence in the early seventies. On the former tunnel Sommeiller used hydraulic compressors. Later developments brought water-piston compressors, with jets or sprays for cooling. Pneumatic haulage locomotives were used in driving these mountain bores. Present practice is largely based on the experiences of these Alpine pioneers. They paved the way for the high grade compressors of to-day.

The Hoosac Tunnel in America first brought the pneumatic rock drill to the front; and since that time this epoch-making device has enjoyed a constant development under the genius of Burleigh, Ingersoll, Sergeant, Rand, and others, who have brought the rock drill to its present perfection.

The current records of the Patent Office show countless pneumatic appliances. But modern improvements are in matters of detail. Basic principles are established and the developments now in progress look toward greater perfection in design and construction, greater economy, and increased power and reliability. Compressed air is to-day recognized as an economic necessity. There is hardly a field of industrial activity in which air power in some form is not used. The importance of the position of compressed air in modern economics will be best appreciated by an investigation of succeeding pages, devoted to a discussion of air power appliances as they stand to-day. In their present forms they approach the limit of economic refinement.

Air Compression.—Pneumatic engineering, in its relation to air compression, rests fundamentally upon the two primary laws of gases. These laws may be stated here and their application will appear in the discussion following.

The first law of gases, known as Boyle's or Marriotte's Law, states that when its temperature is maintained constant, the volume of a gas varies inversely as its pressure; or, at constant temperature, the product of pressure and volume is a constant. This law is expressed thus:

$$P_1 V_1 = P_2 V_2 = P_3 V_3 = K.$$

K is a constant, having different values for different gases. Regnault, by use of instruments of greatest precision, proved that Boyle's Law is not absolutely correct. But the discrepancies are noted only at the very highest pressures and for practical purposes may be ignored.

The second law of gases is known as Charles'

or Gay-Lussac's Law and states that at a constant pressure, the volume of a gas is proportional to its absolute temperature. In another form more applicable to practical use, the law says that at a constant volume, the pressure of a gas is proportional to its absolute temperature. Its algebraic expression is:

$$V_1 (T_2 + 459.2) = V_2 (T_1 + 459.2).$$

The constant 459.2 is the absolute zero Fahrenheit.

Where conditions are such that pressure, volume, and temperature are all variables, the relations are algebraically expressed thus:

$$P_1 V_1 (T_2 + 459.2) = P_2 V_2 (T_1 + 459.2).$$

This expression combines Boyle's and Gay-Lussac's Laws and covers the conditions of practical air compression. For in practice all three quantities—pressure, volume, and temperature—vary at different stages of the compression process.

Whenever air or any gas is compressed, there is an increase in its temperature; and this is true whatever the rate or speed of compression. This phenomenon is the result of an increased molecular activity in the air due to its increased density and manifested in the form of sensible heat. The temperature attained is a function of the degree of compression and is greatest in the early stages, diminishing as higher pressures are approached. This heat of compression has been the stumbling block of compressor designers and their principal efforts have been toward the elimination of the evils it produces.

Isothermal compression is the ideal of pneumatic engineers, but in practise it is never realized. Theoretically, it is a process in which the heat of compression is removed as fast as produced. It is the exemplification of Boyle's Law, in the expression of which— $P_1 V_1 = P_2 V_2 = K$ —the temperature T is not a factor. While the best air compressors of to-day closely approximate its values, it cannot be wholly attained, for there is no perfect cooling device known.

Adiabatic compression is that in which none of the heat of compression is removed. It embodies a combination of Boyle's and Gay-Lussac's Laws, involving the three variables of pressure, temperature, and volume. Its algebraic equation has already been given, under the second law of gases. Adiabatic compression can never be fully realized, since there is always some conduction and radiation of heat by the materials of the compressing mechanism.

Were it possible to compress a volume of air strictly according to Boyle's Law—*i.e.*, isothermally—it is evident that when the original pressure had been doubled, the original volume would have been reduced exactly one half. But in practise it is found that when the pressure has been doubled, the volume has not been reduced one half, and the temperature is very much increased. If now the process of compression be stopped and the temperature of the air allowed to drop to its original value, the volume remains the same but the pressure is found to have fallen to less than twice the original. To reach the required pressure of twice the initial, compression must be carried still further, with another manifestation of heat. A consideration of these facts shows plainly that a part of the work of compression was expended in producing an increased temperature

COMPRESSED AIR LOCOMOTIVES.

COMPRESSED AIR MINE LOCOMOTIVE.

COMPRESSED AIR INDUSTRIAL LOCOMOTIVE FOR SURFACE USE.

COMPRESSED AIR

which, acting momentarily according to Gay-Lussac's Law, increased the pressure of the air volume. But this added pressure was an unstable quantity, disappearing as the air cooled; and it is evident that the energy applied in producing this "heat increment" of pressure was, for all practical purposes, wholly lost. In other words, more power is required to produce a given volume at a given pressure *when the air is allowed to heat itself*, than would be necessary if the air could be *kept cool* throughout compression. In the first case, we have adiabatic compression; in the second, isothermal. This, in brief, is an explanation of the phenomena and the problems which have confronted the designers of the modern air compressor.

Evidently the solution of the thermo-dynamic problems outlined above lies in the removal of the heat of compression before it can have any effect on the air volume. It is impossible to do this with complete success; but two methods or systems have come into almost universal adoption which, in combination, attain the nearest approach to complete cooling.

The first of these is jacket-cooling, in which the compressing cylinder is surrounded as completely as possible with cold water, which carries off the heat conducted from the air through the cylinder walls. The system is useful but not sufficient; first, because only the external film of air is in contact with the cold cylinder walls and, air being a poor heat conductor, none of the heat from the interior volume reaches the surface; second, as the piston advances, the area of cold cylinder walls exposed in front of it constantly diminishes, and when the highest temperature is reached near the end of the stroke, there is practically no cooling surface available. In the best compressors this second defect is improved, but not wholly corrected, by jacketing the cylinder heads as well as walls. Jacket cooling, while not adequate, is useful in keeping the compressor cool and improving lubricating conditions.

The second system of cooling is that of stage compression. Here there are two or more cylinders (according to the final pressure required), in the first of which a moderate pressure and temperature is reached, and from which the air is discharged to an intercooler, where it is reduced by contact with water-cooled surfaces to almost water temperature. It then enters the second cylinder *cool*, and is compressed still further and then again cooled; and so on, until the terminal pressure sought is attained. The best modern practise advocates single-stage compression, or compression in one cylinder, for pressures up to 70 lbs. gauge; for pressures of 75 to 500 lbs., two and possibly three stages; for pressures above 500 lbs., three and four stages. Most of the success of stage compression depends upon the efficiency of the intercooler. The three essentials of a good intercooler are: first, ample cooling area; second, complete subdivision of the air into thin sheets or streams, giving intimate contact with the cold surfaces and dissipating internal heat; third, large capacity, that the air in passing may have a low velocity and long contact under cooling effect.

A third system of cooling was tried in the early days of pneumatics—the injection of water in a spray into the compressing cylinder

in front of the piston. But it was found in practise to introduce difficulties more than counterbalancing its advantages, and it was finally abandoned. Still another early system involved the use of a water column as a piston, but it, too, was ineffective and failed.

Modern single-stage air compressors (simple or duplex) have as complete water-jacketing as possible, depending entirely upon this means for the removal of heat. In the best machines the valves are arranged to permit head as well as barrel jacketing. Multi-stage compressors (two, three, and four cylinders) have complete jacketing as well as thorough intercooling. In advanced types for very high pressures the last two or three cylinders are completely submerged—cylinders, heads, and valves—in a box filled with circulating cold water.

The driving or power ends, valve movements (both steam and air), and mechanical construction of air compressors of to-day embody the best engineering practise. An intelligent and liberal application of metal provides a structure adequate to all strains. Correct design, high-grade materials and first-class workmanship give a very high degree of economy in the best machines. The actual details of design and construction cannot be entered into here, but a good understanding of their development in the best practise will be gained from the discussions of standard machines of representative makers, in subsequent pages. Suffice it to say that the modern air compressor, as an efficient converter of energy, stands high in the scale of economical and mechanical refinement, and represents a splendid combination of correct theory and practise.

Air Expansion.—The fundamental principles of air expansion are contained in Boyle's and Gay-Lussac's Laws, as stated in the section on air compression. The same algebraic expressions indicate the relations of temperature, pressure, and volume in both air compression and air expansion. In fact, the phenomena of air expansion and application in air motors may best be understood by considering expansion as in the nature of a negative compression process.

Isothermal expansion is expansion at constant temperature; no heat is lost. Adiabatic expansion is expansion with the complete proportionate loss of heat; it can never be fully realized in practise, since heat is always present and will be absorbed in some degree. In air expansion, as in air compression, isothermal action is an impossible ideal, which can only be approximated in the best air motors.

It has been seen that, if an amount of air at a given temperature could be compressed isothermally to one half its original volume, the pressure produced would be twice the original. Assume, for the moment, that this ideal condition had been attained in a *perfect* machine, *i.e.*, one in which there was no mechanical absorption of energy, no leakage, no loss. Now, if this diminished volume of air were allowed to expand isothermally, it would return to exactly initial pressure and its original volume. This would be a perfect cycle of compression and expansion, and the exact equivalent of the work expended would be recovered. But isothermal expansion is impossible. Still assuming a perfect machine, the actual result will be that the original volume will not be reached on expan-

COMPRESSED AIR

sion to initial pressure. For this expansion of the air causes a drop in its temperature, due to the reversal of the molecular action which, in compression, gives rise to heat. This reduced temperature, according to Gay-Lussac's Law, reduces the volume of the air at the original pressure. Or, putting it differently, this diminished temperature acting with the expansion, produces the initial pressure before the original volume has been recovered.

In air compression and expansion along adiabatic lines, there is a double loss as compared to isothermal; due, in compression, to the positive heat increment of work referred to in the previous section, and in expansion, to the negative heat increment which, it has already been seen, is simply the result of a reversal of the molecular action. Adiabatic compression gives an abnormal increase of temperature and pressure; adiabatic expansion results in an abnormal reduction of the same quantities.

It has been shown that, in air compression, this resultant loss can be reduced, but not wholly avoided, by removing the heat of compression as produced, with suitable cooling devices. So, in air expansion the loss may be diminished by "removing the cold"—in other words, by heating the air during expansion.

It is manifestly impossible in practise to heat the air in the cylinder *during* the actual process of expansion. But if the temperature be raised in suitable degree before the air enters the engine cylinder, an excess initial pressure will be obtained which will bring the terminal expanded volume to normal value at normal pressure. In such case there is not a direct, positive gain—rather, simply an avoidance of the loss otherwise inherent. But reheating—as this process of heating the air is technically called—is capable of far more than this; it is possible, by heating to a still higher degree, to effect an actual and large gain of power. According to Gay-Lussac's Law, this heating will save air at a given pressure, since the volume is proportional to the temperature. Or, the volume remaining constant, heating will increase the pressure in proportion to the temperature reached. In either case there is a direct increase in the available energy of a given volume of air; and it is possible to make use of this surplus energy, with a positive gain.

Single-cylinder or duplex air engines must rely for economy on pre-heating—heating before expansion. But compound or multi-cylinder air engines, such as are sometimes used on pumps, effect an exact reversal of "stage compression" and intercooling in "stage expansion" and inter-heating. In this case the air is heated *before* entering the cylinders, the discharge from one cylinder, after being heated, being delivered to another and larger cylinder where it does further work at a lower pressure. Coal or other combustible, used in reheating under such conditions, gives a power equivalent from four to six times that which it will yield in a boiler and steam engine of most refined economy.

Aside from all considerations of economy, it is practically impossible to use compressed air expansively in an engine, without reheating. The cold produced by expansion of air at atmospheric temperature freezes the moisture in the air and clogs the engine. But reheated air

can be used with a very short cut-off; and even though the initial temperature may be excessive, the mean cylinder temperature is wholly practicable and high economy can be secured, without lubrication difficulties and without freezing up.

Air engines, or air motors, are used for a variety of purposes and there is a marked tendency toward their greater adoption in larger units for hoists, pumps, and similar work where air power is available. They differ from the best steam engines only in their cylinder clearance, which is kept as small as mechanical considerations permit, for greater air economy. Their most common use is in the small rotary pneumatic tools, but, with proper reheaters, there is no reason why they should not find a prominent place in larger sizes for industrial work. In fact, it may be said that the greatest strides in the future development of compressed air as an industrial power will be along the lines of expansive working as made possible by practical reheaters. The irresistible tendency of the age is toward higher economy; and the air power plant of the future will depend for its economy largely on the efficiency of the air reheaters employed.

Air Transmission.—The theory of transmission of air power by the flow of compressed air through pipes may be dismissed with only a brief mention. Speaking generally, the laws of flow of gases hold in relation to compressed air.

Usually the air is delivered to the pipe line at the temperature of discharge from the compressor cylinder. But there is an increasing tendency toward the use of aftercoolers in large air plants, for the purpose of eliminating the entrained moisture from the air by condensation before it enters the pipe line. The object of this is two-fold; first, to prevent the accumulation of water in the pipe lines, with consequent reductions of pipe cross-section and increase of frictional resistance; second, to assure the delivery of dry air to the air motors. The air aftercooler is similar in design to the intercooler; cooling is secured by subdivision and intimate contact with metallic surfaces cooled by a continuous flow of cold water. A drain is provided for the removal of precipitated moisture.

Where no aftercooler is used and the heated discharge air enters the pipe line direct, the heat is soon dissipated by conduction and radiation, and after that the transmission is isothermal, *i.e.*, at constant temperature. This loss of heat, by Gay-Lussac's Law, produces an initial drop in pipe line pressure. But after that, loss of pressure in transmission is due wholly to frictional causes (assuming there is no leakage), and varies directly with the length of the pipe line and the square (for moderate velocities only) of the velocity of flow, and inversely with the diameter of the pipe. Expressed algebraically, this relation is

$$D_p \text{ (drop in pressure)} = C \frac{V^2 L}{d}$$

V being the velocity of flow, L the length of the line, d the diameter of the pipe, and C a constant depending upon the physical properties of the transmission line (condition of interior walls, number and angle of bends, etc.).

Space cannot be taken here for an extended

COMPROMISE OF 1820—COMPROMISE OF 1833

discussion of transmission formulæ, involving values of pressure, temperature, volume, cross-section and length, to say nothing of the variable physical factors in the pipe line itself. For investigations on these lines, reference must be made to specialized technical publications. It may be said here that each transmission involves its own peculiar problems, and even the best formulæ give only approximations to actual performance.

It is worthy of note here, however, that drop in line pressure due to any causes other than leakage does not mean a total loss. For the reduced pressure results in an increased volume; and by the use of reheaters this pressure may be restored, wholly or in part, and the apparent lost power restored to the system. In this very fact lies the paramount superiority of compressed air transmission over all other modes of power transmission.

Air receivers are an essential part of a compressed air transmission or distribution system. There cannot be too many of them, nor can their capacity be too large. The compressor discharge is essentially pulsating in character. The receivers take up and absorb these pulsations and assure a steady, uninterrupted flow over the system. Furthermore, there will be an accumulation of energy in these receivers, which can be drawn upon in emergencies of excess demand. Large receiver capacity in an air power system acts as a balance wheel, equalizing supply and demand, and smoothing down the load curve. Every receiver, moreover, is in a sense a cooler and will collect a certain amount of condensed moisture, thus adding to the dry quality of the air.

Briefly, the essentials of a correct and efficient air power transmission system are: effective aftercoolers close to the compressor discharge and properly drained; a pipe line of ample cross-section, laid with wide-angle bends and as few valves as possible, with the pipe interior clean and free from obstructions, with all low points properly drained, with proper provision for expansion and contraction, and, *above all*, free from leaks; and ample receiver capacity, in units distributed throughout the system, all properly drained. See AIR COMPRESSORS; PNEUMATIC TOOLS; PNEUMATIC TUBES; POWER, TRANSMISSION OF; POWER, UTILIZATION OF; MINES AND MINING; MINING AND MILLING MACHINERY; COAL MINING MACHINERY; AIR BRAKE; AIR PUMP; PUMPS AND PUMPING MACHINERY.

LUCIUS IRVING WIGHTMAN, E.E.,
Mechanical Engineer, Ingersoll-Rand Company.

Compromise of 1820, in American political history, a national law enacted by Congress 6 March 1820. In 1819 the territory of Missouri, with a population of 60,000, demanded admission into the Union as a slave State. Arkansas was preparing to make similar demands. Such action would have given the South the balance of power in Congress, and the North made this a national issue. The North controlled the House of Representatives, while the South controlled the Senate. A deadlock was inevitable, and a party of compromise sprang up, which succeeded in producing a temporary arrangement acceptable to both parties. This was the compromise of 1820. It divided the Louisiana

Purchase between freedom and slavery by a line drawn at 36° 30' N. lat. See UNITED STATES—ABOLITION AND THE FREE SOIL MOVEMENT.

Compromise of 1833. This was Henry Clay's tariff compromise, to prevent Civil War on account of nullification by South Carolina. The tariff of 1828 was regarded by the South as very injurious and inequitable, raising its expenses and reducing its income, and laying burdens upon it without compensating advantages. The tariff was borne in the hope that Jackson, a southern man, would throw his influence against it, but when he signed the amended act of 1832, leaving the duties much as they were, South Carolina took the lead in revolt. On 19 Nov. 1832, a convention called by its legislature, declared the act of 1828 and its amendments null and void, forbade its enforcement in the State or appeal to the supreme court regarding it, and decreed secession in case the United States should attempt to use force. On 4 Dec. 1832, Jackson's annual message mildly criticised the tariff as overgrown and needing gradual retrenchment to a revenue basis, and apologized for the popular resistance, which he thought the laws adequate to suppress. The nullifiers and their opponents alike thought he had surrendered to the former as in the Cherokee case (see CHEROKEE NATION *v.* GEORGIA); but on the 10th, apparently from a sudden shift of emotional feeling, he issued a powerful proclamation against them, characterizing nullification as an absurdity "incompatible with the existence of the Union," and declaring that it would be resisted by the entire national force. There was great enthusiasm throughout the North, and general approval even in the South, but South Carolina returned a defiant counter-proclamation, and Calhoun resigned the vice-presidency, to be immediately returned to the Senate as the champion of nullification. To remove the grievance the House Committee of Ways and Means on the 27th reported the Verplanck Bill, reducing the tariff within two years to the standard of 1816, the primitive basis. But the President, angered by the new South Carolina threat, asked for a bill to enforce the law by military power, and extend Federal jurisdiction over revenue cases—called by the people the Force Bill, and by the South Carolinians the "Bloody Bill." All parties were perplexed and unable to act. South Carolina had relied on Southern support, which was not forthcoming; the House could not agree on the Verplanck Bill nor the Senate on the Force Bill. On 12 February, 20 days before final adjournment of the 22d Congress, Clay undertook a compromise. He introduced a bill into the Senate which reduced the duties to a general 20 per cent by a sliding scale to end in 1842, enlarged the free list, etc. Clay's assigned motive was, that without some such measure the protective system was likely to be abolished altogether, but not before there had been civil war, in which the South would not let South Carolina stand alone. A further motive was, that he dreaded to see Jackson made a virtual dictator with a large army in his hands, as none could tell what he might do with it. Calhoun, to men's great surprise, struck hands with Clay, though the pending Verplanck Bill was a far greater relief to the South. But Calhoun was far more anxious for a triumph of nullification, and the consequent mastery by the

COMPROMISE OF 1850

South of her own destinies, than for mere lightening of material burdens, and the compromise bill would be notoriously a concession wrung from the North by the threat of nullification, while the Verplanck Bill, even if passed (which was dubious), would be only a bill like another. The compromise bill was referred to a select committee with Clay for chairman. The manufacturers' lobby insisted on amendments, of which the chief was very obnoxious to the South—that for computing *ad valorem* duties on the basis of valuation at the home ports. As they made this an ultimatum, Clay supported it in the Senate, while Calhoun denounced it as both oppressive to the South and unconstitutional. Finally Clayton of Delaware, a strong Protectionist, threatened for his party to lay the whole on the table unless the Calhounists and their leader voted for the amendment, which they did. Meantime the Force Bill had passed the Senate; and Clay urged it to pass the compromise tariff bill also, so that the bill for violence should have that for harmony to counteract it. The objection was raised that the bill was one to raise revenue, and could not originate in the Senate. This was met by the shrewd device of moving the House to strike out all but the enacting clause of the Verplanck Bill and substitute Clay's bill, and send it to the Senate for concurrence—which it did the next day, 119 to 85, and the Senate adopted it, 29 to 16. South Carolina, which had appointed 1 February for the nullification ordinance to go into effect, repealed it, and the country hailed it as a great deliverance. Clay himself later confessed, however, that he doubted whether he had done wisely. The nullifiers denied that they had abandoned a jot of their contention; hailed the result as a proof that it was the only means by which the South could obtain justice; and professed to have postponed the date of its operation only out of friendship to Virginia, which sent a commissioner to deprecate it. It is certain that the South won both the material and the moral fruits of the victory. Consult Schurz, 'Life of Henry Clay,' Vol. II., chap. xiv.; also other lives of Clay, and biographies of Jackson and Calhoun.

Compromise of 1850. The Missouri Compromise of 1820 (q.v.) had divided the Louisiana Purchase between free and slave territory at 36° 30' (the general boundary between Arkansas and Missouri), except that Missouri was to be slave. The extreme pro-slavery members, about one fifth of the House and one fourth of the Senate, based their opposition on the ground that Congress had no power to legislate on slaveholding in the Territories, it being a fundamental right implied in the Constitution; but the majority admitted the jurisdiction by passing the bill. The joint resolution for admitting Texas in 1845 extended the same line to any new bodies formed out of that State; and was supported by the most ultra slavery men, as taking the merest sliver from them and securing solidly the enormous remainder. When the Mexican war seemed likely to add new territory, the Wilmot Proviso (q.v.) of 8 Aug. 1846, attempted to bar slaveholding from it, as did existing Mexican law; and the struggle to prevent this transformed political parties. After the annexation had taken place, 2 Feb. 1848, bills for organizing the Territories of New Mexico and

California were introduced: at first in an omnibus bill with Oregon (the Clayton Compromise), to force all of them to permit slaveholding, then to extend the Missouri compromise line to the Pacific (including in slave territory nearly all the present New Mexico and Arizona, and the entire southern half of California); then the Democratic Senate receded from the Oregon "hold-up," and the House repeatedly attempted to organize the other bodies as territories with the proviso; while the Senate regularly killed the bills, and once attempted to attach its own as rider to an appropriation bill. This went on till the end of 1849, when the gold discoveries in California forced the hand of both the Southern slavery party and its Northern allies. The immense immigrant population there formed a constitution prohibiting slavery, and demanded admission of California as a State. Even the deniers of the right of Congress to legislate on slavery had always admitted that the people of a State had the right to live under any constitution they pleased; and the Democrats, to hold their vote in North and South, now took the position that the inhabitants of an inchoate State should be allowed to decide their own destinies. As this meant the immediate reinforcement and ultimate supremacy of the free States, the Southern Whigs and Democrats began to draw together, and formulated the doctrine that the people of a Territory had no right to exclude the industrial or social system of any part of the Union; that Congress should force them to rescind such exclusion if made; and that the exclusion, if permitted, was a wrong which justified secession. But California was not a Territory: it was a body of unorganized settlers who would come in as a State from the first, and certainly could be admitted by Congress on their own terms. The Southern leaders, therefore, resolved that they should not be admitted except by passing through the territorial stage, so as to come under the congressional prohibition. Zachary Taylor, a slaveholder, but a moderate and just-minded man, had been inaugurated as President in March 1849, and his first congress met in December. The Senate had a large Democratic majority; the House was so evenly divided that the few Free-Soilers held the balance, and it required 63 ballots and three weeks to elect a speaker, Howell Cobb of Georgia. On their meeting Taylor had sent a message recommending California's wish to become a State, to their favorable consideration; on 21 Jan. 1850, he sent a special message, declaring that the people would not sustain them in denying the Californians the right of self-government. The South, nevertheless, was passionately determined not to yield; and Henry Clay undertook one of the great compromises which were the pride of his life, the shortest-lived and most destructive compromise in American history. The difficulty was to find anything that either side wanted badly enough to take as a price for yielding. For the South, this was found in the Fugitive Slave Law (q.v.), which Alexander H. Stephens declared to be the very essence and heart of the whole compromise, and the breach of which by the Northern personal-liberty laws was accounted the crowning justification of secession; and in a money indemnity to Texas for abandoning her claim to the Rio Grande as a western boundary, which that State was ready to fight for, but the payment for

COMPROMISES OF THE CONSTITUTION — COMPTON

which would raise the market value of her bonds, largely held in the South. For the North, it was found in the admission of California as a free State, and the prohibition of the slave-trade in the District of Columbia—the latter a mere sop, as slavery was not abolished in the District. The sacrifices were, that the South gave up the right of insisting that no free State should be admitted into the Union except as paired with a slave State, and so in her own view gave the North the fruits of the Mexican war; the North gave up the proviso, and the right of stopping the interstate slave trade, though this was later stricken out. On 16 January a bill had been brought into the Senate to organize "the Territories of California, Deseret [Utah], and New Mexico"; on the 29th Clay unfolded his compromise, in eight resolutions: (1) admitting California with her free-State Constitution; (2) organizing the remainder of the newly acquired lands as territories, without restriction as to slavery, as it "did not exist [there] by law, and was not likely to be introduced,"—merely staving off the question till they formed State governments; (3, 4) annulling Texas' claim to New Mexico, but paying her a blank indemnity; (5, 6) non-abolition of slavery in the District of Columbia without the consent of Maryland, but prohibition of the slave trade in it; (7) a more effectual fugitive slave law; (8) non-interference with the interstate slave trade. Clay said that the question with the South was one of interests, with the North one of sentiment, and the latter was easier to sacrifice than the former. The northern members and their constituents did not agree to this, nor did the South as to the equivalents; and after two months' debate the question was referred to a compromise committee of 13, of which Clay was chairman. On 8 May it reported a bill of four parts, known in history as the Omnibus Bill (*par excellence*, for there have been others), to be passed or rejected as a whole. The essential changes were, that New Mexico and Utah were forbidden to pass laws respecting slavery, that California should not be admitted unless this were granted, that the blank for the Texas indemnity should be filled with \$10,000,000, and that no mention was made of the interstate slave trade. It will be observed that the gains in this revised "compromise" were pretty much all by the South. The bill of course embodied the specific legislation needed to make the resolutions effective. Part 1 consisted of the provisions for admitting California, New Mexico, and Utah, and indemnifying Texas; Parts 2 and 3 were the Fugitive Slave Law of history; Part 4 the provisions about the District of Columbia. This bill was stormily debated for nearly three months more, until 31 July, and amended until one item only was left, that admitting Utah, which passed the next day. Meantime Texas was arming and threatening war, and other States proposing to aid it; and Congress saw that the bills must be passed in some shape. The items were therefore voted on as separate bills, and all passed in Clay's form: Texas bill—Senate, 10 August, 30 to 20; House, 4 September, 108 to 97. California—Senate, 13 August, 34 to 18; House, 7 September, 150 to 56. New Mexico—Senate, 14 August, 27 to 10; House (together with the Texas bill), 4 September, 108 to 97. Fugitive Slave Bill—Senate, 23 August, 27 to 12; House, 12

September, 109 to 75; District of Columbia—Senate, 14 September, 33 to 19; House, 17 September, 124 to 47. The Fugitive Slave Law, the vital part of the compromise, was also its assured ruin, as it gradually turned the entire North into abolitionists; but the immediate cause of its collapse was the Kansas-Nebraska Bill (q.v.), which repealed not only the Missouri Compromise, but the present compromise which practically reaffirmed that. Consult: Von Holst, 'Constitutional History of the United States,' Vol. III.; Benton, 'Debates of Congress'; Stephens, 'War between the States,' Vol. II.; and lives of Clay.

Compromises of the Constitution. See CONSTITUTION, FORMATION OF THE.

Compsognathus, kōmp-sōg'nā-thūs, a genus of carnivorous dinosaurs (see DINOSAURIA) of the Jurassic Period, of very small size, hardly larger than a domestic cat, and slenderly proportioned. A very perfectly preserved skeleton has been found in the lithographic limestone of Solenhofen in Bavaria.

Comp'ton, Alfred George, American teacher: b. London, Eng., 1 Feb. 1835. He graduated at the College of the City of New York in 1853, and since then has taught chiefly mathematics. At present (1903) he holds the chair of physics in the College of the City of New York. He has written: 'A Manual of Logarithmic Computation' (1881); 'First Lessons in Wood-working'; 'First Lessons in Metal-working' (1890); with De Groot, 'The Speed-lathe' (1898); and 'Some Common Errors of Speech' (1898).

Compton, Henry, English bishop: b. Compton, Wynyates, 1632; d. Fulham 7 July 1713. He was the youngest son of Spencer, second earl of Northampton, studied at Oxford, and after the Restoration became a cornet in a regiment of horse. Afterward he left the army for the Church, became bishop of Oxford in 1674, and bishop of London in 1675. Charles II. made him a member of his privy council, and intrusted to him the education of his nieces Mary and Anne. He was distinguished for his hostility to the Roman Catholic Church. After the accession of James II., Dr. Sharp, rector of St.-Giles'-in-the-Fields, having become highly obnoxious to the court, Compton was required by a royal order to suspend him. His refusal to obey was made the ground of his own suspension. He was restored to his see at the time of the Revolution, and, together with the bishop of Bristol, made up the majority of two in the house of lords for filling the vacant throne. He performed the ceremony of the coronation of William and Mary, and was afterward appointed one of the commissioners for revising the liturgy. During the reign of Anne he was put on the commission for the union of England and Scotland. The reconciliation of dissenters with the Church of England was one of his favorite projects.

Compton, Herbert Eastwick, English novelist and miscellaneous writer: b. 16 Nov. 1853. He was educated at Marlborough College, and has traveled extensively. He has published: 'The Dead Man's Gift' (1890); 'A Master Mariner' (1891); 'Military Adventures of Hindustan' (1892); 'A King's Hussar' (1893); 'A Free Lance in a Far Land' (1894); 'The Inimitable Mrs. Massingham' (1900);

COMPTON — COMSTOCK

'The Ashanti War'; 'A Fury in White Velvet' (1901); 'A Scourge of the Sea' (1902); 'The Wilful Way' (1903); 'The Palace of Spies' (1903); 'Facts and Phantasies of a Folio-grub' (1903); 'Indian Life in Town and Country' (1904); 'The Twentieth Century Dog' (1904); 'The Queen Can Do No Wrong' (1904); etc. In 1904 he was a leader writer to the Tariff Reform League, and in 1905 was appointed organizing secretary to the Anti-Tea-Duty League, organizing the agitation against the excessive duty on tea.

Compton, William Cookworthy, English clergyman and educator: b. West Hackney, 1854. He was educated at Darmstadt, Tottenham, and Jesus College, Cambridge; became assistant master of Chatham House, Ramsgate, in 1877; was ordained deacon in 1878, and priest in 1879 by the Archbishop of Canterbury; was appointed curate of Holy Trinity, Ramsgate, in 1878; assistant master, Uppingham, in 1880; house master in 1881; and since 1892 has been headmaster of Dover College. He has written 'Rudiments of Attic Construction'; 'Cæsar's Seventh Campaign in Gaul'; 'The Athenians in Sicily'; etc.

Comptroller, an officer whose duty is to regulate the financial affairs of a community and supervise the keeping and auditing of its various financial accounts. In the United States treasury department there are three comptrollers, the first and second comptrollers of the treasury and the comptroller of the currency. The duties of the two first are to sign warrants or drafts, examine accounts, prosecute all debts and delinquents in behalf of the government, etc. The comptroller of the currency issues circulating notes to the national banks, superintends the national banks, exchanges old currency for new, etc.

Compurga'tion, a mode of defense allowed by the Anglo-Saxon law in England, and common to most of the Teutonic tribes. The accused was permitted to call a certain number (usually 12) of men, called compurgators, who joined their oaths to his in testimony to his innocence. They were persons taken from the neighborhood, or otherwise known to the accused, and acted rather in the character of jurymen than that of witnesses, for they swore to their belief, not to what they knew; that is, on the accused making oath of his innocence, they swore that they believed he was speaking the truth. Compurgation in the ecclesiastical courts was not abolished till the reign of Elizabeth. See Blackstone, 'Commentaries on the Laws of England'; Pollock and Maitland, 'History of English Law.'

Computing Scales. As is well known, the weight of a commodity is ascertained in order to form a basis for ascertaining its value at a given price per pound if in the United States or Great Britain and her colonies, or at a given price per kilogram if in nearly all other civilized countries.

The computing scale is an instrument by which the value is obtained, mechanically, at a given price per pound or kilo, thus avoiding the possible error of making the calculations mentally, and further, causing the operation of weighing and ascertaining the value to be more speedily accomplished.

The computing scale business, as a successful commercial enterprise for the world, was inaugurated in 1891. Several earlier attempts were made, but without success. The business has rapidly increased since the above date, and hundreds of thousands of these machines are now in use throughout the world. Until recent years the United States was by far the largest market, but they have been introduced into Europe, South Africa, Australia, and both the east and west coasts of South America, besides Canada, Mexico, and the West India Islands, until the export trade in computing scales now aggregates several hundred thousand dollars per year.

Construction of Computing Scales.—Broadly speaking, there are two types of computing scales; first, the variable leverage type, and second, the computed-chart type. The first type consists of a mechanism wherein the leverage of the computing beam may be varied so as to conform to the several units per pound or price per pound.

The computed-chart scale is further divided into two distinct kinds; first, the beam scale with computed chart, and second, the automatic scale with the computed chart. The former, or beam scale with computed chart, is a manually operated scale, operated as in ordinary scales by the movement of a sliding counterpoise, this sliding poise passing over the computed chart, and when the load is balanced by the movement of the poise, pointers on the poise indicate the total value of the commodity being weighed at the several prices per pound provided for on the computed chart.

The second, or automatic computing chart scales, are so constructed that when a commodity is placed upon the scale pan the load is automatically counterbalanced by the use of either counterbalancing springs or a pendulum counterbalancing weight, moving either the computed chart past a stationary indicator, or moving an indicator past or over the stationary computed chart, the indicator in either instance having placed thereon the several prices per pound, and each price per pound placed adjacent to a pointer or other means of indication showing the total value of the commodity being weighed at the several prices per pound provided for in the construction of the scale.

The automatic chart scale is further divided into two distinct types of scales with respect to the construction or arrangement of the chart: No. 1 type being constructed upon the principle of arbitrarily dividing the pound into as many parts as there are cents in the price per pound as a means of computing weight. For instance, at eleven cents per pound the pound is divided into eleven parts, each part representing one-eleventh of a pound. No. 2 type is constructed on the principle of dividing the pound into ounces and fractions of ounces on the binary system as a means of computing values. In other words the pound is divided into uniform fractions of the pound as in ordinary pound and ounce scales, and the true commercial value of each subdivision of the pound is indicated on the chart at the several prices per pound provided therefor.

Comstock, Anna (BOTSFORD). American natural history scientist, artist and engraver; b. Otto, N. Y., 1 Sept. 1854. After graduation

COMSTOCK — COMSTOCK LODGE

from Chamberlain Institute, Randolph, N. Y. in 1873, and from Cornell University in 1878, she studied art at the Cooper Union, New York city, and under John P. Davis. In 1899 she was appointed assistant professor of Nature Study in Cornell University extension work; and 1899-1900 was lecturer in Leland Stanford Junr. University extension work. She was awarded the bronze medal for wood engraving at the Pan-American Exposition of 1901. She is the author of 'Problems of the Six-Footed'; 'How to Keep Bees' (1904).

Comstock, Anthony, American reformer: b. New Canaan, Conn., 7 March 1844. In 1863 he enlisted in the 17th Connecticut regiment, served under Gen. Gilmore, and was mustered out in July 1865. In March 1873 he became secretary and special agent of the New York Society for the Suppression of Vice, and has completely identified himself with its work. It is said that largely through his special efforts 2,500 criminals have been brought to justice, and over 80 tons of indecent literature and pictures have been seized and destroyed. He has written: 'Frauds Exposed; How the People are Deceived . . . and Youth Corrupted' (1880), an exposure of various schemes operated through the mails; 'Traps for the Young' (1883); 'Gambling Outrages; or, Improving the Breed of Horses at the Expense of the Public Morals' (1887), and minor tracts for the furtherance of his work.

Comstock, kŭm'stŏk, Cyrus Ballou, American soldier: b. West Wrentham, Mass., 3 Feb. 1831. He graduated at West Point 1855, was chief engineer of the Army of the Potomac 1862-3, and attained the brevet rank of major-general of volunteers 26 March 1865, having been successively promoted for gallant, faithful, and meritorious services. He was later president of the Mississippi River Commission, and a member of the permanent board of engineers for fortifications. He was retired in 1895 as brigadier-general in the regular army. He wrote: 'Notes on European Surveys' (1876); 'Survey of the Northwestern Lakes' (1877); 'Primary Triangulation, United States Lake Survey' (1882).

Comstock, George Cary, American astronomer: b. Madison, Wis., 12 Feb. 1855. He graduated at the University of Michigan 1877 and from the law department of the University of Wisconsin 1883. He practised law for a time, but later devoted himself entirely to astronomy, and is now (1903) professor of that subject and director of the Washburn Observatory in the University of Wisconsin. He is a member of the National Academy of Sciences. He has written: 'Text-book of Astronomy' (1901); 'Text-book of Field Astronomy for Engineers' (1902).

Comstock, Harriet Theresa (SMITH), American author; b. Nichols, N. Y. 1860. She was educated in public schools and in the academy at Plainfield, N. J. She married Mr. Philip Comstock in 1885. Since 1895 she has become known as a prolific writer of juvenile stories, and is author of 'Molly, the Drummer Boy' (1900); 'Cedric the Saxon' (1901); 'A Boy of a Thousand Years Ago' (1902); 'A Little Dusky Hero' (1902); and 'Tower or Throne' (1902).

Comstock, John Henry, American entomologist: b. Janesville, Wis., 24 Feb. 1849. He graduated at Cornell University 1874; was United States entomologist at Washington, D. C., 1879-81, and since that date has been instructor and professor of entomology and general invertebrate zoology at Cornell. He has been a constant contributor to the literature of his subject, the following being the more important of his works in book form: 'Report on Cotton Insects' (1879); 'Introduction to Entomology' (1888); 'Manual for the Study of Insects'; 'Insect Life' (new ed. 1901); and 'Elements of Insect Anatomy' (3d ed. 1903) (with Kellogg).

Comstock, John Lee, American writer on physics: b. Lyme, Conn., 1789; d. Hartford, Conn., 21 Nov. 1858. He received a common-school education, studied medicine, and during the War of 1812 was assistant surgeon at Fort Trumbull, Conn., and on the northern frontier. He settled in Hartford, Conn., practised medicine until 1830, when he became an author by profession, and attained remarkable success in the compilation of text-books for educational purposes. His 'Introduction to Mineralogy' (1832) was used at West Point; of the 'Elements of Chemistry' over 250,000 copies were sold; while the 'System of Natural Philosophy' (1831) had a sale of over 900,000 copies (94th ed. N. Y. 1847), and was translated into the chief European languages. Others were: 'History of the Greek Revolution' (1828); 'History of the Precious Metals' (1849); 'Natural History of Quadrupeds' (1829); 'Grammar of Chemistry' (1825); 'Introduction to Botany' (3d ed. 1835).

Comstock, Theodore Bryant, American geologist: b. Cuyahoga Falls, Ohio, 27 July 1849. He graduated at Pennsylvania State College 1868, and at Cornell 1870, where he was professor of economic geology 1875-9. He accompanied Hartt's expedition to Brazil 1870, and Jones' Wyoming expedition 1873. He was professor of mining engineering and physics in the University of Illinois 1885-9, and assistant State geologist of Arkansas 1887-8, and of Texas 1889-91. He founded the Arizona School of Mines, was its director 1891-5, and president of the University of Arizona 1893-5. He has been manager, engineer, and consulting expert to many mining companies and syndicates, both American and foreign. He has published: 'Outline of General Geology' (1878); 'Classification of Rocks' (1877); 'Notes on the Geology of the San Juan Country' (1882); 'The Geology and Vein Structure of Southwestern Colorado' (1886); the last two in the 'Transactions' of the American Institute of Mining Engineers; and numerous papers in the 'American Journal of Science'; 'American Naturalist'; and 'Engineering and Mining Journal.'

Comstock Lode, a remarkable vein carrying silver sulphides with some native silver and considerable native gold, near Virginia City, Nev. The wide vein is a faulted fissure following the contact of a basaltic dike with the andesite country rock, the latter of Tertiary Age. The gangue is mainly quartz. The ores are of recent origin, and the waters ascending along the fissure are hot, making mining costly. Some wonderfully rich ore bodies, "bonanzas," were found in certain of the mines along the

COMTE

lode, and the history of its discovery, the great mining speculations based on it, and the final abandonment of nearly all the mines, reads like a romance. At present the deepest shaft on the lode is being reopened. The total yield of the lode from its discovery in 1859 up to July 1880 was over \$306,000,000.

Comte, François Charles Louis, frän-swä shärl loo-ē kônt, French writer on politics and jurisprudence: b. St. Enimie, department of Lozère, 1782; d. 1837. In 1814 he united with Dunoyer in starting a journal, called 'Le Censeur,' in which the adherents, both of Napoleon and the Bourbons, were roughly handled. On the second restoration of the Bourbons judicial proceedings were taken against the 'Censeur,' and the editors were fined and imprisoned. In 1819 Comte converted his journal into a daily newspaper, under the name of 'Le Censeur Européen,' and shortly after amalgamated it with the 'Courrier Français.' In 1821 a new prosecution condemned him to two months' imprisonment and a fine of 2,000 francs. He then went to Geneva, where he obtained a chair of public law, and taught with great success till the Helvetic Diet, in consequence of diplomatic complaints, found it necessary to refuse him an asylum. The work by which his name will be best known to posterity is his 'Traité de Législation Criminelle' (1827).

Comte, Isidore Auguste Marie François (ē-zä-dör ôg-üst mä-rē frän-swä), **Xavier**, French philosopher, founder of the "positive" system of philosophy: b. Montpellier 12 Jan. 1798; d. Paris 5 Sept. 1857. He was educated at the École Polytechnique, and embraced enthusiastically the socialist tenets of St. Simon, which became greatly in vogue in France after the Restoration. As one of his most distinguished pupils, he was employed, in 1820, to draw up a formula of the doctrines professed by the St. Simonian school, which he accordingly accomplished in his 'Système de Politique Positive.' This work did not, however, meet with the entire approbation of St. Simon, who asserted that Comte had made a very important omission by overlooking the religious or sentimental part of human nature. In 1826 he began lecturing on mathematics, and had for an audience such men as Humboldt, Blainville, Carnot, etc. In 1830 he began the publication of his 'Cours de Philosophie Positive,' completed in six volumes in 1842, and freely translated into English and condensed by Harriet Martineau (2 vols. 1853). The following is an abstract of the philosophical system propounded by Comte in that work. It consists of three leading positions. The first is, that the human mind in its progress, historically and individually, passes through three stages of development: (1) The theological, in which all the phenomena of nature are imputed to the active agency of the gods. (2) The metaphysical, in which the gods are supplanted by certain abstractions called "nature," "harmony," "number," etc. (3) The positive or scientific, in which it is discerned that man can know nothing of causes, and is only able to refer phenomena to their general laws of existence or succession. Arrived at this stage, science is born, and knowledge, no longer baffled by the inscrutable or misled by the imaginary, advances from one generalization to

another, to a comprehensive perception of the universe as a whole. The second position is, that in this advance the mind proceeds in a regular hierarchical order, from the simple to the complex, or from the most elementary relations of numbers to the highest and deepest complications of society and life. The hierarchical order of the sciences is arranged by Comte as follows: 1. The most general and simple of all, dealing only with numbers and magnitudes—mathematics. 2. The application of the principles of mathematics to the phenomena of the celestial sphere, or astronomy. 3. The application of mathematics and astronomy to the phenomena of the terrestrial sphere or general physics, including heat, light, optics, electricity, etc. 4. The science of the phenomena of individually organized being, or vegetable and animal life, termed biology. 5. The science of the phenomena of corporate or social life, which he terms *sociology*, and which, as presupposing and containing all the former, he represents as the essence and perfection of all the sciences. The third position lays down the laws and principles which regulate social life, constituting order and liberty. The first element of order is the family; the second the community, composed, not of individuals, but of families, and co-operating, to a certain extent, in their employment; and the third, the government or state. Liberty is the effect of this harmonious organization, and progress the development of it, by the conquest (1) of material nature; (2) of the lower propensities by the higher intellectual faculties; and lastly, of the selfish passions by the noblest social affections. In 1832 he became one of the professors at the École Polytechnique. In 1843 he published a mathematical work, 'Traité Élémentaire de Géométrie Analytique,' and in 1848 'Discours sur l'Ensemble du Positivisme,' in which the doctrines laid down in his previous work are recapitulated. But some change had, in the interval, taken place in Comte's views. The death of a lady, whom he calls Clotilde, and for whom he had conceived the most ardent affection, impressed his mind deeply with the conviction that something more than a mere material array of facts was needed to satisfy the cravings of the human soul. The religious tendencies of the heart had been hitherto wholly overlooked by him, and he now perceived the necessity of presenting some object to supply this want. He invented a religion which consists in referring the whole harmony of existence to, and concentrating its essence in one great Being, whom he termed Humanity. As manifestations and representatives of this Being, he maintained that the proper objects of worship are those who have shown themselves the greatest benefactors to the human race—in fact, a hero-worship. This system is propounded by him in a book published in 1849, entitled 'Culte Systematique de l'Humanite Calendrier Positiviste, ou Systeme Général de Commemoration Publique,' in which he has drawn up a regular calendar of demigods, presiding over the months, weeks, and days of the year, and having each their appropriate festivals. The 13 months into which he divided the year, he called Moses, Homer, Aristotle, Archimedes, Cæsar, St. Paul, Charlemagne, Dante, Gutenberg, Shakespeare, Descartes, Frederick, and Bichat. He assumed the office of high priest of this new religion, performing marriage and

COMTE — CONANT

funeral rites on behalf of the disciples induced to adopt his system. These, however, were never very numerous, and by the time of his death had nearly all dropped off one after another. The last work published by him was entitled 'Système de Politique Positive, ou Traité de Sociologie, instituant la Religion de l'Humanité,' (1851-2). However extravagant many of Comte's theories may appear to be, they nevertheless display in their enunciation a powerful intellect with much universality and comprehensiveness of knowledge. Many new and original ideas are brought forward, and much matter afforded for thought and reflection. His works have been made known to English readers mainly by Mr. G. H. Lewes, 'Comte's Philosophy of the Sciences,' and Miss Martineau's translation above mentioned. See POSITIVISM.

Bibliography.—Robinet, 'Notice sur L'œuvre et sur la vie de Comte' (1860); Mill, 'Comte and Positivism' (1865); Fiske, 'Outlines of Cosmic Philosophy' (1st vol. 1874); Littré, 'Auguste Comte et la Philosophie Positive' (1877); Caird, 'The Social Philosophy and Religion of Comte' (1885); Gruber, 'Auguste Comte, sein Leben und Seine Lehre' (1889).

Comte, Pierre Charles, pē-ār shārl, French painter: b. Lyons 23 April 1823; d. 1895. He studied at Paris as a pupil of Robert Fleury, and exhibited his picture 'Lady Jane Grey,' in 1847, which won him considerable attention. His other works include: 'Henry III. Meeting the Duke of Guise'; 'Joan of Arc at the Coronation of Charles VII.'; 'A Scene at Fontainebleau' (at Washington, D. C.); 'Gipsies Before Louis XI.'; and 'The Last Visit of Charles V. to the Castle of Ghent.'

Comte de Paris, dē pā-rē. See PARIS, COMTE DE LOUIS PHILIPPE ALBERT D'ORLEANS.

Comus, kō'mūs (Greek *kōmos*), in ancient Greece the name given to a kind of festal procession in honor of some of the gods (as Bacchus) and sometimes in honor of victors in the public games. The term had also the wider sense of revel and merry-making. This name was also given to a divinity supposed to preside over such festive occasions, but as his name does not occur in early ancient writers whose works have been preserved, he is evidently a creation of later times. He is first mentioned by Philostratus (about 200 A.D.).

Comus, a masque by John Milton, given before the Earl of Bridgewater at Ludlow Castle, Shropshire, England, 29 Sept. 1634. It was first printed in 1637. An altered version of it was played at Covent Garden Theatre, London, in 1773, and in 1901 it was played at Tufts College, Massachusetts, by the students of that institution.

Comyn, kŭm'in, John, the elder, Scottish noble: d. about 1300. He was one of the commissioners sent to confer about the marriage of the Maid of Norway to Prince Edward of England. On the competition for the Scottish throne in 1291 Comyn put in a claim as a descendant of Donald Bane.

Comyn, John, Scottish noble: d. Dumfries 1306. He was called the "Red Comyn," was chosen one of the three guardians of Scotland, and defeated the English at Roslin in 1302. He submitted to Edward I. in 1304, and was killed

by Bruce in the Convent of the Minorites at Dumfries in 1306, a well-known episode in the life of the great Scottish king.

Con, kōn, an Italian preposition signifying with, and of frequent occurrence in musical phraseology; *con amore*, with feeling: *con brio*, brilliantly; *con gusto*, with taste, etc.

Conan'icut, an island of Rhode Island, situated in the lower part of Narragansett Bay. It is about nine miles long. The town of Jamestown is near the east shore, and there is a lighthouse at the north end.

Co'nant, Alban Jasper, American artist: b. Chelsea, Vt., 24 Sept. 1821. He settled in St. Louis in 1857, and during the Civil War visited Washington, and painted portraits of President Lincoln, Secretary Stanton, and Attorney-General Bates. He was a curator in the University of Missouri for eight years, and made valuable studies of the archaeology and antiquities of the Mississippi Valley. In 1880 he was appointed Délégué Correspondant de l'Institution Ethnographique of Paris. He has published: 'Footprints of Vanished Races in the Mississippi Valley' (1879, 4to 1); 'The Archaeology of the Missouri Valley'; 'My Acquaintance with Abraham Lincoln,' etc.

Conant, Charles Arthur, American economic writer: b. Winchester, Mass., 2 July 1861. He was for some years after 1880 a journalist in Boston, from 1889-1901 was Washington correspondent of the 'New York Journal of Commerce' and in 1903 became treasurer of the Morton Trust Company. He has published: 'A History of Modern Banks of Issue'; 'The United States in the Orient: the Nature of the Economic Problem' (1900); 'Alexander Hamilton'; 'Securities as Payment'; 'Wall Street and the Country' (1904).

Conant, Hannah O'Brien Chaplin, American author: b. Danvers, Mass., 1809; d. Brooklyn, N. Y., 18 Feb. 1865. In 1830 she married Thomas Jefferson Conant (q.v.). She was a woman of versatile talent, having an excellent knowledge of Oriental tongues, which enabled her to share in the biblical studies of her husband. She frequently contributed to the literary and religious periodicals of the day, and in 1838 became editor of the 'Mothers' Monthly Journal' at Utica, N. Y. She published: 'Lea: or the Baptism in the Jordan, by G. F. A. Strauss' (1844); 'First Epistle of John Practically Explained, by A. Neander' (1852); 'The New England Theocracy, by H. F. Ulden' (1859), all translations from the German; 'The Earnest Man: Sketch of the Character and Labors of Dr. A. Judson' (1855); 'The English Bible: Popular History of the Translation of the Holy Scriptures into the English Tongue' (1856; English ed. 1859; new ed. 1881).

Conant, Thomas, Canadian descriptive writer: b. Oshawa, Ont., 15 April 1842; d. there 14 March 1905. He was educated in the public schools and at Eddystone Seminary in Geneva, N. Y., and achieved distinction with brilliant sketches of scenery and articles on Canadian and other subjects. In 1896 he visited Australia, India, and the Orient.

Conant, Thomas Jefferson, American biblical scholar: b. Brandon, Vt., 13 Dec. 1802; d. Brooklyn, N. Y., 30 April 1891. He was graduated from Middlebury College in 1823,

CONATION — CONCEPCION

and between 1825 and 1857 taught the classics and biblical literature in Columbia College, Waterville (now Colby) College, Maine, Madison, now Colgate, University, Hamilton, N. Y., and Rochester Theological Seminary. Taking up the studies that soon gave him a wide reputation, he was appointed by the American Bible Union one of a committee to prepare a revision of the English version of the New Testament. He was also a member of the American committee on the English revision of the Old Testament, and his versions were highly esteemed and constantly used by the English revisers. His numerous publications include translations of the 11th and 17th editions of Gesenius' 'Hebrew Grammar'; 'Job; Revised Version, and Notes' (1856); 'Matthew, Revised Version' (1860); 'Baptizein, Its Meaning and Use' (1860); 'Genesis, Revised Version' (1868; 1873); 'The New Testament; Common Version Revised' (1871); 'Psalms, Revised' (1871); 'Proverbs, Revised' (1872); 'Greek Text of the Apocalypse, as edited by Erasmus' (1873); 'Prophecies of Isaiah, Chapters 1-12' (1874); and 'Historical Books of the Old Testament, Joshua to 2 Kings' (1884).

Cona'tion (from Lat. *conari*, to attempt), a term in its original sense used simply to express the idea or to designate the act of attempting or undertaking something. In present usage it is appropriated by psychologists to the expression of desire and volition as manifested in or constituting voluntary agency, although as a factor in consciousness and effort its precise implications appear not to have been finally determined. In the exertion of the muscles, and in direct conscious attention, the agency of conation in an individual finds its two representative aspects. Attention, desire, and endeavor, with their accompanying states of thought and feeling, are held by some psychologists to be the completing aspects of conation; while others maintain that its function is limited to the sensations of straining, with consequent states of consciousness, pleasureable or otherwise, attendant upon contraction of the muscles. Whether conation is to be regarded as simple or complex in its psychological aspects, remains therefore a question for further research and experiment. Consult: James, 'Principles of Psychology'; 'Experimental Psychology'; Scripture, 'The New Psychology'; Titchener, 'Outline of Psychology'; Hyslop, 'Syllabus of Psychology'; Stout, 'Analytic Psychology.'

Conaty, Thomas James, American Roman Catholic prelate: b. Ireland 1 Aug. 1847. In 1850 he came with his parents to America, the family settling in Taunton, Mass., and in the district schools of that city he received his primary education. He entered the College of Saint Sulpice, Montreal, in 1863, completed his humanities in 1867, and spent the following two years at Holy Cross College, Worcester, Mass., being graduated in 1869. His ecclesiastical course was pursued at the Seminary of Saint Sulpice, Montreal, where he was ordained priest 21 Dec. 1872. First named assistant at Saint John's Church, Worcester, Mass., and afterward chosen pastor of the Church of the Sacred Heart in that city, Father Conaty was actively interested in the advancement of Catholic education. He was likewise an ardent promoter of the temperance cause, being first pres-

ident of the Springfield Diocesan Temperance Union, and, in 1887, national president of the Catholic Abstinence Union of America. Father Conaty was also prominent in establishing the Catholic Summer School in 1892—the same now flourishing at Plattsburg, N. Y.—being its president from 1893 to 1897. In 1889 Georgetown University conferred upon him the title of D.D., and in 1896 Laval University, Quebec, bestowed the same honor. He was chosen rector of the Catholic University in 1896, made a domestic prelate in 1897, consecrated titular bishop of Samos 24 Nov. 1901, and appointed bishop of Monterey and Los Angeles 27 March 1903. He is a frequent contributor to various periodicals, and is the author of 'New Testament Studies' now used in many Catholic schools. At present (1905) Bishop Conaty's diocese has a Catholic population of about 70,000; 136 priests; 149 churches; 24 parochial schools; 4 Indian schools; 6 orphan asylums; 2 hospitals, etc.

Concentra'tion, in chemistry, the act of increasing the strength of solutions. This is effected in different ways: by evaporating off the solvent, as is done in the separation of salt from sea-water; by distilling off the more volatile liquid, as in the rectification of spirit of wine; by the use of low temperatures, as in the purification of benzol; by difference of fusibility, as in Pattinson's process for desilverizing lead.

Concentration Camp, a camp into which non-combatants are gathered in time of war. During the Cuban rebellion of 1895-8 many peaceable and defenseless people were forced to abandon their homes in the agricultural regions and were imprisoned upon the barren waste outside the residence portions of the cities, and within the lines of entrenchment. It is estimated that at least 400,000 persons, mostly old men, women, and children, were thus subjected to concentration under Weyler's administration. They were known as reconcentrados. The British also carried on a scheme of concentration of non-combatants during the Boer war, but those who were kept in the concentration camps were not subject to physical hardships such as disgraced the camps in Cuba. In the "appeal" issued by the Boer generals 25 Sept. 1902, thanks were tendered to those sympathizers who had rendered pecuniary and other assistance to Boer wives and children in the concentration camps. The British government expended about \$1,000,000 per month on the burgher camps and stated that they were still maintained after the close of the war, "only in the cause of humanity." Provision was made at great expense in these camps for the education of the Boer children. The term concentration district may be applied to the rendezvous where troops are gathered during the process of mobilizing an army.

Concen'tric. Similar figures having a common centre are called concentric.

Concepción, Chile, a province lying between the provinces of Ñuble and Bio-bio. Area 3,532 square miles. It is divided into the departments of Coelemu, Puchacay, Rere, Concepción, Talcahuano, and Lautaro. The importance of its capital, its commercial activity, and its numerous ports make this the most interesting province in the south of Chile. Two of the

CONCEPCION — CONCEPT

largest bays in the republic are on its coast, those of Talcahuano, which is defended by fortifications, and Arauco, which includes the ports of Lota and Coronel, notable for their coal mines. The city of Concepción is the capital. Talcahuano (15,500 inhabitants) is a military port, with a dry-dock for repairing warships and mercantile vessels, and at the same time an active commercial port. Products of the whole southern region are brought to it for exportation, and it supplies cities of the interior with a large part of their merchandise. The port of Tomé (5,000 inhabitants), situated near rich agricultural districts, exports a large quantity of wine and has a woolen mill, etc. Penco, a small port 10 miles by rail from the city of Concepción, is a favorite seaside resort and has a sugar refinery and coal mines in the neighborhood. The population of the province is 225,000.

Concepcion, Chile, the capital of the province of the same name. It is situated on the banks of the Bio-bio River, and is connected by a short railway with its ports of entry, Tomé and Talcahuano, 8 miles distant on the Bay of Concepción. In the latter city a United States consular agent resides. The streets and squares of the city are wide, well-paved, well-lighted, and clean. An electric railway traverses the principal streets. Concepción is the seat of a bishop. The chief buildings are the city hall, the cathedral, theatre, the agricultural school, and the normal school. The city is in a fertile agricultural region and has an active trade in agricultural products, hides, tallow, wine, flour, beef, etc.; very little manufacturing is carried on, the largest establishment being breweries, furniture, and carriage factories, saw-mills, flour-mills, distilleries, etc. It is in importance the third city of Chile. Concepción was founded in October 1550 by Pedro de Valdivia, and was originally situated on the site of the present city of Penco. In 1555 the place was pillaged and destroyed by Araucanian Indians; and in 1557 was refounded by Garcia Hurtado de Mendoza. In 1730 the town was totally ruined by an earthquake, and in 1751 suffered from a like catastrophe in consequence of which the site was removed and the city rebuilt in its present location in the fertile plain on the north side of the Bio-bio, 270 miles southwest of Santiago. At the time of the Spanish occupation Concepción was the second largest city in the country. In 1818 the declaration of Chilean independence took place here. In 1835 another disastrous earthquake visited the city and for a long time the place was almost entirely desolate, but it was afterwards resettled and from that time the buildings have been more substantially and pretentiously erected, the streets reconstructed and the area of the city greatly extended. Pop. 55,000.

Concepcion, Paraguay, also called Villa Concepción, the second city of the republic in commercial importance, though not in the number of its inhabitants. It is situated on the left bank of the Paraguay River, 213 kilometers from Asunción. It is a port of entry and delivery, where the steamers navigating the Upper Paraguay regularly touch. The principal buildings are the city hall, custom-house, parish church, market, and some fine private residences.

It has a line of street-cars, telephone service, two banks, and several commercial houses that trade directly with Argentine and European cities. Yerba-maté and cattle are the principal items of the city's commerce. Pop. 13,654.

Concepcion, Philippines, a former district of the island of Panay, now part of the province of Iloilo, situated on the northeast part of the island; area 683 square miles. The former capital, Concepcion is a pueblo situated on the east coast of the island, 47 miles northeast of Iloilo; pop. 5,736. Pop. of the district (1900) 19,342.

Concepcion, Philippines, a town (pueblo) in Tarlac province in the island of Luzon, 12 miles south of the town of Tarlac. Pop. 13,499.

Concepcion, a lake in the central portion of the department of Santa Cruz, Bolivia.

Concepcion del Uruguay, Argentina, a city in the province of Entre Rios, on the Uruguay River about 160 miles north of Buenos Ayres. It is connected by railway with Paraná, and the river is navigable for large vessels, thus rendering the city an important shipping point. It is in an extensive and fertile agricultural region and the trade consists chiefly of these products and cattle and packed meat. There are also some salting establishments in the city. A national college and a normal school are located in the city. Concepción del Uruguay was founded in 1778 and was originally called Concepción-del-de-la-china; was formerly the capital of the province and is now the episcopal city. Pop. about 6,000.

Concept. A concept is an idea which has been formed by thinking, and which is permanently embodied in language by a word or other definite symbolic expression. There are two main differences between a concept and a precept. In the first place, the latter seems to be directly presented through the senses and does not imply any conscious reflection. And again, a precept as presented has always a particular individual form, while a concept is an ideal construction, and, as such, has universal significance. For example, I may perceive through my senses the particular object which I call my watch; but to form a concept of "watch" is to think in general terms the relation of the mechanism of the parts to the purpose of the whole. The concept must also be distinguished from the mental image which appears in memory or imagination when the object is not directly present in sensation. The latter is always a particular psychological process, and therefore cannot adequately represent the general relations of the concept. We must not confuse the presence of images in the mind with thinking. It is true that a concept cannot be represented in terms of psychological content except by a particular image, and it probably always is represented by some such image. But the concept is a universal mode of thinking, and the psychological imagery which accompanies it is largely individual and indifferent. The universal relations of the concept of triangle, for example, are not limited by the form of the particular figure which I represent to myself mentally, or draw upon paper, though the latter may aid me in comprehending those relations. The concept is ideal in character; it is a universal

CONCEPTION — CONCERTINA

significance, and must never be confused with a particular psychological image.

Socrates was the first to bring this universal element of knowledge into clear light. When the Sophists pointed to the differences and variations of perceptions and feelings in individuals, and drew the conclusion that objective knowledge was impossible, Socrates showed that concepts which are true for all men can be discovered and defined, and that this is the true quest of thought. Amid the flux of individual opinion, science is still possible, since it is constituted by this system of universal concepts. Plato and Aristotle developed further the Socratic doctrine of concepts and gave it an ontological application. By means of the concept, the true form or permanent essence of things is said to be apprehended, as opposed to the accidental and changing appearances. The question as to the nature of the concept played an important part during the Middle Ages (See NOMINALISM, REALISM, CONCEPTUALISM). The view that is perhaps most commonly held to-day, regards the concept as derived by abstraction (q.v.) from perceptual experience, by selecting out what is common in a number of instances and combining these common elements into a general idea. It must not be forgotten, however, that concepts are not formed by the piecing together of psychologically common elements in a mechanical way, but are the products of thinking; and that thinking is itself judgment or interpretation of significance in universal terms. It is true, as Kant said, that concepts without percepts are empty; our thinking does not go on in a vacuum apart from concrete experience. But the concept is not universal because it has been compounded out of elements that are common to a number of objects, but because it is the mind's expression in terms of ideal significance. Concepts, however, can scarcely be said to exist without language. The relation between thought and the words which express it is of the closest and most intimate kind. The word sums up in itself the results of the conceptualizing process, thus giving to it a reality and permanence which make progress possible. It is through learning the words of a language that we are able to share in the concepts of other men and other generations. Language is thus a permanent record of thought's achievements, and its development is not something external to the evolution of thinking, but in one aspect may be said to be a different side of the same process. The concept then cannot be defined apart from its expression in language; for this expression is no mere external and accidental feature of the idea, but is organically and necessarily connected with it.

JAMES E. CREIGHTON,
Professor of Philosophy, Cornell University.

Conception, Immaculate, of the Blessed Virgin Mary, a dogma of the Roman Catholic Church, defined as such by Pope Pius IX. The purport of this definition is very commonly misapprehended, being understood to relate to the virginal motherhood of Mary; but the doctrine of the Roman Catholic Church, as expressed in the definition proclaimed by Pius IX. in his Letter Apostolic of 8 Dec. 1854 is that Mary "at the first instant of her conception was, by a singular privilege and grace of Almighty God, in virtue

of the merits of Jesus Christ the Saviour of mankind, preserved immaculate from all stain of original sin." This doctrine, though thus formally declared an article of Catholic belief only in the middle of the 19th century, had for many centuries been believed either explicitly or implicitly by saints and fathers of the Church. When at last the sense of all the bishops and all the churches of the Catholic communion with regard to this belief was elicited by a letter of Pius IX. addressed to them, the reply from the great majority of them was strongly in favor of a definition: yet a good many held it unwise to make the definition for the reason that neither in Scripture nor in Christian tradition could, as they thought, sufficiently clear intimations of it be found, or they doubted the wisdom of promulgating a definition at that time. See IMMACULATE CONCEPTION.

Conception of Our Lady, Sisters of the, an order of nuns, founded in Portugal in 1484 by Beatrix de Sylva, in honor of the Immaculate Conception. It was confirmed in 1489 by Pope Innocent VIII., and the Cistercian rule was adopted. In 1489 Cardinal Ximenes put the nuns under the direction of the Franciscans, and imposed on them the rule of Saint Clara. The order subsequently spread into Italy and France.

Conception. See EMBRYOLOGY.

Conceptualism, kōn-sēp'tū-al-izm, in metaphysics, a doctrine in a sense intermediate between realism and nominalism. Conceptualism assigns to universals an existence which may be called logical or psychological, that is, independent of single objects, but dependent upon the mind of the thinking subject, in which they exist as notions or conceptions. See NOMINALISM; REALISM.

Conceptualist, one of a metaphysical sect — if indeed it has coherence enough to be called a sect — which arose in the Middle Ages during the disputes between the Nominalists and the Realists; or one who holds the views of conceptualism. The conceptualist school sought to occupy an intermediate position, but it approximated much more nearly to the Nominalists than to the Realists.

Concert Pitch, the pitch of a certain note in the musical scale adhered to by the general body of musicians. The middle C (seated on the ledger-line which unites the G and F clefs) is produced by a string making, according to theorists, 512 vibrations per second. In England, however, the pitch has risen to 538, while in Germany it is 528, and in France 522. The gradual rise of the pitch from the theoretical 512 vibrations is attributed to the necessities of piano-tuning on the one hand, and the desire to attain a more intense and brilliant tone on the other. See PITCH; also MUSICAL ELEMENTS AND TERMS.

Concertina, kōn-sēr-tēna, a musical instrument invented by Sir Charles Wheatstone. It is generally polygonal in shape, is held between the hands so that the fingers drop naturally down on studs which raise the valves and allowed the air (supplied by the bellows between the finger-boards) to act upon a series of metal tongues of the same construction as those of the accordion or harmonium. The usual range

CONCERTO — CONCHOLOGY

of the instrument is from the lowest G on the violin to the C three and a half octaves higher, including the chromatic tones. The German concertina is a much less perfect instrument, as only tunes on a limited number of keys can be performed on it.

Concerto, kōn-chār'- or kōn-sēr'to, a kind of composition first introduced by the Italian musicians of the 17th century, for the purpose of showing the capabilities of the violin, or of a particular performer on that instrument. The principal composers and artists in this department are Corelli, Viotti, Rodes, Baillot, Kreutzer, Alard, Beriot, and Vieuxtemps. Subsequently concerti were written for other instruments, such as the flute, the piano, etc. Among the most successful composers for the piano are Bach, Mozart, Hummel, Chopin, Schumann, Ries, Czerny, and Thalberg. Concerti usually consist of three movements, an *allegro*, an *andante*, or *adagio*, and a lively *rondo*. Except in the *tutti* the orchestra should be as subservient to the instrument for which the piece is written as it should to a vocalist.

Concerto grosso is an expression applied to the great or grand chorus of the concert, or to those places of the concert in which the *ripienos* and every auxiliary instrument are brought into action, for the sake of contrast and to increase the effect.

Concerto spirituale was a concert at Paris, performed in the religious seasons, when the theatres were closed. The pieces performed, however, were not always of a spiritual kind. It was introduced in 1725 by Anne Danican, called Philidor.

Conch, kōnk, a name of certain large marine gastropods, especially of the king conch (*Strombus gigas*), abundant in the southern United States and parts of the West Indies. In Florida the shells are made into horns used for calling the farm hands, as is still done in the East Indies with shells of the genus *Triton*. This is one of the shells used for making cameos, and great quantities are collected in the Bahamas and shipped to Liverpool for this purpose to some extent, but more for conversion into buttons and similar small articles, in allusion to which industry the native whites of the Bahamas are called "Conchs." The name is also applied to two large sea-snails, the *Fulgur carica* and *Sycotypus canaliculata*, common on most parts of the Atlantic coast.

Concha, José Gutierrez de la, hō-sā' dā la kōn'chā (MARQUES DE LA HABANA), Spanish general: b. Cordoba, Argentine, 4 June 1809; d. Madrid, Spain, 5 Nov. 1895. He went to Spain in childhood, entered the army, took part in the struggles in South America, and against Don Carlos, was appointed lieutenant-general in 1839, and officiated as captain-general of the Basque provinces 1843-6. He was captain-general of Cuba 1849-52, when he was replaced by Cañedo. Joining his brother in opposing the government, he was banished from Spain in 1854, and fled to France, where he was detained at Bordeaux. After the July revolution of 1854, he was re-appointed captain-general of Cuba, and, with the exception of a short suspension of his functions by Narvaez's administration in 1856, when Lersundi was appointed as his successor, he continued to hold office until December 1858, when he tendered his resignation.

Returning to Spain he was at various times minister to France, president of the senate, and minister of war, and captain-general of Cuba again 1874-5.

Concha, Manuel (mä'noo-ël) de la (MARQUES DE DUERO), Spanish general and statesman: b. Cordoba, Argentina, 25 April 1808; d. Muro 28 June 1874. He was a brother of José de la Concha (q.v.), fought in early life against Napoleon and the revolted Spanish colonists in South America, and afterward against Don Carlos. In 1847, during the complications with Portugal, he was put in command of 6,000 men, and took possession of Oporto. Having issued at the end of 1853, in concert with O'Donnell and Bravo-Murillo, the famous protest against the policy pursued by the government, he was banished from Spain after the revolution of July 1854, and repaired to Paris; but was soon recalled to Madrid by the outbreak which terminated in the exile of Maria Christina, the downfall of Narvaez, and the restoration of Espartero. Concha was now made inspector-general of cavalry and marshal; but on 12 Oct. 1856, when Narvaez came again into power, he was compelled to relinquish these posts. He was killed in the battle of Muro while serving in the republican army against the Carlists.

Conchoid, kōng'koid, a curve, shell-like in flexure (whence the name), invented by Nicomedes in the 2d century B.C., and used by him for finding two mean proportionals. If a straight line always passes through a fixed point *o*, and a point *Q*, fixed into the revolving line, always moves along the line *AB*, then any point *P* in the revolving line always at the same distance from *v* will trace out a conchoid. And, since the length *QP* can in any position of the revolving line be measured either toward or from *o*, it is evident that, corresponding to any given length assigned to *QP*, two conchoids can be described, one above and the other below the line *AB*. These are known as superior and inferior conchoids. Moreover, with a given point *o*, and a given straight line *AB*, any number of pairs of different conchoids can be described by varying the length *QP*. Moreover, the shapes

Conchoid.

of all such curves will vary according to the length of *QP*. Thus, if *QP* is less than the perpendicular from *o* on *AB*, the shape is as given in the adjoining figure, and this isolated point *o* is also a point on the curve.

Conchology, kōng kōl'ō jē, the science of shells. Two well-marked stages in its develop-

CONCHOS — CONCONE

ment are traceable. At first shells were studied without any reference to the animals of which they constituted the hard framework or skeleton. Subsequently the study took a wider scope, and for the first time became worthy of being called a science, when the animals and their shells were viewed as parts of one common whole. When shells were looked upon as little more than ornamental objects, those who studied conchology were not generally of a high order of intellect; but since the rise of geology and the discovery that, of all fossils, shells are able to furnish the most definite information regarding the several strata, and consequently regarding the history of by-gone times, scientific minds of the very first class have given keen attention to shells. Some of these belonging to land animals, others to those inhabiting fresh water, and the great majority to those which are marine.

When shells, and they alone, were studied, conchology was a not unsuitable name, except that the termination -ology suggested that the investigation was more scientific than in most cases it really was. When the animals came to be carefully examined, M. de Blainville proposed for this deeper study the name malacozoology — that is, the study of the softer animals, mollusks; this has been since abbreviated into malacology. At the present time malacology is a highly developed branch of zoological science which treats of everything relating to the great phylum *Mollusca* (q.v.). Conchology is frequently used in the same sense, but cannot altogether escape the opprobrium which attaches to it as a mere collector's pastime. Consult Tryon and Pilsbry, 'Manual of Conchology.'

Conchos, kōn'chōs, or **Conchas**, Mexico, a river in the state of Chihuahua; rises high up in the Sierra Madre, flows southeast, northeast, and then north through a beautiful country, comprising rich table-land, and empties into the Rio Grande near Presidio del Norte, after a course of about 350 miles. It is the largest tributary of the Rio Grande, and very little inferior in size to that river itself. Its principal branches are the Florido, Buenavista, San Pedro, Chihuahua, and Balleza, which, with their lesser tributaries, water more than one third of the state.

Conchyolin, kōn-kī'ō-līn, an organic base allied to chitin (q.v.), which enters into the composition of the shells of mollusks. The conchyolin forms a thick cuticular layer of organic matter containing carbonate and a slight proportion of phosphate of lime. In dead shells the conchyolin soon disappears, leaving the shell much more brittle than when it was alive.

Conciergerie, La, lä kōn-sē-ēr-zhē-rē, a noted prison in Paris, which was a part of the Palais de Justice. Many royal prisoners were there confined, and during the Reign of Terror it was the scene of fearful butcheries, 328 prisoners being put to death in one week. Marie Antoinette went from her cell in this prison to her execution.

Concil'ium in Trullo, or **Concilium Quinisextum** (Council in Trullus, Fifth-Sixth Council), a council or synod of the Church convened in a hall (called the Trullus) of the imperial palace at Constantinople in the year 692. It was an assembly of eastern and western bishops called for the purpose of enacting canons of

Church discipline: this the council did, both adding to the existing canons 102 new ones and confirming ancient canons that had fallen into desuetude. Its work was to supplement the decrees of the 5th and 6th councils of the Church: hence it is known as the Quinisext Council.

Conclave, both the apartment in which is conducted the election of a Pope and the college of cardinals assembled there. The procedure in electing popes is substantially the same to-day as it was in 1274 when it was prescribed by the Council of Lyons. When a Pope dies, a secretary of the college of cardinals summons all the cardinals to an election to be held on the 10th day after the demise. In whatever city the Pope dies, there the conclave must be held. The conclave apartment must be immediately prepared in such a place and manner as will insure safety of person and non-interference from outsiders. If the conclave is held in Rome, the great halls of one of the papal palaces is divided by wooden partitions into small rooms or cells, two or at most three cells for each cardinal and his personal attendants. The apartments all open on one corridor, and to that there is but one means of access from without, and that is strictly guarded. After the 10 days have elapsed, the cardinals all assemble in the Vatican church and assist at the Mass of the Holy Ghost, after which they form a procession and proceed to the conclave, each one taking the apartments assigned to him. The first day the conclave is open to the public, and numerous persons, high and low, avail themselves of the permission to enter. In the evening all outsiders leave, and the cardinals must remain until a Pope is chosen. A two thirds majority vote is requisite. Daily provision of food is brought in from outside, which is closely scrutinized lest any written communication should reach the cardinals: if no election is had after five days the food supply is restricted to bread, wine, and water, or rather used to be, for the rigor of the law is now much relaxed. A cardinal coming from a distance is admitted after closure. The election is made by scrutiny, that is, by ballot, or by compromise, that is, by a committee chosen by a majority of the conclave, or by acclamation. Sometimes a conclave has sat many weeks, or even months, before reaching an election: the conclave which elected Pius VII. (1799) sat during six months. The conclave in which Leo XIII. was elected Pope consisted of 62 cardinals, and it began its session the evening of 18 Feb. 1878. The scrutiny of the morning of the 20th showed that Cardinal Pecci was chosen. The election was then ended and he was made Pope by acclamation. The conclave at which Pius X. (q.v.) was elected began its session 31 July 1903, and the first ballot was cast the morning of 1 Aug. The scrutiny of the morning of 4 Aug., the seventh ballot, showed that Cardinal Sarto, patriarch of Venice, was elected. He chose the name of Pius X. This conclave was remarkable as being the only one of which a cardinal from the United States was a member.

Concone, Giuseppe, joo-sēp'pě kōn-kō'nā, Italian teacher of vocal music: b. Turin 1810; d. there June 1861. From 1838-48 he was a teacher at Paris, and then became organist of the royal chapel at Turin. He wrote a large

CONCORD — CONCORDAT

number of vocal exercises which are still used in the teaching of music.

Concord, kōng'kərd, Mass., a town in Middlesex County, on the Concord River and on the Boston & M. R.R., 20 miles northwest of Boston; settled in 1635. It is situated in a beautiful rural district, and has several manufacturing establishments. Here is located the Massachusetts Reformatory. The town has an excellent public library, a national bank, and an assessed property valuation of over \$4,000,000. At the beginning of the Revolution the Americans had a large stock of arms and military stores at Concord. Gen. Gage, the British commander in Boston, hearing of this, sent a body of soldiers to destroy these stores, and on their way (19 April 1775) they fought the battle of Lexington, the first of the war. When they reached Concord, the same day, they destroyed what stores they could find, but were soon driven off by the Americans. Concord is celebrated as the home of many authors—of Ralph Waldo Emerson, Nathaniel Hawthorne, Henry David Thoreau, Amos Bronson Alcott, Louisa May Alcott, the poet William Ellery Channing, and others.

Concord, N. H., a city, capital of the State and county-seat of Merrimack County, on the Merrimack River, and on the Boston & M. R.R., 75 miles northwest of Boston. The city has an abundance of water-power, and manufactories of carriages, shoes, twine, electrical apparatus, silverware, leather goods, machine-shop products, etc. Near Concord are extensive quarries of a fine-grained white granite. There are three national banks with a combined capital of \$500,000 and a surplus of \$300,000, and several private banking houses. The assessed property valuation exceeds \$20,000,000. The city is well laid out, has finely shaded streets, is well lighted, and its water-works are excellently constructed. The noteworthy buildings include the State-house, a fine building of Concord granite, the city hall and courthouse, the State prison, State insane asylum, and the United States government buildings. The public schools are admirably organized and conducted, and represent a property valued at more than \$325,000. This city is the seat of the well-known St. Paul's School (Episcopal) for boys. Concord was settled by whites in 1725, on the site of the Indian village of Pennacook. It was called by this name until 1733, then incorporated as the town of Rumford, and became a city in 1853. It is noted as the place near where Hannah Dustin (q.v.) made her escape from Indian captors. Pop. (1900) 19,632.

Concord, N. C., a city and county-seat of Cabarrus County, on the Southern R.R. Here are large industrial interests, and among the principal manufactures are those of cotton goods, foundry and machine-shop products, etc. There are also roller mills, a cannon manufactory, and brick works. Concord is an old place to which in recent years new industries have brought rapid growth. Pop. (1890) 4,339; (1903) about 9,000.

Concord, kōng'kōrd, an expression used in music denoting the combination of two or more sounds pleasing to the ear, and requiring no further combination before or after it to make it so. Concords are the eighth (or octave),

the fifth, third, and sixth. Their ratios are 2:1, 3:2, 5:4, 5:3. The two first are called perfect, because as concords they are not liable to any alteration by sharps or flats. The two last are called imperfect, as being alterable. The fourth is considered as a discord by some authorities; as a component part of an inversion of the perfect chord it may be classed among the concords. See COUNTERPOINT.

Concord, Book of (*Liber Concordia*), the name given to a collection of confessions of faith which are generally accepted by the Lutheran Church. The Formula of Concord (1580) was the result of a series of conferences and discussions upon the following subjects: The Rule of Faith and the Creed; Original Sin; Free Will; Justification; Good Works; The Law and the Gospel; The Third Use of the Law; The Lord's Supper; The Person of Christ; The Descent of Christ into Hell; The Customs of the Church; Predestination and Election; Heresies and Sectaries. The whole received the sanction of a large number of the Germans. Other subjects treated in the Book of Concord are: The Three Ecumenical Creeds—Apostles, Nicene, and Athanasian; The Six Particular Confessions of the Lutheran Church—Augsburg, Apology of the Augsburg, Schmalkald Articles, Catechisms of Luther (larger and smaller).

Concor'dance, a book in which the more important words of a volume or collection of writings are arranged alphabetically, part of a passage being extracted with each and the place of its use specifically given. The first known concordance of the Bible in any language was that of St. Anthony of Padua, who was born in 1195, and died in 1231. His work was called ('Concordantiæ Morales,') and was of the Latin Vulgate. It formed the basis of a more elaborate concordance, also of the Vulgate, that of Hugo de Santo Caro, better known as Cardinal Hugo. This was published in 1244 A.D. The first Hebrew concordance was that of Rabbi Mordecai Nathan, begun in 1438 and finished in 1448. The first Greek concordance to the New Testament was that of of Xystus Betuleius, whose real name was Birck; it came forth in 1546 A.D. The first English concordance to the New Testament was that of Thomas Gybson, before 1540 A.D.; the first to the whole English version of the Bible that of Marbeck, 1550 A.D. These, of course, preceded the appearance in 1611 A.D. of the authorized version of the Bible. The elaborate and well-known work of Cruden appeared first in 1737.

The first known concordance to Shakespeare was that of Ayscough, in 1790. Mrs. Mary Cowden Clarke's elaborate and most useful work was first published in London in 1845, and in 1894 appeared a still more excellent one, that of John Bartlett, published in New York. A concordance to Milton was published in Madras in 1856 and 1857, and one to Tennyson in London in 1870.

Concordat, kōn-kōr'dāt (*concordatum*, or, plur., *concordata*), a compact or convention entered into by the Holy See and a secular government to determine their respective powers and rights in the regulation of ecclesiastical affairs within the jurisdiction of the state which is a party to the compact. The earliest example of such compacts is the convention between Calix-

CONCORDIA — CONCRETE

tus II. and the Emperor Henry V., concluded at Worms in 1122: it marked the end of the great dispute about investitures. In 1448 was concluded the so-called concordat with the German nation, or with the Emperor Frederic III., under which the patronage of ecclesiastical dignities in the empire was divided between the imperial crown and the holy see. Memorable is the concordat of 1515 between Leo X. and Francis I.; the king agreed to annul the pragmatic sanction of Charles VII., which restricted the right of appeal to Rome; and in return the Pope conceded to the king the right of nomination to all Church benefices within the realm, with a reservation of the *annates* to the holy see, and with the proviso that the nominees should be acceptable to the Pope. Another celebrated concordat is that concluded 15 July 1801 between Pius VII. and Napolcon as first consul: it recognizes the legal existence of the Catholic Church in France which had been annulled by the revolution. The ecclesiastical topography of France was altered, the number of episcopal sees being reduced from more than 100 to 80. The confiscation of ecclesiastical property by the republican government was to pass for *fait accompli* and *res judicata* and the Pope and his successors were not to move to disturb purchasers or grantees of such properties. The government was to have the right of nomination of bishops, but the Pope that of canonical institution. Provision was to be made by the state for the support of bishops and clergy in lieu of their property, which had been appropriated by the Revolutionary Government. Ever since the concordat was concluded there has been in France an agitation for its abrogation, and this agitation was never more insistent than in 1903.

Concor'dia, or **Concord**, personified and worshipped as a goddess in Rome, where she had several temples, the most important of which was that in the forum, erected by Camillus. An annual feast was celebrated in her honor 16 January. She was represented with wreaths of flowers on her head, and in one hand a cornucopia, in the other an olive branch or a *patra*.

Concor'dia, Kans., a city and county-seat of Cloud County, situated on the Republican River and on the Atchison, T. & St. F.; the Missouri Pac.; and the Union Pac. R.R.'s, 110 miles northwest of Topeka. It has good water power and shows considerable manufacturing activity. There are iron-works and flour-mills and factories for making plows, wagons and cigars. Nazareth Academy is located here, and there is a United States land office. Pop. (1900) 3,400.

Concordia, kōn-kōr-dē'ä, Argentine Republic, a town of the state of Entre Rios, on the Uruguay, 302 miles north of Buenos Ayres by river. It has a custom-house and a river trade exceeded only by that of Buenos Ayres and Rosario, exporting salted meat and Paraguay tea. It has railway connection with Paraná, Uruguay, and South Brazil. Pop. about 13,000.

Concor'dia College, an educational institution in Fort Wayne, Ind., organized in 1839 under the auspices of the Lutheran Church; reported at the end of 1905: Professors and instructors, 10; students, 230; volumes in the library, 10,000; grounds and buildings valued at \$100,000; income, \$12,400; number of graduates, 950.

Concrete (Lat. "to grow together"), an artificial stone, a composition of hydraulic cement, sand and broken stone, used for foundations, especially submarine, and now more and more in place of building stone even when exposed to the air. In place of hydraulic cement pure lime was originally used and the name concrete applied only to this compound, "beton" being the proper term for the composition based on hydraulic cement until it became the only method. The mixture of sand and cement is termed the matrix, and the broken stone or other addition is styled aggregate and is composed of slag, coke, broken bricks, gravel or pebbles. The ideal aggregate is broken, sharply angular and irregular stone, as this material mixes better with the matrix than rounded pebbles, minute particles of gravel, or the more spongy brick, shell or coke, although broken stone or gravel may be used advantageously in connection with pebbles, even in such small proportion as 3 to 5. Broken limestone is considered especially efficacious as an aggregate, possibly because of an affinity between the molecules of carbonate of lime in it and the matrix. The proportions of the various parts approximate 1 part of cement, 1 to 3 parts of sand, and 4 to 6 parts of aggregate, but no fixed norm is to be followed the true rule being that the cement paste is to be thoroughly incorporated with sand coating each particle and that the matrix thus formed shall fill all interstices in the aggregate. In the process of mixture there are two extreme methods of watering, one very wet and the other scarcely more than moist. The spraying is followed by a mixture by shovel or by mixing machines. These machines are of two types: continuous, a trough or cylinder with a revolving screw shaft which works until the mixture is complete; and intermittent, a box being rotated slowly. The concrete is most commonly made into blocks, one layer of comparatively small depth being made at a time. By the newer method it is applied to its place on the building or foundation in the soft state and allowed to harden there. For submarine construction the concrete is usually sent under water in bags, which break because of pressure, or in closed chutes. While concrete is a comparatively modern invention, it was employed in ancient times, and in some of the most renowned works of history. The factitious stones employed by the Babylonians and the early Egyptians, as well as among the Greeks and Romans, and at the present day in Barbary and among the nations of Malabar, were all a species of beton. Pliny mentions that the columns which adorn the peristyle of the Egyptian labyrinth were of this material, and the great length of time it has existed (over 3,600 years) shows the durability of this mode of construction. In Rome the pyramid of Ninus is formed of a single block, as was also the square stone that formed the tomb of Porsena, which was 30 feet wide by 5 feet high. The Romans made free use of this material in constructing their walls, aqueducts, piers, and roads, many portions of which exist at the present day. The mole which shelters the harbor of Algiers is so much exposed to the effect of winds that breaches were continually being made in it by the force of the sea, and to such an extent that in former times the Moors were compelled to employ a large number of workmen constantly repairing it, at an annual

2. Wood Centering and Ransome Steel Bars for 50-foot Floor Span.

CONCRETE CONSTRUCTION

expenditure of over \$60,000. When the French commenced the reconstruction of the mole in 1833, after the failure of partial repairs, the first operation was to raise an outer embankment of large stones, under whose cover the foundation might be properly restored, it being intended to form this embankment of *pierre perdue*, that is, of stones thrown in at random, and allowed to arrange themselves to the necessary slope for equilibrium by the action of the sea. But during the first ensuing winter the embankment was completely destroyed by the action of the waves, one block of 141 cubic feet having been carried completely across the mouth of the harbor. This rendered it necessary to rebuild the entire embankment of blocks so large that no action of the sea could move them; this was of course possible, since the action is proportioned to the surface struck, while the resistance of the block increases as its mass, and there must necessarily be a point where the latter predominates; this was found on trial to be about 353 feet. The expense of quarrying and transporting such enormous blocks of stone, led to the employment of artificial stone or beton. Two kinds of blocks were manufactured: the first in the water, in the place they were intended to occupy, and the second on shore, to be afterward thrown into the sea. In the process of reconstruction, these blocks were used as follows: Those of the first kind, made in lined caissons, formed an outer sea line; on these blocks molds were placed filled with beton, and after these second blocks had set, they were launched into the sea, forming a line in front of the first; the intervening space was then filled up with blocks of natural stone. Behind this embankment thus formed, the ground was dredged to a depth of over six feet, and the whole of this space filled up with a continuous mass of beton. The entire work was performed in five years, at a cost of less than \$420,000, notwithstanding that the mole, at the time of the occupation of Algiers by the French army in 1830, was in a state of complete dilapidation, in spite of the extensive repairs which had been annually executed upon it by the Moors during a period of two centuries. Marine works of the above character present numerous advantages over constructions in which natural stone is employed, of which the following are some of the most prominent: (1) immediate stability, while ordinary *pierre perdue* is never secure; (2) incomparably greater facility in transportation, which is always expensive and troublesome when blocks of stone are to be quarried exceeding 100 cubic feet; (3) a considerable reduction in the sectional area of the pier, and consequent economy of cost; and (4) that the system can be applied in every locality, now that our advanced knowledge of the subject of hydraulic mortars enables us to manufacture beton in any place where it may be needed. On the use of concrete in modern building consult I. O. Baker, 'Treatise on Masonry Construction' (1900).

Concrete Construction. The use of concrete for purposes of construction, while not entirely a new idea, has within the last few years received an enormous impetus, and its use for all kinds of engineering construction has been thoroughly tested by American engineers. As a substitute for stone, steel, hollow tile, etc., its service has been demonstrated by a constantly increasing use. Concrete may be defined

as an artificial stone. It can be used for all structural purposes as a substitute for stone and in addition it has a wide variety of applications where the use of stone is impracticable.

Composition.—Concrete is composed of broken stone or gravel, sand and cement with the addition of water sufficient, after allowing for evaporating and absorption, to unite chemically with the cement. A typical concrete is made as follows: To one barrel of a standard Portland cement is added three barrels of clean sharp sand. The two are intimately mixed—either manually or by a mechanical mixer—and then enough water is added to bring the mixture to a certain consistency, the proper amount of water being readily judged by one experienced in this work. Five barrels of broken stone are then added, the whole thoroughly intermixed and the concrete thus formed is ready to be conveyed to the forms or the excavations prepared for it. Concrete made in the above proportions would be known as a 1:3:5 mixture. The permissible proportions, however, vary widely from 1:2:4 to 1:5:10 according to the nature of the ingredients and the service for which it is intended. In general, the concrete with the smaller proportion of cement will not sustain the same strains as the concretes wherein the proportions are about as indicated in our typical mixture.

The composition of a properly proportioned concrete may be thus considered; sand fills up the interstices between the pieces of rock, and the cement, in turn, fills up the interstices between the particles of sand and between the sand and the rock. As 90 per cent of a standard cement will pass through a sieve of 10,000 meshes to the square inch, it is evident that the cement will effectually fill up all the voids. But the cement also performs an even more important function. It enters into chemical combination with the water used in mixing and acts as a binder, tenaciously holding the whole mass together. As soon as the cement is mixed with water this chemical change commences, or the concrete begins to "set" as it is generally expressed. Therefore the concrete must be put in place immediately after mixing. At the end of about three or four days, the concrete is solid enough for the supporting forms to be removed and after possibly thirty days it is ready for the loads for which it is designed. The hardening continues for months and the concrete becomes stronger as time elapses.

Merits and Advantages.—Concrete as a material for construction has been known for centuries. Some of the most enduring monuments of antiquity are constructed either wholly or in part of this material. The dome of the Pantheon, erected at the beginning of the Christian era, is built of concrete, as are some of the other historic structures of that period. Concrete has ever since been used to a greater or less extent. With the discovery and application of the methods of making Portland cement, which we may ascribe to the period 1820-50, concrete assumed its place as one of the principal materials of engineering and we may say that each year has shown an increase in the amount of concrete construction with a constant widening of the field of its application. Concrete reinforced with steel, has been successfully used in office buildings, apartment houses, theatres, schools, court-houses, public libraries, factories,

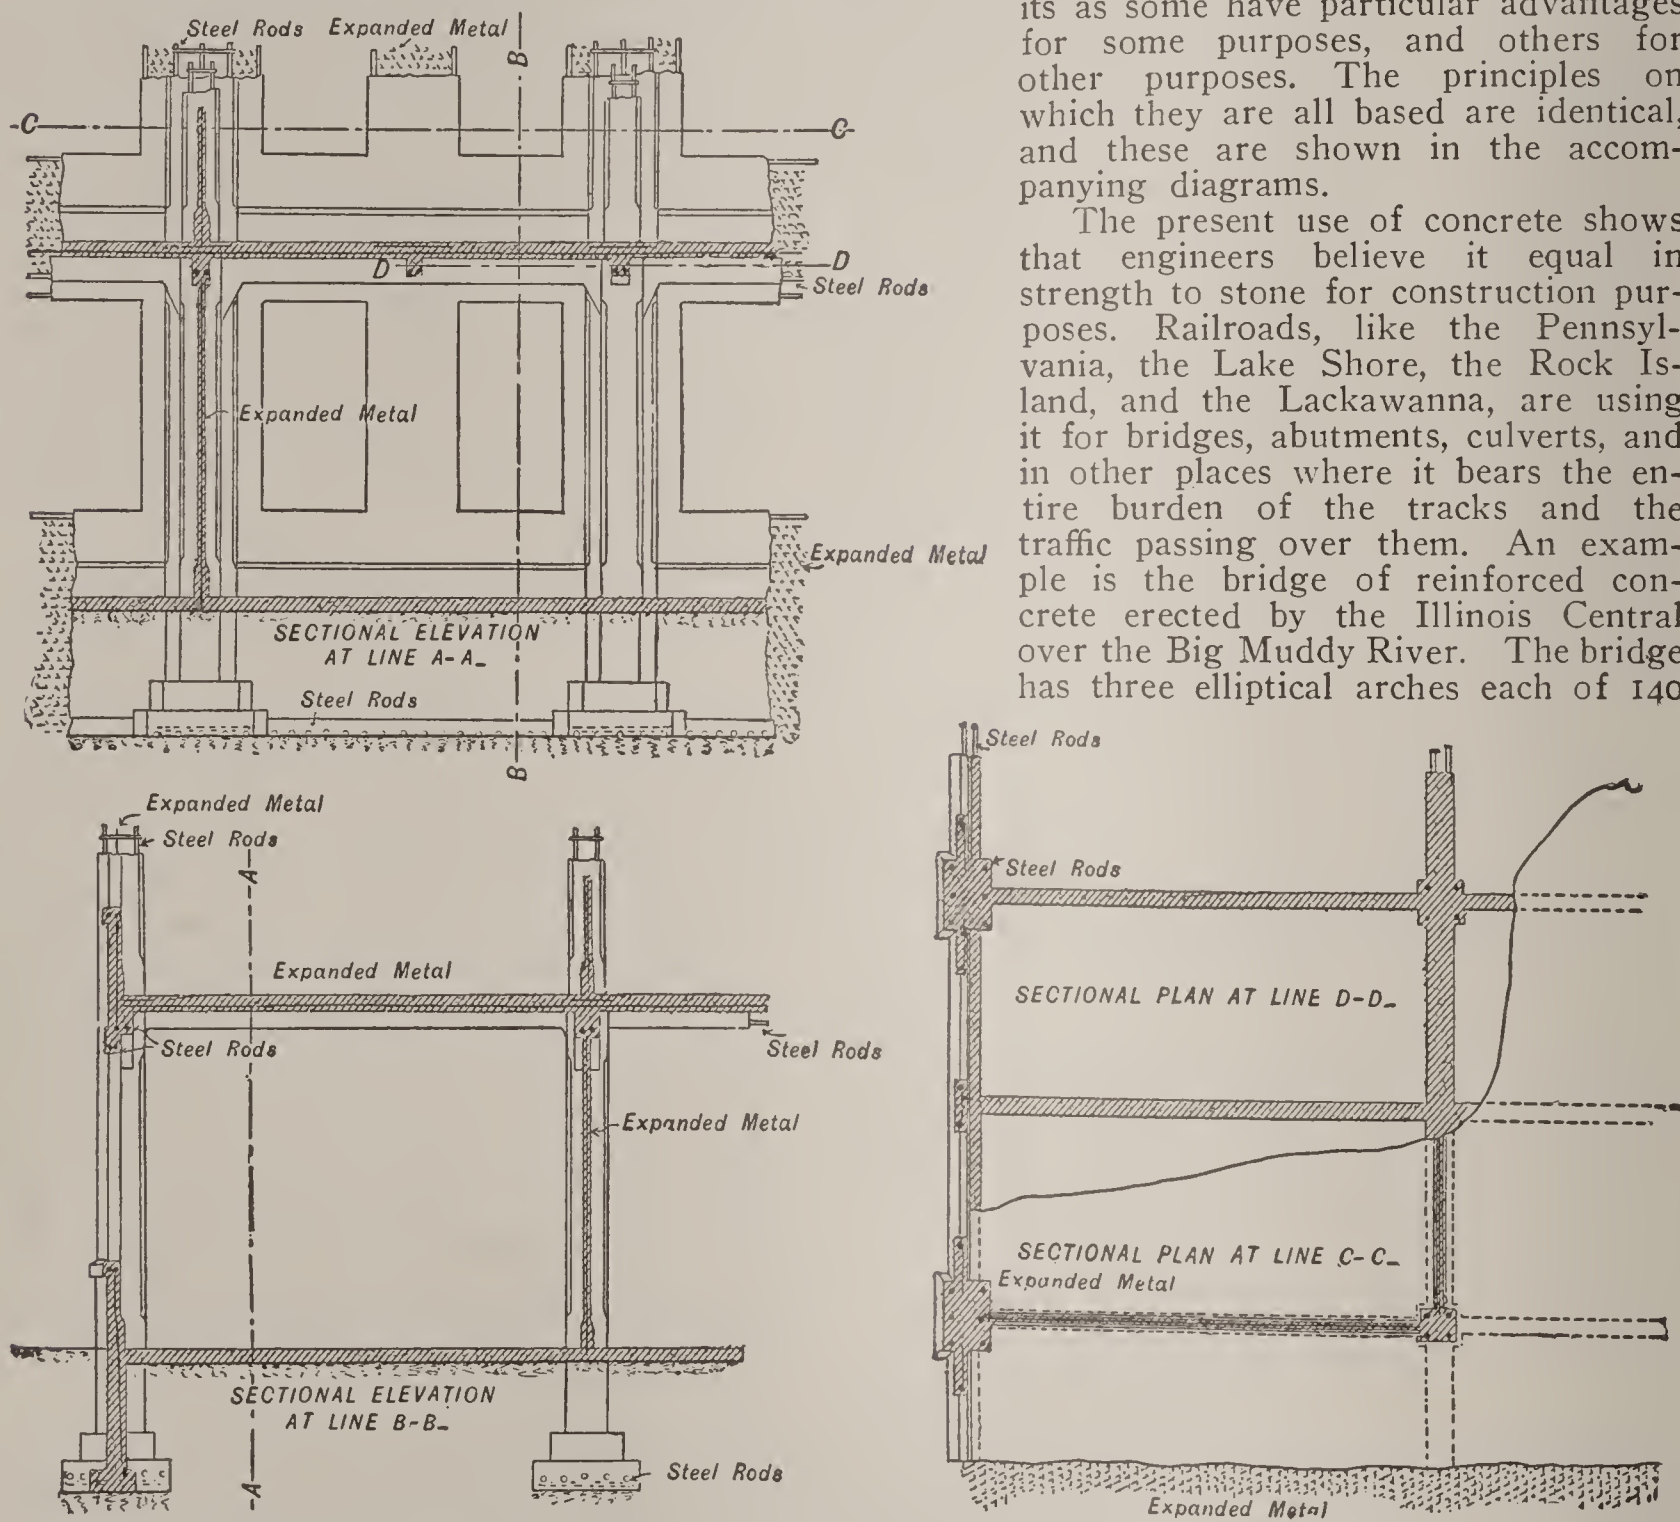

CONCRETE CONSTRUCTION

mills, warehouses, foundries, grain elevators, stables, cisterns, bins, stand-pipes, bridges, culverts, abutments, sea-walls, breakwaters, jetties, piers, reservoirs, tanks, dams, aqueducts, sewers, subways, dust-chambers, and chimneys, besides a great number of minor uses in buildings constructed primarily of other material.

The fact that concrete can be molded into any form desired is a most valuable quality and one which is largely availed of in practice. Aside from such uses as being simply deposited for foundations, abutments, etc., it is molded into shapes as intricate as may be desired, one of the recent applications which is being exten-

predicted. Concrete will withstand enormous compression strains. When heavy strains other than those of compression are to be provided for, the concrete is so strengthened with steel that the metal takes the tensile and shearing strains, and the concrete the compression strains. This construction, known as armored or reinforced concrete, is rendered entirely feasible by the facts that concrete has considerable adhesion for iron and steel, and the co-efficients of expansion (by heat) of the two materials are practically identical. There are a number of "systems" of reinforcing concrete with steel. We need not here discuss their relative merits as some have particular advantages for some purposes, and others for other purposes. The principles on which they are all based are identical, and these are shown in the accompanying diagrams.

The present use of concrete shows that engineers believe it equal in strength to stone for construction purposes. Railroads, like the Pennsylvania, the Lake Shore, the Rock Island, and the Lackawanna, are using it for bridges, abutments, culverts, and in other places where it bears the entire burden of the tracks and the traffic passing over them. An example is the bridge of reinforced concrete erected by the Illinois Central over the Big Muddy River. The bridge has three elliptical arches each of 140

Reinforced Concrete Building Sections Showing Column, Pilaster, Floor Beam, Girder, Footing, Curtain Wall and Partition Construction.

sively developed at the present time being the use of concrete for making hollow blocks for building purposes. The facility with which it can be molded for producing decorative effects, is, of course, well known. Another highly important advantage resulting from the plasticity of the newly-mixed concrete is that other materials, such as iron, may be imbedded in it.

The strength and durability of all concrete depend, of course, upon the quality of the ingredients and the care exercised in mixing and handling. When the work is done under experienced supervision, however, the characteristics of the resulting concrete can be accurately

feet clear span. It was erected at less cost than a bridge of structural steel, it is more enduring and is decidedly more pleasing to the eye. A typical bridge of concrete alone, built on the straight masonry principle, is that of the Pennsylvania Railroad over the Susquehanna River, near Harrisburg, Pa. This structure is faced with a thin veneer of natural stone, which is not, however, an essential part of the structure. The United States government is using concrete in enormous quantities for all sorts of purposes. In the reconstruction of the fortifications around New York harbor during the last few years, concrete has been used to the practical exclusion

FIG. 2.

FIG. 4.

CONCRETE CONSTRUCTION

of all other materials. In other words, the 13-inch guns which guard the City of Steel-frame Skyscrapers are mounted on concrete foundations and are protected from hostile projectiles by the same material. The Ingalls Building, Cincinnati, Ohio, 16 stories high, is made entirely of reinforced concrete. The plans for this building were approved by the city authorities only after a great number of tests had been made which proved beyond the possibility of doubt that the building would be absolutely safe. Concrete enthusiasts predict that this building will be standing long after the steel skeleton structures in the neighborhood have disintegrated. The deterioration of steel when pro-

for from 10 to 15 years, showed no signs of rust or other external deterioration. A lining of "rich" concrete has been found to be the only material which will withstand the corrosive action of the acids in the large storage tanks or vats at pulp mills.

As regards the all-essential quality of ability to resist fire, concrete is absolutely and unqualifiedly superior to all other building materials. This has been shown many times in tests conducted by the building and fire departments of various large cities in this country and abroad. The usual way of conducting such tests is to build a small structure of concrete and to maintain therein a fire of a temperature of about

Floor construction, with ceiling clipped to I-beams.

Method of reinforcing water-mains, sewers, etc.

tected by nothing more than terra-cotta slabs, noted in a number of cases, tends to lend strength to this view. In fact, superior durability is one of the best-substantiated claims for concrete buildings. It has long been recognized that concrete becomes stronger with age, and the same is not true of any other material. Engineers are divided in their estimates as to how long a steel-framed structure will endure.

In reinforced concrete construction the steel is completely imbedded in the concrete which absolutely protects it from fire as indeed it does from rust and all other corrosive action. It has been demonstrated in several instances that cast-iron piping which has been covered with a coat of liquid neat cement and buried underground

1,700° F. for a number of hours. A stream of water is then turned on the fire and concrete and results are carefully noted. In general, a few hair-like cracks in the concrete is the only effect noticeable, the strength of the material being unimpaired. In the great Baltimore conflagration every known type of construction was subjected to the flames. After the fire, engineers came from all over the country to observe what type of construction had best withstood the fire. The opinion of these experts was strikingly unanimous and decisive to the effect that concrete has stood up better than the steel frames with terra-cotta protection and, of course, better than brick and stone. Prof. Norton of the Massachusetts Institute of Technology re-

CONCRETIONARY STRUCTURE

flected the general expert opinion in his report to the 'Boston Transcript': "Stone, whether granite, marble, sandstone or limestone fared badly. Where floor arches and steel coverings were of concrete they stood the test much better than terra cotta. This was due probably to the fact that concrete and steel expand at the same rate while terra cotta expands $2\frac{1}{2}$ times as fast as steel and so the partitions or floor arches buckle or break. In general, the unfitness of terra cotta for beam and post covering and floor construction in comparison with concrete was demonstrated."

Cost.—It might be expected that a material with so many desirable qualities would be more expensive than the materials which it is displacing. The contrary is the case. Concrete is cheaper than stone, or steel frame and terra cotta. It can be manipulated by unskilled labor to a greater extent than any other material. There are many localities in the country where no stone suitable for building purposes exists, but where there is much stone admirably adapted for being crushed and used for concrete. In short, the raw materials for concrete can be laid

and more compact than the rest of the clay, and presenting forms in imitation of nuts, fruits, and different organic substances. The resemblance is so striking that common observers are satisfied that they see actual relics and petrifications instead of mere aggregations of inorganic matter. Through each one of these clay concretions a hole may be traced, which was at some time filled with a rootlet, the carbonaceous residue of which, if not the form of the root itself, may be observed. This appears to have been a nucleus around which the material collected, following the law of attraction by which neighboring particles of the same composition seek out and join with each other when in a medium that admits of their movement. In argillaceous deposits, even among the older stratified rocks, the same tendency appears to have obtained after the deposition of their materials. The calcareous portions separated from the shaly or sandy strata, and arranged themselves in these concretionary layers. But if the quantity of calcareous matter was sufficient to form a stratum of itself, this force appears not to have been exerted to produce the spheroidal

The trussed steel bar for concrete reinforcement.

down at almost any point in this country cheaper than any other material and the cost of putting it in place is less. It will therefore be seen that the strength and durability of concrete, the ease with which it may be reinforced with steel to form a combination of universal applicability, its fire-resisting and time-defying qualities and its low first cost, stamp it as the great construction material of the future.

R. H. JOHNSTON,
Of Engineering Company of America, New York.

Concretionary Structure. Among the strata of rocks formed by deposition of sediment it is a common thing to find lumps of material differing more or less in chemical composition from the strata in which they lie, and, though separated from each other by short intervals, still arranged in layers conforming to the general stratification. The balls of argillaceous iron ore found in the shales of the coal formation are examples of these concretions. They have no regular form, but are generally flattened spheroidal masses, and are commonly called "kidney-shaped." In the clay beds of the Tertiary group, in various parts of the country, are found curious collections of clay concretions, harder

masses; except occasionally the rock is said to have a concretionary structure when it displays a tendency to form here and there along its course bunches or knots, as if these parts had curled and rolled over, presenting very much such an appearance as is observed in very gnarled and knotty wood. In the shales of the Lower Secondary in New York State, particularly in those of the Hamilton and Portage groups, numerous dark-colored calcareous concretions are found of extraordinary size and forms. They abound along the shore of Lake Erie, washed out of the banks by the action of the waves. Very often they are formed about some nucleus of entirely different substance from their own as a fossil shell or a nodule of iron pyrites; and the fossil shell not infrequently has first served as a nucleus for an incrustation of pyrites, by which it was completely buried before both were concealed within the large concretionary mass. After the forming and hardening of the concretions, they appear to have cracked by shrinkage, the cracks sometimes radiating from the centre or taking other irregular directions. The cracks afterward became filled with light-colored clay or calcareous matter, and now appear like mineral veins. As the shape of these bodies often

CONCRETIONS — CONDE

approaches that of the large sea turtles, and the seams resemble the divisional lines of the plates of the shell, they are very naturally supposed by most people who meet with them to be the petrified remains of this animal; and looking at those specimens deposited in the State collection at Albany, one may well suppose that this common belief will not soon be corrected. At Erie and other places in this part of Pennsylvania, concretions in a light-blue limestone are found, which consist of a number of cones closely arranged side by side, and forming a thin layer not more than two inches thick, of which the flat base of the cones constitutes one side, and their points reach nearly through to the other. Little is known of the laws that have caused these matters thus to assume at different localities similar, and, as they appear, fantastic forms. Extraordinary clay concretions from the banks of the Park River in Hartford, Conn., are to be found in many museums.

Concretions, Morbid, in animal economy, hard substances that occasionally make their appearance in different parts of the body, as well in the solids as in those cavities destined to contain fluids; in the former case they are denominated concretions or ossifications; in the latter, calculi. The concretions are named from the parts of the body in which they occur. Pineal concretions, from their being found in that part of the brain called the pineal gland, consist of carbonate and phosphate of calcium with organic matter; salivary concretions, as being discovered occasionally in the salivary glands, also consist mainly of earthy phosphates; pancreatic concretions are hard substances found in the pancreas; pulmonary concretions, which have been sometimes coughed up by consumptive persons, contain mucus and albumen in addition to the salts; hepatic concretions, of which the liver is sometimes full, are composed chiefly of cholesterin, mucus, and coloring matter; urinary concretions are found in the bladder, and their constituents are very variable, uric acid, urates, fibrin, oxalates, phosphates, and several other bodies being found. Gouty concretions consist of urate of sodium and small quantities of other salts with organic matter. Concretions have been discovered in the intestines and stomach of man, but more frequently in the bodies of other animals. Those found in the intestines of a horse were examined by Fourcroy, and found to consist of magnesia, phosphoric acid, ammonia, water, and animal matter. See **CALCULUS**.

Concu'binage, the cohabitation of a man with a concubine. Among the Greeks concubinage was allowed even to married men: the number of their concubines, also, was unlimited. Among the Romans concubinage was neither unlawful nor disgraceful. It was moreover, formally permitted to unmarried men by the Lex Julia, and by the Lex Papia Poppæa, but with the provision that it should be limited to a single concubine, and that only women of mean descent, as freed women, actresses, and the like, should be chosen for the purpose. The children begotten in concubinage were not considered as legitimate, but were called natural, and the right of inheritance of the concubine and her children was very much limited. With the introduction of Christianity concubinage ceased; and, indeed, Constantine the Great made

laws intended to put a stop to it. Concubinage also signifies a marriage with a woman of inferior condition, to whom the husband does not convey his rank. By French law the presence of a concubine in the house entitles the wife to a divorce. The term is used in a more general sense to mean the cohabiting of a man and woman who are not legally married.

Concurrent Jurisdiction, the jurisdiction of different courts authorized to take cognizance of the same case. In criminal cases the court which first takes up a case has what is called the right of prevention, that is, the right of deciding upon that case exclusive of the other courts, which but for that right would have been equally entitled to take cognizance of it. In civil cases it lies with the suitor to bring his cause before any court he pleases, which is competent to take it up. Concurrent, also called cumulative, jurisdiction is opposed to privative jurisdiction.

Concussion of the Brain, a term applied to certain injuries of the brain resulting from blows and falls, though unattended with fracture of the skull. Stupor or insensibility, sickness, impeded respiration, and irregular pulse are the first symptoms, and though these may subside there is always for a time more or less risk of serious inflammation of the brain setting in. The patient should be put to bed at once with the head low, and kept warm; but stimulants should, except in special cases, be withheld. All excitement should be avoided, and for some time after apparent recovery great care is necessary.

Condé, kôn-dā, the name of a French family, the younger branch of the Bourbons, who took their name from the town of Condé, department of Nord. One Godfrey de Condé, about 1200, was in possession of a part of the barony of Condé. His great-granddaughter, Jeanne de Condé, married in 1335, Jacques de Bourbon, Comte de la Marche, and the barony of Condé went to their second son, Louis de Bourbon, Comte de Vendôme, whose great-grandson, Louis de Bourbon, Prince of Condé, in virtue of his blood-relationship to the royal family, assumed the title of Prince, and is regarded as the founder of the new house of this name.

Condé, Henri (õn-rē) II. de Bourbon, PRINCE DE: b. 1588; d. 1646. At the request of Henry IV. he became a Catholic. In 1616 he was sent to the Bastille, where he remained for three years. After the death of Louis XIII. the prince was liberated, and was made minister of state to the regent.

Condé, Louis (loo-ē) I. de Bourbon, boor bôn, PRINCE DE, French general: b. Vendôme 7 May 1530; d. 15 May 1569. He married the grandniece of the Constable de Montmorenci. He served his early campaigns in Piedmont, but first distinguished himself at the defense of Metz, besieged by Charles V. in 1552. Affronted at court, and hated by the Guises, he joined his brother, the king of Navarre, at Nérac, and became a Protestant. In 1560 he was arrested and sentenced to death, but was discharged after the death of Francis I. He soon after appeared as head of the Protestants, and was defeated and captured at the battle of Dreux. In 1567 he fought the battle of St. Denis without decisive result. Two years later the Protestants were defeated, and Condé was slain at Jarnac.

CONDÉ — CONDENSED MILK

Condé, Louis II. de Bourbon, PRINCE OF, French general: b. Paris 8 Sept. 1621; d. near Fontainebleau 11 Dec. 1686. He was the son of Henri II., Prince de Condé (q.v.) and during the life of his father bore the title of Duc d'Enghien. He immortalized this name at the battle of Rocroi, in which, at the age of 22, he defeated the Spaniards (1643). Wherever he appeared he was victorious. He besieged Dunkirk in sight of the Spanish army, and gained this place for France in 1646. During the troubles of the Fronde he at first took the side of the court against the parliament and the nobles, and after a siege of a few months brought back the young Louis XIV. to Paris (1649); but believing himself ill requited by Mazarin for his services he put himself at the head of the faction of the *Petits Maîtres*. Being captured, however, he was imprisoned by Mazarin (1650), and was not released till after the lapse of a year. He at once put himself at the head of a new Fronde, and entered upon negotiations with Spain. In spite of several checks he then marched upon Paris, where he was met and opposed in the suburb St. Antoine (1652). The battle which ensued was indecisive; and Condé, finding himself abandoned by many of his friends, retired to the Netherlands, and joined the Spaniards, who appointed him generalissimo of the Spanish armies. In 1658 he was defeated before Dunkirk, by Turenne, and was only restored to royal favor by the Peace of the Pyrenees in 1659. In 1668 he was charged with the reduction of Franche Comté (then belonging to Spain), which he accomplished in three weeks; and in 1674, at the head of an army sent by Louis XIV. against the United Provinces, defeated the Prince of Orange (afterward William III. of England) at Senef. He was unable, however, to take advantage of this victory, as he was obliged to withdraw into Alsace to defend it against Montecuculi, to whom it was thrown open by the death of Turenne in 1675. He succeeded in driving Montecuculi across the Rhine. This was his last triumph. Four years later he retired to Chantilly, near Paris, where he devoted himself to the sciences.

Condé, Louis Joseph (loo-ē zhō zěf) de Bourbon, PRINCE OF: b. Chantilly 9 Aug. 1736; d. Paris 13 May 1818. In the Seven Years' war he distinguished himself by his courage and skill, and afterward formed in 1792, at Worms, a little corps of emigrant nobility, which joined the Austrian army under Wurmser. In 1795 he entered with his corps into the English service. In 1797 he entered the Russian service, but in 1800, after the separation of Russia from the coalition, reentered the English service. The campaign of 1800 ended the military career of the prince. He returned to Paris in 1814; where, being appointed president of a bureau of the chamber of peers, he remained some time, but at last retired to Chantilly. He published: 'Essai sur la Vie du Grand Condé, par L. J. de Bourbon, son 4me Descendant' (1806).

Condell, kün'děl, Henry, English actor: d. Fulham, England, December 1627. With John Heming (q.v.) he edited the famous first edition of Shakespeare's plays, 1623. He belonged, as did Shakespeare, to the lord chamberlain's company of players and is named in Shakespeare's will.

Condensa'tion, the reduction of anything to another and denser form, as of a vapor or gas to a liquid, or a liquid to a solid; the passage of gases or vapors from the aëriform to the liquid state. It is sometimes called also the liquefaction of vapors. It may be due to one of three causes: cooling, compression, or chemical affinity. Before the first or second of these causes can operate, the vapor must be saturated. Various salts also condense vapors by means of chemical affinity. When vapors are condensed their latent heat becomes free. The condensation of liquids is the reduction of a liquid to smaller bulk, with a proportionate increase in the specific gravity.

Condensed Milk, Definition. Condensed milk as generally manufactured and sold fresh daily for delivery to consumers is pure cow's milk reduced in volume by the evaporation of water in vacuum. No other constituent part of the milk is removed. This article is not put up in hermetically sealed cans nor intended for long-distance shipments.

Condensed Milk, Preserved, as generally manufactured and sold is pure cow's milk reduced as above, but having refined granulated sugar added in proper proportion for the purpose of preservation.

Condensed Skimmed Milk is prepared by removing all or part of the butter fats and then reducing in volume as above described. The dairy laws of various States and the rulings of boards of health are, however, designed to prevent its manufacture and sale.

Evaporated Cream is a trade name established by usage for unsweetened condensed milk sold in hermetically sealed cans which is condensed to a creamy consistency. It is prepared by removing water only and by means of the vacuum process. It is sterilized after the cans are sealed and will keep indefinitely in any climate, being very little affected by heat or cold, dryness or dampness.

Early Experiments.—The first application of a practical process for condensing milk was made by Gail Borden, who was born in Norwich, N. Y., in 1801, and at the time of his experiments a resident of New York, through his adaptation of the vacuum evaporating process on original lines. Most of the earlier experiments of previous investigators were what might be called "open process." The earliest known patents for reducing the volume of milk or attempting to preserve it are the following:

Newton, 1835.—For evaporating "in any known mode," alludes to the vacuum pan as affording a good method of introducing warm air through the milk!

De Lignac, 1847.—Evaporating in large, flat, shallow pans, heated by steam bath to 186 degrees F.; product put in tins, sealed, and again heated to 210 degrees F.

Grimwade, 1847.—Preserving milk by "the mixing of saltpetre with the milk, and then exposing it to heat in vacuo, so as to evaporate and extract the aqueous particles thereof," and then enclosing "in bottles from which the air has been previously exhausted." Never put in practice.

Louis, 1848.—Evaporating in shallow pans, with steam jackets, etc.

Grimwade, 1855.—Carbonate of soda or potash is first added and the milk then evaporated in pans with agitation until a doughlike substance is obtained; sugar is then added, and the mass pressed by rollers into ribbons, further dried, and then pulverized. Practiced for some years.

Cooke, 1855.—Evaporating in steam evaporating pans.

CONDENSED MILK

Borden, 1856.—In vacuo, put into successful practice and has superseded all others.

House, 1857.—Substantially like De Lignac's, except evaporating at lower temperature.

Gail Borden's experiments began shortly after 1851 and his first application for a U. S. patent was made in 1853 which was at first rejected on the ground that it lacked novelty and usefulness. The patent, however (No. 15,553), was granted 19 Aug. 1856 on the following claim:

Producing concentrated sweet milk by evaporation in vacuo, substantially as set forth,—the same having no sugar or other foreign matter mixed with it.

This was followed by other patents: No. 1,306, dated 13 May 1862; No. 1,389, dated 10 Feb. 1863; No. 2,103, dated 14 Nov. 1865; No. 2,226, dated 17 April 1866. Every feature of Borden's various claims as well as the state of the art was carefully and thoroughly investigated by the patent office examiners.

Necessary Sanitary Regulations.—Experience covering a period of over half a century establishes the fact that the sanitary precautions surrounding the manufacture of condensed milk, evaporated cream, etc., are the most stringent and necessarily so because the safety of the business depends on thoroughness. Not only are the cattle inspected by competent veterinaries, but rules and regulations of the strictest kind provide for the cleanliness of these cattle, proper feeding of wholesome, non-fermenting foods, cleanliness of stables, the isolation of the milk-room, cooling facilities, in fact every well tested plan that facilitates the production of pure, rich milk handled in the most cleanly manner. While seemingly these rigid requirements involve some extra expense on the part of the dairyman, he is more than compensated by having a steady, firm market for his product at better prices than he can get anywhere else. The consumer is benefited by obtaining a pure and uncontaminated product at a most reasonable price. There are concerns, of course, in the business whose facilities and experience do not enable them to perform all of this work as thoroughly as the older concerns who have been at it many years.

The Receiving Platform is an interesting sight, for as the farmers deliver their cans of milk each is examined by a trained inspector and tested; if not found to be up to the standard required by the company, it is rejected. From the receiving room the milk is drawn into what is called the "well-room," where the preliminary heating is done in peculiarly constructed heating wells, and if it is to be preserved milk, the necessary sugar is dissolved and mixed with it. From this point it goes to the vacuum pan where the condensing process takes place in accordance with formula as to temperature, vacuum, etc., as found by the manufacturers to be best qualified for making the various grades. The water is removed more or less to obtain a certain density. From the vacuum pan it is drawn into cans and cooled to the desired temperature. From this point, if it is to be condensed milk, it is ready for canning and goes to the sealing room for this purpose, being filled into the various receptacles through filling machines of interesting mechanism, sealed, packed, and sent to the warehouse for final shipment.

If evaporated cream is to be made, from the

sealing room it goes to the sterilizing room where the necessary sterilizing of the sealed package is performed and from this point goes to the storage room.

A condensed milk plant properly operated buys its supplies in large quantities; tin plate for making its cans (each factory containing a complete can-making tin-shop); lumber in shooks for making boxes; so that nearly all the work incidental to completing the product is done in the factory. Such a plant represents a large investment.

Errors of Previous Authorities and Reports.—Some of the earlier descriptions of the manufacture of condensed milk have erroneously stated that it was the general practice to remove a part or all of the cream before manufacture. This has never been practised except by an occasional concern desirous of evading the law, to increase its profit. The dairy laws of the several States where most of the milk is manufactured are very rigidly enforced to prevent removing any part of the cream from the natural fluid milk.

Chemical Analysis.—As condensed milk forms such a very large and important item of food, especially for the infant, it is proper in this article to incorporate information on the question of analysis that the public may be correctly informed on the subject. To determine the butter-fats in plain condensed milk or evaporated cream is comparatively easy, but with the preserved milk where cane-sugar is present it is a difficult piece of work except when performed by a chemist of considerable experience who has made a special study of the matter, for the fat cannot be correctly estimated unless precautions are taken to eliminate the influence of the cane-sugar during the extraction of the fat.

It has become a common error on the part of boards of health whose chemists are not always thoroughly experienced in the business to erroneously designate a brand of milk as skimmed or partly skimmed when the error is solely in the work of the analyst. Prof. J. F. Geisler of New York, who has probably had as wide experience in this especial work as any chemist living, in a paper read at the 21st general meeting of the American Chemical Society, June 1900, pointed out some of the difficulties in the way of proper analysis of condensed milk preserved with sugar. He states as follows:

"There is an abundant and cumulative evidence to show that the correct analysis of sweetened condensed milk is difficult and has proved to be a stumbling block to the efforts of many chemists.

"A law of New York State requires that no condensed milk shall be made—unless the proportion of milk solids shall be in quantity the equivalent of 12 per centum of milk solids in crude milk and of which solids 25 per centum shall be fats." Sec. 25, Chap. 143, L. 1894.

"Aside from insufficient condensation, it is generally assumed that skimming or the removal of butter-fat is the principal temptation to defraud on the part of the manufacturer. To prove skimming, the first essential is the accurate estimation of the fat, assuming the per cent of fat obtained to be butter-fat. That is to say, the mere finding of the required per

CONDENSER

cent of fat, and ratio of fat to milk solids would not prove such milk unadulterated unless the fat found was actually butter-fat.

"The recurring frequency of unjust condemnation of condensed milk makes it particularly necessary for chemists to exercise great caution in expressing opinions upon whether a milk is skimmed or not. There are instances on record where sweetened condensed milks with high content of cane-sugar and of unquestioned purity were condemned as adulterated on the strength of the analysts finding low percentages of fat (3.8 per cent lowest and a considerable number ranging from 5.5 to 6.8 per cent) when more accurate methods demonstrated the presence of over 8 per cent of fat in all the samples.

"The effective manner in which the cane-sugar prevents the action of the solvents upon the fat is well illustrated in the asbestos-tube method for fat estimation, in which 20 cc. of a 20 per cent solution of the milk (4 grams) is deposited upon asbestos fibre, and, after drying, exhausted with petroleum ether. This method has been the means of the unjust and unwarranted condemnation of quite a number of condensed milks. It has been proved that the method failed to exhaust all the fat, often 2 to 3 per cent remaining in the residue, as has been amply demonstrated by exhausting the residue with water and recovering the shortage of fat in the residuum. The asbestos method has found favor in many quarters and was the direct cause of condemnation of pure milks in several instances.

"Even the coil method, which is extensively used by analysts, unless certain precautions are taken, has its pitfalls. The quantity of milk taken for the extraction is not a matter of indifference, nor is the solvent, or the method of extraction.

"As ordinarily applied, the following shows the errors of the coil method: Forty-nine separate examinations showed differences for the second exhaustion of 0.27 to 1.2 per cent. That is to say, if the precaution of exhausting the coils with water had not been taken, the fat in the milks would have been underestimated from 0.27 to 1.2 per cent in actual per cent of fat by the coil method. The large variation is due principally to the varying per cent of cane-sugar in the different samples.

"Accuracy in fat estimation to within 0.2 per cent in sweetened condensed milk is certainly attainable where the necessary precautions are taken. Where 2 grams of the condensed milk are taken the results cannot be depended upon, however, as representing the full yield of fat, unless the exhausted and dried coil is exhausted with water, and again exhausted with volatile solvent.

"A difference of 0.5 per cent fat has a very important bearing in the enforcement of a law defining the fat contents in milk solids. This is particularly true when the Ritthausen method is used for the estimation of the albuminoids, any error in the fat estimation reflecting its deficiency in increase of the albuminoids (the albuminoids being determined by difference) so that the ratio between fat and albuminoid is distorted to a degree which would reflect seriously upon the milk under examination, and indicate probable skimming.

"This no doubt accounts for the discrepancy in quite a number of published analyses of the excess of albuminoid over fat in what probably were unskimmed milks. When such discrepancies are noticed in an analysis it is advisable to check the results by a nitrogen estimation by the Kjeldahl method, if this was not used in the first instance."

Food Value.—An analysis of condensed milk (preserved) of high average quality would be about as follows:

Fat			9.82	
Milk sugar	}	Carbohydrates	{	12.49
Cane sugar				40.50
Albumin	}	Albuminoids proteids	{	8.80
Casein				
Ash			1.90	
Water			26.49	
			100.00	

Evaporated cream of the same high quality would contain the following constituent parts:

Fat			9.52	
Milk sugar and albuminoids.....			20.93	
Ash			1.90	
Water			67.65	
			100.00	

Of all the foods available to the public, it is doubtful if any rank as high in purity, keeping quality and uniformity, for infant feeding, household uses, for supplying the army and navy, shipping trade, exploring parties or pioneer life; no food article prepared has greater value.

The world in the broadest sense has been blessed by the development of Gail Borden's invention.

WILLIAM J. ROGERS,
President Borden's Condensed Milk Co.

Condenser, one who or the thing which condenses. Some of the methods in general use are:

Steam-engine.—An apparatus for reducing to a liquid form the steam in front of the piston, so as to obtain a partial vacuum at that point, and thus utilize the natural pressure of the atmosphere. Watt invented the injection condenser and the separate condenser. The surface condenser has a series of flat chambers or tubes, usually the latter, in which the steam is cooled by a body of water surrounding the tubes. Distilled water for ships' use is obtained by the condensation of steam in a surface condenser.

Distilling.—The still-condenser is an apparatus generally made of the worm-tube form; the coil containing the alcoholic vapor traversing a tub which receives a constant accession of cold water, condensing the vapor in the coil. The liquid escapes at a cock valve below.

Metal.—An apartment in which metallic or deleterious gaseous fumes are condensed to prevent their escape into, and contamination of, the atmosphere. The device consists of a prolonged duct for the fumes, with showers of water to condense the arsenical, sulphurous, and other fugitive volatile matters. It also serves an economical purpose in saving fugitive fumes of lead, zinc, mercury, sulphur, antimony, and similar metals.

Electricity.—(1) An instrument for concentrating electricity by the effect of induction. It usually consists of a confolded sheet of tin-foil, whose layers are separated by a thin sheet having a non-conducting surface. (2) With induction apparatus, a device for absorption or sup-

CONDENSING AND NON-CONDENSING ENGINES — CONDITION

pression of the extra current induced by the rapid breaks in the main current. (3) An instrument in which an electric spark passes between the poles in a closed glass cylinder, so as to be employed in burning metals in an atmosphere of any given tenuity or specific chemical character, to obtain the spectra of metals or gases free from accidental characteristics of the general atmosphere for the time being.

Condensing and Non-condensing Engines.

Steam-engines are classified according to the method in which they use steam. In the non-condensing engine, the steam, after having performed its work in the cylinder, is exhausted into the atmosphere at a pressure equal to that of the atmosphere (14.7 pounds on each square inch of surface at the level of the sea), thereby giving a back pressure equal to that amount which the steam actuating the piston has to work against, or overcome constantly. It is entirely possible, however, to so arrange a method of using the steam that, after having performed its work in the cylinder instead of being exhausted into the atmosphere at a pressure of 14.7 pounds, it shall be exhausted into a reservoir within which a vacuum is constantly maintained, and thus conserve the energy lost in overcoming the back pressure in the cylinder. The most convenient method of securing a vacuum is by condensing the steam which fills a given volume or reservoir back to the form of water, and engines operating on this principle of exhausting into a vacuum are classified as condensing engines. The physical principle on which a partial vacuum is caused by the condensation of steam is, that one cubic inch of water forms 1,700 cubic inches of steam at a pressure of one atmosphere. Therefore, if that volume of steam is condensed back to water, the reduction of volume is in the same proportion less only the volume occupied by the tenuous vapor given off even by cool water in a vacuum. To maintain a vacuum thus obtained, it is only necessary to provide suitable apparatus to draw off the water as it is being created by the condensation of the steam. The earliest steam-engines were all of the condensing type. Steam at pressures slightly above that of the atmosphere was admitted to the cylinder for the working stroke, and the absence of pressure on the working side of the piston due to the vacuum caused by the condensation of the steam was the principal dependence for the power of the stroke. They were called low-pressure engines, while those of the non-condensing type which necessarily required a higher boiler pressure to overcome the back pressure in the cylinder were designated as high-pressure engines, so that at one time the terms high-pressure and low-pressure were synonymous with the terms non-condensing and condensing, respectively. This relation, however, does not apply at the present time, since the majority of modern condensing engines are operated by steam at high-pressure. The advantages of the condensing engine may be stated as follows: The same power can be secured by a smaller cylinder of the condensing type than of the non-condensing type, with all the attendant advantages of diminished bulk, while the condensation of the steam to a temperature of about 130° F. (usual practice) affords a quantity of pre-heated water which can be used to replace the amount turned out of the boiler in the form of steam, thus saving fuel,

and extending the wear of the boiler. Its disadvantages are partly inherent, and partly accidental. The inherent disadvantages are due to four conditions: (1) The lowering of the temperature and pressure of the steam lowers the temperature of the metal of the cylinder and increases the amount of condensation to be expected within the cylinder, so that the actual economy is much less than the theoretical economy; (2) the maintaining of the vacuum imposes an amount of work upon the engine, directly or indirectly, which a non-condensing engine is not required to perform; (3) the serious annoyance caused by the introduction of lubricating material into the cylinder where it fouls and stops up the passage, thence into the condenser, and finally into the boiler, where, by forming a coating on the heating surfaces, causes overheating by preventing the intimate contact of the water with the metal; (4) the condition that it can only be used where a sufficient quantity of water for condensation can be obtained at a small expense, thus limiting the application of the principle to stationary engines on land, although for that very reason it is pre-eminently applicable to all types of marine engines. Locomotives cannot be operated as condensing engines. The accidental disadvantages depend upon the methods employed to apply the principle — (1) if the pumps attached to the condensing apparatus are driven by the engine itself, a high rotative speed is impracticable, since the engine cannot be run at a speed faster than that required for the proper working of the pumps; and (2) if the engine operates its own condensing apparatus at low speeds, the weight and bulk of such appliances become inconvenient.

Condillac, Etienne Bonnot de Mably de, *ā-tē-ēn bōn nō de mā-blē de*, French philosopher: b. Grenoble 30 Sept. 1715; d. Beaugency 3 Aug. 1780. He founded an international reputation on 'The Essay on the Origin of Human Knowledge (or Sense Perceptions)' (1746); duly succeeded by the celebrated 'Treatise on the Sensations' (1754), the central standpoint of these and other works being what is, philosophically speaking, sensationalism; a belief, that is, that what we know we know only through the senses, and hence our ideas of deity, love, the soul, etc., are largely modified forms of the objects that impress us in our daily material experience. These standpoints were practically those of French philosophy till the advent of Cousin. Among his other works are: 'Traite des Sensations' (1755); 'Cours d'Etudes' (1755); 'Le Commerce et le Gouvernement Considérés Relativement l'un à l'autre' (1776); 'La Logique' (1781); 'Langue des Calculs' (1798).

Condition, in law a statement of terms, a provision or stipulation, as in a contract, by which the parties thereto consent to be bound; or an undertaking to do something, pay money or other consideration, etc., as a proviso in an agreement by which the other parties thereto bind themselves to perform some act in return. Conditions must be made at the same time as the original conveyance or contract, but may be by a separate instrument, which is then con-

CONDITIONAL IMMORTALITY — CONDONATION

sidered as constituting one transaction with the original. Unlawful conditions are void. Conditions in restraint of marriage generally are held void; but this is not true of conditions restraining from marriage to a particular person, or restraining a widow from a second marriage. A condition in general restraint of alienation is void, but a condition restraining alienation for a limited time is good. Where land is devised, there need be no limitation over to make the condition good, but where the subject of the devise is personalty without a limitation over, the condition, if subsequent, is held to be *in terrorem* merely, and void. But if there be a limitation over, a non-compliance with the condition divests the bequest. A limitation over must be to persons who could not take advantage of a breach. Performance should be complete and effectual. An inconsiderable casual failure to perform is not non-performance. Any one who has an interest in the estate may perform the condition, but a stranger gets no benefit by performing it. Conditions precedent, if annexed to land, are to be strictly performed, even when affecting marriage. Conditions precedent can generally be entirely performed, and usually at any rate equity will not interfere to avoid the consequences of non-performance.

The word "condition" also means the situation of every person in some one of the different orders of persons which compose the general order of society and allot to each person therein a distinct separate rank. For instance, at common law, a person under 21 is an infant, with certain disabilities and privileges. Every person is presumed to know the condition of the person with whom he deals.

Conditional Immortality, a tenet held by a theological school which denies the inherent immortality of the soul, and the consequent doctrines both of eternal misery and of Universalism as contrary to the teachings both of nature and of revelation. Its advocates maintain that the Bible sets immortality before men as something to be sought after (Rom. ii. 7), as a divine gift offered on certain conditions (Rom. vi. 23; John iii. 15, 16), and as a matter of hope and promise in the present life (Titus i. 2); that this immortality is not a present possession (Mark x. 30), and is to be realized by the assumption of a spiritual body at the resurrection of regenerate men from the dead (Luke xx. 35, 36), an event synchronous with the second coming of Christ (1 Cor. xv. 51, 52). Divine testimony, no less than experience, they say, declares unequivocally that man has the same natural life as all other animals (Eccles. iii. 19), and only those who by faith and obedience are united to Christ have the promise of immortality. The Calvinistic doctrine of eternal misery is untenable, the punishment of sin being death or everlasting destruction, to be inflicted subsequent to a judgment after the Lord returns (2 Thess. i. 9, 10). The dogma of Universalism, the only alternative to endless torment if the soul must live forever, is also, they maintain, unfounded, since the punishment of sin (death) is said to be everlasting, like the life which is the reward of the righteous (Matt. xxv. 46). The Conditional Immortality Mission began in Great Britain in 1878. It has an organ 'The Bible Standard,' published

monthly by the secretary. Churches have been established in the United States.

Conditioned, Philosophy of the, or Philosophy of the Unconditioned, the name given by Sir William Hamilton to certain philosophical views first promulgated by him in an article contributed to the 'Edinburgh Review,' in October 1829, forming a critique on Victor Cousin's philosophy, especially of his doctrine of an absolute cause. The Unconditioned is regarded by Sir William Hamilton as a genus including two species: the Infinite, or the unconditionally unlimited, and the Absolute, or the unconditionally limited; and the thesis which he maintains and expounds in the essay referred to, and which forms one of the leading doctrines of his philosophical system, is that the Unconditioned, as thus explained, is entirely unthinkable. In his own words, "the mind can conceive, and consequently can know only the limited, and the conditionally limited. . . . Conditional limitation is the fundamental law of the possibility of thought." This he illustrates by stating that we can neither conceive an absolute whole, that is, a whole so great that we cannot conceive it also as a part of a still greater whole; nor an absolute part, that is, a part so small that we cannot conceive it as a relative whole, divisible into still smaller parts. And this he declares to hold good as to space, time, and degree. "The Conditioned," he goes on to say, "is the mean between two extremes—two unconditionates, exclusive of each other, neither of which can be conceived as possible, but of which, on the principles of contradiction and excluded middle, one must be admitted as necessary." The Unconditioned, on the other hand, being merely negations of the Conditioned in its opposite extremes, bound together by the aid of language and their common character of incomprehensibility, is not even a notion, either simple or positive. It presents no object to the thought, and can afford no real knowledge. From this, however, we are only to learn that our faculties are weak, and that hence we have no right to constitute our capacity of thought into the measure of existence. Although then we are unable to conceive anything above the relative and finite, it is quite competent to us to believe in the existence of something unconditioned beyond the sphere of all that is conceivable by us. This doctrine was adopted by Mansel, dean of St. Paul's, and applied by him to determine the limits of religious thought. It was combated by John Stuart Mill. Consult: Mansel, 'Limits of Religious Thought'; Mill, 'Examination'; Sir William Hamilton, 'Discussions.'

Condom, kôn-dôn, France, a town in the department of Gers, on the Baise River, which is here crossed by two stone bridges, 25 miles northwest of Auch. It contains an ancient church, a Gothic edifice, and in the outskirts are a number of handsome villas. The manufactures are porcelain, woolen yarn, leather, and brandy. It was formerly the capital of Pays-de-Commois. Bossuet was appointed Bishop of Condom in 1669, but remained here only one year. Pop. 4,500.

Condonation, in law, a forgiveness of injury, such as to restore the person who has committed an offense to the same position which he or she held before it was committed. In

CONDOR

an action on the ground of adultery it is a legal plea in defense.

Condor, the popular name of the great vulture of the Andes, formed by a mispronunciation of the Indian name *kunter*, which, according to Humboldt, is derived from another word in the language of the Incas, signifying "to smell well." This species (*Vultur gryphus*, Linn., or *Sarcoramphus gryphus*) belongs to the family (*Cathartidæ*) of diurnal rapacious birds, and which is distinguished by the following characters: The bill is elongated and straight at base; the upper mandible is covered to the middle by the cere; the nostrils are medial, approximate, oval, pervious, and naked; the tongue is canaliculate, with serrated edges; the head is elongated, depressed, and rugous; the tarsus rather slender; the lateral toes equal; the middle toe is much the longest, the inner free, and the hind one shortest; the first primary is rather short, the third and fourth are longest.

The natural history of the condor was in a fair way to rival the ancient fables of griffins, basilisks, and dragons, or even of exceeding the roc of Sinbad the Sailor, in extravagant exaggeration, until Humboldt placed it upon the basis of truth. His careful measurements established the fact that the wonderfully gigantic condor is not generally larger than the lammergeyer, or bearded vulture, of the Alps, which it closely resembles in various points of character. These birds prefer to dwell above all animal life, and at the extreme limit of even Alpine vegetation, inhaling an air too highly rarefied to be endured, unless by creatures expressly adapted thereto. From such immense elevations they soar upward until their great bulk diminishes to a scarcely perceptible speck, or is lost to sight. The condor is a carrion bird, and is quickly lured to the plains by the sight or scent of a carcass. To such a feast considerable numbers repair, and commence their banquet by first plucking out the eyes, and then tearing away the tongue of the animal; next to these the bowels are eagerly sought for, and devoured with that gluttony which distinguishes the whole vulture tribe. The appetite of these birds seems to be limited only by the quantity of food that can be gorged into their stomachs; and when thus overloaded they appear sluggish, oppressed, and unable to raise themselves into the air. The Indians profit by this condition to revenge themselves for the robberies which they commit upon their flocks, and, watching while they eat until flight has become exceedingly difficult, attack and secure them by nooses, or knock them down with poles before they can get out of the way. If the condor, thus loaded, succeeds in rising a short distance from the ground, he makes a violent effort, kicking his feet toward his throat, and relieves himself by vomiting, when he soon ascends out of reach. Many, however, are surprised, and are captured or killed before they are able to ascend. But the condor does not exclusively feed upon dead or putrefying flesh; he attacks and destroys deer, vicuñas, and other middling-sized or small quadrupeds; and when pinched by hunger a pair of these birds will attack a bullock, and by repeated wounds with their beaks and claws harass him until, from fatigue, he thrusts out his tongue, which they immediately seize and tear from his head; they also pluck out the eyes of the poor beast, which, if not speedily rescued, soon falls

a prey to their voracity. It is said to be very common to see the cattle of the Indians on the Andes suffering from the severe wounds inflicted by these rapacious birds. It does not appear that they have ever attacked man. When Humboldt, accompanied by Bonpland, was collecting plants near the limits of perpetual snow, they were daily in company with several condors, which would suffer themselves to be quite closely approached without exhibiting signs of alarm, and never showed any disposition to act offensively. The nesting-time of the condor varies with the latitude, and the place selected for the nest is usually some inaccessible ledge of rock. It lays two white eggs from three and a half to four inches long, which are hatched in about seven weeks. The development of the young birds is very slow, since they are not able to fly until they are a year old, and they have to remain with the parent birds for a year or two longer. They are occasionally seen even on the shores of the southern ocean, in the cold and temperate regions of Chile, where the Andes so closely approach the shores of the Pacific. Their sojourn, however, in such situations is but for a short time, as they seem to require a much cooler and more highly rarefied air, and prefer lofty solitudes from 10,000 to 15,000 feet above the level of the sea. When they descend to the plains they alight on the ground rather than upon trees or other projections, as the straightness of their toes renders the first-mentioned situation most eligible. Humboldt saw the condor only in New Granada, Quito, and Peru, but was informed that it follows the chain of the Andes from the equator to the seventh degree of north latitude into the province of Antioquia. There is now no doubt that it ranges from nine or ten degrees north of the equator to the Straits of Magellan. The king vulture (*S. papa*) is another bird of the same genus.

The head of the male condor is furnished with a sort of cartilaginous crest, of an oblong figure, wrinkled, and quite slender, resting upon the forehead and hinder part of the beak for about a fourth of its length; at the base of the bill it is free. The female is destitute of this crest. The skin of the head in the male forms folds behind the eye, which descend toward the neck, and terminate in a flabby, dilatible, or erectile membrane. The structure of the crest is altogether peculiar, bearing very little resemblance to the cock's comb or the wattles of a turkey. The auricular orifice is of considerable size, but concealed by folds of the temporal membrane. The eye, which is peculiarly elongated, and farther distant from the beak than the eagle's, is of a purple hue and very brilliant. The neck is uniformly marked by parallel longitudinal wrinkles, though the membrane is not so flabby as that covering the throat, which appear to be caused by the frequent habit of drawing the neck downward to conceal or warm it within the collar or hood. The collar in both sexes is a fine silken down, forming a white band between the naked part of the neck and beginning of the true feathers, and is rather more than two inches broad, not entirely surrounding the neck, but leaving a very narrow naked space in front. The rest of the surface, the back, wings, and tail, are of a slightly grayish-black, though sometimes they are brilliantly black; the feathers are triangular, and placed over each other tile-wise. Humboldt

CONDORCANQUI — CONDOTTIERI

never saw male condors with white backs, though descriptions of such have been given by Molina and others. The primaries are black; the secondaries in both sexes are exteriorly edged with white. The wing-coverts, however, offer the best distinction of the sexes, being grayish-black in the female, while in the male their tips, and even half of the shafts, are white, so that his wings are ornamented with beautiful white spots. The tail is blackish, wedge-shaped, rather short, and contains 12 feathers. The feet are very robust, and of an ashen blue color marked with white wrinkles. The claws are blackish, very long, and but slightly hooked. The four toes are united by an obvious but delicate membrane; the fourth is the smallest, and has the most crooked claw. The largest male condor described by Humboldt was three feet three inches long from the tip of the beak to the tip of the tail; height, when perched, with the neck moderately extended, two feet eight inches; from the tip of one extended wing to the tip of the other, eight feet nine inches. Humboldt states that he never saw a condor which measured more than nine feet across the wings; but a specimen described by Dr. Shaw measured 14 feet. Notwithstanding, therefore, what is said by Humboldt of the general correspondence in size of the Alpine lammmergeyer and the condor of the Andes, we cannot avoid believing that a full-grown individual of the latter species would be much more than a match in every respect for any European species. The condor is peculiarly tenacious of life, and has been observed, after having been hung for a considerable time by the neck in a noose, to rise and walk away quickly when taken down for dead, and to receive several pistol bullets in its body without appearing greatly injured. Its plumage defends its body to a considerable degree from the effects of shot. It is easily killed when shot, or struck sufficiently hard, about the head.

A very similar species is the California condor or vulture, which may be easily distinguished from the true condor, which it nearly equals in size, by the lack of the white neck-ruff and of the caruncle of the male. The California vulture formerly ranged northward on the Pacific coast into British Columbia, but its habitat is said to be shrinking and now reaches only to Monterey on the north. The species may be approaching extinction. Like the condor, in addition to feeding on carrion, it attacks and kills young or sick animals, particularly lambs and calves. The rough nest of sticks, in which two dirty-white eggs are laid, is built on the ground, rock ledges, or stumps.

Condorcanqui, José Gabriel, hō-sā gā'-brē-ěl kōn-dōr-kān-kē' ("TUPAC AMARU"), Peruvian revolutionist: b. Tinta 1742; d. Cuzco, 18 May 1781. He is called "The Last of the Incas," and in 1771 took the name of Tupac Amaru. In 1780 he incited the Peruvian Indians to rebellion against Spain, professing a design of restoring the dynasty of Manco Capac. This rebellion was the most important in South American colonial history. For three years the contest raged with doubtful success; at length, however, the natives fell away from him, and he was taken and executed. The cruelty of the Spaniards in this insurrection ultimately led to the independence of Peru.

Condorcet, Marie Jean Antoine Nicolas de Caritat, mā-rē zhōn ān-twān nīk-ō-lā de kā-rē-tā kōn-dōr-sā, MARQUIS DE, French philosopher and mathematician: b. Ribemont, Picardy, 17 Sept. 1743; d. Clamat 28 March 1794. At the age of 21 he presented to the Academy of Sciences an 'Essai sur le Calcul Intégral.' His 'Memoire sur le Problème des Trois Points' appeared in 1767. Both works were afterward united under the title of 'Essais d'Analyse.' The merit of this work gained for him in 1769 the distinction of a seat in the Academy of Science. With astonishing facility and versatility Condorcet treated the most difficult problems in mathematics; but his genius inclined him rather to lay down beautiful formulas than to pursue them to useful applications. In 1777 his 'Theory of Comets' gained the prize offered by the Academy of Berlin. The aversion of the minister Maurepas to Condorcet delayed his entrance into the French Academy till 1782. During the troubles of the French Revolution his sympathies were strongly engaged on the side of the people. On the intelligence of the flight of King Louis XVI. he represented in a speech which was highly admired, the royal dignity as an anti-social institution. In the national convention, in which the legislative assembly was merged 20 Sept. 1792, he voted for the most part with the Girondists. On the trial of Louis he was in favor of the severest sentence not capital; at the same time he proposed to abolish capital punishments, except in case of crimes against the state. The fall of the Girondist party 31 May 1793 prevented the constitution which Condorcet had drawn up from being accepted. The constitution then adopted he attacked and was accused 3 October of being an accomplice of Brissot. To save his life he concealed himself, and was declared out of the protection of the law. While in hiding Condorcet wrote his curious 'Esquisse d'un Tableau historique des Progrès de l'Esprit humain,' full of enthusiasm for liberty. At Clamat he was arrested as a suspicious person by a member of the revolutionary tribunal of Clamat, and thrown into prison to undergo a more strict examination. On the following morning he was found dead on the floor of his room, apparently having swallowed poison. A collection of his numerous writings, complete with the exception of his mathematical works, appeared in Paris in 1804. Consult Arago, 'Biographie de Condorcet' (1849).

Condottieri, kōn-dōt-tē-ā'rē, a class of mercenary adventurers in the 14th and 15th centuries, who commanded military bands, amounting to armies, on their own account, and sold their services for temporary engagements to princes and states. The bands under command of the Condottieri were well armed and equipped. Their leaders had in many instances considerable military skill; but, as they took no interest in national contests, except to receive pecuniary advantages, the wars between them became a sort of bloodless contest, in which the only object of each party was to take as many prisoners as possible for the sake of the ransom. This singular system of warfare was put to an end by the more serious military operations of the French, who invaded Italy under Charles VIII. Though many Condottieri acquired much honor as well as emolument, one only attained to high rank and independent

CONDUCTION OF HEAT — CONEPATE

power; this was Francesco Sforza, originally a peasant, who in 1451 made himself Duke of Milan, and transmitted that sovereignty to his descendants.

Conduction of Heat. See HEAT.

Conduit, kōn'dīt, in architecture, a long narrow passage between two walls or underground, for secret communication between various apartments, of which many are to be found in old buildings; also a canal of pipes for the conveyance of water, a sort of subterraneous or concealed aqueduct. The construction of conduits requires science and care. The ancient Romans excelled in them, and formed the lower parts, whereon the water ran, with cement of such an excellent quality that it has become as hard as the stone itself which it was employed to join. There are conduits of Roman aqueducts still remaining, of from five to six feet in height, and three feet in width. Conduits in modern times are generally pipes of wood, lead, iron, or pottery, for conveying the water from the main spring or reservoirs to the different houses and places where it is required.

Condurango, kōn-dū-rāng'gō, or **Cundurango**, the bark of the *Marsdenia Condurango*, a medium-sized twining plant of Ecuador and adjacent states. It is somewhat bitter; at one time it was much vaunted as a specific in the treatment of cancer.

Condylarthra, kōn-dī-lār'thrā, a primitive order of ungulates of the early part of the Tertiary Period, collateral ancestors of the later hoofed animals, and connecting them with the primitive clawed animals, especially with the *Creodonta*. They were mostly of small size, five-toed, omnivorous, with bunodont teeth like those of the pigs, long tail, small brain and other primitive features. *Phenacodus*, of the Lower Eocene, of the size of a wolf, is the largest and best known. Remains of *Condylarthra* are found chiefly in North America, but also in Europe and in South America. They became extinct in the Middle Eocene.

Condyle, kōn'dīl, in anatomy, a protuberance on the end of a bone serving to form an articulation with another bone, and more especially applied to the prominence of the occipital bone for articulation with the spine.

Cone, Helen Gray, American poet: b. New York City 8 March 1859. Since 1899 she has been professor of English in the New York City Normal College. She is the author of 'Oberon and Puck: verses Grave and Gay' (1885); 'Baby Sweethearts' (1890); 'The Ride to the Lady and Other Poems' (1891).

Cone, Orello, American educator and author: b. 16 Nov. 1835; d. 23 June 1905. He was professor of biblical languages and literature in St. Lawrence University, N.Y., 1865-80; president of Buchtel College, Ohio, 1880-96; and Richardson professor of biblical theology in St. Lawrence University, 1900-5. He published: 'Gospel-Criticism and Historical Christianity' (1891); 'The Gospel and Its Earliest Interpretations' (1893); 'Paul, the Man, the Missionary, and the Teacher' (1898); edited 'Epistles to the Hebrews, Colossians, Ephesians, Philemon, etc.' (1901); 'Rich and Poor in the New Testament' (1902).

Cone, Spencer Houghton, American clergyman: b. Princeton, N. J., 30 April 1785; d.

28 Aug. 1855. After a varied career as school teacher, actor, journalist, and government clerk, he was converted November 1813, and baptized into the fellowship of the Baptist Church, and soon began to preach with great success. He was chaplain of the House of Representatives, 1815-16; pastor at Alexandria, Va., for 7 years; of the Oliver Street Church, New York, for 18 years, and of the First Baptist Church in the same place until his death. He was president of the American and Foreign Bible Society, 1837-50, and of the American Bible Union from its formation until he died. For many years he was one of the most popular and influential clergymen of his denomination in the United States. There is a 'Memoir' of him by his son, Spencer Wallace Cone (1819-88).

Cone. 1. In geometry, the solid figure traced out when a right-angled triangle is made to revolve round one of the sides that contain the right angle; this is more strictly a right circular cone. A more comprehensive definition may be given as follows: Let a straight line be held fixed at one point, and let any other point of the line be made to describe any closed curve which does not cut itself; the solid figure traced out is a cone. The moving line is known as a generating line or generator of the cone. When the axis of the cone, that is, the line joining the fixed point to the centre of the closed curve, is perpendicular to the plane of the base, the cone is right; and when in addition the curve which the second point describes is a circle, the cone is a right circular cone. Cones whose axes are inclined to their bases at any angle other than a right angle are known as oblique cones. If a cone be cut in two by a plane parallel to the base, the lower portion is called a frustum or a truncated cone. The geometry of the cone is important on account of the curves called conic sections, which are obtained by cutting a right circular cone by planes in various directions. The cubic content of a right circular cone is one third of that of a cylinder on the same base and of the same altitude. The cubical content of the cone is therefore found by multiplying the area of the base by the altitude, and taking one third of the product. The area of the slant or curved surface is obviously equal to that of a sector of a circle of radius equal to the slant height, and arc equal to the circumference of the base. It is therefore obtained by multiplying the slant height by the circumference of the base, and taking one half of the product.

2. In botany, a dry compound fruit, consisting of many open scales, each with two seeds at the base, as in the conifers; a strobilus.

Cone-Nose. A true bug (*Conorhinus sanguisuga*) of the family Reduviidæ, related to the bedbugs and having similar habits in the South; it is nearly an inch long, and black, blotched with red. In 1898 much excitement was occasioned in the North by newspaper accounts of attacks by "kissing-bugs," which were two related species, *Reduvius personatus* and *Melanolestes picipes*, the former frequently found in dirty houses feeding upon cockroaches, bedbugs, etc., and breeding in dusty corners. The bite is painful, but not poisonous.

Conepate, kō'ně-pāt, the name given in Mexico to the large white-backed skunk of that region. See SKUNK.

CONE-SHELLS — CONFARREATIO

Cone-shells, or **Conidæ**, a family of ctenobranchiate *Gastropoda*, so called on account of their form. All the cones have a similar external outline; the aperture is long and narrow, the head of the living animal is more or less lengthened, the proboscis elongated, the foot is splay and abruptly cut off in front, the tentacles are rather widely separate and the eyes are placed on these organs. All of the species are carnivorous, and the bite of some of those found in the South Seas is reputed poisonous. Several hundred species have been described, about one fifth of them from tropical American waters. Owing to their beauty and variety the cones are much sought by collectors, who pay extravagant prices for the rarer forms. The textile cone-shells (*Conus textilis*), brought from Mauritius, a handsome species four or five inches in length, are marked with narrow, angular lines of dark brown, variegated with dashes of yellow and irregular white spots. It haunts the fissures and holes in rocks and the warmer pools in coral reefs. They all take a moderate range of depth, varying from 1 to 40 fathoms.

Cones, Pyromet'ric, or **Segeer Cones**, instruments for measuring heat, consisting of three-sided pyramids about two and a half inches high and one half inch base. They are composed of fusible substances, and are graded so that they melt, each at its own temperature. The cones were invented by Dr. Herman Seger, of Berlin, for use in pottery kilns, and have since been largely adopted. An earlier method of heat measurement was the fusible alloys invented by Prinsep. Alloys of silver, gold, and platinum were so calibrated that they would, as to melting-point, cover the whole range between the two extremes of fusion of the metals. Many objections to these were found in practice, notably the expense and liability to loss. The Seger cones perform the same service and are very inexpensive. The cones range in numbers from 1 to 36 and back from .—1 to .—22. In practice two or three cones, approximating the required temperature, are set upright in the kiln upon a morsel of soft clay. The softer of them will, as the temperature reaches the proper point, bend over and melt, to be followed in regular order by the successive higher numbers. They can be easily seen through the hole left in the kiln wall for the inspection of trials.

Cones'si-bark, the bark of *Holarrhena antidysenterica*, a plant of India, used as a tonic, a febrifuge, and an astringent in diarrhoea. The plant is a shrub with opposite leaves and terminal cymes of flowers.

Conestoga, kōn-ēs-tō'gā, or **Conestogas**, a tribe of Indians belonging to the Iroquois linguistic stock, and formerly living on the lower course of the Susquehanna and at the head of Chesapeake Bay. At the time of the settlement of Virginia (1607) the Conestoga were at war with the Mohawks, whom they had almost exterminated. Later they became a source of serious trouble to the white settlers. With the Dutch and Swedes they were more friendly than with the English. By 1675 the tribe was holding land on the eastern bank of the Potomac River in Maryland. Giving way before the Iroquois they retreated southward, committing depredations upon the white settlements. Some of the refugees of the tribe escaped to North Caro-

lina; others after submission to the Iroquois returned to the Susquehanna. In 1701 the Conestoga made a treaty with William Penn.

Coney, the name formerly given in England to the rabbit. In the western United States, the name is applied to a distant relative, the pika (q.v.), although this creature has little resemblance to the rabbit. The term as found in Scripture is a translation of the Hebrew *shaphen*, the local name for the Syrian species of hyrax, or daman. See HYRAX.

Coney Island, New York city, a small island in the borough of Brooklyn, about 10 miles southeast of the borough of Manhattan. It is about five miles in length and from half to three quarters of a mile in width; separated from the mainland by Coney Island creek. It is connected with the borough of Manhattan and Brooklyn by steam and electric railroads and steamboat lines. It is a noted day summer resort, and has numerous bathing houses, hotels, concert and other amusement halls, carousels, pavilions, electric lights, and a fine cycle path connecting it with Prospect Park, Brooklyn. Coney Island is divided into four sections: Sea Gate, the home station of the Atlantic Yacht Club; West Brighton; Brighton Beach, and Manhattan. There is a lighthouse at Sea Gate and many summer cottages, besides the Atlantic Yacht Club House. Sea Beach is the site of several charitable sanitariums, and is a popular pleasure resort. Brighton and Manhattan have extensive hotels, and are the preferred resorts for the wealthier class. Coney Island was one of the first landing places of the Dutch, and for over 200 years was considered a worthless waste. In 1840 steamboats began making excursions there, and for 25 years it was a popular resort. In 1875 steam railroads were built and since then the island has been the most popular resort in the immediate neighborhood of New York. In 1899 a scheme was proposed by the city authorities to purchase and reclaim a large portion of Coney Island and convert it into a public park. In 1903 the city opened a small public park on the island.

Confarreatio, kōn-fār-ē-ā'tē-ō, the most solemn of the three ceremonies of marriage used among the ancient Romans. The other forms of marriage were *coemptio* and *usus*. These last are the only ones mentioned by Cicero, which shows that confarreation had fallen into disuse before his time. The ceremony was performed by the *pontifex maximus*, or *flamen dialis*. A formula was pronounced in the presence of 10 witnesses, and the man and woman partook of a cake of salted wheaten bread; part of which only they ate, the rest being thrown upon the sacrifice, which was a sheep. The cake was called *far*, or *panis farreus*, hence the term "confarreatio." By this form the woman was said to come into the possession of her husband by the sacred laws, and became a partner of all his substance and sacred rites, those of the penates as well as the lares. If the husband died intestate and without children, the wife inherited the whole property like a daughter; if there were children, she received with them an equal share. The offspring of this form of marriage were called *patrimi* or *matrimi*; and from them were chosen priests and priestesses, especially the *flamen dialis* and vestal virgins. In the reign of Tiberius, he wished for a priest of this pure

CONFECTIONERY — CONFECTIONERY TRADE IN AMERICA

lineage, but the ceremony had fallen into disuse, so that three patricians thus qualified could not be found. *Confarreatio* could only be dissolved by a form of divorce equally solemn, called *disfarreatio*. The custom of bride cake is a relic of *confarreatio*; until within 200 years it was made of wheat or barley, without fruit.

Confec'tionery, (Lat. "to put together," "compound," "prepare"), a general term for any preparation with sugar as a base, used as a sweetmeat and containing nuts, fruits, or other flavoring. In the United States confectionery is commonly called "candy," a name which suggests etymologically conserved fruits or seeds; in England "boiled sweets" is the usual term, derived from the commonest method of preparation. Historically the earliest use of confectionery was to disguise the taste of unpleasant medicines, a method dating back to the primitive smearing with honey the rim of a cup holding a bitter draught, a practice common with Greek and Roman doctors. The medicinal use was long the commonest, fruit conserves being the first exception. In Italy, even in the Middle Ages, *confetti* were used in the mock battles of the carnival maskers. The true development of the manufacture of confectionery begins in the 19th century, and in England, where the trade spread after the great exhibition of English dealers at the Exposition of 1851, to Germany and France. The latter country took the lead in the manufacture of elaborate bonbons and confitures and was especially superior in its chocolate candies. But the greatest growth of the business and especially the greatest increase in the variety of confections has been in the United States. In the manufacture of cheap confections poisonous mineral dyes are used, especially for the more brilliant colors; and other dangerous adulterants, such as kaolin and terra alba, are employed.

Confectionery Trade in America. Although there is good reason to believe that the youths and maidens of the American colonies were not entirely unacquainted with the taste for sweets, and that the formulas for the making of confections which had been brought from the Old World were often tested, on the cold winter nights in the great colonial kitchens, concerning the early history of confectionery-making as a trade little is known, and as the term "confection" has always been used to include a great number of edibles that have had sugar as a base of principal ingredient it is difficult to estimate at just what point the "pastry" ends and the "candy" begins, especially in view of the fact that all so-called records prior to the 19th century are conspicuously obscure in their phraseology.

Of course, we know that, in the early days, the art of manufacturing confectionery was confined almost exclusively to the apothecaries and physicians, both of whom made use of these sweets in their attempts to disguise the unpleasant characteristics of their medicines. This secret was known to the medical fraternity as far back as the days of ancient Greece and Rome, when the physicians made a practice of smearing the outer rim of the cup with honey whenever they were compelled to give a particularly bitter draught to a patient. During the 19th century, however, the confectionery trade has experienced its greatest development, for it

is since the dawn of that century that it has become what it is to-day, one of the world's great business enterprises. In the making of this transition the druggist has not ceased to be a factor in the trade. He still requires his medicated candies, but, in this respect, he has become a purchaser, and the manufacturing confectioner who supplied his wants runs, in addition to this old-time branch of the industry, several entirely distinct branches of the trade.

It is doubtful if there is any modern industry that has experienced more radical changes during the past hundred years than the trade of confectionery-making. Prior to the year 1851, the manufacture of "boiled sweets," as candy was then called, was so largely an English specialty that the manufacturers of Great Britain might be said to have had almost entire control of the industry. In fact, it was not until the time of the great international exposition at London that the confectioners of other countries began to realize just how much their British brethren had achieved, but their unique display of candies and sweetmeats gave such an impetus to the trade that the effect was felt in every part of the civilized world. Germany imitated all its choicest products; France excelled, especially in the making of chocolate bonbons, and the candy-makers of the United States returned from the "big show" with ideas that soon made the importation of English sweets unnecessary.

In spite of the fact that England had long been the great candy-making country of the world, however, there had been confectioners in the United States long before the opening of the London exposition, and there are ample records in proof of the fact that they, too, had produced original creations that other nations were glad to copy. As early as 1816 there were no less than 20 confectioners in the city of Philadelphia, all of whom were engaged in the manufacture and sale of candies. Among these pioneers in the confectionery business one may record the names of Sebastian Henrion, who was succeeded by the firm of Henrion & Chauveau, in 1844, and Sebastian Cheuveau, who was the first candy-maker to manufacture gum-drops, jujube paste, and marshmallows in this country. Another prominent manufacturer of the old time was Paul Lajas, who, in 1831, changed his business from that of candy-making to this of sugar-refining, while the list of Philadelphia confectionery-makers includes the names of George Miller, William N. Herring, S. S. Rennels, and J. J. Richardson. Among the many old-time confectioners in the city of New York were Ridley & Company, a firm that was established as early as 1806; R. L. Stuart, James Thompson, John Stryker, and Delmonico Brothers. In Boston as early as 1816, Arnold Copenhagen, Lawrence Nichols, and William Fenno were prominently identified with the candy industry, while Joseph Bouvey, Augustus M. Price, and John L. Bridges were among the leading manufacturers and dealers in confectionery in Baltimore. Throughout the United States there were some other cities that could boast of candy-makers, but the records of those days are so meagre that but few of the names can be recalled.

In the beginning, of course, the art of candy manufacture was in a very crude state. Prior to 1845, it was almost invariably the rule that the manufacturers themselves sold at retail

CONFECTIONERY TRADE IN AMERICA

practically all the candy that they manufactured. As a rule this stock in trade usually was confined to such ordinary products as the old-fashioned stick candy, sugar plums, and the ordinary molasses candy. Finer goods, or candies in fancy shapes, were almost exclusively imported, and, as the result, were sold at a much higher price than the crude candies of home manufacture. It was about 1825, that the foreign manufacturers began to use a little machinery in their factories, but the actual introduction of machinery in the making of confectionery dates from about 1840. The first machine of this character to be brought to the United States was imported by Sebastian Chauveau of Philadelphia, in 1845. This was a revolving steam-pan. In 1846 Oliver R. Chase, who, with his brother, formed the firm of Chase & Company, invented a machine for the making of lozenges. For some years this firm had been engaged in making this once popular confection as a specialty, and it was to meet the constantly increasing demand for their product that this new invention was conceived and constructed to their model. In 1866, a further innovation in the lozenges manufacture was produced by Daniel G. Chase. This was a machine for printing on candies, and it was to this invention that the well-remembered conversation lozenges owed its existence.

Since that day the history of the confectionery trade has been a constant record of development. Year by year new improvements have been made, and new and more perfect machinery has been invented, all of which have quickly been adapted to the manufacture of the various kinds of goods that the constantly widening demands of the business have required. As a result, while the actual manufacture of candy has extended until it has become one of the nation's great industries, it has created around it a number of dependent industries, each of which now represents a special business of no slight importance. Thus, for example, the making of confectioner's machinery is now a separate industry in which a great amount of capital is invested, and the business of confectioner's supplies represents an annual product that is by no means to be despised. In fact to obtain any sort of an idea of the tremendous growth of the confectionery industry it is necessary to turn to the official census returns for the past half century. As reported by the last census the figures from 1850 to 1900 show the following comparisons:

THE CONFECTIONERY INDUSTRY 1850 TO 1900.

YEAR	No. of Establishments	Hands Employed	Capital Invested	Total Wages Paid	Value Material Used	Value of Product
1850..	383	1,733	\$1,035,551	\$458,904	\$1,691,824	\$3,040,671
1860..	541	2,340	1,568,478	668,423	2,991,186	5,361,100
1870..	941	5,825	4,905,293	2,091,826	8,703,560	15,922,643
1880..	1,450	9,801	8,486,874	3,242,852	17,125,775	25,637,033
1890..	2,921	21,724	23,326,799	7,783,007	31,116,629	55,997,101
1900..	4,297	33,583	31,155,361	10,867,687	45,534,153	81,290,543

Imposing as these figures may seem, they are, at the same time, somewhat misleading as to the actual growth and development of the business, as well as regarding its present magnitude. For example, by giving only the result of the manufacturing interests of the largest

establishments—and they are chiefly those that are centred about the great cities—they take no account of the production of the small candy-makers that are scattered about the country, which, in the aggregate, is a large amount. The great increase in the business between the years 1880 and 1890 is indicated by a gain of more than 100 per cent in the value of the production, and in the succeeding 10 years, which closed the 19th century, while the former figures would probably have been almost doubled if the aggregate production of the small and isolated candy-makers had been added to the sum of more than \$81,000,000 which represented the total output of the larger factories of the country.

Another interesting commentary upon the confectionery situation in the United States during the past century is shown by a comparison of the export and import figures in relation to the candy trade of America. Prior to 1837, all the confectionery that was imported was classed under the head of "sugar." From that year until 1847, however, the imports of candy were small, but following that period and until 1892, there was a steady if irregular increase in the total importations. By that time, however, the increased demand resulting from the growth of the home market had inspired the American manufacturer to improve the character of his production to such an extent that he was not only able to supply the requirements of the local consumer but assumed a position of such importance that he could reach out in search of wider fields and larger markets. Thus while the foundation of America's export trade was not laid until 1865, when goods to the value of \$26,429 were exported, this branch of our foreign trade has shown a fairly steady increase from that day up to the present time.

Of course, it cannot be denied that there are other factors that have played an important part in this extension of the confectionery industry. The low prices of sugar and the other materials used in the making of confectionery has exerted an influence the effect of which cannot be disregarded, while the introduction of new and improved machinery in all our candy factories has had a tendency to reduce the cost of manufacture to such a degree that the American producers have been able to make the best of goods at a cost so comparatively low as to bring them within the reach of the means of the humble purchaser.

It cannot be denied that much of the credit for this hopeful condition of affairs is due to the labors of the members of the National Confectioners' Association of the United States. This organization, which was founded in 1884, and which includes in its membership all the leading candy manufacturers of the country, has for its declared purpose, as stated in its constitution, "to advance the standard of confectionery in all practicable ways, and absolutely to prevent hurtful adulterations; to promote the common business interests of its members, and to establish and maintain more intimate relations between them; to take united action upon all matters affecting the welfare of the trade at large."

Since this association has been in existence the results of its work have been clearly manifested in the securing of necessary legislation in

CONFEDERACY — CONFEDERATE STATES OF AMERICA

the several States by means of which the manufacture or sale of all candies containing harmful ingredients or poisonous coloring matters has now been prohibited by law; by effectually stamping out all attempts at adulteration which were once so common among the makers of the cheaper grades of goods, and by the establishment in the mind of the consumer of a degree of confidence in the purity of the American product that is a strong argument for the purchase of such goods. As the result of this happy combination of circumstances we have the great American confectionery industry of to-day.

Confederacy, Daughters of the. See UNITED DAUGHTERS OF THE CONFEDERACY.

Confederate Veterans' Association, a federation of all organizations of survivors of the Civil War on the Southern side. This association was organized at New Orleans 10 June 1889. Its avowed purpose is strictly social, literary, historical, and benevolent. Its constitution says that it "will endeavor to unite in a general federation all associations of Confederate veterans, soldiers, and sailors now in existence or hereafter to be formed; to gather authentic data for an impartial history of the War between the States; to preserve relics or mementoes of the same; to cherish the ties of friendship that should exist among men who have shared common dangers, common sufferings, and privations; to care for the disabled and extend a helping hand to the needy; to protect the widows and the orphans, and to make and preserve a record of the resources of every member, and, as far as possible, of those of our comrades who have preceded us in eternity." State organizations are authorized, and are called Divisions.

REV. J. WILLIAM JONES,
President Southern Historical Society.

Confederate States of America, the name adopted by the southern States which seceded from the Union and formed a government at Montgomery, Ala., 9 Feb. 1861, comprising South Carolina, Georgia, Florida, Alabama, Mississippi, and Louisiana, with Jefferson Davis of Mississippi President, and Alexander H. Stephens of Georgia Vice-President. Texas, Arkansas, Tennessee, North Carolina, and Virginia afterward joined, and Missouri and Kentucky became disputed territory, the Federal Congress and the Confederate each receiving and welcoming delegations claiming to represent those States.

The act of secession was passed by each State in full confidence that the legal right peaceably to secede was assured by the Constitution. And if the interpretation of any ambiguous provisions or expressions in any contract is to be governed by the joint intent of the parties at the time of making it, this right to secede must be conceded by all impartial historians.

Goldwin Smith, the English historian, has written: "Few who have looked into the history can doubt that the Union originally was, and was generally taken by the parties to it to be, a compact, dissoluble, perhaps most of them would have said, at pleasure; certainly on breach of the articles of union."

Henry Cabot Lodge of Massachusetts has written: "It is safe to say that there was not a man in the country, from Washington and Ham-

ilton on the one side, to George Clinton and George Mason on the other, who regarded the new system as anything but an experiment entered upon by the States, and from which each and every State had the right peaceably to withdraw, a right which was very likely to be exercised."

In 1803, at the purchase from France of the Louisiana territory, and again in 1812, at the declaration of war with Great Britain, influential and leading public men in New England not only asserted the right of secession, but urged its exercise, in the celebrated Hartford Convention (q.v.) in 1814-15.

Nowhere, however, until 1860, was the issue actually made. Had it been made in the earlier days, it would doubtless have been accomplished peacefully. But in all human affairs, political, social, moral, or commercial, there are silently but forever at work forces which make for the survival of the fittest, and the passing away of the unfit; and these forces, when at last a crisis has been reached, declare themselves, and operate with a volcanic power, against which the barriers of no constitution can prevail.

Within the lifetime of a generation the moral sense of a majority of the civilized world had grown to condemn the institution of slavery; and the invention of steam-power, railroads, and telegraphs had begun to knit communities into nations, to their great commercial advantage. The prejudices against slavery gave rise to issues between the sections of the country, which became inflamed by events—such as the raid of John Brown—until certain States were wrought up to the point of seceding.

But now—born, not legitimately of the Constitution, nor of consent between the States, (which could never have generated anything more cohesive than a rope of sand), but of inexorable laws of nature—there stood a giant in the path. Perhaps, indeed, it was of origin unsanctioned by legal form. But it was born of proximity and geographical dependency, and it was nourished by the prosperous tide of commerce already beginning to transform the entire world. It already felt itself the natural heir to the vast and rich territory within its grasp. There it stood in the way of peaceable secession—a young nation, which denied the right of secession and stigmatized it as rebellion.

In vain did President Davis plead his constitutional rights, in a message to his Congress: "We protest solemnly, in the face of mankind, that we desire peace at any sacrifice, save that of honor. In independence, we seek no conquest, no aggrandizement, no concessions of any kind, from the States with which we have lately been confederated. All we ask is to be let alone; that those who never held power over us shall not now attempt our subjugation by arms."

It needed now but a first blow to precipitate a war to the death. Concerning first blows, Richard Cobden once said: "From the moment the first shot is fired, or the first blow is struck, in a dispute, then farewell to all reason and argument: you might as well attempt to reason with mad dogs as with men when they have begun to spill each other's blood in mortal combat."

The first blow came speedily, but by deliberate intent of neither party. In Charleston a *status quo* had been agreed upon by both sides,

CONFEDERATE STATES OF AMERICA

to permit negotiations. On 25 Dec. 1860, Major Robert Anderson seized Fort Sumter. He did so by night, without orders, and contrary to his instructions, abandoning Fort Moultrie and disabling its guns. President Buchanan was about to order him to return to Fort Moultrie; but before the order could be issued the act was approved so enthusiastically by northern politicians that he did not dare to reverse it. Holding Fort Sumter, he was then constrained to dispatch an armed force to provision and supply it. Thus the Civil War was begun, the Confederates not waiting for the arrival of the armed force, but making their attack.

This breaking out of hostilities brought into the Confederacy the Border States, not so vitally interested in the subject of slavery, but with every tradition and instinct keenly alert to their legal rights under the original Constitution.

This was the real issue of the War, and not slavery, as is often loosely asserted. It is attested, not only by the titles "Union" and "Rebel," universally applied to the two armies by the North, but by the passionate claim of the Confederates that their struggle was for that liberty of self-government so dear for ages to the Anglo-Saxon race. And at the Fort Monroe conference in February 1865 between President Lincoln and Vice-President Stephens, the South's surrender of her claim to integrity of the Union was the one point upon which Lincoln insisted, and the one which Stephens could not yield, although utter destruction awaited him scarcely 60 days off. It is further shown in the desperate character of the struggle upon both sides, involving, with equal ardor, individuals and communities of most diverse degrees of interest in the question of slavery.

The combatants were very unequally matched, and as each side was in deadly earnest, the final outcome of the contest was inevitable from its beginning. On the Union side was a population of over 20,000,000, with an army, a navy, a treasury, a highly developed system of transportation by land and sea, as well as of manufactures, of commerce, and of credit. On the Confederate side was a much scattered population, almost entirely agricultural, of about 5,000,000 whites, comparatively destitute of all those elements of military strength. Even their agriculture was so little devoted to food products that actual starvation of men and horses in their armies finally hastened the inevitable end.

Besides the whites, there was a population of 3,000,000 slaves. It was believed by many at the North that if their freedom was proclaimed by President Lincoln, as a war measure, while their masters were absent in the field, they would rise in insurrection, or at least desert their labor in mass. The experiment, however, being tried, proved a failure. The slaves generally remained faithful everywhere, except in the sections overrun by the enemy. During the four years of the war there were actually mustered into the Union army 2,898,304 men. The Confederate numbers cannot be accurately known, but the total white population between the ages of 18 and 45 was, by the census of 1860, 984,475. In 1864 the ages for military service were extended to include all between 17 and 50, an act which was described by Gen. Grant as "robbing the cradle and the grave." Nearly 2,000 battles and skirmishes were fought,

and in them the number of killed and wounded on the Union side is officially given as 389,345. The numbers on the Confederate side are not accurately known, no complete records existing, but they are estimated at about 300,000.

Of lives lost in the war from battle, wounds, and disease, the official records of the Union army report 316,516. The lives lost in the Confederate army could not have been less than 250,000.

The Confederates appreciated the odds against them, but with firm conviction of the righteousness of their cause, they trusted to be able by fortitude and endurance to wear out and discourage their adversaries. The fighting was often very desperate as shown by the casualties upon both sides, which frequently exceeded the casualties of the severest battles of Europe. Upon three occasions, some historians have imagined, the Confederates were within reach of very important results.

At Bull Run, the first battle of the War, the Federals were more completely routed than ever again, and Washington might have been captured, it is supposed, had the victory been followed up. Gettysburg is considered by many to have been the crisis of the war, a desperate attack by the Confederates being repulsed. But there is strong evidence that the greatest period of discouragement on the Union side followed the battle of Cold Harbor, 3 June 1864. It was, however, of brief duration and of no effect. Successes elsewhere soon followed, and made it apparent that the Confederate resources were approaching exhaustion.

There are notable parallels between the war for the Union and the recent war between Great Britain and the Boers, in the issues involved, and in the course of their events. Like the Confederates, the whole of the Boer population considered themselves fighting for personal liberty as against subjection to a foreign power. Like the Confederates, the Boers fought practically without pay; and although they were inferior in numbers, their important engagements were generally victories; or, if not victories, were drawn battles. And as the end came to the Confederates, so it came to the Boers only with their utter exhaustion—through their being worn out, rather than defeated in battle.

But a great contrast is to be found in the treatment of the two peoples after their defeat. That of the Boer was liberal and generous, fully in accord with the civilization of the day. To parallel the treatment of the South every effort must have been made to put the political control of the country into the hands of the Kaffirs. Of course the efforts to give the negro political control over the Anglo-Saxon at the South were foredoomed to failure. They prolonged ill-feeling for 10 years; but subsequent events, notably the Spanish war, at last inaugurated a new era in which few traces of it yet linger. And it is due to history to record that it is unlikely that any such effort would ever have been made, but for the assassination of Lincoln. Although for this unspeakable crime and folly the South was in no way responsible, it brought upon her a whirlwind of resentment, and at the same time it removed a President who, there is evidence to show, had already risen to the height of his great opportunity as a statesman, and was now planning terms

CONFEDERATE STATES OF AMERICA

of liberality upon which to reconstruct the Southern States.

Within the few days that intervened between the surrender at Appomattox and the assassination of Lincoln, one in his close confidence prophesied that his plans of reconstruction would "win over the South's good will and affection, and astonish the world." And in giving his plans effect, no one can doubt that he would have had the cordial as well as powerful aid of Gen. Grant, who had already set the example of magnanimity, and won the gratitude of Lee's army by the generosity of his terms of surrender.

History records no crime greater than that of the assassin, who cheated the civilization and humanity of the world of the great example which Lincoln would have set to all nations, and who sowed bitterness and ill-will between the sections, bringing poverty and distress to the South, to the North the mortifying failure of its political experiment, and to the negro only an injury. But in connection with the negro question, as it confronts us to-day, it may be remarked that the problem of the races can be safely committed to time, and to the racial instincts implanted by the Creator.

The Constitution which was adopted by the six States in Montgomery, February 1861, and in turn accepted by the others, was modeled closely after that of the United States. It forbade the slave-trade, or the importation of slaves from any foreign country other than the slaveholding States and Territories of the United States. It forbade "bounties" or "trusts," and provided a "tariff for revenue." It allowed the President to veto any part of a bill and approve the remainder, giving his reasons for such action; and fixed his term of office at six years, and made him ineligible for a second term.

The internal history of the Confederate States during the Civil War furnished a most instructive lesson as to the weakness of the bond by which they had associated themselves. Already, before the close of the war, it had proved itself but little better than the federation of the colonies for the Revolutionary War. The last message of President Davis to the Confederate Congress, and the answering report upon the message by a committee of the Senate, contained much crimination and recrimination, and revealed an utter loss of confidence between the executive and the legislative branches, fatally paralyzing all action, and impossible to be healed. In a letter to the secretary of war, on 5 March 1865, Judge John A. Campbell, assistant secretary, wrote: "The political condition is not more favorable. Georgia is in a state that may properly be called insurrectionary against the Confederate authorities. Her public men of greatest influence have cast reproach upon the laws of the Confederacy and the Confederate authorities, and have made the execution of the laws nearly impossible." In several of the other States there were also very serious issues between State and Confederate authorities.

In view of these facts, and of the history of all confederations of many small countries, it may now be clearly seen that the prize for which the South contended so strenuously would have proven but a calamity had she won it. There would have been in the country a condition of unstable equilibrium, with many centres of disturbance, which would surely have involved further division and probably further wars. To-

day her people are citizens of a nation second to none in military renown or commercial strength, or in its power and influence for peace and civilization among the peoples of the earth. Were the right peaceably to secede, for which the South cheerfully endured all the bitterness of war, now tendered her as a free gift, every State would unanimously reject it as a curse.

Few generations of modern times have confronted sterner problems than did the men of the South in 1861. In the natural world, whenever the climate has changed, the fauna and flora have had to change to conform to new conditions. This is the law of evolution, the one great truth of which mankind may feel assured. It is not "Eternal Justice" which will prevail. It is "Conformation to Environment." And the natural resistance to change by all interests in possession, makes evolution mean war to the death of the least fit, and the survival of the fittest.

Had the South been quick to apprehend these truths, then being first published to the world by Darwin, she might have accepted compensation for her property in slaves, and surrendered her constitutional right to secede. Had she done so, over 500,000 lives, and \$10,000,000,000 of property, would have been saved.

But the Anglo-Saxon is not a ready barterer of what he deems his "rights." Nor would any nation thus founded upon "consent" have commanded confidence, or ever inspired the national pride and loyalty which form the greatest treasures of a people. The conflict, with all its death and destruction, its sorrows, and its sufferings, was but the necessary baptism of this nation, legitimating its disputed birth by a verdict in the great high court of war, rendered in accordance with the laws of evolution, beyond which there is no appeal.

But while the generation which so lavishly poured forth blood and treasure may rightfully cherish to the last an ardent affection for its "Lost Cause," with its leaders and its heroes; not only its own children, but all succeeding generations, will enjoy great and enduring benefits and blessings, the very fruit of the desperation of its struggle, and of the utterness of its defeat.

And in its influence upon national character, and upon the standing of this nation among other nations, it is no small matter to have made the record for valor and devotion to principle which the South has set; or to have produced such leaders and types as Lee and Jackson and their colleagues.

Briefly it may be said that the rise and fall of the Confederate States of America constitute the most important feature of modern history, marking the sudden birth of a great nation. Such a nation could never have been founded in peaceful debate. The world may eventually reach a stage of development where such an event may be possible, but it had not done so in 1860. Previous to that date there was no assurance of stability to the nation. Since 1865 no convulsion could shake it. Succeeding years only demonstrate to the inhabitants of every section the increasing advantages of living in an undivided and an indivisible country.

Confederation, Articles of. With the American resolve to be free came the necessity of a government with defined legal powers, and the Continental Congress, on the same day (10 June 1776) it appointed a committee to draft a Declaration of Independence, appointed another, one member for each colony, to frame an instrument of government. This was entitled the "Articles of Confederation and Perpetual Union," and reported 12 July; but after debate on it till 20 August, it was laid by till 8 April 1777, and not adopted till 15 November. The Congress sent a circular to the State legislatures, recommending its acceptance, and under their instructions all but five States signed it 9 July 1778, North Carolina and Georgia following on the 21st and 24th, respectively. But there had already been wrangling and heart-burning over the question of the unsettled western lands (see TERRITORIES) which, if given to the respective States according to their theoretical limits, extending to the Pacific, would have made a few overwhelmingly great, and left others too small to maintain their rights, and New Jersey, Delaware, and Maryland held aloof, insisting that the uncolonized lands should be ceded to the general government, for the common behoof of the Union whose common sacrifices must win them. New Jersey, its judgment clarified by the fact of its commerce being at the mercy of New York, protested further that the new government should have power to regulate commerce; but it signed 26 November, relying on the "justice and candor" of the rest in the territorial matter. Delaware, under protest, joined 5 May 1779, but Maryland held off nearly two years longer, till New York had ceded a blanket claim to the entire northwest, and Virginia showed signs of yielding. It finally signed 1 March 1781, and the Articles went into operation as follows:

1. "The style of this confederacy shall be 'The United States of America.'" 2. Reserving to the States full sovereignty, and all rights not expressly delegated to Congress.
3. Declaring a mutual defensive league.
4. Securing mutual citizenship of freemen, and mutual extradition.
5. Organizing a single-chamber Congress; members elected annually by the State legislatures, and subject to recall at any time; each State to have two to seven delegates, but only one vote (population not being then ascertainable).
6. Prohibiting State alliances or treaties with each other or foreign countries, grant of titles of nobility, customs dues infringing treaties already proposed, maintenance of naval or military forces except militia, or engaging in war except on declaration by Congress or imminent danger.
7. Providing for national expense by requisitions of Congress upon the States, which were to levy the needful taxes within the time set.
8. Empowering Congress (but only on the consent of nine States for the chief powers and seven for the rest) to make peace and war, treaties, etc., save that no treaty should

restrain States from laying customs duties binding on their own citizens, even up to prohibition, making it the arbiter of territorial disputes between States; empowering it to fix the standard of coins, weights and measures, to manage Indian affairs (subject to State legislation), and to regulate the postal service; to direct military and naval operations; to borrow money, and make requisitions for that and men on the States; and to appoint committees. The only function it could exercise at will, however, was to adjourn from day to day. 9. On minor matters it could delegate its powers during recess to a "committee of the States," one member from each, nine being a quorum. 10. Authorizing Canada to join, but no other colony except on vote of nine States. 11. Pledging the faith of the States for the money borrowed or appropriated by Congress. 12. Binding the States to abide by the votes of Congress and to observe all these articles inviolably, and declaring that "the union shall be perpetual"; the articles not to be altered except by vote of Congress, confirmed unanimously by the State legislatures.

The organized and carefully barricaded impotence of this scheme of government is probably unequalled in history, with any nation surviving, and is only to be accounted for by a mutual fear on the part of the States greater than their fear of the common enemy — which is usual in federations. The States were independent sovereignties, united in a league of which the first object was, not to guard against Great Britain, but against each other. Its units were the State legislatures, which made and minutely controlled it, of which the delegates were the mouthpieces, and through which every power had to be exercised; and a small minority of which could at any moment quench even its feeble vitality by recalling or not appointing their delegates. Its action was entirely confined to States; it could not even order an individual to do anything, much less compel him to do it; and even as to the States its nominal orders were only requests, which they could and did disregard. If it arbitrated their quarrels, they could disregard its decisions. A "perpetual union" but if any State chose to withdraw there was no power to prevent it except by requesting the others to wage war against it; and no power to bring it about. "Solemnly pledging" their faith to pay the requisitions and abide by the determinations of Congress, they gave no guaranty of the pledge but the empty words. Congress could pass laws and make treaties, but could not move to enforce them or punish their infraction, either by States or persons; could declare war, but not raise or maintain army or navy; could make appropriations, and constitute national departments, but not raise money to make good the one or operate the other; could borrow money, but not repay it. To cap the climax of a balance of powers which paralyzed all movement, while Congress was debarred from executing national functions, the States were debarred from exercising them; all initiative was given to one and all power to the other. And as commerce of any magnitude centred in a half-dozen seaports, the States owning them could strangle their neighbors and cripple the national revenue by levying interstate duties.

The practical result of the scheme more than fulfilled all theoretical calculations of evil. The

CONFEDERATION OF THE RHINE—CONFESSION

eight years of its duration, until the Constitution was inaugurated in 1789, cover the most deplorable and discreditable section of United States history; and foreign nations looked on with a perfectly rational expectation that the republic would shortly fall to pieces, and a fresh European struggle to become its legatees ensue. So distasteful to able men was service in this paper government, issuing edicts in the air, that political ambition sought careers rather in the State legislatures. While the Articles provided for 91 delegates from the 13 States, the actual attendance rarely rose to 30, the ratification of the treaty of peace with England was delayed for some time because only seven States were represented, nine being requisite, and it was not till 14 Jan. 1784 that nine were represented, with 23 delegates. The requisitions of Congress for money were refused or delayed, scarcely ever paid by any State in full and never on time, and generally but in small part and far in arrear. Hence, not only were the principal and interest of the debt heavily defaulted, but the very soldiers were left unpaid and almost unclothed till the end of the war, and then were only given a scanty sop in terror of their leaving the country to its enemies; and a few unpaid militia broke up the session of Congress in Philadelphia by hooting and pointing muskets at them. Treaties were made which the States and individuals on our part, and foreign nations on theirs, trampled on; American commerce was barred from the markets it held before the Revolution, the powerless Congress ignored, and the States offered treaties severally. The British government refused to surrender the north-western forts on the ground of the States refusing to keep the agreements of the treaty of peace; and the people on the frontier were subjected to the horrors of Indian warfare, which the British commandants did nothing to check, and were accused of abetting. Lastly, an insurrection in Massachusetts (see SHAY'S REBELLION) overturned civil government there for months, and showed that there was literally no power in the country to preserve public order, for the States would not let Congress do it, and could not do it themselves. This gave the final impetus to the movement which turned a commercial convention into one for remodeling the entire framework of the government (see CONSTITUTION, FORMATION OF THE), and rescuing the country from an abyss of degradation and the brink of imminent ruin. The one good piece of work to be credited to the Confederation—due to its being a paper instrument which needed no material execution at the moment—was the framing of the Ordinance of 1787, for the government of the Northwest Territory, which barred slavery from it and furnished a fighting ground for others. On 14 July 1788, the ratification of the new Constitution by the requisite nine States was announced, to be inaugurated 4 March 1789. After 1 Jan. 1789, there was no business session of the Congress of the Confederation, there being only one or two delegates present, who adjourned from day to day (the single act not requiring the assent of seven States), till 2 March, when they adjourned *sine die*. The one useful function of the Confederation was in convincing the States that they must have something better; and without the miserable practical experience of the fact they would never have admitted it. Some-

thing of the kind was an absolutely inevitable stage in the existence of the Union; and there was much honest public spirit and ability put into—but for the utility just mentioned, one would say wasted on—its attempts at action. Consult Bancroft's and Hildreth's 'Histories of the United States'; Frothingham, 'Rise of the Republic'; and Curtis, 'History of the Constitution.' See UNITED STATES—ARTICLES OF CONFEDERATION.

Confederation of the Rhine. In the war of 1805, which turned out so unfortunately for Austria, several of the princes of the south of Germany allied themselves to France. The Peace of Presburg (26 Dec. 1805) gave the first impulse to the entire dissolution of the German empire, by conferring crowns on the electors of Bavaria and Würtemberg, and on both, as well as on Baden, complete sovereignty, such as had been already exercised by the other great German states. Ultimately 16 German princes made a formal declaration of their separation from the emperor and the empire, in the act of confederation signed at Paris 12 July 1806, by the kings of Bavaria and Würtemberg, the elector arch-chancellor of the empire, the elector of Baden, the new Duke of Clèves, and Berg (Joachim Murat), the Landgrave of Hesse-Darmstadt, and other less important rulers. Other princes soon joined, and ultimately the confederacy extended over a space of 125,160 square miles, with 14,608,877 inhabitants; and the confederate forces were increased from the originally stipulated number of 63,000 to 119,180. After Napoleon's Russian campaign of 1812 the whole structure fell to pieces.

Conference. 1. In general, a meeting for consultation, discussion, instruction, or the like; or any interview for interchange of views. The term is specifically applied to consultations between committees of the two Houses of Congress in the United States, and to similar consultations between delegates of the two houses of Parliament in Great Britain. Such conferences are usually called to discuss the provisions of a bill with regard to which the two houses are disagreed, with the object of effecting an agreement between them.

2. A term much used in ecclesiastical government, etc. The annual meetings of Wesleyan preachers in England for deliberation on the affairs of the body are called conferences. In the United States the Methodist Episcopal Church has an assembly called the general conference, which meets once in four years; numerous assemblies called annual conferences; district conferences; and quarterly conferences; these assemblies variously dealing with local or general interests of the Church. In the Roman Catholic Church there are instituted pastoral conferences, chapter conferences, etc.; and in various Protestant denominations there are stated local or general assemblies of chosen delegates from individual churches, who meet to consider or adjust denominational affairs.

Conferva, kŏn-fēr'və, a genus of green algæ. Most of the species are marine, though a few are fresh-water.

Confes'sion, in law, is when a prisoner indicted of an offense, and brought to the bar to be arraigned, upon the indictment being read to him, and the court demanding what he can say thereto, confesses the offense and indictment

CONFESSION — CONFESSOR

to be true. Confession, in civil cases, is where the defendant confesses the plaintiff's right; or, in prosecutions under penal statutes, by which confession there may be a mitigation of a fine against the penalty of a statute, though not after a verdict. When the confession is entirely voluntary on the part of the accused it is admissible as evidence; but if it is obtained through fear or by promises of escape, it is not allowed. If the confession is made in answer to questions not containing, or in any way implying threats or bribes, it is then admissible. See **CRIMINAL LAW**.

It is sometimes applied to a profession of faith; for instance, the Confession of Augsburg; the Westminster Confession. (See **AUGSBURG, CONFESSION OF FAITH**). It sometimes also signifies a religious sect; as the three Christian confessions — the Roman Catholic, the Lutheran, and the Calvinistic.

Confession, Sacramental, the act of a penitent accusing himself of his sins to a priest who has power to grant absolution: it is called auricular confession because addressed to the ear (*auricula*) of the minister of the sacrament of penance, and not made in open congregation: though of course were such public confession to be made the priest would, unless the laws of the Church should forbid, possess the same power of absolution as in auricular confession. The law of the Catholic Church as defined by the Council of Trent, requires that the faithful shall confess to a duly commissioned priest all their mortal sins, and advised to confess venial sins, committed after baptism and since a previous confession and absolution, so far as they can recall them by a diligent examination of their conscience. The penitent is strictly required to confess all his mortal sins, their kinds and their number as well as he can recall them: wilful concealment of a mortal sin or even of what the penitent may erroneously deem a mortal sin, renders the confession of the penitent and the absolution of the minister null, and both of these acts must be done over again and made good. If a penitent, after examination of his conscience, fails to recall any mortal sin he is under obligation to confess that sin afterward and to receive absolution for it. See **ABSOLUTION**.

Confession of Faith, Westminster, a document prepared by the Assembly of Divines which met at Westminster in obedience to an ordinance of Parliament issued 12 June 1643. The whole number of the Assembly amounted to 174 members, 32 of whom were members of Parliament appointed as lay assessors. The greater part of the Assembly were Puritans. One of the chief results of the deliberations of the Assembly was the framing of the Confession of Faith, intended to be that of the national Church of Great Britain. In England it nominally held this position for a short time. On the return of the Scottish commissioners it was laid before the General Assembly of the Church of Scotland, by whom it was adopted as the creed of the Church by the act of Assembly of 27 Aug. 1647. It has been adopted by the other Presbyterian churches generally, in some cases, however, with certain reservations. Its theology and discipline are thoroughly Calvinistic. See **CREEDS; WESTMINSTER ASSEMBLY**.

Confessional, in Roman Catholic churches and chapels, a kind of enclosed seat in which the priest sits to hear persons confess their sins. The confessional is often not unlike a sentry-box, the priest sitting within and the penitent kneeling without and speaking through an aperture. Many confessionals are in three divisions or compartments, the centre, for the reception of the priest; the side compartments, which communicate with the centre by grated apertures, are for the penitents.

Confessions of an English Opium-eater, The, a work by Thomas De Quincey, first published in the 'London Magazine' during 1821. The book is one of the most brilliant in literature. As an English critic has said, "It is not opium in De Quincey, but De Quincey in opium, that wrote the 'Suspiria' and the 'Confessions.'" All the essays are filled with the most unexpected inventions, the most gorgeous imagery, and, strange to say, with a certain insistent good sense. As a rhetorician De Quincey stands unrivaled.

Confes'sions, Les, an autobiographical work of Jean Jacques Rousseau. It was written during the six most agitated years of his life, from 1765 to 1770; and his state of health at this time, both mental and bodily, may account for some of its peculiarities. The first six books were not published until 1781, and the second six not until 1788. According to more than one critic, the 'Confessions,' however charming as literature, are to be taken as documentary evidence with great reserve. They form practically a complete life of Rousseau from his earliest years, in which he discloses not only all his own weaknesses, but the faults of those who had been his friends and intimates..

Confessions of Saint Augustine, The, the autobiographic memoirs of Saint Augustine, written in 397. It is divided into 13 books. The first 10 contain an account of his life down to his mother's death, and give a thrilling picture of the career of a profligate and an idolater who was to become a Father of the Church. Side by side with the pictures he paints of his childhood and of his wayward youth and manhood, we have his variations of belief and his attempts to find an anchor for his faith among the Manichæans and Neo-Platonists, and in other systems that at first fascinated and then repelled him, until his conversion at the age of 32. The narrative is intermingled with prayers (for the Confessions are addressed to God), with meditations and instructions, several of which have entered into the liturgies of every section of the Catholic Church. The last three books treat of the opening chapters of Genesis, of prime matter, and the mysteries of the First Trinity. They are, in fact, an allegorical explanation of the Mosaic account of the Creation.

Confessor, in the Roman Catholic Church has two principal significations. 1. Denoting a canonized male saint outside of the classes of the apostles, evangelists, and martyrs. The only saints, who in the earliest times were publicly venerated in the Church after death were, in addition to the Blessed Virgin and the apostles, the martyrs; and such are all the saints named in the Roman canon of the Mass, though the Milan canon (Ambrosian) has the name of other saints. 2. The other meaning of the

word confessor, the priest who hears confessions, answers to the more correct Latin word *confessarius*. The confessor, minister of the sacrament of penance, does not exercise that ministry simply in virtue of his having received priestly order: he must receive jurisdiction from the bishop of the diocese. The general law of the Church requires each of the faithful to resort to the confessional at least once in every 12 months, and to make confession each to his own parochus or parish priest: but under the law they may now lawfully confess to any priest who has due authorization from the bishop.

Confidential or Privileged Communication, in law, a communication made by one person to another which the latter cannot be compelled to give in evidence as a witness. The laws of the United States and of some other countries are, that all communications made between a client and his agent, between the agent and the counsel in a suit, or between the several parties to a suit, shall be treated as confidential; but in some minor points the practice varies in the different States. Legal agents are of course required to produce any papers intrusted to them by their clients, which the clients themselves would otherwise have been required to produce. The privilege of confidentiality regarding disclosures made to a medical adviser, even although it may have been necessary for the patient to make them in order to enable the physician to understand and treat his case, have not been defined by statute, but the custom has been that such communications are privileged. The same holds true regarding confessions made to a priest. No instances are cited where the confession of a penitent has ever been revealed by a priest. Communications made between husband and wife during marriage are in some States not admissible as evidence, although in most civil cases a husband and wife may legally be called as witnesses against each other. The laws in the United States differ in different States regarding the admission of testimony of husband or wife for or against each other.

Confirma'tion, one of the seven sacraments of the Roman Catholic Church; in the Lutheran, the Anglican, and the Protestant Episcopal Church confirmation is not a sacrament, but only a solemn rite wherein the one who is confirmed renews in the face of the Church the promises made on his behalf by his sponsors in baptism. In the early times of the Catholic Church the sacrament or rite of confirmation was administered immediately after baptism, even of infants: hence the two rites have often been even by orthodox writers viewed as one; and in the Greek and Oriental churches this custom still persists. But in the present discipline of the Latin Church confirmation is usually not administered till about the 12th year, though a child might be held competent to receive it at the age of 7. It is customary for the confirmant to take an additional name as a memorial of the rite. In administering it the bishop — and the bishop is the ordinary minister of this sacrament — with chrism (q.v) marks the sign of the cross on the forehead of the recipient, and gives him a gentle slap on the cheek, in signification that he must be ready to suffer for Christ's name's sake. The formula of words used by the bishop in signing the confirmant is, "I sign thee with the sign of the

cross and I confirm thee with the chrism of salvation, in the name of the Father, and of the Son, and of the Holy Ghost."

Confisca'tion, the act of condemning as forfeited, and adjudging to the public treasury, the goods of a criminal in part punishment of a crime. The subject of confiscating the property of those in rebellion was warmly discussed both in and out of the United States Congress, at the beginning of the Civil War. A bill "to confiscate property used for insurrectionary purposes," etc., approved 6 Aug. 1861, providing for the immediate confiscation of all property belonging to office-holders under the Confederate government, and confiscation, within 60 days after the President's Amnesty Proclamation, of all property belonging to disloyal citizens or privates in the Confederate army, was passed by the House 11 July 1862, and the Senate the next day; and after a slight modification suggested by the President in his veto of the same, on constitutional grounds, it was again passed by both Houses on the 16th, and approved, becoming a law the next day. On 22 July the President issued an order that property needed for the support of the armies of the United States should be seized, an account being kept of the same.

Conformity. When strata of sedimentary rocks succeed one another in unbroken order with parallel bedding planes, and have been affected similarly by earth movements, they are said to be conformable, and the structure is a conformity. A false conformity is when, on an eroded surface of horizontal strata, other strata have been laid down. In such a case there may be an enormous time-break, millions of years, between the two series of strata, yet apparently, from a single rock outcrop or the outcrops in a small area, there is no break. Such false conformities are not uncommon in the Rocky Mountains, and, if the strata are not fossiliferous, are very difficult to detect.

Confucius, kōn-fū'shī-ūs (Latinized form of Chinese K'ung-fu-tzu), Chinese philosopher: b. province of Shantung about 550 B.C.; d. 478 B.C. His father, Shuh-liang-heih, who was of royal descent, died three years later, and the boy was reared in comparative poverty by his mother, Ching-tsai. At the age of 17 he was made inspector of corn-markets; at 19 he married; and some four years later he began his career as a teacher. In 517 B.C. he was induced by two members of one of the principal houses in Lu, who had joined his band of disciples, to visit the capital with them, where he had interviews with Lao-tze, the founder of Taoism. Though temporarily driven from Lu to Tsi by a revolution, he soon returned thither with an increasing following, and at the age of 52 was made chief magistrate of the city of Chung-too. So striking a reformation was effected by him that he was chosen for higher posts, became minister of crime, and with the aid of two powerful disciples elevated the state of Lu to a leading position in the kingdom. Its marquis, however, soon after gave himself up to debauchery, and Confucius became a wanderer in many states for 13 years.

In 483 he returned to Lu, but would not take office. The deaths of his favorite disciples Yen Hwin and Tze-lu in 481 and 478 did much to further his own, which took place in the latter year. Confucius left no work detailing his

moral and social system, but the five canonical books of Confucianism are the "Yih-king"; the "Shu-king"; the "Shi-king"; the "Le-king"; and the "Chun-tsien"; with which are grouped the "Four Books," by disciples of Confucius, the "Ta-hëo or Great Study"; the "Chung-Yung or Invariable Mean"; the "Tun-yu or Philosophical Dialogues"; and the "Hi-tse," written by Meng-tse or Mencius. (See SACRED BOOKS OF THE EAST.) The teaching of Confucius has had, and still has, an immense influence in China, though he can hardly be said to have founded either a religion or a philosophy. All his teaching was devoted to practical morality and to the duties of man in this world in relation to his fellowmen; in it was summed up the wisdom acquired by his own insight and experience, and that derived from the teaching of the sages of antiquity. Consult Legge, 'Religions of China'; Douglas, 'Confucianism and Taoism'; Plath, 'Confucius und seiner schüler Leben und Lehren.'

Confusion, in mental diseases acute confusion occurs in the early stages of general paralysis, in acute mania, in melancholia, in dementia precox, and in most of the insanities. It might be called an initial symptom of insanity. The characteristic symptoms are lack of correct appreciation of external expressions, loss of continuity of thought, with a certain enfeeblement of judgment. There are certain insanities characterized purely by acute confusion. See INSANITY.

Confu'so River, Paraguay, a tributary of the Paraguay River. After a winding course in the Gran Chaco, it "pours into the Paraguay, near Villa Hayes, waters as salty as the ocean itself."

Congaree, kōn-ga-rē', a river of South Carolina, formed by the union of the Broad and Saluda, at Columbia, near the centre of the State. After a course of about 50 miles it joins the Wateree, and the united streams take the name of the Santee, which is navigable by steamboats to Columbia.

Cong'don, Charles Taber, American journalist: b. New Bedford, Mass., 7 April 1821; d. New York 18 Jan. 1891. He edited for a time the organ of the People's Party in the Dorr Rebellion in Rhode Island, 1842. From 1857 to 1882 he was on the editorial staff of the New York *Tribune*, and a frequent contributor of critical and literary articles to the magazines. He published: 'Tribune Essays' (1869); 'Reminiscences of a Journalist' (1880).

Congé d'Élire, kōn-zhā-dā-lēr (Fr. "leave to elect"), in England, the sovereign's warrant authorizing the dean and chapter of a vacant see to proceed with a new election. The nomination to bishoprics, originally understood to have been vested in the Christian people, who made it by election, was afterward transferred to the sovereigns of most states, and remained with them till the 11th century, when, by the assistance of the Pope, it was wrested from them and conferred upon the clergy. In England, the Constitutions of Clarendon, in 1164, conferred the election on the chapters, and this right was formally confirmed by Magna Charta, subject, however, to a right in the sovereign to grant a *congé d'élire*, and also to confirm the chapter's choice. Thus matters remained till the Reformation, when

the crown made a very important encroachment, and provided by 25 Henry VIII. c. 20, that though the dean and chapter were still required to go through the form of an election, the person to be chosen should previously be absolutely fixed by the sovereign. This act is still the regulating statute, and not only provides that on every vacancy in a see the sovereign may grant a license to proceed to the election of a successor, and with it a letter containing the name of the person to be elected, but that if the dean and chapter delay the election beyond 12 days, or elect any other person than the one named in the letter, or do anything else in contravention of the act, they incur the penalties of a *præmunire*, that is, forfeiture of goods, deprivation of certain civil rights, and imprisonment. Any bishop or archbishop neglecting to assist at the consecration and investment of the bishop-elect, within 20 days after the legal announcement of his election, is liable also to the penalties of *præmunire*.

Congenital Disease, a disease which the new-born child inherits from its father or mother, or it may be its grandparents. Such diseases are extremely rare. Syphilis, gout, congenital anomalies such as hare-lip, web fingers and toes, etc., are among the few truly congenital diseases. During child-birth children may acquire infections, but these are not truly congenital diseases.

Conger, kōn'gèr, Edwin Hurd, American diplomatist: b. Knox County, Illinois, 7 March 1843; d. Pasadena, Cal., 18 May 1907. He was graduated at Lombard University in 1862, served in the Union army 1862-5, studied law and was graduated at the Albany Law School in 1866. He began the practice of his profession in Galesburg, Ill., removing to Iowa in 1868. He was elected to Congress in 1884 and twice re-elected as a Republican. In 1890 he was appointed minister to Brazil, serving four years. In 1897 he was again appointed to that post and in the following year was transferred to China. He was at his post throughout the Chinese crisis of 1900, in Peking, being imprisoned with his family and the entire diplomatic corps in the British legation compound from 20 June to 15 August. His rescue on 20 August was effected by the allied powers barely in time to save him and his colleagues from a general massacre. He was appointed ambassador to Mexico early in 1905 but resigned in August of that year.

Conger Eel, a species of marine eel (*Leptocephalus conger*) with a long dorsal fin reaching forward nearly to the head and continuous posteriorly with the caudal; the pectoral fins present; strong, close-set teeth in the jaws; mouth and eyes large, and scales absent. The conger is a large eel, the ordinary specimens commonly captured along the New England shores being four feet long, while those taken in the open sea are six to eight feet, and weigh 50 to 60 pounds, or in rare cases upward of 100 pounds. Very little is known of their habits in the natural state, but they are easily kept in aquaria and are known to be ravenous creatures, which devour fishes, crustaceans, and mollusks, and even the smaller members of their own species. From observations made on specimens in captivity in England Dr. Cunningham has concluded that, as in many other fishes, spawning takes place

CONGESTION — CONGREGATIONALISM

but once; the females, upon the approach of that period ceasing to feed and undergoing degenerative changes in respect to the skeleton and other parts. Spawning occurs in the deep sea and during development a transparent band-like larva is formed which was long ago described as a distinct genus under the name of *Leptocephalus*. The conger is a prolific fish, producing about 3,000,000 eggs. After nightfall the conger eel may be induced to take the hook and affords good sport.

Congestion, an abnormal amount of blood in the vessels of a part causes a condition of congestion. This may be present in the arteries or in the veins, arterial or venous congestion respectively. In the former case it is usually due to some acute inflammatory reaction, causing rapidity of the heart beat or dilatation of the blood vessels with consequent congestion in some area. In venous congestion, as a rule, the cause is due to some constriction to the venous return to the heart. See **COLD**.

Congleton, kŏn'gl-tŏn, England, a market town and borough of Cheshire, in a deep valley, on the Dane, 24 miles south of Manchester. Among the chief buildings are the town hall, and the grammar-school. Congleton is a seat of the silk manufacture, ribbons, handkerchiefs, and other articles being made; it also carries on fustian-cutting, the manufacture of agricultural implements, rope-making, brewing, etc. Near it are collieries and quarries. Pop. 10,000.

Conglom'erate, or **Puddingstone**, a firm rock made up of rounded detrital pebbles and even boulders, the interstices usually filled with sand. Silica is the commonest cementing material, calcite, and limonite coming next. The pebbles and boulders may be of any kind of rock, though quartz and quartzite are the most frequent, since the most resistant material in gravels. According to the character of the pebbles, different names are given, as quartz conglomerate, limestone conglomerate, etc. Conglomerates grade through pebbly sands and sandstones into true sands and sandstones. Under dynamic stress, in the folding of rock strata, the pebbles of a conglomerate may be much distorted, and by further metamorphism a conglomerate may pass into a gneiss. A conglomerate is a sedimentary rock. Some notable conglomerates are the copper-bearing Calumet and Hecla conglomerate on the Keweenaw Peninsula, Michigan, of Algonkian Age; the great conglomerate at the base of the coal measures of Carboniferous Age, in Pennsylvania and adjacent States; the Roxbury conglomerate of uncertain age, near Boston, Mass.; and the famous "banket," possibly of Permian Age, on which are located the great gold mines of the Transvaal. See **BRECCIA**; **GNEISS**; **ROCK**; **SANDSTONE**.

Congo. See **KONGO**.

Congo Free State. See **KONGO**.

Congo Snake. See **KONGO SNAKE**.

Congrega'tion, a gathering or collection of persons; usually a religious assembly; in its most ordinary use, an assembly of Christians met in one place for worship. In the Roman Catholic Church, it often designates a sort of board of cardinals, prelates, and divines, to which is intrusted the management of some im-

portant branch of the affairs of the Church. Thus the Congregation of the Index examines books and decides on their fitness for general perusal. The *Congregatio de Propaganda Fide* is instituted for the propagation of the Roman Catholic faith and the government of the Church in non-Catholic countries. The Congregation of Relics inquires into the genuineness of supposed relics. The Congregation of the Holy Office takes cognizance of heresies, etc. The Congregation of Rites regulates the festivals and offices of new saints. There are numerous other Congregations. The word is also used in the Roman Catholic Church to describe communities of ecclesiastics who live together under rule, but without being bound by vow, or at least by solemn vow. Such are the Congregation of the Oratory, the Congregation of the Most Holy Redeemer, usually called Redemptorists, etc.

Congregational Methodist Church, an ecclesiastical body in the United States, organized in Monroe County, Ga., by seceders, lay and clerical, from the Methodist Episcopal Church, in 1852. The movement was in the direction of a more democratic or congregational polity, designed to give the members of individual churches larger and more direct control of their own affairs; but the body still preserves the more essential forms of organization and procedure, such as the conference system, etc., characteristic of the Methodist Episcopal Church. It has a membership of over 20,000 distributed among about 350 churches.

Congregationalism had its origin in an attempt in England to carry the principles of the Protestant Reformation regarding the authority of Scripture to their radical consequences. Accepting the Bible as the sole rule of faith and practice, the founders of Congregationalism sought to find in it not merely an authoritative source of Christian doctrine; but, also, a complete, adequate, and binding pattern of church government and organization. They grew out of the Puritan party of the reign of Queen Elizabeth, of which party they were the most advanced wing. They shared fully the intense Calvinism of that party and differed from it only in matters affecting church organization and government. The great majority of the Puritans held to the conception of a national Church, of which all baptized and non-excommunicated inhabitants of the kingdom were members. The reformation of this Church, though earnestly to be sought by private Christians, they viewed as ultimately the work of the national government, and hence they held it to be a duty to remain in the Church of England, while laboring for what seemed to them its betterment. This reformation involved, in the conception of the Puritans generally, the establishment everywhere of a learned, earnest, preaching ministry; of efficient discipline; of what they deemed a more scriptural organization of the Church; and the disuse of such vestments and forms of worship as seemed to them to be without Biblical authority or to savor too strongly of Roman usages.

The founders of Congregationalism sympathized with these aims and criticisms of the Puritans, but, unlike the majority of that party, they believed that the reforms which they desired in the Church of England should come about through individual initiative, by the separation

CONGREGATIONALISM

from that Church of those who criticised it. Hence the early Congregationalists of England were called "Separatists." They rejected the thought of a national Church. They held that the only proper form of the visible Church is the local congregation, composed of a company of professed disciples of Christ who can claim personal religious experience, and are united to Christ and to one another by a voluntary covenant which transforms a company of Christians into a Church. Of these congregations Christ is the immediate head. Each, they conceived, is completely self-governing, choosing its own officers and administering its own discipline. While no earthly authority outside of such a Church has jurisdiction over it, each such congregation owes advice and aid to its sister congregations as necessity may require. This mutual responsibility and helpfulness has always led American Congregationalists to reject the name "Independent" which is popularly attached to the churches of this order in Great Britain. The officers of such a local Church were conceived by the founders of Congregationalism, following what they thought the New Testament model, to be a "pastor," and a "teacher" who should preach and administer the sacraments; a "ruling elder" who should aid the "pastor" and "teacher" in the administration of discipline; "deacons" to administer the financial affairs and charities of the congregation, and "widows" to care for those in illness and the poor. In their revolt from the prescribed liturgy of the Church of England they held that public prayer should be wholly free; and, like the Calvinists generally, they gave the chief place in public worship to the sermon.

Though Richard Fitz and his associates, whose congregation at London was broken up by the English government in 1567, may be deemed the earliest organized Congregationalists, the first clear presentation of Congregational principles was made in the works of Robert Browne, a graduate of the University of Cambridge in 1572, who passed from Puritanism to Separatism, probably in 1579, organized a church at Norwich in 1580 or 1581, and issued a series of tracts in defense of his views, from his exile at Middelburg in Holland, in 1582. Though Browne not long after conformed to the Church of England, a similar work was taken up by others, notably by Henry Barrowe, a lawyer of London, and Rev. John Greenwood and Rev. Francis Johnson in the same city, where a Congregational Church was organized in 1592. In 1593 Barrowe, Greenwood, and Rev. John Penry were hanged at London for opposing the ecclesiastical authority of Queen Elizabeth, and the Church in London was driven into exile. It found a refuge in Amsterdam under the pastoral care of Francis Johnson and Henry Ainsworth.

Contemporaneously with the later of these events, an apparently independent movement in the vicinity of Gainsborough and Scrooby, led at first by William Brewster, the postmaster at Scrooby, Rev. Richard Clyfton, rector at Babworth, and later also by Rev. John Robinson and Rev. John Smyth, resulted in the organization, about 1606, of congregations at Scrooby and Gainsborough, which were compelled to seek refuge speedily in Holland. That of Scrooby settled, in 1609, at Leyden under the pastoral care of Robinson, and a portion of this

congregation, led by William Brewster, William Bradford, and Edward Winslow, crossed the Atlantic in the Mayflower, and laid the foundations of Plymouth Colony in 1620, thus establishing the first of the Congregational colonies in America.

The settlers of Plymouth were Separatists, but during the years immediately succeeding their establishment in the New World the course of politics in England under James I. and Charles I., was such as to lead many of the Puritans to despair of the attainment of the reforms they desired in Church and State in the home land. The consequence was a large Puritan emigration across the Atlantic; and the establishment, in the course of a decade (1628-38), of the three Congregational colonies of Massachusetts Bay, Connecticut, and New Haven. These Puritan settlers were all led by the radical development of their own principles in a new environment, and the influence of Plymouth example, to establish churches on the Congregational model, at their settlement in New England.

These colonies differed slightly from one another in the degree in which they applied theocratic principles to the organization of the State. In Massachusetts from 1631 to 1664, and in New Haven from 1639 to 1665, when New Haven was absorbed in the Connecticut Colony, the franchise was confined to church members. In Connecticut and Plymouth colonies no such restriction existed. Doctrinal discussion aroused by Mrs. Anne Hutchinson and her adherents at Boston occasioned the meeting of the first "Synod" or council representative of the Congregational churches of New England, in 1637. At the Cambridge Synod, in 1648, these churches, by their pastors and delegates there assembled, adopted the "Cambridge Platform" as a compact manual expressive of their views of the organization, officers, and discipline of the churches. The first century of New England Congregationalism saw, however, little theological debate, for the New England churches stood on the common doctrinal ground of Calvinistic Puritanism. The chief controversy of this period was that regarding church membership known as the "Half Way Covenant" discussion. In the view of the founders of Congregationalism the reception of a parent to church membership by "owning the covenant" involved the admission into church membership of his immature children. But adult membership implied experimental Christian character. When the children of the first settlers began to grow to maturity the question of their status forced itself, therefore, on the attention of the churches. A ministerial convention, representative of Massachusetts and Connecticut, held at Boston in 1657, and a "Synod" of the Massachusetts churches convened in 1662, decided that such as were church members in childhood by reason of their parents' membership, could, when they in turn became parents, bring their children to baptism, and could confer upon such children the same degree of membership which they themselves possessed; but unless consciously and personally of Christian experience could not vote on ecclesiastical questions or partake of the Lord's Supper. Hence a distinction between members in "full communion" and in "half way covenant" was made, which continued till early

CONGREGATIONALISM

in the 19th century, when it disappeared, largely owing to the opposition which Jonathan Edwards and his disciples had manifested to it from 1749 onward.

Congregationalism, like the Calvinistic churches in general, believed in the necessity of education, and therefore the New England colonies speedily after their foundation established schools, and planted Harvard College in 1636. Yale College followed in 1701. This spirit has characterized Congregationalism throughout its history and has led Congregationalists to be pre-eminently founders of schools and colleges as they have extended westward in the United States. The elaborate system of church officers already described, and believed by the founders of Congregationalism to be scriptural, outlasted the first generation of the settlers of New England in only a few instances. While they existed "pastor," "teacher," and "ruling elder" all received salaries from the churches they served; but in most of the New England churches "teachers" and "ruling elders" soon disappeared, leaving only a pastor and a variable number of deacons. The more modern growth of organization and methods of Christian work has led to the establishment of other officers, such as a clerk, a treasurer, a Sunday-school superintendent, and often one or more standing committees, and no feeling now exists that officers should be limited to those mentioned in the New Testament as possessed by the early Church. The pastor remains, with rare exceptions, the only salaried officer. The support of public worship which was originally by voluntary gifts, and has always been so in Great Britain, became, between 1638 and 1655, a matter of public taxation in all the Congregational colonies. In Connecticut this relation to the State which made Congregationalism practically a State-supported Church lasted till 1818, and in Massachusetts till 1834; but since the latter date Congregationalism has nowhere enjoyed State aid.

The high-wrought spiritual impulse manifested by the first settlers of New England was followed by a period of decreasing religious interest affecting the second, third, and fourth generations on New England soil. This condition was terminated by a series of "revivals," of which the first manifestation was in that at Northampton, Mass., under the pastorate of Rev. Jonathan Edwards in 1734, and of which the culminating expression was witnessed in the two years following the preaching tour of Rev. George Whitefield in 1740. This spiritual quickening is known as the "Great Awakening," and undoubtedly added many to the membership of the churches. It was marked, however, by much excitement, and was followed by a period of spiritual decline lasting through the troubled years of public conflict and debate which ended with the adoption of the Constitution of the United States. It resulted in serious controversy in the churches of New England as to its merits, those who opposed it as on the whole harmful being called "Old Lights" while those who favored it were nicknamed "New Lights."

In the teachings of Jonathan Edwards (1703-58) a theological movement of importance in American religious history began; and the modified Calvinism of the Edwardean school was further developed by Joseph Bellamy (1719-90), Samuel Hopkins (1721-1803), the younger Jona-

than Edwards (1745-1801), Timothy Dwight (1752-1817), and Nathanael Emmons (1745-1840) into a distinctive New England theology. In eastern Massachusetts, on the other hand, a "liberal" school arose before the American Revolution, which grew slowly and was made clearly evident in the Unitarian separation of the early years of the 19th century—a separation that had its most conspicuous manifestation in the adherence of Harvard College to the "liberal" side in 1805, though the full significance of the division was not apparent until 10 years later.

With the decade beginning in 1791, the Congregational churches of New England experienced a series of revivals which were repeated at intervals until 1858. Under these impulses not only was the membership of the churches much enlarged, but a rapid development of agencies for missionary evangelization and religious education took place. The churches of Connecticut, which had already done home missionary work in Vermont and New York for more than 20 years, organized their "General Association" in 1798 as the "Missionary Society of Connecticut." A missionary society was formed in Massachusetts in 1799. In 1801 the "New Hampshire Missionary Society" was inaugurated, and in 1807 a similar organization was effected in Vermont. These societies were chiefly engaged in home missions in the then western States and Territories, though some work was done by them among the Indians; but in 1810, the "American Board of Commissioners for Foreign Missions" came into being and enlisted the activities of the Congregational churches in evangelization abroad. This society was followed, in 1815, by the formation of what is now known as the "Congregational Education Society" for assisting ministerial candidates and institutions of learning. In 1826 an "American Home Missionary Society," now known as the "Congregational Home Missionary Society" was organized to undertake home missionary work. These were followed later by the formation of the "American Missionary Association," in 1846, for labor, especially, among the negroes and Indians of the United States—a society which has done a large missionary and educational work in the South since the Civil War. In 1853, the "Congregational Church Building Society" came into being, under the title of the "American Congregational Union"—an organization the work of which is sufficiently described by its more recent name. All these societies still exist and serve as agencies for the missionary activities of the Congregational churches of the United States.

Contemporary with this awakening of missionary activity and immediately consequent upon the passage of Harvard University to the "liberal" side, occurred an extensive development of theological education, beginning with the opening of Andover Theological Seminary in 1808. Bangor Theological Seminary was founded in 1816; and, in 1822, the theological department of Yale University was organized. Local disputes in Connecticut growing out of the modified type of Edwardean theology presented by Prof. Nathaniel W. Taylor of Yale, led to the organization, in 1834, of what is now known as "Hartford Theological Seminary." The theological department of Oberlin College came into existence in 1835, and the westward growth of the denomination brought about the opening of "Chicago Theological Seminary" in 1858, and

CONGREGATIONALISM

of "Pacific Theological Seminary," now at Berkeley, California, in 1869. The latest school for ministerial training is that opened at Atlanta, Georgia, in 1901. These eight theological seminaries are the principal agencies for the training of the ministry of the Congregational churches of the United States. The Congregationalists of Canada have a seat of ministerial education in the "Congregational College of Canada," established in 1830, and now affiliated with McGill University at Montreal. In Great Britain no less than 11 Congregational "colleges" do a work similar to that of the "theological seminaries" on this side of the Atlantic.

To the close of the 18th century the Congregational churches of the United States were practically confined to New England; and, in the subsequent westward extension of New England emigration, Congregationalism and Presbyterianism long worked together in the formation of churches in the newer states under the so-called "Plan of Union" of 1801. This "Plan" was repudiated by the "Old School" wing of the Presbyterian body in 1837, and by the Congregational churches, through the "Albany Convention," in 1852. Congregationalism has now extended in force to those parts of the United States, especially, which have been settled through New England emigration. Throughout the latter half of the 19th century, the Congregational churches of the United States have felt an increasing denominational consciousness, which has found its expression, among other ways, in the gathering of bodies representative of these churches as a whole. A "Convention" met at Albany in 1852, a "National Council" at Boston in 1865, and since 1871 a "National Council" has met every three years. Besides this "National Council" in which delegates of the churches of the United States are regularly assembled, the churches of each State are represented in an annual "Conference," "Convention," or "Association"; and the churches of smaller districts, usually counties, meet in more local "Conferences" or "Associations." None of these bodies are in any sense courts of discipline, but they gather for deliberation, consultation, and joint action by committees, or otherwise, in matters of common concern.

Each Congregational church is a self-governing body, capable of choosing its own officers, expressing its creed in such forms as seem best to it, determining the conditions for the admission of its members, and ordering its public worship as it deems most fitting. But while a Congregational church is a self-governing democracy, Congregationalism, always in the United States, and increasingly in Great Britain, has insisted that its churches are knit together in sisterly fellowship, and owe, therefore, to one another, advice in all matters of importance, discipline in evident error, and mutual helpfulness. Hence in questions of serious ecclesiastical concern, such as the settlement or dismissal of a pastor, the management of a case of discipline which the local church finds it impossible to handle, the organization of a new church, and the like, Congregational usage in the United States, though not in Great Britain, requires the summons of an "advisory council" composed of a variable number of churches, chiefly from the vicinity, which are represented in the council by their pastors and a delegate

each. These councils oftentimes also include a few individuals summoned by name as experts in the matter under consideration. By such an "advisory council," met for the particular occasion, advice is given; and, though this advice is not obligatory, it is seldom that the opinion of such a council is disregarded.

Membership in a Congregational church is conditioned on the vote of the local church itself, in view of the candidate's profession of faith in Christ, evident determination to live a Christian life, and acceptance of the covenant obligations of Christian service in connection with the local company of Christian disciples of which he desires to become a member. While all matters of concern in a local congregation are determined, ultimately, by the votes of the membership, Congregational churches transact their business chiefly through the use of committees, and a standing "prudential committee" to assist the pastor and deacons is appointed in most churches of numerous membership.

But while each church is thus free to establish such a test of the faith of candidates for its membership as it deems proper, Congregationalists in representative assemblies or in a more informal way, have always been ready to testify to their faith by public creed declarations. Examples of such witness-bearing have been the approval of the doctrinal portions of the Westminster Confession by the New England churches by the Cambridge Synod in 1648; the modification of that confession by delegates of the English churches gathered at the "Savoy," London, in 1658, and its publication as the "Savoy Declaration"; and the substantial confirmation of this "Declaration" by the churches of Massachusetts in 1680, and of Connecticut in 1708. Later examples of the same readiness of Congregationalists to witness to their beliefs is seen in the "Principles of Religion" adopted by the "Congregational Union of England and Wales" in 1833; the "Burial Hill Declaration" approved by the "National Council" of the United States in 1865; and the "Commission Creed" issued by a committee of the same American body in 1883. All of these statements have been regarded, however, as testimonies rather than as tests of ministerial fitness or church-fellowship.

Aside from its representation in the United States, Congregationalism is strongly entrenched in Great Britain, where its adherents are often known by the name "Independents." The churches of this order in Great Britain are grouped together in county and district "Unions" and "Associations" and are represented in the "Congregational Union of England and Wales" and the "Congregational Union of Scotland." In general, however, the Congregational churches of Great Britain have emphasized mutual accountability and organization into representative bodies much less than those of the United States. Congregationalism is creditably represented in the Dominion of Canada and in Australia, as well as on missionary soil, where the two extensive Congregational missionary agencies, the "American Board," and the "London Missionary Society," have labored. An "International Council," representative of all lands in which Congregationalism has found a home, held its first session at London in 1891, and its second at Boston in 1899.

CONGREGATIONS

The statistics of the Congregational churches ('Year Book' for 1902), are as follows:

Churches in the United States.....	5,753
“ “ Great Britain	4,873
“ “ Canada and New Foundland	137
“ “ Australia, New Zealand, and Tasmania	349
“ “ Jamaica and British Guiana.....	120
“ “ South Africa	308

The churches of the United States reckoned their members at 647,225, those of Great Britain 436,279, while those of the other districts above mentioned amounted to 43,025. The Congregational ministers on the roll in the United States, as given in the "Year Book" for 1902, numbered 5,717. The enrollment in Congregational Sunday-schools of the United States was 658,405. The home expenses of the churches of the United States for the year 1901 were \$7,580,665; their benevolent contributions \$2,233,722.

The "American Board of Commissioners for Foreign Missions" by which the missionary work of Congregational churches of the United States is carried on, reported the following statistics for the year 1902: Mission stations, 101; out stations, 1,301; American missionaries, 549; native laborers, 3,581; churches, 524; communicants (members), 55,645, of whom 5,609 had been added during the previous 12 months. The "London Missionary Society," through which the foreign work of the churches of Great Britain is chiefly carried on, reported, during the same period, 1,357 stations and out stations, 437 missionaries, 6,203 native laborers, and a church membership of 64,716, of whom 6,657 had been added the previous year.

While the title "Congregational" designates a particular fellowship of churches, or religious denomination, in the United States and Great Britain, the Congregational form of church organization, especially in its aspect of the self-government of the local congregation, is that of many other religious bodies, notably of the Baptists, the Christians, the Unitarians, and of certain branches of the Adventists, and Lutherans, so that the Congregational polity is much more widely extended than the adherents of the churches which officially or popularly bear the Congregational name.

WILLISTON WALKER,

Professor of Church History, Yale University.

Congregations, Religious, communities or orders, bound together by a common rule either without vows or without solemn vows. In France the name is so used as to include associations or confraternities of the laity. A group of monasteries is sometimes called a Congregation; when they unite themselves closely by ties of government and discipline and by similarity of rule. The Cassinese congregations of Benedictines, and the Congregation of Cluny are examples.

Congregations; Roman. A Sacred Roman Congregation is a college or corporation consisting of a certain number of Cardinals, for taking charge of, discussing, and deciding matters which belong to certain particular branches of business. The primacy of the Roman Pontiff of its very nature demands that his counsellors and assistants should be selected throughout the world from among those who have personal knowledge and experience of places and persons in cases submitted for examination or judgment.

To this fact councils owe their origin. They did not, however, suffice. The need of a permanent body at the side of the Pope was felt to be opportune. Thus the College of Cardinals arose. When all the Cardinals were convoked in presence of the Pope to deliberate on a particular point or to transact an affair of importance, this Convocation was called a Consistory. From this Consistory of Cardinals the Roman Congregations took their origin.

The chief author of the Sacred Congregations was Sixtus V. He arranged all the ecclesiastical affairs in a certain system and distributed them among fifteen different congregations.

Afterwards Clement VIII., Gregory XV., Urban VIII., Clement IX., and Pius VII., added other congregations. They are divided into Ordinary and Extraordinary ones according as they are permanent or constituted only for a time.

The congregations consist of Cardinals, only one of whom holds the office of Prefect unless the Holy Father reserves that prefecture for himself. As Secretary, usually a titular Archbishop is appointed. In order that the decisions of the Congregations be valid it is necessary that not fewer than three Cardinals make up each Congregation, unless the Pope by a special indult grants that a less number suffice.

The power of each Congregation is limited to the matters assigned to it by the Pope, and the sphere of its jurisdiction extends over the whole Church.

The form of procedure varies according to the nature of the Congregations, the scope of power that is exercised, and the diversity of the cases presented for deliberation or settlement. Routine matters of no great moment and which are extrajudicial may be settled by the Secretary or the Prefect; while serious questions and judicial causes are laid before the whole Congregation and moreover must be brought to the personal attention of the Pope.

The decisions of the Congregations on the questions proposed are usually given in the simplest forms—for example, "Affirmative" or "Negative."

There can be no true appeal from the sentences of the Sacred Congregations as they are the decisions of the highest tribunals. However, a new hearing may be asked and obtained.

The Roman Congregations are the following:

1. The Congregation of the Consistory.

This Congregation is the solemn gathering of the whole college of Cardinals present in the Curia and assembling before the Pope for consultation and definition of certain most important ecclesiastical affairs. The Consistory is of two kinds, Public and Secret.

According to the present discipline only certain solemn acts are now performed in the Public Consistory, such as the giving of the red hat to the new Cardinals after they have been appointed in the Secret Consistory. In the Secret Consistory are made the promotions to the Cardinalate; appointments of bishops and their transfer from one diocese to another; the granting of Palliums; creation, division, and union of diocese; selection of delegates "a latere" and of coadjutor bishops; solemn allocutions about the most important Church matters, and in general consultations about affairs that are of most serious moment.

The Congregation of the Consistory has or-

CONGREGATIONS

dinarily the Pope for its prefect and consists of from eight to twelve Cardinals. Its secretary is the same as that of the Sacred College of Cardinals.

Annexed to this Congregation is the Congregation for the Examination of Bishops which was instituted by Gregory XIV. Its duties, however, to a large extent, are now performed by the Special Congregation for the appointment of archbishops and bishops, which was first instituted by Benedict XIV. and restored by Leo XIII. on 21 Sept. 1878.

2. The Congregation of the Inquisition or the Holy Office. (See INQUISITION.)

3. The Congregation of the Index of Prohibited Books. (See INDEX.)

4. The Congregation of the Council (*Interpretum concilii Tridentini*).

The Council of Trent in its twenty-fifth session solemnly declared its confidence in the efforts of the Roman Pontiff to remove by opportune declarations and remedies any difficulties or doubts arising from its Tridentine Decrees. Hence Pius IV. instituted a congregation of eight Cardinals to look after the execution and observance of the Council's decrees. Pius V. and Sixtus V. enlarged the faculties of the Congregation. Its duties now lie in the interpreting of disciplinary decrees of the Council of Trent and in the taking of measures regarding the observance of these decrees, and finally it has the power of judging in causes which are implicitly or explicitly contained in these decrees. It has a Prefect, a Secretary, an assistant secretary, and an auditor, and several consultors.

Joined to the Congregations of the Council are:

a. The Special Congregation upon the State of Churches.

b. The Special Congregation upon the Revision of Provincial Synods.

c. The Special Congregation upon the Residence of Bishops.

d. The Congregation of Ecclesiastical Jurisdiction and Immunity.

5. The Congregation of Bishops and Regulars.

This Congregation owes its origin chiefly to Sixtus V. Its special duty is to settle affairs which concern bishops and regulars. Hence it has competency in all cases which regard the proper administration of dioceses by their bishops, excepting only those cases which require an interpretation of the Council of Trent. It receives appeals made to the Apostolic See against bishops, etc., replies to difficulties which may arise in the administration of a diocese; examines, approves, or disapproves the alienation of Church property, etc. It settles contentions which arise between different religious orders; examines complaints caused by the election of a superior general or other superiors or by their administration. In a word this Congregation has competency in all that regards the proper rule and direction of religious orders in the Church. It is constituted upon similar lines to the other Congregations, having a Prefect, Secretary, etc. Annexed to it also are two Special Congregations, namely:

a. The Congregation for Discipline of Regulars, established by Innocent XII.

b. The Congregation of the State of Regular Orders.

6. The Congregations of Rites.

Man is obliged to worship God and he expresses this worship by external rites. These rites and ceremonies which the Church makes use of in the administration of the Sacraments, in the divine offices and generally in the worship of God and the veneration of his Saints, form a grand object lesson for the people of God. They exhibit an external expression of the faith.

To see that these rites are diligently observed, to reform and amend, if need be, books on sacred rites and ceremonies, to make, execute, and interpret liturgical laws, and solve the doubts arising in the execution of them, to prepare the causes of beatification and canonization, the Congregation of Rites was instituted. It owes its origin to Sixtus V., being instituted by him by the Constitution of 22 Jan. 1587.

The Congregation is two-fold; the Extraordinary, which occupies itself only with the beatification or canonization of saints; and the ordinary which decides the other questions pertaining to the jurisdiction of the Congregation of Rites.

The number of cardinals assigned to it depends upon the reigning Pontiff. There is the usual Prefect, the Secretary, an ecclesiastic who is called the Promoter of the Faith, and who has also an assistant, a chancellor, and a hymnographer, whose duty it is to arrange and correct the offices of the Saints and other such matters. Besides these there are a number of Consultors taken from the ranks of the secular and regular clergy.

United with this Congregation is the Holy Ceremonial Congregation, which has supervision of the liturgical and non-liturgical ceremonies used in the Papal Court.

7. The Congregation of Indulgences and Relics.

By his Constitution "in Ipsiis" of 6 July 1669, Clement IX. instituted the Sacred Congregation of Indulgences and Relics. He invested the Congregation with the authority to resolve all doubts and difficulties about indulgences and relics and to correct abuses, to prohibit the publication of false or apocryphal indulgences, to authenticate relics recently discovered, and to oversee the granting of indulgences and the distribution of relics.

The Congregation of Indulgences is formed on similar lines to those of other congregations. It has, therefore, a Prefect, a Secretary, and Consultors, etc. It does not grant any indulgences; the Pope does that. All Rescripts or general concessions of indulgences must be shown under pain of nullity to the Secretary of the Congregation. Leo XIII. ordered an authentic publication of all its decrees from the year 1668 to the year 1882. The work was brought out by Fr. Pustet and Co. and has been declared authentic.

8. The Congregation for the Propagation of the Faith (*Propaganda Fidei*).

The first vestige of the Propaganda is found in a Commission instituted by Gregory XIII. for the purpose of keeping the Catholics of the Greek Rite in the faith and of bringing back schismatics to the unity of the Church. After being perfected by Clement VIII. it was finally erected as it is now constituted by Gregory XIV. on 22 June 1622. Of all the Congregations, the Propaganda for English-speaking countries is the

CONGRESS

most interesting because the dioceses of these countries at the present time are subject to it. All the business which the faithful of missionary countries, clergy and laity, may have with the Holy See is done through the Propaganda.

In these countries it has exclusive jurisdiction and holds the place of all the other congregations. Missionary countries, in the language of the Church, are such as have no episcopal sees and whose ecclesiastical affairs are administered by delegates and vicars of the Pope. These vicars apostolic are usually bishops and are called titular bishops from the fact that they derive their title from some ancient see which no longer exists. But even after episcopal sees and dioceses are canonically erected in these missionary lands with bishops having ordinary jurisdiction, the Propaganda frequently retains the government of them. This is the case in the United States, England, Ireland, Scotland, Australia, Canada, Holland, and some other countries.

The power of the Propaganda is legislative, judicial, and gubernative. Hence it can make laws, decide controversies, and rule over the countries in which it has jurisdiction. The resolutions and general decrees impose upon its subjects the obligation of obedience and are not merely the expression of a probable opinion, as was once asserted.

The Congregation is presided over by a Cardinal who is called Prefect-General. There is also one who is called Prefect of Economy. One of the other officials is a Protonotary Apostolic whose duty it is to collect the acts of martyrs who have sacrificed their lives in missionary countries. Almost every week the ordinary meeting is held, while the general assembly takes place usually once a month.

The principal work of the Propaganda is the spreading of the Catholic faith throughout the world. Consequently it has sent and still sends out many missionaries to preach the Gospel. To prepare young men for their missionary labors Urban VIII. instituted the "College of the Propaganda" which is attached to the Palace of the Congregation. Connected with the Congregation of the Propaganda are:

a. The Congregation for the Affairs of the Oriental Rites.

b. The Congregation for the Correction of Books of the Oriental Rite.

c. The Examination of the New Constitutions of Religious Orders depending on the Propaganda.

d. The Commission for the Examination of the Reports of the Bishops and Vicars Apostolic under the Jurisdiction of the Propaganda.

e. The Commission for the Reunion of Dissenting Churches.

9. The Congregation of Studies.

It was begun by Sixtus V. and instituted by Leo XII. In the bull of Sixtus V. the four famous universities of Paris, Oxford, Bologna, and Salamanca are mentioned. Leo XIII. enlarged the powers of the Congregation and extended its authority over all the Catholic universities of the world.

Its power lies in the erection, constitution, and administration of the Catholic universities for which, having consulted the Pope, it lays down standards concerning the professors, methods, academical decrees, etc.; solves doubts about

rights, privileges and suits or disputes arising between the different universities regarding the degrees or privileges. By a Catholic University is meant one which confers degrees by apostolic authority. Those erected in recent years are the universities of Lille, Paris, Lyon, Angers, Fribourg, Ottawa, Laval, and Washington.

Annexed to the Congregations of Studies is the Commission for Historical Studies.

10. The Congregation for the Fabric of Saint Peter's.

The building of St. Peter's Basilica in Rome was undertaken by Julius II. in 1506. It took years to complete it and a large outlay of money was required in its building and afterwards in its preservation. To administer its affairs Clement VIII. in 1593 erected a special Congregation for the Fabric of Saint Peter's.

The Cardinal Archpriest of the Basilica is its Prefect. The scope and office of the Congregation, inasmuch as it is of practical moment to the Universal Church has regard to donations for pious causes and to certain questions about obligations of saying Masses; for example, the transferring of them from one Church to another or from one altar to another; the extension of time for the saying of them; their reduction in number, etc.

Besides the foregoing Congregations, the Sovereign Pontiff may at any time establish others or diminish the number of those already existing. Thus in 1895 Leo XIII. established a commission for the work of fostering the reconciliation of non-Catholics with the Church.

Consult: Ferraris, 'Congregationes'; 'Decrees of the Council of Trent'; Wernz, 'Jus Decretalium' (Vol. II., Rome 1899); Baart, 'The Roman Court' (Fr. Pustet, New York); Humphrey, 'Urbs et Orbis, or the Pope as Bishop and as Pontiff' (London 1899).

DAVID J. O'HEARN, D.C.L.,
Saint John's Cathedral, Milwaukee.

Congress (Lat. "coming together," "meeting"), a meeting of rulers or representatives of several states, to adjust disputes between different governments. It is necessary to distinguish the meeting in which preliminaries are settled, from the principal congress, which is to bring the affair in question to a decision. The plenipotentiaries when they meet, after mutual greetings, appoint, in a preliminary conference, the day on which the congress is to be opened, and determine the manner in which business is to be transacted, the forms of negotiation, the order of precedence among the different powers, and the time of session. The congress opens by the exchange and perusal of credentials among the plenipotentiaries, which, in case the negotiating parties have referred to the arbitration of a mediator, are given to him. The envoys of the contending powers then carry on their negotiations directly with each other, or by the intervention of a mediator, either in a common hall or in their own residences by turns, or, if there is a mediator, in his residence. These negotiations are continued either by writing or by verbal communication, until the commissioners agree upon a treaty, or until one of the powers dissolves the congress by recalling its minister. Such meetings of the representatives of different countries are sometimes called conferences. The nominal difference between a conference and a

CONGRESS

congress is this, that the representatives of the different countries at the former are the ordinary ambassadors of the respective countries at the court at which the conference is held, while the representatives at the latter are specially deputed for the purpose. Among congresses of the 19th century the chief are the Congress of Vienna, 1815; of Paris 1856; and of Berlin 1878.

Congress, Continental. The first recognition of a solidarity of interests among the English colonies in America, and attempt at joint action against a common foe, was in 1690, by Jacob Leisler, the revolutionary dictator of New York; and this perception was stimulated by the fact that New York bore the first brunt of Canadian invasion, and needed help. He invited the other colonies to send delegates to New York and contribute men and money for a counter-invasion; but none farther south than Maryland responded. A much more comprehensive plan was devised by Franklin in 1754 (see ALBANY CONGRESS), but fell through. In 1765, on occasion of the Stamp Act (q.v.), a colonial congress from all the North except New Hampshire, and only South Carolina of the South below Maryland, met at New York 7-25 October; but took no action except to petition Parliament. In 1773, when the Revolution was impending, Franklin renewed his former suggestion in a letter to the assembly of Massachusetts, whose agent in London he was; but still nothing was done.

The next year, however, on receiving news of the Boston Port Bill, Virginia proposed to the other colonies a Continental Congress in the fullest sense; that is, including Canada, for it was not doubted that this recently subjugated province would gladly join in a revolt against its conqueror. Massachusetts responded 7 June, others followed, and the first real American Congress met in Philadelphia, 5 Sept. 1774, sitting till 26 October. Canada, however, was not represented; nor was Georgia, though it shared in all succeeding Congresses. The instructions to the delegates did not contemplate separation or forcible resistance, but only the proposal of measures to "restore harmony" with Great Britain; and the Congress merely drafted addresses to the king and the people of that country, to the Canadians, and to their own constituents, and recommended non-importation and non-exportation agreements, and the forcible resistance to any forcible attempt to carry out the Parliament's taxation measures. It also advised the immediate election of delegates to a fresh Congress in Philadelphia 10 May 1775; which was carried out by various bodies—legislative assemblies in some cases, popular conventions or committees of safety (q.v.) in others. None of these had any legal power to act for this purpose, and the title of all alike was the will of the *force majeure* of the people; for the loyalist section had equal right to oppose the elections, and it was tacit acceptance of superior fighting force that gave the title. The fact that this Congress was considered necessary at all, and was to have power to organize combined resistance to Great Britain, would be conclusive evidence that the leaders of public opinion had determined on independence unless highly improbable concessions were made, were it not for the extreme reluctance the Congress displayed in declaring it, only doing so under irresistible urgency from public opinion; and had

we not the memory of the hopes of accommodation and conciliation by Union leaders not only in 1860-1, but all through the War. The now frequent charge of hypocrisy against the Revolutionary leaders involves one against all the patriotic statesmen of the decade before 1860.

As soon as war was actually proclaimed by Great Britain the second Congress assumed the fullest powers of sovereignty; much greater than those of the British Parliament, for it combined the powers of that body with those of the king, being itself both executive and legislative head of the nation. It raised military and naval forces and directed belligerent operations with them, authorized privateering, contracted treaty alliances, issued national currency, etc., in both capacities. This was by no usurped power, but by the urgency of the people, who were far more anxious to have it take the powers than it was to exercise them. The provincial congresses appealed to it for authorization, and the people urged it to more energetic action. Its crowning act was the Declaration of Independence; its business from 12 July to 20 August the debating of the scheme of government it had drafted (see CONFEDERATION, ARTICLES OF), but which was not put in force for five years, and for which it was perhaps slight misfortune to have waited. It sat till 12 Dec. 1776.

The session of 20 Dec. 1776 has been hesitantly called the third Continental Congress; for the delegates were selected entirely by the State legislatures, and the body as a whole had a title more definite and regular, though not in reality more legal. But in fact, the second Congress, from the opening on 10 May 1775, was a continuing body in perpetual session; with no definite term of sitting or terms of membership; the State legislatures which had selected members did not specifically send new ones for the new session, but each chose them for such terms as it pleased—Congress exercising no right of control in this matter—and recalled them at will. Each State had but one vote, being thus equal, as in the Senate, where each has two; but in the Senate the members have individual votes. This provision in the Continental Congress was avowedly made only because a census could not then be taken to ascertain the relative populations. As under the Confederation, the Congress dealt with States, not individuals; and much of the impotence with which it is reproached in the Revolution was involved in this, though not all of its follies are thus excusable. Some of its worst performances, however—as the misdealing with the officers which drove some of them from the service permanently and others temporarily, and deeply injured the cause—were directly due to the tenacious individuality of the States, which claimed their share of the military patronage then as they do of the civil patronage now.

A history of the Congress is a history of the country during its lifetime; but some of its migrations are significant of military reverses and recoveries. From 20 Dec. 1776 to 4 March 1777 it sat at Baltimore; 4 March to 18 Sept. 1777, at Philadelphia; 27 Sept. 1777, at Lancaster, Pa.; 30 Sept. 1777 to 27 June 1778, at York, Pa.; 2 July 1778 to 21 June 1783, at Philadelphia. But before this it had ceased to be the Continental Congress, and become the Congress of the Confederation, on 2 March 1781, after the ratification of the Articles by Maryland. Con-

CONGRESS — CONGRESS OF THE UNITED STATES.

sult: Histories of the United States by Bancroft, Hildreth, Schouler, Von Holst, etc.; Fiske, 'Critical Period of American History' (1888).

Congress, Library of, an institution in Washington, D. C., which, despite its restricted name, is really the National Library of the United States. The Library of Congress was established in 1800, destroyed in 1814 by the burning of the capitol, afterward replenished by the purchase by Congress of the library of ex-President Jefferson, 6,760 volumes (cost, \$23,950); in 1851, 35,000 volumes destroyed by fire; in 1852, partially replenished by an appropriation of \$75,000; increased (1) by regular appropriations by Congress; (2) by deposits under the copyright laws; (3) by gifts and exchanges; (4) by the exchanges of the Smithsonian Institution, the library of which (40,000 volumes) was, in 1866, deposited in the Library of Congress, with the stipulation that future accessions should follow it. Fifty sets of government publications are placed at the service of the Library of Congress for international exchanges through the Smithsonian. Other special accessions have been: the Peter Force collection (22,529 volumes, 37,000 pamphlets), purchased 1867, cost \$100,000; the (Count de) Rochambeau collection (manuscript), purchased 1883, cost \$20,000; the Toner collection (24,484 volumes, numerous pamphlets), gifts in 1882 of Dr. Joseph M. Toner; the Hubbard collection (engravings), gift in 1898 of Mrs. Gardiner G. Hubbard; in 1905, 72 manuscript maps once owned by Richard, first Earl Howe, and 860 letters received by President Van Buren.

The collection in the main library now (1905) comprises 1,344,618 books, 250,000 pamphlets, 26,500 manuscripts, 82,744 maps and charts, 410,352 pieces of sheet music, and 183,724 photographs, prints, engravings, and lithographs. Of the printed books, probably one third are duplicates. The law library of 110,978, volumes (which remains at the capitol) is not included in the above. The main collection is rich in Federal documents, history, political science, jurisprudence, and Americana in general, including important files of American newspapers and original manuscripts (colonial, revolutionary, and formative periods). The exhibition cases on the second floor contain many rare books, including the records of the Virginia Company. The Smithsonian deposit is strong in scientific works, and includes the largest assemblage of the transactions of learned societies which exists in this country.

In 1897 the main collection was removed from the capitol to the Congressional Library Building (q.v.). Congress makes an annual grant for the maintenance of the library. In 1899-1900 the grant was \$25,000 for printing and binding and \$31,680 for books and periodicals.

Congress of Religions, an assemblage of representatives of all the Christian denominations and other religious bodies of the world, held at Chicago during the World's Columbian Exposition of 1893. Among these were Buddhists, Mohammedans, and the followers of other Asiatic religions, and the tenets of the various faiths were expounded in many strange tongues. The greatest harmony prevailed, and the meeting was one of the most interesting events of the great exposition.

Congress of the United States. The discussion of this body falls naturally into three parts: (1) the constitutional mandates concerning it; (2) its own rules and usages; (3) its practical functions as developed by historical evolution.

1. By the first article of the Constitution, the legislative power of the country, so far as granted at all, is "vested in a Congress of the United States, which shall consist of a Senate and House of Representatives."

The Senate must consist of two senators from each State (thus equalizing the power of the States to safeguard their own interests), elected by the State legislatures for six years; the terms so arranged that one third are vacated every two years, making it a continuing body. Each legislature fills any vacancy in its State delegation caused by death or resignation, but if one occurs while it is not in session, the governor of the State may fill it pro tem till the legislature meets. A senator must be 30 years old, 9 years a citizen, and an inhabitant of the State which elects him; but the legal definition of residence is impliedly left to the State. The president of the Senate is the Vice-President of the United States, who has only a casting vote; but in his absence, or on his accession to the presidency, it shall choose a president pro tem. All impeachment trials are its prerogative, to be decided by a two thirds vote; if the President is impeached, the chief justice presides; it can inflict no punishment but removal from and disqualification for office. No treaties are valid without the consent of two thirds of the Senate; nor any appointment to office by the President without the consent of a majority of it, unless Congress takes away this power from the senatorial half of itself, which it is not likely to do.

The House must consist of members chosen for two years by popular election, so that each House is a new body; the voters to be the same who choose the most popular branch of each legislature; each member must be 25 years old, seven years a citizen, and an inhabitant of the State. The number from each State must be graded by population, determined by a decennial national census (in the body of the Constitution, three fifths of the slaves are to be counted in, a provision made obsolete by the Thirteenth Amendment). These representatives must not exceed one to 30,000 inhabitants—which would allow a maximum of about 2,550 at present, in place of the actual 386. In case of vacancy, the State executive is to issue a writ of election to fill it. The House chooses its own speaker. And lastly, it has the sole power of presenting the impeachments which the Senate has the sole power of trying.

The State legislatures were to fix the times, places, and manner of electing members of either House, subject to the right of Congress to change anything but the place of electing senators, which of course is the legislative chamber. But the numerous deadlocks and failures to elect, due to the two branches of the legislature being under different political control, and the minority House refusing to meet the other for an election, led to the law of 2 July 1866, prescribing a uniform rule for all States. Congress is to meet at least once a year; on the first Monday in December unless it orders otherwise. The President can convene a special session on

CONGRESS OF THE UNITED STATES

“extraordinary occasions”); but he cannot adjourn or prorogue it except in case of disagreement between the Houses—a provision suggested, like so many others, by the quarrels of the English Parliaments with the kings. Each House is the judge of the qualifications of its own members. A majority of each constitutes a quorum; but a single member can adjourn from day to day, and can compel the attendance of enough absent members to make a quorum if the House will provide a rule for so doing. Each House makes its own rules of procedure, can punish members for disorderly behavior, and two thirds can expel a member. Each must keep a journal of its proceedings (see *CENSURE, Congressional*, for argument on the implications of this), and publish it, except such part as the House judges best to keep secret. One fifth of the members present at any time may compel a yea and nay vote to be taken on any question, and entered on the journal. Neither House during a session shall adjourn for more than three days or to any other place, without consent of the other. Members of both Houses shall be paid by the nation. They shall be exempt from arrest during the session and in journeys to and from, and from liability for any utterances in debate—a reminiscence of the burning need of such provision in older English history; not often invoked now, and still less often for creditable reasons. No member shall be appointed to any office created or its pay increased during his term—again a souvenir of temporary political squabbles; and no officeholder shall be at the same time a member. Bills for raising revenue must originate in the House (originally a safeguard for the large States, against the small ones using their power in the Senate to throw the financial burdens on their richer neighbors); but the Senate can propose amendments. Bills vetoed by the President must be reconsidered by, and the objections entered in full on the journal of, the House where they originated; and a two thirds vote may pass it to the other House, a two thirds concurrent vote of which makes it a law. (The first Congress, on the question arising, decided this to mean two thirds of those present and voting, not of the whole membership.) Such votes must be yea and nay, and entered on the journals. A bill not returned by the President within 10 days (Sundays excepted) becomes a law *ipso facto*, unless Congress adjourns meanwhile, when it lapses. No order, resolution, or vote of the concurrent Houses is valid without the assent of the President, except one to adjourn.

The powers of Congress are generally those inherent in every sovereign assembly of the people; but there are two important restrictions. The President's veto (above) is a very real restraint on tyranny by a bare majority, perhaps not honestly obtained and always inviting dishonesty with such supreme power; and it retains full vitality, while the English royal veto has perished. Still more important is its confinement by the Constitution to the powers expressly granted: its laws are invalid if pronounced by the supreme court contrary to the Constitution, while a majority vote of the English Parliament could theoretically abolish the monarchy or hang the entire population. Too much is sometimes made of this, however. The “implied powers” of caring for the national wel-

fare have been found in practice elastic enough for every claim of sovereignty. As to the supreme court, it is the creature of an act of Congress and could be abolished by another (as a whole system of national courts actually was); more simply, it can be and has been swamped and packed to reverse an unpopular decision, and if its decisions are defied (as they were under Jackson), it is powerless to enforce them. Hence it is very cautious about deciding “political” issues of burning intensity (see *CHEROKEE CASE*), except in the sense of the majority, or opposing a strong current of popular feeling. In a word, Congress is the ultimate sovereign. Its inhibitions by the Constitution reflect past history and the politics of the time curiously enough. It is not to prohibit the slave-trade before 1808, and not to grant titles of nobility—conversely, no one is to receive office, title, or gift from any foreign potentate without its consent; it is not to suspend the habeas corpus except on account of rebellion or invasion, not to pass bills of attainder, not to lay export taxes, nor direct taxes except in proportion to population, not to give preferential duties between the States, or enforce clearances at ports outside a vessel's destined State. Not all of these things were needless fetters; and certainly the prohibition from drawing money except on regular appropriations, and the injunction to publish the disposition of the money drawn, was not one.

There being at present 45 States, the number of senators is 90. The number of representatives has never been determined by the Constitutional provision, whose minimum was fixed when the country had but 2,500,000 or so of inhabitants. A maximum of desirable numbers has been fixed, and this has been slowly enlarged from the reluctance at each census to reduce the actual number of representatives in Congress from any given State; hence each has retained all it had, but the States with increased population have been given more members. In January 1901, on the basis of the census of 1900, Congress fixed the number at 386, to take effect 3 March 1903. The State membership was as follows: Arkansas, 7; California, 8; Colorado, 3; Connecticut, 5; Delaware, 1; Florida, 3; Georgia, 11; Idaho, 1; Illinois, 25; Indiana, 13; Iowa, 11; Kansas, 8; Kentucky, 11; Louisiana, 7; Maine, 4; Maryland, 6; Massachusetts, 14; Michigan, 12; Minnesota, 9; Mississippi, 8; Missouri, 16; Montana, 1; Nebraska, 6; Nevada, 1; New Hampshire, 2; New Jersey, 10; New York, 37; North Carolina, 10; North Dakota, 2; Ohio, 21; Oregon, 2; Pennsylvania, 32; Rhode Island, 2; South Carolina, 7; South Dakota, 2; Tennessee, 10; Texas, 16; Utah, 1; Vermont, 2; Virginia, 10; Washington, 2; West Virginia, 5; Wisconsin, 11; Wyoming, 1.

2. Each house has its own system of rules for business (78 in the Senate, 45 in the House), with vital differences. The most far-reaching is the previous question in the House and the absence of it in the Senate. The reasons for the difference are obvious: the great number of representatives, and the fact that most bills are first introduced there, would make business not merely difficult but impossible if every one could talk at will to any length; the smaller numbers and lesser business of the Senate enable free debate to be retained. The House restricts speeches to an hour; the Senate has no restriction except that a member cannot speak

CONGRESS OF THE UNITED STATES

over twice a day on the same question. Each system of course has its attendant possibility of evil: the suppression of needful public light on bills in the one case, "filibustering" and holding up of public business by a factious or interested minority in the other. The business of both Houses is done by committees; neither will consider bills or memorials at once on presentation, except on suspension of the rules — which to be sure, during the latest days of a session, lets through vast numbers of undebated, unexamined, and unknown bills. But by rule they must be referred to some standing committee, of which there are now 48 in the House and 32 in the Senate, besides 10 select committees in the House and 12 in the Senate; and three joint standing committees. The functions of these committees are assigned by the rules; but as these lap over, two or three committees often contend vigorously for the possession of some one bill. In the Senate, these bills are presented in open session on the floor; in the House, they are handed to the clerk, indorsed with such reference or disposition as the presenting member wishes made. These committees are appointed in the House by the speaker; in the Senate they are chosen by caucus of the majority party, and elected by a single yea and nay vote, though the rules say by ballot "unless otherwise ordered." In case of difference between the Houses, which continually occurs, they are harmonized by committees of conference, three senators and three representatives. The most steadily powerful of these committees, which can obtain the floor at any time, are those on Appropriations in each House, disbursing the money in the treasury, and on Privileges and Elections, deciding the right of every member to his seat; next to these, on revenue (Ways and Means in the House, Finance in the Senate), with enormous power to help or harm the great businesses of the country — many think too much — and on Printing, which of course is an immediate matter. Next in actual favor come, perhaps, those on Rivers and Harbors and on Pensions, branches of that on Appropriations which they involve; and when new States are to be admitted, on Territories. In formal dignity the Senate committees on Foreign Affairs, on the Judiciary, and on Military and Naval Affairs, take high rank; so in the House do those on Rules, Foreign Affairs, Judiciary, Military Affairs, and Naval Affairs; and of course special circumstances at any time may temporarily make any one of these, or almost any other committee, the centre of interest to which everything else must give way. In some respects most important of all except the Appropriations Committee are the special conference committees, which do an immense share of the actual legislation of the country: they compromise conflicting business and political interests, include or exclude bills, decide on appropriations, etc., and being usually appointed in the crowded closing days of a session, generally have their recommendations heeded.

3. The changes in congressional functions and relations, from the intent of the framers of the Constitution, come under three heads: (1) the position of Congress as a whole regarding the executive; (2) the position of the two Houses regarding each other; (3) the position of the whole body regarding legislation.

(1) The Constitution attempted a total separation and absolute equality between the executive and legislative branches, the latter deciding on measures of public welfare and the former carrying them out. How far this would be desirable if perfectly accomplished — altogether forbidding one branch of the government to think and the other to act — might be questioned, but will not be argued here. At any rate, it was never remotely realized except when both were in deadly need of the same thing, or one was content to forego thinking. The ideal example of its best is probably the Lincoln administration, a strong executive and a strong Congress with the same essential purposes; of its worst, the Johnson administration, where the thoughts of the one and the acts of the other were at irreconcilable variance, and what the one most wished done was what the other was most set on not doing. More usually, one side or the other has been master. The extreme instance of executive mastery was the Jackson administration, where a resolute and aggressive leader, with a not too reflective popular majority behind him, got such legislation as he wished; of congressional mastery, each reader may prefer to choose his own instance. But there can be no question that the balance inclines more and more decisively to the congressional side. Of late years the results of attempted executive independence have been more picturesque than successful. The Senate, which has the confirmation of treaties and appointments, cannot be prevented from signifying in some form what treaties and appointments it will confirm; and the body which can grant or refuse money for public purposes can decide what those purposes shall be.

(2) The change of power between the Houses is not so dramatically obvious, but it is quite as notorious, and is easily explicable. The Senate has some superiorities: its long terms both attract superior men on an average, and enable them to acquire parliamentary knowledge and public weight; its committees are still its servants rather than its masters — preparing legislation for it to discuss, rather than merely killing most of it, and leaving the rest to run in an undiscussed huddle through the open sluice at the last; and it has time and rules that permit some genuine argument, for its own and the public's enlightenment. But these very terms render seats so valuable and desirable that members are more loath to peril them than House seats; and the Senate, which was expected to have more independence than the House from the length of terms, has actually of late years had less backbone and less willingness to run counter to popular currents within its own party than the House. Moreover, the license of debate has too often been a mere license of wanton obstruction, bringing forward no new facts or illuminating discussion, but only exhibiting the spectacle of the will of 80,000,000 people nullified by one or two of its servants. This does not contradict, but only supplements, the other evil. On the other hand, the unity and despatch of public business made possible in the House by the nominal autocracy and real leadership of the speaker, aided by the committees and the previous question, have made it seem more and more the body where something is accomplished, and the will of the people carried into execution.

CONGRESS OF THE UNITED STATES

(3) The drift of our form of government, and the coming position of Congress and its organs within it, are to some extent matters of prophecy rather than fact; and political philosophers have been busy with them. But some things are certain, and though commonplace, must be recited. Chief of them are the control of the speaker and the committees over legislation. That the speaker is a totally different officer from the English speaker is obvious. He puts motions, decides question of rule and order, and represses disorder, it is true; but instead of being a sworn judge he is a recognized party chief, with functions which approximate the English premier much more closely than the other. By his appointment of the committees he determines the line which legislation shall take, and in a broad way the bills which shall or shall not be considered; and by his daily power of recognizing members who wish the floor, in which he is held to none but party responsibility, he still further molds the total impression which the measures shall make on the public. But he is no autocrat; his very influence can only be exercised by appointing the chief party leaders to the committees, and once there, it is they and not he who hold the decisive power; he and they together, in fact, form something like the shaping committee which is what the English Cabinet, headed by the premier, has fully become. The Cabinet officers, moreover, are fast becoming advisers of the committees rather than of the President: he does not need their advice in knowing how to act, nearly as much as the committees need it in knowing what to think. These approximations to the English position have caused many to think that the transformation will be fully carried out, and the parliamentary system established in fact if not in form in the future; the speaker having the full power of the premier, and the President becoming a dignified nullity like the sovereign of England. But there are still some vital differences, and it is not easy to foresee the process by which they will be overcome. It is true that the admission of Cabinet officers to the floor of either House, to expound their views and needs and explain doubtful questions, is within a simple permissive vote of that House at any time, and can perfectly well be made a standing rule; and that the consequent necessity of their being skilful speakers and capable expositors would profoundly modify the character of men chosen for that position. But the committee do not want information on the floor of the House of Representatives at least: they have no time to attend to it there, and the rules would mostly shut it off before anything material had been communicated. They want it in their committee rooms, and that needs no change in the men and would involve none before the public. The officers cannot become primarily public speakers and secondarily executive officers unless the House gives up its time to debate; and the whole tendency is the other way, nor is it evident where the new time would be found or taken. The place where the change would have to take place is in the Senate if at all; but the power of legislation more and more drifts away from the Senate except as concurrent; and the new debaters, if they arrive, will seemingly be more in the position of those in the House of Lords than of Commons, which would be imma-

terial. Still greater is the obstacle of fixed terms. The English members of the Commons remain no longer when the people vote that they do not want them, and it is consequently the great party object to obtain such a vote, and to put the other party in a position where they must be disgraced if they do not ask the people to give one pro or con. But the American member must serve out his term, and he can do so if his party has lost all public favor: the tremendous sweep of 1874 did not shorten any Republican member's term for a day, nor imperil any piece of Republican legislation, for which they had an entire session after they were voted down, and as many special ones as the President had chosen to call; and similarly with reverses of the other side. This alone prevents debate from taking up time in the House; it is mainly a sham battle, the real one having been fought in committee. Still further, the English committee called the Cabinet is all of one party, represents it, goes down with it; and the bills it puts forward are the party's bills. But the American committees, though with a party majority, include both parties, and the measures they bring in are not specifically or nominally the party's programme; still less are the bills which are hammered into shape by the conference committees, representing neither one party nor one House. The American Cabinet of speaker and committees cannot be held to such corporate responsibility, and there is no prospect of their so being held.

SESSIONS OF CONGRESS.

- I. 1st session, 4 March to 29 Sept. 1789; 2d session, 4 Jan. to 12 Aug. 1790; 3d session, 6 Dec. 1790 to 3 March 1791.
- II. 1st session, 24 Oct. 1791 to 8 May 1792; 2d session, 5 Nov. 1792 to 2 March 1793.
- III. 1st session, 2 Dec. 1793 to 9 June 1794; 2d session, 3 Nov. 1794 to 3 March 1795.
- IV. 1st session, 7 Dec. 1795 to 1 June 1796; 2d session, 5 Dec. 1796 to 3 March 1797.
- V. 1st session, 15 May to 10 July 1796; 2d session, 13 Nov. 1797 to 16 July 1798; 3d session, 3 Dec. 1798 to 3 March 1799.
- VI. 1st session, 2 Dec. 1799 to 14 May 1800; 2d session, 17 Nov. 1800 to 3 March 1801.
- VII. 1st session, 7 Dec. 1801 to 3 May 1802; 2d session, 6 Dec. 1802 to 3 March 1803.
- VIII. 1st session, 17 Oct. 1803 to 27 March 1804; 2d session, 5 Nov. 1804 to 3 March 1805.
- IX. 1st session, 2 Dec. 1805 to 21 April 1806; 2d session, 1 Dec. 1806 to 3 March 1807.
- X. 1st session, 26 Oct. 1807 to 25 April 1808; 2d session, 7 Nov. 1808 to 3 March 1809.
- XI. 1st session, 22 May to 28 June 1809; 2d session, 27 Nov. 1809 to 1 May 1810; 3d session, 3 Dec. 1810 to 3 March 1811.
- XII. 1st session, 4 Nov. 1811 to 6 July 1812; 2d session, 2 Nov. 1812 to 3 March 1813.
- XIII. 1st session, 24 May to 2 Aug. 1813; 2d session, 6 Dec. 1813 to 18 April 1814; 3d session, 19 Sept. 1814 to 3 March 1815.
- XIV. 1st session, 4 Dec. 1815 to 30 April 1816; 2d session, 2 Dec. 1816 to 3 March 1817.
- XV. 1st session, 1 Dec. 1817 to 30 April 1818; 2d session, 16 Nov. 1818 to 3 March 1819.
- XVI. 1st session, 6 Dec. 1819 to 15 May 1820; 2d session, 13 Nov. 1820 to 3 March 1821.
- XVII. 1st session, 3 Dec. 1821 to 8 May 1822; 2d session, 2 Dec. 1822 to 3 March 1823.

CONGRESS OF THE UNITED STATES

XVIII. 1st session, 1 Dec. 1823 to 27 May 1824; 2d session, 6 Dec. 1824 to 3 March 1825.
 XIX. 1st session, 5 Dec. 1825 to 22 May 1826; 2d session, 4 Dec. 1826 to 3 March 1827.
 XX. 1st session, 3 Dec. 1827 to 26 May 1828; 2d session, 1 Dec. 1828 to 3 March 1829.
 XXI. 1st session, 7 Dec. 1829 to 31 May 1830; 2d session, 6 Dec. 1830 to 3 March 1831.
 XXII. 1st session, 5 Dec. 1831 to 16 July 1832; 2d session, 3 Dec. 1832 to 3 March 1833.
 XXIII. 1st session, 2 Dec. 1833 to 30 June 1834; 2d session, 1 Dec. 1834 to 3 March 1835.
 XXIV. 1st session, 7 Dec. 1835 to 4 July 1836; 2d session, 5 Dec. 1836 to 3 March 1837.
 XXV. 1st session, 4 Sept. to 16 Oct. 1837; 2d session, 4 Dec. 1837 to 9 July 1838; 3d session, 3 Dec. 1838 to 3 March 1839.
 XXVI. 1st session, 2 Dec. 1839 to 21 July 1840; 2d session, 7 Dec. 1840 to 3 March 1841.
 XXVII. 1st session, 31 May to 13 Sept. 1841; 2d session, 6 Dec. 1841 to 31 Aug. 1842; 3d session, 5 Dec. 1842 to 3 March 1843.
 XXVIII. 1st session, 4 Dec. 1843 to 17 June 1844; 2d session, 2 Dec. 1844 to 3 March 1845.
 XXIX. 1st session, 1 Dec. 1845 to 10 Aug. 1846; 2d session, 7 Dec. 1846 to 3 March 1847.
 XXX. 1st session, 6 Dec. 1847 to 14 Aug. 1848; 2d session, 4 Dec. 1848 to 3 March 1849.
 XXXI. 1st session, 3 Dec. 1849 to 30 Sept. 1850; 2d session, 2 Dec. 1850 to 3 March 1851.
 XXXII. 1st session, 1 Dec. 1851 to 31 Aug. 1852; 2d session, 6 Dec. 1852 to 3 March 1853.
 XXXIII. 1st session, 5 Dec. 1853 to 7 Aug. 1854; 2d session, 4 Dec. 1854 to 3 March 1855.
 XXXIV. 1st session, 3 Dec. 1854 to 18 Aug. 1855; 2d session, 21-30 Aug. 1856; 3d session, 1 Dec. 1856 to 3 March 1857.
 XXXV. 1st session, 7 Dec. 1857 to 1 June 1858; 2d session, 6 Dec. 1858 to 3 March 1859.
 XXXVI. 1st session, 5 Dec. 1859 to 18 June 1860; 2d session, 3 Dec. 1860 to 3 March 1861.
 XXXVII. 1st session, 4 July to 6 Aug. 1861; 2d session, 2 Dec. 1861 to 17 July 1862; 3d session, 1 Dec. 1862 to 3 March 1863.
 XXXVIII. 1st session, 7 Dec. 1863 to 2 July 1864; 2d session, 5 Dec. 1864 to 3 March 1865.
 XXXIX. 1st session, 4 Dec. 1865 to 28 July 1866; 2d session, 3 Dec. 1866 to 3 March 1867.
 XL. 1st session, 4-29 March, 3-20 July, 21 Nov. to 2 Dec. 1867; 2d session, 2 Dec. 1867 to 27 July, 21 Sept. 16 Oct. and 10 Nov. 1868; 3d session, 7 Dec. 1868 to 3 March 1869.
 XLI. 1st session, 4 March to 10 April 1869; 2d session, 6 Dec. 1869 to 15 July 1870; 3d session, 5 Dec. 1870 to 3 March 1871.
 XLII. 1st session, 4 March to 20 April 1871; 2d session, 4 Dec. 1871 to 10 June 1872; 3d session, 2 Dec. 1872 to 3 Dec. 1873.
 XLIII. 1st session, 1 Dec. 1873 to 23 June 1874; 2d session, 7 Dec. 1874 to 3 March 1875.
 XLIV. 1st session, 6 Dec. 1875 to 15 Aug. 1876; 2d session, 4 Dec. 1876 to 3 March 1877.
 XLV. 1st session, 15 Oct. to 3 Dec. 1877; 2d session, 3 Dec. 1877 to 20 June 1878; 3d session, 2 Dec. 1878 to 3 March 1879.
 XLVI. 1st session, 18 March to 1 July 1879; 2d session, 1 Dec. 1879 to 16 June 1880; 3d session, 6 Dec. 1880 to 3 March 1881.
 XLVII. Special session of the Senate, 10-29 Oct. 1881; 1st session, 5 Dec. 1881 to 8 Aug. 1882; 2d session 4 Dec. 1882 to 3 March 1883.
 XLVIII. 1st session, 3 Dec. 1883 to 7 July 1884; 2d session, 1 Dec. 1884 to 3 March 1885.
 XLIX. 1st session, 7 Dec. 1885 to 5 Aug. 1886; 2d session, 6 Dec. 1886 to 3 March 1887.

L. 1st session, 5 Dec. 1887 to 20 Oct. 1888; 2d session, 3 Dec. 1888 to 4 March 1889.
 LI. 1st session, 2 Dec. 1889 to 1 Oct. 1890; 2d session, 1 Dec. 1890 to 3 March 1891.
 LII. 1st session, 7 Dec. 1891 to 5 Aug. 1892; 2d session, 5 Dec. 1892 to 3 March 1893.
 LIII. Special session of the Senate, 4 March to 15 April 1893; 1st session 7 Aug. to 3 Nov. 1893; 2d session, 4 Dec. 1893 to 28 Aug. 1894; 3d session, 3 Dec. 1894 to 4 March 1895.
 LIV. 1st session, 2 Dec. 1895 to 11 June 1896; 2d session, 7 Dec. 1896 to 3 March 1897.
 LV. 1st session, 15 March to 24 July 1897; 2d session, 6 Dec. 1897 to 8 July 1898; 3d session, 5 Dec. 1898 to 4 March 1899.
 LVI. 1st session, 4 Dec. 1899 to 7 June 1900; 2d session, 3 Dec. 1900 to 4 March 1901.
 LVII. 1st session, 2 Dec. 1901 to 1 July 1902; 2d session, 1 Dec. 1902 to 4 March 1903.
 LVIII. Special session of the Senate, 5 to 16 March 1903; 1st session, 9 Nov. 1903 to 7 Dec. 1903; 2d session, 7 Dec. 1903 to 28 April 1904; 3d session, 5 Dec. 1904 to 4 March 1905. Special Session 6-18 March 1905.
 LVIX. 1st session 4 Dec. 1905 to 30 June 1906; 2d session 3 Dec. 1906.

PRESIDENTS PRO TEM. OF THE SENATE.

Years	Name	State
1789-1792	John Langdon.....	N. H.
1792	Richard H. Lee.....	Va.
1792-1794	John Langdon.....	N. H.

F. M. COCKRELL,

Late United States Senator from Missouri.

Congressional Library Building, the home of the library of the United States Congress, opened in 1897 and authorized by acts of Congress of 15 April 1886; 2 Oct. 1888, and 2 March 1889, at a cost of \$6,347,000 (limit by law), \$6,500,000) exclusive of the land, which cost \$585,000. The building occupies three and three quarter acres upon a site 10 acres in extent at a distance 1,270 feet east of the capitol, and is the largest and most magnificent library building in the world. In the decorations, some 40 painters and sculptors are represented, all American citizens. The floor space is 326,195 square feet, or nearly eight acres. The book stacks contain about 45 miles of shelving, affording space for 2,200,000 volumes. Were the long corridors, now used in part for exhibition purposes, completely shelved, the building would accommodate over 4,000,000 volumes. The library contains a reading room for the blind, open daily. The library is maintained by annual appropriations by Congress for various purposes. For the year 1899-1900 this amounted to \$213,452 for services (including the copyright department, and including, also, the care of the building); and \$26,500 for fuel, supplies, miscellaneous purposes, including contingent expenses.

Congressional Record, a journal of the proceedings of the Congress of the United States, dating from 1799. Prior to that date the Senate held secret sessions only, but thereafter publication was required, save in the case of "executive sessions." 'Record' has been the title since 1875; before that date the journal was entitled 'Annals of Congress' (1789-99 for the House, and 1799-1824 for both branches), 'Register of Debates' until 1837, and through 1874 'Congressional Globe.' Undelivered speeches on the grant of "per-

mission to print" appear in the 'Record' as if they had actually been given, and stenographic reports of debates are revised by the participants before being printed.

Congressman at Large, a national representative elected by the entire State and not as a member for some district. There is no permanent system of the sort, though many able political thinkers have wished for it, and believed it would greatly raise the average of ability in the House; preventing the restriction of choice to the mediocre notabilities who chance to reside in a given district. In fact, however, there is no legal obstacle now to the voters of a district electing an outsider if they wish; but they rarely wish it, and if the general system were introduced, the experience of other political affairs makes it probable that the memberships would be "claimed" by given districts in rotation. At present, the only use of the plan is in giving a State the fresh memberships assigned to it by the apportionment under a new census, until it can be redistricted, which is sometimes a long process with fierce political opposition. Many States have had one congressman at large, and some two.

Congreve, kōn'grēv, **Richard**, English essayist: b. Leamington, Eng., 4 Sept. 1818; d. Hampstead, Eng., 5 July 1899. He was educated at Rugby and Oxford and was subsequently a tutor in Wadham College, Oxford, resigning his post on becoming a Positivist. Beside editing Aristotle's 'Politics' with notes (1855); he published 'The Catechism of Positivist Religion' (1858); 'Elizabeth of England' (1862); 'Essays: Political, Social, and Religious' (1874).

Congreve, **William**, English dramatist: b. Bardsey, near Leeds, 1670; d. London 19 Jan. 1729. He entered the Middle Temple, London, to prepare himself for the legal profession, but soon deserted the law for literature. At a very early age he wrote a novel entitled 'Incognita,' followed by his comedy of the 'Old Bachelor,' produced in 1693, and pronounced by Dryden the greatest first play that he had ever beheld. His next play, the 'Double Dealer' (1693), was not so successful in representation; but his third, the comedy of 'Love for Love' (1695), proved extremely popular. Its success acquired for the author the patronage of Lord Halifax, who conferred on him several very lucrative posts, so that he was far more prosperous than most men of letters. Not content with his fame in comedy, he essayed tragedy; and in 1697 produced his 'Mourning Bride,' the reception of which was extremely favorable. The composition of four such plays before he had attained the age of 28 is a remarkable proof of early genius in a line of composition demanding great observation and experience. The license of his writings caused him to be attacked by Jeremy Collier in his 'Short View of the Immorality and Profaneness of the English Stage,' to which Congreve published a lame and ineffective reply. He soon after closed his dramatic career with the 'Way of the World' (1700), considered by many critics as the most perfect of his comedies, but which was received so coldly that he resentfully determined to relinquish a species of writing in which, upon the whole, he had been eminently successful. A masque, entitled the 'Judgment of Paris,' and 'Semele,' an opera, the

CONGRESSIONAL LIBRARY, WASHINGTON, D. C.

CONGREVE — CONIC SECTIONS

latter of which was never presented, close the list of his labors for the stage. He, however, continued to write occasional verses on public subjects; and in 1710 published a collection of his plays and poems. Dryden declared him to be the equal of Shakespeare. Steele dedicated to him his 'Miscellanies,' and Pope his translation of the Iliad. He was buried in Westminster Abbey, where a monument was erected to him by the Duchess of Marlborough. Congreve's comedies are chiefly distinguished for the sustained flow of wit in the dialogue. But his characters are repulsive. It is now rare for any of his plays to appear on the stage, which without pruning, to adapt them to modern manners, it would be impossible for them to do. His poetry is of little value. Consult Macaulay, 'Comic Dramatists of the Restoration'; Hazlitt, 'Lectures on the English Comic Writers'; Gosse, 'Life of Congreve' (1888).

Congreve, Sir William, English inventor: b. 20 May 1772; d. Toulouse, France, 16 May 1828. After passing through the Royal Academy at Woolwich he entered the artillery in 1791, served under his father, a lieutenant-general, and in 1814 succeeded him in his post of comptroller, and also as second holder of the baronetcy, conferred in 1812. He invented the rocket which bears his name about 1804. It was first used in active service in the attack on Boulogne, 1806, and on Copenhagen 1807. He took an active part in army improvements; became a Fellow of the Royal Society in 1811; obtained a patent for manufacturing gunpowder in 1815; and one for the manufacture of bank-note paper in 1819.

Con'gruism, Congruist, terms derived from the expression *meritum e congruo*, which signifies the view of some writers on the doctrine of divine grace and human merit, that though a man may not in the strict sense merit a given grace or favor of God he may be said to merit in a looser sense, on the ground that there is a certain congruity, a certain fitness with what we believe concerning the relation between man and his Creator, in assuming that the Creator will out of his infinite mercy grant to his faithful servants favors that they do not in any tolerable sense of the word merit. An example of *meritum e congruo* is had when a saintly man by his prayers obtains the conversion of a sinner: that conversion is not merited at all in any strict sense: but it is congruous, it is what we like to think about the Creator's love for his chosen ones, that he should be moved to grant the petition of one who is admitted to his friendship.

Conhydrin, kōn-hī'drīn, a substance contained, along with conia, in the flowers and seeds of the hemlock. The physiological action of conhydrin resembles that of conia, but it is not nearly so rapid or powerful. See CONIA.

Coni, kō'nē, or **Cuneo**, koo-nā'ō, a town of Italy, capital of the province and district of Coni, on a high hill, at the confluence of the Stura and the Gesso, about 50 miles south of Turin, in a pleasant, well-cultivated district. The old fortifications, the arcades along the principal street, a Franciscan church of the 12th century, a handsome town-house, with a tall tower, and a cathedral, are the picturesque items of the town. There are silk spinning-mills, and manufactures of silk and woolen goods. Grain,

hemp, and silk form articles of commerce. It was taken by Napoleon in 1796, by the Austrians in 1799, and again given up to the French in 1801. Pop. (1901) 27,065.

Conia, or **Coniine** (C₅H₁₇N), an alkaloid in the hemlock, discovered in an impure state by Giesecke in 1827, and subsequently prepared in the pure state by Geiger, who recognized it as a vegetable base. It exists, combined with malic acid, in all parts of the plant, but especially in the not quite ripe seed. When pure it is a colorless oily liquid, specific gravity 0.89, which changes by exposure to air to a brown fluid, and ultimately to a resinous, bitter mass, slightly soluble in water, soluble in alcohol, and when purified yielding a jelly with a butyric odor. It can be distilled without much alteration, provided the air be excluded, its boiling-point being 168° C. At a higher temperature it burns with a bright smoky flame. It is slightly volatile even at ordinary temperatures. It has a very disagreeable odor, sharp and choking when strong; its taste is nauseous. It is somewhat soluble in water, readily in alcohol, ether, and oils, and itself acts as a solvent of sulphur. It has a strong alkaline reaction when moist, and combines with the acids to form salts, most of which are crystalline but deliquescent. The salts are unstable in aqueous solution; they evolve the odor of the base and gradually change color. It precipitates the oxides of iron, zinc, manganese, aluminum, copper, and the other heavy metals, from solutions of their salts. It is attacked by chlorine, bromine, and iodine, and oxidized by nitric acid, yielding butyric acid. The poisonous action of conia has been minutely investigated, but although it has been proved to be rapidly fatal to all classes of animals when administered in doses of from 3 or 4 to 10 or 12 grains, the nature of its action is not fully ascertained; but the breathing and pulse are affected, and the extremities paralyzed. Some experimenters have tried its effect upon themselves, and according to their account the minutest doses produce burning in the mouth, salivation, nausea, and vomiting, pressure in the head, tottering, indistinct vision, cramps, and other symptoms. Similar observations have been made on persons to whom the alkaloid has been given therapeutically. It has been shown that conia can be detected in a poisoned animal, even after a considerable time. The tonic power of conia seems to be little if at all affected by the introduction into it of the alcoholic radicals, methyl, and ethyl. The action is perhaps not so rapid, but it is the same in character, and takes place with quite as small quantities. In this respect conia differs from some other alkaloids, for instance, codeia.

Conibo, kō-nē'bō, a tribe of Indians in eastern Peru, allied to the Ucayali tribe. They were an agricultural people and built villages. The Spanish missionaries tried to convert them in 1683, but were driven out after 1695, when Father Ritchie was killed by the savages. They are now partially civilized and are often employed as canoe men and rubber gatherers.

Conic Sections, three curves, the hyperbola, the parabola, and the ellipse, are called the conic sections, because these curves are formed by the intersection of the surface of a cone with planes that cut the cone in various directions. If the cutting-plane be parallel to the axis of the cone (fig. 1), the curve formed is

CONIFERÆ

the hyperbola, which has two branches, as shown in the figure. If the cutting-plane be parallel to a straight line on the surface of the cone (fig. 2), the curve formed is a parabola. Any other section is an ellipse (fig. 3). It must be noticed, however, that this general description includes three peculiar cases. In the case of a plane parallel to the axis of the cone, when that plane contains the axis, the section, instead of being a hyperbola,

is in this limiting case a pair of straight lines meeting each other at an angle equal to that of the angle of the cone so as to form a triangle (fig. 4). When a plane, which would otherwise form a parabolic section, is a tangent plane to the cone, the parabola degenerates into a straight line passing through the vertex of the cone. Lastly, when a plane that would otherwise form an ellipse is perpendicular to the axis of the cone, the ellipse becomes a circle (fig. 5). The properties of these curves are discussed under their several names. It will there be seen that other definitions may be given of the curves; and that from these their properties are more conveniently derived than from the consideration that they are formed by the sections of a conical surface. The properties of these curves are of the greatest physical interest; and the geometry of the conic sections has, ever since the time of the Greek mathematicians, been considered as the best of the more advanced geometrical studies.

Coniferæ, kō-nīf'e-rē, a natural order of trees and shrubs consisting of about 40 genera and 300 species, which are most numerous in the temperate regions of the world, especially in the northern hemisphere. Among the few species found in the tropics, the most important are those belonging to the genera *Araucaria* (q.v.), *Dammara*, *Phyllocladus*, and *Dacrydium*. In the Arctic region and the correspondingly cold mountain climates various conifers approach very nearly the line of perpetual snow, and like other plants of such climates are reduced to gnarly dwarfed specimens which bear but slight resemblance to those of the same species in less rigorous climates. In the United States and Canada 15 genera and about 100 species and sub-species are indigenous and of these the majority are native to the Pacific coast. In addition to the number of species mentioned fully 400 horticultural varieties must be added. These are listed in Bulletin No. 17 of the Division of Forestry, U. S. Dept. of Agriculture.

No forest trees are of more economic importance than the conifers. Their notable blending of maximum strength, stiffness and durability with minimum weight, and their abundance have won them prominence in house, ship, and bridge building, wharf making and sidewalk constructing, etc. They are also of great importance in planting, both for use and ornament, their evergreen habit (except in Ginkgo

and *Larix*) and the retention of their lower limbs until comparative age, making them especially good for wind breaks; and these characters coupled with their conical form and the striking colors of their foliage rendering them particularly useful for grouping with deciduous trees and shrubs or for individual specimens in parks and upon lawns.

The species are characterized by straight shafts which elongate terminally, and like the shape of the trees, form a more or less attenuated cone, the species of which have broad leaves. They have either needle-shaped or awl-shaped leaves (except in *Podocarous*) which are specially adapted by these forms and by the thickened epidermis to resist excessive transpiration, a necessary adaptation since the leaves are usually retained throughout the year. They have naked ovules which are fertilized directly by the exceedingly light pollen which is produced in enormous quantities and carried by the wind even miles away from the forests, to fall as so-called "showers of sulphur." These ovules are borne in a "strobilus" which enlarges after fertilization into what is popularly known as the cone, the order being named from this character. The cone is an aggregation of scales, above the bases of which are borne the seeds. These are in some species utilized as food, and have been introduced in the markets of the United States by the Syrians. The internal structure of the *Coniferæ* is also peculiar to the group. Like the dicotyledons, the woody cylinder increases in girth by the external development, beneath the bark, of homogeneous woody fibres marked on two sides with circular disks and among which are few true vessels. Since these woody fibres are fitted together without overlapping, the grain of the wood is fine and uniform, which accounts for its easy working qualities, especially in the direction of the "grain."

Botanists divide the species into two great sub-orders, the *Taxaceæ* and *Pinaceæ*. The former includes two tribes, *Podocarpeæ*, the leading genus of which is *Podocarpus*, with about 40 species, and *Taxeæ*, which consists of the genus *Taxus*, the yew. The species of this sub-order have more or less fleshy fruits. The *Pinaceæ* embraces four tribes: *Abietineæ*, the pine family proper, of which the principal genera are: *Pinus*, pine; *Picea*, spruce; *Tsuga*, hemlock; *Abies*, fir; and *Larix*, larch; *Taxodieæ* which includes *Taxodium*, the bald cypress; and *Sequoia*, the redwood; *Cupressineæ*, which includes *Thuja*, arborvitæ; and *Juniperus*; juniper; *Chamæcypris*, cedar; *Araucariæ*, including *Araucaria*, Norfolk Island pine and its allies. (See separate articles upon the various groups, under their popular name titles, except *Araucaria* and *Sequoia* (qq.v.). The most widely distributed of these groups are undoubtedly the genera *Pinus* and *Juniperus*, and the most restricted are *Taxodium*, two species of which are indigenous to the United States and one to China; and *Sequoia*, of which only two species are known, both found in occasional groves on the Pacific Coast. During geological ages these two genera were far more widely distributed.

So far as is known from fossils conifers appeared on the earth in Silurian Time, though they may have appeared earlier. They increased and developed during Devonian Time and the Carboniferous. Unlike the acrogens (ferns,

CONIINE — CONIUM

ground-pines, and horse-tail rushes), the conifers have increased rather than declined since the Carboniferous. Species of the yew were abundant in North America in early Devonian Time. In the Carboniferous the gymnosperms that grew in the great swamps were related to the cycads and yews. True conifers may have grown upon the drier hillsides. The genus *Walchia* began near the close of the Carboniferous, and in Permian Time the conifers included species of *Dadoxylon*, *Pinites*, *Ullmania*, etc.; common Triassic conifers are the genera *Voltzia*, *Baiera*, and *Araucarites*.

Conifers are propagated by means of seeds which may usually be obtained in autumn, though some species open their cones at irregular intervals through the winter and others only when artificial heat such as that of a forest fire is applied. The seed should be planted in a sandy loam, given a light mulch, of pine needles or sphagnum moss, and the seedlings kept free from weeds. They must be kept moist but not wet until they have formed their crown buds, which appear when they are about three months old. If proper methods are practised, transplanting may be done at any time of year, but spring is generally much the best season, since the roots are then most active and the check to growth is then least. As a rule conifers do best upon light soils. They are attacked by a large number of insects and diseases both in foliage and trunk, but since these trees and shrubs are planted mainly for ornament or are growing in the forest where systematic war cannot often be successfully carried on, little attention has been given to the control of these pests. Standard fungicides and insecticides may be used effectively in some cases, care being taken to determine the mode of attack of the particular pest.

Consult: Veitch, 'Manual of Conifers'; Beissner, 'Handbuch der Nadelholzkunde'; Carrière, 'Traité des Conifères'; Bailey, 'Cyclopedia of American Horticulture.'

Coni'ine, kō-nī'in, **Coneine**, **Conia**, or **Conine**, a volatile alkaloid having the formula $C_8H_{17}N$, and constituting the active poisonous principle of the hemlock, *Conium maculatum*. It exists in all parts of the plant, but especially in the not quite ripe seeds. When pure it is a colorless oily liquid with a strong, mouse-like odor, oxidizing, upon exposure to air, to a brown fluid, and ultimately to a resinous mass. It boils at $336^\circ F.$, and, at ordinary temperatures has a specific gravity of about 0.86. It absorbs about 25 or 30 per cent of its own weight of water, and freely mixes with alcohol, benzene, chloroform, and ether. It also dissolves sulphur, though it does not dissolve phosphorus. Coniine is a violent poison, causing death by paralysis of the motor nerves.

Con'ingsby, a novel by Benjamin Disraeli, Lord Beaconsfield, published 1844. It was his sixth and most successful novel. In three months it had gone through three editions, and 50,000 copies had been sold in England and the United States. It was a novel with a purpose; the author himself explained that his aim was to elevate the tone of public life, to ascertain the true character of political parties, and especially to vindicate the claims of the Tories. Incidentally he wished to emphasize the importance of the Church in the development of Eng-

land, and he tried to do some justice to the Jews. There are more than threescore characters in the book, and part of its popularity came from people's interest in identifying them with men and women prominent in English social and political life.

Co'nington, John, English classical scholar: b. Boston, Lincolnshire, 10 Aug. 1825; d. there 23 Aug. 1869. He was educated at Beverley, Rugby, and Oxford, and in 1854 was appointed to the newly founded chair of Latin language and literature at Oxford, which he filled until his death. His greatest work is his edition of 'Virgil' (3 vols. 1861-8), with its singularly subtle and suggestive essays. His edition of the 'Agamemnon' (1848), and 'Choephoroi' (1857), of Æschylus are of less moment, though indeed the latter is admirable. In his last years he gave himself much to translation, the results of which were his metrical version of the 'Odes' of Horace (1863), the 'Æneid' (1866), in Scott's ballad-metre, the 'Iliad' (1868), in the Spenserian stanza, and the 'Satires and Epistles' of Horace (1869), in the couplet of Pope.

Coniston (kōn'is-tōn) **Lake**, England, a lake in north Lancashire at the eastern foot of the Coniston Fells, nine miles west of Bowness on Windermere. It is five miles long, one half mile broad, 147 feet above the sea, and its greatest depth is 260 feet. Its waters abound with trout and perch. On the eastern shore stand Ruskin's home, Brantwood, and Tent House, once Tennyson's residence. The Old Man of Coniston, to the northwest, is 2,633 feet high.

Co'nium ("spotted hemlock"), the full-grown fruit of *Conium maculatum* gathered while green. *Conium maculatum* is a stout, erect biennial, three to six feet high, with a much branching, smooth, furrowed, dark green hollow stem, covered with purplish spots, very widely present throughout Europe and introduced into the United States in ballast. It grows commonly in wet places, wayside brooks, swamps, and dark, moist gardens. All parts of the spotted hemlock are active, but the poisonous principle coniine is found most abundantly in the full-grown but unripe seed, the principle being a volatile alkaloid. Only fresh hemlock is of any service, and much of the lack of uniformity of results in the use of this drug as a remedy has come from the neglect of this precaution on the part of the manufacturers of the drug. The composition of conium is complex. It contains a slight amount of volatile oil and two or three alkaloids, the most important of which is coniine. Coniine is present in small amounts only. It is strongly basic, colorless, oily liquid, with a penetrating odor and a sharp taste resembling tobacco. It boils at $166^\circ C.$; its chemical formula is $C_8H_{17}NH, CH_2CH_2CH_3$. It has been made synthetically, being one of the first of the alkaloids thus synthesized. The physiological action of conium is practically identical with the action of coniine. The general effect is paralysis of the motor end organs of voluntary muscles; it is thus a motor depressant. It is an irritant to the stomach, increasing the salivary secretions. Its effect on the heart is slight; its effect on the nervous system is very little save in extreme poisoning, when blood changes cause changes in the nervous system. The early symptoms of poisoning

CONJEVERAM—CONJURING

are heaviness of the muscles of the legs, and of the eyelids, ptosis, staggering gait, muscular relaxation and muscular paralysis; paralysis of the vocal chords causing derangement of speech, dilatation of the pupil and finally paralysis of the muscles of respiration with asphyxia, convulsions, and death. Treatment of the poisoning is by means of the stomach-pump, strychnine, coffee. Alcohol and rapid elimination by hot baths are desirous.

The therapeutics of conium is restricted. It is very questionable whether it is of use in any affection other than habitual motor spasms of voluntary origin such as spasmodic tics, torticollis, and other like affections. It is certainly of very little value in spasmodic affections not associated with voluntary action such as chorea, epilepsy, myoclonus, etc.

Conjeveram, kōn-jē-vēr-ūm', **Canchipura** ("the Golden City"), a town of Hindustan, in the presidency of Madras, district of Chinglepat. It stands in a valley, is irregularly built, and from five to six miles long, resembling a series of villages, intermingled with gardens and coconut plantations. Conjeveram is one of the Hindu sacred cities, and is sometimes called the "Benares of the south." There are here two splendid pagodas; one dedicated to Vishnu, richly sculptured, and highly venerated; the other, a larger and more imposing structure, dedicated to Siva, from the summit of which a magnificent view is obtained. There are many smaller pagodas; and houses of accommodation for travelers abound. Cottons are manufactured. There is a flourishing school here connected with the Free Church of Scotland. Pop. 43,000.

Conjugal Rights, in law, the right which husband and wife have to each other's society, comfort, and affection. The suit for restitution of conjugal rights is a matrimonial suit, cognizable in the divorce court, which may be brought whenever either the husband or wife lives separate from the other without any sufficient reason.

Conjugate Focus. See LENS.

Conjuga'tion. In some unicellular plants and in one-celled animals (*Protozoa*), after multiplying by self-division perhaps for many generations, reproduction by germs is brought about by a process called conjugation. It may be illustrated by a flagellate monad (*Heteromita*). In this form two individuals come together and completely fuse, the result is a thin-walled sac (the zygote), the protoplasm of which divides by multiple fission into very minute spores or germs. Each of these spores finally grows to become an adult *Heteromita*. In a much more specialized protozoan (*Paramacium*), after self-division has been repeated for a certain number of generations, it is interrupted by conjugation. In this case two individuals become applied by their ventral faces, but do not fuse, but the nuclei melt together, so that the fusion of the two individuals takes place, after which the two original infusorians separate. This process is akin to and anticipates sexual reproduction in animals higher than protozoa. The process seems to lend new life to the species; it is a process of rejuvenescence, and is necessary for the maintenance of the life and vigor of the species.

Conjunction, in astronomy, one of the aspects of the planets. Two heavenly bodies are in conjunction when they have the same longitude—that is, when the same perpendicular to the ecliptic passes through both. If they have, at the same time, the same latitude—that is, if they are both equally far north or south of the ecliptic—they appear from the earth to be in the same spot of the heavens, and to cover one another. The sun and moon are in conjunction at the period of new moon. In the case of the inferior planets Mercury and Venus, the conjunction is inferior when the planet is between the earth and the sun, and superior when the sun is between the earth and the planet. In general, a heavenly body is in conjunction with the sun when it is on the same side of the earth, and in a line with the sun, and it is in opposition to the sun when it is on the opposite side of the earth, the earth being in a line between it and the sun. Planets are invisible when in conjunction with the sun, except in rare cases when an inferior planet passes over the sun's disk, and may be seen as a speck on his surface. Conjunctions are either geocentric or heliocentric, according as they are actually witnessed from the earth, or as they would be witnessed if observed from the sun. In observing a conjunction from the earth's surface it is usual to reduce the observation to what it would be if made from the earth's centre; by this means the exact times of conjunction are more accurately fixed, and the observations of one astronomer made available to every other, wherever he may be on the earth's surface. Grand conjunctions occur when several stars or planets are found together. Chinese history records one in the reign of the Emperor Tehuen-hiu (2514-2436 B.C.), which astronomers calculate actually took place.

Conjunction, that grammatical part of speech which couples words, clauses, and propositions. Conjunctions differ from prepositions in their mode of affecting the cases of the nouns which they connect with the previous word or phrase. The preposition is said to govern the noun, that is, to determine its case; the conjunction also determines the case of the noun, but in a different manner; it always requires the case of the noun or pronoun which follows it to be the same as that of the noun with which it connects the second noun. The conjunction also affects actively the modes of verbs, though less frequently in English than in other languages.

Conjunctiva, kōn-jūnk-tī'va, the mucous membrane which lines the inner surface of the eyelids and is continued over the forepart of the globe of the eye. See EYE.

Conjunctivitis. See EYE, DISEASES OF.

Conjuration, in law, an unlawful compact formed by oath, a term formerly used, especially in the sense of having personal conference with the devil or some evil spirit to discover secrets or effect some malicious purpose.

Conjuring, the production of effects apparently miraculous by natural means. The earlier professors of the art claimed *bona fide* supernatural powers; and in ages when the most elementary principles of physical science were unknown beyond a very limited circle, it was not difficult to gain credence for such a preten-

CONKLIN — CONNAUGHT

sion. The modern conjurer makes no such claim, but tells the public frankly that his marvels are illusory. Of the conjurers of remote antiquity we have few reliable records; though it is a tolerably safe conjecture that the prestige of the ancient mysteries rested in no small degree upon effects of natural magic. Perhaps the earliest really trustworthy authority is Reginald Scot, who in his 'Discoverie of Witchcraft' (1584) has enumerated the stock feats of the conjurers of his day.

The conjurers of Scot's time, and even of much later date, were accustomed, in order to facilitate the substitutions on which a great part of their tricks depended, to wear an apron with pockets, known (from its resemblance to a game-bag) as the *gibeciere*. A later school suppressed this tell-tale article of costume, and used instead a table, with cover reaching nearly or quite to the ground. This table concealed an assistant, who worked most of the required transformations, etc., either handing the needful articles to the conjurer as he passed behind the table, or pushing them up through traps in the table-top. Conus the elder, a French conjurer who flourished at the close of the 18th century, made a further improvement by discarding the concealed assistant, and using an undraped table with a secret shelf (now known as the *servante*) behind it, on which his substitutions were made. His immediate competitors did not follow his example, a whole generation of later conjurers, including Comte, Bosco, and Philippe, retaining the suggestive draped table. Its death-blow, however, was struck by Robert Houdin (1805-71), with whom about 1844 a new era began. The most modern school of conjurers, following the lead of Wiljalba Frikell, etc., represented by Hartz, Herrmann, Bua-tier de Kolta, Verbeck, Lynn, Bertram, etc., generally aim at producing their magical results with the minimum of visible apparatus.

Conk'lin, Edwin Grant, b. 24 Nov. 1863. Graduated Ohio Wesleyan University (S.B. 1885, A.B. 1886, A.M. 1889), Johns Hopkins University (Ph.D. 1891). Investigator Marine Biological Laboratory 1890-1901; Professor of Biology Ohio Wesleyan University 1891-1894; Professor of Zoology Northwestern University 1894-1896; Professor of Zoology University of Pennsylvania 1896—. Trustee Marine Biological Laboratory; Member American Society of Zoologists, American Society of Naturalists, Fellow of American Association for the Advancement of Science, Vice President Academy of Natural Sciences of Philadelphia, Secretary of American Philosophical Society, Past President American Morphological Society; Associate Editor of Biological Bulletin and of the Journal of Morphology. Author of 32 scientific papers published between the years 1891 and 1902 among which the following are the most important: 'Fertilization of the Ovum'; 'The Embryology of Crepidula'; 'Syllabus of Six Lectures on Organic Evolution'; 'Evolution and Revelation'; 'The Phenomena and Mechanism of Inheritance'; 'Factors of Evolution'.

Conk'lin, Jennie Maria (DRINKWATER), American author: b. Portland, Maine, 14 April 1841; d. New Vernon, N. J., 28 April 1900. She was educated in the public schools, and while still in her teens won fame with her stories for children. In 1880 she married Rev. Nathaniel

Conklin. Her works include: 'Miss Prudence'; 'Tessa Wadsworth's Discipline'; and 'Fifteen.' She originated the "Shut-In Society," an organization of invalids for correspondence.

Conklin, Viola A., American historical writer: b. New York 15 Nov. 1849. She has published 'American Political History to the Death of Lincoln' (1901).

Conkling, Alfred Ronald, American lawyer: b. New York 28 Sept. 1850. He graduated at Yale 1870; was geologist in the United States Engineer Corps 1875-7; admitted to the New York bar 1879. He has been active in republican municipal politics, and was a member of the New York board of aldermen 1887-8, and of the State legislature 1892-5. In the Greater New York election of 1897 he was a prominent member of the Citizens' Union Party. He has written much for the New York *Tribune*, *Evening Post*, and *Herald*, and has published: 'Guide to Mexico' (1884); 'Letters of Roscoe Conkling' (1889); 'City Government in the United States' (1894); 'Hand-book for Voters' (1894). While a member of the Engineer Corps, he prepared several valuable reports (1875-7).

Conkling, Roscoe, American legislator: b. Albany, N. Y., 30 Oct. 1829; d. New York 18 April 1888. He removed to Utica in 1846, studied law and was admitted to the bar in 1850. He was mayor of Utica in 1858, and sat in Congress as a Republican 1858-62, and 1864-6. During the Civil War he was an active supporter of the administration, appearing constantly in debates and on committees. He was elected to the United States Senate in 1867, 1873, and 1879, and as senator he supported the reconstruction policy, actively opposed President Johnson and was a staunch supporter of President Grant. He became an extremely influential member of his party; in 1876 receiving 93 votes for the presidential nomination, and in 1880, by his support of Grant and his personal opposition to Blaine, dividing the Republicans into two sections. In May 1881, he and his colleague, Thomas C. Platt, suddenly resigned from the Senate, owing to a dispute with President Garfield on a question of patronage, and sought re-election; but after a warm canvass, both were rejected, though vigorously supported by Vice-President Arthur. Conkling afterward practised law in New York. He was appointed associate chief justice of the United States supreme court in 1882, but declined the position.

Conn, Herbert William, American biologist: b. Fitchburg, Mass., 10 Jan. 1859. He was educated at Boston University and is professor of biology at Wesleyan University, Middletown, Conn. He has published 'Evolution of To-day' (1886); 'The Living World' (1891); 'The Story of Germ Life' (1897); 'The Story of the Living Machine' (1899); 'The Method of Evolution' (1900); 'Agricultural Bacteriology.'

Conn, Lough, lōh kōn, a lake in the north of Mayo County, Ireland, united with Lough Cullin by a narrow channel. The two extend for about 13 miles and are studded with islands.

Connaught, kōn'nât, Arthur William Patrick, DUKE OF, English prince, third son of Queen Victoria: b. Buckingham Palace, 1 May 1850. Besides his position of Duke of Connaught, he is Prince of the United Kingdom, Duke of Saxony, Earl of Sussex, and Prince of

CONNAUGHT — CONNECTICUT

Coburg and Gotha. He entered the Woolwich Military Academy in 1866, became general of brigade in 1880; was created Duke of Connaught and Strathern, and Earl of Sussex, 26 May 1874; and received a seat in the House of Lords 8 June of that year. He married Princess Louise Margaret of Prussia, 13 March 1879. In January 1900 he succeeded Lord Roberts as commander-in-chief in Ireland, becoming commander of the Third Army corps in 1901.

Connaught, Ireland, one of the four provinces, bounded east and northeast by Leinster and Ulster, south by Munster, and north and west by the Atlantic; length, north to south, 112 miles; breadth, 99 miles; area, 6,867 square miles. Its west coast is much broken up by numerous bays and inlets, and is thickly studded with islands. The surface is rugged and mountainous, except in the central part, which is comparatively level. It is, on the whole, the least fertile of all the provinces. Connaught was formerly one of the Irish kingdoms. Its kings were of the race of O'Connor, but they were almost exterminated at Athenry in 1305. In 1590 the English divided it into six counties, one of which, county Clare, was afterward transferred to Munster. Pop. (1901) 649,635.

Conneaut, kōn ne ât', Ohio, a town of Ashtabula County, situated at the mouth of Conneaut Creek, on the Lake Shore & M. S., the New York, C., & St. L., and the Pittsburg, S., & L. E. R.R.'s. It is a coal and ore port of importance, and also exports the agricultural produce. It has railroad shops and other manufacturing interests. Pop. (1900) 7,133.

Connecticut, kōn-nēt'-i-kūt, "the Nutmeg State," "the Land of Steady Habits," or "the Constitutional State" (having framed the first written constitution in America), is the southwesternmost of the six New England States. It is bounded by Massachusetts on the north, Long Island Sound on the south, Rhode Island on the east, and New York on the west. Capital, Hartford. Area, 4,845 square miles land, 145 square miles water. Pop. (1900) 908,420.

There is no doubt that the claim of the Dutch to Connecticut by right of discovery was well founded, for the accounts of the voyages of Henry Hudson in 1609 and of Adrian Bloch in 1614 give the first descriptions which history records of this region. The attempts of the Dutch to maintain their foothold by this right were few and ineffectual, failing to prevent William Holmes of Plymouth colony from establishing a trading post at or near Hartford in 1633.

Settlement.—The first permanent settlement by the English was made in 1636, though a disastrous attempt had been made in the previous year by a party from Massachusetts to occupy the three original towns. In June 1636 Rev. Thomas Hooker and Rev. Samuel Stone, with about 100 men, women, and children, made their way from Massachusetts to the Connecticut valley, and there re-established the almost abandoned settlements at the three towns which bore the transplanted Massachusetts names of Newtown, Watertown, and Dorchester, but were, in the following year, respectively named Hartford, Wethersfield, and Windsor. Within a year from the time of this settlement about 30 of the settlers had been wantonly killed by the Pequot Indians, who appeared to be plotting the ex-

termination of the English. In May 1637 Major John Mason, with a band of 90 men, was despatched to attack the Pequots at their stronghold in the present town of Groton. Reaching, by strategic movements, the stockade, where a large number of them were encamped, he took them completely by surprise, killing about 700 by setting fire to their inflammable wigwams and putting to death in hand-to-hand conflict those who escaped the flames. This resulted in the extermination of the Pequot tribe, and secured to the settlers exemption from Indian depredations for all time to come.

The colonists now began to prosper under the leadership of the pastors, Hooker and Stone. Finding themselves outside of the jurisdiction of Massachusetts, to which they at first supposed that they were answerable, they proceeded to form a civil government of their own, adopting in 1639 the Constitution which stands unique in history as the first written constitution of a self-governing people. Its principles had been preached from the pulpit by Thomas Hooker, and its spirit, if not its form, prevailed in the Federal Constitution which was adopted through the influence of Oliver Ellsworth, Roger Sherman, and William Samuel Johnson of Connecticut just 150 years later. By this Constitution of 1639 much less rigid ecclesiastical control prevailed than in Massachusetts Bay and Plymouth colonies, the people were recognized as sovereign, and the authority and even the existence of the ruler of Great Britain was ignored. Meantime there had sprung up in Quinnipiack a budding colony, afterward known as New Haven Colony, under the leadership of Theophilus Eaton and the Rev. John Davenport. This colony in 1639 adopted resolutions which vested the government in seven pillars of the Church, and disfranchised all who were not church members. In 1662 John Winthrop, the younger, then governor of Connecticut, obtained in England from Charles II., a charter which established Connecticut as an independent colony under the constitution already adopted, and defined the boundaries to include New Haven colony, which was thus absorbed, though sorely against its will.

Charter Rights.—From this time onward, for 50 years, Connecticut was engaged in a constant struggle to maintain the rights which the charter had granted. Conflicting grants by Charles II. to his brother, then Duke of York; boundary disputes; conflicts of authority with other colonial governors; and the fear that the charter might be annulled by royal decree, kept the statesmen of the day in an attitude of continual vigilance, and schooled them in diplomacy, tact, and political alertness. But once in her history, and then only for a year and a half, did Connecticut lose that autonomy which she cherished as her birthright. This was during the usurpation of Andros, in 1687. But the charter was preserved, though Andros demanded it. Its preservation was the result of one of the Yankee tricks for which Connecticut has always been famous, and which may have had something to do with giving her the equivocal title of "the Nutmeg State." The charter was brought into the general court toward nightfall at Andros' request. Candles were lighted and, by some mysterious agency, suddenly extinguished. During the darkness which prevailed the charter disappeared. Andros assumed the government,

and Secretary John Allyn wrote "FINIS" at the close of the record of the proceedings. In May 1689 came the downfall of Andros, and the government and charter reappeared, with the astute Gov. Treat once more in the chair, and an undying reverence established for the old charter oak, where, as tradition tells us, Capt. Joseph Wadsworth hid the precious document when it so suddenly disappeared.

War Services.—From the resumption of the government under the charter to the close of the French war in 1763, Connecticut saw much military service, for which she furnished her full quota, on other soils than her own. The short intervals of peace during this long period did not suffice to regain prosperity, and the year 1763 found the colony impoverished by contributions of men and money in the French and Spanish wars, and confronted with the odious news of the Stamp Act. The enforcement of this measure was prevented by compelling the stamp-master to sign a paper stating that he resigned "of his own free will."

In the War of the Revolution which followed, the share of Connecticut forms a most important feature, still hardly appreciated by historians. The colony was amply, though quietly, prepared in every way for the coming struggle in 1775. Perfect unanimity prevailed. It was unnecessary either to reconstruct the government, as was done in Massachusetts, or to depose the governor, as was done in all the other colonies. Connecticut alone of all the 13 colonies had from the beginning a governor, Jonathan Trumbull, who was an ardent believer in the cause of his country. He became a trusted adviser and helper to Washington. A cherished Connecticut tradition asserts that the national nickname, "Brother Jonathan," is derived from the fact that Washington had used this sobriquet in speaking of Gov. Trumbull. From recent compilations of muster-rolls it is safe to assert that Connecticut furnished 40,000 men in her various enlistments in this war. In the adoption of the Declaration of Independence she was the first colony to instruct her delegates to vote for this measure. During the war, she gained the title of "the Provision State," owing to the unstinted supplies which she sent to the front in all times of need, relieving, for example, the sufferings of the starving soldiers at Valley Forge by sending forward droves of live cattle when Washington wrote Trumbull that the army must disband unless supplies were forthcoming.

As in the French, Spanish, and Indian wars, so in the Revolution, Connecticut's position was, in a certain sense, altruistic, for but little fighting was done on her soil, and it was done at times when her own fighting men were serving their country beyond their own immediate borders. The ravages of two of the most savage massacres and two of the most barbarous raids of the war brought their horror and devastation to this little commonwealth. The Wyoming massacre was an attack on Connecticut settlers on disputed Connecticut soil, justly claimed under grants of the charter, which extended the western boundaries to the "South Sea" or Pacific Ocean, whose location was majestically ignored by Charles II. and his advisers. Wyoming or Westmoreland, now in Pennsylvania, was at the time of the horrible massacre of July 1778 a county of Connecticut, having been previously

a part of Litchfield County, and having been for 25 years settled by a Connecticut company after repeated repulses which only served to strengthen resistance and establish an apparently permanent foothold on the part of the settlers. The refugees, of whom women and children composed a large majority, fled to their homes in Connecticut after the massacre, the terrible results of which did not prevent many of the former inhabitants from returning to Wyoming, and once more establishing themselves in that beautiful region from which they had been so often ruthlessly driven. The other massacre, at Groton, occurred toward the close of the war, 6 Sept. 1781. The raid was commanded by Benedict Arnold, to whom it is unfair to attribute the most disgraceful part of it. He was in New London at the time of the occurrence, his troops having burned a large portion of the town. The little garrison of Fort Griswold at Groton made a brave resistance against forces outnumbering them six to one. When, at last, the British entered the fort, Ledyard, the American commander, presented his sword to the officer in command of the British in token of surrender. This brute, whose name, fortunately for his memory, has never been discovered, received the sword and plunged it at once through Ledyard's heart. This was a token for indiscriminate slaughter, in which hardly a man of this surrendered force was left unhurt, and but few left alive.

The raids of Gov. William Tryon on Danbury in April 1777, and on New Haven, Fairfield, and Norwalk, in July 1779, resulted in great destruction of property by fire and plunder, and in the loss of many lives on both sides. It may be truly said that never but twice did these invaders remain on Connecticut soil over night, and in each case took to their ships the next morning with Connecticut troops in hot pursuit.

Notwithstanding the terrible drain which the Revolution made upon her resources, Connecticut, through her wise financial policy, was better prepared, at the close of the war, to avail of the advantages of peace than were any of the other States with the exception of Delaware. It is hardly surprising that the war of 1812 should have been unpopular in Connecticut as well as in all New England; but too much opprobrium has been heaped on Connecticut by giving the protesting convention for all New England the name of the Hartford Convention for the simple reason that it was held, for convenience, in Hartford. It will be found that Connecticut furnished for this war, too, a goodly number of men, though there were some disputes as to the manner and form of doing it. For the half century following this war, peace and prosperity prevailed, broken only by the comparatively insignificant, but sufficient, contribution which was made to the Mexican war.

The outbreak of the Civil War in 1861, like the outbreak of the Revolution in 1775, found Connecticut with a governor in office who was equal to the emergency. Gov. William A. Buckingham, upon his own responsibility, called for a regiment of volunteers, 16 April 1861, when there was not a regiment of organized militia in the State to meet Lincoln's first call. The private citizens and the towns voted money to forward troops; and soon, instead of one, three regiments of volunteers reported for service, making it necessary for the governor to go to

CONNECTICUT

Washington to have three times the quota accepted under the call. At the close of the war, the official record shows that Connecticut had furnished 54,882 volunteers, which number was largely in excess of her quota.

Industries.—This war stimulated the industries of Connecticut, which had, at the time, reached a high stage of development. The demand which the large and suddenly equipped army and navy of the country made upon these industries could not fail to have this effect. During the 40 years which have followed the War, the development of manufactures has continued to keep up a healthy growth. This little commonwealth, originally composed of intelligent farming communities, has, by a perfectly natural process of evolution, developed into a manufacturing State which, small though it is in area, holds the rank of eleventh in the gross value of its manufactured products, and the rank of second in the per capita value of these products among the 52 States and Territories enumerated in the census of 1900. Still more significant is the fact that a larger number of patents in proportion to the population have been issued to Connecticut inventors than to those of any other State in the Union during the past 10 years.

It appears to be a fact that in early colonial times the same inventive genius which has developed in this little commonwealth was born of necessity, and that it was transmitted by heredity down to the present day. The first settlers brought with them intelligence, broadened views of ecclesiastical control, and little or nothing more. There were no industrial specialists among them; and a century after the towns of the colony had taken root in various parts of the soil the leading townsmen, besides being still farmers with a growing tendency to trade, were each of them equal to any industrial or political emergency which might arise. Diaries covering the first half of the 18th century show, for example, that the diarist was a ship-carpenter, house-carpenter, millwright, surveyor, judge of probate, soldier, and deputy to the general assembly, while pursuing the regular occupation of a trading farmer; and that his neighbors were equally versatile in their industrial and political pursuits. This diversity of individual talents naturally grew, in time, to specializing, as the resources and needs of the commonwealth developed. In 1705 the Granby copper mines were discovered, and unprofitably worked, leaving as souvenirs the Granby copper coins, and the old mine itself, which was used as a prison during the Revolution, and abandoned at the time of establishing the State prison at Wethersfield in 1827. Other attempts at mining for precious metals were equally unsuccessful, but the working of the Salisbury iron mines, which have been in operation since 1730, proved to be a lasting success. From these mines cannons, balls, camp-kettles, and other useful articles were furnished during the Revolution, including the chains which were used to bar the progress of the British fleet on the Hudson. The anchor of the famous ship *Constitution* was forged from Salisbury iron in later days. The ore is a rich hematite, which, prepared by the use of charcoal, yields pig-iron which rivals the famous product of the Swedish and Norwegian mines.

As early as 1749 we find that John Allyn had experimented in brass-making; and in 1768 the first paper-mill of Connecticut, if not the first in the country, was successfully established by Christopher Leffingwell of Norwich. Tin-ware was first made in Berlin in 1770, and furnished for a century or more an important industry in which the Yankee peddler exercised his wit and shrewdness. In 1773 Thomas Harland from London established at Norwich a shop for making and repairing watches and clocks. In this shop Eli Terry learned the mechanism of the timepieces of the day, and afterward applied his inventive genius to the manufacture of pillar-scroll and case clocks, which he perfected in 1793. Other Connecticut inventors, especially Seth Thomas and Chauncey Jerome, have brought clock-making to, or very near, its present advanced stage. Eli Whitney, the inventor of the cotton-gin, though not a Connecticut man by birth, owed his fortune to the successful manufacture of firearms at New Haven in 1798, after having been robbed of his great invention in the South in 1792.

The first manufacture of sewing-machines on an extended scale was established by Elias Howe, at Bridgeport, followed in the same city by the improvements of Wheeler and Wilson. In 1844 Charles Goodyear of New Haven obtained his first patent for the process of vulcanizing india-rubber, a process entirely of his own discovery, which revolutionized this important industry in his day, or rather made a new and still enormously increasing industry in the use of material which, without this invention, would have continued to occupy an unimportant place in the industries of the world. The invention of electro-silver plating is traced to the Rogers Brothers of Hartford. In 1846 these three brothers, Asa H., William, and Simeon S., succeeded, after much experimenting, in finding a successful way of applying this process to articles made of various metals. From small beginnings, the business grew to large proportions, resulting in great establishments in Hartford, Meriden, Waterbury, Norwich, and elsewhere.

The manufacture of textile fabrics had its beginnings in a small woolen factory in Hartford in 1788, and a small cotton-mill in Vernon in 1804, but the growth of this industry to its present proportions did not begin in any marked degree until after the enactment of the joint-stock act in 1837, allowing small sums to be capitalized and small proprietors to join their forces in manufacturing. It may be remarked in passing that this act, forming a long step in the evolution of the modern "trust," was copied by nearly every State in the Union, and by Great Britain. The cotton-mills of the State have found their most available water-power on the Shetucket and Yantic rivers and their tributaries, which form the Thames River at Norwich. Of these mills the Ponemah Company at Taftville has one which, when it was built, was said to be the largest cotton-mill in the world. At Baltic, farther up the Quinebaug River, the large cotton-mill, which had been destroyed by fire, has been rebuilt within a few years. The Willimantic Linen Company is one of the largest thread-producing companies in New England. More than seven tenths of the cotton spindles in the State are operated at Norwich, Thompson, Plainfield, Killingly, and Willimantic. The woolen mills are more widely distributed

CONNECTICUT

throughout the State, at Vernon, Stafford, Broad Brook, New Britain, Norwich, and elsewhere. Among the textile manufactures silk forms an important feature, the industry having had its small beginnings as early as 1732. The silk mill of the Cheney Brothers at South Manchester, established in 1838, and still in active operation, is one of the largest in the country. Connecticut holds its own well in its rank as a textile manufacturing State, having been sixth of all the States in 1900 in the value of its textile products. Of the smaller and more varied manufactures of all kinds, the number, like the aggregate product of the larger ones, has increased largely. The leading industries may be enumerated as brass manufactures, carriage-making, and the manufacture of clocks, corsets, cutlery, electrical apparatus, foundry and machine-shop products, hats, paper, plating, rubber goods, sewing-machines, and textiles.

The most important industry which the State has acquired of late years is that carried on at the large establishment of the Eastern Shipbuilding Company at Groton on New London harbor. Here has just been launched the steel steamship *Minnesota*, soon to be followed by her sister ship, the *Dakota*, of the same model and dimensions. It is claimed for these two ships that, although their length is 70 feet less than that of the great steamship *Cedric*, their excess in other proportions makes them the largest ships in the world. Their length is 630 feet each, width 73½ feet, depth 53 feet, with a displacement of 40,000 tons when loaded to a draft of 40 feet. Their approximate cost is \$2,500,000 each. They are intended for the Pacific and Oriental trade. Among the new and important industrial establishments of the State and of the world is that at Norwich for supplying compressed air as a motive power through long conduits from a central station. After several years of experiment, and a large expenditure of money, this station is now in successful operation as a pioneer in a new and probably vastly important invention.

The amount of capital invested in manufactures in this State in 1900 was \$314,696,736, and the value of the manufactured product was \$352,824,106, showing an increase of 42 per cent over the same values of 10 years before, which is the largest increase since 1870. The number of wage-earners engaged in manufactures was 176,694, or 19½ per cent of the total population. The number of officials, clerks, etc., in the same business was 9,981.

Agriculture.—Although the history of agriculture in Connecticut presents a contrast to the history of manufactures by showing a decline in proportion to the population, agriculture is still second in importance among the industries of the State. In considering this industry it must be remembered that it has for its limits a little commonwealth, being fiftieth in area of the 52 States and Territories enumerated in the census of 1900. In its relation to agriculture, as to physical geography, its area may be rather indefinitely divided into the central lowland, the coast, the eastern upland, and the western upland. Of these the central lowland, lying in the valley of the Connecticut River, is, from Middletown to the northern boundary, best adapted to cultivation; and here it was, that, after spying out the land, the first colonists, whose sole industry was agriculture, settled. From Mid-

dletown to the coast the river leaves the lowland, and cuts a narrow valley through the eastern upland. The portion of the central lowland between Middletown and New Haven is less fertile. Along the lower portions of the coast some market-gardening is carried on, as the cities nearby offer suitable outlets for the products. The eastern upland varies in fertility, but contains some rich farming land. It has also the advantage of a lower average elevation than the western upland, where the only mountains of the State are found. One of these, known as Bear Mountain, reaches an elevation of 2,000 feet or over.

The cultivation of tobacco began in the Connecticut valley, near Hartford, as early as 1680; and the crop of the present day probably reaches a higher value than any other single product of the soil grown in the State. Improved methods of curing the harvested plant have added much to its value of late years. Peach orchards have been quite productive, and after a lapse of many years they again yield an important product. The dairy farms contribute to the central creameries, or are still carried on by individual farmers who can reach a city market. The raising of cattle for food has decreased as an industry.

The amount of capital invested in agriculture is \$113,305,580; and the value of farm products in 1899 was \$28,276,948. The value of domestic animals in 1900 was \$10,247,634. The number of persons engaged in agriculture is reported as 45,596, and the number of farms as 26,948.

Railroads.—The railroads are: the New York, N. H. & H., 4,072 miles; the Central N. E., 233 miles; the New London N. (leased to the Central V. R.R.), 160 miles; and the South Manchester, 5 miles, making a total of 4,470 miles of railroad operated by companies of the State. The latest reported gross earnings of these railroads are:

New York, New Haven & Hartford....	\$43,521,087.11
Central New England.....	593,965.43
New London Northern.....	992,546.67
South Manchester.....	18,049.49
Total	\$45,125,648.70
Total of operating expenses.....	32,627,503.35
Total net earnings.....	\$12,498,145.35

The street railways of the State number, at last reports, 28, and are rapidly extending, two additional charters having been recently granted. The main lines, exclusive of sidings, etc., cover 517½ miles, according to the report of the State railroad commissioners to 30 June 1902. The gross earnings of these companies for the year ending 30 June 1902 were \$3,937,771.46; expenses, \$2,550,236.69; net earnings, \$1,387,534.77.

Banking.—In the banking business of the State the most important item is the deposits in the 90 savings banks, making a total of \$205,908,034.80 on 1 Jan. 1903, showing an increase during the year 1902 of \$10,180,796.74. There are in the State 81 national banks of deposit, with an aggregate capital of \$20,257,070 and a surplus amounting to \$9,455,220.48; 8 State banks, with capital amounting to \$2,240,000 and a surplus of \$878,000; 25 trust and investment companies, capitalized at \$6,143,474, with surplus of \$1,326,487.41; and 16 building and loan associations, with assets amounting to \$4,145,197.32. The oldest bank of

CONNECTICUT

deposit in the State is the Union Bank of New London, chartered in 1792, and still doing business under its old State charter. The Hartford National Bank was chartered at the same session of the general assembly, and changed to a national bank 13 June 1865.

Insurance.—The insurance business of the State centres in Hartford, where there are six of the eight stock fire-insurance companies, representing \$9,750,000 in capital, and \$13,939,214.03 in surplus. The other two companies represent \$350,000 in capital, and \$213,420.26 in surplus. Of the 16 mutual fire-insurance companies, 11 only appear active, representing gross assets of \$2,198,677.31, and surplus of \$1,715,019.24. The six life insurance companies of the State are all in Hartford. The latest report of their assets shows an aggregate of \$180,302,652.64, with policies in force amounting to \$35,405,746. There are also in the State six fraternal societies with assets amounting to \$863,769.08, and policies or certificates in force amounting to \$30,246,750.

Religion.—The ecclesiastical history of Connecticut would fill a large volume, and could only be properly treated by a profound theologian. It is enough to say that, at the beginning, the colony stood unique as a compromise between the rigid ecclesiasticism of Massachusetts Bay and Plymouth colonies, and the religious liberty which Roger Williams was, at the time, establishing in Rhode Island. Unique though it was, it can only be called a theocracy at the beginning, for the State was then the Congregational Church, pure and simple, and though others than church members could vote, they were obliged by the early code to vote taxes for the support of the Church. The process of emancipation from these theocratic conditions was slow, and did not reach perfection until the adoption of the new Constitution in 1818. Through this period of nearly two centuries there were executions for witchcraft; at Stratford in 1651; at Fairfield in 1653; and possibly at Windsor in March 1646 or 1647, if the journal of John Winthrop is to be taken as authority; and in the theological tenets which were adopted from time to time under direction of the general court and otherwise, we pass through a maze of solemn discussions of the Half-way Covenant, the Cambridge Platform, the Saybrook Platform, with the later New Lights and Old Lights arrayed against one another as Separatists and Conservatists. Legislation exempting the Church of England from taxation for support of the Congregational Church was had in 1727, and in 1729 was extended to cover the cases of Baptists and Quakers. In 1791 the right of incorporation was allowed, under certain restrictions, to all religious bodies. The first Baptist elder was ordained at New London in 1726, but the sect did not gain largely until the beginning of the 19th century. The Protestant Episcopal Church was not established under a regularly ordained bishop until after 1784, although it had made beginnings before that time, but was practically exterminated during the Revolution, owing to the toryism of its clergy. In 1789 the first Methodist Episcopal Church in the State was established at Stratford. The first Roman Catholic Church in Connecticut was established in 1830, and in 1843 the diocese of Hartford, embracing the entire State, was established.

The statistics of religious denominations are but partially available, only a few of the denom-

inations publishing reliable figures, most of them none whatever, and some inflated "estimates." The Protestant denominations are as usual divided into many sects. Of these the strongest is the historic original Church, and for generations the established one, the Congregational; it has nearly twice as many churches as any other one denomination, and fully twice as many members. The Protestant Episcopal and the Methodist Episcopal are about equal, next in order; and the Baptist not very far behind. The Roman Catholic Church is very strong, numbering from a third up to nearly half of the population of the cities and manufacturing villages, but less numerous in the rural districts. There are small numbers of Presbyterian, Lutheran, Universalist, and Catholic Apostolic churches, a few Unitarian, and some Jewish synagogues.

Charitable Institutions.—The educational institutions which are partly or wholly sectarian in character will be mentioned later in speaking of the general subject of education. The Roman Catholic Church maintains the following charitable institutions: one hospital, two orphan asylums, one home for the aged poor. Other charitable institutions in the State, not dependent on church support, but wholly or in part dependent on public funds are: 14 hospitals, 8 temporary county homes for children, 1 home for disabled soldiers, 1 home for soldiers' orphans, 1 hospital for the insane, 1 retreat for the insane, 2 institutions for instruction of the deaf, one institute and industrial home for the blind, 1 school for imbeciles, 1 almshouse for State paupers, 88 almshouses for town paupers, the paupers in 80 towns being provided for by securing board for them, or by assisting them at their homes. The charitable institutions depending solely on private support, are: 5 hospitals, 15 homes for the aged and friendless, 13 homes and asylums for the young. In addition to the foregoing there are 10 private sanitariums licensed by the State. A fee is charged to patients in these institutions. An additional State hospital for the insane has been authorized by the General Assembly of 1903.

Penal and Reformatory Institutions.—These are: 1 State prison, 8 county jails, 1 reform school for boys, called "the Connecticut School for Boys," 1 industrial school for girls.

The total amount expended for charities and corrections in 1901 was \$1,598,514.

Education, etc.—The educational system of Connecticut was planted almost literally with the first corn that was planted by the early settlers. From the small beginnings in the few towns the present system of public schools has evolved, aided materially in 1795 by the proceeds of Western Reserve lands, now in the State of Ohio, which were sold in order to establish a school fund. These lands, to the extent of about 3,500,000 acres, were granted to Connecticut by the United States in 1786, as a tacit compensation for her loss of the Wyoming territory by a decree of 1782. About 500,000 acres were granted by Connecticut to those within her jurisdiction who had suffered from the incursions of the British during the Revolution, and the remaining 3,000,000 acres were sold for the establishment of a school fund. This fund remains intact to the present day, and amounts to \$2,020,732.91, yielding an income of \$107,824.39, being less than one fourth of the amount paid by the State for the support of public schools under

CONNECTICUT

the law providing for payment by enumeration. Another fund, which the State has appropriated to the towns, is known as the town deposit fund, which was Connecticut's share of the apportionment from the surplus of the United States treasury in 1837, and which was apportioned by the State to the towns. Under the law of 1859, the entire income of this fund was to be used for education; but it has become so merged in the general treasuries of the various towns that it is difficult to get any specific account of the manner in which it is used. It amounted in 1901 to \$763,661.83, yielding a nominal interest of \$29,151.96. According to latest reports of the State board of education, "in most cases this interest exists on paper only." Beyond this State support, the common school system depends on taxation in the various towns and school districts to meet expenses. By a recent decision of the courts, a school district may, in lieu of the payment made by the State of \$2.25 for each enumerated school child, receive from the town the actual expense of conducting the schools for 36 weeks in the year. Education is compulsory, the limit of age for school attendance being from 7 to 16 years.

The control of the common school system is varied. A single town may conduct its schools by means of a committee, or it may divide itself into an indefinite number of school districts, each in charge of a committee, and all under the supervision of school visitors; or these districts may each be incorporated under the sole control of a board of education. The tendency, of late years, is toward the consolidation of the various districts in each town. Recent legislation provides for the extension of high school education. In addition to the common schools, to whose support it contributes, the State now supports three normal training schools for teachers, and has made an appropriation for the establishing of a fourth. It also controls and supports an agricultural college and experiment station. The public school buildings number 1,592, employing continuously 3,973 teachers, with many others employed during portions of the year. The number of children between the ages of 4 and 16 enumerated in 1902 was 209,019.

In addition to the public schools, there are in the State 161 private schools, of which 59 are parochial schools of the Roman Catholic Church, 4 parochial schools of the Lutheran Church, and the rest non-sectarian, being business colleges, boarding schools, and secondary or high schools. These 161 private schools employ 929 teachers, and are attended by 31,347 pupils. The higher institutions of learning are all supported by endowments or church funds. The principal of these are Yale University, Wesleyan University, Trinity College, the Hartford Theological Seminary, the Berkeley Divinity School, St. Thomas Catholic Seminary, and St. Joseph Catholic Seminary. Each of these has a large library of its own, that of Yale University being the largest in the State.

The State Library contains a large and valuable collection of the laws and official documents of other States and the general government; besides which it has accumulated a general collection, in which history is prominent. It also contains many rare and original documents, including the charter of 1662. There were, at last reports, 130 general public libraries

in the State, of which 99 were free and 33 charged fees for the use of books. Library legislation encourages the establishment of free libraries by giving books to the value of \$300 annually to towns which make appropriations to that extent.

The newspapers published in the State number 141, of which 37 are daily, 11 semi-weekly, and 93 weekly.

The principal historical societies are the Connecticut, New Haven Colony, New London County, Middlesex County historical societies, and the Bridgeport Scientific and Historical Society.

Government.—The government of Connecticut has been conducted under two different constitutions, the first of which was adopted in January 1638-9, and was fortified and protected by the charter of 1662; and the second of which was adopted as the result of a constitutional convention in 1818. This constitution, with its subsequent amendments, forms the organic law of Connecticut at present. Under it the governor, lieutenant-governor, secretary of state, treasurer, comptroller, and members of the General Assembly are chosen biennially by the people. Other State officers are appointed either by the governor, sometimes with and sometimes without the consent of the Senate, or by the General Assembly. This body is composed of a Senate, consisting of 24 members, and a House of Representatives, consisting of 255 members. One senator is elected from each of the 24 senatorial districts; two representatives each from 87 towns; and one representative each from 81 towns. The courts are the supreme court of errors, the superior court, the court of common pleas, and the district court, the judges of which are appointed by the General Assembly on nomination by the governor. Judges of city, borough, and town courts are appointed by the General Assembly. There are in the State 112 probate districts, the judges of which are elected by the people.

Population.—The population of the State is 908,420 by the census of 1900, showing an increase of 162,162 in 10 years. Of this population 670,210 are native born, and 238,210 foreign born. Only 3.8 per cent of the entire population are classified as illiterate, being the smallest percentage of illiterate population of any State in the Union except Massachusetts, which shows 3.5 per cent of illiterates.

The latest reported total of grand lists of taxable property is \$649,571,791. The State debt is \$1,663,100. The receipts for the year ending 30 Sept. 1902, were \$3,275,112.23; expenses \$3,113,687.57.

Owing mainly to dissatisfaction with the unequal town representation in the House of Representatives, a constitutional convention was called in January 1901, which drafted a new constitution, which was rejected by popular vote 16 June 1902. The representation in the House for the largest city and the smallest town thus remains often equal and practically the same as that for which the original constitution of 1638-9 provided. The division of senatorial districts, though intended to remedy this inequality, is not entirely a satisfactory solution of the difficult problem of establishing equal representation.

JONATHAN TRUMBULL,
Librarian of Otis Library, Norwich.

CONNECTICUT — CONNEMARA

Connecticut, a river of the United States, rising on the northern border of New Hampshire; it forms the boundary between Vermont and New Hampshire, passes through the western part of Massachusetts and the central part of Connecticut, and falls into Long Island Sound. The western branch forms by treaty the boundary between the United States and Canada to lat. 45° N. It is navigable for vessels drawing from 8 to 10 feet to Hartford, 50 miles from its mouth. Above this the navigation is impeded by rapids and falls, but subsidiary canals now make navigation possible for 25 miles above Hartford. The river is famed for its shad fisheries.

Connecticut Lakes, four small lakes in the northern part of Coos County, N. H., which are connected with the Connecticut River in the beginning of its course. They are named in numerical order, from southwest to northeast, the largest one, Connecticut Lake proper, being known as First Lake. The smallest two, Third Lake and Fourth Lake, which are very near the Canadian boundary, are the ultimate sources of the river.

Connecticut Reserve. See WESTERN RESERVE.

Connecticut Yankee in King Arthur's Court, a humorous tale by Mark Twain published in 1889. It is the story of a superintendent of an arms factory in Hartford, Conn., who one day lost consciousness from a blow received in a quarrel with his men, and when he awoke found himself in England at the time of King Arthur. The contact of Connecticut Yankee-dom with Arthurian chivalry gives rise to strange results; yet amidst all the fun and pathos, the courtliness, the sincerity, and the stern virtues — as well as what seems to us the ridiculousness — of the age are well shown.

Connective Tissue, the most important supporting tissue in the body. It is one of a general class, being associated with cartilage and bone. In connective tissues in general the cellular elements are inconspicuous, the intercellular substance giving character to the tissue. Connective tissue, in the limited sense, as well as the other connective tissues belonging to the group, are developed from the mesoderm, and consist of variously branched cells which possess a small amount of protoplasm and relatively large nuclei. The branches of the neighboring cells are united by threads of protoplasm, and between the cells there is usually a homogenous network. Three main types of connective tissue proper are described. These are mucous connective tissue, fibrillar connective tissue, and reticular connective tissue. The mucous connective tissue, such as is seen in the Wharton's jelly of the umbilical cord, consists of round or star-shaped branched cells with a large amount of differentiated mucous-like intercellular substances. This contains a few fine fibrils sometimes collected in bundles. It is very common in developing animals, and is not often represented in the adult human animal, but is very common in many adult lower animals. The fibrillar connective tissues or fibrils are of several kinds. In these there is an abundant intercellular substance, composed of fibrils which are fine filaments less than one micromillimetre in diameter, which are united in small bundles by a cement substance. The fibres vary

somewhat in color and somewhat in elasticity, and according to these minute variations they are white fibrous tissue, elastic fibrous tissue, yellow elastic fibrous tissue (qq.v.). Reticular connective tissue consists of a delicate network of anastomosing star-shaped cells, or a fibrous connective tissue in which the intercellular substance has disappeared. Such tissues are very common in the lymph nodes, spleen, and the mucous membrane of the intestinal canal.

Con'nelley, William Elsey, American author: b. Johnson County, Ky., 15 March 1855. Though almost entirely self-educated, he was for a number of years a school teacher in Kentucky and Kansas 1872-82. For four years (1888-92) he was in the wholesale lumber business, and then engaged in banking. His leisure has been chiefly devoted to the study of the history and antiquities of the North American Indians, and the States of the middle west. He compiled the first vocabulary of the Wyandot language, and has made valuable studies of the languages of the Delawares, Shawnees, and other tribes. His papers have mostly appeared in the publications of the Ontario, Kansas, Nebraska, and Ohio Historical societies, the Bureau of Ethnology, and Smithsonian Institution. Some of their titles are: 'The Provisional Government of Nebraska Territory' (1899); 'Notes of the Clan System of the Wyandots' (1899); 'Notes on the Folk-Lore of the Wyandots' (Journal of American Folk-Lore, 1900); 'James Henry Lane, the Grim Chieftain of Kansas' (1899); 'Kansas Territorial Governors' (1900); 'John Brown: the Last of the Puritans' (1900); 'The Overland Stage to California' (with Root, 1902).

Con'nellsville, Pa., a borough in Fayette County, on the Youghiogheny River, and the Baltimore & O. and the Pennsylvania R.R.'s, 57 miles east of Pittsburg. It is the centre of the most extensive coke-burning region in the United States, the ovens here producing half of the total coke output of the country. It also contains one of the largest lock factories in the country. Other important industries are machine shops, pump works, brick works, and coal mining. It is the seat of Cottage State Hospital. Pop. (1900) 7,160.

Con'nelly, Celia Logan, American journalist: b. Philadelphia 1837; d. New York City 19 June 1904. She was married to an American artist, M. K. Kellogg, in 1859. Her literary career began in London, but she returned to the United States after the death of her husband, and in 1872 married James H. Connelly (q.v.). Her novels include: 'Her Strange Fate' (1891); 'Saraz' (1891); etc. She has also written plays, notably 'An American Marriage'; and 'Gaston Cadol.'

Connelly, James H., American journalist: b. Pittsburg, Pa., 1840; d. 1903. He began newspaper work when 17 years old, writing for leading Chicago, New York, and San Francisco journals, and was a volunteer officer in the Civil War. His writings include short stories and special articles for newspapers and magazines, 'My Casual Death' and other novels. From 1889 till his death he was prominent in the Theosophist movement.

Connemara, kōn-ne-mā'ra, Ireland ("the Bays of the Ocean"), a boggy and mountainous district occupying the western portion of county

CONNER — CONQUEST OF PERU

Galway, about 30 miles long and 15 to 20 miles wide. Its coasts are very broken, and there are numerous small lakes. It is subdivided into Connemara Proper in the west, Jar-Connaught in the south, and Joyce County in the north.

Con'ner, David, American naval officer: b. Harrisburg, Pa., 1792; d. Philadelphia, 20 March 1856. He entered the navy as a midshipman in 1809; took part in the action between the *Hornet* and the *Peacock*, 24 Feb. 1813, becoming lieutenant on the former, 24 July 1813. He was severely wounded on the *Penguin* 23 March 1815, and his gallantry was rewarded by a medal from Congress, and a sword from his native State. During the Mexican war he blockaded the Gulf ports of Mexico, captured the port of Tampico; directed the landing of Gen. Scott's army at Vera Cruz, and took part in the reduction of San Juan de Ulloa. He was commandant at the Philadelphia Navy Yard when he died.

Con'nersville, Ind., the county-seat of Fayette County, situated on the Whitewater River and on the Cincinnati, C., C. & St. L. and the Cincinnati, H. & D. R.R.'s. It has a number of manufactures, including furniture, carriages, blowers, and woolens. There are several natural gas wells, and also electric lights. Pop. (1900) 6,836.

Con'nery, Thomas Bernard Joseph, American journalist: b. Ireland, 13 Oct. 1838. The greater part of his career was spent in the service of the *New York Herald*, on which he held nearly every position except that of financial editor, 1856-84. He was editor of *New York Truth*, 1885; 'Once a Week,' 1893-5; 'Collier's Weekly,' 1895. He was United States secretary of legation and *charge d'affaires* in Mexico, 1866-8. He has published: 'Don Tiburcio'; 'Black Friday'; 'History of American Comic Journalism'; 'Character Marks Autorial'; 'Essays on Literary Women of England.'

Conning Tower, the place in modern battleships where the commander stands during a naval engagement, and from which he directs the movements of the ship and men. The conning tower is built over the forward turret and is a circular chamber, scarcely six feet across and protected by walls of steel 12 inches thick. The roof is also of solid steel. Between the arched roof and the walls is a narrow slit from which the eye can sweep the whole horizon. The sharp pointed bow of the boat is just below, and directly in front are the two big guns that protrude from the turret. Throughout the engagement the commander is invisible to his men, his voice alone being heard through the speaking tubes and telephone with which the turret is fitted. In its centre are the steam-steering wheel, binnacle, and compass, and by the directing hand of the commander, standing beside the compass, the battle is fought. He touches one button and the great engines drive the boat through the water; another signals the discharge of the heavy guns; the touch of a third loosens the torpedoes, while a word through a tube sends a storm of steel and lead flying from the machine guns on the upper decks and in the round top.

Con'nor, Ralph. See GORDON, CHARLES WILLIAM.

Connor, Selden, American soldier: b. Fairfield, Maine, 25 Jan. 1839. He graduated at Tufts College, 1859; enlisted as a private in the 1st Vermont regiment 1861; became lieutenant-colonel of the 7th Maine regiment 1861, colonel of the 19th Maine 1864, and brigadier-general of volunteers June 1864. He was present at the battles of Fredericksburg, Gettysburg, and the Wilderness, where he was severely wounded. After the War he held several minor Federal offices, was governor of Maine 1876-8, United States pension agent 1882-6, and 1897. On 3 October 1889 he delivered the oration at the dedication of the Maine monuments at Gettysburg.

Conodonts (Gr. "cone-teeth"), minute fossils found in Palæozoic strata. They look very like the teeth of different kinds of fishes, some being simple slender pointed sharp-edged cones, while others are more complex, resembling in form the teeth of certain sharks. The old opinion was that they are minute teeth of fishes allied to the living hag-fishes and lampreys, but it is more likely that they are the jaws of annelids and naked mollusks.

Co'noid, in geometry, a surface generated by a straight line moving in such a manner that it constantly touches a curve and another straight line; similar to the cone, but having a straight line instead of a point for its apex.

Co'non, Athenian general: d. after 392 B.C. Having been defeated in a naval engagement at Ægospotamos by Lysander, he for a time went into exile; but being aided by Artaxerxes, king of Persia, he returned and defeated the Spartans near Cnidos, 394 B.C. Conon then began to rebuild the fortifications of Athens, and restored it to liberty and security.

Conon, of Samos, Greek astronomer and geometer who lived in the 3d century B.C. He was a friend of Archimedes and invented the curve known as the Spiral of Archimedes.

Conon'icut, R. I., an island in Narragansett Bay, eight miles long by one broad, about nine miles south of Providence. On its south end is a lighthouse.

Conoscope, kō'nō-skōp. See POLARISCOPE.

Conquest, Ida, American actress: b. Boston, Mass. Her first stage experience was at the age of eight, when she appeared as Little Buttercup in the Boston Museum juvenile production of 'Pinafore,' a part she played over 300 times. Her professional début was made in 1892 with Alexander Salvini at a special matinee performance at the Tremont Theatre, Boston, in which she played Isobel in 'Rohan the Silent.' Others of her parts are Phyllis Lee, in 'The Charity Ball'; Carey, in 'Alabama'; Sybil, in 'The Dancing Girl'; Renée de Cochefort, in 'Under the Red Robe'; Babiole, in 'The Conquerors.' See Strang, 'Famous Actresses of the Day.'

Conquest of Mexico, The, a noted history by William Hickling Prescott, published 1843. It was most favorably received by the public, 4,000 copies being sold in America within four months of the date of issue.

Conquest of Peru, The, a history published by William Hickling Prescott (1847). Of the five books into which this work is divided, the first treats of the wonderful civili-

CONRAD

zation of the Incas, the second of the discovery of Peru; the third of its conquest; the fourth of the civil wars of the conquerors; and the fifth of the settlement of the country. The first book hardly yields in interest to any of the others, describing as it does, on the whole, an unparalleled state of society. From the necessities of its material, the work is more scattered in construction than is the 'History of the Conquest of Mexico,' usually regarded as the author's most brilliant production.

Conrad I., emperor of Germany: d. 23 Dec. 918. He was elected king of Germany in 911; but Arnulf, Duke of Bavaria, and Henry, Duke of Saxony, disputed his title, and engaged the Huns to overrun Germany. Conrad is said to have received a mortal wound in combat with these revolted chiefs. He is chiefly noteworthy for the revival in his case of the elective title to the crown.

Conrad II., emperor of Germany: d. Utrecht 4 June 1039. He was the son of Henry, Duke of Franconia, and was elected king of Germany in 1024. Attempts were made to displace him, but without success, and in 1027 he was crowned emperor at Rome, in the presence of Canute, king of England, and Rudolph, king of Burgundy. He is regarded as the true founder of the Franconian or Salic line. He was often engaged in contests with the greater barons and princes of the empire, and endeavored to form a counterpoise to their influence by encouraging the formation of minor independent fiefs. With the same view he endeavored to appropriate several of the larger duchies to members of his own family, and thus convert the elective empire into a hereditary monarchy similar to that of France. These designs, though conducted with considerable ability, failed, mainly in consequence of the incessant contests in which he was engaged with the popes.

Conrad III., emperor of Germany: b. 1093; d. Bamberg, Germany, 15 Feb. 1152. He was of the house of Hohenstauffen; and was elected emperor in 1138. His title was disputed by Henry the Proud, Duke of Saxony, and the rivalry of these two princes was the germ of the factions afterward so famous under the names of Guelfs and Ghibellines. In 1146, at the diet held at Spire, Conrad was persuaded by the eloquence of St. Bernard to undertake a crusade, on which he set out the following year. It was fruitless and disastrous, and Conrad returned with the wreck of his army in 1149.

Conrad IV., emperor of Germany: b. Andria, Italy, 25 or 27 April 1228; d. Lavello, Italy, 21 May 1254. He was chosen king of the Romans in 1237, was a son of the great Emperor Frederick II., and like him excommunicated by the Pope, Innocent IV., who set up a rival emperor in William, Count of Holland. On the death of his father in 1250, Conrad marched into Italy to recover the towns which had declared against him. He took Naples, but could not get the investiture of the kingdom of Sicily from the Pope.

Conrad V., or **Conradin**, German prince: b. 1252; d. Naples 22 Oct. 1268. He was the son of Conrad IV., and the last of the Hohenstauffen. He accepted the invitation of the Italian Ghibellines to place himself at their head and the sale of a large portion of his pos-

sessions enabled him to raise troops. In the autumn of 1267 he crossed the Alps with 10,000 men, and at Verona was warmly received by the Scala family, the chief of the Ghibelline party. His relatives here, persuading him to part with his remaining possessions at a low price, deserted him with their followers, leaving but 3,000 men. The Ghibellines, however, remained true to him. Verona raised a large army, Pisa a fleet, and Rome, whose pontiff was forced to flee to Viterbo, opened its gates to him. Conradin entered lower Italy, and at Tagliacozzo met the French army under Charles d'Anjou, on whom the crown of Naples had been bestowed by Pope Urban IV. He beat Charles back, and his men, supposing the victory won, dispersed in search of plunder, when they were attacked by the French and utterly routed, 23 Aug. 1268. Conradin escaped, but was betrayed into the hands of Charles at Astura, who caused him to be beheaded in the market place of Naples.

Conrad, kōn'räd, **Frederik Willem**, Dutch engineer: b. Delft 1769; d. 1808. He was the pupil and friend of Brunings, who did so much for the construction of the sea dykes of Holland, and on his death succeeded him in his situation of inspector-general of sea dykes in the province of Rynland. He afterward held the office of administrator-general of the sea dykes in the Low Countries. He rendered a lasting service to his country by reclaiming large tracts of land from the sea, and more especially by the formation of a proper outlet for the waters of the Rhine.

Conrad, **George**, pseudonym of Prince George of Prussia (FRIEDRICH WILHELM GEORG ERNST), German dramatist: b. 12 Feb. 1826. He has experimented successfully with various forms of dramatic literature; and among his productions are: 'Cleopatra'; 'Yolantha'; 'The Talisman'; 'Christine of Sweden'; 'Elfrida of Mount Salerno' (1875); 'Catharine de Medici' (1884); 'Sappho' (1887); 'Where is Happiness?'; 'The Marchioness of Brinvilliers'; 'Phædra.'

Con'rad, **Joseph**, English novelist: b. Poland 1856, the son of a Polish revolutionist. He was educated in Cracow, and at 13 went to sea, becoming subsequently a captain in the merchant service. After a long experience as a sea rover, he settled in England and began putting his various experiences into literature. His writings include: 'Almayer's Folly' (1895); 'An Outcast of the Islands' (1896); 'The Nigger of the Narcissus,' issued in America as 'The Children of the Sea' (1897); 'Lord Jim' (1900); 'The Inheritors' (with F. M. Hueffer, 1901); 'Youth and Other Tales' (1902); 'Typhoon' (1902).

Conrad, kōn'räd, **Michael Georg**, gā'örg, German novelist: b. Gnodstadt, Franconia, 5 April 1846. He founded at Munich, in 1885, 'Society,' a journal intended to be an organ of the "naturalistic" school. He spent several years in Paris, and many of his sketches relate to phases of life in France. Among his novels are: 'The Wise Virgins'; 'The Fool's Confession.' He is author of a comedy, 'The Emancipated,' and the drama, 'The Firm of Goldberg.' On social and political questions he has written: 'The German Reveille'; 'Justice, the State, and the Modern Spirit.'

CONRAD — CONSCIENCE

Con'rad, Robert Taylor, American lawyer and dramatist: b. Philadelphia, 10 June 1810; d. there 27 June 1858. He wrote: 'Aylmere' (1852), a tragedy in which Edwin Forrest played the role of Jack Cade; 'Conrad of Naples,' a tragedy; 'Poems' (1852); etc.

Conrad, Timothy Abbott, American naturalist: b. New Jersey Aug. 1803; d. Trenton, N. J., 9 Aug. 1877. His special study was American palæontology, but he investigated many other departments of natural history. He prepared the New York State geological report for 1837, was palæontologist of the New York Geological Survey, 1838-41, and made the reports on the palæontological discoveries in the Pacific R.R. survey and the Mexican boundary survey. He published: 'American Marine Conchology' (1831); 'Fossil Shells of the Tertiary Formations of the United States' (1832); 'Monography of the Unionidæ' (1835-47); 'Check List of the Invertibrate Fossils of North America' (1866). A very full list of his numerous papers will be found in the Royal Society's 'Catalogue of Scientific Papers.'

Conrad von Wurzburg, kōn'rād fōn vūrts'-boorH, German poet: d. Basel 1287. Fertile in imagination, learned, and, although marking the decline of Middle High German poetry by his prolix and artificial style, he was probably the most perfect master of German versification that had appeared up to his own day. His last poem, left unfinished, has for its subject, 'The Trojan War.' But he appears to most advantage in his smaller narrative poems, of which the best are: 'Engelhart'; 'Otto'; 'Der Welt Lohn'; 'Silvester'; 'Alexius'; 'Der Schwanritter'; and 'Die Goldene Schmiede.' His 'Lieder' have been edited by Bartsch (1870).

Conradi, Hermann, hēr'män kōn-rä'dē, German literary critic and essayist: b. Jetznitz 1862; d. 1890. As lyricist and critic he was a representative of radical realism, a follower of Tolstoy, Ibsen, and Nietzsche. His genius was forceful, but undisciplined, and his writings lack repose and polish.

Conradin (kōn'rä-dēn) of Suabia. See CONRAD V.

Conried, Heinrich, American impresario: b. Bielitz, Austrian Silesia, 13 Sept. 1855. Graduated from the Oberrealschule of Vienna, he came to the United States, and was for several years a manager of German theatrical and operatic organizations. As director of the Irving Place Theatre, New York, he became known for excellent presentations of German classic drama, frequently repeated at Cambridge and other university centres. In 1903 he became director of the Metropolitan Opera-house, where on 24 Dec. of that year he presented Richard Wagner's 'Parsifal' for the first time outside of Bayreuth.

Conring, Hermann, hēr'män kōn'rīng, Dutch scholar: b. Norden, East Friesland, 9 Nov. 1606; d. Helmstedt, Brunswick, 12 Dec. 1681. He studied at Helmstedt and Leyden, devoting himself chiefly to theology and medicine; was appointed, in 1632, professor of philosophy at Helmstedt, in 1636 professor of medicine, and remained in this city until his death. He was distinguished in almost every department of knowledge, and the title of a counselor was conferred on him by the kings of Denmark and Sweden and the elector of the Palatinate. He

was then made professor of law. The German emperor likewise distinguished him. From far and near his advice was sought in political and legal cases. He did a great deal for the history of the German empire, and for the improvement of German public law, in which he opened a new path. He wrote: 'De origine juris Germanici' (1643); 'Excertationes de re publica Germanica' (1675); and very many other treatises to the number of over 100. His works, with his biography, were published in 1730.

Consalvi, Ercole, ər-kō'lē kōn-säl'vē, Italian statesman and cardinal: b. Toscanella 8 June 1757; d. Rome 24 Jan. 1824. Having in 1797 entered the public service of the court of Rome in an humble capacity, he was four years later one of the 12 auditors of the Rota, a commission in effect a supreme court of appeal in all matters secular as well as ecclesiastical. The French having taken possession of Rome, Consalvi falsely accused of having had part in an assassination, was for a while held in prison and then banished. When Pius VI. died, Consalvi was largely instrumental in procuring, in the conclave held at Venice, the election of Cardinal Chiaramonti to the papal throne as Pius VII., and thereafter was that pontiff's chief counselor: he was now second only to the Pope in all dealings with the European powers and specially with Napoleon. In the course of the controversies between Rome and the French emperor, he showed a firmness that won for him the unwilling respect indeed of Napoleon, but also his irreconcilable enmity. It was while the emperor was flushed with the victory of Austerlitz that he sent to Consalvi through Cardinal Fesch the message, "Tell Consalvi that if he loves his country he must either resign or do what I demand"; and the cardinal prudently withdrew from public life for a season. In 1809 he had an interview with Napoleon at Paris, in which the emperor in effect made an apology for that act; but Consalvi persisted in his opposition to Napoleon's designs; and was one of the 13 cardinals who refused to concede the lawfulness of the second marriage of Napoleon. In punishment of his obstinacy in that matter he was held in confinement three years at Rheims. After the fall and banishment of Napoleon, he resumed his station in the papal court and devoted himself to the institution of many reforms in the government, being in effect chief governor of Rome and the papal states. He was always a liberal patron of art, literature and science. He left the bulk of his property to the poor. Consult Créteineau-Joly, 'Mémoires du Cardinal Consalvi.'

Conscience, kōn-syāns, **Hendrik**, Flemish novelist: b. Antwerp, 3 Dec. 1812; d. Brussels 10 Sept. 1883. Having educated himself, he taught for a short time in a school, and then served in the army from 1830 till 1836. He was for a time tutor in Flemish to the royal princes, and from 1868 conservator of the Wiertz museum at Brussels. His novels are partly based on the history of his country, partly pictures of everyday Flemish life. Among the former may be mentioned: 'The Year of Wonders' (1837); 'The Lion of Flanders' (1838); 'Jakob van Artevelde' (1849); 'The Peasants' War' (1853); 'Batavia' (1858); 'The Burgomaster of Liège' (1866); and 'Everard T'Serclaes' (1874); and of the latter, which

CONSCIENCE — CONSCIOUSNESS

are well written, very accurate and highly sympathetic, the chief are: 'What a Mother Can Endure' (1843); 'The Conscript' (1850); 'Wooden Clara' (1850); 'Blind Rosa' (1850); 'The Poor Nobleman' (1851); 'The Miser' (1853); 'The Young Doctor' (1860); and 'Maternal Love' (1862). He wrote also a musical drama, 'The Poet and His Dream' (1872). Many of his works have been translated into almost every European language. In 1881, on the occasion of the appearance of his hundredth volume, the Flemish people paid him a splendid tribute. The 10th anniversary of his death was observed in Antwerp with public ceremonies.

Con'science, the judgment or dictate of the practical intellect which from general moral principles pronounces that something is to be avoided because it is evil, or to be done because it is good. (See ETHICS.) Conscience Clause is the term applied to a clause in an act or law when it relieves persons who object on religious grounds to do something enjoined by the act or law, from any penalty to which they would otherwise be liable.

Conscience Money, stolen or wrongfully acquired money returned to its rightful owner when conscience is awakened to a sense of right dealing. In the United States such money paid into the treasury at Washington by self-avowed debtors anonymously is known as the conscience fund. In England the phrase is applied to money forwarded, as a rule anonymously, to the chancellor of the exchequer for unpaid income tax. It amounts to some thousand pounds a year.

Conscience Whigs. See WHIGS.

Consciousness (Ger. *Bewusstsein*; Fr. *conscience*; It. *conscienza*) is the term by which modern psychology aims to distinguish that which is characteristically and actively mental from that which is merely physical or vital. A number of statements regarding the inclusions and exclusions of the concept might be made, but a concise and accurate definition, in the present state of psychological knowledge, is impossible. This for two reasons: First, no particular group of objective phenomena can be pointed out as answering to what we mean when we employ the term, though there are numerous groups which may be taken as signs or manifestations of consciousness. Hence one common means of definition in the sciences, namely, the designation, analysis, and reduction to common and indispensable properties of similar phenomena, is unavailing in the present instance. Secondly, consciousness cannot be in any sense identified with any of the manifestations which signalize its presence. When I am actively engaged in some thought process, I am certainly conscious, but this is not what I mean by consciousness; for the term means something more than the sum of the states or manifestations of mind.

In lieu of a definition the best way of approaching a knowledge of the meaning of the term is analysis of its connotation. The word consciousness is an abstract noun derived from the more concrete adjective conscious. When we apply this latter adjective we mean to call attention to the awareness characterizing the normal mind when active, that is, when not asleep or in a swoon. Conscious is therefore used in opposition to unconscious, and implies

a condition of mind in which the subject is to some degree, be it ever so slight, aware of his own activity. The use of the two words conscious and unconscious brings to our notice a peculiar fact. An unconscious state is more striking than a conscious state just because it is less an integral part of the subject's ordinary experience. It is also from the observer's point of view wholly objective for the simple reason that the observation of an unconscious state in one's self would be in the nature of things a contradiction in terms. When we are in the profoundest sleep, we can make no observations upon our own states. This peculiarity permits us to draw one accurate distinction between consciousness and non-consciousness (including unconsciousness), namely, the state of consciousness is always to some degree its own object, or, in other words, the possessor of conscious mind is always in some wise looking in upon his own active ongoings. On the contrary, the non-conscious can never be an object for itself, but must always be an object for some (other) consciousness. It follows that one of the principal means of psychological investigation, introspection, can never apply to the unconscious. It would be no more absurd to ask a log of wood how "woodiness" feels than to ask an unconscious mind to give a first-hand account of itself. And when people speak of their experiences during a fainting fit what they really refer to is their sensations just as they are coming back to the world of life and light. Although introspection is not applicable to unconscious conditions of the normally conscious, observation and experiment can be applied with good results, and some interesting data have been secured in this way; though they are strictly speaking physiological rather than psychological.

This reference to the unconscious has seemed necessary here because the conscious has to be determined so largely by limitation. All that has been said, it will be observed, does not aim to define the term we are discussing, but simply seeks to make its psychological application better known by connecting it with ordinary usage. Bearing this purpose in mind, we cannot do better than to quote the explanation of the word given in Ladd's 'Psychology, Descriptive and Explanatory' (p. 30).

Whatever we are when we are awake, as contrasted with what we are when we sink into a profound and dreamless sleep, that it is to be conscious. What we are less and less, as we sink gradually down into dreamless sleep, or as we swoon slowly away, and what we are more and more, as the noise of the crowd outside tardily arouses us from our after-dinner nap, or as we come out of the midnight of the typhoid fever crisis, that it is to become conscious.

We detect in this descriptive statement of the characteristic phenomena of consciousness a recognition of degrees or stages, as well as of a limen or threshold, at which the unconscious mind awakes to consciousness, even though it be but a minimal consciousness. Of these we must now speak.

The phrase, threshold of consciousness, which has figured very largely in recent psychological literature, is a metaphorical expression for the common experience that a certain intensity of stimulus is necessary in order that the subject may have a conscious state. It might be used with perfect propriety broadly enough to include every form of coming to consciousness. In reality, however, the phrase, which Herbert

CONSCIOUSNESS

coined and Fechner used in his psycho-physical investigations, is limited to sense experience, being employed to designate the point where an increasing stimulus arouses a responsive sensation, or where a decreasing stimulus ceases to be perceived. In this instance there is a case of arising to the consciousness of a given object, rather than the return to consciousness as a mode of mind. However, the two cases are not so unlike as might at first sight appear, for the return from consciousness after sleep is usually signaled by the tardy perception of a sensory stimulus that has perhaps been knocking at the vestibule of consciousness all unheeded for some time.

We may pass over the various intervening degrees of consciousness with a mere allusion, and go on to consciousness in its most alert form, namely attention. Psychologists are accustomed to recognize two sub-species of attention, voluntary and non-voluntary. The distinction between them is based upon the presence or absence of volition at the initial moment of the redirection of consciousness. Otherwise they are essentially the same; and as non-voluntary or forced attention usually becomes voluntary after the first reception of the stimulus, both may be described by an inventory of the attributes of the voluntary variety. Prof. James in his interesting chapter on 'Attention' (Psychology, Vol. I., ch. xi.) calls our notice to the neglect of attention by the psychologists of the English empiricist school, and assigns as the reason their proneness to neglect and minimize the spontaneous tendencies of the mind. It is on attention as marking something especially self-initiated in mental activity, that the advocates of a rationalistic view of mind love particularly to dwell. This furnishes us with a clue to one of the attributes of attention. It is in a very special sense an active and energizing state of mind. When a sense stimulus impinges on an end-organ, the state of mind ensuing is in a way passive and receptive; but the moment consciousness awakens to the presence of the sensation and grows absorbed in contemplating it, there is an end to passivity. Whatever be said of sensation, attention, once aroused, is a pre-eminently active form of consciousness, and from the instant that the mind lays a selective hold upon the object soliciting it until it voluntarily lets go of it, there are numerous signs of the most intense phase of mental activity. The sympathetic workings of the facial muscles during such a period, the feeling of tension and uneasiness about the head, the firm set of the teeth, all these things bear witness to the forth-putting of great nervous energy. Another marked characteristic of attention is its tendency to fluctuate even when under what is seemingly the most steadfast control. Though the more noticeable and lasting fluctuations may with training be subjected to control, the insensible variations which are always to be discovered by experiment, persist in spite of the best training of the will.

The nature of attention is not fully made out. Some of the older schools of psychologists regarded it as a special faculty. This view is not tenable. Non-voluntary attention may perhaps be regarded as an absorbed form of consciousness, while voluntary attention is but the entire conscious self dominated by intelligent will. What we mean by attention is so well illus-

trated by experience that a formal definition scarcely seems necessary. A happy comparison which aids somewhat in understanding the working of attention is that borrowed from vision. Just as one may at any moment bring what is on the periphery of the field of vision to the point of keenest vision by a slight turn of the eyeball, so that which is at any moment on the bounds of the field of consciousness may be brought under the searchlight of the attention by a shifting of the mind in that direction.

WILLIAM J. TAYLOR,
Yale University.

Consciousness, Biological Aspects of. Consciousness is at once the oldest problem of philosophy and one of the youngest problems of science. The time is not yet for giving a satisfactory definition of consciousness, and we must fain content ourselves with the decision of the metaphysician, who postulates consciousness as an ultimate datum or concept of thought, making the brief dictum *cogito, ergo sum* the pivot about which his system revolves.

Opinions concerning consciousness are many and so diverse as often to be mutually exclusive, but they may be divided into two principal classes. The first class includes all those views which make of consciousness a real phenomenon; the second, those views which interpret it as an epiphenomenon. The fundamental question is: Does or does not consciousness affect directly the course of events?—or, stated in other words, is consciousness a true cause? In short, we encounter at the outset the problem of free-will.

The opinion that consciousness is an epiphenomenon has gained renewed prominence in recent times, for it is a collateral result of the doctrine of monism. Monism itself is postulated chiefly upon the two greatest discoveries of the 19th century—the law of the conservation of energy, and the law of the evolution of species. Both laws establish a greater unity in the phenomena of the universe than mankind had previously been able to accept. With these two unities in mind, what could be nearer than the thought that the unity goes still deeper, and that the phenomena of the inanimate or physical, and of the living world are fundamentally identical? The progress of physiological science has greatly increased the impetus toward the adoption of this thought as the cardinal dogma of the new faith, because the work of physiologists has been so devoted to the physical and chemical phenomena of life, that the conviction is widespread that all vital phenomena are capable of a physical explanation. As to what is behind the physical explanation, complete agnosticism is the only possible attitude. Such in barest outline is the history of modern monism—the

CONSCIOUSNESS

doctrine that there is only one kind of power in the universe.

It is evident that monism involves the elimination of two concepts, God and consciousness. It is true that monists sometimes use these words, but they deny the concept for which the words actually stand. Now consciousness is too familiar to all men to be summarily cast aside and dismissed. Some way must be found to account for it. From the monistic standpoint there is a choice between the alternatives; consciousness is either a form of energy, like heat, etc., or merely an epiphenomenon. As there is no evidence that consciousness is a form of energy, only the second alternative is available, and it has been adopted by the monists.

It is essential to have a clear notion of what is meant by an epiphenomenon. Etymologically the word indicates something which is superimposed upon the actual phenomenon. It designates an accompanying incident of a process which is assumed to have no causal relation to the further development of the process, and corresponds to the logical term "accident" as distinguished from cause. In practice it is used chiefly in regard to the relation of the mind or consciousness to the body, and is commonly employed by those philosophers who believe that consciousness has no causal relation to any subsequent physiological process.

The epiphenomenon hypothesis of consciousness scarcely does more than explain consciousness very easily by merely assuming that it does not require to be explained at all. Is not that really the confession made by the famous assertion that the consciousness of the brain no more requires explanation than the aquosity of water?

Consciousness is better regarded as a biological phenomenon, which the biologist has to investigate in order to increase the number of verifiable data concerning it. In that way, rather than by speculative thought, is the problem of consciousness to be solved, and it is precisely because biologists are beginning to study consciousness that it is becoming, as I said in opening, the newest problem of science.

We must look to biologists for the mighty generalizations to come rather than to the philosophers because great new thoughts are generated more by the accumulation of observations than by deep meditation. The principal contribution of science to human progress is the recognition of the value of accumulating data which are found outside of ordinary human experience.

So, in regard to consciousness, for the present it is more important to seek additional positive knowledge than to hunt for ultimate interpretations. It is the department of biology to which properly belongs the problem of consciousness. The results of experimental psychology are still for the most part future. But we may obtain valuable preliminary notions concerning consciousness from our present biological knowledge.

We must begin by accepting the direct evidence of our own consciousness as furnishing the basis. We must further accept the evidence that consciousness exists in other men essentially identical with the consciousness in each of us. The anatomical, physiological, and psychological evidence of the identity of the phenomena in different human individuals is, to a scientific mind, absolutely conclusive.

The most striking distinction of the processes in living bodies, as compared with those in inanimate bodies, is that the living processes have an object—they are teleological. The distinction is so conspicuous that the biologists can very often say why a given structure exists, or why a given function is performed, but how the structure exists or how the function is performed he can tell very imperfectly, more often not at all. Consciousness is a particular example, and an excellent one of this peculiarity of biological knowledge. We do not know what it is, we do not know how it functions, but we do know why it exists. Those who are baffled by the elusiveness of consciousness when we attempt to analyze it will do well to remember that all other vital phenomena are equally and similarly elusive.

In order to determine the teleological value of consciousness, we must endeavor to make clear to ourselves what the essential function is which it performs. As I have found no description or statement of that function which satisfied me, I have ventured, perhaps rashly, to draw up the following new description:

The function of consciousness is to dislocate in time the reactions from sensations.

The description calls for a brief explanation. We receive constantly numerous sensations, and in response to these we do many things. These doings are, comprehensively speaking, our reactions to our sensations. When the response to a stimulus is obviously direct and immediate we call the response a reflex action, but a very large share of our actions are determined in a far more complicated manner by the intervention of consciousness, which may do one of two things: (1) Stop a reaction, as, for example, when something occurs, calling, as it were, for our attention, and we do not give our attention to it. This we call conscious inhibition. It plays a great role in our lives; but it does not mean necessarily that inhibited impressions may not survive in memory and at a later time determine the action taken; in such cases the potential reaction is stored up. (2) Consciousness may evoke a reaction from a remembered sensation and combine it with sensations received at other times. In other words, consciousness has a selective power, manifest both in choosing from sensations received at the same time and in combining sensations received at different times. It can make synchronous impressions dyschronous in their effects, and dyschronous impressions synchronous. But this merely paraphrases our original description. The function of consciousness is to dislocate in time the reactions from sensations.

This disarrangement and constant rearrangement of the sensations, or impressions from sensations, so that their connections in time are altered seems to me the most fundamental and essential characteristic of consciousness which we know. The characteristic we are considering is certainly important, and so far as the available evidence goes it belongs exclusively to consciousness. Without it life would have no interest, for there would be no possibility of experience, no possibility of education.

Now the more we have learned about animals, the better we appreciate the fact that in them only such structures and functions are preserved as are useful, or have a teleological value. Formerly a good many organs were

CONSCIOUSNESS

called rudimentary or vestigial, because they had no known function. But in many cases the functions have since been discovered. Such, for example, were the pineal gland, the pituitary body, the suprarenal capsules and the Wolffian body in man. It is accordingly well-nigh impossible for us to imagine that consciousness was evolved, as it has been, unless it had been bionomically useful. Let us therefore consider the value of consciousness from the standpoint of bionomics (a convenient term, recently gaining favor, for the economics of the living organism. Bionomics seems preferable to ecology, which some writers are adopting from the German).

We must begin with a consideration of the nature of sensations and the object of the reactions which they cause. In the simpler forms of nervous action a force, usually but not necessarily external to the organism, acts as a stimulus which causes an irritation; the irritation produces a reaction. Within the ordinary range of the stimuli to which an organism is subjected, the reaction is teleological, that is, it tends to the benefit of the organism. An organism might conceivably be maintained solely by this mechanism in co-operation with the physical laws which govern all matter. Life in such an organism would be a succession of teleological processes, essentially mechanical and regulated automatically by the organism. By far the majority of biologists regard plants as essentially conforming to this type of life.

A sensation involves the interpolation of consciousness between the stimulation and the reaction, and in consequence there is established the possibility of a higher order of adjustment to the external world than can be attained through the teleological reaction to a stimulus. This possibility depends upon the fact that the intervention of consciousness permits an adjustment in accordance not merely with the immediate sensation, but also, and at the same time, in accordance with earlier sensations. Thus, for example, the child sees an object, and its reaction is to take hold of the object, which is hot and hurts the child. Later the child sees the object again and its natural reaction is to take hold of it again, but the child now reacts differently because its consciousness utilizes the earlier as well as the present sensation; the previous sensation is dislocated in time and fused with the present sensation and a new reaction follows. No argument is necessary to establish the obvious conclusion that an organism which has consciousness has an immensely increased scope for its adjustments to the external conditions; in other words consciousness has a very high value for the organism.

A sensation gives information concerning the external world. Perhaps science has achieved nothing else which has done so much to clarify philosophy as the demonstration that the objective phenomena are wholly unlike the subjective sensations. Light is a series of undulations, but we do not perceive the undulation as such, but as red, yellow, and green. Objectively red, yellow, and green do not exist. Similarly with the vibrations of the air, certain of which cause the sensation of sound, which is purely subjective. But the sound gives us information concerning our surroundings, which we utilize for our teleological needs, although in nature external to us there is no sound at all. Similarly

all our other senses report to us circumstances and conditions, but always the report is unlike the external reality. Our sensations are symbols merely, not images. They are, however, bionomically sufficient because they are constant. They are useful not because they copy the external reality or represent it, but because, being constant results of external causes, they enable consciousness to prophesy or foresee the results of the reactions of the organism, and to maintain and improve the continual adjustment to the external reality.

Consciousness is not only screened from the objective world from which it receives all its sensations, but also equally from immediate knowledge of the body through which it acts. As I write this sentence I utilize vaso-motor nerves, regulating the cerebral blood currents, and other nerves which make my hand muscles contract and relax, but of all this physiological work my consciousness knows nothing, though it commands the work to be done. The contents of consciousness are as unlike what is borne out from it as they are unlike what is borne in to it.

The peculiar untruthfulness to the objective which consciousness exhibits in what it gets and gives would be perplexing if we had not recognized in consciousness a device to secure better adjustment to external reality. For this service the system of symbols is successful, and we have no ground for supposing that the service would be better if consciousness possessed direct images or copies instead of symbols of the objective world.

Our sensory and motor (and other organs in efferent relations to consciousness) organs are the servants of consciousness. A large part of our anatomical characteristics exist for the purpose of increasing the resources of consciousness, so that its bionomic function may be more efficient. Our eyes, ears, taste, etc., are valuable, because they supply consciousness with data; our nerves, muscles, bones, etc., are valuable, because they enable consciousness to effect the needed reactions.

Let us now turn our attention to the problem of consciousness in animals. The comparative method has an importance in biology which it has in no other science, for life exists in many forms which we commonly call species. Species, as I once heard it stated, differ from one another with resemblance. The difference which resembles we term an homology. Our arm, the bird's wing, the lizard's front leg, are homologous. The conception of homology both of structure and of function lies at the basis of all biological science. That animals have a consciousness homologous with the human consciousness there is conclusive proof. As regards at least mammals—I think we could safely say as regards vertebrates—the proof is the whole sum of our knowledge of the structure, functions and life of these animals.

As we descend the animal scale to lower forms there is no break and therefore no point in the descent where we can say, "Here animal consciousness ends, and animals below are without it." It seems inevitable therefore to admit that consciousness extends far down through the animal kingdom, certainly at least as far down as there are animals with sense organs or even the most rudimentary nervous system.

CONSCIOUSNESS

The series of considerations which we have had before us lead directly to the conclusion that the development and improvement of consciousness has been the most important, really the dominant, factor in the evolution of the animal series. The sense organs have been multiplied and perfected in order to supply consciousness with a richer, more varied, and more trustworthy store of symbols corresponding to external conditions. The nervous system has grown vastly in complexity in order to permit a constantly increasing variety in the time dislocations of sensation. The motor and allied apparatus have been multiplied and perfected in order to supply consciousness with more possibilities of adjustment to external reality which might be advantageous.

If we thus assign to consciousness the leading role in animal evolution we must supplement our hypothesis by another, namely, that conscious actions are primary, and reflex and instinctive actions secondary; or, in other words, that, for the benefit of the organism, conscious actions have been transformed into reflexes and instincts. As we all know, new actions are performed with difficulty and slowly, but if often repeated they are soon easier and more rapid. If a given reaction to a sensation or group of sensations through consciousness is advantageous to the organism and the environment is such that the sensation is often repeated, then a habit is formed and the response becomes more rapid, and almost without participation of consciousness. The usefulness of conscious reactions is that they are determined not merely by the present sensation, but also by past sensations, but they have the defect that they are slow. We can readily understand that it would aid an organism to have the quicker reaction substituted, and we thus recognize a valid teleological reason for the replacement of conscious action by habits in the individual, by instincts in the race.

A frank unbiased study of consciousness must convince every biologist that it is one of the fundamental phenomena of animal life, at least, if not of all life.

The teleological impress is stamped on all life. Vital functions have a purpose. The purpose is always the maintenance of the individual or of the race in its environment. The entire evolution of plants and animals is essentially the evolution of the means of adjustment of the organism to external conditions, and consciousness is a conspicuous, a commanding factor of adjustment in animals. Its superiority is so great that it has been, so to speak, eagerly seized upon by natural selection and provided with constantly improved instruments to work with. A concrete illustration will render the conception clearer. In the coelenterates, the lowest animals in which we can recognize sense organs, the structure of them is very simple, and they serve as organs of touch and of chemical sensation resembling taste. In certain jellyfishes we find added special organs of orientation and pigmented spots for the perception of light. In worms we have true eyes and vision. In vertebrates we encounter true sense of smell. Fishes cannot hear, but in the higher vertebrates, that is, from the amphibians up, there are true auditory organs. In short, both the senses once evolved are improved and also new senses are added. It is perfectly conceivable that there

should be yet other senses, radically different from any we know. Another illustration, and equally forcible, of the evolution of aids to consciousness might be drawn from the comparative history of the motor systems, passing from the simple contractile thread to the striated muscle fibre, from the primitive diffuse musculature of a hydroid to the highly specialized and correlated muscles of a mammal.

In the lowest animals the range of possible adjustment is very limited, and the variety of possible actions small, and they cover also a small period of time. In animals which have acquired a higher organization the adjustments are more complex; the reactions are more varied and cover a longer period of time. The next great advance is marked by the establishment of communication between individuals of the same species. The investigation of this phenomenon is one of the most important duties of the comparative physiologist. Its bionomic value is obviously great, for it allows an individual to utilize the experience of another as well as its own. We might, indeed, compare it with the addition of a new sense, so greatly does it extend the sources of information. The communication between individuals is especially characteristic of vertebrates, and in the higher members of that sub-kingdom it plays a very great role in aiding the work of consciousness. In man, owing to articulate speech, the factor of communication has acquired a maximum importance.

It seems to me inconceivable that the evolution of animals should have taken place as it has, unless consciousness is a real factor and dominant. Accordingly I hold that it actually affects the vital processes. There is, in my opinion, no possibility of avoiding the conclusion that consciousness stands in immediate causal relations with physiological processes. To say this is to abide by the facts, as at present known to us, and with the facts our conceptions must be made to accord.

The future investigation of consciousness must separate the study of what it does from the study of what it is. Consciousness has been viewed here as a device to regulate the actions of the organisms so as to accomplish purposes which on the whole are useful to the organisms, and accordingly we have termed its function teleological. If this view is correct it accounts for the limitations of consciousness, its mechanical mode of work, its precision, and definiteness of action. The very fact that consciousness is of such high value in the bionomy of an animal renders it obvious that it must be subject to law. Accordingly it appears to us regulated as do the functions of protoplasm. Hence to certain modern thinkers it presents itself as a function of protoplasm, or, as it may be better stated, as a state or condition of protoplasm.

The internal evidence of consciousness is against the view that consciousness is a state or condition of protoplasm; it presents to us conscious actions depending upon consciousness. As before stated I believe that this evidence must be accepted. Now all the sensations of consciousness are derived from physical force, and all the acts of consciousness are manifested through physical force; hence if it has any real power consciousness must be able to change the form of energy. I propose the hypothesis:

CONSCIOUSNESS

Consciousness has the power to change the form of energy, and is neither a form of energy nor a state of protoplasm.

By this hypothesis there are two fundamentally different things in the universe, force and consciousness, and the universe consists of force and consciousness. As consciousness by our hypothesis can initiate the change of the form of energy, it may be that without consciousness the universe would come to absolute rest.

CHARLES SEDGWICK MINOT,
Harvard Medical School.

Consciousness, Disorders of. Consciousness as evidenced in action is here under discussion. Consciousness *per se* as an entity is here regarded as incomprehensible. It is accepted solely as a mode of interpretation. The variations of normal consciousness are so manifold and extended that it is only by snatching, as it were, some fragments of peculiar character and by force of words more or less descriptive, that it is possible to circumscribe and limit the phenomena within bonds sufficiently narrow to permit of a classification. Thus any discourse on disorders of consciousness must be fragmentary at best, and when it is realized that the gamut of normal consciousness in individuals can be bound only in isolated fragments, the difficulties in the way of similar subdivision of personalities in the pathological field become apparent.

One of the first difficulties is drawing a line between normal and abnormal states of consciousness, as all states of consciousness may be said to glide one into another. In the intoxicated, disordered consciousness so alters the individual as to render him not only obnoxious to society, but a menace to himself and to society. Thus any definition of normal or abnormal should take into consideration the fact that society itself makes the definitions and that abnormal conduct is a matter really of considerable range in time and place and social customs. Distinctly anti-social conduct is branded abnormal at once.

In discussing the subject of disorders of consciousness it has been the custom in times past to describe three general types such as exalted, diminished, and perverted conscious states. This method of classification, however, is solely artificial and has no relation whatever to any pathological state which may bring about a disturbance of consciousness, for exalted states may occur in a variety of diseases as may depressed conditions also, and in fact both depressed and exalted consciousness occasionally occur in the same type of disease.

For general purposes the disorders of consciousness may be divided into four general groups. These are: (1) Disorders of sleep and their allied phenomena; (2) conscious states in the allied neuroses, hysteria, and epilepsy, including automatism, amnesia, double personality, etc.; (3) disordered conscious states due to exogenous intoxications; (4) insanities. This outline has certain justification in clinical experience at least. Under the first subdivision there may be included a large number of allied conditions, the most striking feature of which is a so-called dissociation of consciousness. By this is meant that normal waking consciousness with its accuracy of observations is in temporary abeyance and that lower cerebral centres are

operative, causing the individuals to perform motor acts of which they may have only a dim conscious recollection. Somnambulism or sleep walking is one of the simplest types of this disordered conscious state. Individuals who walk in their sleep should not be considered as unconscious. They are distinctly conscious, but the consciousness is an extremely restricted one. The clinical phenomena of sleep walking are not constant. The eyes may be closed or even wide open. The pupils may be sluggish to light; they may be dilated or contracted or they may be normal. It is of interest to know that both suicide and homicide have been committed by persons said to be in the somnambulistic state.

Nightmare is another extremely interesting and at the same time suggestive modification of consciousness. Here all sorts of odds and ends are thrown together in an illogical and disordered manner. At times the resulting mixture is highly pleasing to the individual who remembers the ebb and flow of thought with pleasure. At other times the stream of consciousness is much agitated and muddy and the individual awakens in great distress under the influence of a bad dream. Such conditions are naturally temporary and may be associated with disordered digestive function. Disagreeable nightmares are also associated with grave cerebral degenerations.

In catalepsy, trance, and lethargy there is a peculiar sluggishness in motor consciousness. The will to move is modified in such a way that there is wax-like rigidity of the limbs. See CATALEPSY.

Hypnosis is an allied form of modified consciousness that is but little understood and largely written about. A very small proportion of the alleged hypnotic phenomena are true, but there seems little question that for a few people most of the time and for many people under certain conditions a certain amount of dissociation of consciousness may be brought about by appropriate physical or psychological stimuli. In this condition people are very highly suggestible and do as others indicate for them what they desire to have done. In other words, they behave largely like tractable children who have no desire or will of their own, for the most part consciously obeying what is told them to do. This phenomenon of modified consciousness is further discussed under hypnotism.

In hysteria and in epilepsy there are often very marked modifications of the conscious state. The phenomena of trance, catalepsy, hypnotism, anæsthesia, etc., are almost constant accompaniments of the hypnotic condition, and automatism and amnesia are also extremely common accompaniments of the hysterical temperament. See HYSTERIA; EPILEPSY.

The phenomena of many of the intoxications are too well known to need description in this place, but they are here spoken of because of the alliance that they show to other forms of disordered mental action. Alcohol, opium, cannabis indica bring about states of consciousness which are modifications of normal conditions, and the poisoning of the bacteria of pneumonia, typhoid, and other infectious diseases also may induce forms of delirium that are extremely suggestive in this connection.

Finally there is a large group of disordered mental states which are classed under one head

CONSCRIPTION — CONSECRATION

as the insanities. These are largely characterized by antisocial conduct, and the disordered states of consciousness vary very widely. Thus in some of the milder forms of paranoia or the minor obsessions perverted consciousness may be present to a very minor degree. In the death-like stages of organic or terminal dementia consciousness is practically wiped out, although the individual eats, drinks, sleeps, and grows fat. See INSANITY.

Conscription, the enlisting of men for military service by a compulsory levy, at the pleasure of the government. It is distinguished from recruiting, or voluntary enlistment. The name is derived from the Roman military constitution. Every Roman citizen was obliged to serve as a soldier from his 17th to his 45th year; the consuls announced every year by a herald or written order that a levy was to be made (*militēs cogere* or *conscribere*); and all citizens capable of bearing arms assembled in the Campus Martius or near the capitol, where the consuls assisted by the legionary tribunes made the levy, choosing as many men as were needed from each tribe. The word conscription as well as the system were introduced into France by the law of 5 Sept. 1778, which declared that every Frenchman was a soldier, and bound to defend the country when in danger. Excepting in times of danger it provided that the army should be formed by voluntary enrollment or by conscription. The conscription included all Frenchmen from 20 to 25 years of age, and the number of conscripts to be called into the service each year was to be determined by the Corps Législatif. Complaints of the conscription did not begin till 1802, on the introduction of a principle of indemnity, by which a payment ranging from 50 to 1,200 francs (\$10 to \$240), according to the annual taxation of the parents of the conscript, secured him exemption.

During the last years of First Empire the conscription was attended with gross abuses in the matter of exemption and substitution, and it was chiefly in consequence of these that on the restoration of the Bourbons it was abolished. It was, however, re-enacted in its substantial features by the law of Marshal Gouvion de St. Cyr, and continued through the revolution of 1848 and the Second Empire. According to a new army bill passed by the national assembly in 1872, the term of service in France was 20 years, but by subsequent enactments this has been extended to 25, namely 3 in the regular army, 10 in the army reserve, 6 in the territorial army, and 6 in the territorial reserve. A youth may volunteer into the army at 18, but at 20 he is compelled to serve, with certain exceptions. The military system of Prussia was extended to the German empire by a law passed in 1887. Its terms in regard to conscription are obligatory service for all subjects, the total length of the service being 12 years, 3 in the active army, 4 in the reserve, and 5 in the landwehr. By the army bill of 1893 the three years' term was reduced to two. The Russian army has been completely remodeled in recent years. It has long been partly raised by conscription, and by a law (subsequently modified) which came into force in 1874 an annual conscription was established, to which all men who have completed their 21st year and are not physically

incapacitated, are liable. The men have to serve in the active army for 5 years, after which they pass into the reserves for 18 more years, during which they are liable to active service only in time of war. In Austria military service is compulsory for all citizens, and the length of service is 12 years, 3 in the standing army, 7 in the reserve, and 2 in the landwehr. In Great Britain volunteer recruiting is commonly found sufficient to raise the contingents needed for the regular army, as well as to keep up the militia required from the several counties. In the United States, both the regular army and the State militia are regularly recruited by voluntary enlistment. During the Civil War compulsory levies were made several times; such levies were always known as drafts, though the term conscription might properly be applied to them. See DRAFTS.

Conscrit de 1813, Histoire d'un (HISTORY OF A CONSCRIPT OF 1813), a famous story, by Erckmann-Chatrian, published 1868-70. The narrative turns mainly on the contrast between the perpetual mourning that is going on in families and the perpetual Te Deums for disastrous victories. This is the dominant note; and in the mouth of the humble conscript, this thesis, interpreted by scenes of daily carnage, is more eloquent and persuasive than if it borrowed arguments from history or philosophy. The style is simple, familiar; but never trivial or commonplace, and is always in harmony with the speaker. As the work was hostile to the Napoleonic legend, numerous obstacles were put in the way of its circulation at the time of publication. But notwithstanding, it was scattered in profusion throughout France by means of cheap illustrated editions.

Consecration, an act by which material things and persons are dedicated to sacred uses and sacred ministries. The word Consecration is also used in the Roman Catholic ritual and liturgy to signify the act by which the bread and wine are in the Mass changed into the body and blood of Christ. In the Roman *Pontificale* or ritual for episcopal functions there is a form for consecration of a bishop, consecration of a church, consecration of the sacred vessels used in the liturgy of the Church. In the consecration of a bishop—ordinarily performed by the metropolitan and two other bishops—the consecrating bishops impose hands on the bishop-elect and the metropolitan delivers to him the pastoral staff and the ring, emblems of his office, and anoints him with chrism, pronouncing the formula of words by which is expressed the commission of authority to rule the Church committed to his charge. The consecration of a church is a very elaborate ceremony, requiring several hours to complete it: there is chanting of the office of Matins and Lauds by the clergy; there are processions of clergy, headed by the consecrating bishop and other bishops who may be present, around the walls outside and thrice around the interior, with continuous chanting of psalms; there is anointing of the doors, of the walls, of the high altar; and a number of other rites. The consecration of the vessels destined for the service of the altar is also an episcopal function: it is a rite that has descended from high Christian antiquity: in this rite also chrism is employed.

CONSENT — CONSERVATORY

Consent, in law, a free and deliberate act of a rational being. Any voluntary act by which the agent takes away his own power of giving a deliberate consent, such as partial intoxication, will not invalidate the consent; but it is invalidated by any undue means—intimidation, improper influence, or imposition—used to obtain it. The law does not, in general, take cognizance of the wisdom or folly of men in entering into contracts before it enforces them; but where clear proof can be brought that a person has been wilfully misled or entrapped into a contract, it will refuse to enforce it.

Consequential Damages, in law, are losses incurred in consequence of an act, but not flowing directly from it. The liability for consequential damages resulting even from an unlawful act is more limited than that for direct damages, as it is evident that the power of the law in tracing and enforcing such damages must be limited; but in some cases they can be enforced.

Conservation, the act of preserving, maintaining, supporting, or protecting. The conservation of energy is a principle based on the general one that energy communicated to a body or system of bodies is never lost; it is merely distributed, and continues to exist as potential energy, as motion or as heat. Faraday directed attention to the subject, Grove elaborately treated it, and it now stands as one of the axioms of physics. It is sometimes called correlation of forces.

Conservation of Energy. See ENERGY.

Conservation of Matter. See MATTER.

Conservative, as applied to one of the two great parties in English politics, was first used by J. W. Croker in an article in the 'Quarterly Review' for January 1830, and was by Macaulay, in the 'Edinburgh Review' for 1832, referred to as a "new cant word." Conservative accordingly began to supersede Tory about the time of the Reform Bill controversies. The plural form of the word, or its equivalent in other tongues, has been assumed as a distinctive name by certain political parties in many nations. These parties are sometimes actually, and always avowedly, opposed to changes from old and established forms and practices. In United States history these names have never been in general use, but in Van Buren's administration the name of Conservatives was applied to those Democrats that at the special session of Congress of September 1837 opposed the establishment of the sub-treasury system. In the Congress that met in December 1839 they had practically disappeared. The name was also assumed by Southern whites during the reconstruction period following the Civil War, to show their adherence to the old State governments, the abolition of which by Congress they opposed. In Virginia the name was in use until 1872. The name was also used at the North during this period. The Democrats applied it to themselves to draw moderate Republican votes. See TORY; WHIG.

Conservatives, in American history. 1. In 1837-40 the name of Conservatives was adopted by seceding Democrats, 4 in the Senate and 14 in the House, who voted with the Whigs against the sub-treasury, though voting with their party on other

questions. They called themselves Conservatives, as wishing to conserve the prosperity of the State banks, which they held the sub-treasury to be a disguised attempt to ruin. They held the balance of power in the House 1837-8, and voted down in two successive sessions Silas Wright's sub-treasury bill, which had been passed by the Senate. The elections of 1838, however, returned only four of them to the House, and these ceased their active opposition—partly because the government had only escaped bankruptcy in 1838, on account of uncollectible claims against banks and individuals, by issuing fresh treasury notes in place of those canceled. The Whigs held the power, and passed the Wright bill in 1840. 2. In the Civil War the Northern Democrats, and especially the border State Democrats, often called themselves Conservatives, as wishing to preserve the old balance of State and national powers; and the name was much ridiculed by the other side. 3. During the Reconstruction period, the Southern whites to a considerable extent took the name of Conservatives as wishing to preserve their old State governments, which they held to have the same existence and sovereignty as before the War, according to the declarations of the Northern leaders and Congress themselves, in stating the purposes of the War. The name, more particularly in Virginia, lasted down to 1872.

Conser'vatory. 1. A systematic school of musical instruction. In Great Britain the term is usually applied to foreign schools of music. Conservatories were originally benevolent establishments attached to hospitals, or other charitable or religious institutions. In Naples there were formerly three conservatories for boys; in Venice four for girls; the Neapolitan group being reduced in 1818 to a single establishment under the name of the Royal College of Music. In Milan a conservatory was established in 1808. In France the musical school established in connection with the Opera received its final organization in 1795 under the name of *Conservatoire de Musique*. Among its teachers have been Méhul, Cherubini, Grétry, Boieldieu, and others of like standing. The Conservatorium founded at Leipsic in 1842 under the auspices of Mendelssohn is perhaps the most influential in Germany, though of late years other schools have pressed closely upon it. Institutions of the same description exist in Warsaw, Prague, Munich, Berlin, and Vienna. Several conservatories have been established in the United States; prominent among them are the National Conservatory in New York and the New England Conservatory at Boston.

2. The glass house in which plants are displayed after being grown in other greenhouse structures; also, any ornamental greenhouse, especially such as are attached to private dwellings for the pleasure of the inmates. In the first sense the house is of great importance to the more pretentious private establishments, since plants brought to perfection may there be placed in an appropriate setting so long as their attractiveness lasts; they cannot be viewed to advantage upon the benches where they are grown. Conservatories are variously arranged internally, some having stationary benches, some rockeries, fountains, etc., and some permanent beds upon the ground. See GREENHOUSE,
